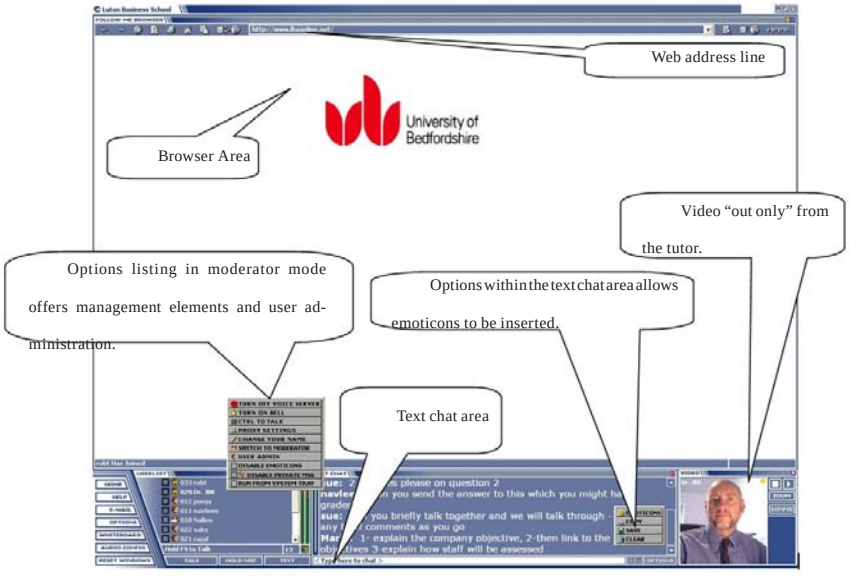
Early models of learning suggested the "extended classroom" as a good design for online teaching and learning. VIPER would certainly enable this, either in the form of "one to many" or "many to many" with respect to tutors and students. Criticism exists, however, that online tutors and instructors come to the new medium from traditional backgrounds with skills that do not translate well (Schieman, Taere, & McLaren, 1992), an issue, which is still reported (Salmon, 2003). This is mostly based, however, on text-based online learning models and this MDC application. Because VIPER incorporates voice and basic IT skills, may need a shorter learning curve and as a result such difficulties may not arise. Even so, the online environment is dynamic with developments in design continually being added to the knowledge base of this domain. Laurillard's important work in 1993 has been re-evaluated, and this original taxonomy cannot easily be applied to group work (Britain & Liber, 1999). Indeed, Laurillard (2000) herself has added more in the light of recent developments. It is perhaps as a result of this and the variety of online tools available within the "blended suite" that a single framework for teaching and learning to which a majority can subscribe as best practice has yet to emerge. This exploratory evaluation of the VIPER is therefore set against participant experience, observation, and interactivity.

Figure 1. Screen shot of Viper software



Evaluation of VIPER

These were conducted with three student groups and faculty:

1. Six selected undergraduate business studies students.
2. A dissertation support group.
3. An MBA student group.
4. Faculty staff.

Selected Marketing and Business Undergraduate Students

Of six students, four were connected via computers that were "on campus," whilst the remaining two were connected via external connections to the University. Of particular interest were set up issues, learning curves of participants, and techniques of verbal discussion online. The two sessions began with the tutor outlining a topic and then inviting discussion. The set up and installation phase went well without event for all of the students. Anticipated firewall problems did not arise, and all equipment and software functioned appropriately. As a consequence, the use of the software was reliable.

Initially, students and the tutor engaged only in verbal discussion, and in the first session text chat used only very occasionally while a participant was talking. In the second session, however, particularly the students who considered themselves IT literate used the text function much more extensively. At one stage the tutor did ask the students to stop using the text function since they were using it to organize a forthcoming social function. This did appear to be similar to a face-to-face session where the tutor was asking the students in the "back row" to be quiet!

There are a number of tools in the VIPER suite available to both participants and tutor. It was not unexpected that only the voice, text and browsing functions were used but these were, toward the end of the second session all were used extensively. When asked, after the sessions had been completed, participants reported that they found the software acceptable, but two of the six stated that they would prefer face-to-face lectures. One commented:

I would not like to study in this way, being on my own in front of a computer. I would miss my friends.

Participants in the demonstration classes reported the software was "interesting." The quality of sound was reported as being acceptable. There was a request, however, by some "to slow down," since speaking quickly prevented comprehension. This appeared to be overcome in the first instance by asking participants to speak relatively carefully, but was not noted as an issue in later sessions. The sessions were deemed by the students and staff, however, as being successful, with the lectures having been conducted successfully.

Dissertation Student Group

This postgraduate group was completing their MSc in business related studies, and two were abroad for the data gathering exercise (Germany and India). Initial meetings were held face-to-face to begin the study process and resolve issues of subject matter and research directions. The set up of the software was straight forward and uneventful for all of the students. This was unexpected since all participants reported a mistrust of IT in general, reporting critical failures at some stage in their academic lives. The dissertation was a major academic stage, and seemed to heighten their lack of confidence in IT.

Regular meetings were arranged, at which it was intended that all participants would login at a set time. Students produced Word™ documents for discussion, for example literature reviews, questionnaires, and the group and tutor would discuss issues that arose. The tutor printed the

Word™ document in an Adobe Acrobat™ format, and then placed them on a Web site so they could be accessed by the software and viewed by all in the group. In one instance, while the group was actively engaged, the student who was in India e-mailed a document (draft questionnaire), which the tutor converted "on the fly" and uploaded to a Web site for group discussion. It was noted that adequate IT skills on the part of the tutor are needed for this, not least the ability to "multitask" while the discussions are ongoing. After the sessions were completed, participants reported that they found the software relatively straightforward to use, and had the convenience of saving travel time. One participant stated:

I found VIPER to be really good for preparation, but for the really difficult issues that I did not understand, I really needed to meet my tutor to talk things through. It was frustrating, and I really needed to be in front of my tutor. (Student 9)

While the students were in the data collection phase, face-to-face contact was not possible. Although this might be preferable, learning objectives were achieved using VIPER. This student achieved good grades without the face-to-face communication, but none the less felt the need for this type of support and viewed VIPER methods for deep learning, secondary. A similar result found by Katz and Yablon (2003), where no significant differences in grade performance between Internet and traditional lecture based courses were reported, but attitudinal differences, however, was identified where students preferred off-line methods.

MBA Student Group

Twenty-two participants were involved in learning and teaching situation, and 12 were selected for the evaluation on a random basis. Although this study concentrated upon the use of VIPER, other in course tools and techniques were also being used. These included face-to-face teaching, Blackboard™ virtual learning environment, and bespoke CD-ROM materials. The students on the MBA course met for an induction session at the beginning of the course. The intention was to create a better environment for socialization processes to take place rather than using online communication methods.

Those who considered themselves IT competent found no problems with the set up or use of the software. The following statement typified this for one such participant:

Good. Simple to use and a good way to hold tutorials. I have also found it excellent for our study group to use weekly to keep in touch.

One student, due to work commitment was posted to Saudi Arabia during the course. He was able to set up his laptop from his hotel room and participate as effectively as others within sessions. Although positive statements were received about the software and its use, comments of problems in this category are interesting and provide a different perspective:

Examples of problems reported were:

1. **A problematic Internet service provider (ISP), (blocked port access):** This was resolved by IT support by informing the student to request the ISP provider of the appropriate instructions.
2. **A PC well below the required and notified specification:** Overcome by the student purchasing a computer that was a reasonably new specification and not seven years old.
3. **Smooth functioning not occurring at peak periods due to a "free" ISP provider:** Resolved by the student "upgrading" to a paid service.
4. **Some individuals reported difficulties**

with audio settings: This last aspect was resolved by providing a "set up routine," which students undertook when first logging into the system. This appeared in later sessions to resolve the problems.

Both moderated and un-moderated meetings were observed, and this provided an important collaborative mechanism for students. From these groups VIPER was reported as being very helpful for students to "stay in touch," and the level of academic use for the collaborative work varied from complex assignment oriented to social conversations. Better learning independence is noted as one of the higher order skills of learning sometimes characterized by the preference by students for un-moderated meetings to challenge the given "norms" (Salmon, 2000). Students appeared to require a need to develop "online" meeting skills, however, when they met through VIPER, which improved over time. Conversations were more relaxed in later meetings, with almost no problems being reported.

Where moderated group meetings were organized with tutors with no set agenda, requests were made for more information relating to assessment and other issues, for example, housekeeping matters such as the "font size" and "layout" of documents to be submitted. Both faculty and students felt that questions such as these improved the face-to-face meetings because much of the "trivia, but necessary trivia" had been resolved leaving the physical meetings to more important matters on the course. Students also considered this to be valuable, and saved considerably on travel time.

THE FACULTY PERSPECTIVE

Salmon (2000) emphasizes that the skills of the moderator are paramount in the success of an online course. Theoretically, the basic use of the system should not impede the communication of the group and tutor. This appeared to be the case within the MBA group. One tutor commented:

…It has improved my listening and understanding skills of what a student was doing. Sometimes there would be a silence, and at first I was trying to work out what was going on. Then I began to realize the difference between when the student was thinking and when they were writing down notes. It enabled me to be more effective about who to draw into discussion and when there appeared to be some delay. It is a different kind of skill. (Tutor 1)

In addition to audio from the perspective of interaction and the available online tools, VIPER appeared to provide subtle additional aspects of communication.

…The communication was surprisingly active. It was not just all one way, it engaged many senses, and I had all my things around me, which I could quickly refer to. I was able to set myself up because they could not see. (Tutor 3)

This tutor went on to say:

…One soon learnt to bring the students in by asking questions, searching questions. Some students cannot bear to have a silence; others can so noting those who had not answered and bringing them in later.

More extensive use of the system was made following requests from some of the students. Observations of the seven tutors involved provided the following main usages of the system, and can be grouped under three headings: (a) voice only with hands up indicator, (b) voice only with hands up indicator plus Web browsing, (c) voice only with hands up indicator, Web browsing plus the use of the whiteboard.

Level I: Voice Only and Hands Up Indicator

Tutors and students engaged in conversations about topics, using the hands up indicator for dichotomous questions of the group. Often this was used to bring contributions together to redirect the flow of a discussion, a technique described by Salmon (2000) as "weaving." There was a perception by the tutors that Level I use was straightforward and easy enough after the set up procedures were complete. The text chat facility appeared to be used very rapidly within all sessions, contained questions, brief replies, clarity, or confirmation of issues between participants while the session was progressing. It was a main supporting communications channel supporting the voice discussion. It also served as a tangible record post meeting via a "copy of text" function.

Level II: Voice, Hands Up Indicator and Web-Based Materials

The browser capability enabled Web-based materials to be presented in conjunction with the other tools. The materials were either Web sites relevant to the topic or learning materials prepared for the Web specifically for the session, normally PowerPoint™ files saved in an HTML Web format or pdf files. One tutor demonstrated the dynamic use of the system:

We were discussing an assignment case study that was due, and one of the students mentioned that because they were at work did not have the material with them. The assignment was converted to a pdf document on the fly, posted to a Web site, and then used in the discussions. (Tutor 6)

The VIPER system operates by sending the Web address to participants, and thereby providing the same image to all those connected within that session. One obvious advantage of this method is the saving of bandwidth. Some equivalent systems send an "image" to connected participants. This can require a high bandwidth due to the file size of the images being sent.

Level III: Voice, Hands Up Indicator, and Web-Based Materials Plus the Whiteboard

The whiteboard "background Web browser capture" capability means documents and diagrams can be presented for participants to interact as a part of the discussion using the integrated tools. Students were requested to "mark" or "write text" on the images to elicit participant viewpoints pre, post, and during discussion. The same group and tutor also used the "capture browser" function to create an image of the assignment upon which all participants could put questions and comments for discussion.

…It was interesting; I could go through the issues in a much more interesting way. It was much more interactive than in class. (Tutor 4)

On an operational level, significant variations existed. In terms of the skills ability of tutors, some required very little guidance, while others needed considerable support both prior to, during, and post sessions. Tutors as individuals it would appear will need to go through a learning curve process if this type of system is to be used within teaching and learning. As a result, depending upon the ICT of the individual tutors varying levels of support will be required, an issue reported by other studies (Garrison, 1998; Salmon, 2000, 2003).

An interesting aspect has arisen in the use of VIPER between tutors in distant geographic regions. International courses require much administration, management, and communication "staying behind" after sessions to discuss issues of management, quality, and pragmatic housekeeping issues. This does represent an important ad-

vantage over previous communications methods. These were prohibitive due to cost, or limiting since they were based on text-based systems, telephone, or face-to-face meetings.

SENIOR MANAGEMENT PERSPECTIVE

The view of senior management focused upon the strategic advantages of the software:

VIPER currently provides a USP, a unique advantage, which is very difficult in today's HE market place. It enables personal teaching at a distance. It also gives us further reach in terms of target markets. It has enabled us to win two overseas contracts against other HE institutions, and has dragged us to the attention in front of others…I am surprised, however, that other Universities have not used this type of software more extensively. (Dean, University of Luton Business School)

One contract, for example, to provide the MBA with the British Council in India, was won in competition against a number of other Universities. Although the distance learning packages were all similar, the inclusion of VIPER was unique and provided the significant advantage. Other issues raised by faculty concerned how the software was going to develop, over time with suggestions of video to improve the "comfort" of communication although the mechanics of large student numbers may be problematic.

SUMMARY

VIPER has shown itself to be a useful communications tool, for both students and tutors. It has currently given a unique advantage to the University of Luton Business School product portfolio enabling it to win contracts in competition with other Universities.

The technical issues surrounding its use were mostly straight forward, with the only problems appearing where some wanted to use the system from within a commercial network that had stringent firewall policies. These were overcome once the appropriate network staff were contacted and appropriate ports opened. The low bandwidth requirement also enabled VIPER to function where other, more demanding MDC software applications might not have been possible.

Overall, the general view of the students that have used the system was positive. This was particularly true of those who were distant geographically and needed to make contact on a regular or emergency basis. Students and faculty did need repetitive use to gain confidence and expertise in the use of VIPER. The system was used for a wide range of applications from important learning issues, very basic house keeping matters, to a social aspect of students keeping in regular contact with each other. Students as recipients of the teaching management approaches appear also to demand the highest level of interaction available, irrespective of the tutor capability or indeed perhaps the need of the subject matter. As a result, the student learning curve appeared to progress ahead of the faculty learning curve, which can be a source of stress for members of staff, with the consequence of training resource implications.

Staff also found VIPER useful, from the perspectives of teaching and learning as well as keeping good communications with staff in partnership colleges that were based abroad. Issues of pedagogic design were important in conjunction with the three levels of use of VIPER from voice only to full use of all tools and the interactive whiteboard. Good planning and preparation to provide the maximum benefit for the student experience also emerged as important from a tutor's perspective. As a result, VIPER would appear to offer another helpful communications

platform to add to the blended mix of online tools that are available for teaching and learning in an HE, business school context.

Chapter 3.17
A Pliant-Based Software Tool for Courseware Development

Marcus Vinicius Santos Kucharski
Pontifical Catholic University of Paraná, Brazil

Isaac Woungang
Ryerson University, Canada

Moses Nyongwa
University of Manitoba CUSB, Canada

ABSTRACT

The increasing importance of e-learning has been a boosting element for the emergence of Internet-based educational tools. As we move into the information age, tremendous efforts are made in the development of new information and communication technologies for educational purposes. The ultimate goal is to facilitate e-learning methodologies and acquisition. The chapter's contribution is in the area of open source software for technology-enhanced learning. First, we report on the capabilities of Pliant, a novel software framework for Web-based courseware development. Pliant' design features upon which e-learning capabilities are built are presented, showing that Pliant has some advantages over existing software, including flexibility, efficiency, and universal usability. A case study of the use of Pliant in the project "Multilanguage Database for Localization" developed at the CUSB School of Translation is presented. Second, we present Academia,[3] a Pliant-based courseware development Web portal, and its use in translation studies at CUSB.

INTRODUCTION

The widespread availability of Web-based educational systems and standard-based courseware systems, and their deployment in educational institutions, including educational community as a whole, has raised a clear concern regarding their "universal usability" scope (Hochheiser & Shneiderman, 2001). A thorough analysis of

the situation and informal discussions with "online teachers" and teacher educators show that Web-based educational tools are quite far from achieving their main goal—that is, being used by a wide distance audience in a cost-effective and educationally sound manner, and in particular, endowing Web literacy to both young, old, novice, expert, and end users with less computing background. This chapter reports on the capabilities of Pliant, a high-level and flexible programming language and Web development framework. It shows how Pliant can be used both for high-level programming and e-learning purposes, while meeting educational and software-oriented expectations. Academia, an example of an open-source, lightweight, Web-based courseware tool fully implemented in Pliant, is presented. This portal has been designed to help instructors quickly create, post, manage, and deliver Web-based courses and other e-learning resources. A case study of the usability of Academia at a Canadian institution is presented. This Pliant-driven application is meant to show the efficiency of the Pliant's framework as a supporting tool for e-learning methodologies and acquisition.

The chapter is organized as follows. First, we briefly introduce the main streams driving the development of Web-based educational tools, and situate Pliant in that context. We then present an overview of the Pliant approach in terms of language constructs—here, we present our view of the Pliant architecture, and its underlying design features upon which e-learning capabilities can be supported. Next, we discuss various e-learning capabilities of Pliant, while highlighting their relationships to some of the main topics of this book. These include:

a. A description of Pliant as a tool for consolidating e-learning methodologies/acquisition—here, elements for exploration, data management, teaching, communications, and users' management are presented;
b. A description of Pliant as a tool for learning programming languages and Web programming—a case study of the use of Pliant in a project entitled "Multilanguage Database for Localization," developed at the CUSB School of Translation, is also presented; and
c. A description of Academia—here, our focus is on showing how this portal has been used as a tool for supporting translation studies at the CUSB School of Translation.

We also introduce Co-op Web,[4] a Pliant-based Web portal developed at Ryerson University, Canada, used to administer the Cooperative Education and Internship Program.

Some shortcomings of our framework and how these can be addressed as future research themes are then offered, in the perspective of enhancing e-learning methodologies and acquisition. Future developments of our framework are also highlighted, and finally, our conclusion synthesizes our discussion and presents our final remarks on Pliant's e-learning features.

BACKGROUND

Web-Based Educational Tools

The exponentially increasing number of educational courses being offered over the Web has spurred a growing industry of software tools to assist in the creation of Web-based curriculum and in performing class management tasks. For this reason, Web-based educational tools and standard courseware systems are two main research and development streams in the field of e-learning. The development of these systems can be categorized in two complementary streams. The first stream is based on the traditional approach of "hardwiring" high-quality educational material items in the course content—that is, the learning content used by the student resides in the system. Well-

known examples of course management systems built upon this approach are Blackboard (2002) and WebCT (2002). The second stream is based on an adaptive approach, where a model of goals, preferences, and knowledge of each individual student is built and then used throughout the interaction with the student in order to adapt to the needs of that particular student. In this case, the learning content does not reside in the system, but in other distributed servers. Independently of the approach used, the majority of Web-based educational systems are based on technologies developed in the areas of hypermedia and intelligent tutoring systems (Brusilovsky, Stock, & Strapparava, 2000; Brusilovsky, 2001). The Pliant-based educational tool introduced in this chapter falls within the first stream. Pliant is a standalone and Web-based language, which encapsulates both the "human" and "computer" levels of thinking and coding programs. This unique privilege makes it an exceptional language, compared to any other existing one. It demonstrates that Pliant has a higher level of flexibility, adaptability, and integration, providing for higher software development capabilities and enhancements. Thanks to Pliant's HTTP (hypertext transfer protocol) server power, including server-side rendering, any mainstream Web browser should always be enough to access Pliant's documents, and by extension, Pliant e-learning materials. These features can be used to develop standalone Web portals for teaching/educational purposes, or to improve the current state-of-the-art e-learning development tools, while maintaining educational expectations, and economical, time constraints, and human resources limitations.

MAIN FOCUS OF THE CHAPTER

An Overview of the Pliant Approach

The Pliant project[5] was initiated in 1984 by Hubert Tonneau (Tonneau, De Mendez, & Santos, 1984). In his analysis of numerous software developments, Tonneau realized

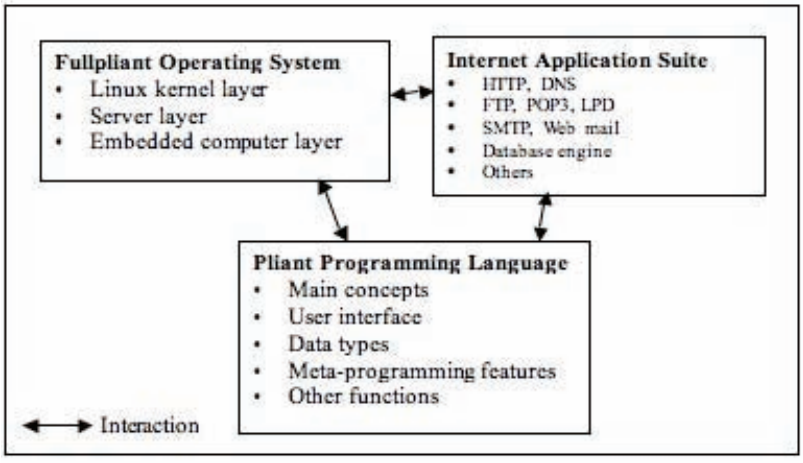
1. The lack of coherence between applications, libraries, and so forth often required a large amount of glue between relevant pieces of code.
2. It seemed impossible to conciliate high-level constructions allowing improved expressiveness and conciseness in specific contexts, with low-level adaptability allowing efficiency and optimized handling of exceptional cases.

From these considerations, the introduction of a new, efficient, and multi-level language with a flexible syntax and structure, which could be adapted to particular application contexts, seemed appropriate. The Pliant language is thus oriented towards efficiency, understood in terms of computational resources, as well as programming adaptability (De Mendez, De Mendez, Santos, & Tonneau, 2000). The main design structures of the language can be described as modularity, dynamic compilation, and full reflexivity, allowing for the redefinition of the syntactical, compilation, and code optimization rules. New application services have then been integrated at the language level (good examples are scheduling primitives and database management), hence suppressing usual gaps and interfaces between applications. From this point of view, an application is seen as a set of libraries, or even as a language extension possibly introducing its own syntactical changes. These applications may also be gathered into a coherent execution context, leading to an actual operating system, called *Fullpliant* (whose source code is a size of 4.2 Mb only). This framework can be executed in two different ways: as a program executing various servers (on Linux or Windows platforms), or as an operating system lying on top of a Linux kernel. Pliant comes with many pre-built servers including DNS (Domain Name System), FTP (File Transfer Protocol), POP3 (Post Office

Protocol version 3), HTTP, SMTP (Simple Mail Transfer Protocol), LPD (Line Printer Daemon protocol), remote execution, secured channel, and a database engine. The HTTP multi-site Web server provides the standard application interface. A powerful server-side dynamic page mechanism has been introduced, on which existing applications (Forum, photography correction and high-fidelity printing, Web-mail, etc.) rely, as well as additional HTTP-related servers (such as Web-based Distributed Authoring and Versioning–WebDAV). The limitation of the HTML (Hyper Text Markup Language)/Javascript scheme has led to the introduction of an enhanced extended Pliant browser, valuable as a state-of-the-art user interface for possibly distributed application software. Being used in an industrial context since 2000, *Fullpliant* is also concerned with security issues. The transparent integration in the dynamic page extension of signature and right verification mechanisms obviously demonstrates that security may be achieved without unnecessary additional programming complexity. Pliant (De Mendez et al., 2000) may thus be seen as a triad (see Figure 1): (1) the *Pliant programming language* and low-level libraries, (2) an *Internet applications suite*, and (3) the *Fullpliant operating system.*

The *Pliant programming language* is human oriented, that is, its syntax is trivial and strongly typed. Its expressiveness allows the user to program in a high abstraction level. The language is also reflexive, allowing the user to change the way Pliant parses and compiles expressions. In other words, users have a high degree of freedom to redefine the Pliant language itself, should they dislike a particular feature of the language or want to extend it (De Mendez, 1998). In addition to these meta-programming[6] capabilities of Pliant, the framework includes other modern programming principles, such as static typing, dynamic objects, lazy evaluation, reflective compiling, reference counting garbage collection, built-in debugger utility, scalability from low-level systems programming to high-level control languages, and an easy-following syntax. The Pliant compiler is dynamic and efficient, producing code, on-the-fly, as efficient as the best C compilers. The *Pliant Internet applications suite* consists of a set of servers, a database engine, data encryption tools, and a handful of Web application tools, such as the

Figure 1. Pliant architecture



HTTP server configuration tool, an online forum, Web mail, and printer configuration tool, to name a few. In the core of the suite is the Pliant HTTP server. It is in charge of hosting and dynamically translating Pliant Web pages, written in a subset of the Pliant language called the page format into HTML. The *Fullpliant operating system* (to be used by advanced users) has two main goals: facilitate the system administration of a set of computers, and make it easy to automate repetitive tasks. It appears from the above description that the two key design features of Pliant, upon which e-learning capabilities can be developed and supported, are the Pliant' intrinsic meta-programming constructs and the Pliant' ability to accommodate several multi-site Web servers.

Pliant' E-Learning Capabilities

E-learning can be defined as the use of network technology to design, deliver, select, administer, and adapt learning activities. Here, two basic types of technological solutions can be used: synchronous model (such as audio-video streaming and videoconference), and asynchronous model (such as hypertext publication). Existing e-learning management systems such as WebCT and Blackboard incorporate both models and corresponding services in different ways. However, due to certain limitations inherent to system stability, troubleshooting, cost-reduction, file format accommodations, Web browsers, customization, and others, none of these platforms includes a support to help manage the dynamics of e-learning activities. In an attempt to overcome these disadvantages, studies of management issues in e-learning environments has become critical for the success of Internet-based educational services. A relatively recent work on the management of e-learning environments has shown the effectiveness of using the workflow concepts (E-Workflow, 2003), techniques, and tools to help manage e-learning. Under this concept, the e-learning process is considered as a two-level interconnected process: the e-learning environment and the e-learning activities. The e-learning environment is further broken down into five different phases, each with its own set of tasks. These are:

1. **The conceptual phase:** Course subject, target audience, contents, budget organization, and so forth;
2. **The planning phase:** Details for the establishment and preparation of a specific instance of an e-learning action;
3. **The execution phase:** Period of time during which the students are active in the learning process; and
4. **The procedural evaluation phase:** An analysis of how the e-learning fulfilled its aims; additionally, the workflow e-learning environment model incorporates features such as improved efficiency, better process control (i.e., standardization of working methods), improved users service (i.e., greater predictability in levels of response to users), flexibility (i.e., ease of redesigning in line with changing needs); and
5. **The business process improvement:** Streamlining and simplification of processes.

The e-learning activities are concerned with the monitoring of actions and interactions among the above described phases. They are controlled by means of *learning objects*. The efficiency of an e-learning management system using workflow is measured by its capability in reusing learning objects. In this respect, workflow software and XML (Extensible Markup Language) are viable tools for describing learning objects. Any attempt to provide implementation techniques that could result in promoting the deployment of reusable contents or learning objects for e-learning purpose, while enhancing the integration capability of its underlying software platform, is therefore highly desirable for both the providers of educa-

tional services and the e-learning research community. Pliant seems to be a suitable candidate able to fulfill these requirements because of the versatility of the language constructs.

Pliant as a Tool for Consolidating E-Learning Management Systems Platforms

Any e-learning management system is driven by its underlying software platform (i.e., the set of programs that provide functionality to the application). At a human level, programs appear as algorithms, that is, a list of tasks, each being expressed by a single word or by a full sentence with subordinate clauses referring to subtasks. At a high (symbolic) level, a program is stated as a list of expressions. Each expression is a piece of raw data characterized by its semantics. At a low (i.e., code) level, a program is a set of instructions, where each instruction is a function call with a set of parameters. At this level, no ambiguity should remain.

A programming language is a bridge between the human way of thinking of an algorithm and the computer way of coding a program. Prior languages, including those on which the existing e-learning management systems are built, focus either on the semantics, but fail to be efficient at code level, or on efficiency, hence failing to be intuitive and easy to use by a human. To our knowledge, Pliant is the *first language* that makes the "single language" option a possible one by acting as a bridge between the aforementioned two levels. We assert that Pliant is the best one available, because it addresses this bridging goal at the highest level of flexibility and the best level of efficiency. This ability to write all code using a "single language" means better internal communication, time-saving improvements, load sharing, and shorter code. It also means reasonable scalability, adaptive user interface, easy switching from a closed software-like model to an open software-like model, more flexibility, customization, development power, strong design and high-quality program, low cost, dynamic highly reflexive compiler, less hardware limitations, adaptive hardware, and so forth. The list of goods is long. In order words, Pliant tries to bring as much expression power as possible, without impacting low-level code performance. These capabilities allow Pliant to be seen as a kit that greatly simplifies the distribution of software. In addition, Pliant can also offer e-learning potential, such as Internet-based learning and didactical requirements.

As a developed Web technology, Pliant is an Internet suite containing material needed to start an Internet site, including a database engine, a forum, a graphical toolkit, dynamic pages, and mail support. Therefore, it provides a suitable multimedia support to teachers and students, just as other proven e-learning systems, but with the added flexibility and adaptability of the underlying software and hardware platforms as pointed out previously. Pliant provides the choice to select elements according to the needs of teachers and students, and independently of their program of study. These elements can be divided into three interrelated groups, classified as: (1) elements for exploration and data management, (2) elements for teaching and communications, (3) and elements for users' management.

Elements for Exploration and Data Management

Pliant allows for a selection of various types of advanced Web browsers—Netscape, Mozilla, Internet Explorer, Konqueror—and is open to other better ones available. The choice of a browser depends on the security, portability, and computer power requirements. It also provides various types of servers suitable for Internetworking, such as HTTP, FTP, DNS, SMTP, POP3, Web mail, backup system, files browser, database engine, and so forth.

Elements for Teaching and Communications

Pliant can be used as a tool for enhancing course management systems. It provides a flexible software support for a variety of learning processes such as the distribution of documents and communications through the Internet. Pliant's online forum application provides asynchronous communication between instructors and students. The simple structure of the language allows one to easily create course Web sites on which one can post course notes for anytime access by students. With some training in Pliant programming, novices can quickly move on to the development of their own handy, tailor-made teaching tools, such as course assessments, online tests, and an online grade book. To illustrate the above points, we consider a simple case of a typical course Web page written in Pliant, and its results as shown in Figure 2.

Several interface options are provided:

1. *Access to course documents*, in this case exemplified by a link to the *course management form* and the course work, but can be a list of documents, such as readings, lecture notes, schedules, syllabi, course management forms, organization of course projects, priorities, and details, and so forth. It also supports the import and export capabilities by means of inserted Web site links, allowing the instructors to gain access to a complete set of teaching tools provided by academic publishers, or to create a package of the course content that can later be imported into another course.
2. *Course announcements*, a key place to put daily, weekly, or monthly time-sensitive course information such as deadline changes, clarifications, remainder of upcoming class chats, schedules, important events and dates, and so forth.
3. *Forum* is a Web portal that behaves as a virtual classroom and lightweight chat. It enables users to participate in an online collaboration with students and instructors. As a discussion board, messages are posted to the board, and every permitted user is able to read the messages and reply to them. Like a bulletin board, one copy of the message exists, and only the course designer has the right to delete the messages. A forum is a tool that fosters communication and collaboration as a way to enhance course material. Several forums can be created simultaneously, providing for a frame for team working. Each forum is assigned a thread

Figure 2. Typical course Web page in Pliant

```

 cell
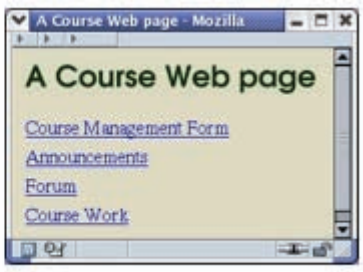
  link "Forum" "forum.html"
 cell
  note "Course Work"
    title "Course work"
```



(i.e., a discussion session) so that all replies to a given message are contained within the same thread. Within a forum, a messaging program is implemented that allows one to send e-mail messages to the users who are members of the forum, and to keep track of those messages. As a collaboration tool, a forum allows its users to enter into a real-time discussion with instructors, students, and colleagues; to access the Web; and to engage in question-and-answer sessions. The option of considering grouping student lists into several small groups can also be applied to keep the conversation manageable due to the synchronous nature of the discussion forum panel. It is important to point out that collaboration sessions throughout forums are recorded by means of subjects and messages. The leader of the session (course designer) must start the recorder to create an archive.

Elements for Users Management

In an e-learning prospective, the user management capabilities of Pliant is mostly reflected on the ways that Pliant enables the instructor to manage the users in their course sites. This involves the following types of setting privileges: enrolling users in the course, which means that the user must already have an account; removing users from the course; and creating groups of users within a course with the right to modify groups. The instructor has the option of giving the group access to its own private discussion board, virtual classroom, group file exchange, or group e-mail.

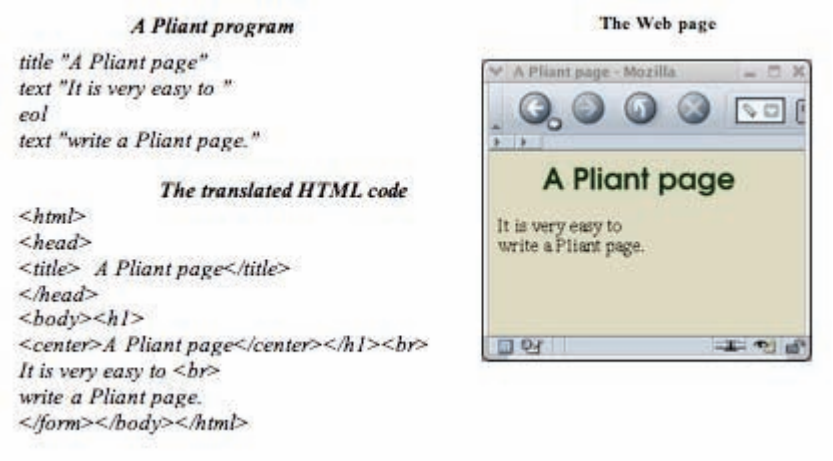
Pliant as a Tool for Learning Programming Languages and Web Programming

Due to the Pliant's meta-programming features, Pliant can be customized for learning and teaching purposes. Standard Pliant applications are browser based—that is, the programmer can host his or her Pliant program in the Pliant HTTP server and then interact with it using a Web browser. Browser-based Pliant programs have file extension *.page* and are written using Pliant's Web page programming instructions, called the *.page format*, an alternative to HTML/XML. Throughout the aforementioned interaction, the HTTP server works as follows: it keeps listening to requests from clients (i.e., other browsers on the Web); once it gets a request for a page, it translates the respective *.page* Pliant program into HTML and JavaScript code and sends it to the client (browser). If the client requests a plain HTML page hosted in the server, then the server simply sends it as it is. Hence, for the client, there is no difference; it is plain HTML/JavaScript coming from the server side. If the requested page does not point to a *.page* or static HTML file, then the Pliant HTTP server recursively searches for a file called *virtual_tree.page* in the path of the requested URL. This Pliant concept, called *virtual tree mechanism*, provides an easy mapping of data sets to URLs. Without it, HTTP options would be used—a not as clever and convenient solution. We relied heavily on such contrivance to implement one of Academia's[7] subsystems—the course Web content renderer.

To illustrate this simplicity and power of the Pliant language combined with the HTTP server, we now present short examples of Web applications written in Pliant. The Pliant program presented in Figure 3 illustrates how easy it is to write a simple static Web page with a title and some text. It shows a simplified HTML code generated by the Pliant HTTP server. The client will see this application as shown in Figure 3 (right side). As illustrated, Pliant has the capability of generating and caching online graphics when server-side font rendering has been requested.

The command title "A Pliant page" produces a page title; the command text, whose argument is a string, outputs text. Pliant provides a

Figure 3. A Pliant program and its resulting Web page



plethora of commands for writing Web pages. The interested reader should check the Pliant Documentation Initiative site (De Mendez et al., 2000). The next example illustrates how Pliant can be used to generate dynamic Web pages, such as a Web page for converting currency from Euros to Canadian Dollars. The programmer writes a page as follows:

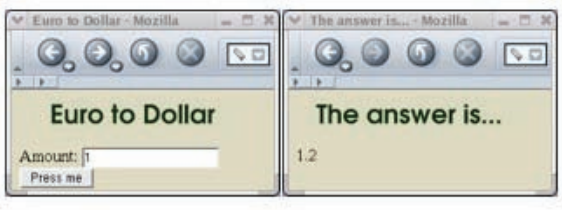
```
title “Euro to Dollar”
  var Float euro := 1
input “Amount: “ euro
  button “Press me”
title “The answer is…
text (string euro*1.2)
```

The user types in the amount in Euros he or she wants to convert (left of Figure 4). When the user clicks on the button, a new page, whose code is defined in the shadow of the button (i.e., indented with respect to the button instruction), will present the result of converting the input value from Euros to dollars (right of Figure 4). Notice that the function call (*string euro**1.2) transforms the numerical result of the expression *euro**1.2 into a string.

For programming languages development purposes, Pliant’s default syntax is lighter than others because of the following main features:

1. Many parentheses are implied by indentation,
2. The ‘:’ operator replaces some extra parentheses, and
3. There is no ‘,’ operator to separate the parameters of a function.

Figure 4. Dynamic Web page in Pliant



These features, combined with the meta-programming ones, make Pliant a language of choice for teaching the programming concepts. Because the purpose of this chapter is not on "experiencing programming languages," we will not elaborate much on Pliant's language specifications referred to the main concepts, user interface, data types, meta-programming optimizers, and other programming features. Interested readers can find detail information at http://old.fullpliant.org/pliant/language/.

In short, beginners can use Pliant as an interpreted language by writing small pieces of code and running them directly. Experienced programmers can run Pliant as a compiled language—that is, by writing efficient programs while using most high-level programming features of object-oriented languages and the expression power of logical programming languages. Pliant is also an ideal linker, in the sense that one can write different pieces of a project in different programming styles with all parts interacting.

Case Study on the Use of Pliant in the "Multilanguage Database for Localization" Project

In today's world of global operations and international technical communication, the Internet is fast becoming the primary port of call for information, education, training, and services. Consequently, more and more development initiatives go beyond local borders. Experienced professionals understand that to be effective, training must be done in the right language and with culturally appropriate resources and methodologies. In response, Canadian businesses, corporations, and universities have quickly become aware of the benefits of *localization* as one of the boosted agents shaping the new economy.

Localization can be defined as the process of taking a product and making it linguistically and culturally appropriate to a target locale (country, region, and language) where it is used and sold. This multi-layered process requires programming, linguistic skills, translation skills, cultural knowledge, and most importantly, an *e-learning development platform support.* It has been recognized as an important part of the educational program in Translation and Computer Science schools at Canadian universities and abroad, where students obtain basic education and training (both onsite and Web based) in both computational methods and localization techniques.

The increasing importance of terminology banks and translation memories in the translation process, a sub-component of the localization process, has created a need for developing language-based repositories for the purpose of using them in the localization training and practices. As a response to this deficiency, the "Multilanguage Database for Localization" project (Nyongwa & Aubin, 2004) was launched at the CUSB School of Translation, in collaboration with Ryerson University. The objective of this research is to develop a comprehensive database framework of languages which can efficiently support the localization training and practices. One subcomponent of this project entitled "Enhancement of the Pliant Language Database Engine" has been to investigate how the Pliant system, although not originally meant for language acquisition, can be used as a benchmark tool to support the user interface design of the aforementioned database framework, at least for the online localization training portion. In this context, thanks to its meta-programming feature, the Pliant language design has been altered and successfully tested to allow for customized content-building instructions. These later features were then used through *Academia—a Pliant-based courseware tool*,[8] to support the localization training in various capacities. Two scenarios are described later in this chapter to illustrate some of these capacities. The first scenario, described in the subsection entitled "Case Study of a Course Delivery," dis-

cusses a particular instance in the teaching of the "translation process" portion of the course in localization. The second scenario, described in the subsection entitled "Pliant System, Translation and CALL," illustrates how the "terminology" component of the localization course is taught using Academia.

Usability of Pliant in Teaching and Project Management Contexts

To further assess the usability of Pliant in teaching and project management contexts, we have implemented two Pliant-based applications. The first one is *Academia*, a courseware development Web portal, and the second one is *Co-op Web*, a management Web portal. In the sequel, we describe the first application in-depth, followed by a brief description of the second one. The reason is that the second application does not directly serve the purpose of this book.

Why Academia?

For instructors to carry on the mundane activity of setting course Web pages, two options are possible: design new course Web sites from scratch or resort to a courseware tool. However, such a tool is usually expensive and complex. The source code is usually proprietary, that is, it does not allow end users to further customize the code to suit their needs. Academia can address these deficiencies. The reader may then ask why one would use Academia and not another well-known courseware tool that provides every single feature an instructor can possibly fancy. Our answer: because as a Pliant-based application, end users can build on Academia's design and source code to develop more advanced and customized courseware materials, since there is no need to resort to different languages (as traditional approaches do) to develop applications that involve dynamic pages and databases.

Academia Features

Courseware products such as Blackboard (2002) and WebCT (2002) will take HTML documents, along with other media and resources, and quickly organize them into a framework specifically designed for delivery of Web-based courses and other learning resources. Frequently, they are used to complement traditional lecture-based programs. Courseware products are helpful to educators who are unfamiliar with programming, allowing easy integration of password protection, interactive activities, tracking of student progress, and so forth. Overall, the interface is fairly simple for the designer, as many use templates and wizards extensively to assist in course content creation. Step-by-step guides support creation of a range of components, from the course homepage, to bulletin boards, to quizzes and marking systems. When compared to the aforementioned courseware tools, Academia is a much 'lighter' application in the sense that it provides only the essential features required to set up a simple Web page for a course. Such a Web page may include links to a locally hosted copy of the course syllabus, assignment descriptions, instructor's lecture notes, and other materials.

Academia's User Interface Design

The design concept behind Academia's user interface was: *it should be as simple as possible, but not simpler.* In the first stage of the design process, a list of the functionality required of the system to accomplish the goals of the project and the potential needs of the users was prepared. From the instructor, manager, and students' viewpoints, this list included the major functionalities illustrated in the user-case diagrams presented in Figure 5. In the second stage of the design process, an analysis of the potential users of the system was carried out through discussion with instructors who already had previous experience

with other computer-based teaching tools, with instructors who had no previous experience with such systems, and with university students attending courses taught by the authors of this chapter. Typical questions presented to these individuals were of the sort:

- What would the user want the system to do?
- How would the system fit in with the user's normal workflow or daily activities?
- How technically savvy is the user and what similar systems does the user already use?
- What interface look-and-feel styles appeal to the user?

The answers were then compiled and cross-checked with the functionality list obtained in the respective analysis, resulting in a new minimal functionality set and overall look-and-feel style.

In the next stage, a site flow of the system that showed the hierarchy of the pages was developed. Next, prototyping and usability tests (Nielsen, 1993) were performed. In this stage, a proof-of-concept Web application was developed that showed the basic functionality set and content. Fast prototyping of the system was facilitated by the intrinsic features of the Pliant programming language. In regards to usability tests, the so-called *talk aloud protocol* (Wang, 2000), where you ask the user to talk about their thoughts during the experience, was performed via personal interviews with a small set of users—only instructors who volunteered to serve as guinea pigs during this tests—or 'looking over their shoulder' while they attempted to perform specific tasks with the system.

The ultimate goal of the Pliant software is "universal usability." As such, the Pliant user interface, or equivalently, the communication channel between the user and the functional elements of the system, has been intentionally made *text mode* based. This allows the user to focus on the task at hand and reduce the amount of overhead knowledge required to communicate effectively with Pliant and its underlying e-learning system (Academia). The function of the Pliant interface subsystem resumes in assigning user input to internal representations of Pliant's application and internal representations of the application to output that is comprehensible to the user. Thanks to the meta-programming features of the Pliant language and its reflective architecture, we believe that Pliant is compliant with the CALL aspects (i.e., the teaching and learning processes) with respect to online learning.

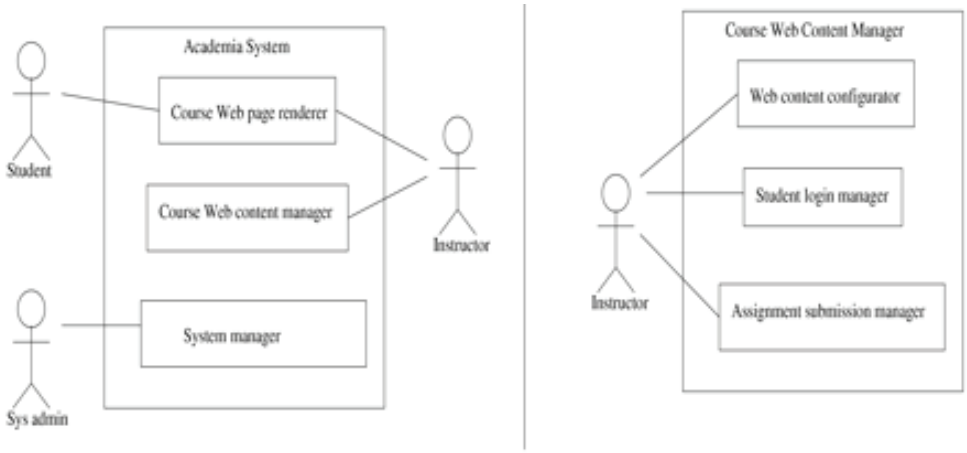
Academia's System-Level Capabilities

These are presented here by means of use cases and sequence diagrams. Such notations are commonly used in the area software engineering for describing a system without revealing or implying any particular implementation of the system (Booch, Rumnaugh, & Jacobson, 2005). The use case (left of Figure 5) presents Academia's subsystems and its actors.[9] The system administrator actor uses the *system manager subsystem* to keep track of the instructors registered in the system and the courses they teach. Instructors use the *course Web content subsystem* to set up the Web page of their courses. Once a course Web page has been configured, students can then visit the respective Web page, which is dynamically created by the *course Web page renderer.*

Course Web Content Manager Subsystem

Figure 5 (right side) depicts the course Web content manager subsystems. The *student login manager* subsystem allows the instructor to upload and manage the student's login access to the system. The *assignment submission manager* subsystem allows the instructor to view currently online submitted assignments and to download a compressed file containing all the assignment

Figure 5. Academia system-level architecture



submissions. The *course Web content configurator* subsystem allows the instructor to interactively configure a template design for the course Web page. The instructor can define his or her contact information, such as office number, office hours, lecture times, and locations; upload course syllabi, assignment descriptions, and lecture notes to the server; add an announcement board to the course Web page; and set up an online discussion board for the course.

Course Web Page Renderer

The course Web page configurator subsystem stores the configuration settings of a course Web page template design in a database. This database indexes courses by their term, year, code, and section number. The course Web page renderer uses this information and Pliant's virtual tree mechanism (explained earlier) to retrieve and display the Web content stored for a particular course. More specifically, suppose that an instructor whose username is *john.doe* has already configured the Web content for the following course:

***Term**: Winter*
***Year**: 2005*
***Code**: Phil 660*
***Section**: 001*
***Name**: Philosophy of Love and Sex*

If a client (browser) requests the URL[10] *http://academia.org/browse/mycourses/john.doe/,* then the Academia course Web page renderer would dynamically create a Web page that lists links to all currently hosted courses of instructor *john.doe.* It does that by using the virtual tree mechanism because there is no *index.html* file in the above location on the server. The Pliant program that implements the course Web page renderer resides in the *virtual_tree.page* file, located at the root of the path /browse/. Therefore, when the client requests the above URL and the server finds the *virtual_tree.page* file in /browse/, it stores in the internal variable *virtual_path* the remainder subpath */mycourses/john.doe/* and runs the *virtual_tree.page* program. For this particular case in which the above path starts with *mycourses,* the renderer parses the path and extracts the relevant informa-

tion needed for determining which courses to list on the dynamically created Web page.

A similar process takes place when a client (browser) requests the following URL: *http://academia.org/browse/courses/Winter/2005/Phil660/001/index.html*. However, no *index.html* (or *index.page*) file actually exists in the above location. Hence, analogous to what we explained above, the Pliant virtual path mechanism will again run the renderer. This time, the internal variable *virtual_path* will hold the sub-path */courses/Winter/2005/Phil660/001/*. Notice that this path provides all the information to locate the Web content for a course in Academia's database. The renderer parses this path to extract the course information (code, term, etc.). It then retrieves the Web content for the course from the database and dynamically creates a Web page for the course.

Towards Integrating Academia with Other Learning Management Systems

The initial idea underlying Academia's design was to provide an "*as simple as possible*," but not simpler courseware development and e-learning tool. As such, integration with more robust learning management systems (LMSs) was not a priority during the development. Notwithstanding, all database files used or produced by Academia are in ASCII text, and information is stored in XML-like data structures. As an example, below we list an excerpt of a user database:

```
<pdata path="/user/marcus/contact">7062</pdata>
<pdata path="/user/marcus/email">marcus.santos@mac.com</pdata>
<pdata path="/user/marcus/first_name">Marcus</pdata>
<pdata path="/user/marcus/homepage">www.cs.ryerson.ca/m3santos</pdata>
<pdata path="/user/marcus/language">English</pdata>
```

Notice that each entry in the database is encoded as simple XML code. Therefore, interfacing such data with an LMS would be straightforward. Pliant also includes many modern programming principles such as meta-programming, static typing, objects, reflective compiling, reference counting garbage collection, built-in debugger, clean syntax, and many pre-built components such as HTTP, FTP, SMTP, POP3 servers, a tree-based distributed data model, and a database engine. The intrinsic features of these core components can be used to support open Internet standards such as ECMAScript, thus, a-fortiori, to facilitate the compliance of Pliant with SCORM, but there still a long way to go to achieve this goal, and we have left it for future work.

A Case Study of Academia

This section reports on the findings from a study to experimentally compare some available Web-based learning tools used for the CUSB Certificate Program in Translation. These findings are discussed in relation to basic usability issues of Web-based tools, in terms of online course pedagogy, technological infrastructure, and students' perceptions. Our investigation attempts to justify the use of Academia as an e-learning methodology and acquisition tool.

The Context

Translation is a professional activity that requires both mental and physical settings, where profits and ethics must be met, just like in any other profession. Becoming a professional translator requires hard work, curiosity, open-mindedness, and experience. Based on these basic facts, the School of Translation at CUSB foresaw the importance of Web-based education in the mid-

1990s, then introduced a few online courses in its Translation program. By the year 2000, the entire Certificate Program, composed of 10 three-credit courses, was successfully launched. This program (referred to as the *TOP* program) was designed to accommodate the draft curricula for various areas of expertise within translation and the actual needs of the translation industry. It has been set up primarily for people who are interested in studying translation while maintaining their current employment. It was particularly aimed at those who work in remote areas and would find it impossible to attend classes at a local university. At each session, students may decide to take only one course at a time, or more, depending on their own personal timetable. A number of Internet-based courses, including *Localization,* were gradually introduced into the TOP program.

Technological Infrastructure

The CUSB infrastructure is made up of three servers, a dozen PCs for instructors, and a 10-PC laboratory for students. There are also three other high-tech laboratories and a multimedia center where on-campus students can work. Several programming tools and Blackboard (2002) are used by students and professors to develop and manage Web-related documents. Although this courseware tool was greatly appreciated by the students and staff, complaints were quickly raised, mostly on usability issues—such as long login sequence and difficult navigation. To address these drawbacks, Academia was used to supplement Blackboard.

Online Course Methodology

Unlike traditional courses, online courses are space and time independent. Meanwhile, in the case of the TOP program courses, a framework has been developed that meets the traditional division of an academic year—into sessions of 15 weeks each. Courses are delivered according to this division. The content of each course is organized as followed: knowledge review, lectures, practices, debates and discussions in the forum, exchanges of e-mails with instructors, and evaluation. Courses content is built into modules to facilitate individual learning. The evaluation consists of four formal tests, one in the fourth week, the second in the eighth week, the third in the twelfth week, and the last one in the fifteenth week.

Case Study of a Course Delivery

To demonstrate the capability of Academia as a support for e-learning methodology and acquisition, we have implemented an instance of a particular course entitled "Localization" on a specific problem: the problem of encoding/decoding the characters in a text file during the lifetime of the localization process. Localization is a process by which a product (in this case a text file) should be adequately adapted to the characteristics of each country and equipped with a presentation that is acceptable at least at the level already reached for its original locale. This process requires various types of operations involving the targeted language and written communication (localization of translations), as well as the supported technical infrastructure for data processing (software localization). Both types of localization sub-processes are technology dependent and are mandatory in a training program in Translation such as the TOP program. Here, we focus only on the software localization process. One of the major problems when running this process is the lack of a clear mechanism that ensures the identification of the encoding used to save/open any type of document, or to escape extended characters that are not supported by the targeted encoding technique. This issue is particularly important in this context since it determines translatable and non-translatable data. Among proposed solutions, XML has been proposed as a viable one (Savourel, 2000)

for the implementation of a multilingual solution. However, handling XML-like data structure files within the localization process is still a difficult task. To circumvent this difficulty, the Pliant-based capabilities of Academia are embodied in new standards or software processes such as XPath (Extensible Path), which provide several new features of dealing with data in general and localizable text in particular, based on the file format. Many state-of-the-art translator tools, available at *http://www.w3.org/*, are then used to apply the above mechanism in a concrete example. Depending on the power of the translator tool, the *Fullpliant*, and the type of XML file to be translated, the required steps are:

1. *Mark up the information in the text to be localized,* that is, find answers to the following questions: What text is translatable? Which language is chosen? Which local is referred to? What are the acronyms explanations? What constitutes the verbals and nominals in short sentences of the targeted text?
2. Using the Translator tool, *create an XSL template (document) with appropriate parameters.* This is achieved by writing a skeleton of HTML elements and by using the XSL style sheet commands to provide the text.
3. *Process the file to be localized by using the above template and by choosing the locale to work with.* Steps 1 and 2 are not always straightforward and need some good understanding of XML and XPath.

The following methodology was used. Prior to the localization course, students are given some basics in HTML and XML programming. They are introduced to the structural power of both languages and to Academia as a programming platform. Their attention is then focused on the simplicity of XML, and the way its features can be used to extract the translatable and non-translatable text in the file format to be localized. Students are taught, by means of examples, on how XML code can be written based on the file format and content, and then structured in a way that the translator can use it to generate the desired output. Students are then asked to compare the XML and corresponding HTML files. Then, the localization course is taught to students through different modules (process, Web site, project management, etc.), providing them with necessary material to tackle other steps of the translation process. At the end, students are asked to extract HTML and XML files in English and to localize them in Canadian French.

Findings

The separation of the content from the format allows the translation task to move faster while reducing the time allocated to pre-translation and post-translation processing. Due to the expressive power capabilities of the Pliant-based framework upon which Academia is built, students have gained a great level of confidence when integrating the localization information as a component of XML, rendering the translation process more achievable than ever. This integration would have been more difficult without the use of built-in and enticing capabilities for data processing provided by the Academia platform, which greatly simplifies the entire localization process.

Pliant System, Translation, and CALL

Even though the Pliant system was not originally meant for language acquisition, the flexibility it provides in terms of integration features makes it possible. In technical translation and specialty languages teaching, terminology is an essential topic that should be studied. The teaching of terminology in the context of the localization course using Academia has been addressed in a CALL-like methodology manner. For a *given text* that needs to be translated from one language

to another, the *steps* followed by the students, as well as the corresponding *Pliant-based methods* implemented to achieve these steps, are shown below.

1. Identify and establish a list of "appropriate" terms from the text to be translated. This task is achieved through the design of the Data Discovery Module (DDM). Here, some predefined language-based metrics are used to identify the aforementioned terms, and a Pliant-based user-interface is developed to extract these terms and stored them in DDM.
2. Ask the students to search for two or three contexts of the usage of each term from an established list obtained from various terminology repositories. This task is achieved through the design of the Data Context Module (DCM), where dictionaries and textual databases are stored. It mandates the implementation of a Pliant-based Web interface for data search and retrieval (using the Pliant mainstream servers) in these repositories.
3. Search for equivalent terms in the target language through available dictionaries and databases. This task is achieved by means of the Pliant-based Web interface for data search and retrieval described in Step 2.
4. Divide the text to be translated into individual sentences to be translated, and then allocate one sentence per student. This task is achieved through the design of the Division Module (DM). A Pliant-based script is developed to build this module.
5. Each sentence is translated by a student and sent to the discussion forum for revision by other students within the group. This task is achieved through the design of the Translation Module (TM). A Pliant-based forum is designed and implemented to handle the communication and transfer of information between all participants.
6. The revised sentences are put together again to create the translated text. This task is achieved through the design of the Assembly Module (AM). A Pliant-based script is developed to build this module.
7. The translated text is sent to the instructor for evaluation, verification, and validation. This task is achieved through the design of the Quality Assessment Module (QAM)—a set of Pliant-based evaluation and validation methods (or functions). This module also provides the potential for integrating the Pliant system in a distributed environment.

Co-Op Web

The Department of Computer Science at Ryerson University offers a five-year bachelor's program in Computer Science with a Co-op option (CSCC). The program requires the management of students' applications, admissions, career planning resources, course selection requirements, graduation requirements, financial requirements, and job placements, to name a few. To efficiently address these challenges, Co-op Web was developed using Pliant; it is currently use to administer the CSCC program and has shown great satisfaction from its usability' point of view.

Actual Management Aspects of Pliant after Development

Our current challenge remains to understand the experiences of instructors (and students) as they adopt Academia as a course management system and integrate it into their teaching (respectively learning), either in isolation or as a complement to existing learning management systems. Our plan is to study several patterns explaining how instructors/students experiment with individual features of Academia, facing both technical and integration challenges, and attempting to adapt Blackboard or any other sophisticated learning system to match their goals and practices. Aca-

demia has become "mission critical" in fulfilling some of the teaching and learning central goals: enriching the student/instructor learning experience and advancing access to resources for teaching, learning, and research. Academia's training programs are currently being handled throughout the university, in parallel with Blackboard training programs, where faculty and students can receive assistance with all aspects of Academia and Blackboard operations. Several upgrades have been done and are continuously done to the Pliant framework in order to solidify its underlying e-learning capabilities and integration features, both transparent through Academia. For example, at the departmental site, faculty members can now upload their final grades from a Blackboard grade book into a Web grade roster, instead of having to enter them manually. A tracker has also been set to report general bugs, feature requests, fixes, and other issues such as sensitive security problems.

In its current form, the dynamic compilation structure of Pliant offers many opportunities of experimentation for academic and industrial research as well. Thanks to Pliant's control over generated codes, academic and industrial fields used Pliant for physical modeling purposes. For example, in thermic equilibrium when injecting thermoplastic material in a mould, Pliant was used to update some models without having to recompile the system. In Mathematics, Pliant was used to re-implement some graph manipulation tools.

The integration of Pliant with SCORM, NLN, and IMS format learning objects is possible due to the dynamic compilation architecture of Pliant and its reflectivity. This option is currently under investigation. Another current application scenario is the use of Pliant to manage distributed systems. This has been achieved so far in some cases thanks to the meta-programming feature of Pliant and its tree-based distributed data model, which allows one to maintain a database of hardware available on each machine and of software to be deployed there.

To circumvent some of the drawbacks of Pliant's architecture, it is suggested that we look at some high-level optimization algorithms in academic literature and implement them in the Pliant language, the goal being to rewrite the entire framework in Pliant. This will facilitate the pliant deployment, its integration with other systems including learning management systems, and its ability to embrace and extend existing services, as well as enhancing Pliant's robustness in terms of code generation and reusability.

FUTURE TRENDS

The Pliant *.page* mechanism, which we have used to implement Academia, has proven very convenient for quickly prototyping and writing simple user interfaces. However, the current (and future) trend is to provide programming languages and Web application development platforms rich in interactive features, such as graphical user interface elements, to create dynamic, nice-looking, and functional user interfaces. To this aim, the Pliant team recently started the development of the Pliant browser. The Pliant browser consists of a new language (an extension to the *.page* language) for developing Web applications and an HTTP "bridge" for translating the Pliant browser interface to HTTP/Javascript.

For the future, once the additional features provided by the Pliant browser are in place, we plan to give Academia a new makeover on its user interface and features, such as a quiz/survey tool, and added flexibility to course Web page design and "look-and-feel." The style sheet mechanism used by the Pliant browser should greatly facilitate the implementation of a more flexible styling mechanism for Academia. Ultimately, Academia will stand as an example of how end users (teachers) of Pliant tend to become developers of Web-

based software solutions. An instructor with little or no programming background can smoothly migrate from a user of a simple system to a programmer of also simple pragmatic systems. The contribution of this framework to students is also noticeable. Student engagement can be improved by online instructional multimedia material, and course online content can be easily tailored to the students' needs.

Since new technologies always afford new roles for teachers as learners and researchers, we also intend to pursue our current research program endeavors, aiming at developing e-learning strategies for the purpose of promoting reflection on teaching and collaborative learning using the Pliant framework. For example, how might teachers/teacher educators use Pliant tools for reflection and research into their classrooms? What are the most critical Pliant design patterns that would optimize their knowledge-building efforts? How will they use that information in their instructional decisions? These challenges are currently under investigation, and our ultimate goal is to produce a solution in the form of an analysis toolkit.

Finally, we would like to initiate a comprehensive evaluation (empirical study) of the use of Academia at both CUSB and Ryerson University. Our targeted audiences are students and staff. We are currently preparing an online questionnaire with the aim of gaining substantial and quantitative-based reactions to the use of Academia as a complement to the already sophisticated Blackboard platform for the purpose of e-learning. Our intention is to measure how far our framework can be useful in delivering and managing online courses.

CONCLUSION

We have described Pliant as a "standalone" and "Web-based" language that encapsulates both the "human" and "computer" levels of thinking and coding programs. This unique privilege makes it an exceptional language, compared to any other existing one. It also demonstrates a higher level of flexibility, reasonable adaptability, and integration, providing for higher software development capabilities and enhancements. These qualities can be exploited to improve the current state-of-the-art e-learning development tools, while meeting educational expectations, economical and time constraints, and human resources limitations. The main advantages of Pliant over other integrated software solutions are high transferability, flexibility, and maintainability. We have also presented Academia, a lightweight courseware application fully implemented in Pliant. When compared to mainstream courseware applications, Academia is surely over-simplified. Finally, a simple, yet concrete example of how Academia was used in a Translation program at CUSB was proposed, along with some insights on the e-learning methodology and pedagogy that were used.

KEY TERMS

Academia: A courseware development Web portal, fully implemented in the Pliant language.

Courseware: Computer software and associated materials designed for educational or training purposes.

E-Learning: The use of network technology to design, deliver, select, administer, and adapt learning activities.

Fullpliant: Name given to the Pliant' operating system.

Pliant: The first efficient, truly extendable, customizable programming language. It is suited both for small scripts and for very large applications, and could be described as a combination of reflexive C, C++, typed Lisp, and clean syntax in a single language.

Software Design: Process of problem solving and planning for a software solution.

Usability: A measure, in our context, of how easy it is to use software to perform prescribed tasks.

ENDNOTES

Section IV
Utilization and Application

This section introduces and discusses the ways in which information technology has been used to shape the realm of software applications and proposes new ways in which IT-related innovations can be implemented within organizations and in society as a whole. These particular selections highlight, among other topics, intelligent software agents in e-commerce and utilizing open source software in organizations. Contributions included in this section provide excellent coverage of today's changing environment and insight into how evolutions in software applications impact the fabric of our present-day global village.

Chapter 4.1
Intelligent Software Agents with Applications in Focus

Mario Janković-Romano
University of Belgrade, Serbia

Milan Stanković
University of Belgrade, Serbia

Uroš Krčadinac
University of Belgrade, Serbia

INTRODUCTION

Most people are familiar with the concept of agents in real life. There are stock-market agents, sports agents, real-estate agents, etc. Agents are used to filter and present information to consumers. Likewise, during the last couple of decades, people have developed software agents, that have the similar role. They behave intelligently, run on computers, and are autonomous, but are not human beings.

Basically, an agent is a computer program that is capable of performing a flexible and independent action in typically dynamic and unpredictable domains (Luck, McBurney, Shehory, & Willmott, 2005). Agents are capable of performing actions and making decisions without the guidance of a human. Software agents emerged in the IT because of the ever-growing need for information processing, and the problems concerning dealing and working with large quantities of data.

Especially important is how agents act with other agents in the same environment, and the connections they form to find, refine and present the information in a best way. Agents certainly can do tasks better if they perform together, and that is why the multi-agent systems were developed.

The concept of an agent has become important in a diverse range of sub-disciplines of IT, including software engineering, networking, mobile systems, control systems, decision support, information recovery and management, e-commerce, and many others. Agents are now used in an increasingly wide number of applications — ranging from comparatively small systems such as web or e-mail filters to large, complex systems such as

air-traffic control, that have a large dependency on fast and precise decision making.

Undoubtedly, the main contribution to the field of intelligent software agents came from the field of artificial intelligence (AI). The main focus of AI is to build intelligent entities and if these entities sense and act in some environment, then they can be considered agents (Russell & Norvig, 1995). Also, object-oriented programming (Booch, 2004), concurrent object-based systems (Agha, Wegner, and Yonezawa, 1993), and human-computer interaction (Maes, 1994) are fields that constantly drive forward the development of agents.

BACKGROUND

Although the term 'agent' is widely used, by many people working in closely related areas, it defies attempts to produce a single universally accepted definition. One of the most broadly used definitions states that *"an agent is an encapsulated computer system that is situated in some environment, and that is capable of flexible, autonomous action in that environment in order to meet its design objectives"* (Wooldridge and Jennings, 1995).

There are three main concepts in this definition: *situatedness*, *autonomy*, and *flexibility:*

- *Situatedness* means that an agent is situated in some environment and that it receives sensory input and performs actions which change that environment in some way.
- *Autonomy* is the ability of an agent to act without the direct intervention of humans. It has control over its own actions and over its internal state. Also, the autonomy implies the capability of learning from experience.
- *Flexibility* means that the agent is able to perceive its environment and respond to changes in a timely fashion; it should be able to exhibit opportunistic, goal-directed behaviour and take the initiative whenever appropriate. In addition, an agent should be able to interact with other agents and humans, thus to be 'social'.

For some researchers - particularly those interested in AI - the term `agent' has a stronger and more specific meaning than that sketched out above. These researchers generally mean an agent to be a computer system that, in addition to having the properties identified above, is either conceptualized or implemented using concepts that are more usually applied to humans. For example, it is quite common in AI to characterize an agent using mentalistic notions, such as knowledge, belief, intention, and obligation (Wooldridge & Jennings, 1995).

INTELLIGENT SOFTWARE AGENTS

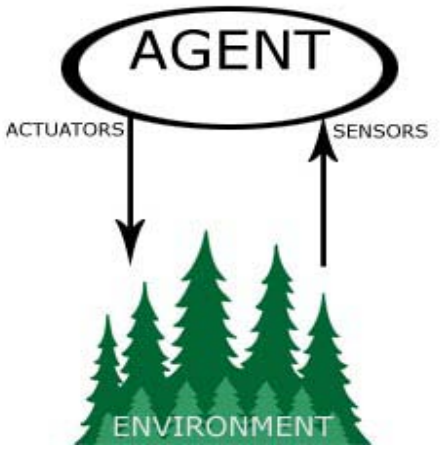
Agents and Environments

An agent collects its percepts through its sensors, and acts upon the environment through its actuators. Thus, the agent is proactive. Its actions in any moment depend on the whole sequence of these inputs up to that moment. A decision tree for every possible percept sequence of an agent would completely define the agent's behavior. This would define the function that maps any sequence of percepts to the concrete action – *the agent function*. The program that defines the agent function is called the *agent program*. So, the agent function is a formal description of the agent's behavior, and the agent program is a concrete implementation of that formalism. (Krcadinac, Stankovic, Kovanovic & Jovanovic, 2007)

To implement all this, we need to have a computing device with appropriate sensors and actuators on which the agent program will run. This is called *agent architecture*. So, an agent is essentially made of two components: the agent architecture and the agent program.

Also, as Russell and Norvig (1995) specify,

Figure 1. Agent and environment



one of the most sought after characteristics of an agent is its *rationality.* An agent is rational if it always does the action that will lead to the most successful outcome. The rationality of an agent depends on (a) the performance measure that defines what is a good action and what is a bad action, (b) the agent's knowledge about the environment, (c) the agent's available actions, and (d) the agent's percept history.

The Types of Agents

There are several basic types of agents with respect to their structure (Russell & Norvig, 1995):

1. The simplest kind of agents are the *simple reflex agents*. Such an agent only reacts to its current percept, completely ignoring its percept history. When a new percept is received, a rule that maps that percept to an action is activated. Such rules are known as *condition-action rules.*
2. *Model-based reflex agents* are more powerful agents, because they maintain some sort of internal state of the environment that depends on the percept history. For maintaining this sort of information, an agent must know how the environment evolves, and how its actions affect the environment.
3. *Goal-based agents* have some sort of goal information that describes desirable states of the world. Such an agent's decision making process is fundamentally different, because when a goal-based agent is considering performing an action it is asking itself "would this action make me happy?" along with the standard "what this action will have as a result?".
4. *Utility-based agents* use a utility function that maps each state to a number that represents the degree of happiness. They are able to perform rationally even in the situations when there are conflicting goals, as well as when there are several goals that can be achieved, but none with certainty.
5. *Learning agents* do not have a priori knowledge of the environment, but *learn* about it. This is beneficial because these agents can operate in unknown environments and to a certain degree facilitates the job of developers because they do not need to specify their whole knowledge base.

Multi-Agent Systems

Multi-Agent Systems (MAS) are systems composed of multiple autonomous components (agents). They historically belong to *Distributed Artificial Intelligence* (Bond & Gasser, 1998). MAS can be defined as a loosely coupled network of problem solvers that work together to solve problems that are beyond the individual capabilities or knowledge of a single problem solver (Durfee and Lesser, 1989). In a MAS, each agent has incomplete information or capabilities for solving the problem and thus has a limited viewpoint. There is no global system control, the data is decentralized and the computation is asynchronous.

In addition to MAS, there is also the concept of a *multi-agent environment,* which can be seen as an environment that includes more than one agent.

Thus, it can be cooperative, or competitive, or a combined one, and creates a setting where agents need to interact (socialize) between each other, either to achieve their individual objectives, or to manage the dependencies that follow from being situated in a common environment. These interactions range from simple semantic interoperation (exchanging comprehensible communications), client-server interactions (the ability to request that a particular action is performed), to rich social interactions (the ability to cooperate, coordinate, and negotiate about a course of action).

Because of the issues due to heterogeneous nature of agents involved in communication (e.g., finding one another), there is also a need for *middle-agents*, which cover cooperation among agents and connect service providers with service requesters in the agent world. These agents are useful in various roles, such as *matchmakers* or *yellow page agents* that collect and process service offers ("advertisements"), *blackboard* agents that collect requests, and *brokers* that process both (Sycara, Decker, & Williamson, 1997). There are several alternatives to middle agents, such as Electronic Institutions – a framework for Agents' Negotiation which seeks to incorporate organizational concepts into multi-agent systems. (Rocha and Oliveira, 2001)

Communication among agents is achieved by exchanging messages represented by mutually understandable language (syntax) and containing mutually understandable semantics. In order to find a common ground for communication, an *agent communication language* (*ACL*) should be used to provide mechanisms for agents to negotiate, query, and inform each other. The most important such languages today are *KQML* (Knowledge Query and Manipulation Language) (ARPA Knowledge Sharing Initiative, 1993) and *FIPA ACL* (FIPA, 1997).

AGENT APPLICABILITY

There are great possibilities for applying multi-agent systems to solving different kinds of practical problems.

- *Auction negotiation model*, as a form of communication, enables a group of agents to find good solutions by achieving agreement and making mutual compromises in case of conflicting goals. Such an approach is applicable to trading systems, where agents act on behalf of buyers and sellers. Financial markets, as well as scheduling, travel arrangement, and fault diagnosing also represent applicable fields for agents.
- Another very important field is *information gathering*, where agents are used to search through diverse and vastly different information sources (e.g., World Wide Web) and acquire relevant information for their users. One of the most common domains is Web browsing and search, where agents are used to adapt the content (e.g., search results) to the users' preferences and offer relevant help in browsing.
- *Process control software systems* require various kinds of automatic (autonomous) control and reaction for its processes (e.g. production process). Reactive and responsive, agents perfectly fit the needs of such a task. Example domains in this field include: production process control, climate monitoring, spacecraft control, and monitoring nuclear power plants.
- *Artificial life* studies the evolution of agents, or populations of computer simulated life forms in artificial environments. The goal is to study phenomena found in real life evolution in a controlled manner, hopefully to eliminate some of the inherent limitations and cruelty of evolutionary studies using live animals.

- Finally, *intelligent tutoring systems* often include pedagogical agents, which represent software entities constructed to present the learning content in a user-friendly fashion and monitor the user's progress through the learning process. These agents are responsible for guiding the user and suggesting additional learning topics related to the user's needs (Devedzic, 2006).

Some of the more specific examples of intelligent agent applications include Talaria System, military training, and Mobility Agents. Talaria System (The Autonomous Lookup And Report Internet Agent System) is a multi-agent system, developed for academic purposes at the University of Belgrade, Serbia. It was built as a solution to the common problem of gathering information from diverse Web sites that do not provide RSS feeds for news tracking. The system was implemented using the JADE modeling framework in Java. (Stankovic, Krcadinac, Kovanovic & Jovanovic, 2007) Talaria System is using the advantages of human-agent communication model to improve usability of web sites and to relieve users from annoying and repetitive work. The system provides each user with a personal agent, which periodically monitors the Web sites that the user expressed interest in. The agent informs its user about relevant changes, filtered by assumed user preferences and default relevance factors. Human-agent communication is implemented via email, so that a user can converse with her/his agent in natural language, whereas the agent heuristically interprets concrete instructions from the mail text (e.g., "monitor this site" or "kill yourself").

Simulation and modelling are extensively used in a wide range of military applications, from development, testing and acquisition of new systems and technologies, to operation, analysis and provision of training, and mission rehearsal for combat situations. The Human Variability in Computer Generated Forces (HV-CGF) project, undertaken on behalf of the UK's Ministry of Defence, developed a framework for simulating behavioral changes of individuals and groups of military personnel when subjected to moderating influences such as caffeine and fatigue. The project was built with the JACK Intelligent Agents toolkit, a commercial Java-based environment for developing and running multiagent applications. Each team member is a rational agent able to execute actions such as doctrinal and non-doctrinal behaviour tactics, which are encoded as JACK agent graphical plans. (Belecheanu et al., 2005)

Mobility Agents is an agent-based architecture that helps a person with cognitive disabilities to travel using public transportation. Agents are used to represent transportation participants (buses and travelers) and to enable notification of bus approaching and arrival. Information is passed to the traveler using a multimedia interface, via a handheld device. Customizable user profiles determine the most appropriate modality of interaction (voice, text, and pictures) based on the user's abilities (Repenning & Sullivan, 2003). This imposes a personal agent to take care that abstract goals, as "go home", are translated into concrete directions. To achieve this, an agent needs to collect information about user-specific locations and must be able to suggest the right bus for the particular user's current location and destination.

FUTURE TRENDS

Future looks bright for this technology as development is taking place within a context of broader visions and trends in IT. The whole growing field of IT is about to drive forward the R&D of intelligent agents. We especially emphasize *the Semantic Web, ambient intelligence, service oriented computing, Peer-to-peer computing* and *Grid Computing.*

The Semantic Web is the vision of the future Web based on the idea that the data on the Web can be defined and linked in such a way that it can

be used by machines for the automatic processing and integration (Berners-Lee, Hendler, & Lassila, 2001). The key to achieving this is by augmenting Web pages with descriptions of their content in such a way that it is possible for machines to reason automatically about that content. The common opinion is that the Semantic Web itself will be a form of intelligent infrastructure for agents, allowing them to "understand" the meaning of the data on the Web (Luck et al., 2005).

The concept of *ambient intelligence* describes a shift away from PCs to a variety of devices which are embedded in our environment and which are accessed via intelligent interfaces. It requires agent-like technologies in order to achieve autonomy, distribution, adaptation, and responsiveness.

Service oriented computing is where MAS could become very useful. In particular, this might involve web services, where the Quality Of Service demands are important. Each web service could be modeled as an agent, with dependencies, and then simulated for observed failure rates.

Peer-to-peer (P2P) computing, presenting networked applications in which every node is in some sense equivalent to all others, tends to become more complex in the future. Auction mechanism design, agent negotiation techniques, increasingly advanced approaches to trust and reputation, and the application of social norms, rules and structures - presents some of the agent technologies that are about to become relevant in the context of P2P computing.

Grid Computing is the high-performance agent-based computing infrastructure for supporting large-scale distributed scientific endeavour. The Grid provides a means of developing eScience applications, yet it also provides a computing infrastructure for supporting more general applications that involve large-scale information handling, knowledge management and service provision. The key benefit of Grid computing is flexibility – the distributed system and network can be reconfigured on demand in different ways as business needs change.

Some considerable challenges have still remained in the agent-based world, such as the lack of sophisticated software tools, techniques and methodologies that would support the specification, development, integration and management of agent systems.

CONCLUSION

Today, research and development in the field of intelligent agents is rapidly expanding. At its core is the concept of autonomous agents interacting with one another for their individual and/or collective benefit. A number of significant advances have been made over the past two decades in design and implementation of individual autonomous agents, and in the way in which they interact with one another. These concepts and technologies are now finding their way into commercial products and real-world software solutions. Future IT visions share the common need for agent technologies and prove that agent technologies will continue to be of vital importance. It is foreseeable that agents will become the integral part of informational technologies and artificial intelligence in the near future, and that is why they should be kept an eye on.

KEY TERMS

Actuators: Software component and part of the agent used as a mean of performing actions in the agent environment.

Agent Autonomy: Agent's active use of its capabilities to pursue some goal, without intervention by any other agent in the decision-making process used to determine how that goal should be pursued (Barber & Martin, 1999).

Agent Percepts: Every information that an agent receives trough it's sensors, about the state of the environment or any part of the environment.

Intelligent Software Agent: An encapsulated computer system that is situated in some environment and that is capable of flexible, autonomous action in that environment in order to meet its design objectives (Wooldridge & Jennings, 1995).

Middle-Agents: Agents that facilitate cooperation among other agents and typically connect service providers with service requesters.

Multi-Agent System (MAS): A software system composed of several agents that interact in order to find solutions of complex problems.

Sensors: Software component and part of the agent used as a mean of acquiring information about current state of the agent environment (i.e., agent percepts).

This work was previously published in Encyclopedia of Artificial Intelligence, edited by J. Dopico; J. de la Calle; A. Sierra, pp. 950-955, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 4.2
Simulation Modelling within Collaborative Spatial Decision Support Systems Using "Cause–Effect" Models and Software Agents

Raja Sengupta
McGill University, Canada

ABSTRACT

Solutions to spatial environmental problems often require the integration of dynamic simulation models within GIS to create spatial decision support systems (SDSS) that can generate responses to theoretical "What if?" scenarios. Extending this paradigm to a collaborative spatial decision support system, however, faces significant challenges. This includes the inability of computationally intensive models to provide real-time results, and the inability of novice end users to effectively parameterize the models. Effective solutions to these problems proposed here include the use of "cause-effect" models to link inputs to outputs for a limited number of scenarios, as well as utilizing software agents that assist novice users in determining the correct input parameters for the models. Examples from the St-Esprit watershed SDSS serve to elucidate the proposed solutions.

INTRODUCTION

Sprague (1980) defined decision support systems (DSS) as computer software that are: (a) designed to solve the kinds of semi- and unstructured problems that upper level managers often face; (b) able to combine analytical models with traditional data storage and retrieval functions; (c) user-friendly and accessible by decision makers with minimal computer experience; and (d) flexible and adaptable to different decision-making approaches. Extending this definition, Armstrong, Densham, & Rushton (1986) used the term spatial decision support systems to refer to computer programs

that help decision-makers solve semistructured spatial problems through the integration of analytical models, spatial data, and traditional geoprocessing software (such as GIS). Therefore, an SDSS supports the spatial decision-making process by providing access to models that help users assess the impact of alternative solutions on stakeholders in collaborative environments (Armstrong, 1994).

Several spatial decision support systems (SDSS) implementations have been proposed or demonstrated in literature that incorporates analytical modeling with traditional GIS software packages for decision support. For example, the NELUP DSS was developed to study the impact of policy changes (at a global, European, national, regional, county, or local level) on the rural landscape, agriculture, and environment using economic, hydrologic, and habitat models (Watson & Wadsworth, 1996). Another SDSS, which relocated supply stores for school districts, was developed to find the optimal number of regions and service locations within each region to serve a dispersed geographical pattern of demand (Armstrong, Rushton, Honey, Dalziel, Lolonis, De, & Densham, 1991). The "WaterWare" DSS was developed as a comprehensive SDSS to support the development of an integrated river basin management plan to resolve conflicting uses such as recreation, agriculture, water supply, and the environment (Jamieson & Fedra, 1996). And finally, faunal habitat and landscape ecology models are being increasingly integrated with GIS to support decision making at the landscape level (McGarigal & Marks, 1993; Larson & Sengupta, 2004; Zhu, Healey, & Aspinall, 1998)

However, current SDSS often act as a basic interface to complicated models, leaving the end user to figure out model input parameters on their own. Therefore, the execution of such models in the SDSS in real time creates three hurdles for end users of the SDSS:

1. The models are computationally demanding, and can take up system resources that essentially render them impossible to execute in real time;
2. Most SDSS expect the end user to be well versed with the input data requirements and critical parameters of the model, which requires scientific knowledge of the process being simulated; and
3. Most models integrated within SDSS aren't well suited to assisting a collaborative decision-making process, with the above two points creating significant complexity while running models in group settings.

In effect, the lack of real-time model runs forces the collaborative decision-making process to rely on preset examples and/or static map outputs of sophisticated numerical simulations. This limitation not only severely restricts the range of options that can be evaluated by the group, it also forces individuals to rely on third-party technical support for generation of key scenarios.

This chapter describes the development of two strategies that can allow dynamic simulation scenarios to be incorporated within an SDSS to make it capable of supporting collaborative research, namely (i) "cause-effect" models linking outputs to spatial inputs, and (ii) software agents to assist users in selecting and understanding model parameters and input variables. Taken together, these two approaches can be combined with traditional multicriteria analysis (e.g., analytical hierarchy process or AHP) and GIS-based overlay procedures, thereby providing multiple decision-makers access to real-time generation of "What if?" scenarios incorporating dynamic spatial process simulations and allowing for collaborative problem-solving (Jankowski, 1995).

The effectiveness of this procedure in creating the prototype of a collaborative planning tool is tested using the example of the St-Esprit watershed in Quebec. In the first part, "cause-effect" models of stream discharge linked to varied land use scenarios are generated using the Soil and Water Assessment Tool (SWAT) program. In the

second part, conceptual models of software agents are discussed that could assist users in mastering the nuances of SWAT.

CAUSE-EFFECT MODELS

Modelling Runoff and Sediment Loading of the Saint-Esprit Watershed using SWAT

The watershed modeled in SWAT drains a portion of the St. Esprit County in Québec, 50 km north of Montreal (Figure 1). The St. Esprit River is a tributary of the L'Assomption River, which flows into the St. Lawrence. The St. Esprit watershed is 26.1 Km^2, of which 28% is forest, 26% corn, 12% hay, 8.5% wheat, and 7.3% residential (Figure 2). Generally, the relief of this region is rolling with a 64 m difference from the highest to lowest point, and slopes generally well below 5%. The soils are more gravelly and sandy in the headwaters, while clays predominate at the lower reaches of the basin. The soil texture classes are mainly loamy sands, sandy loams, and clays (see Figure 3).

SWAT, developed by the Blackland Research Center of the Texas A&M University System, the Grassland, Soil, and Water Research Laboratory of the USDA, and the US EPA Office of Science and Technology, is a public domain, physically based, distributed parameter hydrologic model specifically designed for agricultural watersheds (Srinivasan & Arnold, 1994).

SWAT relates a set of spatially distributed input parameters representing land use, soils, and climate to the output parameters of streamflow, sediment concentration, and nitrate and phosphate loading. For example, Figure 2 shows the land-use maps for the St. Esprit watershed, obtained in 1995 by a land survey carried out by the Brace Water Resources Center at the Macdonald Campus of McGill University (Enright, Papineau, & Madramootoo, 1998). This data, combined with nonspatial climate data obtained from Environment Canada (consisting of solar radiation, temperature, rainfall, evapotranspiration, and wind speeds from 1994 to 1998) and spatially explicit soil (Figure 3) and topographic maps obtained from the "Institut de Recherche et Development en Agroenvironnement" (IRDA), can be used to estimate stream discharge and sediment output from the mouth of the river (Figure 4). Obviously, there exists a complex mathematical relationship within the model where the output of the model

Figure 1. Location map of Saint-Esprit watershed

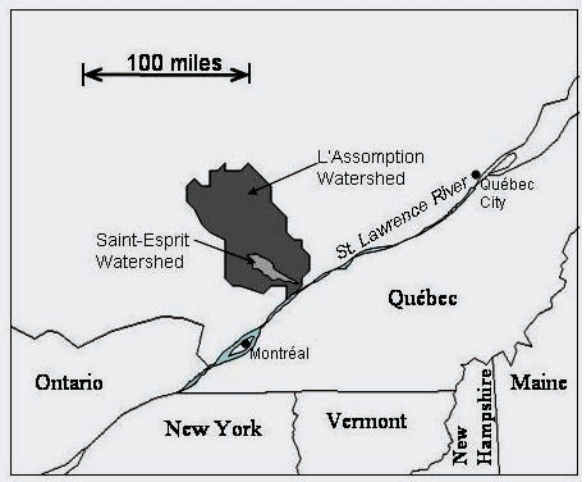

Figure 2. Landuse Map of Saint-Esprit Watershed

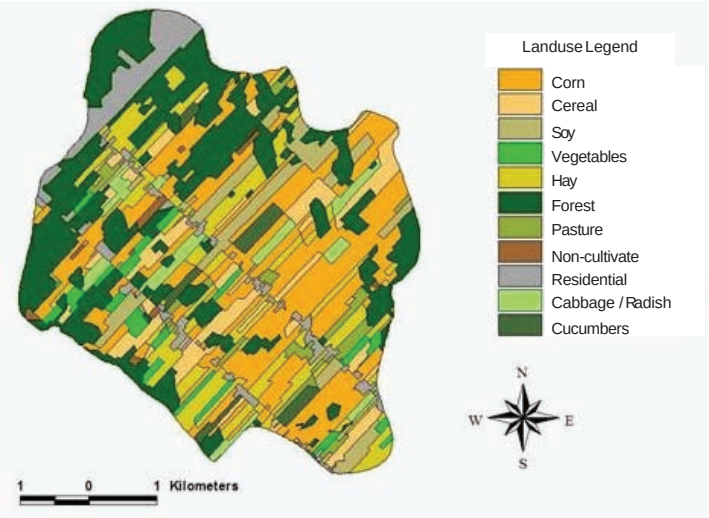

Figure 3. Soils Map (with streams overlay) of Saint-Esprit Watershed

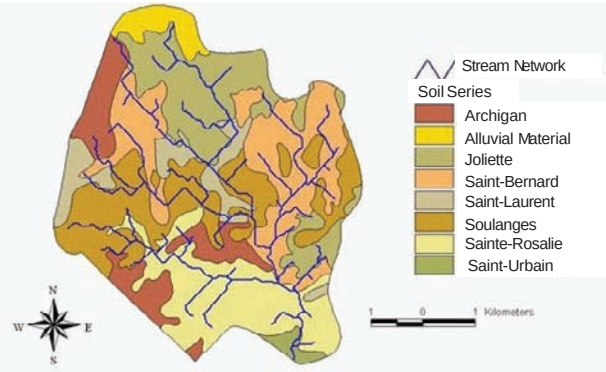

Figure 4. SWAT output showing simulated monthly discharge and sediment loading at the mouth of the St-Esprit River (1994-1998).

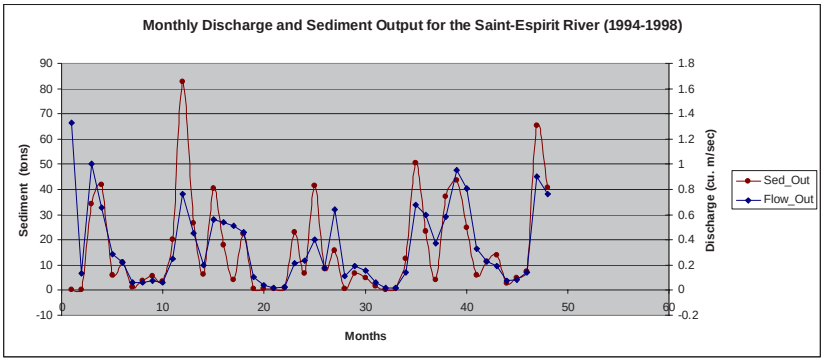

(e.g., discharge) is dependent on the input parameters (e.g., land use, soils, and climate), as shown in a simplified manner in Figure 5.

Modelling the Model: "Cause-Effect" Models that Link Nonspatial Inputs to Outputs

The interesting feature of the relationship shown in Figure 5 is that for an unchanged set of spatial data, the relationship between inputs and outputs is nonspatial in nature, and can be derived using either statistical techniques or with heuristic methods such as neural networks (Bekele & Nicklow, 2005). In other words, if land use, topography, or soils are not altered, then the relationship of the independent nonspatial variable, that is, climate, to the dependent nonspatial output, for example, discharge, varies with time but not across space. This important characteristic of SWAT and other similar spatially distributed hydrological models can therefore be exploited to build simplified models of relationships between the two nonspatial components, which is termed a "cause-effect" model here.

As demonstration, two cause-effect models were built for the Saint-Esprit SWAT simulation using a neural network software and linear regression respectively. In both cases, an identical dataset consisting of select climate variables (i.e., rainfall, snowmelt, and evapotranspiration) and discharge for 241 monthly simulations (1994-1998) were used to derive the relationship between these variables. For the first model, the neural network software Neurosolutions (http://www.neurosolutions.com) consisting of two layers of neurons connected in a feed-forward fashion was used. Eleven sample points were set aside as test cases, and the remaining 230 points used to train the neural network. Within the software, a genetic algorithm is used to train the neurons multiple times, and the default value of 1,000 iterations was selected to converge the neurons on a solution. The neural network was, however, able to converge within the first hundred iterations, indicating that a robust solution had been found. This solution was then used to predict discharge values. Figure 6 shows the comparison of the actual values for discharge for the eleven test points compared with the values predicted by the Neural Network.

The second cause-effect model was built statistically using linear regression. Its results were even more striking in that a single climate variable, snowmelt, explained over 78% of the variability in discharge. The strong correlation

Figure 5. Relationship between Input and Output variables

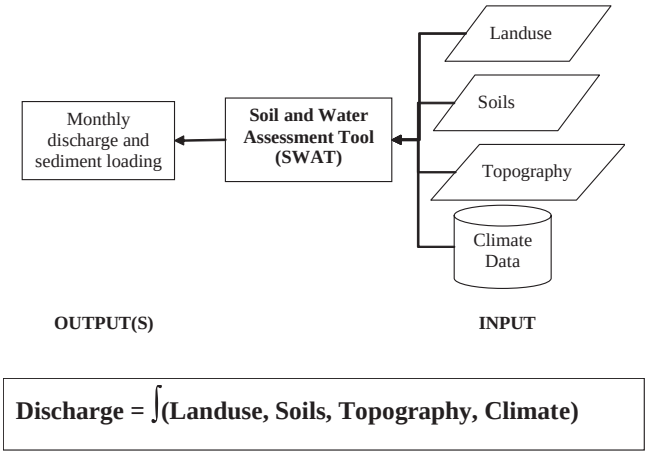

Figure 6. Comparison of discharge values predicted by the Neural Network with actual values; statistical results and scatter plot indicate a correlation coefficient of 0.78

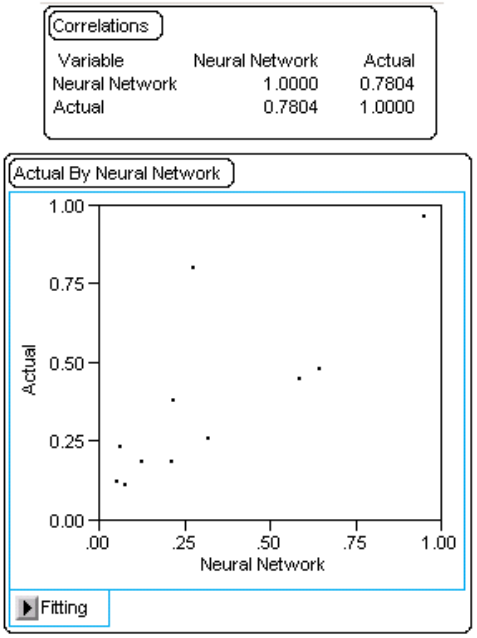
Predicted Values (cu. m/sec)		Actual Values (cu. m/sec)
0.2158	0	.3854
0.5858	0	.4558
0.9506	0	.97
0.0506	0	.129
0.2118	0	.1915
0.3167	0	.2661
0.6421	0	.4862
0.2723	0	.8089
0.0772	0	.1198
0.0623	0	.2373
0.1251	0	.1919



amongst these two variables can be observed in a time-series plot and explained with the help of simple linear regression, as shown in Figure 7.

The cause-effect models discussed above indicate that if the spatially-explicit input datasets are not altered between model runs, it may be possible to devise simplified relationships that mimic the model's output without having to re-run the model itself. This would allow real-time simulations in a collaborative –decision-making environment, whereby users could get to work with instantaneous model outputs. In the case of SWAT shown previously, it was possible to relate only the climate variables to discharge (given that land use, topography, and soils remained constant). But what about land-use change scenarios, which entails changes to a spatially explicit input? For example, decision makers may wish to evaluate the effectiveness of placing riparian buffer strips adjacent to major streams, an accepted management practice that reduces nonpoint source pollution (Cey, Rudolph, Aravena, & Parkin, 1999; Peterjohn & Correll, 1984). In that case, it is proposed that a "cause-effect" model be developed for the finite set of land-use change scenarios that are likely to be evaluated by the decision makers. Figure 8 provides the example of four scenarios where decision makers must evaluate the establishment and effectiveness of riparian buffer strips of varying widths. In such a case, four 'cause-effect" models, one for each scenario, would need to be developed to assist in collaborative decision making.

SOFTWARE AGENTS

What are Intelligent Software Agents?

The term "intelligent agents" originated as an extension of artificial intelligence (AI) research

Figure 7. Statistical relationship between snowmelt and discharge (r2 = 0.78, p < 0.0001)

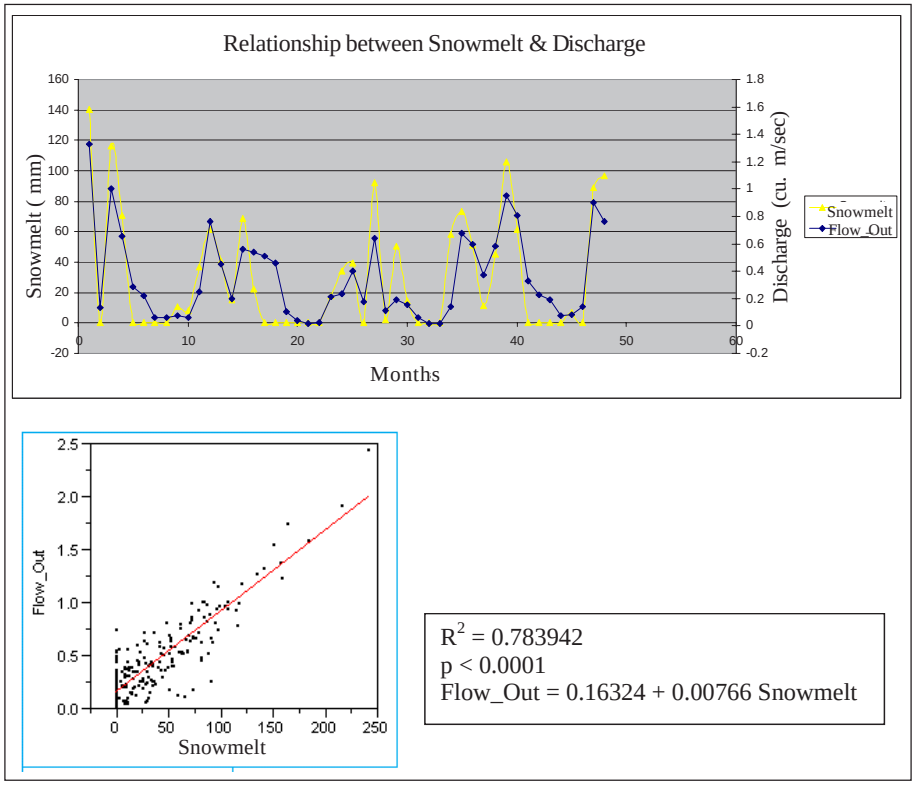


Figure 8. Varying widths of riparian band in the four scenarios, each with its own 'cause-effect' model

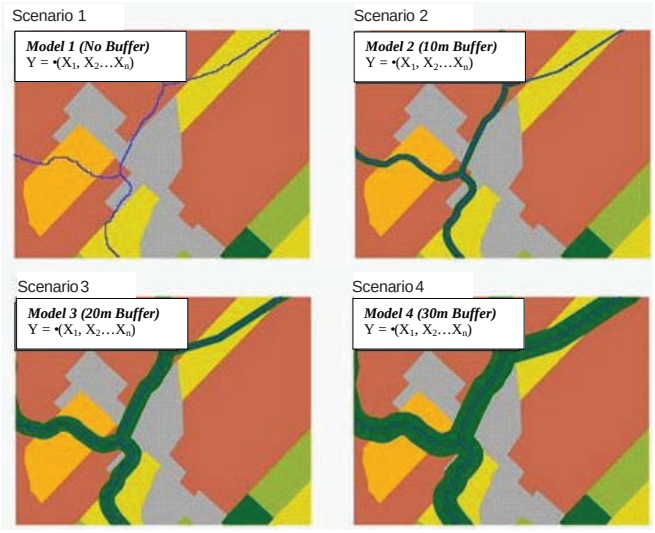


in late 1980s and early 1990s (Woolridge & Jennings, 1995). It refers to relatively autonomous software that manages information searching/retrieval and simulation in complex and changing operating environments such as the Internet. There is general consensus that to be considered an intelligent agent, the software must possess the following four properties: (a) autonomous behavior, (b) ability to sense its environment and other agents, (c) ability to act upon its environment alone or in collaboration with others (sometimes via an agent communication language), and (d) possession of rational behavior (Woolridge, 1999; Woolridge & Jennings, 1995). In some cases, intelligent agents should not only be able to respond to, but also learn from their environment (Maes, 1994). Humanistic characteristics such as beliefs, desires, intentions, (Shoham, 1993) and emotions and trust (Maes, 1994) also could form a part of agent behaviour. Since their inception, agents have become a popular technology for a variety of computer applications, ranging from managing human-computer interactions to simulating social interactions.

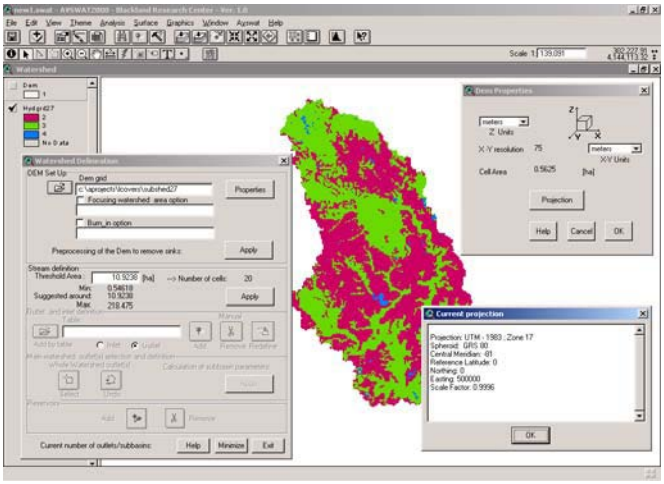
Software agents, a subclass of intelligent agents, are designed to act autonomously to manage complex information. Generally in GIScience, software agents can be oriented by four tasks (Nwana, 1996). First, *interface agents* assist users in interacting with a specific software or hardware environment by automating routine or difficult computing tasks. For example, Campos, Naumov, & Shapiro (1996) describe a user interface agent that provides assistance to users of the GIS software ARC/INFO. Interfacing is the primary task of software agents. Second, *collaborative agents* enable interagent, interhuman, or agent-human collaboration for tasks that require cooperation and consensus building. A subset of interface agents learns from observing repeated user-software interactions, thereby acting on behalf of users. Sengupta and Bennett (2003) detail an agent-based environment that uses multiple interacting agents to retrieve and manipulate data and spatial models to support decision-making environments. Third, *mobile agents* specialize in navigating networks by moving between computers, sensing security, and Internet protocols. Tsou and Buttenfield (2002) describe a mobile, distributed, geospatial analysis environment using mobile agents. Last, *information agents* specialize in data mining and information retrieval. An example of an information agent in GIScience/geography is one that surfs the Web for digital geospatial data, given a specific map extent and cartographic scale (Luo, Wang, & Xu, 2003).

Here I propose that *interface agents* be used to help users of collaborative SDSS parameterize the SWAT model, freeing them to focus on metatasks such as evaluating alternative land-use scenarios. The complexity of the input variables and the possible assistance afforded by agents is described in the following sections.

A Look at the Complexity of SWAT's Input Parameters and its Implications for Collaborative Decision-Making

Although there is an Arcview extension called AVSWAT available for SWAT (De Luzio, Srinivasan, & Arnold, 2004), it still requires the end user to have adequate knowledge of GIS data formats, structure of attribute tables, and projections. For example, the screen shot in Figure 9 shows how novice users may have to navigate pop-up windows with terminology like "DEM Set Up" and statements like "Project UTM – 1983; Zone 17." More complications arise when setting up soil parameters, where the users must deal with STATSGO/SURGO soil scheme classifications in order to complete one simulation cycle. This often leads to a bottleneck where most end users of SDSS rely on a GIS technician to operate the system (Armstrong & Densham, 1995). As a result, an interactive process dialog between the system and the decision makers is no longer possible. This severely distracts from the collaborative

Figure 9. Setting up input parameters for SWAT; Step 1 involves delineating sub-watersheds from a DEM



decision-making environment as members of the group wrestle with the nuances of the software. In addition, technologically adept members of the group begin to gain an unfair advantage in the collaborative decision-making process.

Agents to the Rescue

The *interface agents* proposed here assist users in two instances: first to parameterize models, and second to evaluate plausible scenario alternatives. The key to agent-based modeling is flexibility. Therefore, the *interface agents* themselves are simply front ends to a larger knowledge base that can take the form of other agents within Blackboard Architectures (Sengupta & Bennett, 2003) or changeable elements of knowledge stored in a database. The key function of the *interface agents* is to search the knowledge base to find possible sequence of transformations/solutions that completes the task at hand.

In the case of parameterizing SWAT, end users should not need to deal with complexities and specificities of the model, such as the land use code used by SWAT for representing vegetation. This information can be embedded in a database. An *interface agent*, as shown in Figure 10, is able to retrieve this and other details from database searches and place it in the model input files for the user, when necessary. Further, the agent is also able to assist users enter missing pieces of information, such as composition of the buffer strips, by converting user input into the numerical equivalents (e.g., land-use codes) desired by the model.

A second *interface agent* can be used to define spatially explicit scenarios. For example, in Figure 11, the agent is used to define regions within the map where land-use change is desired, which is then used as input to SWAT. In the figure, the user is prompted to demarcate areas on the map that need to be converted to buffer areas. Following the demarcation, the agent automatically creates buffer strips within the land use map (note that a second pop-up window not shown in the figure asks for the width of the buffer strips, and places the strips adjacent to land use coded as "water"). Both these agents hide the actual complexity of setting up the SWAT input files from the user.

Figure 10. Interface Agent assistance in defining parameters for the model SWAT.

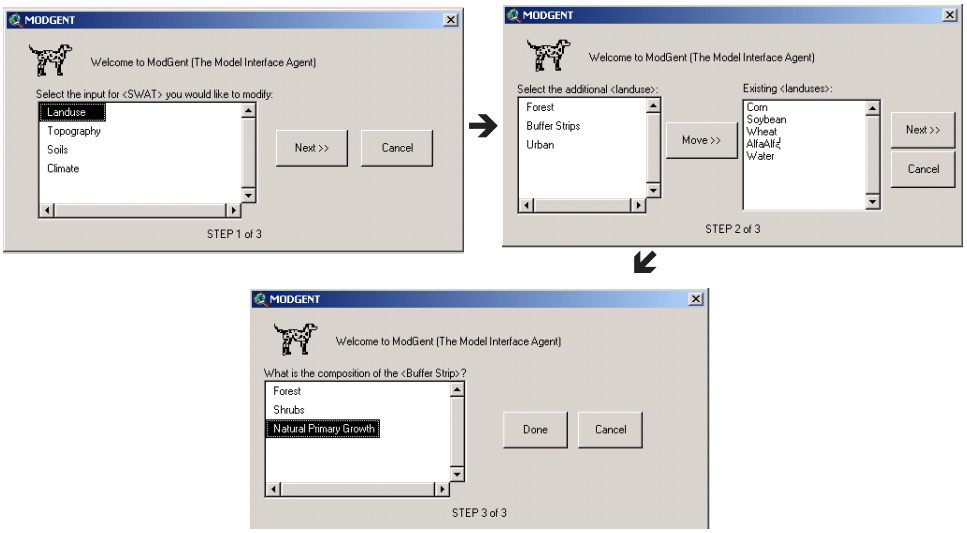


Figure 11. Interface Agents assist in development of land use scenarios

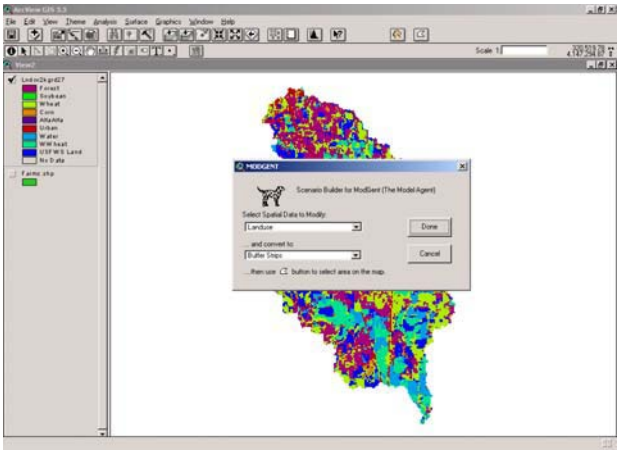

CONCLUSION

Using either the "cause-effect" models or intelligent agents or a combination of the two, it is possible to reduce both the time required to run a model multiple times, as well as the complexity of setting up its input parameters. As shown with examples from the St-Esprit SDSS, these methods can be very useful in real-world scenarios where decision makers, who are often nonGIS experts, may have to contend with deriving discharge information from simulation models like SWAT. Simplifying these tasks should enable better use of the SDSS in collaborative decision-making environments and restore the tool to its rightful position: in the hands of decision makers who have no GIS experience, but feel comfortable using it to make informed decisions.

Chapter 4.3
Intelligent Software Agents Analysis in E-Commerce I

Xin Luo
The University of New Mexico, USA

Somasheker Akkaladevi
Virginia State University, USA

INTRODUCTION

Equipped with sophisticated information technology infrastructures, the information world is becoming more expansive and widely interconnected. Internet usage is expanding throughout the web-linked globe, which stimulates people's need for desired information in a timely and convenient manner. Electronic commerce activities, powered by Internet growth, are increasing continuously. It is estimated that online retail will reach nearly $230 billion and account for 10% of total U.S. retail sales by 2008 (Johnson et al. 2003). In addition, e-commerce entailing business-to-business (B2B), business-to-customer (B2C) and customer-to-customer (C2C) transactions is spawning new markets such as mobile commerce.

By increasing the degree and sophistication of the automation, commerce becomes much more dynamic, personalized, and context sensitive for both buyers and sellers. Software agents were first used several years ago to filter information, match people with similar interests, and automate repetitive behavior (Maes et al. 1999). In recent years, agents have been applied to the arena of e-commerce, triggering a revolutionary change in the way we conduct online transactions in B2B, B2C, and C2C. Researchers argue that the potential of the Internet for transforming commerce is largely unrealized (Begin et al. 2002; Maes et al. 1999). Further, He and Jennings noted that a new model of software agent is needed to achieve the degree of automation and move to second generation e-commerce1 applications (He et al. 2003). This is due to the predicament that electronic purchases are still largely unautomated. Maes et al. (1999) also addressed that, even though information is more easily accessible and orders and payments are dealt with electronically, humans are still in the loop in all stages of the buying process, which inevitably increase the transaction costs. Undoubtedly, a human buyer is still responsible

for collecting and interpreting information on merchants and products, making decisions about merchants and products, and ultimately entering purchase and payment information. Additionally, Jennings et al. (1998) confirmed that commerce is almost entirely driven by human interactions and further argued that there is no reason why some commerce cannot be automated.

This unautomated loop requires a lot of time and energy and results in inefficiency and high cost for both buyers and sellers. To automate time-consuming tasks, intelligent software agent (ISA) technology can play an important role in online transaction and negotiation due to its capability of delivering unprecedented levels of autonomy, customization, and general sophistication in the way e-commerce is conducted (Sierra et al. 2003). Systems containing ISAs have been developed to automate the complex process of negotiating a deal between a buyer and a seller. An increasing number of e-commerce agent systems are being developed to support online transactions that have a number of variables to consider and to aim for a win-win result for sellers and buyers.

In today's e-commerce arena, systems equipped with ISAs may allow buyers and sellers to find the best deal taking into account the relative importance of each factor. Advanced systems of e-commerce that embody ISA technologies are able to perform a number of queries and to process phenomenal volumes of information. ISAs reduce transaction costs by collecting information about services and commodities from a lot of firms and presenting only those results with high relevance to the user. ISA technologies help businesses automate information transaction activity, largely eliminate human intervention in negotiation, lower transaction and information search cost, and further cultivate competitive advantage for companies. Therefore, ISAs can free people to concentrate on the issues requiring true human intelligence and intervention. Implementing the personalized, social, continuously running, and semi-autonomous ISA technologies in business information systems, the online business can become more user-friendly, semi-intelligent, and human-like (Pivk 2003).

LITERATURE REVIEW

A number of scholars have defined the term *intelligent software agent*. Bradshaw (1997) proposed that one person's intelligent agent is another person's smart object. Jennings and Wooldridge (1995) defined agents as a computer system situated in some environment that is capable of autonomous action in this environment to meets its design objective. Shoham (1997) further described an ISA as a software entity which functions continuously and autonomously in a particular environment, often inhabited by other agents and processes. In general, an ISA is *a software agent that uses Artificial Intelligence (AI) in the pursuit of the goals of its clients* (Croft 2002). It can perform tasks independently on behalf of a user in a network and help users with information overload. It is different from current programs in terms of being proactive, adaptive, and personalized (Guttman et al. 1998b). Also, it can actively initiate actions for its users according to the configurations set by the users; it can read and understand user's preferences and habits to better cater to user's needs; it can provide the users with relevant information according to the pattern it adapts from the users.

ISA is a cutting-edge technology in computational sciences and holds considerable potential to develop new avenues in information and communication technology (Shih et al. 2003). It is used to perform multi-task operations in decentralized information systems, such as the Internet, to conduct complicated and wide-scale search and retrieval activities, and assist in shopping decision-making and product information search (Cowan et al. 2002). ISA's ability of performing continuously and autonomously stems from human desire in that an agent is capable of operat-

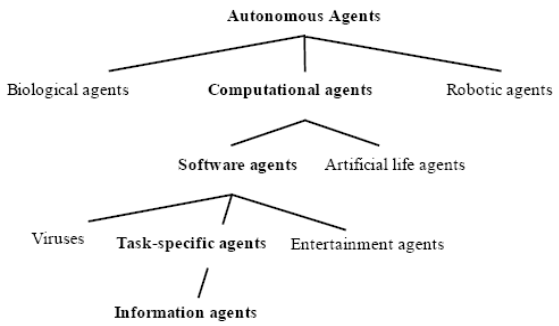
ing certain activities in a flexile and intelligent manner responsive to changes in the environment without constant human supervision. Over a long period of time, an agent is capable of adapting from its previous experience and would be able to inhabit an environment with other agents to communicate and cooperate with them to achieve tasks for human.

Intelligent Agent Taxonomy and Typology

Franklin and Grasser (1996) proposed a general taxonomy of agent (see Figure 1).

This taxonomy is based on the fact that ISA technologies are implemented in a variety of areas, including biotechnology, economic simulation and data-mining, as well as in hostile applications (malicious codes), machine learning and cryptography algorithms. In addition, Nwana (1996b) proposed the agent typology (see Figure 2) in which four types of agents can be categorized: collaborative agents, collaborative learning agents, interface agents and smart agents. These four agents have different congruence amid learning, autonomy, and cooperation and therefore tend to address different sides of this topology in terms of the functionality.

Figure 1. Franklin and Grasser's agent taxonomy (Source: Franklin & Grasser. 1996)



According to Nwana (1996b), collaborative agents emphasize more autonomy and cooperation than learning. They collaborate with other agents in multi-agent environments and may have to negotiate with other agents in order to reach mutually acceptable agreements for users. Unlike collaborative agents, interface agents emphasize more autonomy and learning. They support and provide proactive assistance. They can observe user's actions in the interface and suggest better ways for completing a task for the user. Also, interface agents' cooperation with other agents is typically limited to asking for advice (Ndumu et al. 1997). The benefits of interface agents include reducing user's efforts in repetitive work and adapting to their user's preferences and habits. Smart agents are agents that are intelligent, adaptive, and computational (Carley 1998). They are advanced intelligent agents summing up the best capabilities and properties of all presented categories.

This proposed typology highlights the key contexts in which the agent is used in AI literature. Yet Nwana (1996b) argued that agents ideally should do all three equally well, but this is the aspiration rather than the reality. Furthermore, according to Nwana (1996b) and Jennings and Wooldridge (1998), five more agent types could be derived based on the typology, from a panoramic perspective (see Figure 3).

In this proposed typology, mobile agents are autonomous and cooperative software processes capable of roaming wide area networks, interacting with foreign hosts, performing tasks on behalf of their owners (Houmb 2002). Information agents can help us manage the explosive growth of information we are experiencing. They perform the role of managing, manipulating, or collating information from many distributes sources (Nwana 1996b). Reactive agents choose actions by using the current world state as an index into a table of actions, where the indexing function's purpose is to map known situations to appropriate actions. These types of agents are sufficient for

Figure 2. A Part View of Agent Typology Source: Nwana (1996b)

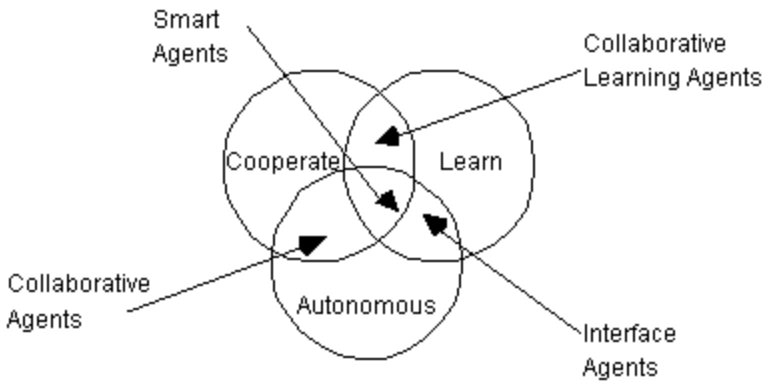


Figure 3. A panoramic overview of the different agent types (Source: Jennings & Wooldridge, 1998)

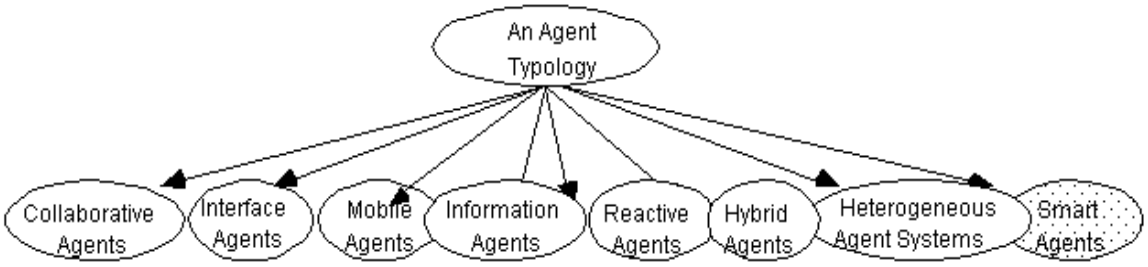

limited environments where every possible situation can be mapped to an action or set of actions (Chelberg 2003). Hybrid agents adopt strength of both the reactive and deliberative paradigms. They aim to have the quick response time of reactive agents for well known situations, yet also have the ability to generate new plans for unforeseen situations (Chelberg 2003). Heterogeneous agents systems refer to an integrated set-up of at least two or more agents, which belong to two or more different agent classes (Nwana 1996b).

CONCLUSION AND FUTURE WORK

This paper explores how ISAs can automate and add value to e-commerce transactions and negotiations. By leveraging ISA-based e-commerce systems, companies can more efficiently make decisions because they have more accurate information and identify consumers' tastes and habits. Opportunities and limitations for ISA development are also discussed. Future technologies of ISAs will be able to evaluate basic characteristics of online transactions in terms of price and product description as well as other properties, such as warranty, method of payment, and after-sales service. Also, they would better manage ambiguous content, personalized preferences, complex goals, changing environments, and disconnected parties (Guttman et al. 1998a). Additionally, for the future trend of ISA technology deployment, Nwana (1996a) describes that *"Agents are here to stay, not least because of their diversity, their wide range of applicability and the broad spectrum of companies investing in them. As we move further and further into the information age, any information-based organization which does not*

invest in agent technology may be committing commercial hara-kiri."

KEY TERMS

Agent: A computer system situated in some environment that is capable of autonomous action in this environment to meets its design objective.

Business-to-Business E-Commerce: Electronic transaction of goods or services between businesses as opposed to that between businesses and other groups.

Business-to-Customer E-Commerce: Electronic or online activities of commercial organizations serving the end consumer with products and/or services. It is usually applied exclusively to e-commerce.

Customer-to-Customer E-Commerce: Online transactions involving the electronically-facilitated transactions between consumers through some third party.

Electronic Commerce (E-Commerce): Consists of the buying and selling of products or services over electronic systems such as the Internet and other computer networks. A wide variety of commerce is conducted in this way, including electronic funds transfer, supply chain management, e-marketing, online transaction processing, and automated data collection systems.

Intelligent Software Agent: A software agent that uses Artificial Intelligence (AI) in the pursuit of the goals of its clients.

Ubiquitous Commerce (U-Commerce): The ultimate form of e-commerce and m-commerce in an 'anytime, anywhere' fashion. It involves the use of ubiquitous networks to support personalized and uninterrupted communications and transactions at a level of value that far exceeds traditional commerce.

ISA OPPORTUNITIES AND LIMITATIONS IN E-COMMERCE

Cowan et al. (2002) argued that the human cognitive ability to search for information and to evaluate their usefulness is extremely limited in comparison to those of computers. In detail, it's cumbersome and time-consuming for a person to search for information from limited resources and to evaluate the information's usefulness. They further indicated that while people are able to perform several queries in parallel and are good at drawing parallels and analogies between pieces of information, advanced systems that embody ISA architecture are far more effective in terms of calculation power and parallel processing abilities, particularly in the quantities of material they can process (Cowan et al. 2002). According to Bradshaw (1997), information complexity will continue to increase dramatically in the coming decades. He further contended that the dynamic and distributed nature of both data and applications require that software not merely respond to requests for information but intelligently anticipate, adapt, and actively seek ways to support users.

E-commerce applications based on agent-oriented e-commerce systems have great potential. Agents can be designed using the latest web-based technologies, such as Java, XML, and HTTP, and can dynamically discover and compose E-services and mediate interactions to handle routine tasks, monitor activities, set up contracts, execute business processes, and find the best services (Shih et al., 2003). The main advantages of using these technologies are their simplicity of usage, ubiquitous nature, and their heterogeneity and platform independence (Begin and Boisvert, 2002). XML will likely become the standard language for agent-oriented E-commerce interactions to encode exchanged messages, documents, invoices, orders, service descriptions, and other information. HTTP, the dominant WWW

protocol, can be used to provide many services, such as robust and scalable web servers, firewall access, and levels of security for these E-commerce applications.

Agents can be made to work individually, as well as in a collaborative manner to perform more complex tasks (Franklin and Graesser, 1996). For example, to purchase a product on the Internet, a group of agents can exchange messages in a conversation to find the best deal, can bid in an auction for the product, can arrange financing, can select a shipper, and can also track the order. Multi-agent systems (groups of agents collaborating to achieve some purpose) are critical for large-scale e-commerce applications, especially B2B interactions such as service provisioning, supply chain, negotiation, and fulfillment, etc. The grouping of agents can be static or dynamic depending on the specific need (Guttman et al., 1998b). A perfect coordination should be established for the interactions between the agents to achieve a higher-level task, such as requesting, offering and accepting a contract for some services (Guttman et al., 1998a).

There are several agent toolkits publicly available which can be used to satisfy the customer requirements and ideally they need to adhere to standards which define multi-party agent interoperability. For example, fuzzy logic based intelligent negotiation agents can be used to interact autonomously and consequently, and save human labor in negotiations. The aim of modeling a negotiation agent is to reach mutual agreement efficiently and intelligently. The negotiation agent should be able to negotiate with other such agents over various sets of issues, and on behalf of the real-world parties they represent, i.e. they should be able to handle multi-issue negotiations at any given time.

The boom in e-commerce has now created the need for ISAs that can handle complicated online transactions and negotiations for both sellers and buyers. In general, buyers want to find sellers that have desired products and services. And they want to find product information and gain expert advice before and after the purchase from sellers, which, in turn, want to find buyers and provide expert advice about their product or service as well as customer service and support. Therefore, there is an opportunity that both buyers and sellers can automate handling this potential transaction by adopting ISA technology. The use of ISAs will be essential to handling many tasks of creating, maintaining, and delivering information on the Web. By implementing ISA technology in e-commerce, agents can shop around for their users; they can communicate with other agents for product specifications, such as price, feature, quantity, and service package, and make a comparison according to user's objective and requirement and return with recommendations of purchases, which can meet those specifications; they can also act for sellers by providing product or service sales advice, and help troubleshoot customer problems by automatically offering solutions or suggestions; they can automatically pay bills and keep track of the payment.

Looking at ISA development from an international stand point, the nature of Internet in developed countries, such as USA, Canada, West Europe, Japan, and Australia, etc. and the consequent evolution of e-commerce as the new model provide exciting opportunities and challenges for ISA-based developments. Opportunities include wider market reach in a timely manner, higher earnings, broader spectrum of target and potential customers, and collaboration among vendors. This ISA-powered e-commerce arena would be different than our traditional commerce, because the traditional form of competition can give way to collaborative efforts across industries for adding value to business processes. This means that agents of different vendors can establish a cooperative relationship to communicate with each other via XML language in order to set up and complete transactions online.

Technically, for instance, if an information agent found that the vendor is in need of more

airplane tickets, it would notify a collaborative agent to search for relevant information regarding the ticket in terms of availability, price, and quantity etc. from other sources over the Internet. In this case, the collaborative agent would work with mobile agents and negotiate with other agents working for different vendors and obtain ticket information for its user. It would be able to provide the user with the result of the search, and, if needed, purchase the tickets for the user if certain requirements can be met. In the meantime, interface agents can monitor the user's reaction and decision behavior, and would provide the user with informational assistance in terms of advice, recommendation, and suggestion for any related and similar transactions.

On the other hand, however, this kind of intelligent electronic communication and transaction is relatively inapplicable in traditional commerce where different competitive vendors are not willing to share information with each other (Maes et al., 1999). The level of willingness in ISA-based e-commerce is, however, somewhat limited due to sociological and ethical factors, which will be discussed later in this paper. In addition, designing and implementing ISA technology is a costly predicament preventing companies from adopting this emerging tool. Companies need to invest a lot of money to get the ISA engine started. Notwithstanding the exciting theoretical benefits discussed above, many companies are still not sure about how much ISA technology can benefit themselves in terms of revenue, ROI, and business influence in the market where other players are yet to adopt this technology to cooperate with each other. Particularly, medium or small size companies are reluctant to embark on this arena mainly due to the factor of cost.

Additionally, lack of consistent architectures in terms of standards and laws also obstructs the further development of ISA technology (He et al., 2003). In detail, IT industry has not yet finalized the ISA standards, as there are a number of proprietary standards set by various companies. This causes a confusion problem for ISAs to freely communicate with each other. Also, related to standards, relevant laws have not surfaced to regulate how ISAs can legally cooperate with each other and represent their human users in the cyber world.

Additionally, ISA development and deployment is not a global perspective (Jennings et al. 1998). Despite the fact that ISA technology is an ad-hoc topic in developed countries, developing countries are not fully aware of the benefits of ISA and therefore have not deployed ISA-based systems on the Web because their e-commerce development levels and skills are not as sophisticated or advanced as those of the developed countries. This intra-national limitation among developed and developing countries unfortunately hinders agents from freely communicating with each other over the globally connected Internet.

SOCIOLOGICAL AND ETHICAL CHALLENGES

In the preceding sections of this paper, the technical issues involved in agent development have been addressed. However, in addition to these issues, there are also a range of social and cyber-ethical problems, such as trust and delegation, privacy, responsibility, and legal issues, which will become increasingly important in the field of agent technology (Bradshaw 1997; Jennings et al. 1998; Nwana 1996b).

- **Trust and delegation:** For users who want to depend on ISA technology to obtain desired information, they must trust agents which autonomously delegate for users to do the job. It would take time for users to get used to their agents and gain confidence in the agents that work for them. And users have to make a balance between agents continually seeking guidance and never seeking guidance. Users might need to set proper limitations for their

agents, otherwise agents might surpass their authorities.

- **Privacy:** In the explosive information society, security is becoming more and more important. Therefore, users must make sure that their agents always maintain their privacy in the course of transactions. Electronic agent security policies may be needed to encounter this potential threat.
- **Responsibility:** Users need to seriously consider how much responsibility the agents need to carry regarding the transaction pitfall. To some extent, agents are rendered responsibility to get the desired product/service for their users. If the users are not satisfied with the transaction result, they may need to redesign or reprogram the agent rather than directly blame the fault on electronic agents.
- **Legal issues:** In addition to responsibility, users should also think about any potential legal issues triggered by their agents, which, for instance, offer inappropriate advice to other agents resulting in liabilities to other people. This would be very challenging to the ISA technology development, and the scenario would be complicated since the current law does not specify which party (the company who wrote the agent, the company who customized and used the agent, or both) should be responsible for the legal issues.
- **Cyber-ethical issues:** Eichmann (1994) and Etzioni & Weld (1994) proposed the following etiquettes for ISAs which gather information on the Web.
    - Agents must identify themselves;
    - They must moderate the pace and frequency of their requests to some server;
    - They must limit their searches to appropriate servers;
    - They must share information with others;
    - They must respect the authority placed on them by server operators;
    - Their services must be accurate and up-to-date;
    - Safety: they should not destructively alter the world;
    - Tidiness: they should leave the world as they found it;
    - Thrift: they should limit their consumption of scarce resources;
    - Vigilance: they should not allow client actions with unanticipated results.

CONCLUSION AND FUTURE WORK

ISA technology has to confront the increasing complexity of modem information environments. Research and development of ISAs on the Internet is crucial for the development of next generation in open information environments. Sociological and cyber-ethical issues need to be considered for the next generation of agents in e-commerce system, which will explore new types of transactions in the form of dynamic relationships among previously unknown parties (Guttman et al. 1998b). According to Nwana (1996a), the ultimate ISA's success will be the acceptance and mass usage by users, once issues such as privacy, trust, legal, and responsibility are addressed and considered when users design and implement ISA technologies in e-commerce and emerging commerce, such as mobile commerce (M-commerce) and Ubiquitous commerce (U-commerce). It is expected that future research can further explore how ISAs are leveraged in these two newly emerged avenues.

Chapter 4.5
A Semantic Web–Based Information Integration Approach for an Agent–Based Electronic Market

Maria João Viamonte
GECAD – Knowledge Engineering and Decision Support Research Group, Porto Polytechnic Institute, Portugal

Nuno Silva
GECAD – Knowledge Engineering and Decision Support Research Group, Porto Polytechnic Institute, Portugal

ABSTRACT

With the increasing importance of e-commerce across the Internet, the need for software agents to support both customers and suppliers in buying and selling goods/services is growing rapidly. It is becoming increasingly evident that in a few years the Internet will host a large number of interacting software agents. Most of them will be economically motivated, and will negotiate a variety of goods and services. It is therefore important to consider the economic incentives and behaviours of e-commerce software agents, and to use all available means to anticipate their collective interactions. Even more fundamental than these issues, however, is the very nature of the various actors that are involved in e-commerce transactions. This leads to different conceptualizations of the needs and capabilities, giving rise to semantic incompatibilities between them. Ontologies have an important role in Multi-Agent Systems communication and provide a vocabulary to be used in the communication between agents. It is hard to find two agents using precisely the same vocabulary. They usually have a heterogeneous private vocabulary defined in their own private ontology. In order to provide help in the conversation among different agents, we are proposing what we call ontology-services to facilitate agents' interoperability. More specifically, we

propose an ontology-based information integration approach, exploiting the ontology mapping paradigm, by aligning consumer needs and the market capacities, in a semi-automatic mode. We propose a new approach for the combination of the use of agent-based electronic markets based on Semantic Web technology, improved by the application and exploitation of the information and trust relationships captured by the social networks.

CURRENT SITUATION

As the result of technological developments, e-commerce, namely business-to-consumer (B2C), is emerging as the new way of doing business.

In most current (first generation) e-ecommerce applications, the buyers are generally humans who typically browse through a catalogue of well-defined commodities (e.g., flights, books, compact discs, computer components) and make (fixed price) purchases (often by means of a credit card transaction). However, this modus operandi is only scratching the surface of what is possible. By increasing the degree and the sophistication of automation, on both the buyer's and the seller's side, e-commerce becomes much more dynamic, personalized, and context sensitive.

We believe that over the course of the next decade, the global economy and the Internet will merge into a global market with a large amount of autonomous software agents that exchange goods and services with humans and other agents. Agents will represent, and be, consumers, producers, and intermediaries.

When interactions among agents become sufficiently rich, a crucial qualitative change will occur. New classes of agents will be designed specially to serve the needs of the other agents. However, in order to harness the full potential of this new mode of e-commerce, a broad range of social, legal, and technical issues need to be addressed. These issues relate to things such as security, trust, payment mechanisms, advertising, logistics, and back office management. Even more fundamental than these issues, however, is the very nature of the various actors that are involved in e-commerce transactions.

In an efficient agent-mediated electronic market, where all the partners, both sending and receiving messages have to lead to acceptable and meaningful agreements, it is necessary to have common standards, like an interaction protocol to achieve deals, a language for describing the messages' content and ontologies for describing the domain's knowledge.

The need for these standards emerges due to the nature of the goods/services traded in business transactions. The goods/services are described through multiple attributes (e.g. price, features and quality), which imply that negotiation processes and final agreements between seller and buyers must be enhanced with the capability to both understand the terms and conditions of the transaction (e.g. vocabulary semantics, currencies to denote different prices, different units to represent measures or mutual dependencies of products). A critical factor for the efficiency of the future negotiation processes and the success of the potential settlements is an agreement among the negotiating parties about how the issues of a negotiation are represented and what this representation means to each of the negotiating parties. This problem is referred to as the ontology problem of electronic negotiations (Ströbel, 2001). Distributors, manufactures, and service providers may have radically different ontologies that differ significantly in format, structure, and meaning. Given the increasingly complex requirements of applications, the need for rich, consistent and reusable semantics, the growth of semantically interoperable enterprises into knowledge-based communities; and the evolution; and adoption of Semantic Web technologies need to be addressed. Ontologies represent the best answer to the demand for intelligent systems that operate closer to the human conceptual level (Obrst, Liu,

and Wray, 2003).

To achieve this degree of automation and move to new generation e-commerce applications, we believe that a new model of software is needed.

PROBLEM STATEMENT

In order to make possible the interaction between agents in a Multi-Agent Systems, it is necessary to have a communication platform, a communication language and a common ontology.

With respect to communications, there are some implications:

- There are many different ontology languages.
- Different ontology languages are sometimes based on different underlying paradigms.
- Some ontology languages are very expressive, some are not.
- Some ontology languages have a formally defined semantics, some do not.
- Some ontology languages have inference support, some do not.

However, even if the exact same language is used, the resulting ontologies can be incompatible in various ways:

- People or agents may use different terms for the same thing.
- People or agents may use the same term for the different things.
- A given notion or concept may be modeled using different primitives in the language.
- A given notion or concept may be modeled with very different fundamental underlying primitives.

Once we take this problem as a challenge, representing these differences in a common ontology becomes essential. The ontology includes the entire domain's knowledge, which is made available to all the components active in an information system (Huhns & Singh, 1997). The use of a common ontology guarantees the consistency (an expression has the same meaning for all the agents) and the compatibility (a concept is designed, for the same expression, for any agent) of the information present in the system. However, we cannot assume that all the agents will use a common ontology. In fact, as stated in (Hepp, 2007), the adoption of ontologies in e-commerce has some drawbacks, namely concerning the comprehension and correct use of the adopted ontology which is a difficult and time consuming task, often leading to conflicting interpretations and eventually wrong use of the ontology and data. Usually, each agent has its heterogeneous private ontology and it cannot fully understand another agent's ontology, giving rise to semantic incompatibilities between them. Consequently, different actors involved in the marketplace must be able to independently describe their universe of discourse, while the market is responsible for providing a technological framework that promotes the semantic integration between parties.

However, it is necessary to consider that the solution proposed to overcome theses problems, has to take into consideration the technological support already existent, namely a well-proven e-commerce platform, where agents with strategic behaviour represent consumers and suppliers.

PROPOSED SOLUTION

We propose an agent-based electronic market with an ontology-based information integration approach, exploiting the ontology mapping paradigm, by aligning consumer needs and the market capacities throughout the negotiation conversations in a semi-automatic mode, improved by the application and exploitation of the information and trust relationships captured by the social networks.

To study our proposal we will combine the use of ISEM and MAFRA Toolkit into a novel electronic marketplace approach, together with the exploitation of social semantic network services.

ISEM – Intelligent System for Electronic MarketPlaces (Viamonte, Ramos, Rodrigues & Cardoso, 2006) is a simulation platform developed at our research group. ISEM is a multi-agent market simulator, designed for analysing agent market strategies based on a complete understanding of buyer and seller behaviours, preference models and pricing algorithms, considering user risk preferences and game theory for scenario analysis. Each market participant has its own business objectives and decision model. The results of the negotiations between agents are analyzed by data mining algorithms in order to extract knowledge that gives agents feedback to improve their strategies. The extracted knowledge will be used to set up probable scenarios, analyzed by means of simulation and game theory decision criteria.

The main objectives of ISEM are: first, the ISEM system addresses the complexities of online buyers' behaviour by providing a rich set of behaviour parameters; second, the ISEM system provides available market information that allows sellers to make assumptions about buyers' behaviour and preference models; third, the different agents customise their behaviour adaptively, by learning each user's preference models and business strategies. The learning agent capacity is achieved through data mining techniques applied on-line during the market sessions within the ISEM system.

MAFRA Toolkit is the instantiation of the MAFRA-MApping FRAmework (Maedche, Motik, Silva & Volz, 2002), addressing the fundamental phases of the ontology mapping process. In particular, it allows the identification, specification and representation of semantic relations between two different ontologies. These semantic relations are further applied in the execution phase of the interoperation, by transforming the data (messages' content) as understood by one of the actors into the data understood by the other. In this sense, ontology mapping allows actors to keep their knowledge bases unchanged while supporting the semantic alignment between their conceptualizations (ontologies).

On the other hand, social network repositories aim to capture collaboratively created information and trust relationships between individuals according to different subjects (e.g. business, family, music, sport, travel, and hobbies). Social networks together with security oriented technologies form the basic infrastructure to encompass collaboration and trust relationships in many internet based activities, including e-commerce transactions and information integration.

Objectives

The proposed approach introduces a novel agent-based marketplace architecture that will be deployed within the ISEM simulator in order to assure that different agents can establish deals in a more flexible and evolved form. In order to judge the feasibility and relevance of the approach, we will use the Consumer Buying Behaviour model (CBB) as a reference (Runyon & Stewart, 1987).

Another important goal is to support the identification stage of the CBB model using ontologies to construct the most accurate model of the consumer's needs. Moreover, at the product brokering, buyer coalition formation, merchant brokering and negotiation stages, the ontology mapping process will provide the integration of the seller and consumer's models (HarmoNet, 2007).

Complementarily, the repository of relationships provided by emergent social networks will support establishing more accurate trust relationships between businesses and customers, as well as providing a better alignment (mapping) between their models. This new information is very important to feed the agents' knowledge

bases to improve their strategic behaviour. Market participant's strategic behaviour is very significant in the context of competition.

Overview

In the following sections, we will describe the electronic market objectives and model, the ontology mapping features and the proposed ontology-based, socially-driven information integration approach.

Our ontology-based services will be provided through an additional Market service provided by a specific agent, the Market Facilitator agent. This agent will be responsible for providing structural and semantic relationships between different vocabularies, which carry appropriate conversations and make agreement possible.

The Marketplace Objectives

Agents can be used in many ways in the electronic commerce applications and for this it will be necessary to create a scenario where they can interact with each other. The Marketplace function is to permit and facilitate the interaction between the agents. We support the idea of a Web site where users go to trade items. All agents are notified by the market about existing buying agents and selling agents and about what they want to sell and what they want to buy. We expect that we have agents interested in buying and selling the same category of commodities. At any time, we can have a variable number of partners in our market and every transaction has specific parameters.

A language support for inter-agent communication has to be defined; we need to ensure that all the agents participating in the market use the same language, or that the languages in use can be translated; and an ontology-based information integration to ensure transparent semantic interoperability.

Another objective is supporting some of the stages of the CBB model:

- *Need Identification*, "the consumer can be stimulated through product information". Although all the buyer agents are notified by the market about existing selling agents and about their products, the marketplace needs some additional expertise to notify the users about products available based on their profiles and last deals.
- *Product Brokering*, "the evaluation of product alternatives based on consumer-provided criteria." The agent system must be able to assist consumers in deciding which products best fit their personal criteria, they must act as recommendation agents, make predictions based on profiles and "business intelligence", possibly derived by data mining techniques and based on social-driven information.
- *Buyer Coalition Formation*, "having determined the product to buy, customers may move directly to the merchant brokering phase (see below) or they may interact with other similar buyers to try and form a coalition before moving to the merchant brokering phase. Here, a coalition is viewed as a group of agents cooperating with each other in order to achieve a common task. In these "buyer coalitions," each buyer is represented by their own agent and together these agents try to form a grouping in order to approach the merchant with a larger order (in order to obtain leverage by buying in bulk). Normally a buyer coalition model is composed of five stages: negotiation, leader election, coalition formation, payment collection, and execution stages. It is essential to have a trustworthy and reliable agent that will collect the buyer's information, divide the agents into coalitions, and negotiate with sellers (refer to Yamamoto & Sycara, 2001 and Tsvetovat & Sycara, 2000 for a full discussion of these issues).
- *Merchant Brokering*, "who to buy from, includes the evaluation of merchant alterna-

tives based on consumer-provided criteria". Having selected the desired product, and perhaps after having formed a buyer coalition, merchant brokering involves the agent finding an appropriate seller to purchase the item from. The customer agent must be able to find several providers for each item, taking into account different user preferences and based on past events and users satisfaction with certain providers.

- *Negotiation*, "this stage is about how to determine the terms of the transaction". Having selected a merchant (or set of merchants), the next step is to negotiate the terms and conditions. We believe that this is one of the major changes that will be brought about by agent-mediated e-commerce. The agents negotiate with each other by using strategies based on rule systems and users' criteria, searching for an agreement on multiple goals and considering tradeoffs between the goals.

The Marketplace Model

Our Marketplace facilitates agent meeting and matching, besides supporting the negotiation model. In order to have results and feedback to improve the negotiation models and consequently the behaviour of user agents, we simulate a series of negotiation periods, D={1,2,…,n}, where each one is composed by a fixed interval of time T={0,1,…,m}. Furthermore, each agent has a deadline $D_{\max}^{Agt} \in D$ to achieve its business objectives. At a particular negotiation period, each agent has an objective that specifies its intention to buy or sell a particular good or service and on what conditions. The available agents can establish their own objectives and decision rules. Moreover, they can adapt their strategies as the simulation progresses on the basis of previous efforts' successes or failures. The simulator probes the conditions and the effects of market rules, by simulating the participant's strategic behaviour.

Our simulator was developed based on "A Model for Developing a MarketPlace with Software Agents (MoDeMA)" (Viamonte, 2004). MoDeMA is composed of the following steps:

- Marketplace model definition, that permits doing transactions according to the CBB model.
- Identification of the different participants, and the possible interactions between them.
- Ontology specification, that identifies and represents items being transacted.
- Agents' architecture specification, and information flows between each agents module.
- Knowledge Acquisition, defining the process that guarantees the agent the knowledge to act in pursuit of its role.
- Negotiation Model, defining the negotiation mechanisms to be used.
- Negotiation Protocol, specification of each of the negotiation mechanism rules.
- Negotiation Strategies, specification and development of several negotiation strategies.
- Knowledge Discovery, identification and gathering of market knowledge to support agents' strategic behaviour.

ISEM is flexible; the user completely defines the model he or she wants to simulate, including the number of agents, each agent's type and strategies.

The Negotiation Model and Protocol

The negotiation model used in ISEM is bilateral contracting where buyer agents are looking for sellers that can provide them with the desired products at the best conditions.

We adopt what is basically an alternating protocol (Fatima, Wooldridge & Jennings, 2004 and Osborne & Rubinstein, 1994).

Negotiation starts when a buyer agent sends a request for proposal (RFP) (Figure 1). In response, a seller agent analyses its own capabilities, current availability, and past experiences and formulates a proposal (PP).

Sellers can formulate two kinds of proposals: a proposal for the product requested or a proposal for a related product, according to the buyer preference model.

On the basis of the bilateral agreements made among market players and lessons learned from previous bid rounds, both agents revise their strategies for the next negotiation round and update their individual knowledge module.

The negotiation protocol of the ISEM simulator (Figure 2) has three main actors:

- *Buyer* (B) is the agent that represents a consumer or a buyer coalition. Multiple Buyers normally exist in the marketplace in an instant.
- *Seller* (S) is the agent that represents a supplier. Multiple Sellers normally exist in the marketplace in an instant.
- *Market Facilitator agent* (MF), usually one per marketplace, coordinates the market and ensures that it works correctly. MF identifies all the agents in the market, regulates negotiation, and assures that the market operates according to established rules. Before entering the market, agents must first register with the MF agent.

The Ontology

Ontologies, as knowledge representation artefacts, allow the "explicit formal specification of a shared conceptualization" (Studer, Benjamins

Figure 1. Sequence of bilateral contracts

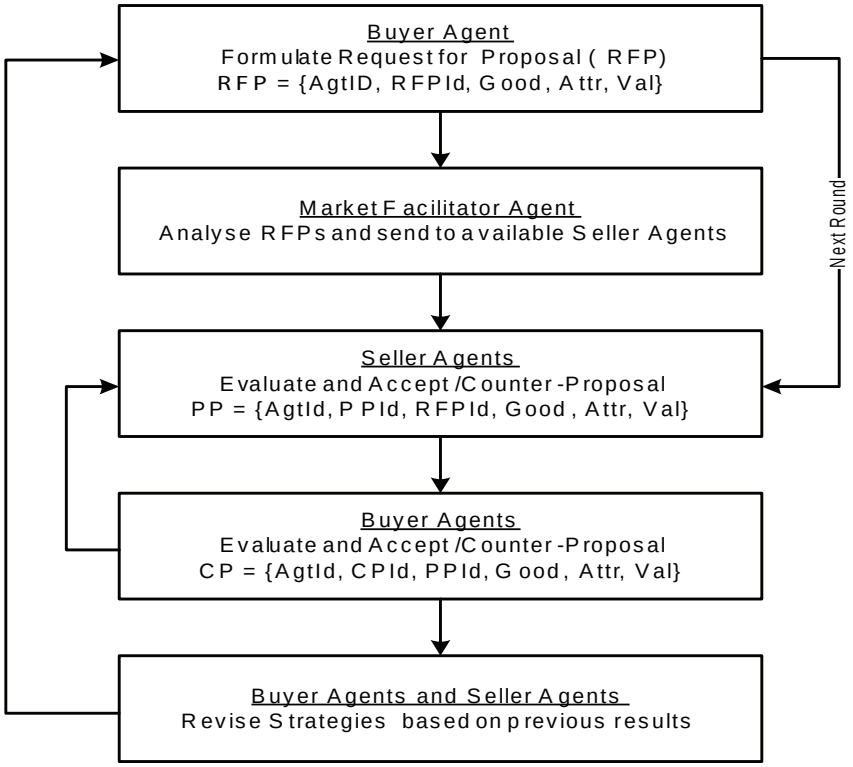

Figure 2. ISEM bilateral contract protocol

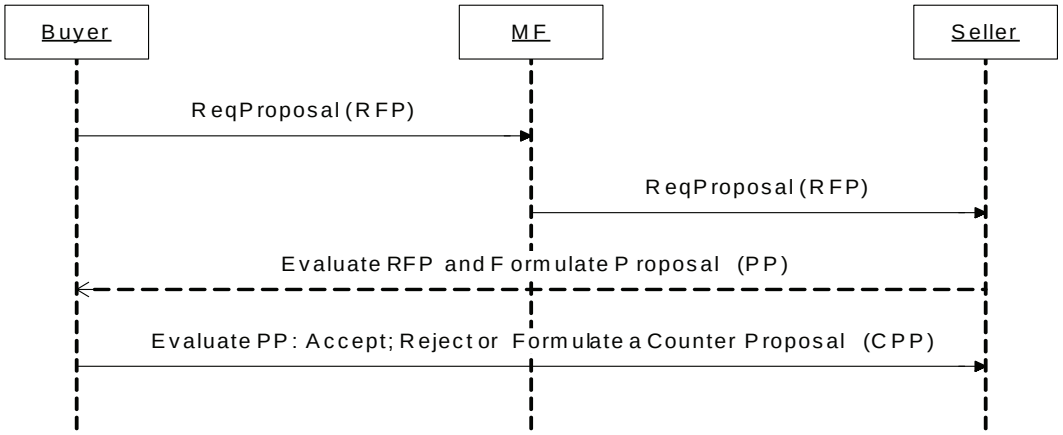


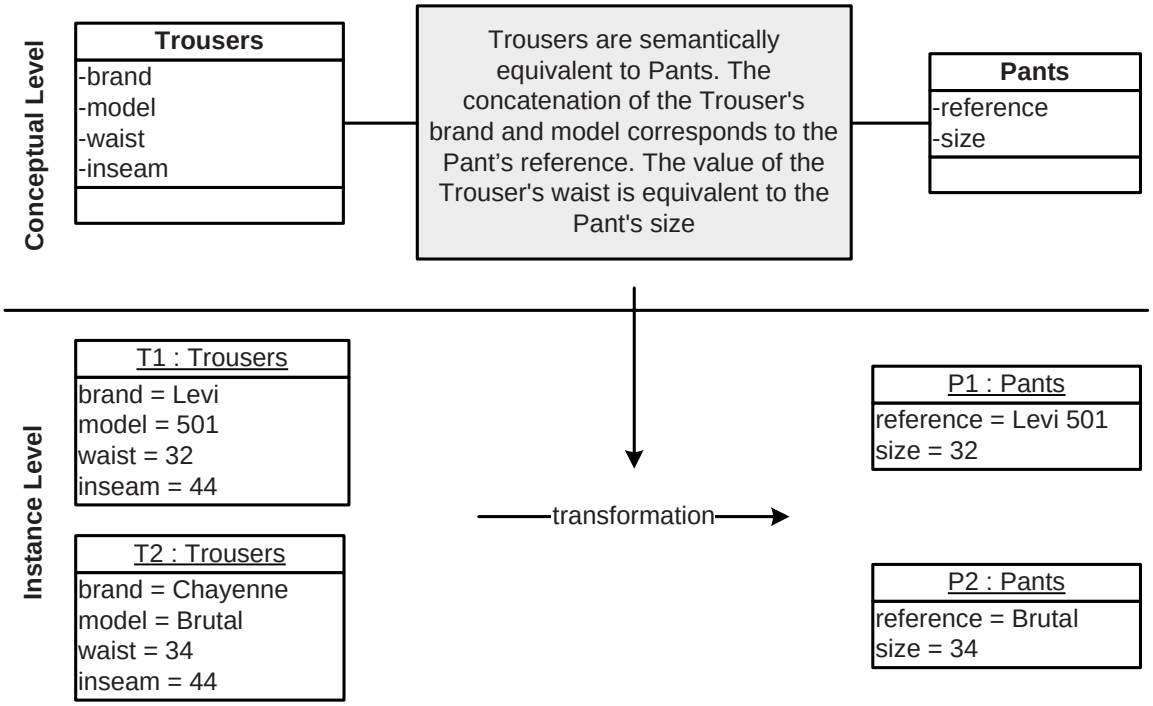
& Fensel, 1998). Ontologies raise the level of specification, incorporating semantics into the data, and promoting its exchange in an explicit understandable form. The resulting artefact is then shared between interoperating actors and is used for querying and reasoning about each others knowledge base. Ontologies are therefore fully geared as a framework for capturing, specifying, representing and sharing the domain of discourse in the scope of distinct types of e-commerce, namely B2C or business-to-business (B2B).

However, ontologies per se are not able to overcome information interoperability incompatibilities and it is hardly conceivable that a single ontology can be applied to all kinds of domains and applications. Information integration mechanisms are necessary in order to identify, represent and apply the diverse relationships between concepts and relations of two or more ontologies. Ontology Mapping is one of the most successful information integration paradigms used in the Internet and in particular in the Semantic Web. Despite a more holistic description of the Ontology Mapping Process (Maedche et al., 2002), ontology mapping is primarily the process whereby semantic relations are defined at an ontological level between source ontology entities and target ontology entities and then further applied at instance level, transforming source ontology instances into target ontology instances (Figure 3).

Therefore, unlike other information integration paradigms (e.g. Merging and Integration) (Pinto, Gómez-Pérez & Martins, 1999) that lead to definitive semantics and information loss, through ontology mapping, repositories are kept separated, independent and distinct, maintaining their complete semantics and contents.

The approach followed in MAFRA Toolkit adopts a declarative specification of semantic relations through the use of the SBO-Semantic Bridging Ontology, itself an ontology. When instantiated it becomes the description of the syntactic and semantic relations between entities of two ontologies. MAFRA Toolkit's support of the SBO manipulation hides the procedural complexity of specification and execution of relations. Additionally, its open Service-oriented architecture allows the incorporation of new types of mapping relations into the system (Services), improving the expressive power and mapping capabilities of the system. Additionally, Services play the important role of driving the semi-automatic specification of semantic relations, releasing the user from this time consuming and difficult task. Instead, the user is invited to supervise the

Figure 3. Informal representation of ontology mapping



services' process and confirm the automatically generated proposals.

MAFRA Toolkit has been successfully adopted in the EU-funded project Harmo-Ten (www.harmo-ten.org) devoted to the exchange of information in tourism. The outcome of this project is now being applied in the HarmoNet initiative (HarmoNet, 2007).

The Social Networks

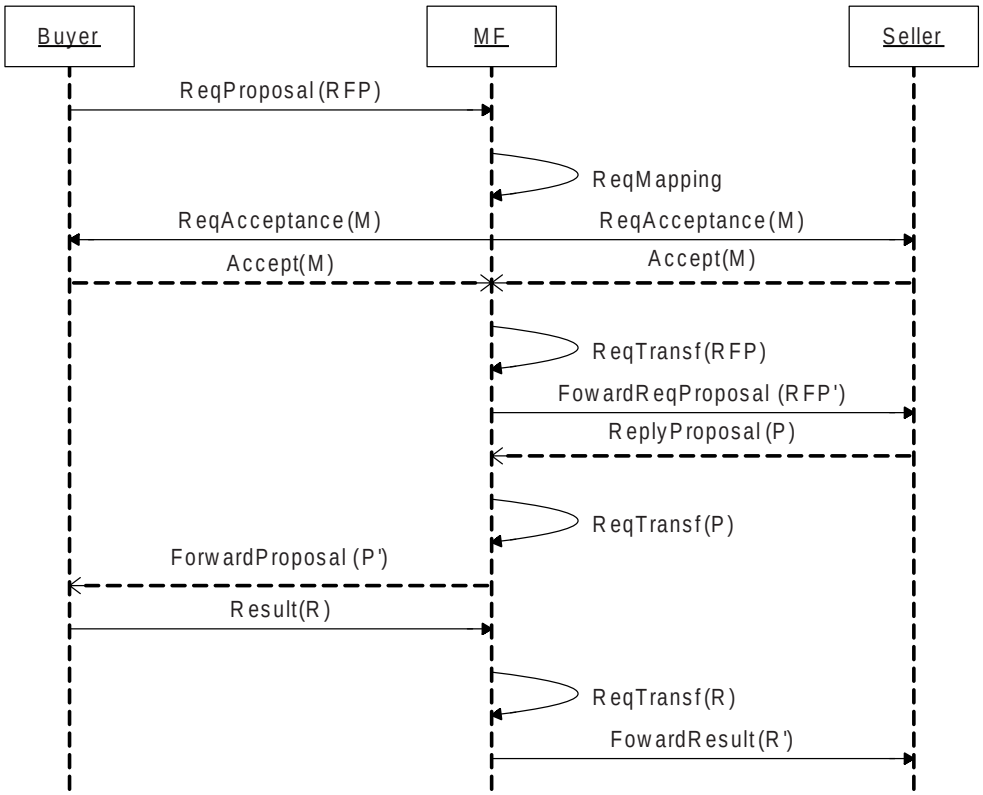
Social Networks are one of the grounding theories behind the promotion and success of Web 2.0. Social Networks connect people around issues or causes. Different interests give rise to and promote different communities (e.g. music, sports, technology, religion, fashion), which simplify many customer target initiatives such as pricing, marketing, advertising and selling. Social Network Analysis (SNA) unveils clusters of users with similar interests, even when such relations are vague or implicit. Based on users' manually created relationships, SNA provides important formal metrics such as Activity, Betweenness and Closeness. Yet, either explicit social relationship expressed through social network tools (e.g. LinkedIn, MySpace, Friendster) or through email analysis, the so called social network mapping tools are emerging that are capable of exposing relevant links between users (e.g. InFlow) and generate statistics on almost anything. As often stated in many blogs and editorials, business managers expect that Web 2.0 will bring more information about users, customers and their trends, allowing business efforts to focus on specific target communities.

Through tagging and social bookmarking, folksonomies are emerging as a valuable clas-

sification mechanism of documents and goods. Moreover, folksonomies, seen as very simple ontologies (Van Damme, Hepp & Siorpaes, 2007) are perceived as an important social interrelation mechanism allowing systems to track the relationships between individuals and groups across the social networks. This assumption is based on empirical evidence showing that users follow the tendencies originated by specific users (or groups of users). With this approach, i.e. decentralized, cooperative and intuitive development (Siorpaes & Hepp, 2007), folksonomies tend to better represent the conceptualization of a community, while at the same time the community is able to cooperatively participate in other ontology-based processes, such as information integration and evolution. This permeating process promotes discussion about future communities' tendencies, their similar desires, interests and knowledge patterns, supporting the idea of exploiting the intrinsic social knowledge for improving the e-commerce interactions.

It is expected that social network services will soon provide automatic access to SNA metrics, improved content classification and many statistical reports. For that, API, agent-based or Web Services will be used instead of the traditional Web page interaction. The Web-Of-Trust and PKI (Public Key Infrastructure) (Aberer, Datta & Hauswirth, 2005) infrastructures will be combined with such services in order to assure identity, trust and no repudiation between users and systems. Kondifi and FOAFRealm are two examples of such systems. The FOAFRealm aims to integrate several types of social semantic information sources through the same infrastructure,

Figure 4. The information integration basic protocol



and its access control rules are based in FOAF data (http://www.foaf-project.org/). Kondifi deploys and exploits relations between the formal identification mechanisms available through PKI infrastructure, and RDF-based (Resource Description Framework) information provided by accessed documents.

SOLUTION DETAILS

While the use of ontologies allows e-commerce actors to describe their needs and capabilities into proprietary repositories, the use of the ontology-mapping paradigm allows transparent semantic interoperability between them. This is the technological basis for the alignment between needs and capabilities of consumer and supplier, even when they use different ontologies. Based on this approach we can obtain the minimal requirements to support our proposed solution.

Minimalist Approach

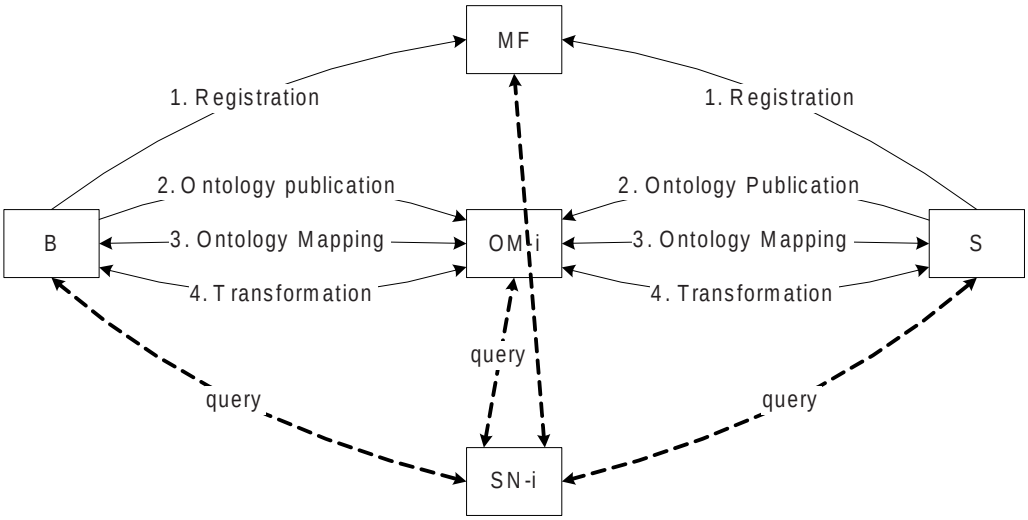
The first proposed version of the protocol (Figure 4) models the simplest interactions between the three types of agents, minimizing the changes in interactions between B (Buyer) and S (Seller) agents with the MF (Market Facilitator) agent, based on the ISEM protocol (Figure 2).

This minimal approach aims to overcome the simplest information integration problems mentioned above.

In this protocol, the MF agent is responsible for the specification of the mapping between the B and S ontologies. When the B requests a proposal (ReqProposal), the MF agent generates (or queries) the ontology mapping repository for a mapping between the two agents' ontologies, and proposes it to the agents. The agents are free to accept or reject the mapping, but in case both accept, the messages' content will be transformed between agents according to that ontology mapping specification.

The changes to the original protocol are minimal. In fact, most of the changes affect the MF agent only, in the sense that the ReqMapping and ReqTransf messages will trigger MF's internal processes.

Figure 5. Marketplace's actors and interactions



Extended Approach

However, this system infrastructure is too simple to be effective especially because:

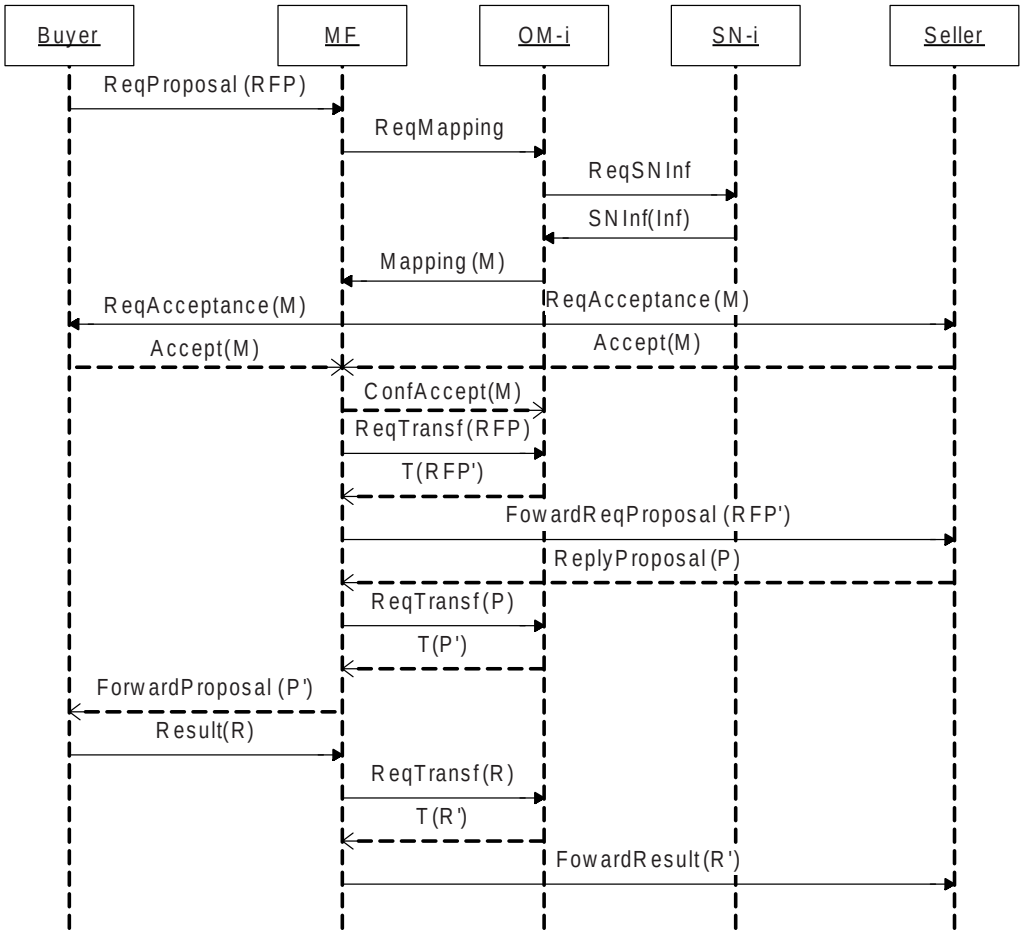
- It neglects the complexity and subjectivity of the ontology mapping process.
- It does not consider the social relationships emerging in the Web and their potential in disambiguation and decision-making processes.

As a consequence, a new system infrastructure is proposed, recognizing two new types of actors:

- *Ontology Mapping Intermediary* (OM-i), is the agent that supports the information integration process during the market interoperability, typically one per marketplace.
- *Social Networks Intermediary* (SN-i), is the agent that provides trust relationship information holding between B, S and other agents that undertake similar experiences (e.g. a trader agent), typically one per marketplace.

These actors deploy a set of relationship types whose goal is to automate and improve the quality of the results achieved in the e-commerce transactions. Figure 5 depicts the types of interactions

Figure 6. The integration protocol



between the marketplace supporting agents (i.e. MF, OM-i and SN-i agents) and the operational agents (i.e. B and S).

Considering the previous descriptions, a more complete and complex protocol is now detailed, including the OM-i and SN-i agents in the system (Figure 6).

The integration starts when the B agent sends a request for proposal message (ReqProposal) to the MF agent. In response, the MF sends to the OM-i a request for mapping message (ReqMapping) between B and S's ontologies.

Once OM-i receives the ReqMapping message, it will start the ontology mapping specification process, with the support of other entities, including matching agents, ontology mapping repositories and SN-i. SN-i is responsible for retrieving the relevant information from ontology mapping repositories and social networks. Past similar ontology mapping experiences undertaken by agents with trust relationships with B and S will be used by SN-i to compile the social network repository information (i.e. SNInf(Inf)). Because the ReqSNInf is the sole responsibility of OM-i, both B and S are advised to perform a similar verification (eventually using other SN-i) once the ontology mapping is submitted for acceptance (i.e. ReqAcceptance(M)). Despite the fact that figure 6 represents only the acceptance scenario, a rejection scenario is also possible, in which case no further interaction will occur between B and S. In case the mapping is accepted, MF resumes the protocol by requesting to OM-i the RFP data transformation. Using the ontology mapping document, RFP data represented according to B's ontology is transformed into data represented according to S's ontology. The transformed data (RFP') is forwarded to S, which will process it and will reply to MF. MF will then request the transformation of the proposal data (P) and will forward P' to B. B processes it and will accept or formulate a counter-proposal (CP). As can be seen, once a mutually acceptable ontology mapping is established between B's ontology and S's ontology, all messages exchanged between B and S through MF are forwarded to OM-i for transformation.

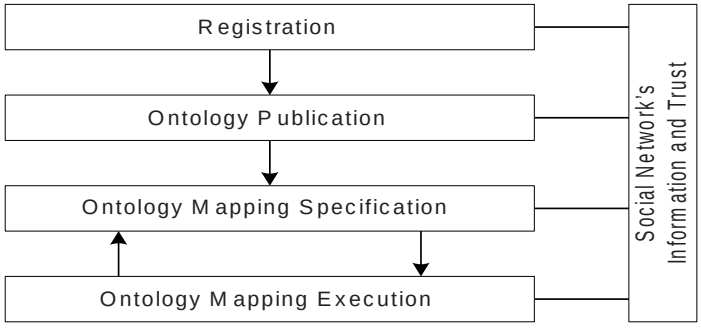
Notice that Figure 6 represents one single S in the system, but in fact multiple S's capable of replying to the request may exist in the marketplace. In such case, the protocol would replicate the previous protocol for as many capable S's. In order to decide which S's are capable of answering the request, a simple approach based on a keyword matching algorithm is taken. The B agent specifies a few keywords along with its formal request (RFP). The MF, with the aid of SN-i, matches this list against every S's publicized keyword list. In case the match succeeds to a certain level, the S is classified as capable.

The interaction protocol just described emphasises the information integration problem occurring in the negotiation stage of the CBB model. However, other interaction protocols are needed to improve the marketplace in accordance to the objectives stated in section 2.1. In fact, in every stage of the CBB model, both the SN-i and OM-i are major players in the proposed solution. Notice that the social network information and trust component of the system is orthogonal to previous processes, as depicted in Figure 5. Also notice that the trust component of the system is orthogonal to previous processes, as depicted in Figure 7.

In particular, the Social Network component is envisaged as a source of information for disambiguation and decision-making to the other processes, along with trust relationships between users and groups:

- The Registration process will profit from the Trust component in several ways. For example, the S agents can better decide which Services to provide in a marketplace, depending on the segment of customers traditionally found in specific marketplace. This is achieved by the social characterization of the B agents according to the social

Figure 7. Marketplace's ontology-based services



networks they belong to. In the same sense, B agents can more accurately choose the marketplaces to register to, depending on the social network advice, based on a social characterization of the other marketplace participants (i.e. Buyers and Sellers);

- During the Ontology Publication process, agents need to decide which ontologies are advisable in that particular marketplace (e.g. simple or more detailed). The agent is able to choose the ontology that conveniently describes the semantics of its data in a certain context. In order to decide the more convenient ontology, S agents require a social characterization of the marketplace. Similar decisions are taken by B agents. Notice however, that the agent's published ontology should not be understood as the complete representation of its internal data, but the semantics the agent intends to exteriorize through the Ontology Publication process. As a consequence, the agent should encompass the mechanisms allowing the internal transformation between the internal data semantics (e.g. data schema) and the external semantics (ontology), and vice-versa;
- The Ontology Mapping Specification process is typically very ambiguous, thus it can potentially profit from the social characterisation and social trust relationships provided by SN-i. This process is understood as a negotiation process, in which B and S try achieving a consensus about the ontology mapping. The SN-i agent participates in this process as an information provider to the OM-i in order to disambiguate the ontology mapping achieved through automatic mechanisms and protocols. A possible approach for this negotiation can be found in (Silva, Maio & Rocha, 2005);
- The Ontology Mapping Execution process is very systemic (in accordance to the ontology mapping specification document). Yet, the messages' data may be inconsistent in respect to the B's and S's data repository. In such cases, social knowledge is often required in order to decide/correct the consistency of the data. Through the use of social relationships, SN-i is a facilitator of this process.

ALTERNATIVES

Some approaches to agent-based applications for competitive electronic markets are more targeted or limited than our proposal: some of them not address a multi-issue negotiation type; do not consider behaviour dependent dynamic strategies, or expected future reactions. Others, although considering behaviour dependent dynamic strate-

gies, frequently assume that agents have complete information about market, such as the distribution of buyer preferences or its competitor's prices like (Dasgupta & Das, 2000) and (Sim & Choi, 2003), and, in general, all of them assume that actors be aware of understand each other. Nevertheless, we can find approaches where the semantic problems are been considered.

For example, in (Malucelli, Rocha & Oliveira, 2004) ontology-based services are proposed to be integrated in the ForEV architecture in order to help in the Virtual Enterprise formation process (B2B). ForEV is an appropriate computing platform that includes and combines a multi-issue negotiation method in the context of Multi-Agent Systems, which makes the platform more open, enabling the establishment of the negotiation process between agents with different ontologies although representing the same domain of knowledge. They propose an ontology-based services Agent which is responsible for providing the ontology-based services. However we are interested in studying Multi-agent systems for B2C domain where other stages, as advocated by the CBB model, need to be contemplated in order to represent real situations. We are interested in studying how the identification stage of the CBB model can be supported by using ontologies to construct the most accurate model of the consumer's needs. Moreover, at the product brokering, buyer coalition formation, merchant brokering and negotiation stages, the ontology mapping process will provide the integration of the seller and consumer's models and guarantee the agent's heterogeneity. On the other hand, they don't explore the repository of relationships provided by emergent social networks, which can carry out the establishment of more accurate trust relationships between businesses and customers, as well as providing a better alignment (mapping) between their models.

In (Paolucci, Sycara, Nishimura & Srinivasan, 2003) authors present a capabilities matchmaker for applications in the Web, wrapped by Web Services. DAML-S is an ontology of capabilities that is instantiated for describing the capabilities of Web Services, which are then matched against other Web Services' capabilities. Thus a semantic matchmaking approach is adopted, ahead of the syntactic description approach commonly adopted. A very important limitation of the approach is the lack of a decision-making mechanism. In fact, as stated by the authors, "DAML-S requires applications that look more like intelligent software agents than traditional e-commerce applications".

Instead, the approach proposed in this chapter suggests the adoption of an orthogonal information and trust and social relationship service, capable of supporting the overall e-commerce processes, especially the decision-making and disambiguation processes.

A similar concept is adopted by the on-going myOntology project (http://www.myontology.org), in which the ontologies are perceived as socially evolving descriptive artefacts of a domain of discourse, namely that of e-commerce. This project aims to create infrastructures capable of capturing the social interactions in developing/evolving the ontologies, and exploit such information "to improve the expressiveness and disambiguity of informal concept definitions in an ontology".

Therefore, this project is complementary to the approach we propose, in the sense that it is focused on capturing, populating and systematizing the repository with the ontology changes carried by the social groups. The approach suggested in this chapter will profit form this technology as a social information and Web-of-trust source of information. It is up to the SN-i to conveniently exploit such information in e-commerce scenarios.

COST AND BENEFITS

In an efficient agent-mediated electronic market it is necessary to have common standards: an

interaction protocol to achieve deals; a language for describing the messages' content; and ontology for describing the domain's knowledge.

The interaction protocol is usually announced at the marketplace and composed of a set of interaction phases. The language for describing the messages' content is usually provided by the communication platform used to develop the e-commerce application. Platforms for distributed agent's communication are also available, however, an ontology for describing the domain's knowledge needs to be incorporated and represent the best answer to the demand for intelligent systems that operate closer to the human conceptual level.

With regard to ontologies, many studies are being done but, currently, there is neither a standard ontology language nor a standard ontology knowledge representation. This lack of standardization, which hampers communication and collaboration between agents, is known as the interoperability problem. However, *ontologies per se* are not able to overcome information interoperability incompatibilities and it is hardly conceivable that a single ontology can be applied to all kinds of domains and applications. Information integration mechanisms are necessary in order to identify, represent and apply the diverse relationships between concepts and relations of two or more ontologies. Ontology Mapping is one of the most successful information integration paradigms used in the Internet and in particular in the Semantic Web. The use of a common ontology guarantees the consistency and the compatibility of the information present in the system.

In this work, the different actors involved in the marketplace are able to independently describe their universe of discourse, while the market is responsible for providing a technological framework that promotes the semantic integration between parties through the use of ontology mapping.

On the other hand, we propose an approach where the agents are free to accept or reject the mapping done by the marketplace. With this approach we can test several scenarios and explore a valid future agent-based platform for B2C. Additionally, through the integration information process carried out in the different stages, the searching space is enlarged, promoting the access to goods/services otherwise inaccessible.

Nevertheless, this solution has some drawbacks related to development and deployment. The development problems are specially related with the heterogeneity of the main technology requirements. The deployment issues are related with the configuration of the agent according to the user's constraints and strategic behaviours.

RISK ASSESSMENT

During this chapter, several assumptions were considered in order to support the proposed system. In particular, it is assumed that the social network paradigm will continue growing and that processing mechanisms will be provided. In particular it has been assumed that:

- The social participation in the Web will continue growing, namely tagging, social bookmarking and collaborative activism;
- The capabilities of the social network infrastructures will increase, providing and promoting services exploiting the information brought online by each individual;
- The relation (dependency) between Web-Of-Trust systems and Social Networks (based on FOAF or other representation mechanism) will tighten. This relation will be of fundamental importance in the effective development of the proposed infrastructure since it will provide the identification and trust infrastructure between communities and systems.
- The social network concept will evolve in order to encompass some explicit semantics, turning into semantic social networks. More than an enabler, such evolution would

facilitate the adoption of the proposed approach.

According to what has been stated, the proposed approach has several internal strengths and weaknesses.

Strengths:

- The CBB reference model is widely recognized as a correct interaction model in B2C.
- The proposed approach adopts concepts and behaviours not supported by traditional agent-based approaches.
- Permeation of ideas, domain modelling and content characterization between individuals and communities leads to socially supported decisions and disambiguation.

Weaknesses:

- Intrinsic semantic ambiguity of the proposed approach, which might lead to users having difficulty in accepting the decisions recommended by the system.
- Novelty of the suggested model, which might lead to poor results which are not fully geared and tweaked.

At the same time, the proposed approach profits and suffers from the technological, social and economic context.

Opportunities:

- Limitations of the user-driven portal-based and of the traditional agent-based B2C.
- Social network relationships, giving rise to communities of interests with some degree of mutual trust.
- SNA metrics and statistics, enabling the characterization of (implicit) communities, and hence promoting business activities according to target community.
- Social network engagement, promoting the cooperation between individuals, thus facilitating technological solutions, such as information integration and decision support.

Threats:

- Maturity of the Social Networks and related technologies.
- Lack of the supposed social network services.
- Lack of social network services accessibilities for software agents (e.g. API, Web Services).

FUTURE TRENDS

One of the largest problems this approach faces is related to the access and processing of social relationships. Despite the fact that the social networks and social network analysis are well established concepts, their implementation in the scope of the Internet started a couple of years only. As a consequence, some of the available services supporting online social communities (e.g. LinkedIn, MySpace, FaceBook) are now facing relevant problems, such as duplication of registers inside and across services, abandoned registers, ghost (virtual) registers. Instead, the evolution seems to follow the specialization trend (e.g. one service is used to create music relationships, another one is used for sports relationships) and respecting the age of user (i.e. one service is mostly used by young people, while another is used by middle age people). Additionally, organizations are now creating their own business-oriented social networks, either for employers or customers. Social networks are spreading on the Web, which will require an immense effort of integration. Our approach would profit from this characterization as it will be possible to better characterize the customer needs in respect to buyers and other customers.

We need to develop our approach and test several scenarios in order to obtain and explore new market information, which will be used to feed agent's knowledge-bases and the social networks repositories.

CONCLUSION

The meaningful interaction between distributed, heterogeneous computing entities (e.g. software agents), in order to be both syntactic and semantically compatible, needs to follow appropriate standards well understood by all participants. Some standards are being developed with regard to ontologies specially the Ontology Web Language (i.e. OWL) in the context of Word Wide Web Consortium.

Several problems involved in the overcoming of syntactic and semantic heterogeneity are difficult to be solved, at least nowadays. However, some efforts have been made in order to find possible ways to resolve parts of this complex problem.

A big challenge for communicating software agents is to resolve the problem of interoperability. Through the use of a common ontology it is possible to have a consistent and compatible communication. However, we maintain that each different actor involved in the marketplace must be able to independently describe their universe of discourse, while the market has the responsibility of providing a technological framework that promotes the semantic integration between parties through the use of ontology mapping. In addition, we think that the solution to overcome theses problems has to take into consideration the technological support already existent, namely a well-proven e-commerce platform, where agents with strategic behaviour represent consumers and suppliers.

This chapter has proposed the use of agents and Multi-Agents Technology as a platform for B2C. We propose an agent-based electronic market with an ontology-based information integration approach, exploiting the ontology mapping paradigm, by aligning consumer needs and the market capacities, in a semi-automatic mode, improved by the application and exploitation of the trust relationships captured by the social networks. Additionally we explore the repository of relationships provided by emergent social networks, which can carry out the establishment of more accurate trust relationships between businesses and customers, as well as providing a better alignment (mapping) between their models. Social networks form the basic infrastructure to encompass trust in many internet based activities, including B2C transactions and information integration.

ABSTRACT

This paper investigates the collective use of a simple modeling technology by highly complex, heterogeneous and numerous groups of stakeholders who heavily depend upon it to mediate their interactions. We use economic theory, design theory, complex systems theory and business process modeling concepts to analyze deregulation and business to business interaction in the UK electricity industry, and the strategic business and IT response of Electric Co, a large electricity supply company. The relevance of this study comes from its investigation of a novel example of the shaping of a whole sector's e-business through regulatory law and thus we are concerned with enterprise and inter-enterprise systems not purely with ERP systems. We focus on model-based business interaction and its effect upon the business and consumer behaviors of a

whole country's electricity sector. This sector is a socio-technical system; so business processes and consumer behaviors are not only shaped by the regulator's legally enforced business to business process interaction model, but the opinions of businesses and the public also influence how the regulator updates its model. Thus business behaviors, consumer behaviors and the model interact to shape each other. By moving from intra to inter-organizational business processes we seek to demonstrate and explain the value of models in e-business where the complexity of interacting business systems involves many thousands of parameters. We show how developments in technical standards and business process management are related to inter-organizational interaction and coordination.

INTRODUCTION

Networks of businesses are complex systems that are joined by complex interrelations (Anderson, 1999). These interrelations take the form of business processes that join the elemental businesses. Business process modeling literature seeks to describe business processes from different perspectives, according to different objectives or goals. To do this, it uses modeling constructs such Curtis, Kellner, and Over's three constructs of agent, role and artifact to do so (Curtis, Kellner, & Over, 1992). This paper illustrates the use of regulatory power over modeling methodology sophistication. By moving from intra to inter-organizational business processes it demonstrates and explains the value of models in e-business where the complexity of interacting business systems involves many thousands of parameters (Scheer & Habermann, 2000). The importance of this study is that it moves away from the single firm Enterprise Resource Planning (ERP) system perspective. Here we focus upon enterprise and inter-enterprise systems and not purely upon ERP systems. Rather, this study focuses upon model-based business interaction and its effect upon the business and consumer behaviors of a whole country's electricity sector.

The relevance of this study comes from its investigation of a novel example of the shaping of a whole sector's e-business through regulatory law. It is also an example of a collective use of a simple modeling technology by highly complex, heterogeneous and numerous groups of stakeholders who heavily depend upon it to mediate their interactions. Most interestingly it is a socio-technical system; so not only are business processes and consumer behaviors shaped by this legally enforced model, but the opinions of business and the public also influence how the regulator updates the model. Thus business behaviors, consumer behaviors, and the model shape *each other.*

The business processes that embody business-to-business (B2B) interaction can be decomposed into sub-processes; and sub-processes into sub-sub-processes *ad infinitum* (Rescher, 2000). For example, the production process for a car can be decomposed into the main production processes of all the first tier suppliers to the car company, whose brand appears on the front of the car. These main production processes can be further decomposed into those of second tier suppliers and so on. Additionally, all the on site business processes of all these companies can be also be decomposed, seemingly, *ad infinitum* and so can the business processes that are the interactions between suppliers and customers. This has both theoretical and practical implications.

Theoretical Implications

The infinite decomposability of business processes is a possible reason for why there is no theoretical basis for business process model constructs. In the literature, these constructs use supporting theories from semiotics (Falkenberg et al., 1998; Stamper, 1987; Liu, 2000), Shannon's Communications

Theory (1948), Classification Theory (Parsons, 1996) and Ontology Theory (Wand & Weber, 2002; Green & Rosemann, 2000). Scheer's ARIS House Of Business Engineering, for example, is one of many modeling architectures (Scheer & Nüttgens, 2000); Hommes lists several hundred on his Web site (Hommes, 2005). ARIS' four levels provide four useful perspectives for abstracting salient real world properties. The first two levels, (1) process design and (2) process control, are process-centric (what happens) and its second two levels, (3) inter-application workflow coordination and (4) application used, are application-centric (by whom/what). Also, these perspectives are grouped into low and high specificity: levels (1) and (2) are general designs whilst levels (3) and (4) specify users (Scheer & Nüttgens, 2000). These are all useful perspectives for abstraction but because process modeling has no underlying theory other perspectives (e.g., regulatory, data quality, or even environmental) could equally be included. Such a theory may never be discovered because at some level processes are not pre-definable and their composition only becomes possible to know during enaction (ibid, p. 375). Complex systems are not modelable below a certain level of detail, or past a certain point in time, because emergence cannot be forecast (Checkland, 1981).

However, these are theoretical bases for the *communication* or *representation* of the process model constructs rather than for its *generation*. The model constructs in the business process modeling literature "merely list properties" (Lindland, Guttorm, & Solvberg, 1994), thus there is no way to judge the relative or absolute quality of different lists of model constructs. If processes are infinitely decomposable systems, as asserted by the Process Philosophy literature (Rescher, 2000), then an "atomic" process component does not exist and business process models can be compared to skyscrapers built upon mud. Their foundations do not rest upon bedrock but are deep enough to derive support from the mud itself. In modeling terms we can say that the model constructs only emulate properties of the subject in the domain of the modeler's concern. The lack of a theory also removes the possibility of a theory-derived heuristic.

Practical Implications

Secondly, businesses experience connection problems in practice. The composition of business processes from an immense number of elemental sub-processes enables many different configurations. This leads to many potential configuration mismatches between businesses (Scheer & Habermann, 2000). For example, car parts delivered to an assembly plant could arrive at the wrong time or in the wrong quantity, type, specification or batch size. Instead of "wrong" a more precise word is "unsynchronized". The delivered parts are not wrong for the deliverer but they hold properties that do not synchronize with the business processes that the receiver is enacting. The complex nature of B2B systems, and the business processes that join them, generates the potential for unsynchronized interdependencies. Synchronizing, or *managing interdependencies*, requires an act of *coordination* (Malone & Crowston, 1994) and one form of coordination uses standards (Langlois & Savage, 2001).

The objective of this study is to understand *how* and *why* the interdependencies (business processes) and interactions between businesses in a complex network can be managed, so as to reduce prices through increased competition while at the same time increasing interaction complexity, in other words, this is a *coordination* problem. Coordination involves business process composition and decomposition by all managers each time they make managerial choices, for example, choosing to incorporate one supplier's process output versus another's. We view business process coordination as the overall function of business process composition and decomposition. We attempt to do this by using theories from several different disciplines but which are *all* designed

to make sense of complex systems of one type or another. This includes design theory's and systems theory's intriguing *intersection* at the concept of "fit". We also develop a type-structural-volume flexibility model of inter-organizational interaction, which is build up gradually throughout the paper. It is grounded in the concepts of Requisite Variety, Bounded Rationality, Scale Economies, and Transaction Costs. It is illustrated using the case both at sector and firm level and its implications are set out for regulators and practitioners in our conclusion.

The contributions of our article apply both to academics and business practitioners, and are in its investigation of the use of business process standards to mitigate the complexities B2B interaction. In one such network, an electricity market, we illustrate how one company uses a business process standard at strategic management, business process and technical levels. This cross-disciplinary paper describes some of the problems of inter-organizational human interaction and how they have been solved by using a business process model.

RESEARCH METHOD

This paper illustrates a sector where very high consumer churn rates have forced very high volumes of business-to-business and business-to-consumer interaction. The paper analyzes how this produces data-exchange problems for electricity suppliers and how these problems are reduced by the regulator and then solved in detail by one particular electricity supplier. This solution is explained with a conceptual framework that is constructed using the theoretical concepts of *standards* from Economics, *fit* from Design Theory and Ashby's Law of Requisite Variety from Cybernetics. We apply this framework to the context of modeling the business processes that constitute the regulated interactions of the main actors in the UK electricity industry. Then we explore the practical implications of this by showing how the sector model is used by one electricity supplier to solve its own acquisition interconnection problems. Current literature does not adequately cover complex, high volume, politically sensitive, and high frequency business interactions across whole sectors.

We take an interpretive stance, because of the subjective nature of human interaction, and iterate around a hermeneutic circle, comparing sectoral *and* organizational perspectives so as to consider an interdependent whole joined by a standardized interaction model (Klein & Myers, 1999). We use a qualitative approach because our investigation is concerned with questions of "*how*" and "*why*" rather than of "how many". In seeking to answer "how" and "why"-type questions we follow Yin's recommendations (2003, pp 5) and use a case study approach: "how can a whole industry sector organizations be coordinated?" and "why do electricity prices reduce even when B2B interaction complexities seem to be greatly increased?", i.e., "how is it possible that standardization increases flexibility and why is this so?" A case approach is fitting because we are concerned with contemporary phenomena which we have no control over (ibid).

We are concerned with dynamic phenomena, so we have used several different data collection methods (Eisenhardt, 1989). Most data was obtained from interviews with members of "Dataflow Software's" board, marketing staff and design teams. Dataflow described the history of the use of modeling and modeling technology both in the sector and in helping their client "Electric Co". They also provided us with technical product information. Additionally, a full version of the regulator's industry business process model, the Master Registration Agreement (MRA) process diagrams were obtained from the MRA Service Company (MRASCo) Web site serviced by Gemserv Limited. Finally, other historical back-

ground data relating to government-led change in the sector was obtained from public Web sites as referenced.

STANDARDS FOR BUSINESS-TO-BUSINESS (B2B) INTERACTION

Kindleberger distinguishes between two types of standards: standards that create scale economies and standards that reduce transaction costs (Kindleberger, 1983; Langlois & Savage, 2001). Both types of standards act by reducing variety. Standards create scale economies by reducing the variety of *problem types* and *solution types* in a particular domain, which increases the volume of use of the remaining *problem types* and *solution types.* For example, consider a market with a size of 100 widgets per year where four different types of widgets are produced and consumed. If the market's customers change to a standard consisting of two widget types then the average volume of these two types could be expected be approximately double the volume of any one of the previous four solution types. This assumes an equal demand for all types and neglects reduction in demand from buyers who could only tolerate a discontinued widget type. The higher volumes permit economies of scale from longer production runs and reduced stock costs that are brought about by narrower product portfolios.

Transaction cost standards reduce the costs of a transaction between two people, or organizations, by aligning expectations and increasing the predictability of outcomes (Langlois & Savage, 2001). This acts to reduce the costs of the interaction by *limiting* the interaction, in other words, standards are a form of coordination (Schilling, 2000). Standards manage interdependencies by limiting their values to a subset of all possible values, for example, the use of standard shoe sizes increases the predictability of a fit when we try on a new pair of shoes in a shoe shop; so fewer shoes need to be tried on.

Standards can be technical (for example the Standard International units used in the physical sciences and engineering) or behavioral (such as taboos and traditions). Standards reduce "perceived" variety by improving communication precision, which leads to the increased alignment of expectations. By reducing the variety that has to be managed standards enable the *variety management* "capacity" of boundedly rational managers to be applied *elsewhere* (Newell, 1989). Standards are applicable whenever there are options or choices. They can also reduce variety when applied to the interdependencies between businesses and thus can be used to *synchronize* B2B processes. They reduce variety when applied to multiple occurrences of the same process, or even single instances, in a single business. For example, businesses may have standard delivery times; standard production processes may be reproduced many times on a production line; and a product specification is a design standard that is created only once because redesigned products are separate, unique and have different part numbers. Whether between businesses, between process instances or in the enaction of one process instance, all three examples contain options that have to be decided between.

Standards limit the requirement for *variety management* in a particular instance but this produces savings for either the producer (supply-side scale economies) or the consumer (demand-side transactions costs) only if the modular architecture of the chosen standard *fits* the architecture of the problem. Modules are components of a system that are arranged according to a set of rules, the *system architecture* (Schilling, 2000; Parnas, Clements, & Weiss, 1985). The system architecture is an abstraction of the full system based upon the concept of loose coupling between modules and tight coupling between sub-modular components within modules. Loose coupling is where the interdependencies between system elements are of low intensity (Weick, 1974; Orton & Weick, 1990). It is an example of Herbert Simon's

concept of near decomposability (Simon, 1969). In systems every element is connected to every other via interdependencies but the interdependencies between some elements are less intense than between others. For example, couplings are stronger within organizations than between organizations (depending upon the observation criteria). Thus organizations can be thought of as modules within socio-economic systems. The set of human rules or natural laws that govern the coupling tightness of elemental interdependencies is the *architecture of the system*. These same rules, or laws, also govern the *arrangement* of system modules.

In order for a standard to reduce variety, and so produce either scale economies or reduced transactions costs, there has to be *fit*. This concept of *fit* is a match between context and structure (Drazin & Van de Ven, 1985; Alexander, 1964). It is the fit between the architectures of the *problem system* and the *solution system* that join into a larger system when the solution is implemented. If the solution does not fully fit the problem then it is sub-optimal. The solution system may not address a subsystem in the problem system such as a product portfolio containing purely *desktop* PCs that fails to address a customer's *mobile* computing requirements. Another example would be a human designed standard for shoe sizes that must architecturally fit with the naturally evolved architecture of human foot growth and shoe use. Firstly, the architectural *cover* of the standard must include the cover of most of the human population. The subset of the population not covered by the standard would amend it or just not use it because it would not reduce variety for them. This concept of *cover* applies to both the *hierarchical levels* of the standard relative to the population of foot sizes and shoe use (the solution architecture) but also the *span* of the standard. A system can be decomposed conceptually into related subsystems and these subsystems can be further decomposed into related sub-subsystems and so on. The system, the subsystems and the sub-subsystems, and so forth, exist upon three different hierarchical levels. These are levels of recursion like national economies, businesses and departments; or departments, human bodies and cells. In order to reduce variety a standard must cover the appropriate hierarchical *levels* of the subject to be standardized (e.g., the feet and foot use). The *span* of a system relates to the sum of the properties of its subsystems on any one level (Simon, 1969). For a standard to fit it must be applicable across all the hierarchical levels and the full span of system properties that its users find *relevant*. These hierarchical concepts are similar to Allen, O'Neill, and Hoekstra's *grain* and *extent* (1984).

Secondly, the standard's classification system must *reflect* the modularity of the subject system. In this example the architectural structure of the standard's classes must follow the architectural structure of human feet. If the standard does not reflect the modularity of the subject system, in other words, if it includes classification boundaries in regions of tight coupling in the subject system, then variety would not be reduced and so choosing between classifications would not be made easier. For example, a standard with a classification system that specified sole size *independently* of upper shoe size would double the variety of choice for the buyer by decomposing a single class of "whole shoe size" into two sub classes. If human shoe use required similar uppers but with different soles then this added variety would be *requisite*, in other words, there would be enough solution variety to match the variety of the problem (Beer, 1979). But humans tend to change shoe uppers and shoe soles at the same time so in human shoe *use* upper variety is tightly coupled to sole variety and the problem variety does not require a standard that decouples shoe upper and shoe sole classifications. There may also be a lack of fit if the standard includes too *few* classification boundaries in regions of loose coupling in the subject system. For example, we tend to use shoes independently of clothes. Our use

of foot coverings and body coverings are loosely coupled, so clothes that incorporate foot coverings are rare. Some examples of tight coupling between foot coverings and body coverings are space suits, certain types of wet suits and anglers' waders. In these three examples the *purposes* of the foot coverings and body coverings are tightly coupled and thus so is the construction of the covering. The hierarchical level and the span granularity at which the standard's classification system best reflects the modular architecture of the subject system is a trade off between increased fit versus increased variety.

We also use fit to assess the compatibility between the industry process model and the regulator's objectives (i.e., does the market function? Is market efficiency improved?). There is an architectural fit because although the industry process model is merely an abstraction of all possible supplier-customer-regulator interactions it includes enough of their fully set of behaviors to allow each role to interact successfully.

CASE ANALYSIS OF ELECTRIC CO AND DATAFLOW SOFTWARE

The UK Electricity Market

In 1990, 12 regional electricity companies were formed to supply business and domestic customers in the UK. Each Regional Electricity Company (REC) controlled a geographically defined market. At the same time there were just three major electricity generating companies: BNFL; Powergen; and National Power. Powergen and National Power used fossil fuels to produce 80 percent of the electricity and BNFL produced the remaining 20 percent using nuclear energy technology. Now we have a situation where Credit Suisse First Boston can trade on the future prices of electricity in the electricity wholesale marketplace and a grocery firm, Sainsbury, can supply electricity to a domestic customer through cable owned by any of the distribution companies, such as Scottish Power. There is now competition at every stage of the supply chain in the electricity market and a wide variety of competitive strategies have emerged. These range from large organizations attempting to dominate a particular stage of the supply chain to niche operators that focus on a very specific customer set. A transition has occurred from a highly regulated set of regional monopolies to an open and competitive marketplace. For this to happen in practice, in tandem with de-regulation, individual companies have developed and used advanced information systems and common industry standards for information exchange. This information exchange has in turn enabled the free flow of information to support the rapid changes in industry structure and interactions between electricity suppliers and users that include large corporate companies, small and medium sized enterprises, and domestic users. The range of participants now includes traders, generators, distributors and suppliers.

Electric Co is one of the new breed of electricity companies that is competing in multiple geographic regions, and is supplying electricity to all types of customers from domestic to large industrial users. A major part of its success in competing to attract and retain new customers is its advanced use of information systems that support both its internal business processes and the exchange of market data with competitors. One of its key technology partners is Dataflow Software whose software forms an integral part of the IT infrastructure of the industry as well as the communication flows between Electric Co's internal systems and its economic partners, customers, competitors and the industry regulator.

Deregulation and New Trading Agreements

In March 2001 the UK government introduced New Electricity Trading Arrangements (NETA) in England and Wales (NAO, 2003). These arrange-

ments were designed to increase competition in the electricity wholesale market, to reduce the price of bulk electricity, and ultimately to reduce the prices that the end users would have to pay. Prior to this the arrangements for trading electricity, known as the Pool, were thought to be uncompetitive and open to manipulation. The Office of Electricity Regulation (OFFER) and the Office of Gas Supply (Ofgas) were combined in 1999 to form The Office of Gas and Electricity Markets (Ofgem). In October 1997 the Minister for Science, Energy and Industry asked OFFER to review the way that electricity was traded in England and Wales and suggest a number of improvements. The areas of the review included reducing the price charged to the user and improving choice, quality and security of supply for electricity users (Ofgem, 1997).

OFFER's review of the Pool pointed to problems of over-regulation that limited the effect of normal market forces such as competition in price setting together with supply-side and demand-side price influencing. The Pool, one of the first examples of a wholesale electricity market in the world, was limited by the complexity of its bidding and price setting mechanism, the inflexibility of its regulations and openness to manipulation of its payment rules (NAO, 2003). The main proposal from the review was that the trading of electricity should become much more market-based. OFFER recommended that the electricity market should operate more like other commodity markets, subject to special requirements for physically balancing supply and demand in order to maintain the security and quality of electricity supply. These special requirements came from the fact that electricity is a commodity that is very difficult and costly to store and whose supply cannot be varied instantaneously but whose demand can. So only balancing, rather than buffer stores, can be used to stop frequent small power cuts caused by high user demand volatility. In addition to this the government required that users should be shielded from short-term price volatility and the financial instruments that are used within other commodities markets can also help with this.

These recommendations led to the current trading arrangements known as NETA. With NETA the value chain for the industry is now divided up into two main marketplaces (see Figure 1). These are the wholesale marketplace and the supply marketplace. The wholesale marketplace is made up of the six main generators: Innogy, London Electricity, Powergen, Centrica, Scottish Power and Scottish & Southern Electricity. These generators are vertically integrated into the supply marketplace, in other words, they produce *and* sell electricity to end customers. The six generators have evolved from very different starting points. For example, Centrica was originally only a supplier of electricity and had no generation capabilities. Powergen started in the power generation field and has now moved into the supply marketplace. Other companies in the wholesale electricity marketplace are banks, which trade on the price and availability of electricity just as they do in other commodity markets. Many of the small electricity generators have particular niches, for example they may use green energy sources such as hydroelectric and wind power. The supply, or "retail", electricity marketplace is made up of the six large, vertically integrated generators, several very large supply-only companies and tens of smaller companies. These smaller companies are frequently associated with well-known brands, or extensive customer networks, from sectors such as media, banking and food retail.

One significant outcome of deregulation was market instability caused by artificially high retail electricity prices normalizing under more natural market conditions. This instability caused a significant drop in the wholesale price of electricity, which in turn led to financial problems for the two electricity generation companies, British Energy and TXU Energy. British Energy had to ask the UK government for financial assistance and TXU Energy sold its European subsidiary to Powergen. However, the UK's National Audit Office (NAO)

has reported that overall "NETA has facilitated lower wholesale prices", a decrease of "over 20% between the introduction of NETA in March 2001 and October 2002". In the same period the NAO reported that electricity prices for industrial and commercial customers had fallen 18 percent. Prices for domestic customers fell less than this but still in line with the reductions in suppliers' overall costs. Customers who switched suppliers secured an average price reduction of 17 percent, but greater price reductions for domestic customers have been prevented by increases in supplier's environmental costs and "the substantial costs of processing changes of supplier" (NAO, 2003).

The Challenge to Electric Co and Other Electricity Suppliers

From the viewpoint of the customer one of the biggest changes caused by NETA is to enable customers to change their electricity supplier whenever they wish to do so. This has created responsiveness to demand-side market pressures and has vastly increased the number of customers who switch suppliers, which has produced an associated increase in the economic costs of market change, for example, customer churn: losing existing customers and acquiring new ones. The UK's National Audit Office found that from May 1999 to June 2000, "6.5 million customers — one in four — had saved money by changing supplier, and customers were changing at the rate of 400,000 a month" (NAO, 2004). The right of electricity users to easily change their supplier and the resulting increase in customer churn has forced Electric Co to develop systems that can cope with large numbers of customer registrations and deregistrations.

The Office of Gas and Electricity Markets (Ofgem), the electricity regulator, specifies a series of service level agreements that electricity suppliers must meet in this new open marketplace. In this industry Ofgem specifies how every organization operates. This specification describes all business processes and their input and outputs; the exchange of information and the information's meaning; and the timescales of the exchange. The model of the whole industry's business processes is described in the Master Registration Agreement (MRA) using dataflow diagrams that are extremely complicated. Over 96 detailed diagrams describe more than 21 main processes and many sub-processes that contain main varied process steps.

The MRA process diagrams are managed and maintained by the MRA Service Company (MRASCo, 2003). The business processes are

Figure 1. Elements of the English and Welsh electricity industry value chain in 2003

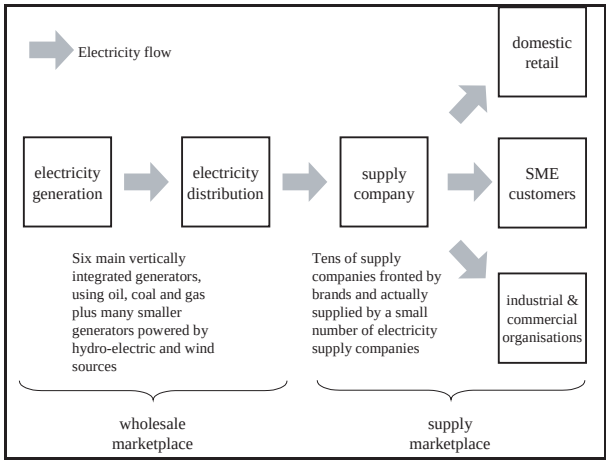

Figure 2. Overview diagram of the UK electricity industry key business processes (MRASCo, 2003)

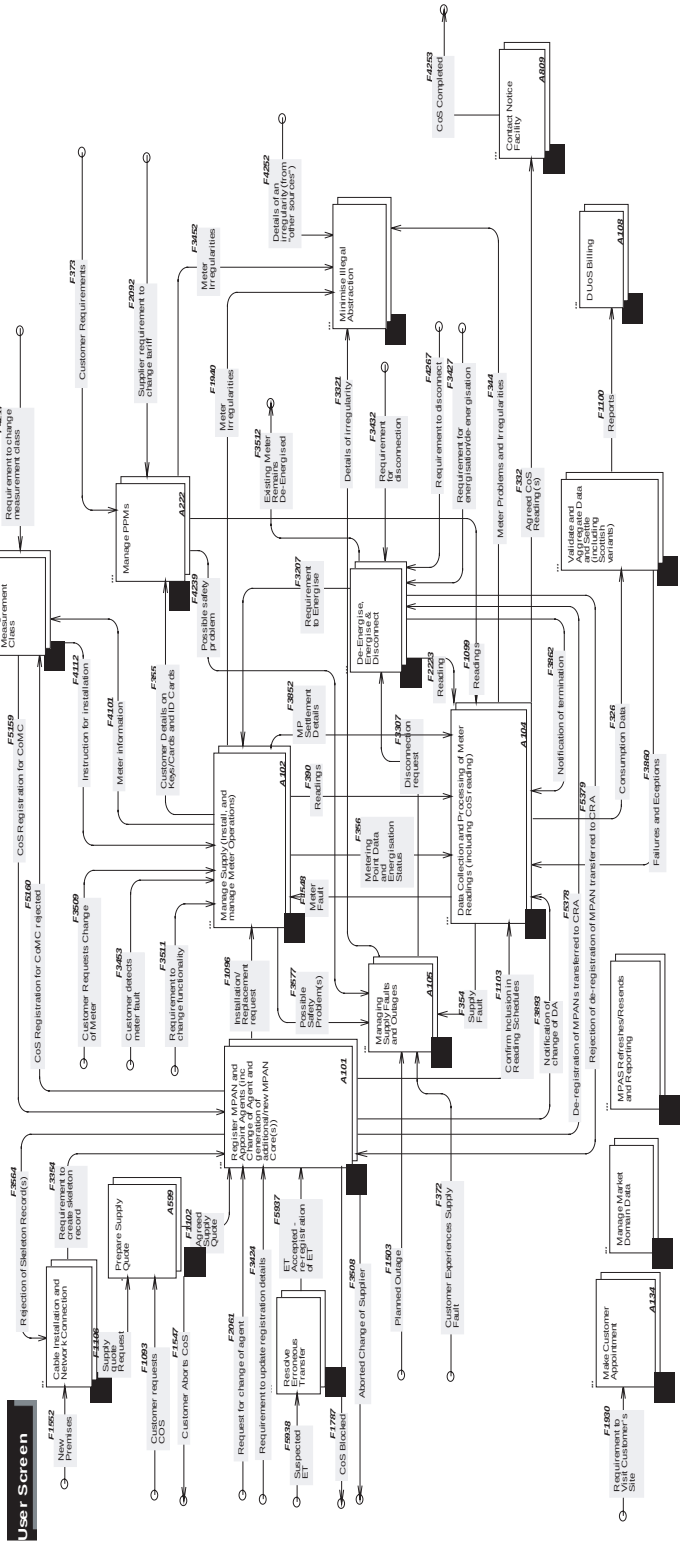


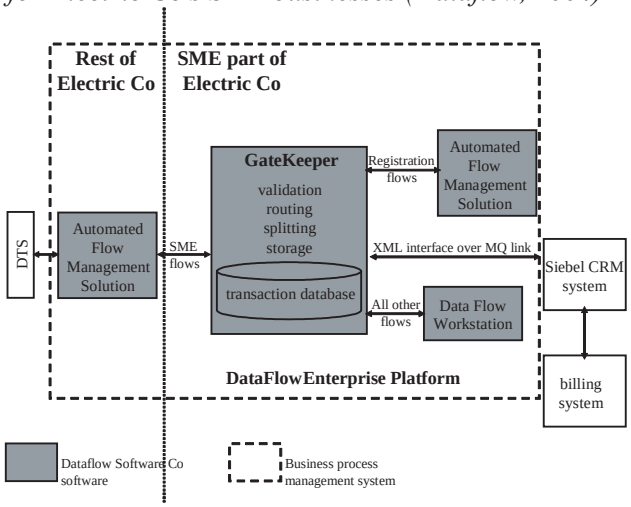
modeled in Enterprise Modeler by Enterprise Modeler Solutions Limited. An overview of the electricity industry's key business processes is shown in Figure 2. We use this to illustrate how complicated the MRASCo model is rather than for analysis purposes. Each change in supplier starts a formal deregistration process in one supplier and a formal registration process in another supplier. Each deregistration and registration process requires a complicated set of interrelated activities to take place in a pre-defined format, sequence and time. Although in concept this is straightforward, in practice the data structures are quite complicated and the high volumes of data exchanged exacerbate the information exchange and internal process problems. Every month 400,000 customers change suppliers; so suppliers have to process 9,600,000 deregistration and registrations per year. On a process level the cost of this from labor and potential errors is immense.

For example, each registration or deregistration incurs labor costs from taking customer telephone calls to maintaining the information systems that process each transaction. The potential for damage to the supply company's reputation from errors that reduce service levels is considerable because the registration process will fix a customer's first impressions and a customer that has already switched supplier will have few worries about switching again. Even deregistration is dangerous to the suppler because a customer may try to deregister in order to miss paying a bill. A supplier that allows a customer to transfer to another supplier with an outstanding debt may then find it harder to get the customer to pay.

Within this overall framework, Ofgem define what they call "Golden Threads". These are all the data flows and data processing operations that need to take place in order to enact a specific process, such as switching suppliers. The process diagram for switching suppliers is just one of the processes contained in MRA process diagrams and it includes interaction and service level specifications such as maximum times for the whole user disconnection-reconnection process.

Electric Co is greatly helped by software developed by Dataflow Software. For the parts of Electric Co acquisitions that service Small to Medium Sized Enterprises (SME) we can see (in Figure 3) that Dataflow Software's software manages the flows of data from and to the Data Transfer Service (DTS); between the SME parts of Electric Co; and between Electric Co's single Customer Relationship Management (CRM)

Figure 3. The data flows for Electric Co's SME businesses (Dataflow, 2004)



systems and multiple billing systems. The DTS is an Information and Communications Technology network, that is operated by Electralink, which enables business-to-business data communications between any electricity supplier that is connected to it (Electralink, 2004). Dataflow Software's GateKeeper software uses the DTS and provides data validation, routing, splitting and storage services together with a transaction history database.

Electric Co's Business and IT Strategy

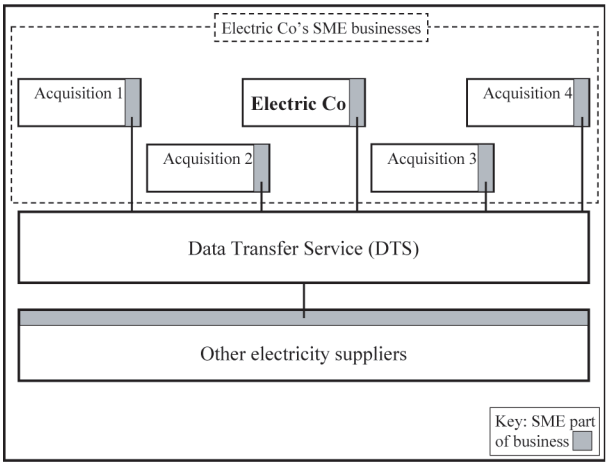
Electric Co has grown rapidly since 1995 through the acquisition of four large electricity suppliers composed of two original Regional Electricity Companies and two newer suppliers. Electric Co had the architectural legacy problem shown in Figure 4. Taking Electric Co's SME business as an example, we can see that each of the four acquisitions had their own information systems supporting their own SME businesses.

Upon acquisition Electric Co connected the separate SME systems via the Data Transfer Network. The DTN provided the interface for internal message passing in the same way that it was used as a medium for message passing to and from systems that were *external* to Electric Co. Whilst this did support business processes, such as the registration and deregistration processes examined above, the issues associated with increased external data flows concerning customer and supplier changes still needed to be resolved for the *internal* business processes.

Dataflow Software's IT solution strategy was to use software to integrate the SME components of the various legacy systems through a single communications and validation point. The actual software used was a product called Gatekeeper Data Exchange, a part of their Dataflow Enterprise Platform (Dataflow, 2004). Gatekeeper integrated valid dataflows with different back office applications, such as Credit Checking, CRM, Billing, and Registration, which run on different systems. Gatekeeper was able to do this because it was designed to use the governing industry data transfer rules to translate between information systems in different organizations and different systems in the same organization. This allowed Electric Co to consolidate its IT systems from a geographic architecture to a product/market architecture. This gives Electric Co the strategic benefits of being able to operate as a single entity, and has led to significant cost savings in IT expenditure.

It also improves the levels of customer service

Figure 4. Internal legacy system connection problem



because the *automation* of business processes and the associated data flows reduces errors and increases the speed of information flows to and from customers and competitors. This is a great benefit to Electric Co, given the huge volume of messaging associated with the customer churn for all electricity suppliers. After using the governing industry data rules to integrate the dataflows transmitted between the different industry organizations *and their software applications* Dataflow Software took the next logical step and created their Enterprise Automated Flow Management software. This software is able to automatically enact key processes because of its ability to process dataflows between the different back office applications used in the industry. The back-office software already obeys the governing industry data rules and Gatekeeper integrates valid dataflows. Dataflow Software were thus able to create a set of Automated Applications for customer registration and deregistration, and other volume intensive business processes, that uses the data held within back-office applications such as Credit Checking, CRM, Billing and Registration. Electric Co successfully integrates its SME business using Dataflow Software's solution and will extend this competitive advantage to its Domestic and Industrial & Commercial businesses.

ANALYSIS AND DISCUSSION

The Enterprise Automated Flow Management software is an example of a Business Process Management System (BPMS) (Aalst, Hofstede, & Weske, 2003; Basu & Kumar, 2002; Smith & Fingar, 2003; Sayal, Casati, Dayal, & Shan, 2002; Hollingsworth, 2004). BPMS, e.g., Intalio's N3 (Intalio, 2005), are distinct from ERP systems; i.e., business process management is only one component in some more sophisticated ERP systems. One example of this is SAP's Netweaver, which is *only part* of its larger ERP product offer (SAP, 2005). BPMS are significant developments of Workflow Management Systems (WFMS) with a more developed process design, diagnosis, and redesign functionality (Aalst et al., 2003). Hollingsworth describes BPMS as supporting a similar process design-execution-redesign cycle via an evolution of WFMS and its convergence with Enterprise Application Integration and World Wide Web technologies (2004). Dataflow's BPMS called Gatekeeper Data Exchange uses a model in the form of the governing industry data rules to translate between information systems in different organizations and different systems in the same organization. As such it is not itself an ERP system with a vast library of standard processes options but rather it manages other system components by manipulating the flows of data between intra and inter-system components, i.e., it *manages* business processes which are enacted by other entities. This differentiates it from ERP systems, which normally span a single enterprise rather than as in this case several quasi-integrated acquisitions.

This BPMS *includes* middleware capabilities but critically *also* contains process management capabilities. Bernstein (1996) defines middleware as "middleware services and/or frameworks" and a middleware service as "a general purpose service that sits between platforms and applications" (p. 89). The objectives of a business process management system, and of process modeling, are to facilitate human understanding and communication, to support process improvement, to support process management, to automate process guidance and to automate execution support (Curtis et al., 1992). Bernstein classes database management software as a type of middleware, but BPMS software also includes an internal process model for manual or automated process manipulation (Warboys, Kawalek, Robertson, & Greenwood, 1999). BPMS software is reliant on middleware for aspects of its execution but it obviously constitutes much *more* in terms of its functional scope and objectives. Smith et al point out that the reengineering of business pro-

cesses and natural business process changes create highly complex and unmanageable topologies in the "point-to-point" solutions of middleware companies (2002, p. 5). Only a process-centric approach, modeled on the *actual* business processes concerned, can remove the need for redundant and complex "layers" of higher and higher order interface and protocol combinations.

This is a further contribution of BPMS to business to business (B2B) interaction: (1) BPMS operate through the direct human or machine manipulation of process models and (2) help integrate human or machine actors that are joined by business processes. Historically, middleware has been used to facilitate B2B interaction but each interaction between different software applications running upon different hardware platforms requires a different interface and protocol combination, i.e., different middleware (Bernstein, 1996). These interface and protocol combinations have built up in layers in parallel to the hierarchies of interacting platforms, e.g., computer to computer, LAN to LAN, WAN to WAN, and so on . By focusing upon the business processes model of the actual B2B interaction BPMS bypass the layers of interface and protocol combinations, which differ by hierarchical level as well as by depending upon the interfacing party's hardware and software. This applies even more strongly to human to human interactions which are commonly less formal than technological interactions. Given an adequate model a BPMS can naturally execute across different systems and across different organizations but, unlike layers of interaction protocols, they are a direct abstraction of the user's focus of business concern rather than a 'fossilized' record of the negotiation between systems vendors.

The business process model at the heart of Dataflow Software's BPMS is a good *fit* with the reality of business in this sector because it is based upon the regulator's behavioral *standard* for electricity supply companies; the governing industry data rules in the MRA business process diagrams (see Figure 2). The regulator enforces this behavioral standard and so enforces a good fit between the behavior of the BPMS and its environment. It is this fit that enables the automation of many of Electric Co's business processes, which in turn enables it to deal effectively with the complexity of its environment. The usefulness of applying the concept of fit to businesses interactions is that it describes and explains the joining of two roles into a single system of "role components" while still preserving the role players' identities and supporting their business goals. Thus it is a *compatible* interaction. This can be contrasted with an incompatible interaction where either or both party's goals or even identities are not supported. Interaction compatibility is enforced in a one-to-many "top-down" sense as opposed to being "organically" built up in a series of one-to-one "bottom-up" negotiation processes. Interactions between the electricity suppliers in our case fit *by design* rather than by negotiation, i.e., forced interaction fit allows cost effective high volume data exchange between many agents

The regulator forces supplier-supplier interaction compatibility by defining a standard for supplier-supplier interaction, e.g., the standard includes the design of an electricity user's customer record and how and when this is exchanged between suppliers. Such records contain all the information that the new supplier needs in order to do business with the user, e.g., billing, usage, tariffs and customer requirements. The standard is represented using simple dataflow diagrams. This type of modeling notation does not provide a *natural architectural fit* with the complex marketplace of electricity companies and users. For example, it is *static* whereas the modeled subject is *dynamic*; the number of *hierarchical levels* is few in the model and infinite in the subject; and the *span* of this behavioral standard does not include organizations that support the suppliers. Dataflow Software's BPMS is a novel solution to a frequent post-merger problem because it makes used of predefined (regulated) interactions rules

and because it primarily manages inter-organizational interactions rather than intra-organizational interactions like most BPMS. We explore these three points next.

Firstly we can see that the *static* nature of the dataflow diagrams does not reflect the changing regulatory nature of the marketplace. The regulator attends to this by employing the MRA Service Company to update and publicize changes to the process standards as needed (MRASCo, 2003). In this case the UK government, via Ofgem the industry regulator, controls changes to the behavioral standard. This is in contrast to other industry standards whose definition is a *competitive* change process between organizations (Garud, Jain, & Kumaraswamy, 2002; Shapiro & Varian, 1999).

Secondly, the finite number of *hierarchical levels* in these dataflow diagrams does not reflect the infinite decomposability of a complex subject system such as the *actual* electricity marketplace of a national economy. This is true for all models, which are always abstractions of subjects. But in order for it to be a *useful* abstraction it has to abstract *salient* properties. In this case the salient properties are the descriptions of how the electricity suppliers must behave towards each other, the electricity users and the regulator from the perspective of data transferred. Modeling the non-salient properties of this system, such as the low level modeling of how they operate their businesses internally, is not required in this *interaction* standard. If we view the whole marketplace as our focal system then the standard achieves architectural fit, whilst using a only limited number of hierarchical levels by concentrating upon behavioral outcomes between high-level system elements (the market participants). The marketplace participants are natural modules so their *internal* complexities can be ignored with little reduction in the accuracy of the model.

Thirdly, the *span* of this behavioral standard does extend to specifications for organizations that support the electricity suppliers such as recruitment agencies, catering subcontractors, consultants, builders and lawyers. The behavior of the electricity suppliers is regulated but the behavior of the organizations that they depend upon to operate (in this constrained way) is not. The reason for this is again saliency. By concentrating on the behaviors of the electricity suppliers the standard leaves the management of these supporting organizations to them. These supporting organizations could be regulated, such as in a centrally planned economy, but the support organizations affect the marketplace only *through* the supply companies and as companies are natural modules this can be ignored just like internal complexities.

The Data Transfer Service (DTS) is another standard that Electric Co uses in the implementation of its acquisitive growth strategy. The DTS is an interconnectivity standard for data transfer between Electric Co and other electricity suppliers. It is an *information infrastructure* that supports data transfer between all electricity suppliers in this marketplace (Ciborra& Associates, 2001). For this reason Electric Co can also use it to connect between the legacy systems of its SME businesses. Thus the MRA is a behavioral, or business process, standard and the DTS is a interconnection technology standard.

CONCLUSION

The problem is that electricity supply companies are legally required to exchange vast quantities of customer data, which is costly. At the same time as they are under intense competitive pressures to reduce prices because of deregulation. The solution is a simplification of B2B interaction rules, which is embodied in the MRASCo model and which produces practical implications that Electric Co takes advantage of in the form of a Business Process Management System (BPMS) created by Dataflow Software.

Our theoretical argument is that human interaction on the scale of a whole industry, its consumers and its government can be standardized in *some* characteristics in order to promote flexibility in *others*, e.g., innovation-led consumer price reductions. Standardization is operationalized as a very large but unsophisticated business process model. The case phenomenon is market adjustment to deregulation and the theoretical basis of explanation is Ashby's Law of Requisite Variety applied to a network of boundedly rational actors. As a whole the electricity suppliers are *flexible* enough to reduce their prices from pre-deregulation levels, even though they are forced to interact with many different competitors using limited resources. This is because the complexity of supplier-supplier interactions is also limited by a regulatory standard and so flexibility is 'reserved' for price reductions rather than for interaction.

Models are architectures abstracted *from* a subject and standards are architectures projected *onto* a subject. The regulatory standard in our case fits even though its architecture is much simpler than that of the subject system because the subject system (the electricity marketplace participants) is legally *made* to fit it. This *reduces* requisite variety (interaction transaction costs) for all the electricity suppliers not just (Electric Co). The deregulation of the electricity marketplace can be viewed as environmental flexibility demands that can be categorized into three broad areas:

- Type flexibility — from the variety of different information types that is exchanged between suppliers;
- Structural flexibility — from the variety of other suppliers that suppliers have to connect with ;
- Volume flexibility — from the amount of information that is exchanged between suppliers.

The regulatory standard limits type flexibility requirements, because data types are standardized, and the DTS limits structural flexibility requirements because all suppliers connect via the same DTS. Even volume flexibility is limited because their service to the electricity users is standardized, so user demand aggregates, which smooths demand spikes. In this way the standard reduces requisite variety for all the electricity suppliers. For Electric Co, there are additional benefits from automating business processes whose variety is reduced to the extent that they can be fully *described* by a business process model that is based upon the business process standard itself.

We have shown that the case phenomena are linked to our conceptual framework as follows: (a) Standardization is used to explain the savings to electricity suppliers by following a common business process interaction model; and (b) The concept of system architecture from System Theory is used in conjunction with the concept of architectural fit from Design Theory to explain the prerequisites of such a model, i.e., dynamic, level and span fit. Theoretically we can see that this use of a whole industry interaction model works because the Requisite Variety of the sector's inter-organizational business processes is limited by legislation to those behaviors contained in the model. This allows Boundedly Rational electricity suppliers to concentrate their limited flexibility upon a finite subset of all competitor and consumer behaviors. Thus electricity suppliers are left with enough information processing capacity to reduce prices via innovation as well as deal with a very high consumer churn rate.

The most important benefit to Electric Co, from using these information systems, is achieving *structural* flexibility in compliance with industry regulations. These systems have also enabled Electric Co to grow its business and handle higher volumes of customer information; whether new customers have been won through competition with rivals or acquisition of competitors.

This paper draws upon multiple disciplines to make several theoretical and management contributions:

- it documents the changing environment of the UK electricity industry and the challenges facing an electricity supply company in terms of information management;
- it introduces, illustrates and explains a simple but widely applicable type-structural-volume flexibility model for examining business-to-business flexibility issues in e-commerce;
- it describes and explains an application of theoretical process modeling together with actual IT applications to manage business processes that cross between separate and newly merged organizations. This demonstrates an implementation of model-driven process reconfiguration that is supported by operationally integrating different software application packages.

We have used a parsimonious framework based on constructs from strategy, business process modeling and IT systems architecture, to explain an industry phenomenon of price reductions *at the same time* as increasing interaction complexity. We have also examined the implications of this in the form of Electric Co's strategic business and strategic IT responses to deregulation; and demonstrated the interrelationships between Electric Co's business strategy of growth by acquisition, its complex regulatory environment and its use of a business process management system to implement its operational systems. The high level strategy and the complexity of the operational requirements are clearly related to each other through the business process linkage.

The limitations of our approach are in its focus upon one industry in one country and in the enforcement of the business process model. Firstly this implies a limit upon generalization; a possible restriction upon the application of our model for examining business-to-business flexibility to this industry only. However, we can generalise to theory and abstract useful and insightful properties, as explained by Klein and Myers (1999). This is dependent upon the quality of our reasoning rather than purely on how representative our chosen case is. In fact our reasoning, linking interaction rules to theory from the domains of Economics, Cybernetics and Design, implies that our findings could be generalized to other B2B interactions (and, possibly, complexity management as a whole) because the theoretical framework itself is generalizable. So we suggest that this model-based approach could be applied to other B2B interaction problems and interaction flexibility problems. Secondly, the regulatory enforcement of the MRASCo model removes from the electricity suppliers any choice in how to interact other than to leave the industry. Thus we can make no general comment upon how to persuade many companies to follow a common interaction framework.

Chapter 4.7
IT and Software Industry in Vietnam

Yuko Iwasaki
Yokkaichi University, Japan

ABSTRACT

Vietnam has been advancing toward a market economy since 1986. Industrialization has progressed with a high rate of growth. One of the factors of the economic growth of Vietnam has been FDI. Japanese companies are among those that have a strong interest in Vietnam. Japanese companies are recently taking note of Vietnam's IT and software industries. Now, however, interest is increasing in offshoring as a means for developing in this sector.

INTRODUCTION

Vietnam has been advancing toward a market economy since 1986. After the Asian currency crisis in 1997, foreign direct investment (FDI) decreased and the growth rate slowed down, but since then, the country has followed a trend of recovery and industrialization has progressed with a high rate of growth.

One of the factors of the economic growth of Vietnam has been FDI. Japanese companies are among those that have a strong interest in Vietnam.

Up until now, the manufacturing industry has been at the center of Japanese companies' investment in Vietnam. However, Japanese companies are recently taking note of Vietnam's IT and software industries. Now, interest is increasing in offshoring as a means for developing in this sector.

In this chapter, the Vietnamese IT and software industries are surveyed, and the relations between Japan and Vietnam that have led to offshoring are considered.

RECENT ECONOMIC DEVELOPMENT

Since its adoption of the Doi Moi policy in 1986, Vietnam has promoted a market economy while also maintaining a socialist system. Due to the effort of the Doi Moi policy, FDI increased up to the first half of the 1990s, and high growth was recorded. However, after the Asian currency crisis of 1997, FDI decreased again, and the growth rate became slow. Since then, the present tendency has been maintained and the growth rate in 2005 showed a high 8.4% rate of growth with the progress of industrialization. Domestic demand was strong, and exports also remained strong.

While the manufacturing and service sectors expanded, the share of agriculture in the economy continued to decline (although it is still a major sector in terms of employment). Exports of electric goods continued to drive growth. Good performance was recorded.

FDI has been one of the factors of economic growth since 2000. Recently, with the increasing risks posed by the worsening business environment in China, Vietnam, with its low labor costs and stable political climate, is highly appreciated by investors anxious to spread their risks. Investment is increasing mainly in the manufacturing industry. Major investors are Japanese companies related to computers, electrical parts, automobile parts, motorbikes, and printers. Also, the Vietnamese government has improved businesses conditions for foreign firms.

Vietnam enjoys an especially high estimate among Japanese companies, whose direct investment in the country is increasing. In a medium-term survey conducted by the Japan Bank for International Cooperation (JBIC, 2005), Vietnam was ranked fourth in the world as a promising site for enterprise development (in approximately the next 3 years). For the longer term (approximately 10 years), it was ranked third by Japanese companies (Table 1).

Table 1. Promising countries and regions for overseas business operations over the medium and long terms (Source: JBIC, 2005)

Rank	Medium Term (next 3 years or so)	Long Term (next 10 years or so)
1	China	China
2	India	India
3	Thailand	**Vietnam**
4	**Vietnam**	Russia
5	U.S.A.	Thailand
6	Russia	U.S.A.
7	South Korea	Brazil
8	Indonesia	Indonesia
9	Brazil	South Korea
10	Taiwan	Malaysia

Among the reasons given for this were the cheap labor force, the country's attractiveness as a catcher for the risk, and its outstanding human resources. On the other hand, problems still to overcome include the insufficient infrastructure and the inadequacies and lack of transparency in the legal system.

As for its external economic relations, Vietnam participates in such organizations of regional integration as the Association of Southeast Asian Nations (ASEAN), the ASEAN Free Trade Area (AFTA), and the Asia Pacific Economic Cooperation (APEC). Its affiliation with the World Trade Organization (WTO) is expected to come about in 2006. Once Vietnam is affiliated with WTO, trade liberalization and the opening of the domestic market to foreign companies will be pursued.

In Vietnam, state-owned enterprises have so far borne an important role in achieving national prosperity through industrial development. However, with the current trend toward trade liberalization seen in economic globalization, the affiliation with WTO, and so on, competition with other countries has become very severe. For Vietnam, it is now vital to press on with the reform of state enterprises and to strengthen its competitiveness in the international market.

THE LEVEL OF IT IN VIETNAM

Vietnam is behind in its IT progress by any world standard. For example, in *The 2006 E-Readiness Rankings* (Economist Intelligence Unit), which investigated the diffusion of IT and the state of the fulfillment of businesses based on digital environments in countries around the world, Vietnam is placed at the very low level of 15th out of the 16 Asian nations surveyed, and 66th among 68 nations worldwide. (In 2005, it was ranked 15th out of 16 Asian nations and 61st among 65 nations worldwide.) This is a report that summarizes statistics on the diffusion of PCs (personal computers) and the Internet, the use of IT by firms and consumers, the digital response level of legal facilities and educational organizations, and so forth in various countries.

However, the diffusion of main and cellular phones and the Internet is now picking up in pace. Table 2 gives the diffusion of phones, the Internet, and PCs in Vietnam and other Asian countries. The data show the IT diffusion on an upward trend for Asian countries. In Vietnam, the diffusion of main phone lines was 18.8% and that of mobile phones was 9.54% (in 2005). The Internet user data of Vietnam and China was behind ASEAN4 countries in 2000, but are picking up. Vietnamese IT infrastructures have improved rapidly, especially for main phones and the Internet. However, most Internet users are concentrated in Hanoi and Ho Chi Minh City (approximately 70%). The Ministry of Posts and Telecomatics continues to lower charges for Internet and telecommunications services to expand the number of Internet users.

IT DEVELOPMENT IN ASIA

Asian countries have played an important and active role in IT development, especially in the PC industry. The newly industrialized economies (NIEs) and ASEAN countries showed rapid growth in IT manufacturing and trading since 1980s. These economies have made significant contributions to the global supply of IT products and components. As products matured, their production was relocated to low-cost areas.

During the last 10 years, China and India have joined in IT development. China has become a major production hub for IT products, and now the IT software industry has developed in both India and China. China's software exports have expanded rapidly. In 2005, China's software exports were valued at $3.6 billion, up from $7 million in 2001. Major export partners are Japan (approximately 60%) and the Unites States and Europe (20%).

Table 2. IT indicators in Vietnam and Asian countries (Source: International Telecommunication Union [ITU])

	Main Telephone Lines per 100 Inhabitants		**Cellular Mobile Subscribers per 100 Inhabitants**	
	2000	2005	2000	2005
Vietnam	3.23	18.81	1.00	9.54
China	11.18	26.63	0.35	29.90
India	3.20	4.51	6.58	8.16
Asia	9.73	15.77	6.63	23.22

	Internet Users per 100 Inhabitants		**PCs per 100 Inhabitants**	
	2000	2005	2000	2005
Vietnam	0.25	12.72	0.76	1.26
China	1.74	8.44	1.59	4.08
India	0.25	5.44	0.76	1.54
Asia	3.10	9.78	3.24	6.51

	Main Telephone Lines per 100 Inhabitants		**Cellular Mobile Subscribers per 100 Inhabitants**	
ASEAN4	2000	2005	2000	2005
Indonesia	3.23	5.73	1.78	21.06
Malaysia	19.92	16.79	22.01	75.17
Philippines	4.00	4.16	8.44	39.5
Thailand	9.10	10.95	4.97	42.98

	Internet Users per 100 Inhabitants		**PCs per 100 Inhabitants**	
ASEAN4	2000	2005	2000	2005
Indonesia	0.92	7.18	1.02	1.36
Malaysia	21.39	42.37	9.45	19.16
Philippines	2.01	5.32	1.93	4.46
Thailand	3.74	11.03	2.79	5.58

India is now a major IT software producer and exporter in the world. IT development in India has differed from that in the other Asian countries. Highly trained scientific and technical personnel from India have been migrating to the United States since the 1960s, and many of them were engaged in the development of computers and the communications industry. The high-level skills of India supplied qualified personnel to do jobs on site (in the United States) at first. After that, major IT producers set up subsidiary software centers in India (Braum, 2001).

As mentioned, India has highly skilled IT workers, and the business form of India is converting from that of onshore to offshore. While operating onshore means doing business in the customer's country (for example, in the United States or Europe), offshoring means producing software in India by Indian personnel. Lower prices and high-level skills have made the Indian software industry very competitive.

THE MARKET SCALE OF THE VIETNAMESE IT INDUSTRY

The market volume of the IT industry in Vietnam in 2005 was $828 million ($630 million in hardware and $190 million in software), an increase of 20.9% compared with the year before. In 1996, the market had only been worth $150 million, rising to $300 million in 2000 (Table 3).

IT-RELATED POLICY

The 2005 Plan for IT Use and Development was announced as a national policy in 2001. This plan proposed the following basic targets in order to bring the country's IT level up to the global standard by 2005:

- The diffusion of IT across the whole of Vietnam.
- 4 to 5% of the population as Internet users.
- An annual growth rate of 20 to 25% in the IT industry.
- The training of 50,000 IT specialists.

The putting in place of a telecom infrastructure was achieved ahead of the target. However, the training of competent personnel fell short of the target, not going above 20,000 employees. IT specialists are in short supply in Vietnam.

The announcement followed in 2005 of the Development Strategy for Information Communication Technology up to 2010 and of the Policy Plan up to 2020. This strategy and plan will serve as the foundation of Vietnam's future IT policy. In them, the most effective tool for national information development and modernization, and the importance of utilizing IT in economics and industry were brought out (e-citizenship, e-government, e-enterprises, e-transactions, and e-commerce). Moreover, high priority was given to the nurturing of an IT industry, especially the software and information-content industries, as a means of encouraging the creation and development of an information society. The policy also attaches importance to the laying of an IT infrastructure and the training of component specialists. The targets up to 2010 and 2015 for the promotion of IT use in economics and industry are as follows:

- By 2010, the IT industry will be promoted to the country's top industry, with a year-to-year growth rate of 20 to 25% and gross annual earnings of $6 to 7 billion.
- Through promotion of the IT infrastructure, the target for 2010 is to ensure 30 to 42 telephones per 100 people, 8 to 12 Internet service accounts (30% of them broadband), an Internet diffusion rate of 25 to 30%, and personal computer ownership of 10 per 100 people.

Table 3. Trends of the market scale (millions USD; Source: Ho Chi Minh City Computer Association, 2006)

Year	Total	Hardware	Software
2000	300	250	50
2001	340	250	60
2002	400	325	75
2003	515	410	105
2004	685	545	140
2005	828	630	178

- By 2015, the diffusion of fixed telephones will be lowered to 20 per 100 people, while that of cellular phones will be raised to 30.

To ensure that the targets for 2010 and 2015 are attained, a range of definite measures have been specified:

- Diffusion of IT knowledge.
- Promotion of practical uses for IT.
- Reinforcement of state's IT administration capacity.
- Ensuring of attractive conditions for foreign capital.
- Increasing of quantity and quality of IT labor.
- Strengthening of research and development system.
- Enhancement of legal environment in support of IT.
- Domestic and international cooperation.
- Integration with international IT market, especially for software and contents.

THE SOFTWARE INDUSTRY AND OFFSHORING

Within the industry, one of the fields that the government sees as very important is the software industry. The value of the software industry market in Vietnam in 2004 was $140 million. This marked a spectacular increase from $75million in 2002 and $105 million in 2003. 25% of the profits in the software industry are obtained from exports overseas. Vietnam started exports of software in 1997.

OFFSHORING

Behind the recent market expansion in Vietnam, one factor that can be mentioned is an increase in outsourcing (offshoring) for overseas products. Offshoring is the entrusting of part of a system development to a firm in another country (Figure 1). It has the advantage when using cheap and plentiful workforces.

Inspired by the example of India, which achieved rapid growth through offshoring from America and Europe, moves have been made by Vietnam to make use of its trained labor force to build up a software industry. Firms have also increased to about 600 by the end of 2005. Looking at them regionally, about 30% of these firms are located in Ho Chi Minh City or Hanoi. Corporate competition is intensifying with the increase in the number of companies. The following are some examples of the main software companies.

- FTP Software (Hanoi)
- TMA Software (Ho Chi Minh City
- Paragon Solutions Vietnam (PSV; Ho Chi Minh City)
- Silk Road (Ho Chi Minh City)
- Global Cybersoft (Ho Chi Minh City)

These companies have earned a name for reliable quality by acquiring CMM (capability maturity model) and CMMI (capability maturity model integration) under a quality-control stan-

Figure 1. An example of offshoring (Source: Ministry of Economy, Trade, and Industry [MEIT], 2006)

dard code that objectively shows their capacity in developing software. Vietnam enjoys the following advantages in its software industry. First, its labor costs are cheap (about 60 to 70% of the cost in China), and the proportion of young people in the population is high. Second, the will to study is high and levels are excellent in the scientific and math fields. The potential for competitiveness in the software industry is ample.

However, there are few software companies of a scale exceeding 100 employees, and a lot of small and medium-sized enterprises exist. This poses the problem of a shortage of outstanding human resources in the industry as a whole. The training of competent personnel will be a challenge for the future. The government is setting preferential measures of taxation for the promotion of the software industry.

The market value of offshoring in 2005 was $70 million. In 2002 the market had only been worth $20 million.

OFFSHORING BY JAPANESE COMPANIES

Offshoring by Japanese companies can be seen to have increased rapidly in the past several years. The scale of Japanese offshoring, which was ¥20 billion in 2002, rose to ¥48.9 billion and then ¥52.7 billion in 2004 (Table 4). The background cause for this increase is that while the scale of software development is growing, the shortage of trained labor in Japan is serious, and in order to cope with shortening development times and the need for cost cutting, firms are therefore seeking a cheep and abundant labor force overseas.

With their cheap and plentiful workforces, India and China both make attractive offshoring sites, but for firms in Japan, China is the country most usually chosen on account of the geographical nearness and the fact there is a high level of aptitude for mastering Japanese.

Table 4. The scale of offshoring by Japanese companies (millions of Yen; Source: Japan Information Technology Services Industry Association [JISA], 2005)

	2004	Share (%)	Compared with 2003 (%)
China	33,241	63.1	+26.5
U.S.A.	5,147	9.8	+3.2
India	4,255	8.1	-32.6
Australia	3,133	5.9	+19.3
U.K.	2,126	4.0	+16.4
Philippines	2,117	4.0	-15.1
South Korea	1,415	2.7	-24.4
France	548	1.0	-34.3
Canada	262	0.5	-57.5
Vietnam	216	0.4	+620.0
Others	237	0.4	-78.1
Total	52,697	100.0	+28.1

The technical levels of companies in China and India are improving with the increase in the offshoring from Japan and the West. Points particularly attended to by Japanese companies when choosing an offshoring partner are the quality and quantity of technical workers available, whether Japanese can be understood, and whether the dealing prices are right. Although the volume of business with Vietnam is still small, Japanese companies are considering it as a new offshoring site. The scale of offshoring in Vietnam in 2004 showed a rapid seven-fold increase compared with the year before. Behind this growth lies the fact that the Vietnamese software industry recognizes Japan as an important market and has expanded its business in that direction. In 2005, the software association of Vietnam (Vietnam Software Association, VINASA) announced its 5-year plan for the development of the software industry (2006 to 2010). This plan sets a target of $1 billion in annual sales for software by 2010, with $400 million heading for Japan. Japanese companies are keenly observing Vietnam as a country where they can rely on finding excellently skilled workers at low cost.

As we have seen, Vietnam's purpose is changing to a market economy and introducing foreign capital to promote the IT industry with the aim of rapidly catching up with its nearby neighbors. With affiliation with WTO scheduled for 2006, this trend toward open markets and economic reform will progress further. Furthermore, there will also no doubt be improvement in the investment climate for foreign companies. For relations between Japan and Vietnam with regard to IT, while it is important to continue with the economic relations built up in the past through official development assistance (ODA) and FDI, it is also especially vital that the Japanese government and private firms should cooperate in the training of Vietnamese personnel.

CONCLUSION

For the ordering company, offshoring has merits, such as a reduction in development costs and the shortening of development times. On the other hand, for the country receiving orders, the government and private firms put more importance on policies for the fostering of information technology industries, both for the sake of economic growth and secure employment, and also for the furtherance of the information society. The proof of the effectiveness of this approach has already been seen in India.

In offshoring activities of Japanese companies, the values recognized with regard to China and India are well-established, and the time is now ripe to move on to the next stage. As a new location for offshoring, firms are taking close note of Vietnam, although many challenges exist in the present development of Vietnamese enterprises. One of the problems is a shortage of outstanding human resources in the industry as a whole. The training of competent personnel will be a challenge for the future. This will create a pool of highly skilled personnel that will be a foundation for the industry.

For Japan and Vietnam, which is still a developing country, it is important on both sides to work for an expansion of business by building a partnership for such aims as the training of IT personnel.

ABSTRACT

The use of Semantic Web technologies in e-business is hampered by the lack of large, publicly-available sources of semantically-demarcated data. In this chapter, we present a number of intermediate steps on the road toward the Semantic Web. Specifically, we discuss how Semantic Web technologies can be adapted as the centerpiece of an agent-based travel support system. First, we present a complete description of the system under development. Second, we introduce ontologies developed for, and utilized in, our system. Finally, we discuss and illustrate through examples how ontologically demarcated data collected in our system is personalized for individual users.

In particular, we show how the proposed ontologies can be used to create, manage, and deploy functional user profiles.

INTRODUCTION

Let us consider a business traveler who is about to leave Tulsa, Oklahoma for San Diego, California. Let us say that she went there many times in the past, but this trip is rather unexpected and she does not have time to arrange travel details. She just got a ticket from her boss' secretary and has 45 minutes to pack and catch a taxi to leave for the airport. Obviously, she could make all local arrangements after arrival, but this could mean that her personal preferences could not be observed and also that she would have to spend time at the airport in a rather unpleasant area where the courtesy phones are located or spend a long time talking on the cell phone (and listen to call-waiting music) to find a place to stay, and so forth. Yes, one could assume that she could ask her secretary to make arrangements, but this would assume that she does have a secretary (which is now a rarity in the cost-cutting corporate world) and that her secretary knows her personal preferences well.

Let us now consider another scenario. Here, a father is planning a family vacation. He is not sure where they would like to go, so he spends countless hours on the Web, going over zillions of pages, out of which only few match his preferences. Let us note here, that while he will simply skip pages about the beauty of Ozark Mountains—as his family does not like mountains, but he will "have to" go over a number of pages describing beach resorts. While doing this he is going to find out that many possible locations are too expensive, while others do not have kitchenettes that they like to have—as their daughter has special dietary requirements, and they prefer to cook most of their vacation meals themselves.

What do we learn from these two scenarios? In the first case, we have a traveler who, because of her unexpected travel, cannot engage in e-business as she does not have enough time to do it, while she could definitely utilize it. Yes, when in the near future airplanes will have Internet access, she will possibly be able to make the proper arrangements while traveling, but this is likely going to be an expensive proposition. Furthermore, the situation when a traveler is spending time on the plane to make travel arrangements is extremely similar to the second scenario, where the user is confronted with copious volumes of data within which he has to find few pertinent gems.

What is needed in both cases is the creation of a travel support system that would work as follows. In the first case, it would know personal preferences of the traveler and on their basis, while she is flying and preparing for the unexpected business meeting, would arrange accommodations in one of her preferred hotels, make a dinner reservation in one of her favorite restaurants, and negotiate a "special appetizer promotion" (knowing that she loves the shrimp cocktail that is offered there). Upon her arrival in San Diego, results would be displayed on her personal digital assistant (PDA) (or a smart cell phone) and she could go directly to the taxi or to her preferred car rental company. In the second case, the travel support system would act as an interactive advisor—mimicking the work of a travel agent—and would help select a travel destination by removing from considerations locations and accommodations that do not fit the user profile and personalizing content delivery further—by prioritizing information to be displayed and delivering one that would be predicted to be most pertinent first. Both these scenarios would represent an ideal way in which e-business should be conducted.

The aim of this chapter is to propose a system that, when mature, should be able to support the needs of travelers in exactly the previously described way. We will also argue that, and illustrate how, Semantic Web technologies combined with

software agents should be used in the proposed system. We proceed as follows. In the next section we briefly discuss the current state of the art in agent systems, Semantic Web, and agent-based travel support systems. We follow with a description of the proposed system illustrated by unified modeling language (UML) diagrams of its most important functionalities. We then discuss how to work with ontologically demarcated data in the world where such resources are practically nonexistent. Finally, we show how resource description framework (RDF) demarcated data is to be used to support personal information delivery. We conclude with a description of the current state of implementation and plans for further development of the system.

BACKGROUND

There are two main themes that permeate the scenarios and the proposed solution presented previously. These are: *information overload* and need for *content personalization*. One of the seminal papers that addresses exactly these two problems was published by Maes (1994). There she suggested that it will be intelligent software agents that will solve the problem of information overload. In a way it can be claimed that it is that paper that grounded in computer science the notion of a *personal* software *agent* that acts on behalf of its user and autonomously works to deliver desired personalized services. This notion is particularly well matching with travel support, where for years human travel agents played exactly the role that *personal agents* (PAs) are expected to mimic. Unfortunately, as it can be seen, the notion of intelligent personal agent, even though extremely appealing, does not seem to materialize (while its originator has moved away from agent research into a more appealing area of ambient computing).

What can be the reason for this lack of development of intelligent personal agents? One of them seems to be the truly overwhelming amount of available information that is stored mostly in a human consumable form (demarcated using hypertext markup language (HTML) to make it look "appealing" to the viewer). Even a more recent move toward the extensible markup language (XML) as the demarcation language will not solve this problem as XML is not expressive enough. However, a possible solution to this problem has been suggested, in the form of semantic demarcation of resources or, more generally, the Semantic Web (Berners-Lee, Hendler, & Lassila, 2001; Fensel 2001). Here it is claimed that when properly applied, demarcation languages like RDF (Manola & Miller, 2005), Web ontology language (OWL) (McGuinness & Van Harmelen, 2005) or Darpa agent markup language (DAML) (DAML, 2005) will turn human-enjoyable Internet pages into machine-consumable data repositories. While there are those who question the validity of optimistic claims associated with the Semantic Web (M. Orłowska, personal communication, April 2005; A. Zaslavsky, personal communcation, August 2004) and see in it only as a new incarnation of an old problem of unification of information stored in heterogeneous databases—a problem that still remains without general solution—we are not interested in this discussion. For the purpose of this chapter we assume that the Semantic Web can deliver on its promises and focus on how to apply it in our context.

In our work we follow two additional sources of inspiration. First, it has been convincingly argued that the Semantic Web and software agents are highly interdependent and should work very well together to deliver services needed by the user (Hendler, 1999, 2001). Second, we follow the positive program put forward in the highly critical work of Nwana and Ndumu (1999). In this context we see two ways of proceeding for those interested in agent systems (and the Semantic Web). One can wait for all the necessary tools and technologies to be ready to start developing and implementing agent systems (utilize ontological

demarcation of resources), or one can start to do it now (using available, however imperfect, technologies and tools)—among others, to help develop a new generation of improved tools and technologies. In our work we follow Nwana and Ndumu in believing that the latter approach is the right one. Therefore, we *do not* engage in the discussion *if* concept of a software agent is anything more but a new name for old ideas; *if* agents should be used in a travel support system; *if* agent mobility is or is not important, *if* JADE (2005), Jena (2005), and Raccoon (2005) are the best technologies to be used, and so forth.. Our goal is to use what we consider top-of-the-line technologies and approaches to develop and implement a complete skeleton of an agent-based travel support system that will utilize semantically demarcated data as its centerpiece.

Here an additional methodological comment is in order. As it was discussed in Gilbert et al. (2004); Harrington et al. (2003); and Wright, Gordon, Paprzycki, Williams, and Harrington (2003) there exists two distinct ways of managing information in an *infomediary* (Galant, Jakubczye, & Paprzycki, 2002) system like the one discussed here (with possible intermediate solutions). Information can be *indexed*—where only references to the actual information available in repositories residing outside of "the system" are stored. Or, information can be *gathered*—where actual content is brought to the central repository. In the original design of the travel support system (Angryk, Galant, Gordon, & Paprzycki, 2002; Gilbert et al., 2004; Harrington et al., 2003; Wright et al., 2003) we planned to follow the indexing path, which is more philosophically aligned with the main ideas behind the Semantic Web. It can be said metaphorically, that in the Semantic Web *everything is a resource* that is located somewhere within the Web and can be found through a generalized resource locator. In this case indexing simply links together resources of interest. Unfortunately, the current state of the Semantic Web is such that there are practically no resources that systems like ours could use. To be able to develop and implement a working system "now" we have decided to gather information. More precisely, in the central repository we will store sets of RDF triples (*tokens*) that will represent travel objects (instances of ontologies). We will also develop an agent-based data collection system that will transform Web-available information into such tokens stored in the system.

Obviously, our work is not the only one in the field of applying agents and ontologies to travel support, however, while we follow many predecessors, we have noticed that most of them have ended on a road leading nowhere. In our survey conducted in 2001 we have found a number of Web sites of agent-based travel support system projects that never made it beyond the initial stages of conceptualization (for more details see Paprzycki, Angryk, et al., 2001; Paprzycki, Kalczyński, Fiedorowicz, Abramowicz, & Cobb, 2001 and references presented there). The situation did not change much since. A typical example of the state of the art in the area is the European Union (EU) funded, CRUMPET project. During its funded existence (between approximately 1999 and 2003) it resulted in a number of publications and apparent demonstrations, but currently its original Web site is gone and it is really difficult to assess which of its promises have been truly delivered on.

Summarizing, there exists a large number of sources of inspiration for our work, but we proceed with development of a system that constitutes a rather unique combination of agents and the Semantic Web.

System Description

Before we proceed describing the system let us stress that what we describe in this chapter is the core of a much larger system that is in various stages of development. In selecting the material to be presented we have decided first, to focus on the parts under development that are finished or almost

finished. This means that a number of interesting agents that are to exist in the system in the future and that were proposed and discussed in Angryk et al. (2002); Galant, Gordon, and Paprzycki (2002b); and Gordon and Paprzycki (2005) will be omitted. Furthermore, we concentrate our attention on these parts of the system that are most pertinent to the subject area of this book (Semantic Web and e-business) while practically omitting issues like, for instance, agent-world communication (addressed in Galant, Gordon, & Paprzycki, 2002a; Kaczmarek, Gordon, Paprzycki, & Gawinecki, 2005) and others.

In Figures 1 and 2 we present two distinct top level views on the system. The first one depicts basic "interactions" occurring in the system as well as its main subsystems. It also clearly places the repository of semantically demarcated data in the center of the system. More precisely, starting from right to left, we can see that *content* has been divided into (a) *verified content providers* (*VCP*) that represent sources of trusted content that are consistently available and format of which is changing rarely and not "without a notice" and (b) *other sources* that represents all of the remaining available content. Interested readers can find more information about this distinction in Angryk et al. (2002) and Gordon and Paprzycki (2005).

While the dream of the Semantic Web is a beautiful one indeed, currently (outside of a multitude of academic research projects) it is almost impossible to find within the Web large sources of clean explicitly ontologically demarcated content (in particular, travel related content). This being the case, it is extremely difficult to find actual data that can be used (e.g., for testing purposes) in a system like the one we are developing. Obviously, we could use some of the existing text processing techniques to classify pages as relevant to various travel topics, but this is not what we attempt to achieve here. Therefore, we will, for the time being, omit the area denoted as *other sources* that contains mostly weakly structured and highly volatile data (see also Nwana & Ndumu, 1999, for an interesting discussion of perils of dealing with dynamically changing data sources). This area will become a source of useful information when the ideas of the Semantic Web and ontological content demarcation become widespread.

Since we assume that VCPs carry content that is structured and rarely changes its format (e.g., the Web site of Hilton hotels), it is possible

Figure 1. Top level view of the system

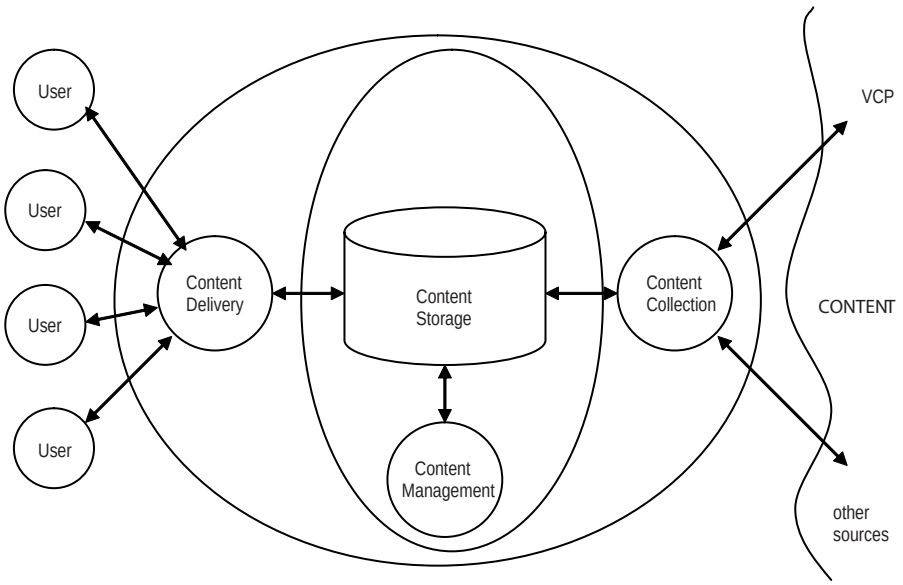

Figure 2. Top level use case diagram

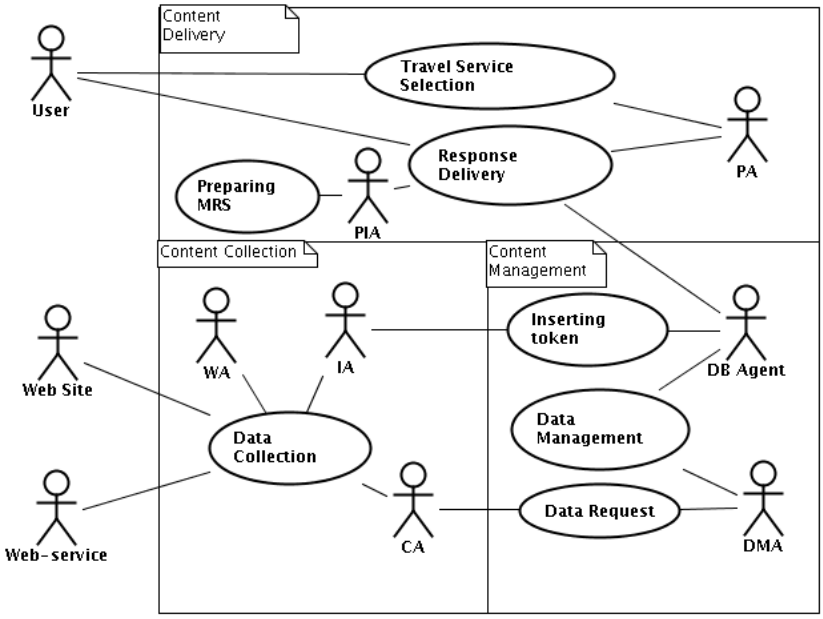


to extract from them information that can be transformed into a form that is to be stored in our system. More precisely, in our system, we store information about travel objects in the form of instances of ontologies, persisted in a Jena (2005) repository. To be able to do this, in the *content collection subsystem* we use *wrapper agents* (*WA*) designed to interface with specific Web sites and collect information available there (see also Figure 2). Note that currently we have no choice but to create each of the WAs manually. However, in the future, as semantic demarcation becomes standard, the only operation required to adjust our system will be to replace our current "static WAs" with "ontological WAs." This is one of the important strengths of agent-based system design, pointed to in Jennings, 2001 and Wooldridge, 2002.

As mentioned, the *content storage* is the Jena repository, which was designed to persist RDF triples (RDF is our semantic demarcation approach of choice). The *content management subsystem* encompasses a number of agents (considered jointly as a *data management agent* [*DMA*]) that work to assure that users of the system have access to the best quality of data. These agents, among others deal with: time sensitive information (such as changes of programs of movie theaters), incomplete data tokens, or inconsistent information (Angryk et al., 2002; Gordon & Paprzycki, 2005).

Content delivery subsystem has two roles. First it is responsible for the format (and syntax) of interactions between users and the system. However, this aspect of the system, as well as agents responsible for it, is mostly outside of scope of this chapter (more details can be found in Galant et al., 2002a and Kaczmarek et al., 2005). Second, it is responsible for the semantics of user-system interactions. Here two agents play crucial role. First, the *personalization infrastructure agent* (*PIA*) that consists of a number of extremely simple rule-based "RDF subagents" (each one of them is a class within the PIA) that extend the

set of travel objects selected as a response to the original query to create a *maximum response set* (*MRS*) that is delivered to the PA for filtering and ordering. Second, the PA that utilizes *user profile* to filter and hierarchically organize information obtained from the PIA as the MRS. It is also the PA that is involved in gathering explicit user feedback (see section "RDF Data Utilization: Content Personalization") that is used to adjust user profile.

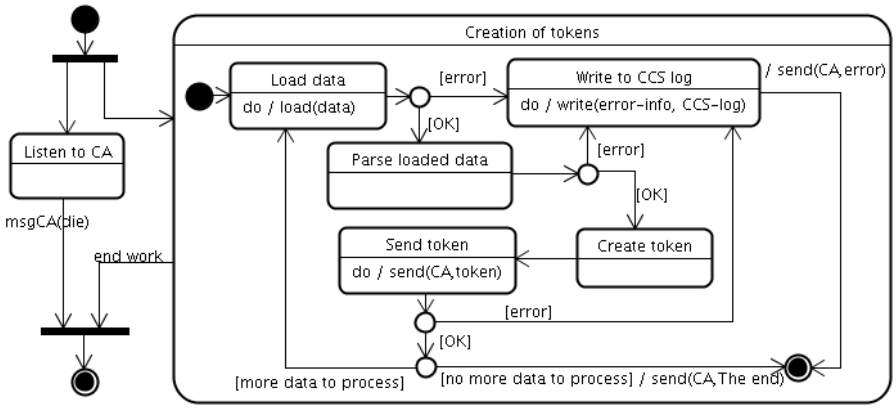
In Figure 2 we represent, in the form of a UML use case diagram, the aforementioned agents as well as other agents that are a part of the central system infrastructure. This diagram should be considered together with the system visualization found in Figure 1.

Since we had to abandon, hopefully temporarily, *other sources*, in Figure 2 we depict only Web sites and Web services that belong to the VCP category. They are sources of data for the function *Data Collection* that is serviced by WAs, *indexing agents* (*IA*), and a *coordinator agent* (*CA*). The IA communicates with the *DB agent (DBA)* when performing the *Inserting tokens* function. Separately, the CA receives data requests from the DMA. These data requests represent situations when data tokens were found to be potentially obsolete or incomplete (as a part of the *Data Management* function) and a new token has to be delivered by an appropriate WA to refresh/complete data available in the system. The DMA and the DBA are the only agents that have a direct access to the Jena database. In the content delivery subsystem we have three functions specified. The *Travel Service Selection* function is related to User(s) querying the system (information flow from the User to the central repository), while the *Response Delivery* function involves operations taking place between the time when the initial response to the query is obtained from Jena and when the final personalized response is delivered to the user (information flow from the central repository to the *User*). During this process the PIA performs the *Preparing MRS* function. Let us now discuss in some detail agents and their interactions. Before we proceed let us note that we omit a special situation when the system is initialized for the very first time and does not have any data stored in the Jena repository. While this situation requires agents started in a specific order, since it is only a one-time event it is not worthy of extra attention. We therefore assume that there is already data stored in the system and focus on interactions taking place in a working system.

The WA interfaces with Web sites, mapping XML- or HTML-demarcated data into RDF triples describing travel objects (according to the ontology used in our system [Gawinecki, Gordon, Nguyen, Paprzycki, & Szymczak, 2005; Gawinecki, Gordon, & Paprzycki, et al., 2005; Gordon, Kowalski, et al., 2005]). It is created by the CA on the basis of a *configuration file*. The configuration file may be created by the system administrator and sent to the CA as a message from the *graphical user interface (GUI) agent* or may be contained in a message from the DMA that wants to update one or more tokens. Each completed token is time stamped and priority stamped and send back to the CA. Upon completion of its work the (or in the case of an error) WA sends an appropriate message to the CA and self-destructs. A new WA with the same functionality is created by the CA whenever needed. Note that to simplify agent management we create instances of WA for each "job," even though they may produce tokens describing the same travel resource. For instance, when one WA is working on finding information about *all* Westin Hotels in Central Europe (task assigned by the system administrator), another WA may be asked to find information about Westin Hotel in Warszawa (job requested by the DMA). It is the role of the IA to assure that the most current available token is stored in the repository (see Figure 3). An UML statechart of the WA is contained in Figure 3.

CA manages all activities of the content collection subsystem. When started, it creates a certain number of IA (specified by the system

Figure 3. Statechart of the WA



administrator—*Servicing agent management request* function in Figure 4) and enters a listening state. There are six types of messages that may be received: (1) a self-destruction order received from the GUI Agent (send by the system administrator)—resulting in the CA killing all existing WAs and IAs first, and then self-destructing; (2) message from the WA that it encountered an error or that it has completed its work and will self-destruct—resulting in appropriate information being recorded; (3) message from the WA containing a token—to be inserted into the priority queue within the CA*;* (4) message from one of the IAs requesting a new token to be inserted into the repository—which results in the highest priority token being removed from the priority queue and send to the requesting IA. When the queue is empty, a message is send to the IA informing about this fact (as seen in Figure 5, IA will retry requesting token after some delay); (5) message from the DMA containing a request (in the form of a configuration file) to provide one or more tokens—resulting in creation of an appropriate WA (or a number of WAs); and, finally, (6) message from the GUI Agent ordering adjustment of the number of IAs in the system. A complete statechart of the CA is depicted in Figure 4.

IA is responsible for inserting tokens into the central repository as well as initial pre-processing of tokens to facilitate cleanness of data stored in the system. For the time being the IA performs the following simple checks: (1) time consistency of tokens to be inserted—since it is possible that multiple WAs generate tokens describing the same travel resource (see above), the IA compares time stamps of the token to be inserted with that in the repository and inserts its token only when it is newer; (2) data consistency—token to be used to update/append information has to be consistent with the token in the repository (e.g., the same hotel has to have the same address); and (3) inconsistent tokens are marked as such and they are to be deconflicted (Angryk et al., 2002). In the case when the priority queue is empty, request will be repeated after delay *T.* The statechart of the IA is represented in Figure 5 (top panel presents the overall process flow, while the bottom panel specifies processes involved in servicing tokens).

Let us now briefly describe the next three agents visible in Figure 2. The DBA represents interface between the database (in our case the Jena repository) and the agent system. It is created to separate an agent system from an "outside technology" in such a way that in case of changes in the repository all other changes will be localized to that agent, while the remaining parts of the system stay unchanged.

Figure 4. Statechart of the CA

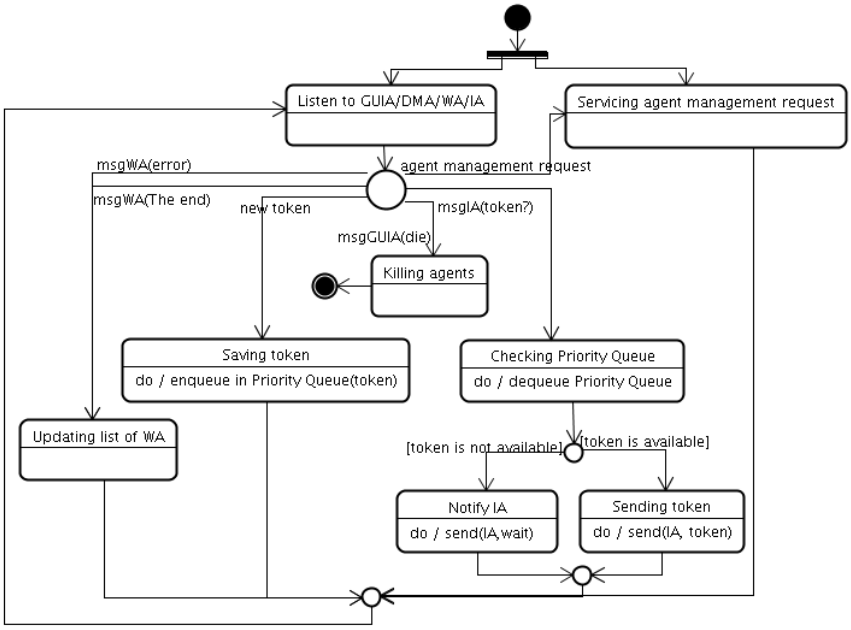


Figure 5. Statechart of the IA

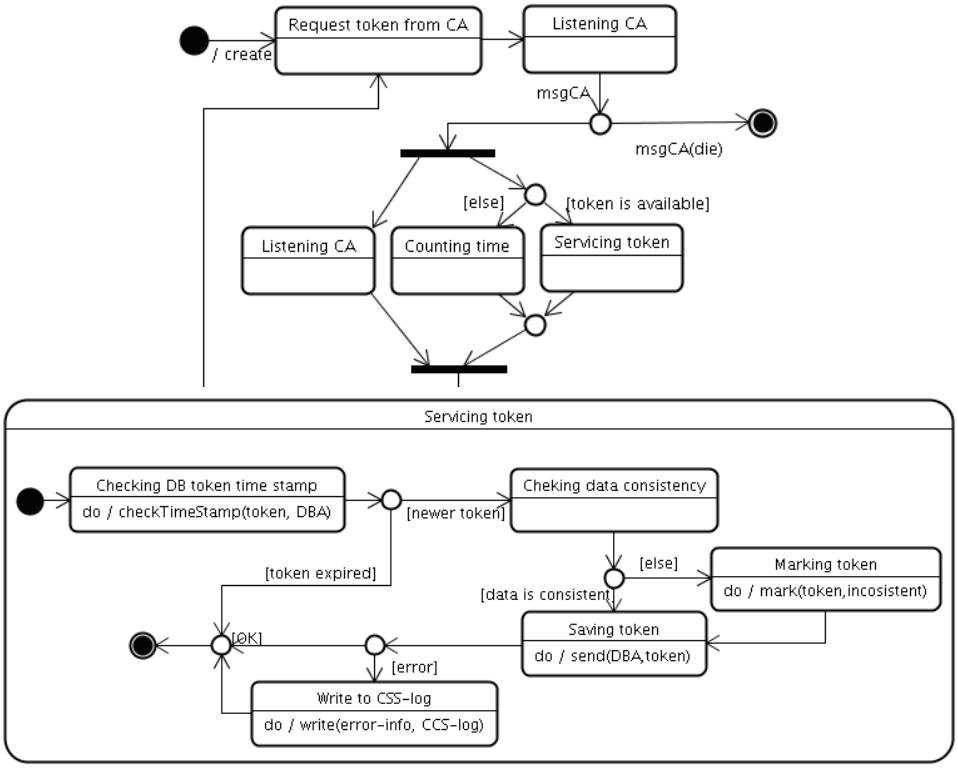
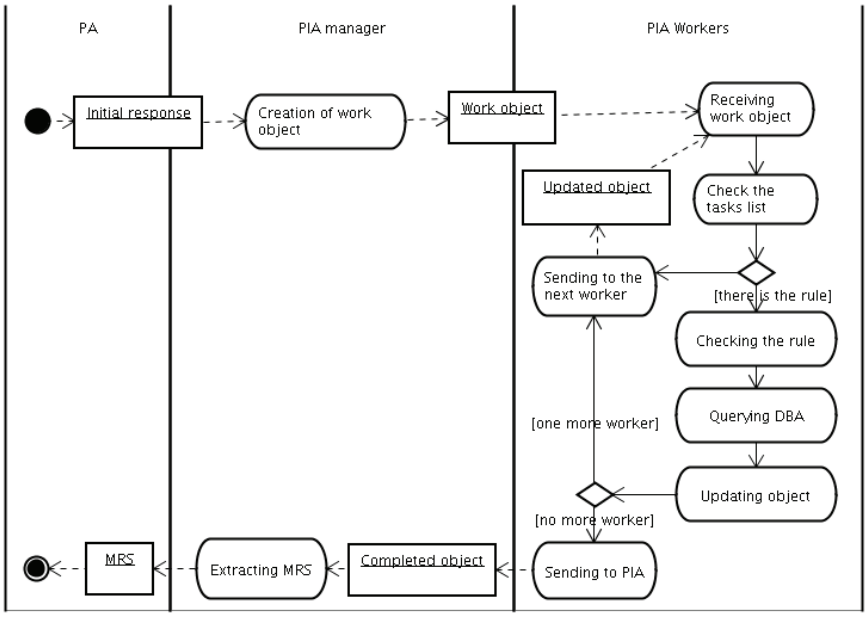


In the current system the DMA is a simple one. A number of agents of this type, responsible for different travel objects, are created upon system startup. Their role is to "traverse" the repository to find outdated and incomplete tokens and request new/additional ones to be generated to update/complete information stored in the repository. To achieve this goal DMAs generate a configuration file of an appropriate WA and send them to the CA for processing. In the future DMAs will be responsible for complete management of tokens stored in the repository to assure their completeness, consistency, and freshness.

The PIA consists of a manager and a number of "RDF subagents" (*PIA workers* in Figure 6). Each of these subagents represents one or more of simple rules of the type "Irish pub is also a pub" or "Japanese food is Oriental food." These rules are applied to the set of RDF triples returned by the initial query. Rule application involves querying the repository and is expected to expand the result set (e.g., if the user is asking for a Korean restaurant then other Oriental restaurants are likely to be included). The PIA subagents operate as a team passing the result set from one to the next (in our current implementation they are organized in a ring), and since their role is to maximize the set of responses to be delivered to the user no potential response is removed from the set. Final result of their operation is the MRS that is operated on by the PA. Action diagram of the PIA is depicted in Figure 6.

A separate PA will be created for each user and will play two roles in the content delivery subsystem. First, it is the central coordinator—for each user query it directs it from one agent to the next, constantly monitoring processing progress. Second, it utilizes user profile to filter and order responses that are to be sent to the user. More precisely, the user query, after being pre-processed and transformed into an RDQL query (see Kaczmarek et al., 2005 for more details), is being sent to the DBA. What is returned is the initial response consisting of a number of tokens that satisfy the query. This response is being redirected (by the PA) to the PIA to obtain the MRS. Then the PA utilizes the user profile to: (1) remove from the set responses that do not belong there (e.g., user

Figure 6. Action diagram of the PIA



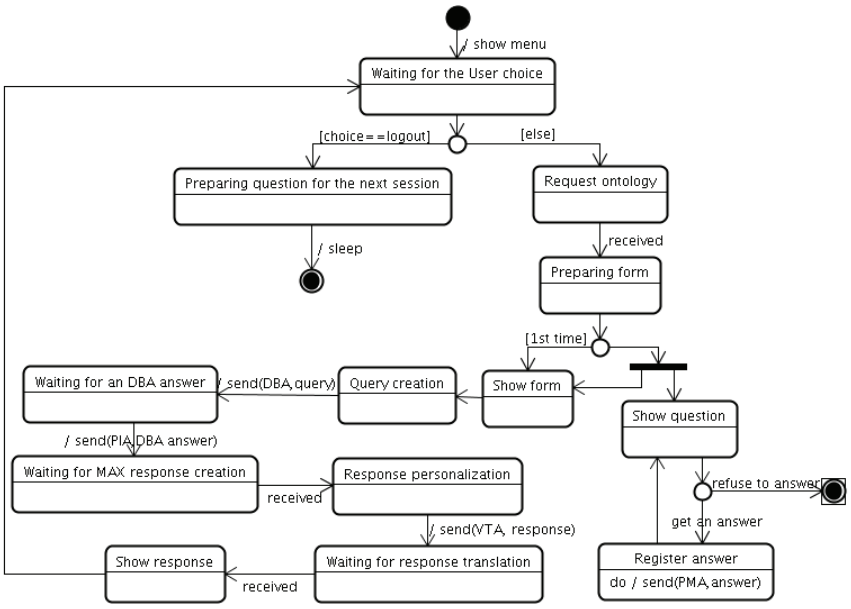
is known to be adversely inclined toward Italian food, and pizza in particular, and thus all of the Italian food serving restaurants have to be excluded); (2) order the remaining selections in such a way that those that are believed to be of most interest to the user will be displayed first (e.g., if user is known to stay in Hilton hotels, they will be displayed first). The statechart diagram of the PA is contained in Figure 7.

As we can see the PA behaves differently depending if the user is using the system for the first time or if it is a returning user. In the latter case, the PA will attempt at gathering explicit feedback related to the information delivered to the user during the previous session. This will be done through a generation of a questionnaire that will be shown to the user, who may decide to ignore it (see also Galant & Paprzycki, 2002). Obtained responses will be used to adjust the user profile. We can also see how the PA plays the role of response preparation orchestrator by always receiving responses from other agents and forwarding them to the next agent in the processing chain. We have selected this model of information processing so that "worker agents" like the DBA or the PIA know only one agent to interact with (the PA). Otherwise, an unnecessary set of dependencies would be introduced to the system making it substantially more difficult to manage (any change to one of these agents would have to be propagated to all agents that interact with it—while in our case only a single agent needs to be adjusted).

Replacing Semantic Web with a Semantic Database

As noted before, currently the Semantic Web is an attractive idea that lacks its main component—large repositories of semantically demarcated (in particular travel-related) data. This was one of the important reasons to change the design of our systems from data indexing into data gathering. As a result we are able to create our own "mini Semantic Web" (in the form of a semantic database) and store there information that in the future will allow us to extend our system beyond the basic skeleton described here, and start experimenting with its true projected functionalities—like content personalization.

Figure 7. Statechart of the PA



Let us describe how the HTML-demarcated information available on the Web is turned into semantic tokens representing travel objects in our repository. Before proceeding let us discuss briefly ontologies utilized in the system. As reported in Gawinecki, Gordon, Nguyen, et al., 2005; Gawinecki, Gordon, Paprzycki, et al., 2005; and Gordon, Kowalski, et al., 2005, while there exists a large number of attempts at designing ontologies depicting various aspects of the world, we were not able to locate a complete ontology of the most basic objects in the "world of travel" such as a *hotel* and a *restaurant*. More precisely, there exists an implicit ontology of restaurants utilized by the Chef Moz project (Chef Moz, 2005), but it cannot be used directly as a Semantic Web resource, due to the fact that data stored there is infested with bugs that make its automatic utilization impossible without pre-processing that also involves manual operations (see Gawinecki, Gordon, Paprzycki, et al., 2005 and Gordon, Kowalski, et al., 2005 for more details).

This being the case we have proceeded in two directions. First, as reported in Gawinecki, Gordon, and Paprzycki, et al. (2005) and Gordon, Kowalski, et al. (2005) we have reverse engineered the restaurant ontology underlying the Chef Moz project and cleaned data related to Polish restaurants. Separately we have proceeded with designing hotel ontology using a pragmatic approach. Our hotel ontology is to be used to represent, manipulate, and manage hotel information actually appearing within Web-based repositories (in context of travel; i.e., not hotels as landmarks, or sites of historical events). Therefore we have studied content of the 10 largest Internet travel agencies and found out that most of them describe hotels using very similar vocabulary. Therefore we used these common terms to shape our hotel ontology and the results of this process have been reported in Gawinecki, Gordon, Nguyen, et al. (2005); Gawinecki, Gordon, Paprzycki, et al. (2005); and Gordon, Kowalski, et al. (2005). As an outcome we have two fully functional, complete ontologies (of a hotel and of a restaurant) that are used to shape data stored in our Jena repository.

In this context, let us illustrate how we transform the VCP featured data into travel tokens. As an example we will utilize the Web site belonging to Hilton hotels (www.hilton.com). More precisely, let us look at some of the information that is available at the Web site of Hilton Sao Paulo Morumbi depicted in Figure 8.

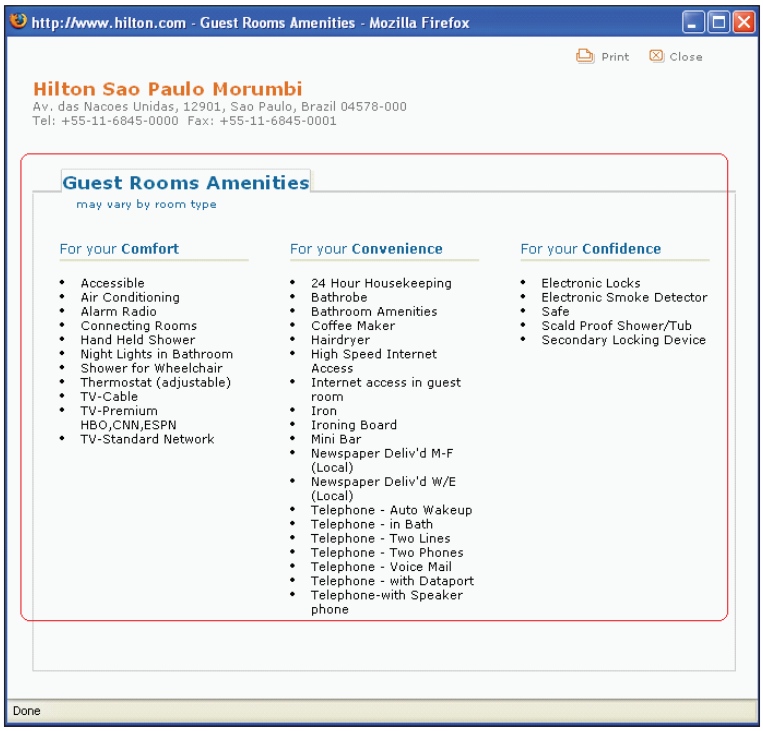
As clearly seen, from this page we can extract information such as the hotel name, address, and phone numbers. This page would also have to be interacted with, in case we planned to utilize our travel support system to make an actual reservation (which is only in very long-term plans and out of scope of this chapter). To find the remaining information defined by the hotel ontology requires traversing the Web site deeper. Therefore, for instance, the WA has to go to the page contained in Figure 9, to find information about hotel amenities.

As a result the following set of RDF triples (in XML-based notation) will be generated:

```
<rdf:Description
rdf:about="http://www.agentlab.net/travel/hotels/Hilton/
      SAOMOHI">
   <j.1:roomAmenit rdf:resource="http://.../hotel.
      rdf#AccessibleRoom"/>
   <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#AirConditioning"/>
   <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#ConnectingRooms"/>
   <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#Shower"/>
   <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#CableTelevision"/>
   <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#CNNavailable"/>
   <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#Bathrobe"/>
  <j.1:roomAmenity rdf:resource="http://.../hotel.rdf#Bathro
      omAmenities"/>
 <j.1:roomAmenity rdf:resource="http://.../hotel.rdf#Coffee_
      TeaMaker"/>
   <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#Hairdryer"/>
 <j.1:roomAmenity
      rdf:resource="http://.../hotel.rdf#HighSpeedInternetC
      onnection"/>
   <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#InternetAccess"/>
```

Figure 8. Hilton Sao Paulo Morumbi main page

Figure 9. Hilton Sao Paulo Morumbi amenities page



```
<j.1:roomAmenity rdf:resource="http://.../hotel.rdf#Iron"/>
  <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#IroningBoard"/>
  <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#Minibar"/>
  <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#Newspaper"/>
 <j.1:roomAmenity rdf:resource="http://.../hotel.rdf#Wake-
      upCalls"/>
  <j.1:roomAmenity rdf:resource="http://.../hotel.rdf#Two-
      linePhone"/>
  <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#VoiceMail"/>
<j.1:roomAmenity
      rdf:resource="http://.../hotel.rdf#TelephoneWithData
      Ports"/>
  <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#SpeakerPhone"/>
  <j.1:roomAmenity rdf:resource="http://.../hotel.
      rdf#SmokeDetektors"/>
 <j.1:roomAmenity rdf:resource="http://.../hotel.rdf#Safe"/>
</rdf:Description>
```

These RDF triples represent a part of our hotel ontology, but this time they became its instance representing a given Hilton hotel (values of various aspects of the hotel are filled-in). Our WA will then continue traversing the hotel site to find, for instance, information about fitness and recreation as well as check-in and check-out times. An appropriate page belonging to the same hotel is depicted in Figure 10 while the resulting set of RDF triples follows.

```
<rdf:Description
rdf:about="http://www.agentlab.net/travel/hotels/Hil-
      ton/SAOMOHI">
 <j.1:recreationService
      rdf:resource="http://.../hotel.rdf#FitnessCenter
      Onsite"/>
 <j.1:recreationService
rdf:resource="http://.../hotel.rdf#IndoorOrOutdoorCo
      nnectingPool"/>
     <j.1:petsPolicy rdf:resource="http://.../hotel.
      rdf#NoPetsAlowed"/>
 <j.1:additionalDetail
```

      ton/SAOMOHI/CheckIn-CheckOut"/>
</rdf:Description>

<rdf:Description
rdf:about="http://www.agentlab.net/travel/hotels/Hil-
      ton/SAOMOHI/CheckIn-CheckOut">
 <j.1:detail>Check-in: 2:00PM, Check-out: 12:00PM</
      j.1:detail>
</rdf:Description>
```

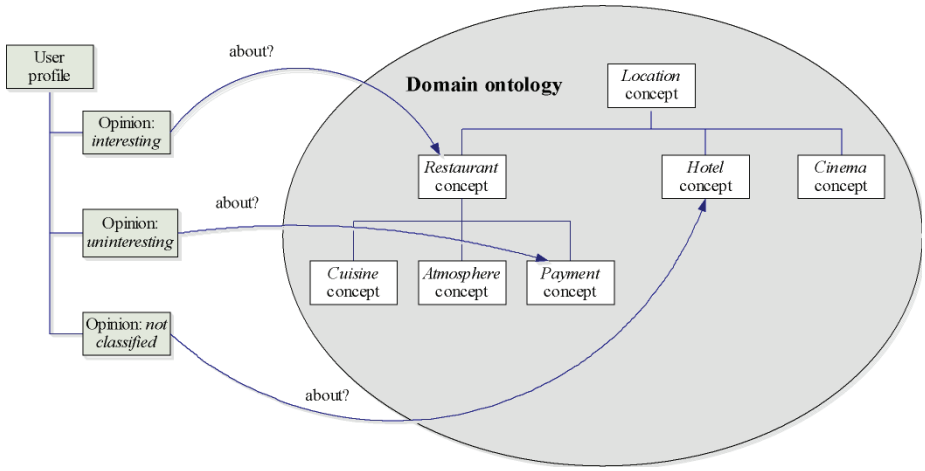
In this way the WA processes all necessary pages belonging to the Hilton Sao Paulo Morumbi and as a result obtains a set of RDF triples that constitute its complete definition (from the point of view of ontology utilized in our system). This set of RDF triples is then time and priority level stamped, packed into an ACL message and send to the CA that inserts it into the priority queue—to be later inserted, by the IA, to the semantic database. Depending on the assignment the WA may continue producing tokens of other Hilton hotels or, if work is completed, it informs the CA about this fact and self-destructs. In this way in our system, by manually creating WAs for a variety of travel information sources, we can collect real-life data representing actual travel objects.

RDF Data Utilization: Content Personalization

Let us now discuss how the data stored in the system is used to deliver personalized responses to the user. While our approach to user profile construction and utilization is based on ideas presented in Burke (2002); Fink and Kobsa (2002); Galant and Paprzycki (2002); Kobsa, Koenemann, and Pohl (2001); Montaner, López, and De La Rosa (2003); Rich (1979) and Sołtysiak and Crabtree (1998), however utilization of these methods in the context of ontologically demarcated information is novel and was proposed originally in Gawinecki, Vetulani, Gordon, and Paprzycki (2005).

To be able to deliver personalized content to the user of the system, we have to be able to represent the user in the system first—define user profile. Furthermore, the proposed user profile has to be created in such a way to simplify interactions in the system. Since our system is oriented toward processing of ontologically demarcated data, it is very natural to represent user preferences in the same way. Thus we adapted an *overlay model* of user profile, where opinions are "connected" with appropriate concepts in the domain ontology. This approach is also called a *student model*, since it has been found useful to describe knowledge of the student about specific topics of the domain

Figure 11. Overlay model utilized to represent user profile



(Greer & McCalla, 1994). Basic tenets of the overlay model are depicted in Figure 11.

For instance, let us consider our hotel ontology and assume that the user likes to stay in hotels that have both a *pool* and *fitness center*. Both these features are subclasses of the concept *amenities*. We can represent user interest by assigning weight to each amenity (the larger the weight the more important the given feature is to the user). In case of our hypothetical customer, both pool and exercise room will be assigned large weights, while features that user is not particularly interested in (e.g., availability of ironing board—see Figure 9) will be assigned small weight—the lesser the interest is the closer to 0 the value will be. In the case of features about which we do not know anything about users' preferences, no value will be assigned (see Figure 11). Let us observe that in this approach we are mimicking the notion of probability—all assigned values are from the interval (0, 1). This means that even in the case of strong counter preference towards a given feature we will assign value 0 (there are no negative values available). Proceeding in this described way, we will create a special instance of hotel ontology, one that represents *user-hotel-profile*. The following fragment of an instance of hotel ontology (this time represented in an N3 notation) depicts user (Karol) profile as it is represented in our system:

```
:KarolOpinions    a sys:OpinionsSet;
  sys:containsOpinion
    [sys:about hotel:Pool;
      sys:hasClassification sys:Interesting;
      sys:hasNormalizedProbability 0.89].
    [sys:about hotel:ExerciseRoom;
      sys:hasClassification sys:Interesting;
      sys:hasNormalizedProbability 0.84].
    [sys:about res:AirConditioning;
      sys:hasClassification sys:Interesting;
      sys:hasNormalizedProbability 0.89].
    [sys:about hotel:BathroomAmenities;
      sys:hasClassification sys:Interesting;
      sys:hasNormalizedProbability 0.73].
    [sys:about hotel:IroningBoard;
      sys:hasClassification sys:NotInteresting;
      sys:hasNormalizedProbability 0.11].
    [sys:about hotel:Iron,
      sys:hasClassification sys:NotInteresting;
      sys:hasNormalizedProbability 0.15].
```

The previous hotel profile of Karol, tells us that he likes to stay in hotels with swimming pool and exercise room, while the availability of an iron and ironing board is inconsequential to him.

Obviously, somewhere in the system we have to store, in some form, information about the user. To assure consistency across the system, this is done in the form of a simplistic user ontology. Next, we present a fragment of such ontology:

```
:hasDress a rdf:Property ;
    rdfs:range :Dress ;
    rdfs:domain :UserProfileData.

:hasAge a rdf:Property ;
        rdfs:range :Age ;
        rdfs:domain :UserProfileData .

:hasWealth a rdf:Property ;
        rdfs:range :Wealth ;
        rdfs:domain :UserProfileData .

:hasProfession a rdf:Property ;
        rdfs:range :Profession ;
        rdfs:domain :UserProfileData .
```

Let us now assume that Karol is a 24-year-old painter, who has enough money to feel rich and whose dressing style is a natural one, then his profile would be represented as:

```
:KarolProfile a sys:UserProfile;
  sys:hasUserID 14-32-61-3456;
  sys:hasUserProfileData :KarolProfileData;
  sys:hasOpinionsSet :KarolOpinions.

:KarolProfileData a sys:UserProfileData;
  sys:hasAge 24;
  sys:hasWealth sys:Rich;
  sys:hasDress sys:NaturalDress;
  sys:hasProfession sys:SpecialistFreeLancer.
```

Rather than keeping them separate, we combine instances of user ontology with the previously described user profile into a complete ontological description—a comprehensive user profile. This user profile is then to be stored in the Jena repository.

One of the important questions that all recommender systems have to address is, how to "introduce" new users to the system (Galant & Paprzycki, 2002). In our system we use stereo-

typing (Rich, 1979). Obviously, we represent stereotypes the same way we used to represent user profiles, with the difference that instead of specific values representing preferences of a given user, we use sets of variables of nominal (to represent categories—e.g., profession), ordinal (e.g., low income, medium income, high income), and interval (e.g., age between 16 and 22) types. For values of nominal and ordinal types we have established sets of possible values, while for the values of interval types, we defined borders of intervals considered in the system. Using results of a survey and expert knowledge, we were able to create restaurant-related stereotypes (one instance of restaurant ontology of each identified stereotype). To illustrate such a case, here is a fragment of artistic profile in the area of restaurants:

```
:ArtistStereotypeOpinions    a sys:OpinionsSet;
 sys:containsOpinion
   [sys:about res:CafeCoffeeShopCuisine;
     sys:hasClassification sys:Interesting;
     sys:hasNormalizedProbability 1.0].
   [sys:about res:CafeteriaCuisine;
     sys:hasClassification sys:Interesting;
     sys:hasNormalizedProbability 0.75].
   [sys:about res:TeaHouseCuisine;
     sys:hasClassification sys:Interesting;
     sys:hasNormalizedProbability 0.9].
   [sys:about res:WineBeer;
     sys:hasClassification sys:Interesting;
     sys:hasNormalizedProbability 0.8].
   [sys:about res:WineList;
     sys:hasClassification sys:Interesting;
     sys:hasNormalizedProbability 1.0].
   [sys:about res:HotDogsCuisine;
     sys:hasClassification sys:NotInteresting;
     sys:hasNormalizedProbability 0.0].
```

In this stereotype we can see, among others, that an *artist* has been conceptualized as a person who likes *coffee houses* a bit more than *tea houses* and is willing to eat in a *cafeteria*, likes *wine* (a bit more than *beer*), but does not like *hot dogs* (*fast food*). Other stereotypes have been conceptualized similarly and their complete list and a detailed description of their utilization can be found in Gawinecki, Kruszyk, and Paprzycki (2005).

When a new user logs onto the system he/she will be requested to fill out a short questionnaire about age, gender, income level, occupation, address (matching user features defined by the user ontology), as well as questions about travel preferences. While the basic user ontology-based data will be required, answering questions about travel preferences will be voluntary. Personal data collected through the questionnaire will be used to match a person to a stereotype. More precisely, we will calculate a distance measure between user-specified characteristics and these appearing in stereotypes defined in the system and find one that matches his/her profile the closest. To achieve this we will use the following formula:

$$d\left(\hat{S},\hat{u}\right)=\frac{\sum_{f=1}^{k} w^{f}\delta_{\hat{S}\hat{u}}^{f}d_{\hat{S}\hat{u}}^{f}}{\sum_{f=1}^{k} w^{f}\delta_{\hat{S}\hat{u}}^{f}}$$

Where: w^f – weight of attribute, $d^f_{S,u}$ – distance between values of the attribute in the stereotype S and user's data u, $\delta^f_{S,u}$ – Boolean flag that informs whether attribute f appears in both: stereotype's data (S) and user's data (u).

To illustrate this, let us consider Karol, the painter, again. In the Table 1 we present Karol's data and the artist stereotype data and show how the closeness between Karol and that stereotype is calculated.

The same process is then repeated comparing Karol's data against all other stereotypes to find the one that fits him the best. In the next step this stereotype is joined with his user data to become his *initial profile*. In the case when he answers any domain-specific questions (recall, that he may omit them), this data will be used to modify his user profile. For example, let us assume that he has been identified as student stereotype, but he has also specified that he does not like coffee houses (while in the student stereotype coffee

Table 1. Calculating closeness between user profile (Karol) and a stereotype (artist)

Attribute (f)	Attribute weight (w^f)	Data of artist stereotype (comma means OR relation): (S)	Karol's Data: (u)	Distance between value of attribute: ($d^f_{S,u}$)	Weighted distance: ($w^{f*} d^f_{S,u}$)
Age	2	20-50	24	0.00	0.00
Wealth	4	Not Rich, Average Rich	Rich	0.33	1.33
Dress	1	Naturally, Elegantly	Naturally	0.00	0.00
Profession	2	Student/Pupil, Scientist/ Teacher, Specialist/ FreeLancer Unemployed/WorkSeeker	Specialist/ FreeLancer	0.00	0.00
			COMBINED		1.3(3) / (2+4+1+2)= 0.14(6)

houses have been assigned a substantial positive weight). Obviously, in his profile, this positive value will be replaced by zero—as explicit personal preferences outweigh these specified in the stereotype (see also Nistor, Oprea, Paprzycki, & Parakh, 2002):

```
:KarolOpinions a sys:OpinionsSet;
  sys:containsOpinion
    [sys:about res:CafeCoffeeShopCuisine;
      sys:hasClassification sys:Interesting;
      sys:hasNormalizedProbability 0.0].
```

Observe that as soon as the system is operational we will be able to store information about user behaviors (Angryk et al., 2003; Galant & Paprzycki, 2002; Gordon & Paprzycki, 2005). These data will be then used not only to modify individual user profiles, but also mined (e.g., clustered) to obtain information about various group behaviors taking place in the system. This information can be used to verify, update, or completely replace our initial stereotypes. Such processes are based on the so-called implicit relevance feedback (Fink & Kobsa, 2002; Kobsa et al., 2001). As described earlier (see Figure 7) we will also utilize explicit feedback based on user responses to subsequent questionnaires. Currently as explicit feedback we utilize only a single question: "Did you like our main suggestion presented last time?" but a more intricate questionnaire could also be used. Specifically, at the end of each user system interaction, on the basis of what was recommended to the user, a set of questions about these recommendations could be prepared. When the user returns to the system, these questions would be then asked to give him/her opportunity to express his/her direct opinion. Both implicit and explicit feedbacks are used to adjust user profile (see also Gawinecki, Vetulani, et al., 2005). Note here, that in most recommender systems stereotyping is *the* method of information filtering (demographic filtering); thus making such systems rather rigid—in this case individual user preferences cannot be properly modeled and modified (Kobsa et al., 2001). In our system we use stereotyping only to solve the cold-start problem—and modify them over time—and thus avoid the rigidity trap.

User profile is utilized by the PA to rank and filter travel objects. Let us assume that after the query, the response preparation process has passed all stages and in the last one the PIA agent has completed its work and the MRS has been delivered to the PA. The PA has now to compute a *temperature* of each travel object that is included in the MRS. The temperature represents the "probability" that a given object is a "favorite" of the user. This way of calculating the importance of selected objects was one of the reasons for the way that we have assigned importance measures to individual features (as belonging to the interval

[0,1]). Recall here that the DBA and the PIA know nothing about user preferences and that the PIA uses a variety of general rules to increase the response set beyond that provided as a response to the original query.

To calculate the temperature of a travel object (let us name it an *active object*) three aspects of the situation have to be taken into account. First, features of the active object. Second, user interests represented in the user profile—if a given feature has no preference specified then it cannot be used. In other words, for each token in the MRS we will crop its ontological graph to represent only these features that are defined in user profile. Third, features requested in user query. More specifically, if given keywords appear in the query (representing explicit wishes of the user), for example, if the query was about a restaurant in Las Vegas, then such restaurants should be presented to the user first. Interactions between these three aspects are represented in Figure 12.

Here we can distinguish the following situations:

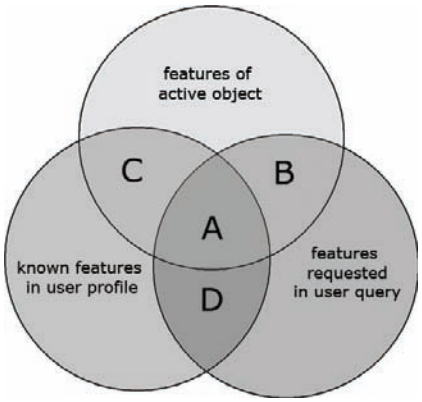
A. Features explicitly requested by the user that appear in the active object as well as in the user-profile;
B. Features requested by the user and appearing in the active object;
C. Features not requested that are a part of the user profile and that appeared in the active object; and
D. Features that do not appear in the active object (we are not interested in them).

Ratings obtained for each token in the MRS represent what the system believes are user preferences and are used to filter out these objects temperatures of which are below a certain threshold and rank the remaining ones (objects with highest scores will be displayed first). We will omit discussion of a special case when there is no object above the threshold. The MRS is processed in the following way:

1. Travel objects are to be returned to the user in two groups (buckets)
   a. Objects requested explicitly by the user (via the query form) – Group I
   b. Objects not requested explicitly by the user but predicted by the system to be of potential interest to the user – Group II

   Thus, for each active object we divide features according to the areas depicted in Figure 11. Objects for which at least one feature is inside of either area A or B belong to Group I, objects with all features inside area C belong to Group II, while the remaining objects are discarded.

Figure 12. Construction of final response: Interactions between features



2. Inside of each bucket travel objects are sorted according to their temperature computed in the following way: for a given object *O* its temperature

$$temp(0) = \sum_{f \in O} temp(f)$$

where $temp(f) = 1$ if $f \in A \cup B$, or $p_n(f)$ if $f \in C$, while $temp(f)=temp(f) - 0.5$. This latter calculation is performed to implicate that these features that are not of interest to the user (their individual temperatures are less than 0.5) reduce the overall temperature of the object. Function $p_n(f)$ is a normalized probability of feature *f*, based on the user profile.

Let us consider Karol, who is interested in selecting a restaurant. In his query he specified that this restaurant has to serve Italian cuisine and has to allow smoking. Additionally, we know, from Karol's profile, that he does not like *coffee* (weight 0.1) and *outdoor dining* (weight 0.05). Thus for the restaurant X:

```
:RestaurantX a res:Restaurant;
      res:cuisine res:ItalianCuisine;
      res:cuisine res:PizzaCuisine;
      res:cuisine res:CafeCoffeeShopCuisine;
      res:feature res:Outdoor.
```

the overall score will be decreased due to the influence of *Outdoor* and *CafeCoffeeShopCuisine* features, but will receive a "temperature boost" because of the *ItalianCuisine* feature (explicitly specified feature). However, the restaurant X it won't be rated as high as the restaurant Y:

```
:RestaurantY a res:Restaurant;
      res:cuisine res:ItalianCuisine;
      res:smoking res:PermittedSmoking.
```

which serves *ItalianCuisine*, where smoking is also permitted. To be more specific, let us consider these two restaurants and the third one described by the following features:

```
:RestaurantZ a res:Restaurant;
      res:cuisine res:WineBeer;
      res:smoking res:PermittedSmoking.
```

Then Table 2 represents the way that temperatures of each restaurant will be computed.

As a result, restaurants X and Y belong to the first bucket (to be displayed to the user as they both have features that belong to area B). However,

Table 2. Computing temperature of a restaurant

Restaurant N3 descriptions (bold – requested by the user, underlined – in the user profile; could be conjunctive)	Calculations
:RestaurantX a res:Restaurant; res:cuisine **res:ItalianCuisine**; res:cuisine res:PizzaCuisine; res:cuisine res:CafeCoffeeShopCuisine; res:feature res:Outdoor.	+0.5 (=1-0.5) requested; B +0 -0.49 (=0.01-0.5) profile -0.45 (=0.05-0.5) profile **= -0.44**
:RestaurantY a res:Restaurant; res:cuisine **res:ItalianCuisine**; res:smoking **res:PermittedSmoking**.	+0.5 (=1-0.5) requested; B +0.5 (=1-0.5) requested; B **= 1**
:RestaurantZ a res:Restaurant; res:cuisine res:WineBeer; res:smoking res:PermittedSmoking.	+0.3 (=0.8-0.5) not requested; profile; C +0.5 (=1-0.5) not requested; profile; C **= 0.8**

while restaurant Y has high temperature (1) and definitely should be displayed, restaurant X has very low temperature (-0.44) and thus will not likely be displayed at all. Interestingly, restaurant Z, which belongs to the second bucket (belongs to area C), has an overall score of 0.8 and is likely to be displayed. This example shows also the potential adverse effect of lack of information (e.g., in the ChefMoz repository; but more generally, within the Web) on the quality of content-based filtering (at least done in a way similar to that proposed previously). Simply said, what we do not know cannot decrease the score, and thus a restaurant for which we know only address and cuisine may be displayed as we do not know that it allows smoking on the premises (which would make it totally unacceptable to a given user).

RDF Data Utilization: Content Delivery

Let us now present in more detail how the delivery of content to the user is implemented as an agent system. To be able to do this we need to briefly introduce additional agents (beyond these presented in Figure 2) and their roles (using Prometheus methodology [Prometheus, 2005])—as represented in Figure 13.

In addition to the PA (described in details in Figure 7) and the DBA, we have also: (1) *view transforming agent* (*VTA*) responsible for delivering response in the form that matches the user I/O device; (2) *proxy agent* (*PrA*) that is responsible for facilitating interactions between the agent system and the outside world (need for these agents as well as a detailed description of their implementation can be found in Kaczmarek et al. (2005); (3) *session handling agent* (*SHA*), which is responsible for complete management and monitoring of functional aspects of user interactions with the system; and (4) *profile managing agent* (*PMA*) which is responsible for (a) creating profiles for new users, (b) retrieving profiles of returning users and (c) updating user-profiles, based on implicit and explicit relevance feedback. Let us now summarize processes involved in content delivery through a UML action diagram. While rather complex, descriptions contained in Figure 14 represent a complete conceptualization of actions involved in servicing user request from the moment that the user logs on to the system, to the moment when he/she obtains response to their query.

State of the System

As indicated earlier in this chapter, we have concentrated on these features of our system that are currently being implemented and close to being ready, while omitting the features that

Figure 13. Content delivery agents and their roles

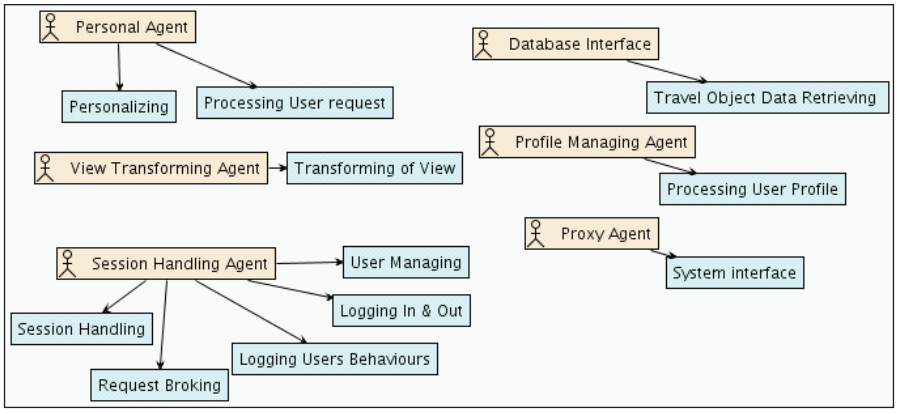


Figure 14. Content delivery action diagram

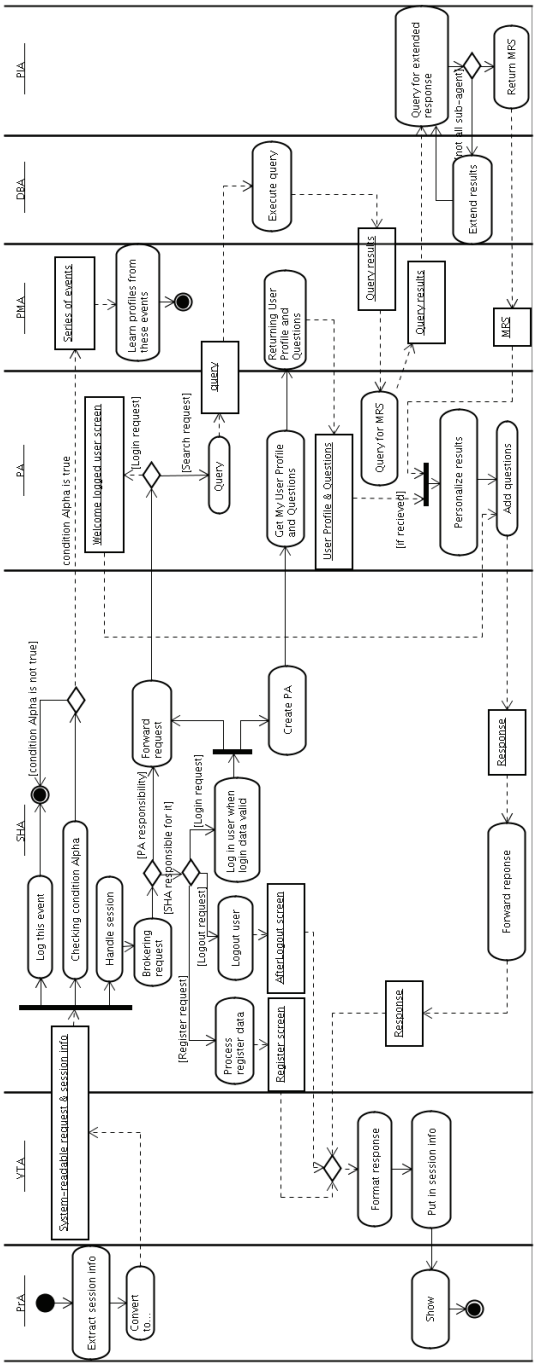

we would like to see developed in the future. While the interface to the system is still under construction, it is possible to connect to it from a browser. Furthermore, we have emulated WAP-based connectivity. As of the day this chapter is being written, we have implemented a function-complete content collection subsystem consisting of: (1) a number of hotel wrappers (WA) that allow us to feed hotel data into the system; (2) CA and IA agents that collaborate with the WAs to insert data into Jena-based repository; and (3) an initial version of the DMA and the PIA. For the CCS we have semi-automatically cleaned-up subsets of Chef Moz data, describing selected restaurants. We have also a relatively complete content delivery subsystem. In particular, (1) the PrA, the SHA, and the VTA that facilitate user-system interactions have been implemented and tested; (2) the PA is working as described in this chapter (with the PIA working in the case of restaurants only); (3) the PMA has only limited capacity, it is capable of creating and managing a single user profile; (4) while the existing set of stereotypes involves only restaurants. Let us briefly illustrate the work of the system, by screen-shots of the query (Figure 15) and the response (Figure 16). The query was a general query about restaurants in Greensboro, NC; note the box that attempts at asking a question about *Bistro Sophia* that was suggested to the user in the previous session (Figure 16).

One of the biggest problems related to testing our system is the fact that, being realistic, no user would be interested in a system that only provides a few hotel chains and restaurants (e.g., in Poland). This being the case we can ourselves test features of the system like: (1) is the user query handled correctly, that is, do the returned results represent the correct answer taking into account the current state of the system; (2) do the WAs correctly deliver and the CA and IAs accurately insert tokens into the system; and (3) are agent communication and interactions proceeding without deadlocks and does the system scale. Unfortunately, it is practically impossible to truly test adaptive features

Figure 15. System query screenshot

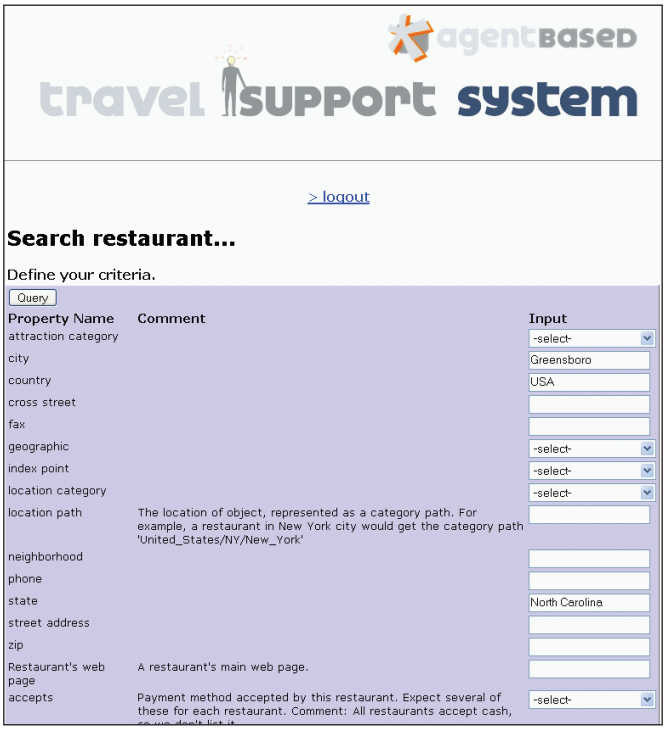

Figure 16. System response screenshot

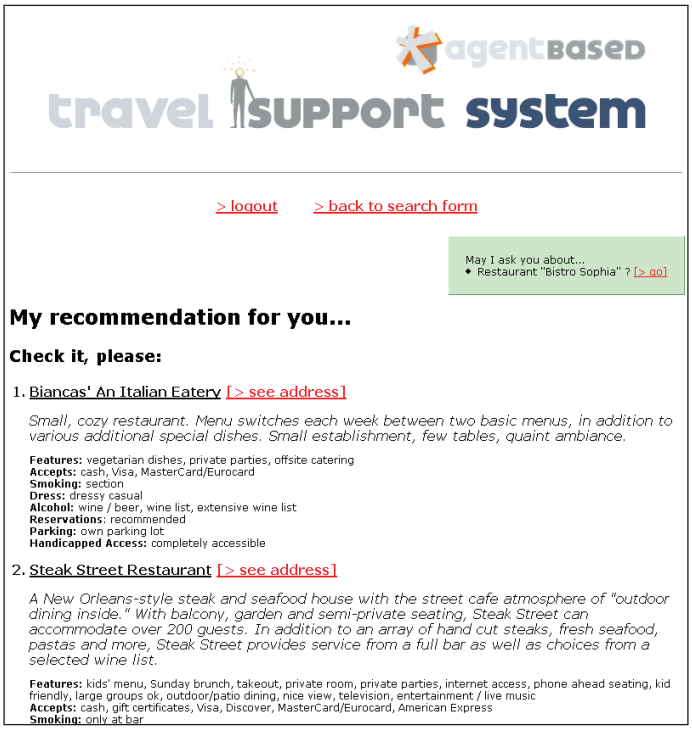

of the system. Without actual users utilizing the system to satisfy their real travel needs, all the work that we have done implementing the system cannot be practice verified.

This is a more general problem of the chicken-and-egg type that is facing most of Semantic Web research (regardless of its application area). Without real systems doing real work and utilizing actual ontologically demarcated data on a large scale (to deliver what users need) it is practically impossible to assess if the Semantic Web, the way it was conceptualized, is the way that we will be able to deal with information overload, or is it just another pipe dream like so many in the past of computer science.

FUTURE DEVELOPMENTS

As described previously, it seems to be clear what the future of the development of Semantic Web technologies applied in context of e-business (or in any other context) has to be. It has to follow the positive program put forward by Nwana and Ndumu (1999). The same way as agent systems and a large number of systems utilizing Semantic Web technologies have to be implemented and experimented with. Furthermore, it is necessary to develop tools that are going to speed up ontological demarcation of Web content. Here, both the content that is about to be put on the Web as well as tools supporting demarcation of legacy content need to be improved and popularized. Only then, we will be able to truly assess the value proposition of the Semantic Web. Furthermore, since software agents and the Semantic Web are truly intertwined, the development of the Semantic Web should stimulate development of agent systems, while development of agent systems is likely to stimulate development of the Semantic Web.

To facilitate these processes we plan to continue development of our agent-based travel support system. The first step will be to complete integration and testing of the aforementioned described system skeleton. We will proceed further by: (1) developing ontologies of other important travel objects, for example, movie theaters, museums, operas, and so forth; (2) fully developing and implementing the PIA and the DMA infrastructures—according to the previously presented description; (3) continuing implementing WAs to increase the total volume of data available in the system; (4) adding a geographic information system (GIS) component to the system, to allow answering queries like: which restaurant is the closest one to that hotel?; (5) developing and implementing an agent-based collaborative filtering infrastructure; and (6) investigating the potential of utilizing text processing technologies for developing new generation of adaptive WAs.

Chapter 4.9
Online Synchronous vs. Asynchronous Software Training Through the Behavioral Modeling Approach:
A Longitudinal Field Experiment

Charlie C. Chen
Appalachian State University, USA

R. S. Shaw
Tamkang University, Taiwan

ABSTRACT

The continued and increasing use of online training raises the question of whether the most effective training methods applied in live instruction will carry over to different online environments in the long run. Behavior Modeling (BM) approach – teaching through demonstration — has been proven as the most effective approach in a face-to-face (F2F) environment. A quasi-experiment was conducted with 96 undergraduate students who were taking a Microsoft SQL Server 2000 course in a university in Taiwan. The BM approach was employed in three learning environments — F2F, online synchronous and online asynchronous classes. The results were compared to see which produced the best performance, as measured by knowledge near-transfer and knowledge far-transfer effectiveness. Overall satisfaction with training was also measured. The results of the experiment indicate that during a long duration of training no significant difference in learning outcomes could be detected across the three learning environments.

CONCEPTUAL FOUNDATIONS

The Internet's proliferation creates a wealth of opportunities to deploy alternative online learning environments to facilitate many users in their learning processes. The information technology (IT) skills training market represented 76% of the entire online learning market in year 2000, according to a Jupiter Research report (CyberAtlas, 2003). The worldwide corporate online learning market may grow to $24 billion ($18 billion in the U.S.) by 2006 with a compound annual growth

rate of 35.6% (IDC, 2002). The burgeoning online learning/training market, and the increasing training budgets of businesses and schools has provided these key users of online training and marketing tools with practical reasons, as well as compelling research motives, to investigate the effectiveness of training and education in different online formats.

Online learning differs primarily from the traditional face-to-face (F2F) learning in that it is a user-centered, rather than instructor-centered, learning mode. Other benefits of substituting online learning for F2F learning include (1) self-paced instruction; (2) the ability to incorporate text, graphics, audio and video into the training; (3) opportunity for high levels of interactivity; (4) a written record of discussions and instructions; (5) low-cost operation; and (6) access to a world-wide audiences (Aniebonam, 2000). In addition, online learning can remove a certain degree of space and time limitations, speed up the learning process for motivated learners, lower economic costs of attending F2F classes and have higher information accessibility and availability.

Although IT has changed the training and educational approaches and environments, the ultimate goal of learning has not changed, that is, to transfer knowledge to students and allow them to apply the acquired knowledge in real situations. In the field of IT, the success of software training can be assessed with a trainee's IT skills of, and knowledge of the use of, particular software to solve problems. Surprisingly, after attending a training session, very few students know how to properly apply the acquired knowledge and skills to real situations. This raises an important issue, that is, how to improve knowledge transfer capability of learners in different online learning environments.

The importance of knowledge transfer is self-evident. However, the knowledge transfer process does not occur naturally. There is a need to assist learners in transferring their acquired knowledge into future applications. One effective approach to assisting the learning transfer process is "behavior modeling" (BM). This approach teaches learners through demonstration and hands-on experience. Simon, Grover, Teng, and Whitcomb (1996) and Compeau and Higgins (1995) found that in the field of information technology, BM is the most effective approach compared to the other two knowledge transfer approaches: exploration — teaching through practice on relevant example, and instruction — teaching software characteristics.

Distance education is defined as "teaching through the use of telecommunications technologies to transmit and receive various materials through voice, video and data" (Bielefield & Cheeseman, 1997, p. 141). In the same token, Leidner and Jarvenpaa (1995) define distance learning as "the transmission of a course from one location to another" (p. 274). These definitions provide an analogy to distance learning in the field of information technology or online software training. Online software training can be the transmission of instructional IT programming or contents to geographically dispersed individuals or groups.

There are two general modes of online learning: synchronous and asynchronous modes. Each mode can be marshaled with IT tools to deliver software training. Case in point, audio and video conferences are two types of online synchronous training mediums. Online asynchronous training mediums range from Web pages, file download, e-mail, e-mail list, newsgroup, forum, chat, response pad, whiteboard and to screen sharing. Built on his personal distance training and education experiences since 197 -+ 1, Horton (2000) suggests that online synchronous and asynchronous learning and training be designed for different purposes. Incorporating synchronous learning demands the control of schedule, time, people, class size, video and audio equipment and place. These factors constrain the possibility of reaching large numbers of students at any given time and in any given place.

However, the BM approach for trainees can be a problem in online asynchronous and synchronous training. For instance, any demonstration presented by a live instructor would need to be replaced with a scripted or videotaped demonstration in asynchronous mode, and live transmission or Webcam in synchronous mode. This raises several important questions. Can the scripted, videotaped, live transmission or Webcam approach still be as effective as the traditional classroom? How receptive are students to different online learning environments with differential degrees of student-centered interaction compared to an instructor-centered F2F environment? Most importantly, it is an unknown but interesting question to ask whether knowledge can be effectively transferred in different online environments. This research is to address these important issues faced by any instructor who intends to apply the BM approach in either online synchronous and asynchronous environments.

Behavioral Modeling and Knowledge Transfer

Social learning theory is the basis of the behavior modeling approach. Therefore, it is important to assess the applicability of the theory and approach in the online learning environment. Learning outcomes can be measured by different types of knowledge transfer and end-user satisfaction.

Behavior Modeling in Online Environments

Bandura (1977) proposed the Social Learning Theory to explain the interactive learning process between individuals and their social environment. He asserted a series of social learning needs take place to direct an individual from biological and self-centered response to social and group behaviors. Since the social learning process takes place within a society, individuals learn to establish their behavior models by observing and imitating other individuals' behaviors or through the enforcement of the media and environment. Online learning in different environments needs to be delivered via different media. Different online learning environments, therefore, may have different degrees of enforcement to learners' individual behaviors.

Learning by modeling or observing people's behaviors may be more effective than learning by trial-and-error because the former approach can avoid unnecessary mistakes and harm. Modeling an instructor's behaviors empowers students to (1) learn new behavior from the instructor, (2) self-evaluate their behaviors against the instructor's and (3) enforce students' current behavior.

Learning by modeling takes place in four sequential steps: (1) attention, (2) retention, (3) motor reproduction and (4) motivation and reinforcement (Bandura, 1977). Enforcement forces, such as the duration of training, praise, motivation and attention of others, allows learning to move along these four steps against counter forces. Enforcement forces, such as retention enhancement and practice, can contribute to better cognitive learning (Yi & Davis, 2001).

Lewin (1951) argued that the effectiveness of Behavior Modeling is a function of people interacting within an environment. The BM approach is different from learning by adaptation. The former approach teaches through demonstration, while the latter approach influences the behaviors of learners by reward and punishment (Skinner, 1938). The BM approach was first applied in the training of interpersonal communication and management skills (Decker & Nathan, 1985). Gist, Schwoerer and Rosen (1989) further applied the training to the context of information technology.

BM may be readily employed in face-to-face instruction, but cannot be easily simulated in online asynchronous instruction, which lacks the interactive immediacy necessary for optimally effective instructor demonstration and correction. The richness of information media in online

synchronous instruction is another constraint and may also have less enforcement force than F2F instruction to the learning outcomes. For example, in a live training class, the instructor is able to demonstrate a software process and immediately ask the students to repeat the activity under the instructor's close supervision. However, in an online asynchronous situation where there is no live instructor, the demonstration loses the benefit of that immediate feedback. In the same token, in an online synchronous situation bandwidth constraints and compromised reciprocity may undermine the enforcement force of the demonstration. In both online environments, enforcement forces can be further compromised with the missing of "learning by doing," another key element of F2F BM training (McGehee & Tullar, 1978).

Therefore, there is a strong possibility that the BM approach cannot be fully replicated in either the online synchronous or asynchronous situation and will not be as effective a method in online training as in the traditional environment.

Knowledge Transfer

Knowledge transfer is the application of acquired skills and knowledge into different situations. Unless the transferring process occurs, learning has little value. The applied situations could be similar or novel to the learning situation. Depending on the situation, knowledge transfer can take place in different formats. In general, there are four different types of knowledge transfer.

Positive Transfer vs. Negative Transfer

Positive transfer of learning means that learning in one situation stimulates and helps learning in another situation. Negative transfer of learning hinders the application of learning in one situation to other situations. Positive learning experience can be enhanced via analogy, informed instruction (Paris, Cross & Lipson, 1984), tutorial (Morris, Shaw & Perney, 1990) and so forth. Learning effectiveness can be improved by triggering positive learning and mitigating negative learning experience.

Near Transfer vs. Far Transfer

Salomon and Perkins (1988) argued that transfer of learning could have a differential degree of transfer. The effectiveness of near-transfer learning depends on the learner's ability to solve problems similar to those encountered in the learning context. For instance, learning how to add two digit numbers allows learners to add three digit numbers. Near-transfer learning occurs in two similar situations and at a lower level. Therefore, the level of learning is more easily acquired and applied. In contrast, applying the acquired skills and knowledge in two dissimilar and sometimes novel situations is much harder to achieve. For instance, a table tennis player can apply skills of playing pinball to playing tennis. Although both sports look similar on the surface, the techniques to control pinballs and tennis balls are very different. The learning transfer is much harder to be acquired and retained. Therefore, the transfer is defined as far-transfer learning. Near-transfer and far-transfer of knowledge seem to be the most widely used measures of learning outcomes in the field of information technology since learners must utilize the knowledge learned in a computing environment.

Specific Transfer and General Transfer

Depending on learning content, there are two different learning transfers: specific transfer and general transfer (Bruner, 1996). The former refers to the extension and association of habit and skills. The latter refers to the transfer of principles and attitudes that can be used to deepen the understanding of basic concepts.

Lateral Transfer and Vertical Transfer

Gagne (1992) asserted that the transfer of learning includes lateral and vertical transfers. Lateral learning is to apply one domain of knowledge to another domain. Lateral learning does not follow step-by-step instruction and is considered as provocative learning. Vertical learning means that a higher level of learning needs to be created by integrating acquired skills, and experiences with new situations. Vertical transfer of learning is analytical and sequential.

Other Knowledge Transfer Theories

Theories related to knowledge transfer are not limited to the above mentioned ones. For instance, the theory of identical elements asserts that the more identical elements different learning contains, the more efficient the transfer of learning (Thorndike, 1949). Baldwin and Ford (1988) proposed a general training theory to classify three categories of factors affecting transfer of training: (1) training inputs, (2) training outputs and (3) conditions of transfer. The situated learning theory argues that individuals are affected by learning environment when trying to solve practical problems. Therefore, the interaction between learners and the environment is an important factor that needs to be taken into account when measuring the transfer of learning. Finally, the theory of formal discipline argues that knowledge transfer skills can be acquired by training learner's sensuality, such as thinking, judgment, classification, imagination, creation and so forth.

The objective of this study was to investigate the impacts of the learning environment in online and offline formats on the transfer of learning. The situational changes rationalize the adoption of situated learning theory. To accomplish this objective, we sought to train end-user to learn how to use Microsoft SQL server 2000 software. Therefore, we adopted the near-transfer and far-transfer measures of learning outcomes for our information technology related experiment.

Hypotheses

Hypotheses are formulated to investigate whether the BM approach is as effective in online synchronous and asynchronous environments as in the traditional face-to-face environment. We measured learning outcomes by trainees' performances in near-transfer and far-transfer tasks, as well as overall satisfaction levels. The study also considered the importance of time variant. Hence, training and performance measurement were conducted over five weeks.

Knowledge Near-Transfer (KNT) Tasks

H1: End-users trained using F2F behavior modeling perform near-transfer information system tasks better than those trained in asynchronous behavior modeling.

H2: End-users trained in F2F behavior modeling perform near-transfer information system tasks better than those trained in synchronous behavior modeling.

H3: End-users trained in synchronous behavior modeling perform near-transfer information system tasks better than those trained in asynchronous behavior modeling.

Knowledge Far-Transfer (KFT) Tasks

H4: End-users trained in F2F behavior modeling perform far-transfer information system tasks better than those trained in asynchronous behavior modeling.

H5: End-users trained in F2F behavior modeling perform far-transfer information system tasks better than those trained in synchronous behavior modeling.

H6: End-users trained in synchronous behavior modeling perform far-transfer information

system tasks better than those trained in asynchronous behavior modeling.

Overall Satisfaction

H7: End-users trained in synchronous behavior modeling have a higher overall satisfaction level than those trained in asynchronous behavior modeling.

Research Design

This study applied Simon, Grover, Teng and Whitcomb's (1996) well-constructed software training theory to experimentally test behavior modeling training in three learning environments — F2F, online asynchronous and online synchronous environments. In doing so, it should be possible to detect the effects of the single independent variable (training environment) on training outcomes. The experiment was conducted in a field setting that enabled the study to garner greater external validity than would be the case with a laboratory experiment. A field experiment methodology has the merits of "testing theory" and "obtaining answers to practical questions" (Kerlinger & Lee, 2000). The exploratory nature of the study requires that variables (e.g., training environments and subject areas of study) under investigation be manipulated.

Subjects Control

The setting for the field experiment was the Tamkang University in Taiwan. The experiment was prompted by the need of 96 college sophomores, who are Management Information Systems (MIS) majors, to learn a Microsoft SQL Server 2000 software program in a database processing course. The schedule agreed on with the faculty at Tamkang University was to run the experiment for an hour training each week for four weeks. The author's graduate assistant Ms. Lin helped administer the experiment to collect the data. The subject pool had a mean age of 22 years. Subjects who participated in the structured experiment had little database-related experience. Their intellectual levels are relatively the same because subjects scored the same range of scores in a national entrance exam. The national entrance exam system has been adopted for more than 40 years in Taiwan and is considered a relatively reliable test. Subjects' individual backgrounds should not have influence on learning outcomes.

For the purposes of this study, subjects were chosen if they lacked a theoretical and procedural understanding of the particular subject area being tested. Participants were given a pretraining questionnaire that includes important study units on Microsoft SQL Server 2000. Two experts of the domain administered the Delphi study to finalize the study units and questionnaires. This is to improve the content validity. The subjects voluntarily answered whether they knew those study units and answered their database-related experiences. Based on their answers, a correlation test of database and usage experience of the target system showed no significant differences among three experimental groups. Subjects of the study may be considered representative of novice end-users. Many studies (Ahrens & Sankar 1993; Santhanam & Sein, 1994) support using students as experimental subjects to represent the general populations. Hence, all subjects' questionnaires were used for further data analysis. This segmentation was used to mitigate the effects of computer literacy and experience on the findings, thereby improving the internal validity of the study.

Training Treatments

Face-to-face BM (FBM) is instructor-centered training while online Asynchronous BM (ABM) and Synchronous BM (SBM) are learner-centered training. Course materials used in online learning environments were created to properly reflect the key elements of a behavior modeling approach. AniCam simulation software was used to record

the demonstration of instruction. Hyperlink structure was used to help users assimilate nonlateral conceptual, and procedural knowledge.

Feedback activities of behavior modeling approach in online asynchronous environment are supported with e-mail and hyperlinks. SBM differs from ABM in providing feedback functions via real-time discussion forums. Training materials integrate key elements of behavior modeling approach: (1) control of three different learning environments, (2) demonstration of the instructor, (3) continuous feedback (verbal feedback in F2F and online synchronous environments; e-mail feedback in the online asynchronous environment). Three training environments were designed to maximize the effect of size on their differences (Figure 1).

Training Procedures

The experimental study lasted for four weeks. There was a 50 minute training session each week for each class. Figure 2 shows the experimental procedures used at each time period. The X's, Y's and Z's represent online asynchronous BM training, online synchronous BM training and F2F BM training methods, respectively. The subscripts next to each alphabet indicate the ith observation or training session, respectively. Before executing experimental treatments (the pretest period O1), the instructor asked the subjects to complete a short questionnaire soliciting demographic information, database software-related experience and attitudes towards learning in the subject's assigned online learning environment (Pretest). Approximately one-third of the subjects pooled received the same experimental treatment for four straight weeks (Week1 to Week4). The assigning process was random on the class basis. Randomizing the execution of O4 and O5 in Week2 and Week3 for Group A and Group B can help avoid possible confounding results from the interactive effects of the pretest of O1 and O3. This randomization process can further ensure that difference in learning outcomes of O6 is not possibly due to the sensitization of the participants after the pretest and the interaction of their sensitization, O4 and O5 (Kerlinger & Lee, 2000).

Before or after each training session, subjects were asked to complete database design tasks using the MS SQL commands to assess their prior knowledge in the trained subjects and immediate learning outcomes that involve both near-transfer and far-transfer knowledge. On week five, students were evaluated again for their attitude changes towards the e-learning sessions and performance

Zi FBM (F2F BM Training)

in near and far-transfer tasks (Post-test). The final exam concludes the five-week training sessions.

Training materials were designed to integrate key elements of the three training environments, as illustrated in Figure 3. Course materials used in the online asynchronous training session were stored on the school's server for students to learn at their own pace after each training session was completed. At the end of the experiment, students were asked about their affect for their learning environments.

Outcomes Measurement

Regardless of the teaching environment, computer training is intended to instill in users a level of competency in using the system and to improve their satisfaction with the system. A user's competency in using a system is contingent upon the user's knowledge absorption capacity. Ramsden (1988) finds that effective teaching needs to align students with situations where they are encouraged to think deeper and more holistically. Kirkpatrick (1967) also suggests that learning effectiveness needs to be evaluated by students' reactions, learning and knowledge transfer. The levels of knowledge absorbed by students, Bayman and Mayer (1988) suggest, may include syntactic, semantic, schematic and strategic knowledge. Mennecke, Crossland and Killingsworth (2000) believe that experts of one particular knowledge domain possess more strategic and semantic knowledge than novices. Knowledge levels, as Simon, Grover, Teng and Whitcomb (1996) suggest, can be categorized as near-transfer, far-transfer or problem solving. Near-transfer knowledge is necessary for being able to understand software commands and procedures. This type of knowledge is important for a trainee to be able to use software in a step-by-step fashion. Far-transfer knowledge seeks to ensure that a trainee has the ability to combine two or more near-transfer tasks to solve more complicated problems.

Both the use of software and information systems and the satisfaction levels of using them are useful surrogates to properly measure the effectiveness of an information system (Ives, Olson, & Baroudi, 1983). The end-user satisfaction level has been widely adopted as an important factor contributing to the success of end-user software training. Since the study was to replicate Simon, Grover, Teng and Whitcomb's (1996) research in a dissimilar environment, near-knowledge and far-knowledge transfer, and end-user overall satisfaction levels were adopted in this study to measure training outcomes. Cronbach's alpha reliability for Simon et al.'s (1996) instrument to measure satisfaction is r = 0.98. Users need to use the Likert scale from one to five to answer 12 test items related to their satisfaction with the use of online system.

Data Analysis

shows F and P values of the dependent variables (near-transfer and far-transfer task performances, and overall satisfaction) across treatment groups and in different times. Pretest scores (Q1, Q2 and Q4) in varying weeks were used to tell apart students with prior experiences and knowledge on the studied topics. After learning in a weekly session, students participated in a post-test. Their scores (Q3 and Q5) were used for KNT effectiveness comparison across training sessions. Scores of Q6 are KFT effectiveness and end-user satisfaction levels. A cursory examination of means (Table 1) indicates that no patterns can be identified for near-transfer performance from time Week1 to Week5. Subjects in ABM performed better than those in FBM, followed by SBM at Week1 while at Week2 and Week3 the order was changed to FBM>ABM>SBM and SBM>FBM>ABM, respectively. The findings are not in agreement with a consistent pattern as predicted by Hypotheses H1 and H2. For KFT tasks, subjects in ABM performed better than those in SBM, followed by FBM. This is the reversed order of a pattern as predicted by Hypotheses H3 and H4. The measurement of overall satisfaction level somewhat follows the predicted patterns of Hypotheses H5 and H6.

Table 1. Descriptive statistics - means (standard deviations)

	ABM (N=40)	SBM (N=26)	FBM (N=30)	Overall (N=96)
KNT (Week 1)	27.63 (5.77)	25.38 (7.06)	26.00 (7.24)	26.51 (6.61)
KNT (Week 2)	28.50 (3.43)	28.46 (3.09)	29.83 (0.91)	28.91 (2.83)
KNT (Week 3)	56.05 (14.06)	64.27 (17.52)	62.27 (12.71)	60.22 (14.98)
KNT (Week 5)	71.70 (16.21)	70.50 (19.78)	67.00 (17.27)	69.91 (17.49)
KFT (Post-test)	9.63 (1.33)	9.42 (1.63)	8.83 (2.15)	9.32 (1.72)

Table 2. Performance on differentlLearning outcomes over five weeks

	F	p-value	Power
KNT (Week 1)	1.035	0.359	0.337
KNT (Week 2)	2.415	0.095*	0.605
KNT (Week 3)	2.891	0.061*	0.677
KNT (Post-test)	0.634	0.532	0.246
KFT (Post-test)	1.913	0.153	0.517
OS (Post-test)	0.420	0.519	0.169

We took a closer look at the mean difference at the significance level of 0.05. The study used one-way ANCOVA to analyze the effects of behavior modeling approach on learning outcomes over different time. Levene's Test (1960) was used to examine the variance homogeneity of three groups. Its F-statistics showed that KNT was 3.04 (p=0.053) at Week1, 13.01 (p=0.000) at Week2, 1.71 (p=0.187) at Week3, and 0.47 (p=0.627) at the Post-test. In contrast, the F-statistics of Levene's Test for KFT and OS were 7.64 (p=0.001) and 1.75 (p=0.191) at the Post-test. With the exception of KNT at Week2 and KNF at the Post-test, all dependent variables met the $p > 0.05$ criterion for assuring homogeneity of variances. The heteroscedasticity of variances for these two exceptions suggested that the statistical test results may not be valid. As such, the following discussion will ignore these two variances and focus on KNT and OS. For other effects that show significance, the study adopts the Scheffe post-test to analyze data. In addition, Pearson Correlation Analysis was used to assess the carry-over effects of different training sessions.

ANCOVA was performed using the general linear model approach; the results are presented in Table 3. It shows that the treatment effects are significant for KNT (Week2) and KNT (Week3) with F-statistics of 2.415 (p=0.095) and 2.891 (p=0.061), confirming a univariate treatment effect of learning environments on the dependent variable: KNT. However, the treatment effects are not salient for other dependent variables: KFT and OS. These lacks of effect may have been due to small effect sizes.

Least-Squares Deconvolution (LSD) was used to test cross-correlations for KNT (Week2) and KNT (Week3). LSD is a cross-correlation technique for computing average profiles. LSD is very similar to most other cross-correlation techniques, though slightly more sophisticated in the sense that it cleans the crosscorrelation profile from the autocorrelation profile (Donati, 2003). For KNT (Week 2), the LSD results indicate that subjects in FBM perform better than

Table 3. Results for training methods

Variable	*Hypothesis*	*Result in Correct Direction?*	*Significant p-value? (n.s. - not significant)*
Week1	H1: FBM > ABM	F	n.s. (p=0.312)
	H2: FBM > SBM	T	n.s. (p=0.729)
	H3: SBM > ABM	F	n.s. (p=0.182)
Week2	H1: FBM > ABM	T	p=0.051
	H2: FBM > SBM	T	p = 0.069
	H3: SBM > ABM	T	n.s. (p=0.956)
Week3	H1: FBM > ABM	T	p=0.083
	H2: FBM > SBM	F	n.s. (p=0.612)
	H3: SBM > ABM	T	p = 0.029
Week4	H1: FBM > ABM	F	n.s. (p=2.71)
	H2: FBM > SBM	F	n.s. (p=0.459)
	H3: SBM > ABM	F	n.s. (p=0.787)
Post Test (KFT)	H4: FBM > ABM	F	p=0.057
	H5: FBM > SBM	F	n.s. (p=0.2)
	H6: SBM > ABM	F	n.s. (p=0.639)
Post Test (OS)	H7: SBM > ABM	F	n.s. (p=0.579)

those in ABM (p=0.051) and SBM (p=0.069). This supported the Hypotheses 1 and 2. However, Hypothesis 3 cannot be supported because the mean difference between ABM and SBM is not significant. For KNT (Week3), the LSD results indicate that (1) subjects in FBM performed better than those in ABM (p=0.083), and (2) subjects in SBM performed better than those in ABM (p=0.029). Hypotheses 4 and 6 are supported. Worthy to be noted is that H4 is upheld but in the reversed direction. This indicates that ABM is a more effective method than FBM at improving knowledge far transfer.

Four out of nine hypotheses in total are supported. Although not all hypothesized relationships are fully supported, the results obtained are interesting. The most intriguing result is that although there is statistically-justified reason for preferring FBM to ABM or SBM or software training, the pattern of results is not persistent in the long run. FBM resulted in better outcomes than ABM and SBM at Week2, and than ABM at Week3 for KNT. Although it never does so at a statistically significant level, subjects in ABM performed better than those in SBM, followed by those in FBM for KNT (Post-test) and KFT (Post-test). One interpretation of this is that either

ABM or SBM training is no worse than FBM training across all dependent variables. The pattern of results for FBM suggests that trainers might choose ABM or SBM, which should to be a less costly alternative to FBM, without making any significant sacrifices in either learning or trainee reaction outcomes.

Another result of interest is that, with respect to the three online asynchronous training methods, the pattern of results suggests that FBM might be the best for KNT in the short term. Of the nine hypotheses concerning relationships between these methods, four are in the expected direction, and significantly so. This indicates that use of ABM or SBM may be a better – and certainly no worse – software training strategy in the long term.

Implications for Research

This article studied the impact of training duration on performance and trainee reactions. Trainees were exposed to the same training methods with different degrees of social presence for different durations. These findings indicated that training duration and social presence have little impacts on learning outcomes. Despite this, the findings here raise additional questions for research.

It may be more important to investigate the impacts of information richness (Fulk, 1993) features of online training media on training outcomes. Future studies might vary the social presence features of training media or their combination with social presence features (e.g., with instructor's feedbacks versus discussion boards, e-mail response or playback features). Information richness may be a more influential factor affecting the performance of training approaches.

It may also be useful to replicate the experimental equivalence of FBM, ABM and SBM methods of software training with different software and subjects. Since in the long term different treatments have similar impacts on learning outcomes, it may be practical to demonstrate the cost-based advantage of ABM over SBM, and SBM over FBM for software training in practical settings.

Another way to improve the reliability of the study is to manipulate some useful blocking variables. A series of comparative studies can be conducted to assess the impact of individualism as a cultural characteristic, computer self-efficacy, task complexity (simple tasks vs. fuzzy tasks), professional backgrounds and the ratio of the training duration to the quantity of information to be processed, among others.

Learning style may be an important factor to consider in the online learning environment. According to social learning theory, learners interact with the learning environment to change their behavior. Learning style is situational and can vary with different learning environments. Therefore, it is possible that the combination of training methods, learning style and social presence information richness (SPIR) attributes may jointly determine learning outcomes. This is not the case for BM approach in F2F environment. The self-paced online learning environment may alter the assertion. Hence, it may be necessary to conduct longitudinal studies of the influence of learning style on learning performance and trainee reaction.

Implications for Practice

The largest implication for practice is that ABM and SBM may provide cost-effective substitutes for FBM without significant reductions in training outcomes in the long term. While it may still be true that FBM is still the most effective approach to improve KNT in the short term, ABM and SBM have similar leverage in KFT in the short term and KNT in the long term. Regardless of training environments, trainees have same satisfaction levels in the near- and long-term. These findings strongly indicate that the cost issue is more important than learning effectiveness. When given the options to decide which BM approach to take in the long term, nonperformance issues (teacher

and facility availability, trainee's preferences, location and convenience issues) have to be first taken into account.

CONCLUSION

The success of an online training strategy depends on its effectiveness in improving learning outcomes. This study, built on well-accepted frameworks for training research (Bostrom, Olfman & Sein, 1990; Simon & Werner 1996), examines the relative effectiveness of the behavior modeling approach in online synchronous, online asynchronous and face-to-face environments. The results from this experiment provide an empirical basis for the development of an online behavior modeling strategy: (1) FBM is more effective than ABM and SBM for knowledge transfer in the short term (KNT), and (2) ABM and SBM are as effective as FBM for knowledge transfer and overall satisfaction in the long term (KFT).

What is learned from this study can be summarized as follows: When conducting software training, it may be almost as effective to use online training (synchronous or asynchronous) as it is to use a more costly face-to-face training in the long term. In the short term face-to-face knowledge transfer model still seems to be the most effective approach to improve knowledge transfer in the short term.

The limitation of this experimental study is that it was conducted with a homogeneous group with Taiwanese cultural and educational backgrounds. Therefore, this study may be constrained with the generalizability of its findings to different cultural contexts.

Hofstede (1997) stated that the domains of education, management and organization have nurtured the values context that differs from one country to another. Cultural influences have been discerned in the study of Internet usage (Lederer, Maupin, Sena & Zhuang, 2000; Moon & Kim, 2001; Straub, 1997) and Web site design (Chu, 1999; Svastisinha, 1999). Users from different cultures have different perceptions about the usefulness and ease of use regarding different information systems (Straub, 1994). E-learning systems may differ based on the cultural backgrounds of the learners to improve their satisfaction levels and cognitive gains. Benefits of the congruence may include the improvement of (1) global e-learning adoption rate and (2) learning outcomes (attitude and cognitive gains). From the perspective of research design (Kerlinger & Lee, 2000), a cross-cultural study to replicate the study with American or European subjects may further validate and extend the generalizability of the findings.

The study has accomplished its major goal; it provides evidence as to the relative effectiveness of the behavior modeling approach in different learning environments for software training. This research somewhat improves the generalizability of theories on the behavior modeling approach in different learning environments.

ABSTRACT

Within the United States, the greatest job growth is in software engineering and information management. Open source software (OSS) is a major technology base for enterprise application development. The complexity of technologies used by industry is often an obstacle to their use in the classroom. In this chapter, a major software development paradigm change that occurred in about the year 2000 is explained. CS education programs have been slow to adapt to the paradigm change due to problems such as the tenure system, inexperienced student laboratory assistants, lack of leading-edge software tool support, lack of software team project servers, unavailability of help and mentoring services, and software unavailability. This chapter explains how these problems can be solved by creating an open source-based shared software infrastructure program (SSIP) sponsored by industry, but planned and implemented by SSIP member universities at no cost to member universities.

INTRODUCTION

Today students are saying no to computer science (Frauenheim, 2004). CS faculty members have panicked in what David Patterson (2005) calls Chicken Little rumor mongering. He tells everyone to stop whining about outsourcing. In our opinion, CS faculty should panic and adapt to a new software development paradigm. Pat-

terson makes an invalid implied assumption for his article in that CS in some way is related to information technology (IT) jobs in U.S. industry (or, for that matter, that CS is useful to a software engineer). He is correct to say that U.S. IT jobs are increasing. Also, software engineering (SE) degree programs and jobs are increasing. His domino theory of job migration is not correct. We agree with Patterson that U.S. programmers should worry about both India and China. We do not agree that either India or China will have to worry much about the Czech Republic. Both India and China have such large populations and low wages that major CS job migration will mainly be to these two countries. The middle processes of a software product development software life cycle (DSLC) may completely migrate from the United States.

Every Fortune 1000 company with which we are familiar takes advantage of low labor costs in India and/or China. Unfortunately for CS, approximately 80% of high-paying CS jobs in the past have been with Fortune 1000 companies. Jobs that will remain in the United States will go to students that are familiar with open standards, a wide variety of solutions including open source solutions, software development tools that support open standard visualization design models and open source integrated development environments. In this chapter, open standards will be defined as standards that are publicly available. The Object Management Group (OMG) (2006) is an example of an organization that was created to produce open standards. OMG is an open membership, not-for-profit consortium that produces and maintains computer industry open standards for interoperable enterprise applications. OMG membership includes virtually every large company in the computer industry and hundreds of smaller ones. OMG's most widely used standard is described by the unified modeling language (UML) specification. UML is used worldwide to model application structure, behavior, architecture, business process, and data structure. We use the term open source software (OSS) to refer to software that has Open Source Initiative (OSI) (2006) licenses. Examples of OSS are Linux, Apache, Eclipse, and Derby. We also include open-standard compliant software that is provided free for classroom use to universities. An example is IBM Rational Software Architect (RSA).

The objective of this chapter is to explain how leading-edge industrial-strength software can be introduced into the university classroom by using OSS, open standards, distance learning, and infrastructure shared among cooperating universities. In this chapter, we will describe the evolution of software development during the 20th century, the paradigm change at the beginning of the 21st century, and the problems with existing university information technology education. Then we will describe a shared software infrastructure program (SSIP) to rapidly introduce leading-edge industrial software solutions into university classrooms at no cost to SSIP member universities.

BACKGROUND

Software education emerged during the last 50 years of the 20th century. During the mid-1900s, computers were applied to create firing tables for the military. Scientists programmed these computers using computational algorithms. Computer memories were small and expensive, and successful software depended on efficient algorithms. As computer use grew, universities began to offer programming courses based on algorithm methodology. The application of mathematical science of algorithms to computers led to a new field called computer science. As demand for computer programmers grew, computer science programs at U.S. universities grew in number. U.S. universities had the computers, while universities outside the United States and Europe did not have access to computers. As the size and complexity of computer systems continued to grow, one could not rely on the theory of algorithms to provide

acceptable solutions. At a 1968 NATO conference in Europe (Naur & Randell, 1968), computer professionals realized that the software for major systems would have to be engineered based on engineering science and practice. That is when the term *software engineering* was introduced. In 1984, the U.S. Department of Defense created a Software Engineering Institute at Carnegie Mellon University (2006) to advance the practice of software engineering.

Throughout the 1990s, the cost of computers continued to decline, and the capabilities of computers increased. Computer cost was no longer a barrier to the spread of computer-related education programs to universities throughout the world. This has been aided by the creation and expansion of the World Wide Web (WWW) over the Internet.

Education Programs at the Beginning of the 21st Century

Computer-related educational programs at the beginning of the 21st century fall under the umbrella term information technology, which includes computer science, computer engineering, information management, and software engineering. Overall, the demand for information technology knowledge workers worldwide is increasing. The U.S. information technology education programs hit hardest by use of off-shore contractors are the science-based computer science programs. Enrollment in U.S. computer science programs is on the decline. These programs emphasize the middle or coding process of the DSLC. The coding process is the easiest to outsource from high labor cost regions to off-shore low-labor cost regions. All indications are that the computer science down trend will continue. Demand for computer engineering graduates remains strong. The fastest growing demand is for information management and software engineering graduates. Software engineering and information management programs teach students about all phases of the DSLC. The U.S. Department of Labor Statistics (2005) projects software engineers to be one of the fastest growing occupations through at least 2014. Major universities are beginning to offer software engineering certificates, bachelor degrees, and master degrees.

At the beginning of the new millennium, the outlook for software engineers is strong. Distance learning technology is becoming common. Software development is being practiced with project members distributed around the globe. Open source, open standards, and interoperable software are being demanded by customers. Software knowledge will continue to change and expand at a very rapid rate.

MAIN FOCUS OF THE CHAPTER

University Environments

At present, all students that come to the university are computer literate and have their own computers. Many already know how to program and are connected to the Internet. They are looking for software knowledge that will qualify them to find jobs in which they can create complex software products. They are not finding this software knowledge in most computer science (CS) departments.

We now return to David Patterson's problems. As the president of the Association for Computing Machinery (ACM), he has to be a cheerleader for CS faculty who run around yelling that the sky is falling. For most of the CS degree programs, the sky is falling. Many of the CS degree programs are in small liberal arts colleges and former teacher colleges. These schools do not have the technical background or faculty required to give students the software knowledge that will be provided by the increasing number of IT and SE degree programs. As CS job demands decline, CS programs will continue to shrink with the faculty having to face problems of dying programs unless they

adopt new methodologies to quickly introduce into classrooms the latest software knowledge required by industry

Woodie Flowers (2000), a mechanical engineering professor at MIT, recently asked, "Why should education change, we have been doing it this way for 4,000 years?" He said that over the next decade, educators will have to restructure their curricula in order to accommodate the World Wide Web. Change in the university moves at glacial speed. Software knowledge is continually expanding and growing much faster than the current education process can adapt to in order to meet the needs of industry. Ways must be found to upgrade software knowledge that is taught to IT professionals graduating from universities today.

The problem with education of the IT professional can be traced back to the first programmers. The first IT professionals were scientists and engineers who knew how to build and operate the first computers. Many programmers were mathematicians. When universities began to use computers in the 1950s and 1960s, engineering schools emphasized teaching hardware, science schools emphasized teaching programming languages, and business schools emphasized business applications. The science schools originally placed programming languages courses in mathematics departments. As time progressed, mathematicians teaching programming languages separated from the mathematics departments to create CS departments. Instead of teaching the latest software knowledge, the mathematicians began to teach what they knew best: computational mathematics and theory of algorithms. An algorithm is a procedure for solving a mathematical problem in a finite number of steps that frequently involves repetition of an operation (*Webster's new Collegiate Dictionary,* 1981). It can be shown that for any problems other than toy problems, it is impossible to prove that complex software products terminate in a finite number of steps. Thus, the time spent teaching theory of algorithms is time wasted. Tenured faculty members hired to teach mathematical algorithms will probably continue teaching algorithms until they retire. Since faculty members decide which young faculty members are hired and later tenured, they will probably continue to hire computational mathematics and algorithm specialists.

During the 1960s and 1970s, computers came into common use in industry. People with almost any background could be trained to operate the computer applications in industry. With the advent of the personal computer in the 1980s, the people familiar with computers continued to expand. With the commercialization of the Internet in the 1990s and the introduction of Internet browsers and computer games, virtually everyone below middle age used computers. Essentially every high school graduate that enters a university today has a computer that can be connected to the Internet. They learn how to program in high school and are usually familiar with some form of database management system. They learn how to access Internet servers through the use of browsers. If they would like to become an IT professional, they expect to learn the latest software knowledge that industry demands. CS departments that hire specialists in computational mathematics, theory of algorithms, and computational complexity theory will continue to lose students. Unless they change, CS departments probably will be absorbed eventually back into mathematics departments. By working with industry, university IT programs can teach the latest software knowledge to their students who will then be in high demand when they seek jobs in industry.

Year 2000 Productivity Paradigm Change

During the latter part of the 20th century, the demand for U.S. software developers continued to exceed the supply. During the 1950s, 1960s, 1970s, and 1980s, computer hardware was expensive and many developing countries could not

afford computers. Thus, if you wanted to become an IT professional, you almost had to study in the United States. As a result, virtually every university created CS degree programs that were advertised as the correct degree program for the IT professional. The result is a huge oversupply of PhD and Master's degree graduates who learned mathematics theory but obtained very little software knowledge. During the 1990s, computer costs continued to decline to where students and universities even in the poorest countries could afford computers. The *Wall Street Journal* pointed out that the auto worker salary in Germany was $33 per hour, while an auto worker in China earned $0.98 cents per hour. The salary differential for knowledge workers such as software developers is similar. Leading up to the year 2000 was the conversion of all legacy software in the United States to handle a four-digit year instead of a two-digit year built into existing software products. There were not enough experienced programmers in the United States to handle the demand for COBOL programmers. Companies turned to the software houses in India to help with the conversion. The large Fortune 1000 companies were very pleased with the results, and after 2000, they began to out source computer coding to offshore companies in India. Recently, the Chinese commercial software industry, although lagging behind India's, has been undergoing major structural shifts that could make it the Asian industry leader (Kshetri, 2005). Chinese developers are making a major commitment to OSS. Large U.S. companies are out-sourcing the middle processes of the DSLC, while the upstream requirements elicitation, requirements specification, and software architecture processes and downstream acceptance testing and software product installation will remain in the United States. CS educational programs emphasize the middle DSLC processes, while SE and information management programs emphasize the upstream and downstream DSLC processes. While the demand for IT workers in the United States is increasing, the demand for CS professionals is decreasing.

As mentioned earlier, CS faculty members have begun to panic and grasp for schemes to restore CS popularity. Former ACM President David Patterson (2005) suggests expanding student recruiting in high schools by ACM's new CS Teachers Association. He recognizes that software knowledge continually changes and places emphasis on keeping job skills up to date. Former ACM President Peter Deming along with Andrew McGettrick (Denning & McGettrick, 2005) point out that CS places too much emphasis on coding and not enough emphasis on other DSLC processes, including the use of advanced software tools to support requirements gathering, defect tracking, configuration management, middleware services, advanced software solutions, and software process visualization tools. They recognize that emphasis placed on analysis of algorithms and complexity theory as the heart and soul of computing is a mistake. Their solution is wrong. Recruiting of students is not the solution to declining enrollments. What is needed is emphasis on software knowledge that today's computer professional needs in order to be competitive in the global marketplace. A solution must be found to overcome the current problems with CS programs.

CS Education Program Problems

Major problems that must be corrected in order for CS graduates to be attractive to employers include tenure system, inexperienced laboratory assistants, software tool support, software team project servers, inadequate department support personnel, help and mentoring services, and available software.

The university tenure system is a type of union for university faculty. It is almost impossible to remove a tenured faculty member once tenure has been granted. Tenure empowers faculty but does not make them accountable. Tenured CS faculty

members who are specialists in computational mathematics and algorithms will remain faculty members for approximate 30 years between the time tenure is granted and retirement. In most cases, they will continue to teach computational mathematics and algorithm theory even though there is very little industrial or student interest in these areas. Also, these subject areas are unnecessary for an understanding of the software knowledge required by the IT professional.

In universities with major research programs, many of the funded graduate student teaching assistants that oversee laboratories for software team projects have never used any advanced software tools used in industry to create software products. Even though companies may provide these tools to universities at no cost, the laboratory assistants must understand them and be able to help and mentor student teams in project courses.

Many software products can be used directly out of the box. Software users expect to be able to load a new software system and then begin to immediately start using the system. Heavy-duty software tools are not out-of-the-box. To set up a software tool environment, a software tool administrator must create directories and security as well as initialize parameters in which the tools in an environment work together. The typical CS department does not have enough software support staff or funds to hire additional staff to administer a suite of advanced tools.

Student teams working on a capstone project to create a software product must have access to a server for testing the software product. Often student projects crash servers during testing and interfere with other people trying to use that same server. Software projects need a server as a type of sand box for operating their software product. Normally, CS departments do not have the resources to dedicate servers to student projects.

Many software vendors provide free training and use of software tools to universities. But they provide minimal help facilities to answer specific questions that arise while trying to use the tools. Students must be able to contact knowledgeable people who will answer their questions in a timely manner. When students are learning to use complex software design and testing tools, they would like access to a mentor to guide them. Ideally, help and mentoring services should be available 24 hours a day, seven days a week (24/7).

As part of students gaining software knowledge required by industry, students must have easy access to software products and tools. Many vendors will provide free software and licenses to universities. Acquiring the software and licenses to use the software can be a problem when universities are not paying for the software. There needs to be a service to expedite the process of acquiring software for classroom use at no cost to universities.

By helping universities to quickly introduce best software development practices, improved processes, and advanced software tools, students that graduate from these programs will gain software knowledge that is in high demand by industry. The goal of the SSIP is to set up an infrastructure shared among universities in which universities can easily introduce the latest leading software knowledge into both undergraduate and graduate classrooms without building a costly infrastructure at each university. Member universities will contribute software knowledge infrastructure to the SSIP and will use the SSIP as a resource to support their classes. Operation of the SSIP is supported by industry sponsors at no cost to universities. Eventually, the SSIP would like to provide infrastructure to every interested university in order to teach the latest leading-edge software knowledge to their students.

Shared Software Infrastructure Program (SSIP)

SSIP was created in spring 2005. Current industrial sponsors of the program are AVNET, IBM, and Intel. The program is sponsored by companies who share a vision of integrated information flow

within and among enterprises based on OSS, open standards, and global interoperability. The SSIP will support tools compliant with the OMG computer industry specifications for interoperable enterprise applications. Services provided by the SSIP will be determined by the member universities that use the SSIP Web site. Services and software will be provided to member universities at no cost to the universities. Costs of operating the SSIP and developing the infrastructure will be borne by sponsors.

Initial courses supported by the SSIP were capstone software engineering courses that had a software project in which teams of students develop a software product starting with the customer requirements and finishing with a demonstration of a working product. Students are introduced to a full set of computer-aided software engineering (CASE) tools. CASE tools were introduced across all phases of the DSLC. Each week a new tool with open was introduced. For each tool, the SSIP staff provided an overview, tool use examples, and online tutorials, and suggested assignments and a tool Web site. SSIP 34 Member Universities for fall 2006 include the following:

- Arizona State University, Tempe, Arizona
- Auburn University, Auburn, Alabama
- California State University, Los Angeles, California
- DePaul University, Chicago, Illinois
- Iowa State University, Ames, Iowa
- Louisiana State University, Baton Rouge, Louisiana
- Marquette University, Milwaukee, Wisconsin
- Mississippi State University, Mississippi State, Mississippi
- Neumont University, South Jordan, Utah
- North Carolina State University, Raleigh, North Carolina
- Pace University, New York City, New York
- Purdue University, West Lafayette, Indiana
- Queens University, Kingston, Canada
- Rutgers University, New Brunswick/Piscataway, New Jersey
- San Jose State University, San Jose, California
- Sacramento State University, Sacramento, California
- Southern Methodist University, Dallas, Texas
- Texas A&M International University, Laredo, Texas
- Texas A&M University, College Station, Texas
- Texas A&M-Corpus Christi, Corpus Christi, Texas
- Texas State University, San Marcos, Texas
- Texas Tech University, Lubbock, Texas
- University of Arizona, Tucson, Arizona
- University of Arkansas, Fayetteville, Arkansas
- University of California – San Diego, San Diego, California
- University of Houston -- Clear Lake, Houston, Texas
- University of Kentucky, Lexington, Kentucky
- University of Missouri – Rolla, Rolla, Missouri
- University of North Texas, Denton, Texas
- University of Oklahoma, Norman, Oklahoma
- University of Tennessee at Chattanooga, Chattanooga, Tennessee
- University of Tennessee at Knoxville, Knoxville, Tennessee
- University of Texas at Arlington, Arlington, Texas
- University of Texas at Dallas, Dallas, Texas

The current OSS tools supported by the SSIP for the software engineering capstone courses are the following:

- **Apache:** HTTP server and application server
- **CVS:** Configuration management system
- **Derby:** Database management system
- **Eclipse:** Platform for building an integrated development environment with plug-ins for tools
- **FireFox:** Web browser
- **Gantt Project:** Project planning software
- **Java:** With supporting tools
- **JRequire:** Requirements engineering tools
- **Linux:** Operating system
- **Tomcat:** Application server

At no cost to SSIP member universities, SSIP sponsors are very helpful in closing the information technology gap between software used by industry and software used in classrooms at universities. Avnet has agreed to provide computer server hardware, and Intel has agreed to support software and provide access to the Intel Software College (2006) where students can learn how to optimize and accelerate applications and to enhance software design, anticipate and address potential issues, and improve application performance. They also provide online courses as well as live and recorded Webcasts. IBM and IBM Rational provide computer servers, operational support, and the following software tools:

- **ClearCase:** Configuration management system
- **ClearQuest:** Defect tracking and change management system
- **DB2:** Database management system
- **ProjectConsole:** Visual project monitoring tool
- **PureCoverage:** Code coverage tool
- **Purify:** Automatic error detection tool for finding runtime errors and memory leaks
- **Quantify:** Performance analysis tool
- **RequisitePro:** Requirements tracking tool
- **Robot:** Automated functional regression testing tool
- **RSA:** Rational Software Architect visual modeling tool
- **SoDA:** Report generation tool that supports day-to-day reporting and formal documentation requirements
- **Test Manager:** Test management tool
- **Websphere:** Web server technologies
- **SSIP distributes content using the SSIP Web site located at the following URL:** http://ssi7.cs.tamu.edu/ssi/

For each software tool, the SSIP Web site contains a short tool overview describing the tool in terms easily understood by a student. There are also online tutorials for how to use the tool as part of the student team project. Use-cases are used to describe the relationship of the user to the sample application of the tool. Where available, a WWW link points to the tool Web site. New SSIP member universities are provided WWW linkages to course Web sites for courses that use SSIP content and services. The SSIP provides a user help service to answer questions about any of the tools. Where required, mentors are made available to provide one-on-one tool use help. SSIP servers are available for student project teams to test their project software products. SSIP user forums can be set up for member schools to discuss all aspects of introducing the latest software technology into classrooms.

Many of the CS education program problems are solved by using the SSIP. Students that come to the university today have their own personal client computer that can connect to the Internet. They can connect to computer servers for everything needed in a university curriculum. The SSIP has servers available to SSIP member universities to support member university courses. By using OSS and free software tools provided by industry, the latest software solutions used by industry can be introduced into classrooms at very little cost to the SSIP member university.

Tenured university faculty members who control the courses taught can reduce the time it takes to introduce into the classrooms the latest advanced software solutions used by industry. In the lecture part of a course, the faculty member introduces software development theory, practice, and processes. In the software project laboratory, tools used to support software development are introduced by distance learning through an SSIP Web site. Examples showing the use of each tool are provided. When additional assistance is required, the SSIP operates a help desk and can supply mentors.

The problem of inexperienced laboratory assistance is solved by SSIP supplying services in which students in the laboratory obtain all of the knowledge that is necessary to learn and effectively use software tools. As a result, laboratory assistants spend most of their time managing the student laboratory assignments and activities.

Software tools and support of the tools are provided through the SSIP Web site. The goal is to minimize the support staff that must be provided at the local university. The cost of development tools is minimized by use of OSS and by free software provided by industrial sponsors. Interoperability of applications developed by student software development teams is assured by emphasizing open standards.

Industry today is looking to hire students who know how to be a productive team member. Often universities are reluctant to let student projects use department computer servers shared with other applications for fear that the students will cause the servers to fail. Student project teams need a type of sand-box server on which the student team can build a software product. Sand-box computer servers are provided by the SSIP for use by SSIP member universities.

Help desks and mentoring services are expensive. Industry provides extensive help desk and mentoring services to their customers at great costs. Individual universities cannot afford to provide these infrastructure services to students for the wide variety of software tools needed to support team software development projects in order to create the latest software solutions. By member universities sharing these services, the SSIP can provide services to a large number of universities at a low cost to SSIP sponsors and at no cost to the universities. The SSIP can make these services available 24/7.

Without outside help, universities have difficulty making the latest software solutions available to the students in the classroom. Three barriers to availability are cost, training, and licensing. An SSIP goal is to solve the availability problem by providing open source or free software tools at no cost to SSIP member universities, software tool training classes by distance learning through the SSIP Web site, and free licensing to SSIP member universities.

The SSIP has been well received by member schools. Leading-edge software knowledge is being introduced into university classes at no cost to the university. We are very encouraged with the SSIP success to date. We plan to continue to take advantage of the existing environment in which every student has his or her own Internet-connected client computer on which the student can access the latest software knowledge content from Internet-connected SSIP servers.

CONCLUSION

With the beginning of the new millennium, software development is in a state of change. Low-cost client computers that can be interconnected by the Internet are available worldwide. Software development teams can be globally distributed around the world. OSS tools can be used to create infrastructures to help introduce industrial strength software into university classrooms. The latest software development process and practices along with open standards can help university students learn how to create enterprise-level interoperable software solutions. The SSIP is an example of how

universities working with industry can cooperate to share infrastructure to rapidly close the gap between advanced software technology used by industry and the software knowledge and skills taught in the classroom.

KEY TERMS

Capstone Project: Designed for students to synthesize and integrate knowledge acquired through course work and other learning experiences.

Computer-Aided Software Engineering (CASE) Tools: Software tools used to assist in the development and maintenance of software.

Development Software Life Cycle (DSLC): Includes the multiple phases during which defined information technology work products are created or modified as part of the software development process. The last phase of development occurs when the software product is placed into operation.

Interoperable Software: Software that operates with various kinds of software applications and systems by agreeing on a common method with which to communicate and exchange data with one another.

Open Source: Refers to software that has Open Source Initiative (OSI) (2006) licenses. Examples of open source software are Linux, Apache, Eclipse, Derby, and so forth. Also included is open standard compliant software that is provided free

to universities for classroom use. An example is IBM Rational Software Architect (RSA).

Open Standard: Refers to standards that are publicly available. The Object Management Group (OMG) (2006) is an example of an organization that was created to produce open standards.

Outsource: To send work that would normally be done by employees in a company to workers that are employed by an outside company.

Productivity Paradigm Change: The improvement of productivity by use of the Internet, clients and servers connected to the Internet, improved communication technologies, advanced software tools, and outsourcing to low-cost labor regions.

Shared Software Infrastructure Program (SSIP): The goal of SSIP is to set up an infrastructure shared among universities in which universities can easily introduce the latest leading software knowledge into both undergraduate and graduate classrooms without building costly infrastructure at each university.

Software Tool: A software product that software developers use to create, debug, or maintain software.

Chapter 4.11
The Migration of Public Administrations Towards Open Source Desktop Software:
Recommendations from Research and Validation through a Case Study

Kris Ven
University of Antwerp, Belgium

Dieter Van Nuffel
University of Antwerp, Belgium

Jan Verelst
University of Antwerp, Belgium

ABSTRACT

Several public administrations (PA) have expressed an increasing interest in open source software in the past few years and are currently migrating to open source software on the desktop. Given the large impact such a migration has on the organization, there is a need for learning from the experiences of previous migrations. In this chapter, we deduct a number of recommendations and lessons learned from previous research conducted on the migration of PAs to open source desktop software. Next, we describe a case study on the migration of the Brussels-Capital Region towards OpenOffice.org, and compare their experiences to these recommendations. In general, our results are quite consistent with previous findings, but also indicate that additional research is still required in order to create a set of best practices—based on empirical research—for the migration towards open source software on the desktop.

INTRODUCTION

In the past few years, open source software has become a viable solution for organizations, and is being increasingly adopted. This increased popularity has been enabled by the fact that open source vendors (e.g., RedHat and SUSE) and traditional software vendors (e.g., IBM and HP) provide reliable support for open source solutions. Studies indicate, however, that organizations are primarily using open source software for server applications (see e.g., Dedrick & West, 2003; Lundell, Lings, & Lindqvist, 2006; Ven & Verelst, 2006; Wichmann, 2002). This can be explained by at least two factors. First, open source software has a strong tradition in developing server-side applications. Given this background, most open source projects are situated in horizontal domains such as Internet applications, developer tools, and technical tools (Fitzgerald, 2005). Thanks to the maturity level of most well-known open source server software (e.g., Apache and Linux), these packages are widely diffused through organizations. Successful open source software for the desktop has surfaced only recently with applications such as OpenOffice.org, Mozilla Firefox, and Mozilla Thunderbird. Second, a migration towards open source software on servers is far less disruptive for members of an organization than a migration at the desktop. In case a Web server running Microsoft IIS is replaced by the Apache Web server, or the operating system for an ERP system is changed from Unix to Linux, end users in the organization will not (or hardly) be affected by this change. A migration from Microsoft Office to OpenOffice.org will, however, affect all end users in an organization, possibly even impacting productivity.

Recently, there has been an increased interest in migrations towards open source software on the desktop. Interestingly, this trend is primarily driven by public administrations (PA). In fact, PAs can be considered pioneers in the adoption of open source desktop software. At first sight, this is actually quite remarkable. In the past, it was frequently assumed that PAs are restricted by their organizational structure, and thus limited in their innovative behavior (Nye, 1999; Moon & Bretschneider, 2002). Other studies have found PAs to be surprisingly innovative with respect to certain innovations (Bretschneider & Wittmer, 1993; Moon & Bretschneider, 2002). The use of information technology is currently considered to be an opportunity for PAs to improve their efficiency, as illustrated by the large number of recent e-government initiatives. There are two important drivers for the adoption of open source desktop software in PAs. First, it has been suggested that PAs should be conscious of their IT expenses, to make efficient use of taxpayers' money (see e.g., Applewhite, 2003; Brink, Roos, Weller, & van Belle, 2006; Fitzgerald & Kenny, 2003; Waring & Maddocks, 2005). Since the license costs for open source software are either absent or at least lower than for proprietary software, open source software has often been touted as a means for reducing overall software expenses. Since the number of desktop licenses is far greater than the number of server licenses, cost savings on the desktop may be considerably larger. Second, some authors argue that PAs should use open standards in their communication with citizens, to avoid that citizens need to buy a commercial product for communicating with the PA (see e.g., Applewhite, 2003; Kovács, Drozdik, Zuliani, & Succi, 2004b; Rossi, Scotto, Sillitti, & Succi, 2005). Other reasons for the adoption of open source software by PAs include supporting the local economy, increased flexibility and avoiding vendor lock-in (see e.g., Drozdik, Kovács, & Kochis, 2005; Kovács et al., 2004b; tOSSad, 2006; Waring & Maddocks, 2005).

Notwithstanding the advantages that open source software can offer, the migration towards open source software on the desktop will be disruptive for most users within a PA. Hence, special attention should be paid to planning the migration in order to minimize discomfort and disruptions

for end users. Although the migration towards open source desktop software is a relatively new phenomenon, a number of academic studies have already described case studies of migrations of PAs towards open source software (mainly OpenOffice.org and Linux). As a result, some lessons can be learned from these migrations. Due to the exploratory nature of this research, results of these migrations are rather fragmented.

The purpose of this chapter is to integrate the recommendations from various studies on the migration of PAs towards open source software on the desktop. Subsequently, we will report on the migration of the Government of the Brussels-Capital Region towards OpenOffice.org and compare their approach to the recommendations made in previous reports. The chapter is structured as follows. First, we will provide a brief background on migrations undertaken by PAs in Europe, and the academic literature on this topic. Next, we will derive a number of recommendations with respect to the migration towards open source software on the desktop. In the fourth section, we will present the migration of the Brussels-Capital Region and compare our results to the recommendations made in previous research. Finally, we will discuss a number of implications for practice and research, and will offer our conclusions.

RELATED INITIATIVES AND STUDIES

Open standards and open source software are increasingly used by PAs in Europe. In fact, it has been suggested that PAs will be one of the driving forces behind open source software in Europe in the next few years (González-Barahona & Robles, 2005). Indeed, several initiatives for studying the adoption of open source software have been taken at different levels in the European administration (i.e., the European Community, national governments, regional governments, and municipalities). In fact, most European countries have initiated programs to study the advantages and drawbacks of open source software in the PA (Canonico, 2005; González-Barahona & Robles, 2005), or have created policies with respect to the use of open source software[1]. The interest of the European Commission (EC) in open source software dates back to 1999, when the European Working Group on Libre Software[2] was founded. Since then, there has been increased commitment from the EC to open source software. Most important in this regard is the IDA (Interchange of Data between Administrations) program, and its successor IDABC[3] (Interoperable Delivery of European eGovernment Services to public Administrations, Businesses and Citizens). The aim of the program is to develop cross-European e-government services towards citizens and businesses. As part of the IDA program, the eEurope 2005 Action Plan[4] was written. The document states that to ensure interoperability, open standards will be used in e-government services. Furthermore, the use of open source software will be encouraged. Today, the IDABC Web site offers much information on migrations towards open source software in PAs[5]. Similarly, several research projects on the adoption and use of open source software are funded by the EC (e.g., COSPA[6], FLOSSPOLS[7], Calibre[8] and tOSSad[9]).

In Europe, several PAs have already migrated—or are planning to migrate—to open source software, including on the desktop. Several migrations of PAs are known in Austria, the Czech Republic, Finland, France, Germany, Spain, the Netherlands, and the United Kingdom[10]. Although these national initiatives vary from country to country, many of the PAs seem to at least investigate the use of open source software (González-Barahona & Robles, 2005). An illustrative sample of these initiatives is listed in Table 1. Many other initiatives are however known, especially concerning the use of open source software on servers. An example of a famous successful migration is found in Extremadura in Spain. In order to increase the IT literacy in this region—but faced

Table 1. Migrations of public administrations towards open source desktop software

Country	Projects
Spain	*Extramadura region:* Project to increase connectivity and IT literacy of the region. A custom Linux distribution, gnuLinEx (http://www.linex.org), was created.
France	*Gendarmerie Nationale:* Migration towards OpenOffice.org and Mozilla Firefox on ± 80,000 desktops. *City of Paris:* Migration towards OpenOffice.org and Mozilla Firefox on 17,000 desktops.
The Netherlands	*City of Haarlem:* Migration of 2,000 desktops to OpenOffice.org. *City of Amsterdam:* Currently conducting pilots to investigate the feasibility of migrating towards OpenOffice.org. *City of Groningen:* Decided to migrate 3,650 desktops to OpenOffice.org.
Germany	*City of Munich:* Migration of 14,000 desktops to Linux.
Austria	*City of Vienna:* Migration of 7,500 desktops to OpenOffice.org and Linux. A custom Linux-distribution, Wienux (http://www.wien.gv.at/ma14/wienux.html), was created.

with a limited budget—it was decided to base the project on open source software. This resulted in the creation of a custom Linux distribution, called *gnuLinEx*. Originally, this distribution was intended for classroom use, but is used nowadays in PAs as well (Vaca, 2005). On the other hand, some of these migrations fail—or are delayed by various problems—as illustrated with the migration of the city of Munich[11] in Germany.

Several academic studies have been devoted to investigating the difficulties encountered in migrating towards open source software on the desktop and to obtaining an overview of the use of open source software by PAs. An overview of these studies is shown in Table 2. Most of these studies have used a qualitative, case study-based approach to study the migration of various public administrations. Their aim was to investigate the feasibility of the transition, describe the migration itself, and to highlight any difficulties experienced during the transition, as well as recommend solutions. Some authors have combined the qualitative approach with an experiment to investigate the usage patterns of OpenOffice.org in comparison with Microsoft (MS) Office, to provide quantitative data on the migration (Rossi et al., 2005; Rossi, Russo, & Succi, 2006).

An important study in this field is the recent FLOSSPOLS study (Ghosh & Glott, 2005), that conducted a large-scale survey among 955 PAs in 13 European countries. The study provides insight into the perceived advantages of and barriers to the use of open source software. The study also provides an overview of the extent and type of open source software that is being used by European PAs. Results show that 49% of PAs intentionally use open source software. Interestingly, many PAs seem to be unaware of their use of open source software. In about 29% of the cases, open source software is being used without the respondent being aware of the fact that the software is open source. Results further show that half of the respondents would find an increase in open source software usage useful. The use of open source software is still mainly focused on servers, with only about 20% of the organizations using OpenOffice.org to some degree (Ghosh & Glott, 2005). The use of open source software on the desktop seems, however, to be somewhat higher than three years earlier, as reported by the first FLOSS study (Wichmann, 2002). This study showed that only 6.9% of PAs and businesses used open source software on the desktop[12] (Wichmann, 2002).

Table 2. Studies on the adoption of open source software by public administrations

Study	Research design
Wichmann (2002)	Large-scale survey as part of the FLOSS project to study the use of open source software in organizations and PAs in Germany, UK, and Sweden.
Russo et al. (2003)	Presents the results of a trial migration performed by the Province of Bolzano-Bozen (Italy) in 10 local PAs.
Fitzgerald and Kenny (2003)	Describes the migration of an Irish (public sector) hospital towards open source software.
Zuliani and Succi (2004b)	Reports on some lessons learned on the migration towards OpenOffice.org of 60 PAs in the Province of Bolzano-Bozen (Italy).
Kovács et al. (2004b); Kovács, Drozdik, Zuliani, and Succi (2004a)	Presents an overview of the advantages and challenges in migrating towards open standards and open source software in the PA.
Zuliani and Succi (2004a)	Provides the results of a migration towards OpenOffice.org of 60 PAs in Bolzano-Bozen (Italy).
Ghosh and Glott (2005)	Follow-up survey of the FLOSS project, investigating the use of open source software in PAs in 13 European countries.
Drozdik et al. (2005)	Investigates the risks involved in migrating desktops completely to open source software (i.e., OpenOffice.org and Linux), based on a PA in Törökbálint (Hungary).
Rossi et al. (2005)	Reports on an experiment on the transition from MS Office to OpenOffice.org, studying the use of OpenOffice.org throughout 32 weeks.
Waring and Maddocks (2005)	Reports on advantages and disadvantages of open source software for the UK public sector, including the results of eight case studies.
COSPA (2005)	Reports on the experiences of the migrations in seven European PAs, conducted as part of the COSPA project.
Rossi et al. (2006)	Reports on an experiment in a PA to compare the use of MS Office and OpenOffice.org documents after migrating towards OpenOffice.org.
Brink et al. (2006)	Reports on three case studies in South African organizations who have migrated towards open source software on the desktop. Two of the cases are situated in the public sector.
Jashari and Stojanovski (2006)	Survey of 14 municipalities in Macedonia to highlight the challenges and obstacles to use open source software.

RECOMMENDATIONS FROM PREVIOUS LITERATURE

The studies that are described in the previous section, have provided more insight into the migration process that was followed by a number of PAs. Potential adopters of open source software can draw important lessons from these studies to avoid running into the same problems that previous migrations already handled effectively. Unfortunately, given the exploratory nature of this research, the literature on this topic is rather fragmented. Few attempts have been made to integrate these results, although the COSPA and tOSSad projects are currently working towards this. Hence, our aim is to integrate the results from the currently available empirical literature, to provide a comprehensive overview of the recommendations and "*lessons learned*" from previous migrations.

Although ideally we would like to present a number of guidelines or best practices, we feel that this is currently not yet feasible because of a number of reasons. First, this type of research is

Table 3. Recommendations and lessons learned from previous research

1. Analysis and Preparation

(a) Planning

- Prepare well for the migration by performing proper analysis and planning (Brink et al., 2006).
- Make a detailed business case for the migration, including the expected cost (IDA, 2003).
- Cost is (one of) the most important reasons for migrating to open source software (Zuliani & Succi, 2004a; Brink et al., 2006; COSPA, 2005; Fitzgerald & Kenny, 2003; Waring & Maddocks, 2005).
- The migration will however imply important switching costs (e.g., training and migration), which may become a barrier (Drozdik et al., 2005; Kovács et al., 2004b, 2004a; Waring & Maddocks, 2005; IDA, 2003).
- Consequently, the real cost savings (if present at all) are difficult to quantify (Drozdik et al., 2005; Russo et al., 2003; Wichmann, 2002; COSPA, 2005).
- Other factors such as quality and productivity may also be important (Zuliani & Succi, 2004a).

(b) Pilot Study

- The use of a pilot study is recommended (IDA, 2003; Brink et al., 2006).

2. Migrating towards Open Source Software

(a) Pace of Migration

- A "big bang" approach should be avoided since it increases the risk of the migration (IDA, 2003).
- When migrating to a fully open source desktop on Linux, users should first be migrated to open source desktop software such as OpenOffice.org and Mozilla on MS Windows. In a second phase, MS Windows can be replaced by Linux (COSPA, 2005; Drozdik et al., 2005).
- When replacing MS Office by OpenOffice.org, there should be a transition phase in which users have access to both office suites to lower user resistance (Zuliani & Succi, 2004b; Zuliani & Succi, 2004a; COSPA, 2005). On the other hand, users are then likely to expect the same behavior from OpenOffice.org as from MS Office (Drozdik et al., 2005).

(b) Top Management Support

- Top management support has been found to be critical during deployment (Brink et al., 2006; Fitzgerald & Kenny, 2003).

(c) Attitude of End Users

- It is important to create a positive attitude with end users before the migration, since personnel resistance is the most important issue in the migration (Drozdik et al., 2005; Rossi et al., 2005; Zuliani & Succi, 2004b, 2004a).
- Personnel may perceive the transition negatively if they are satisfied with the current application that they may be using at home as well (Russo et al., 2003; COSPA, 2005).
- It is important to consult and communicate with users in order to minimize discomfort for users (Drozdik et al., 2005; IDA, 2003).
- Users may fear becoming "deskilled" in using a non-industry standard, thereby decreasing their value on the labor market (IDA, 2003; Fitzgerald & Kenny, 2003).

3. Training

- Although users with a good knowledge of MS Office tend to experience few problems with the transition to OpenOffice.org (Kovács et al., 2004b; Kovács et al., 2004a; Russo et al., 2003), it is important that employees receive proper training to improve user acceptance (Rossi et al., 2005; Brink et al., 2006; IDA, 2003; COSPA, 2005; Kovács et al., 2004b, 2004a).
- Training is also important because some functions in OpenOffice.org behave differently than in MS Office or have different names (Jashari & Stojanovski, 2006; COSPA, 2005; Drozdik et al., 2005).
- Training should immediately precede (or follow) the migration, so that users can start practicing their skills in OpenOffice.org (Zuliani & Succi, 2004b; Zuliani & Succi, 2004a; COSPA, 2005).
- Training should focus on generic capabilities in office productivity, i.e., functionalities that are used each day (Russo et al., 2003; COSPA, 2005).
- The training approach can vary, e.g., face-to-face training, interactive tutorials over the Intranet and seminars (Russo et al., 2003; Brink et al., 2006).

continued on the following page

Table 3. continued

4. Support

- A lack of external support for assisting in the migration can be a barrier, if the required knowledge is not available in-house (Kovács et al., 2004b; Kovács et al., 2004a; Jashari & Stojanovski, 2006).
- It is important that users have access to several kinds of support, e.g., knowledge bases containing FAQs, guides, and manuals; access to telephone and e-mail support; and access to a contact person (e.g., a product champion) in case of questions (Zuliani & Succi, 2004b; Zuliani & Succi, 2004a; Brink et al., 2006; IDA, 2003).

5. Document Conversion

- The conversion of OpenOffice.org documents from and to MS Office format does not cause many issues in most cases, although some incompatibilities may occur (e.g., wrong image size or margin settings) (COSPA, 2005; Drozdik et al., 2005; Russo et al., 2003).
- However, when using complex documents with precise formatting or MS Office macros, conversion may become a very labor-intensive task, and conversion incompatibilities may arise, especially if these files are frequently converted from MS Office to OpenOffice.org format and vice versa (COSPA, 2005; Zuliani & Succi, 2004b, 2004a; Drozdik et al., 2005).

6. Functionality

- Perceptions towards the functionality offered by OpenOffice.org tend to vary. Some users report that OpenOffice.org offers the same functionality as MS Office (Rossi et al., 2005; COSPA, 2005), while other users complain about missing features (Rossi et al., 2005).
- In general, the functionalities of OpenOffice.org seem more than adequate for daily use, and a migration is possible with no or few problems (Zuliani & Succi, 2004b; Rossi et al., 2005; COSPA, 2005).
- It should be noted, however, that depending on the use of OpenOffice.org, specific issues may arise (e.g., mail merge feature, and differences in hard and soft line breaks) (Zuliani & Succi, 2004a; COSPA, 2005).
- Interoperability and compatibility with existing systems (e.g., databases and desktop applications) can be a problem in certain situations (Kovács et al., 2004b; Kovács et al., 2004a; Zuliani & Succi, 2004a).

still exploratory, and there are still many variations in the adoption processes followed and in the context in which the migration takes place, leading to a more or less—depending on the situation—successful migration. Second, and more importantly, the studies that are currently available are not likely to be representative for all PAs. Studies in this domain tend not to report how the cases in their sample were chosen. Hence, the possibility cannot be excluded that the cases were selected out of practical considerations (e.g., having access to the site), rather than based on their theoretical relevance. Consequently, the lessons learned that are presented here should be considered preliminary, and the results of future studies should be contrasted with this set of recommendations.

Based upon previous studies, we derived a set of recommendations and lessons learned in a number of different areas. This set was derived as follows: first, the literature was searched for studies on the adoption of open source desktop software by PAs. We restricted our search to empirical studies in academic literature, discussing the experiences and results from migrations in PAs. We also chose to include the *IDA Open Source Migration Guidelines* (IDA, 2003) in the literature study. Although this is not an academic study, it was one of the first studies to provide recommendations on how PAs should migrate towards open source software. It has been reported, however, that these guidelines are not very often used in practice (Zuliani & Succi, 2004a). The studies included in this literature study are listed in Table 2. Next, the studies were analyzed by one of the authors and any lessons learned or recommendations were coded in the text. The initial coding categories were based on several aspects related to a migration process that are commonly known to be relevant (e.g., training, analysis, and

document conversion). Coding was flexible and opportunistic, adding new categories when they were encountered. This initial list of lessons learned was subsequently reviewed, and data were further integrated as necessary. The revised list was then reviewed by a second author and some additions were applied as required. The result of this analysis is shown in Table 3. In total, six different areas regarding the transition were identified, namely *analysis and preparation*, *migration*, *training*, *support*, *document conversion*, and *functionality*. Each area contains a number of recommendations and lessons learned from previous research.

CASE STUDY IN THE BRUSSELS PA

In this section, we will present the results of a case study on the migration of the Government of the Brussels-Capital Region in Belgium. The Brussels-Capital Region consists of the 19 municipalities of Brussels. The Government of the Brussels-Capital Region consists of eight Ministries, each having its own cabinet. The *Brussels Regional Informatics Center (BRIC)*, responsible for the promotion and assistance of information technology (IT) within the Government of the Brussels-Capital Region, was responsible for organizing the transition towards OpenOffice.org. Our aim is to compare the approach taken by BRIC to the list of lessons learned that was compiled in the previous section. Due to space limitations, we will focus exclusively on the areas present in Table 3.

Methodology

A descriptive case study approach was used to study the transition towards OpenOffice.org at the Government of the Brussels-Capital Region. The case study approach allowed us to study the phenomenon in its real-life context (Benbasat, Goldstein, & Mead, 1987; Yin, 2003). An embedded case study design was used in order to investigate the migration towards OpenOffice.org at BRIC as well as at the ministerial cabinets of the Brussels-Capital Region. Using the key informant method, we selected two informants within BRIC, since the use of a single informant may lead to unreliable results (Benbasat et al., 1987; Phillips, 1981). Our informants were the director of the IT department and the project leader who was assigned to the OpenOffice.org project. Both informants were highly involved in the migration towards OpenOffice.org, and were responsible for planning and coordinating the migration, developing documentation, designing the training sessions, and conducting user evaluations.

The primary mode of data collection consisted of two face-to-face interviews which were conducted by a two-person team. During the first interview, important background information on the transition was gathered. Based on this information, the case study protocol was completed, leading to the generation of a detailed set of questions. During the second interview, detailed information on the migration was gathered from our informants. This interview was digitally recorded for future reference. One researcher of the team was primarily responsible for posing the interview questions, while the other was responsible for taking notes and supplementing the interview with additional questions. Using different roles for each researcher also allowed us to view the case from two perspectives and to compare the impressions of both researchers afterwards (Eisenhardt, 1989; Yin, 2003). Additional sources of evidence were internal documents of BRIC, legislative texts, and secondary information such as press releases. Extensive follow-up questions on the interview and recent developments took place via e-mail. A draft copy of the case study report, as well as a draft of this chapter, was reviewed by our informants to increase the validity of our findings.

Findings

Analysis and Preparation

Planning

The migration to OpenOffice.org in the Brussels PA was driven by two political decisions. First, a resolution was voted in which the use of open standards and open source software was encouraged by the Brussels-Capital Region in order to facilitate communication with its citizens. Consequently, BRIC was required to consider at least one open source alternative in each new project. Second, following this resolution, the coalition agreement of the Brussels-Capital Region in 2004 also stated that the use of open standards and open source software would be encouraged within the Brussels-Capital Region. Based upon this coalition agreement, the Government of the Brussels-Capital Region decided that open source office software would be used by the ministerial cabinets of the Brussels-Capital Region. OpenOffice.org was, however, not mentioned by name at that time. The migration involved installing OpenOffice.org 1.1 on 400 workstations running on MS Windows XP. In addition, four out of eight servers of the ministerial cabinets were migrated from MS Windows to Linux.

Preceding the migration, no formal TCO analysis was carried out. Although the main argument for migrating towards OpenOffice.org was to facilitate communication with citizens, cost savings realized by the migration were also stressed, especially in public announcements. License costs were cut back by 185,000 EUR during the first year and 15,000 EUR in the subsequent years (when a limited number of remaining workstations will be migrated). On the other hand, our informants confirmed that significant hidden costs of training and support occurred. Unfortunately, it was not possible to accurately quantify these hidden costs.

Pilot Study

To verify the feasibility of a transition from MS Office to OpenOffice.org, BRIC performed a pilot project in March 2004. This pilot consisted of migrating the workstations of BRIC personnel to OpenOffice.org. The outcome of the pilot project confirmed the feasibility of migrating the ministerial cabinets. As soon as OpenOffice.org 2.0 was available, BRIC again executed an internal pilot study. In contrast to the prior pilot, the aim was not only to prepare the upgrade towards OpenOffice.org 2.0, but also to enable BRIC to market the new version towards end users. They therefore invited the key users of each cabinet (i.e., the cabinet clerk and the local IT responsible) to participate in the pilot. Based on these experiences and significant improvements of OpenOffice.org 2.0 in comparison with version 1.1, it was decided in December 2005 to upgrade the ministerial cabinets to OpenOffice.org 2.0.

Migrating Towards Open Source Software

Pace of Migration

As a new Government of the Brussels-Capital Region is elected every five years, the computer equipment of the ministerial cabinets is updated simultaneously. Because of efficiency reasons, and to minimize discomfort for end users, BRIC decided to have the migration towards OpenOffice.org 1.1 coincide with the replacement of the PCs. When the user's workstation was replaced, only OpenOffice.org was installed and MS Office was no longer available to the user, except in a limited number of cases in which the user required advanced functionality of MS Excel or MS Access (e.g., in the finance department). Concurrently, the default data format for internal communication changed from MS Office to OpenOffice.org format. This change did not pose any insur-

mountable problems thanks to the import/export filters of OpenOffice.org. These filters enabled opening and saving previously existing MS Office documents, or MS Office documents that are sent from and to external users.

The decision to use a "big bang" approach was motivated by a number of reasons. First, BRIC judged that it would be more manageable to instantaneously switch to OpenOffice.org without temporarily installing MS Office. Furthermore, it was expected that users with an initial negative attitude towards OpenOffice.org would continue using MS Office as long as it was still available on their workstation. Finally, by changing the default document format to OpenOffice.org, BRIC wanted to encourage staff members to use OpenOffice.org.

Top Management Support

Top management support has frequently been shown to be positively related to the acquisition and successful implementation of new technologies (see e.g., DeLone, 1988; Rai & Patnayakuni, 1996). As already mentioned, the migration to OpenOffice.org was mandatory since it was a political decision. Therefore, top management (i.e., the Government of the Brussels-Capital Region) was formally supporting the migration. Given that the migration was mandated by law, BRIC was endowed with a powerful mandate while performing the migration. This helped in countering possible user resistance. It should be noted that some cabinet clerks were not in favor of the migration towards OpenOffice.org. It is likely that they have had an impact on the attitudes of end users. Unfortunately, it was not possible to empirically confirm this hypothesis.

Attitude of End Users

Within the ministerial cabinets, it could be observed that users who showed an initial negative attitude towards OpenOffice.org, remained rather skeptical. This fact confirms the importance of training and providing users with adequate information before migration takes place. The fear of becoming "deskilled" (Fitzgerald & Kenny, 2003) did not seem to have occurred. According to our informants, end users articulated no concerns about moving away from the industry standard, possibly reducing their value in the job market.

Training

According to the recommendations from previous literature, users should be able to start practicing with OpenOffice.org immediately after training. However, this was not always possible because of the narrow time frame in which the migration took place. Nevertheless, all users obtained their training within one week before or after their workstation was migrated.

The training consisted of a voluntary training course in the offices of BRIC and a CD-ROM. During the course, the basic functionality of OpenOffice.org Writer and Calc was explained. The first sessions of this course were intended for the key users of the different cabinets to enable them to provide first-line support to their users. Representatives of two out of eight ministerial cabinets found the training too basic, and did not encourage members of their cabinet to attend the training sessions. Afterwards, a survey among end users indicated that users who did not attend the course reported more problems in using OpenOffice.org.

It was observed that people tried to work in the same manner as they were used to in MS Office. This is however not always possible because some functions in OpenOffice.org are fundamentally different from their MS Office counterpart. Therefore, short personal demonstrations were organized during which BRIC personnel illustrated the procedure to be used in OpenOffice.org.

Although the general training session proved to be useful, BRIC noticed that additional, focused

training sessions would be required following the upgrade to OpenOffice.org 2.0, due to functional differences with OpenOffice.org 1.1. These sessions will be organized as short workshops: each session will focus on a particular functionality that different groups of end users require (e.g., using the Mail Merge feature or working with document templates). The workshops will also be more practically oriented than the initial training sessions.

Support

Three important sources of support are available to end users in the ministerial cabinets. First-line support for common problems can be provided by the key users in each cabinet. Second, BRIC itself provides end user support for OpenOffice.org. Third, during the pilot study and training, BRIC employees have built an extensive knowledge base on OpenOffice.org. This knowledge base—which is regularly updated by new questions formulated by end users—is sufficient to solve most problems.

Part of the knowledge base consists of a CD-ROM containing a manual, a FAQ list and the OpenOffice.org installation files. This CD-ROM was handed out to the participants of the training session. The manual and FAQ list were based on the documentation provided by the OpenOffice.org communities. However, since the Brussels-Capital Region is bilingual (with Dutch and French being the official languages), documentation had to be sourced from two different OpenOffice.org localization communities. It then became apparent that significant differences in quality between these online communities exist. While the French community is very vivid and provides much information, the Dutch counterpart does not produce the same quantity of documentation. This did lead to some difficulties, since BRIC is required to provide (equivalent) training material in both languages. Another indication of the difference between the French and Dutch community are delays in the release of upgrades. For both OpenOffice.org 1.1 and 2.0, the French localization was available much earlier than the Dutch version. This has been criticized by some end users as a disadvantage of working with open source software.

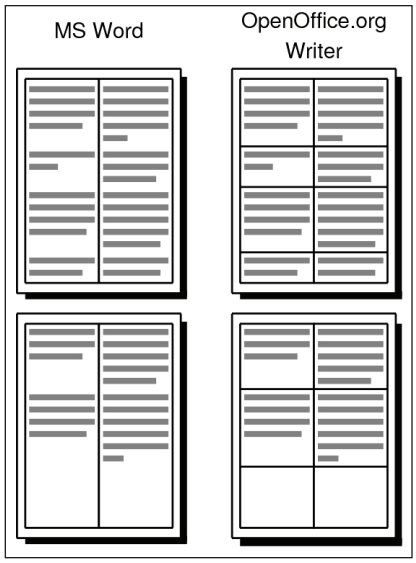
Document Conversion

In general, few problems concerning document conversion between MS Office and OpenOffice.org were reported. However, in three specific cases, some issues did occur. First, difficulties arose when documents with extensive and complex layout were exchanged with external parties. When these documents were converted several times back and forth between OpenOffice.org and MS Office format, incompatibilities in layout became unmanageable. As a result, it was decided to exchange documents without formatting as long as they needed revision. Once the final version of the document had been approved, the formatting was done either in OpenOffice.org or in MS Office. The use of the PDF-format was also promoted for documents requiring no further revisions.

Secondly, the conversion of MS Office document templates to OpenOffice.org posed some problems, mainly because a number of incompatibilities exist between the two products, for instance, with respect to margin settings. Since the Brussels PA has a very rigorous style guide, these templates had to be migrated very accurately. As a result, BRIC only recently finalized the OpenOffice.org templates.

A third issue, concerning the editing of legislative texts, was again caused by very specific format prescriptions. Since the Brussels-Capital Region is bilingual, these texts have to be published in two columns, one for each language. Moreover, each paragraph has to start on the same height as the corresponding paragraph in the other language. Given that French paragraphs are somewhat lengthier than the Dutch equivalents,

Figure 1. Formatting of legislative texts in MS Office vs. OpenOffice.org



some adjustments in vertical spacing between paragraphs must be made (see Figure 1). In MS Word this layout was realized by using a table with two columns and one row. OpenOffice.org 1.1, however, did not support multi-page table cells. Hence, the layout had to be changed by putting each paragraph in a different cell. When a cell does not fit on a single page, it is moved automatically to the next page. In OpenOffice.org 2.0 this workaround has become obsolete, since it is possible to use multi-page rows in the new version[13].

Functionality

Regarding functionality, several remarks can be made. First, a number of end users did not consider OpenOffice.org a fully fledged alternative to MS Office. This was mainly caused by the absence of certain features which are present in MS Office. The fact that MS Excel and MS Access are still used by a limited number of users, confirms that OpenOffice.org does not yet support all advanced features of MS Office. On the other hand, most users do not experience any problems in their daily tasks.

Furthermore, users reported problems concerning the Mail Merge feature. When using this feature to create a mailing based on an address list in a database, OpenOffice.org creates a new document for each addressee. To solve this issue, a script was developed to merge the separate files into one document. In OpenOffice.org 2.0, however, this problem does not occur anymore because the user can choose whether to generate one large file or to generate separate documents. It is therefore hoped that the improved functionality of OpenOffice.org 2.0 will enhance the perceived quality of OpenOffice.org by end users. Nevertheless, a number of deficiencies are still reported by users working with OpenOffice.org 2.0. Although workarounds are possible for most of these problems, these defects still have a negative impact on the general perception of OpenOffice.org.

The use of data sources by OpenOffice.org is considered to be a mixed advantage and disadvantage. In contrast to MS Office, OpenOffice.org allows a document to access more than one data source. The implementation of these data sources is, however, significantly different from MS Office: while in MS Office the data source is included in the document itself, OpenOffice.org stores it in the user profile at the user's workstation. Thus, when exchanging the document between users, the data source is lost. To solve this problem, BRIC wrote a script to ensure that each user has access to the commonly used data sources.

The perceived usability of OpenOffice.org 1.1 is also reported to be inferior compared to MS Office. The most often heard critique is that the look and feel of OpenOffice.org 1.1 feels outdated. Again, OpenOffice.org 2.0 could provide a solution because its look and feel has been updated considerably to resemble that of MS Office.

Discussion

In general, the findings in this case study are consistent with the experiences and recommendations from previous literature. The case study illustrated that a migration towards OpenOffice.org was possible within the Government of the Brussels-Capital Region. Nevertheless, the case study also confirms that there are a number of important issues that should be paid attention to when planning and performing the migration.

Following the recommendations from previous literature, it can be observed that the documentation available and training given to end users are very important. With respect to training, the case study showed that in a first phase, the training can focus on general office suite capabilities applied to OpenOffice.org. Therefore, it serves as a revision course of skills that are also applicable to MS Office. This is consistent with recommendations made in previous literature (see, e.g., COSPA, 2005; Russo, Zuliani, & Succi, 2003). In a second phase, however, it seemed useful to offer short, focused training sessions on particular tasks in working with OpenOffice.org. Both training and documentation can positively influence the attitude of end users. While the resistance of end users is frequently a major problem (Rossi, et al., 2005; Zuliani & Succi, 2004b), we feel that in this case the acceptance was facilitated not only by strong top management support, but also by the fact that the adoption of OpenOffice.org was mandated by law, giving end users no choice but to conform with the transition. In terms of interoperability, the document conversion facilities of OpenOffice.org seemed to be sufficient in most cases (COSPA, 2005; Russo et al., 2003). However, advanced use of OpenOffice.org, or specific applications (e.g., bilingual legislative texts) may lead to certain issues (COSPA, 2005; Zuliani & Succi, 2004a). Conducting a pilot test may help in identifying potential issues that arise during implementation within the specific context in which the migration will take place. Although the decision to start using OpenOffice.org was primarily politically motivated, there was an emphasis on the cost savings realized by the transition. It must be noted, however, that considerable effort was invested in developing appropriate training, documentation, and document templates.

One important difference with previous studies is that the "big bang" approach taken by BRIC did seem successful. Previous studies have recommended that a transition phase is planned in which MS Office and OpenOffice.org are installed concurrently on the users' workstation (COSPA, 2005; Zuliani & Succi, 2004a, 2004b). Based on the present study, we feel that there are situations in which MS Office can be replaced immediately with OpenOffice.org. While the transition period enables users to continue using MS Office in case they experience problems with OpenOffice.org, the immediate migration towards OpenOffice.org forces users to start using (and learning) OpenOffice.org. By having to rely solely on OpenOffice.org to complete office productivity tasks, users might become familiar more quickly with the functionality of OpenOffice.org, shortening the learning period. It also encourages users to start adopting the preferred OpenOffice.org methods, instead of trying to work with OpenOffice.org in the same way as with MS Office (Drozdik, et al., 2005). Therefore, we feel a "big bang" migration from MS Office to OpenOffice.org is feasible in certain situations. On the other hand, if a PA would decide to replace the MS Windows desktop with Linux desktops, it seems better to use a phased approach, as recommended in previous studies (COSPA, 2005; Drozdik, et al., 2005) (see also Table 3).

IMPLICATIONS

This study has a number of implications for both practice as well as research.

Implications for Practice

Several PAs have already decided to migrate towards open source software based solutions or have already completed their migration. It is likely that, thanks to the encouragement of open standards and open source software by the European Commission, many other PAs will also decide to migrate to open source software. The results of currently ongoing research projects such as COSPA, FLOSSPOLS, and tOSSad will probably further help PAs to decide on the possible risks and advantages. The lessons learned identified in this chapter should serve as a first step towards developing research-based best practices for the adoption of open source software on the desktop. The presented overview can be of help to PAs contemplating a migration. It will assist in identifying possible barriers or issues that should be anticipated in the project to avoid difficulties during implementation. As a result, PAs can learn from previous efforts of early adopters. We believe that by promoting the sharing of experiences of such migrations, future migrations can be handled more effectively (both in time and financially).

Based on available research, we believe that a migration towards open source software on the desktop is possible, but is contingent on the specific environment in which the migration will take place. If the PA is using advanced features of MS Office (e.g., the extensive use of macros), or when interoperability with existing systems and applications is important (e.g., database servers, or proprietary tools written for MS Office), it will be more difficult to migrate. Although workarounds can be devised, this will imply additional costs, and productivity may be negatively affected. We believe, however, that as more organizations and PAs decide to start using open standards and open source software, software vendors will be more likely to provide interoperability with open source solutions[14].

When the use of MS Office is mainly restricted to basic functionality—which seems to be the case in most PAs currently studied in literature—the functionality of OpenOffice.org should suffice in most cases. Nevertheless, PAs should consider the issues raised in this chapter, and sufficient attention should be paid to areas such as planning, training, and support. Moreover, PAs should be aware that specific requirements in their environments may lead to a number of issues that were not previously encountered. For example, due to the bilingualism in the Brussels PA, the implementation of tables in OpenOffice.org resulted in changing the way documents were formatted. This implied altering the daily work habits of end users, which may prove to be very difficult. Hence, having top management support—and possibly a product champion—may be required to ensure that new working practices are adopted. Furthermore, the use of a pilot study may help in encountering issues in the daily work habits of employees that need to be resolved before migrating.

Our results may also be relevant to the open source community. Results from previous studies, as well as the current study, indicate that one of the main drivers for a migration towards open source software is cost reduction. This is consistent with literature on the organizational adoption of open source software, which has shown that the lower or non-existing license costs of open source software is a major reason influencing the adoption decision (see e.g., Dedrick & West, 2003; Ven & Verelst, 2006). This is in contrast with the attitude of the open source community that tries to downplay the cost advantages, and tends to emphasize other advantages such as having access to the source code of the application, and being allowed to modify it. Studies in this field may offer the open source community a better insight into the perceptions of organizations and PAs, since it has been noted that the open source

community in general has limited access to the opinion of its customers (Fitzgerald, 2005). A more profound insight into the main motivations of adopters of open source software may lead the open source community (and especially the open source vendors) to emphasize different advantages of open source software. Similarly, open source communities (especially projects such as OpenOffice.org and Mozilla) may also try to actively solicit feedback from PAs in order to include missing features and further improve functionality.

Implications for Research

This study has a number of limitations. First, given the fact that the migration of PAs towards open source software on the desktop is a new phenomenon, relatively little research has been devoted to studying the migration process. Consequently, our lessons learned are based on the limited amount of studies that were available at the time of writing. Furthermore, it is difficult to assess the representativeness of these studies. Second, we compared the lessons learned with a single case study in the Brussels PA. Hence, the external validity of this study cannot be ascertained, and we therefore cannot generalize our results to all PAs. Future research can therefore study additional migrations that can be compared to the issues raised in this chapter. By incorporating additional findings from different contexts, a set of research-based best practices for the adoption of open source software on the desktop may be deducted. These may further help clarifying the factors that influence a successful migration. This study should be considered a first step in this direction.

Another interesting avenue for further research is to investigate to which degree the migration process in PAs is different from the process in enterprises. For example, PAs may be better suited to motivate—or force—their users to make the migration succeed. In the case of the Brussels PA, the migration towards OpenOffice.org was mandated by law, making it very difficult to resist this change. It is likely that enterprises are not capable of supporting the migration in such a strong way. Second, it is possible that enterprises generally make more advanced use of MS Office, or use it in a more complex environment, making the migration more difficult.

CONCLUSION

There has been an increased interest in open source software by PAs in the past few years. Some authors expect that this trend will continue in the following years, making PAs a driving force behind open source software in Europe (González-Barahona & Robles, 2005). Lately, much attention has been given to migrations towards open source software on the desktop. Given the apparent success of several attempts in this direction, we expect that PAs will continue to consider these migrations in the future. However, given the fact that a migration towards open source software on the desktop is quite disruptive for end users, it is important that guidelines are available. The recommendations deducted from previous research that are listed in this chapter can be considered a first step in this direction. By comparing the lessons learned from previous migrations to a case in the Brussels PA, it was noted that, in general, there was a good match between the literature and the current case. Due to the specific context of the case, we were able to highlight a few issues that may be of interest for future adopters. Furthermore, we feel that it is important to conduct additional case studies on the migration towards open source software and compare the results to the recommendations described in this chapter. This way, the recommendations will be based on a substantial body of knowledge, leading to a set of best practices for the migration towards open source software on the desktop.

9. http://www.tossad.org
10. See IDABC "open source case studies" (http://ec.europa.eu/idabc/en/chapter/470) and news (http://ec.europa.eu/idabc/en/chapter/491).
11. http://www.muenchen.de/Rathaus/referate/dir/limux/89256/
12. It must be noted that the results of these two studies cannot be directly compared. The first FLOSS study included commercial businesses as well as PAs, and included subjects from only 3 European countries.
13. The workaround is however still used, since it is a better approach for formatting these documents.
14. Actually, at the time of writing, Microsoft has announced its support to an independent open source project, developing an ODF plug-in (Open Document Format) for MS Word 2007 (http://odf-converter.sourceforge.net). Coincidently, this announcement was issued a number of days after the Belgian government announced that it would start using the ODF-format exclusively from September 2008. Other governments (e.g., the state of Massachusetts) have announced similar initiatives, or are studying them.

This work was previously published in Emerging Free and Open Source Software Practices, edited by S. Sowe, I. Stamelos and I. Samoladas, pp. 191-214, copyright 2007 by IGI Publishing (an imprint of IGI Global).

Chapter 4.12
Issues and Aspects of Open Source Software Usage and Adoption in the Public Sector

Gabor Laszlo
Budapest Tech, Hungary

ABSTRACT

This chapter introduces L-PEST model as the proposed tool for better understanding the fields are influenced by motivations and adaptation policy on FLOSS of public authorities and governments. Software usage in the public sector is a highly complex topic. In the confines of this chapter the selected case studies will show consideration to the vastly different needs and capacities and the different approaches and motivations towards the utilization of FLOSS by governments and/or local authorities. The primary objective of this chapter is to identify and describe the actors associated to the usage of FLOSS within and by the public sector. This chapter has made an attempt to fill this research gap and place the different actors into one complex model. It is hoped the proposed model assists better clarifying the intricate relationship between relevant factors. Nevertheless, much more research work is needed in the years to come. According to Michel Sapin, French Minister in charge of Public Administration and e-Government (2001), "The next generation e-government has two requirements: interoperability and transparency. These are the two strengths of open source software. Therefore, I am taking little risk when I predict that open source software will take a crucial part in the development of e-Government in the years to come."

INTRODUCTION

The digital economy transforms governments and governments took on new roles in those areas of the economy most affected by technological changes. Governments play important roles in creating the proper environment for ICT development, and also have a significant leading role as users of these technologies by creating new modes of public's behavior. Governmental functions and

operations can be managed only by the extensive use of ICTs and by using software applications (Lanvin, 2003).

The world's largest consumers of computer software are usually governments and they thus can have considerable influence on the software market. Governmental usage of software can impact on virtually all aspects of civil life: the inclusion and participation of citizens in public life, the transparency and openness of decision making, and the elimination of the digital divide, digital persistence, and digital literacy. The question of which software is utilized by public administrations is, therefore, of fundamental importance. Free Software advocate Eben Moglen has said, "Who controls the software, controls life."[1]

In the early days of computing the common software model was based on the open source model. Software and hardware were often combined in a single package. The software was usually traded in the form of source code and computer users have shared their computer code. Many important early programs, also with government funding, were widely shared (Bessen, 2002).

Then, the late 1970s and early 1980s with the appearance the consumer computing saw the beginning of the commercialization of software products based on the proprietary model. The software that operates the hardware has become as important as the hardware itself.

A significant difference between open source and proprietary software is that the open source (as it is called) software source code is freely available to the user. In contrast, the proprietary software vendors release their product only in binary form and it is illegal for end users to decompile the binary machine code to usable source code.

Free/libre open source software (or FLOSS as it is commonly referred to) has gained enormous momentum all over the world. While this movement has been closely followed with attention by many advocates and practitioners, academic research on the subject has only started emerging. These research projects have focused mainly on individual motivations, knowledge sharing and the user communities themselves.

The primary objective of this chapter is to identify and describe the factors related to the usage of open source software within and by the public sector.

To achieve this objective, background is given on the discussion about government roles and policies towards open source software, as in the selected case studies.

One of the strengths of this chapter is that it presents a theoretical framework, a general model of software usage at large within the public sector and the identified factors assigned to global perspectives.

BACKGROUND

ICTs have the capacity to play a valuable role in improving the quality of life, particularly in health, education, agriculture, and the environment. To take one example, in the healthcare sector ICTs enable the implementation of tele-health programs in remote areas, allowing some health care to be provided remotely, independent of person-to-person contact. Further, improvements in medical equipment are also a result of advances in ICTs. In education, remote access to the knowledge bases, e-libraries and even e-learning systems and universities can deliver knowledge to rural areas, where such opportunities for learning would be unavailable without ICTs. Agriculture and environmental issues can be better managed by, for example, geographic information system (GIS) and weather forecasts.

However, at the same time, there exists the so-called digital divide, an umbrella term that is commonly understood to mean the gap between ICT *haves* and *have-nots*. Generally, the approach to the question of the capacity of ICT to increase standards of living and to that of the digital divide has focused on two main issues.[2] One focuses mainly on actual connectivity—infrastructure

and access. Another approach beyond connectivity is to consider the level of the ICT literacy and skills of a particular population and as well, consequently take into consideration political and social cohesion aspects.

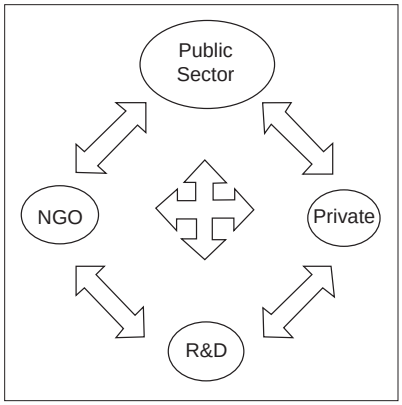
An improved economy can not alone eliminate the gap, so governmental "intervention" is a prerequisite for overcoming the digital gap. Today, governments, businesses, international groups, and nongovernmental organizations (NGOs) have undertaken numerous initiatives aimed at eliminating this digital divide (http://www.bridges.org/digital_divide). These initiatives have targeted not just the consequences of economic differences between countries and peoples and the relevant differences in access to technologies, but also the cultural capacity and political will necessary to apply these technologies for effective development. A nation's intellectual capital and capacity for innovation are based on its human capital, which is why it is so important for governments to make steps to strengthen the equality.

Wilson pointed to a four-sided social formation—a Quad—that has emerged at the heart of the still-inchoate knowledge society. "Conceptually 'quad' refers to persistent four-sided networked interactions of small groups of elites across four sectors of the political economy—government, private sector, research centers, and NGOs" (Wilson, 2003, p. 6).

The Quad theory predicts causal relationships between the architecture of the Quad and the subsequent performance of the ICT sector. The more robust the architecture of the Quad, the better performance of the ICT sector as a whole. The architecture and dynamics of the Quad relationships are different in every country and change time to time.

As a member and part of the Quad, the government has a special obligation to protect the integrity, confidentiality and accessibility of public information, to protect the privacy of its citizens, to educate the "next generation", to create jobs, and to preserve and make available the national heritage (also in electronic format) for the public and for the next generation. Other important roles for the governments are to make the country competitive in the globalized marketplace, and to carefully manage the budget (Stanco, 2003).

Figure 1. The Quad (Source: Used with permission by E. J. Wilson)



METHODOLOGY

This chapter provides an inductive general conceptual model—based on known and publicly available strategy documentation of various public sector and government initiatives for promoting or using FLOSS. The selection of key factors is grounded in available research literature on FLOSS and the above mentioned documentation and case studies.

OPEN GOVERNMENT

The average citizen has limited access to important government records, and what is available is often incomprehensible. An open government must be transparent and accountable and information related to the decisions an open

government makes must be open to the public and freely available. Access to government and public information is regulated by law in many countries. Perrit states:

Freedom of information issues are centrally important in countries around the world, and the Internet's World Wide Web offers the potential to provide freedom of information at low cost. Achieving a sound information policy to promote open government requires constant vigilance by those who care about the goal. (Perrit, 1997, p. 397)

In the aftermath of 9/11 the relationship between IT, governments and their citizens has dramatically and radically changed. Security has become the most important factor. Yet, in the face of increased demands for security, for many within societies, the demands of privacy and trust remain paramount, thus giving rise to conflict between governments and their citizenry. Governments make greater efforts based on anti-terrorism legislation[3] to monitor their citizens' activities, while simultaneously citizens demand a greater ability to monitor the activities of his or her government.

INITIATIVES FOR FLOSS IN GOVERNMENT WORK

E-government work and what is commonly understood as general government work are now too closely intertwined to be realistically separated. At the same time, public administrations have special functions and operations which cannot be adequately handled with proprietary software applications on the market that are developed for multiple purposes (Stanco, 2003). The moderate opinions which stress that there is no need to make a choice between FLOSS and proprietary software vendors gather ground but the feasible solution is mixing these software.

It seems likely that all governments use FLOSS applications on some level, with or without open source label—though perhaps without deliberate policy. Whereas many governments have policies or consideration towards FLOSS usage, the motivations may vary from cost reduction to security or dependency issues and within the broader context of policies to support such issues as equity or education. However, FLOSS policies and legislation as developed by national, regional or local governments around the World (USA, Canada, Australia, many countries in Africa or in Europe) are more often than not inadequate to support the viable realization of such policy goals.

The Center for Strategic & International Studies (2004) maintains—Government Open Source Policies—a list of such initiatives that were approved or proposed. This section highlights different approaches of adaptation and policy considerations for the implementation of FLOSS.

European Union

In the recent years many open source-related programs have been launched by the European Union. Fields of development of FLOSS within the EU include security, interoperability and e-participation. The software usage and the interaction between different systems is a complex approach. Interoperability is one of the key factors. One early Commission Working paper stressed the need for interoperability of program for public administration across the EU. It states that the proposed interoperability framework "will be based on open standards and encourage the use of open source software." "Interoperability, therefore, for both the public and enterprise sectors, is at the heart of the eEurope 2005 Action Plan and the achievement of the Lisbon goals" (Linking up Europe, 2003, p. 5).

In the European Union, the public sector were advised to avoid proprietary document formats, known as lock-in. Using the open standards would assure the desired interoperability and open stan-

dards would more greatly be supported by open source software. Using interoperable systems would guarantee equality among the citizens using different kind software applications (Promotion of Open Document Exchange Format, 2003).

On the other hand, notwithstanding the above-mentioned initiatives, the relationship between governments and open source is not unambiguous.

Extremadura

Extremadura was the poorest region of Spain, lagging behind the rest of the country in both the economic and technological field. Though short on financial resources, the region set very high goals for itself in its Regional Strategy on Information Society in 1997. The policy lay "in the application of technological innovation for the promotion of freedom and equal opportunities, taking advantage of and putting at the disposal of everyone, what is nobody's property: the knowledge gathered by Humanity all through History." Two formal strategic objectives were put forth: "Accessibility for all—the Internet as a public service" and "The stimulation of technological literacy."

Given the combination of Extremadura's strategic goals and the limited financial resources available, the use of FLOSS was a logical choice. The LinEx project, a combination of "Linux" and "Extremadura," was born of these strategic initiatives. The objective of the Linex project was to create a fully functional platform, based on FLOSS, providing universal access of IS tools to all citizens. While doing so, its aim was to provide adaptability, economic benefits, and security to as great a degree as possible, without losing sight of actual feasibility. LinEx is specifically designed for use in regional administration and schools. Early on in the project, it was decided that LinEx would not innovate the software itself, but rather concentrate on localization of the software and take care of the distribution. To avoid technical problems during the initial phase of the project, a Spanish company was hired. The region's government ships the resulting software for free to all of its citizens.

Extremadura was also simultaneously funding a development center whose task was to create accounting software, hospital applications and agricultural applications (IDABC, 2003).

Munich

Coming after the switch to Linux in the servers of the Bundestag in 2002, Germany's interior minister signed an agreement with IBM to offer the German government offices deep discounts on computer systems based on Linux (IBM signs Linux deal with Germany, 2002). Soon afterward, Germany's third largest city government, Munich, commissioned Client Study for the State Capital Munich (UNILOG Integrata, 2003) comparing the alternatives and assigning 6,218 (out of 10,000) points to a Linux/OpenOffice migration, versus 5,293 to an upgrade of Microsoft Windows. Based on this study the Munich municipal government made a decision to adopt for their computer systems open source software. The Council of Munich voted on May 2003 in favour of the adoption for its desktop and notebook computers an open source operating system and office applications. This move, unprecedented in scale in the European public sector, has been widely commented upon and discussed since then.

Following a test phase conducted in cooperation with SuSE Linux and IBM, the Council formally adopted on June 16, 2004 detailed plans to manage the migration process, which is expected to last until 2009. According to the plan the migration was to be gradual, starting in 2004 with office desktop applications (OpenOffice.org office suite and Mozilla Web browser running on the existing Windows NT desktops), and then moving to operating systems and more specialized applications over a period of five years. The municipal government of Munich released a statement in September 2005 that the completion

of migration phase one, scheduled to be completed in 2005, had been pushed back to at least 2006. The reasons were that Novell Inc. announced in late 2003 the acquisition of SuSE and meanwhile legal problems regarding a proposed EU patent law. The chosen new Linux distribution was the Debian (Grassmuck, 2005).

USA

The most famous report concerning FLOSS usage within the Department of Defense (DOD) was released in 2003. "The goals of the study are to develop as complete a listing as possible of FOSS applications used in the DoD, and to collect representative examples of how those applications are being used." Over a two-week period the survey identified a total of 115 FLOSS (in the report named as FOSS) applications and 251 examples of their use. "The main conclusion of the analysis was that FOSS software plays a more critical role in the DoD than has generally been recognized. FOSS applications are most important in four broad areas: Infrastructure Support, Software Development, Security, and Research" (The MITRE Corporation, 2003, p. 2).

The Commonwealth of Massachusetts launched a new policy regarding the planning, development, and implementation of IT systems. "The goal of the Commonwealth's open initiatives is to ensure that investments in information technology result in systems that are sufficiently interoperable to meet the business requirements of its agencies and to effectively serve its constituencies" (Open Initiatives of Massachusetts, n.d.). The Massachusetts case illustrates the technology based considerations concerning software usage.

Brazil

The Government National Institute of Information Technology is charged with implementing open source software in Brazil. They released the first strategy planning document in 2003.

On the surface, the decision of the Brazilian government was a simple cost cutting measure. According to the National Information Technology Institute, Brazilians spend $1.1 billion every year on software licensing fees, and the federal government was the nation's biggest customer. The government is paying around $500 to Microsoft for license fees for every workstation. The government accounted for 6% of Microsoft's 2003 Brazilian revenues of $318 million. Switching to FLOSS would save millions of dollars (Kim, 2005). The decision to migrate to open source software on a national scale was not simply a matter of choosing one product over another. Although the Brazilian government identified economic reasons to migrate to open source software, it was a political decision that validated open source software as a movement. Through numerous open source projects, the government has tried to bridge the technology divide within the Brazilian population. While in the European Union the research experts recommend free software licenses for software deriving from public funds, Brazil has become the first country to require any company or research institute that receives government financing for the development of software to license it as open-source, meaning the underlying software code must be free to all (Benson, 2005).

Peru

Peru passed a law encouraging the procurement of free software by the government in September 2005. The bill was originally introduced in 2002. A Peruvian congressman stated in his letter to Microsoft: "The basic principles which inspire the bill are linked to the basic guarantees of a state of law, such as: the free access to public information by the citizen; the permanence of public data; the security of the state and citizens" (Greene, 2002). This bill has as its aim to establish measures and policies which will permit the acquisition of software licenses by the public administration under

conditions of technology neutrality, and the free concurrence and equal treatment of suppliers. The technical evaluation of the software and hardware required by the public administration will be according regulations dictated by the National Informatic System governing body. The bill offers an excellent summary of the idea of neutral software usage: "The entity will ensure that the procurement answers to the principles of effectiveness and technological neutrality, transparency, efficiency, within the boundaries of austerity and economizing of public resources" (Peruvian bill translation, 2005). One essential item included in the bill also stress the need for the education of the employees and users of computer and IT technology.

South Africa

One of the best-known case studies concerns the South African government's official strategy for FLOSS. This was one of the first strategies, that officially recognized the legitimacy of the adoption of FLOSS within the public sector. The South African strategy highlights that "the government will implement OSS, where analysis shows it to be the appropriate option. The primary criteria for selecting software solutions will remain the improvement of efficiency, effectiveness and economy of service delivered by the government to its citizens" (Using Open Source Software in the South African Government, 2003, p. 24). One of the main strengthens of this strategy is the appreciation of the social benefits that could include, but are not limited to, better education, greater governmental transparency, more effective e-government services, and wider access to governmental information.

China

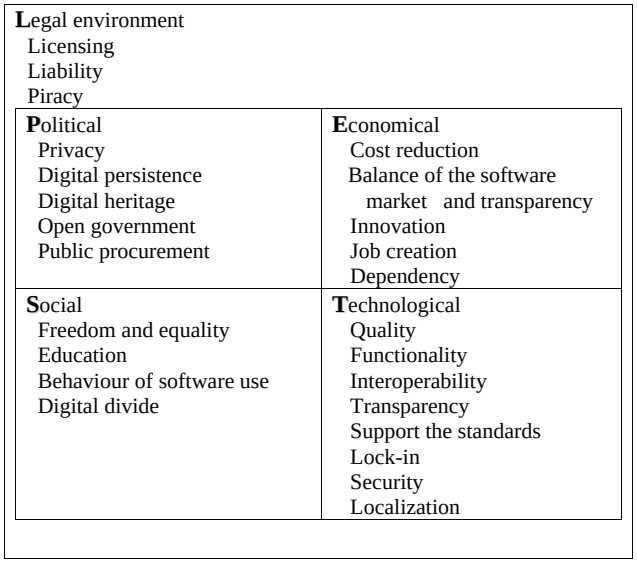
China has been very aggressively promoting Linux. The military has been one of the earliest adopters of Linux. The Red Flag Linux was designed for use in government offices, schools and on home computers. Red Flag Linux, a Beijing-based provider of Linux software and services, is connected to the Chinese Academy of Sciences, the central government's top research institute. The main reasons for the adoption of Linux were political and the desire for independency from Microsoft (Einhorn, 2003). Membership in the World Trade Organization (WTO) and access to its benefits are strongly affected by the level of protection given to intellectual property rights in a country (Wong, 2004). According the Piracy Study (BSA, 2005), in the country there is a high frequency of pirated software. Since China became a full member of the World Trade Organization, the government has been trying to reduce software piracy within its country. This is another strong reason why government agencies and business are currently adopting the Linux operating system on their desktop workplaces.

L-PEST MODEL

As is shown in the above selected case studies there are many different approaches around the world to using FLOSS within the public sector. In this section a general model is introduced. The L-PEST model is a theoretical creation. The idea of the model reaches back to IDABC "The Many Aspects of Open Source" (n.d.) material. The original text summarized some of the various reasons for choosing different organizations of FLOSS. This idea was then extended, modified, and put into a model based on the research by the author. The author's proposed L-PEST model can give a broader picture as to the aspects of software usage in the public sector. With further and ongoing work, it can be applied to all kinds of software as a comprehensive tool.

The key factors were derived from motivations of governments within their environments, which were revealed in the case studies. The five key actors of the model—as shown on Figure 2—are:

Figure 2. L-PEST model



political, economic, social, and technical and all around these fields the legal environment can be founded. This structure maps real life.

Every actor has its own attributes, however in some cases there are attributes with different meanings. In this case, when an attribute could be assigned to more than one field it was put into the most characteristic actor (e.g., lock-in which is based on the technical elements may well also influence the economical aspect, or transparency has quite a different meaning in economics than in technology).

Legal Environment

The legal environment surrounds the model because it has an effect on the other four factors. It has own attributes as well. The constitution determines the framework activity of the country; the law determines the operation of society, while the economy is influenced by the law of economics. Acts regulate and ensure competition, and technology is also regulated by industrial law (including, patents, trademark, and copyright law).

Copyright is the most usual method of protection for software products. The copyright automatically and implicitly protects all intellectual creation, including computer software.[4] "The copyright laws, by default, do not allow for redistribution (nor even use) of software. The only way that redistribution can be done is by granting specific permission in a license (Working group on Libre Software, 2000, pp. 20-21). A license is a contract between the user and the licensor. The licensing model of about FLOSS differs from the proprietary software, but is based on same idea. In fact, open source licenses are also enforceable because they use, in one form or another, copyright law. Most open source licenses were designed according to the United States law. Open source (OSS) licenses are more permissive than free software (FS) licenses.[5]

One of the main threats for open source may be software patents—which are not currently

common outside of the USA—but efforts to introduce them are in progress worldwide, usually lobbied for by large multinational corporations. The issue of software patents[6] divides even the governments of countries and the parliaments within them, as can be seen in many cases in Europe. On the other hand, many companies which have huge software patent portfolios in the USA, such as IBM and Novell, open numerous of their owned patents and put them at the OSS developing community's disposal. At the same time, many companies adopt and encourage OSS policy and business model.

Liability means that the software producers are responsible for their own products, warranties, and indemnifications. In reality almost all kinds of software, even the proprietary kind, are shipped on an "AS IS" basis, which means that the producer wriggles out of any kind of responsibility. In many countries, legislation does not allow the exclusion or limitation of this kind of liability.

Software piracy is a problem all around the globe and it can hurt a country in many ways. A country with poor protection for intellectual property rights is not as attractive to foreign investors. This is the reason why China, since joining the World Trade Organization (which strongly defends and pursues intellectual property rights protection), has made enormous efforts to reduce the prevalence of piracy within its borders. In a developing country, piracy is much more prevalent than in the industrialized nations; however, the greater dollar losses are incurred in the latter situation (BSA, 2005).

Political Aspects

The political aspect is related to government's function and roles. They may be distinguished between such roles as promoting social justice and functions such as tax collection (Lanvin, 2003). The government's role ensures the viable environment for ICT development and also the ICTs for Development. This can be summarized as a National Information Strategy that was well defined by the Library and Information Association of New Zealand:

A National Information Strategy addresses strategic issues to ensure that all citizens have the opportunity to access and utilize a nation's knowledge wealth in a way that will enhance the social, political and economic well-being of that country. It states the government position on the creation, management and use of information, and sets direction for government action in support of the strategic goals. (LIANZA, 2002, p. 7)

A national information strategy can be defined in terms of political planning or political action planning for development.

Privacy is a key factor in the interaction between governments and citizens. Whatever software is utilized by governments to control, manage and transmit the citizenry's personal data must be transparent in order to protect the citizen's right to privacy (Stanco, 2003). For example, an e-voting system without transparency leaves organizations and governments at the mercy of software providers.

The preservation of digital heritage and digital content has become a major challenge for society.

Digital persistence means continued accessibility to the stored content, even as the technology is changed—in this case for the governments' and public administrations' documentation. (It also preserves the original documents, in the case of national heritage.) It is in close relation with lock-in and dependency that it will be introduced. The secretary of administration and finance of the Commonwealth of Massachusetts, stated:

Our public policy focus is to insure that public records remain independent of underlying systems and applications, insuring their accessibility over very long periods of time. In the IT business a long period of time is about 18 months. In government

it's over 300 years, so we have a slightly different perspective. (Kriss, 2005)

Economic Aspects

Within the scope of this chapter only several issues can be highlighted. Governments sometimes need to undertake intervention into the market on behalf of common good. A high degree of market transparency can result in disintermediation due to the buyer's increased knowledge of supply pricing. Transparency is important since it is one of the theoretical conditions, which reaches back to Adam Smith's invisible hands theory, required for a free market to be efficient. Consequently, it may well be true, that the government should not intervene in the free market except to assure neutrality and a level playing field for all types of software. The governments should to be assuring the neutral decision on software and public procurement and choices on software products should be made objectively, flexibly, and with a focus on a range of factors.

One of the primary economic concerns is the cost of software usage. Total cost of ownership (TCO) shows the real cost of software utilization. The purchased software will usually remain the property of the supplier; the consumer pays for the right to use the software. Total costs need be divided into two main categories, direct and indirect costs. The measurement is difficult because the indirect costs are extremely difficult to assess and measure (Wheeler, 2005). Another approach to the issue of value and cost can be to focus on the examination of return on investments (ROI). Both methods are extremely sensitive to the set of assumptions made by the individual or group taking the measure.

Research and development (R&D) and other innovation are more important than ever before. In their role as a member of the Quad (see Figure 1), governments should undertake to stimulate innovation. The economic benefits of such stimulation, as in the case of job creation, for example, are well known. There are numerous arguments that R&D that is financed through public funding should be released under FLOSS license. This kind of license supports the sharing of scientific results and dissemination of created information and value—and "there is not need to reinvent the wheel." Many FLOSS licenses are business friendly (Wong, 2004).

One of the major arguments in favor of FLOSS is concern over the issue of dependency; that is, the public becomes reliant on software suppliers. In many instances, there are painfully few options as to software vendors. Beyond the issue of economic costs incurred from near monopoly, the question of dependency also speaks to the issues of security and privacy protection.

Social Aspects

The ICTs have a huge potential to make life better, despite the consequences of the so-called digital divide. The dual societal pursuits of freedom and equality are furthered via the ability of citizens to access the information and services of national and municipal governments. The goal of open, transparent government is dependent upon ever-greater access that ICTs offer. Meanwhile, the choices governments make as regards open or proprietary software, and the value they place on either, act as an example to the public, as well as reflecting the governments' position vis-à-vis issues such as privacy and security.

Education, of course, also greatly impacts on the economic development and potential of a country. Governments, of course, play a major role in creating a proper environment for education. Digital literacy and elimination the digital divide are close correlation with education. In educational systems there are two major expenses related to software: in using proprietary software, schools must buy licenses for every single computer that uses the software, while at the same time, the school has to ensure the possibility that students do not abuse its use after the class.

Many NGOs are not able to afford commercial, non-pirated software. This is a compelling reason to seriously consider FLOSS as a viable option for NGOs. An excellent example of the benefits of open source is the "Human Rights Tool" open source software named Martus (http://www.martus.org/). The developer uses the new model of social entrepreneurship, which combines market forces with philanthropic capital and entrepreneurial drive. Social entrepreneurship as a focus of academic research has a relatively brief history and as yet no research has been made on the connection with FLOSS communities and businesses.

Technical Aspects

The measurable technical parameters are, among others, the reliability, performance and scalability of the systems. These parameters can be compared using the same technical analyses (Wheeler, 2005). The quality of a software product is a controversial field. Functionality of software means the software functions fit the users demand and requirements.

In technical context interoperability is used to describe the ability of different software and hardware form different vendors to exchange data and utilize the same protocols and to operate effectively together. If the competitors' products are not interoperable, the result may be monopoly. To avoid the vendor lock-in, it may be prudent for governments to take steps to encourage interoperability in various situations.

Transparency refers to the fact that, when software is developed, the original source code is available (or not) to public (or user) review. The government is responsible for storing a large amount of data in name of the public. *Lock-in* means that if the data is stored in closed format using proprietary software, the information will only with difficulty be available and retrievable for many decades to come. Since FLOSS and open standards make available the source code, the way in which information is stored is publicly known, or at least traceable. Lock-in can be only avoided by using open standards. Moreover, lock-in may also refer to education where the brand-specific trainings confine the students and users.

Security is one of the main issues when software is used by governments and public administrations. Computing is crucial to the infrastructure of countries. Nowadays the information environment is extraordinary complex and fragile. Modern society is increasingly vulnerable in its technological and economical infrastructure, in its telecommunications, its energy sources, and its transportation. The infrastructure and information systems can be attacked, destroyed, disrupted, and corrupted by small groups or even single individuals. It is not necessary to destroy the infrastructure in its entirety, nor to attack it physically via traditional means: it can be crippled electronically, and virtually anonymously (Steele-Vivas, 1996). This vulnerability is a reason why the choice of software used is relevant and important. This refers also to the political actions.

Countries where English is not commonly spoken face a serious disadvantage when it comes to the uptake and dissemination of ICTs. However the translation is one of the major parts of localization, moreover, localization involves the task for adapting and customizing the products for local users' specific cultural and/or technical needs.

FUTURE TRENDS

The consideration and utilization of FLOSS by national and municipal governments will continue to grow in the coming years. One of the main fields where FLOSS can best be utilized is in the e-government services increasingly in demand.

A related area where FLOSS can be adopted is within Public Authorities, which are quite different in the each country and which therefore require the flexibility of localization, which

FLOSS affords. Another main issue where FLOSS is already utilized with success regardless of cost consideration is in healthcare, which is one of the costliest segments within governmental services around the world. FLOSS can also improve the performance of healthcare services, whilst ensuring both interoperability and patient privacy.

Around the world, governments are developing e-voting systems, but the resistance to these systems by citizens link back to a lack of the trustworthiness of closed systems, which can be avoid by using freely available source code.

Countries in the developing world can gain the possibility to use high-quality free software as opposed to scaled-down versions of more costly proprietary software.

CONCLUSION

Information and communication technologies have drastically changed societies, influencing the everyday activities of both individuals and governments. The information society has become a reality and acted as a call to action by governments. Although much research has been done on the use and consequence of FLOSS in the public sector, not enough knowledge exists on public sector and government policy options and behaviour as regards the adoption of this software. In addition, there are numerous negative perceptions and misunderstanding about FLOSS.

This chapter has made an attempt to give a comprehensive overview of the different fields and aspects relevant to governments and peoples that are influenced by the choice of software that governments make. Another aim has been to delineate the relationship between these related issues and factors. FLOSS touches upon multiple areas as it was introduced in the paper, using the L-PEST model. Beyond a well-known cost consideration, the case studies and the proposed model showed the FLOSS and open standards could afford a workable social-economic-technological solution.

In using the model, it has become clear that the utilization of and decisions regarding software adoption, there are numerous factors that could, and should have impact on software decisions. Within networked societies, interconnectivity was the first step, and nowadays interoperability has gained emphasis. There are numerous arguments that software application that is financed through public funding should be released under FLOSS license. It is not enough that this software is freely available at no cost. With the freely available source code there is the opportunity for improved quality, while simultaneously avoiding lock-in and the development for only one platform. This can bolster the elimination of the digital divide and help foster participation and inclusion programs.

As it was introduced in the Quad theory, the relationships between the Quad's elements determine the performance of the information society and development as a whole. The members of the Quad are involved in the different categories of the L-PEST model.

Much empirical and theoretical work is still needed in this field and in reference to the presented model as well as a better graphical representation of the model. Future research will focus on a detailed examination of motivations and a more precisely defined analysis of every factor involved. In reference to Wilson's Quad model, it might be interesting to investigate stakeholder analysis in contrast of the Quad and L-PEST model.

Protagoras, Greek philosopher (c 485- c 410 BC) said: "There are two sides to every question." And this case there do exist disadvantages in the utilization of FLOSS. It should be noted that the advantages and disadvantages can be measured and evaluated in relation to those incurred by using proprietary software. This model has considered general recommendations focusing on FLOSS but also makes possible comparison between proprietary and FLOSS software.

ACKNOWLEDGMENT

The author wishes to thank Nora for her encouragement and patience throughout the duration of research and writing process, Matthew Strauss for his valuable feedback and improvement of wording of the manuscript, and the anonymous reviewers for their helpful comments and all those who provided advice and suggestions on earlier versions.

KEY TERMS

Dependency: In this context, dependency means that the users are dependent on the software vendor for products and services so that he or she cannot move to another vendor without substantial cost.

Interoperability: Means the ability of systems to operate effectively together independently of different software or hardware vendors.

Localization: Means more than simply the translation of software; it refers to the customization of the software for local needs and demands.

Piracy/Copyright Infringement: The software piracy refers to the duplication, distribution, or use of software without the permission of the copyright holder.

Return on Investment (ROI): Generally, a ratio of the benefit or profit received from a given investment to the cost of the investment itself. This approach also focuses on the benefits and the measurement of the value of making an investment, not only the cost savings.

Total Cost of Ownership (TCO): A financial estimate for such things as (but not limited to) computer software or hardware. TCO is commonly used to support acquisition and planning decisions for a wide range of assets that bring significant maintenance or operating costs across a usable life of several years or more. TCO analysis is not a complete cost-benefit analysis. It pays no attention to business benefits other than cost savings.

Transparency: Transparency involves openness, communication, and accountability. In this context it refers to the fact that, when software is developed, the original source code is available (or not) to public (or user) review.

Lock-In, **Vendor Lock-In:** In technical terms it means that, if the data is stored in closed format using proprietary software, the information will only be available and retrievable with difficulty. The term also refers to dependency of different types of lock-in, such as when the users are 'locked-in' when trained for a specific technology or the dependency of the specific vendor.

ENDNOTES

1 "Who controls the software, controls life. Well, it had better us. That's the real political meaning of the free software movement, " said Eben Moglen, professor of law, General Counsel, Free Software Foundation at Open Source Conference, May 2004, Toronto.

2 The digital divide has a number of definitions and approaches. Examples can be found at: Bridge the Digital Divide (http://www.bridgethedigitaldivide.com/digital_divide.htm) Digital Divide Network (http://www.digitaldivide.net/)

3 Many governments passed anti-terrorism laws, aimed at enhancing security and facilitated the capture of terrorists. Global Policy Forum Web page (http://www.globalpolicy.org/empire/terrorwar/liberties/libertindex.htm) looks at cases where the "War on Terrorism" threatens civil liberties. The European Union ratified controversial data retention legislation (Directive 2006/24/EC) on the retention of data generated or processed in connection with the provision of publicly available electronic communications services or of public communications networks and amending Directive 2002/58/EC). A week later on, EU and US representatives met for an informal high level meeting on freedom, security, and justice where the US expressed interest in the future storage of information.

4 Creative Commons has built upon the traditional copyright law based on the all-rights-reserved concept to offer a voluntary some-rights-reserved approach. The Creative Commons licenses provide a flexible range of protections and freedoms for authors, artists, and educators. http://www.creativecommons.org

5 FLOSS licensing approach based on differences between FS and OSS movement. The free software licenses do not allow closing"the source code while the permissive (OSS) licenses permit the creation of proprietary development. ABSTRACT

The aim of the article is to report the results of a migration to Open Source Software (OSS) in one public administration. The migration focuses on the office automation field and, in particular, on the OpenOffice.org suite. We have analysed the transition to OSS considering qualitative and quantitative data collected with the aid of different tools. All the data have been always considered from the point of view of the different stakeholders involved, IT managers, IT technicians, and users. The results of the project have been largely satisfactory. However the results cannot be generalised due to some constraints, like the environment considered and the parallel use of the old solution. Nevertheless, we think that the data collected can be of valuable aid to managers wishing to evaluate a possible transition to OSS.

INTRODUCTION

Open Source Software (OSS) and Open Data Standards (ODS) emerged in recent years as a viable alternative to proprietary solutions. There are many cases in which the adoption of OSS has

proven advantageous for companies deciding to adopt it in replacement or in conjunction with closed solutions. The limitation of these migrations for our point of view is that they were very often server-side oriented and not supported by empirical evidence of the benefits of the new solution. In this sense, there are very few case studies that report successful transitions on the desktop side (ZDNet, 2005) and some are still underway (Landeshauptstadt München, 2003; Stadt Wien, 2004). It is our opinion that the reason of the apparent different results in the two fields is due to the nature of OSS development (Feller & Fitzgerald, 2001) that leads to repercussions on the resulting usability (Nichols & Twidale, 2003).

When comparing OSS and proprietary software and when comparing software solutions in general, it is impossible to get a global index referring to quality in order to compare two solutions (Fenton & Pfleeger, 1997).

If we consider the most important aspects under which it is significant to analyse software, as:

- Reliability
- Performance
- Price
- Security
- Interoperability
- Usability
- Extendibility
- Functionalities
- Privacy protection

The categories have to be balanced with the requirements of the environment and users in which the solution is deployed. Where the aspects of security, reliability, and extendibility are of key importance, OSS has proven a valid solution, if not superior to proprietary solutions. Where functionalities, usability, and in general user interaction acquires importance as on the client side, OSS has yet to prove as a valid alternative. Price is a controversial issue as there is the need not only to evaluate the license price but also the software maintenance and other costs inherited from the migration. These considerations originated the study we propose.

The purpose of the study is to evaluate in a rigorous way the introduction of OSS in a working environment, following the criteria of a controlled experiment from the selection of the sample to the evaluation of the results. We selected a sample of 22 users from different offices in the public administration target of the experiment. We divided the sample in two groups, one to be migrated, the other to be used as a control group. The results obtained seem to report that the initial reduction of productivity is not as consistent as we thought, also taking into account that half of the users considered the introduced solution as offering less functionality than the proprietary one.

STATE OF THE ART

There are many studies available evaluating the Total Cost of Ownership (TCO) of OSS. The original model derived from the work of the Gartner Group in 1987 and has since then been inserted in different models. The TCO model helps managers by considering not only the cost of purchase but also further costs as maintenance or training.

All the studies are not unanimous as the savings that can be reached with the adoption of OSS (Robert Frances Group, 2002; The Yankee Group, 2005). One of the reasons is probably the different weight given to costs and benefits that are difficult to measure. Two of such measures are, for example, the risks of lock-ins and the development of local economies. The risks of entering a mechanism of lock-in, for example, by relying only on a single software supplier or storing massive amounts of data by means of closed data standards are real and must be considered in a TCO model evaluating a transition (Shapiro & Varian, 1999). On the other side, the adoption of OSS can be of benefit to local software companies

that can exploit the possibility given by the available source code and open data standards. Also in this case, the amount of this kind of externality is difficult to quantify.

Considering OSS, there are many projects worth mentioning, we will name here two of the most famous and see how they perform on the market against proprietary solutions:

- the Apache Web server[1]
- the Mozilla Firefox Web browser[2]

Table 1 shows that the Apache Web server detains almost 70% of the whole market share (Netcraft Survey, 2005). As virus attacks of the last years have proven (CERT, 2001), one of the reason of such wide adoption is the security proposed by the Apache architecture.

Table 2 shows the market share of the Mozilla Firefox browser between January and April 2005. As it can be seen also in this case the software is gaining constant market shares in the last months. The software is still behind in market shares but it represents an important competitor for the market dominator, Microsoft Internet Explorer.

These are surely two of the most popular OSS that emerged during the last few years; there are many more that can compete with proprietary solutions. By looking at these and other examples, we can conclude that OSS already could represent an important alternative to proprietary software.

Another important consideration on OSS is represented by the cases in which a large migration has been performed or is in the process of being performed. Having a look at the different case studies available for the migration to OSS, we summarise the most famous during these years in Table 3; three are European, while one is U.S.-based.

Table 1. Web servers in September and October 2005 (Netcraft Survey, 2005)

Developer	September 2005	Percent	October 2005	Percent	Change
Apache	49598424	69.15	52005811	69.89	0.74
Microsoft	14601553	20.36	15293030	20.55	0.19
Sun	1868891	2.61	1889989	2.54	-0.07
Zeus	584598	0.82	585972	0.79	-0.03

Table 2. Browsers market share ("Browser Market Share Study," itproductivity.org, 2005)

Browser	January 2005 (%)	April 2005 (%)
Internet Explorer	84.85	83.07
Firefox	4.23	10.28
Mozilla	4.48	3.81
Netscape	3.03	0.92
AOL	2.20	0.85
MSN	0.58	0.67
Opera	0.34	0.41
Total	99.71	100.01

Table 3. Large scale migrations to OSS of public administrations

Region	Clients to migrate	Side	Distribution
Extremadura	80,000	Desktop/Servers	gnuLinex
Munich	14,000	Desktop	Debian
Vienna	7,500	Desktop	Wienux (Debian/KDE)
Largo, FL	900	Desktop/Servers	Linux KDE 2.1.1

One of the most remarkable deployments of OSS on the desktop side is surely the one of the Extremadura region in Spain, recently installing 80,000 Linux systems, 66,000 for the educational system and 14,000 for administrative workstations. The local administration created their Linux distribution called gnuLinex.[3] According to their IT department, the savings have been of the order of €18M (ZDNet, 2005). Another case of success is the one of the city of Largo, FL where the migration has involved 900 clients; the savings have been estimated at $300,000-$400,000 (Newsforge, 2002). The migration of the city of Munich and the one of the city of Vienna are currently underway (Landeshauptstadt München, 2003; Stadt Wien, 2004). As the delay of the Munich migration seems to demonstrate, a transition to OSS is not a process to underestimate. There are also cases where the proprietary solution has been considered as more convenient, like the city of Nürnberg, where according to their own migration study the transition from Windows 2000/Office 2000 to Windows XP/Office XP was considered €4.5M cheaper than the transition to Linux/OpenOffice.org (Stadt Nürnberg, 2004).

A final consideration on studies performed on OSS usability. Of certain interest for our study, albeit a little dated, is the experimentation conducted by the Berkeley University in November-December 2001 (Everitt & Lederer, 2001), comparing two different solutions in the office automation field, namely Sun StarOffice Writer 5.2 and Microsoft Word 2000. Authors report about an experiment on 12 users, regarding the user interface integration. As a result of the study, the two products were comparable, although the Microsoft solution proved to be more satisfactory and easier to use.

THE STUDY

Our study has been inserted into this framework; the intention is to contribute to the field with a solid and sound analysis of a real transition to OSS on the client side, specifically the analysis of a migration in the office automation field in one public administration.

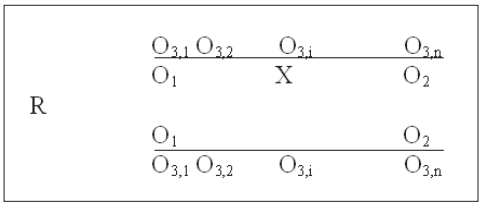
In particular the study related the introduction of the OpenOffice.org[4] suite. The suite offers comparable functions as the one offered by Microsoft Office.[5] It is composed of several applications, a text-processor, a spreadsheet, software for presentations, for drawing operations and for the creation of formulae. The only functionality missing in the version installed was the possibility to create small local databases. In the organisation where we performed the study, this was a feature rarely employed by users and, in general, deprecated by IT managers. We focused our analysis mainly on word-processors and spreadsheets.

The experiment was performed on 22 users of a public administration (PA) during the transition to OSS. In the following sections we expose the methodology adopted, the tools employed, and the main results obtained from the qualitative and quantitative data collected. The limitations and possible future additional work is listed at the end of the article. The overall sample of 22 users has been selected from three departments of the PA under exam. Some constraints had to be followed, for example, the fact that the head

Table 4. The selected sample and distribution among groups

Group	Women	Men	Total	Departments	Notes
Group 1	6	3	9	3	Only using MS Office
Group 2	9	4	13	3	Using MS Office and OpenOffice.org
Total	15	7	22	3	-

Figure 1. Experimental design adopted



of the different offices posed a limitation on the number of the available workers per office. Table 4 represents the different groups, with two office directors per each group as part of the sample. The average age of participants to both groups was uniform between groups and has not influenced the results; users were selected from such departments in a random way with the limitations described previously. Regarding the protocol, the selection of the experimental groups has been done in a way to enable that the participants were, when possible, in some way in relation with each other, physically near and if possible coming from the same organisational units, to take advantage of possible network externalities that arise in terms of document exchange and reciprocal help (Shapiro & Varian, 1999).

One group experimented with the introduction of OpenOffice.org (our treatment X, in Figure 1), while the other group was used as a control group. The experimental design followed an experimental pretest-posttest control group design (Campbell & Stanley, 1990).

A questionnaire has been submitted to both groups before (O1) and after (O2) the introduction of OpenOffice.org to evaluate the effects of the experimentation on the attitude towards OSS. The activities of both groups have been constantly monitored by an automatic system for data collection (Sillitti, Janes, Succi, & Vernazza, 2003) that permitted the gathering of a series of objective process data (the series of observations O3,i).

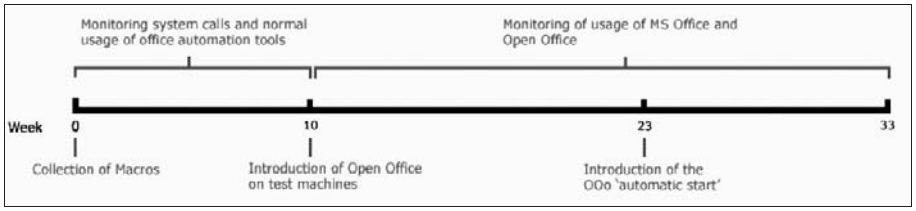
In some other cases where there has not been the possibility to have a control group and a proper randomisation of the sample, a "quasiexperimental" and a "one-shot" design have been employed (Campbell & Stanley, 1990). We are aware that in this way the results obtained are less extendible to the general case and more subject to exogenous effects.

TIME EVOLUTION OF THE EXPERIMENT

The experiment lasted for 32 weeks; during the first 10 only Microsoft Office was monitored and the different system dependencies were collected. OpenOffice.org was introduced in group 2 after week 10 and during the 23rd week of experimentation OpenOffice.org has been associated with Microsoft Office formats .doc and .xls. The results of the choice will be exposed in the subsequent sections. Figure 2 shows a graphical representation of the evolution of the experimentation.

In detail, the steps performed during the experimentation were the following:

Figure 2. Evolution of the experiment expressed in weeks



1. Selection of the participants to the experiment;
2. Submission of the questionnaires on the attitude towards OSS;
3. Motivational seminar on the reasons of the experimentation;
4. Identification of the OpenOffice.org experimental group and control group;
5. Analysis of the most used documents and the possible software dependencies;
6. Installation of OpenOffice.org and translation in the OpenOffice.org format of the most used documents and on a per request basis;
7. Installation of the monitoring and data collection system to define the situation before the transition;
8. Training, performed on a single day, trying to focus on the different approach proposed by the new software; users were instructed on how to perform the usual office automation tasks;
9. Start of the OpenOffice.org data collection;
10. Support given to users through an online forum and a hotline;
11. Periodic verification meetings with users of OpenOffice.org to identify possible problems;
12. Automatic start of OpenOffice.org with files with Microsoft Office extension starting from week 23;
13. Submission of the final questionnaires.

Two types of questionnaires have been submitted to users. The first one identical before and after the experimentation, to understand the attitude towards OSS and the effects of the experimentation on such attitude; the second one has been submitted only at the end, where all the final results of the project have been collected and more information for the replication of the experiment have been determined. The Goal Question Metrics (GQM) paradigm (Basili, 1995) was employed in every phase of the project, from the overall design to the creation of the questionnaires. The GQM is a methodology that was developed at the University of Maryland in the mid-1980s that relates the goals of an organisation to a set of questions. Questions are further associated to a set of metrics. In this way it is always possible to evaluate whether a goal has been reached and what are the informational needs of a certain goal are.

SOFTWARE EMPLOYED

The tools used during the experimentation were useful to assess the evolution of the experiment and in particular to gather quantitative and objective data about the migration process. In particular, two applications were employed for the ex-ante analysis and one was continuously employed during the transition to monitor the usage of the proposed solutions.

- PROM (PRO Metrics), a noninvasive monitoring tool was used to evaluate the usage of OpenOffice.org and Microsoft Office during all the transition process (Sillitti et al., 2003). Metrics of interest were the number of documents handled and time spent per single document. The software has been running during all weeks of the experimentation, permitting us to acquire objective data on the experimentation.
- DepA (Dependency Analyser) has been employed to evaluate at the beginning of the project the existing dependencies of Microsoft Office in terms of called and calling programs (Rossi & Succi, 2004). The program is a simple agent running on workstations to determine the calls from different applications, collecting in this way information on the different interrelations

between applications. The program has been running on client desktops for the first 10 weeks.

- FLEA (FiLe Extension Analyser) has been used to perform a scan of the data standards available on the users' drives and analyse the eventual presence of macros. The software permits us to collect information on the type of extension, date of creation, date of last access, size of the file, and for particular extensions also information about the macros contained. The scan was performed at the beginning of the experimentation.

All tools deployed are not noninvasive in order not to bias the results. From the final questionnaires emerged that users did not notice the presence of any external software during the experimentation.

DATA ANALYSIS

In this section we report the results of the data collection activities. In particular we can distinguish the data collection across a temporal boundary (*ex-ante, during, and ex-post*) and between *qualitative* and *quantitative* data.

The biggest effort during the project has been to monitor constantly the users during the experimentation. To gather objective data on the migration, we used the PROM software. Data collected included the time spent on documents and the number of documents opened using the selected office automation suite. A more fine-grained analysis on the function utilised has not been performed. During every phase of the project, the quantitative data collected has been backed with qualitative data coming from interviews and questionnaires. As a side effect, we noticed that the periodic meetings performed with users caused a small increase in the usage of the open source solution during the immediate subsequent days.

We will briefly review all the data collected, starting from the analysis of the existing situation, performed at the beginning of the experimentation.

EX-ANTE ANALYSIS

The aspects we analysed for an overview of the existing situation were concerned with the presence of interoperability issues in the users' environment and the presence of possible dependencies in the form of macros inside office automation documents. Macros are a series of commands inserted in the form of code inside documents, to perform a series of repetitive actions. They are generally very common in office automation documents, to permit the automation of repetitive tasks. As the usage in OpenOffice.org of macros written for Microsoft Office is not possible – at least at the time the experimentation was carried out – this is an interoperability issue. Macros need, in this way, to be completely rewritten.

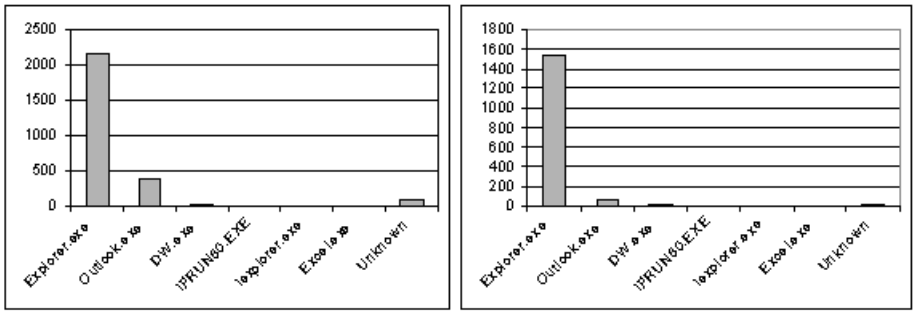
Table 5. Type of data collected during the experimentation

	Ex-ante	During	Ex-post
Qualitative	Interviews/questionnaires	Periodic meetings for feedback	Interviews/Questionnaires
Quantitative	Collection of data standards (FLEA), Collection of dependencies (DepA)	Monitoring of SW usage (PROM)	Number of OOo files created during the project.

Table 6. Number of documents and macros during the pretransition phase; LOC = Lines of Code, CNO = Could Not Open

Location	Microsoft Word				Microsoft Excel			
	Files	Macros	LOC	CNO	Files	Macros	LOC	CNO
Users' driver	19144	2	12	-	1367	8	1070	14
Network driver	4484	-	-	-	816	43	21482	331
Network drives (templates)	2182	-	-	-	9	3	10197	-

Figure 3. Number of incoming dependencies of Microsoft Word (left) and Microsoft Excel (right)



The number of templates in the preexisting format represents another interoperability issue. Our software for data collection granted us the possibility to evaluate the number of this type of documents, but not the complexity, another factor to take into account when there is the need to migrate a document. The collection of such data has to be crossed with interviews with the IT personnel to evaluate the real relevance of the macros discovered and the real necessity of the conversion of templates.

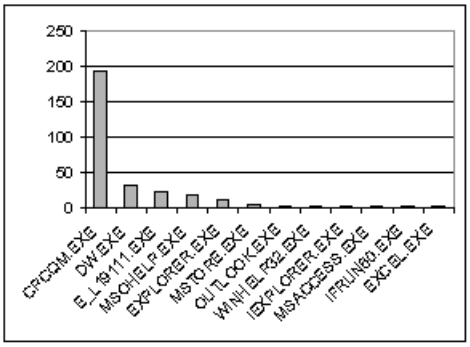
The first step for performing the initial analysis of the experimentation environment was the one related to the presence of macros inside documents and the distribution of the documents. Another important issue was to find the number of templates available. This analysis has been performed statically at the beginning of the project. In the evaluation of macros impact, Microsoft Word and Microsoft Excel documents of the participants to the project were considered. Two different locations were considered:

- Users' drives
- Network drives

In the last location, both normal documents and templates were considered. Table 6 reports a summary of the results. We found 25.810 Word documents and 2.192 Excel documents. Among these, only 2 Word documents (0.01%) and 49 Excel documents (2.24%) contained macros. Moreover, our tool has identified a high number of Excel documents protected by password (near 16% of the total). In this case, it is not possible to determine whether they contain macros.

The second step has been the identification of the software dependencies that existed in the office automation environment. A dependency is either a call to an external application (outgoing

Figure 4. Number of outgoing dependencies for Microsoft Word/Excel



call) or a call from an external application to the office automation suite (incoming call). As the dynamic evaluation of the calls, two different typologies have been considered:

- Applications that call Microsoft Word or Excel (Figure 3)

In this category we discovered that 80% of the times, Microsoft Word was called from explorer.exe which means a normal start from its icon or a file on the file manager. Furthermore, 12% of the times it was called from the e-mail client Outlook. Microsoft Excel was called 95% of the times by explorer.exe and 4% of the times from Outlook (for a total of 99% of the calls).

- Applications called from Microsoft Word or Excel (Figure 4)

74% of the global calls have been towards printer drivers. Almost 11% of the calls of Microsoft Word and Excel have been towards the program to report problems in Microsoft applications, and about 6% for the help guide.

Further interviews with IT managers confirmed the situation outlined by data collection tools. Globally, the system environment of the experimentation was less turbulent than we had thought initially. Templates, macros, and dependencies collected were not so critical to increase significantly the migration costs.

ONGOING EXPERIMENT ANALYSIS

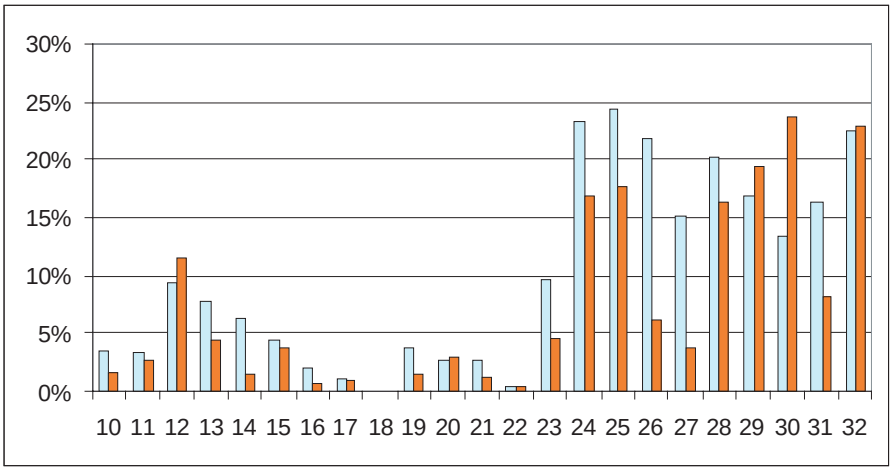
The experimentation has been monitored constantly by PROM software. Figure 5 shows two different measures of productivity, the percentage of documents opened by using OpenOffice.org and the percentage of time spent within the OpenOffice.org suite. As an example, a percentage of 5% means that users spent in that week 95% of the time using Microsoft Office.

From the data collected, we can notice, in particular, two effects:

- As expected, the level of adoption of the new software has been increased by the decision to associate the Microsoft Office file formats with OpenOffice.org. We expected to have complaints and reports of incompatibilities deriving from this decision. What happened was instead that users learned when it was convenient for compatibility reasons to adopt one solution or the other.
- Even after 32 weeks of experimentation, the time spent with OpenOffice.org was below 25% of the total time dedicated to the two suites for office automation. Also to note is the fact that the time and documents of Figure 5 are inclusive of the Microsoft Office documents opened with OpenOffice.org.

It is noteworthy that, during the experimentation, we did not benefit fully from the network effect that can be raised by the growing number of documents in one format and the subsequent exchange between users (Shapiro & Varian, 1999). In a broader migration such effects can also have an impact increasing the usage of the new platform proposed. In our experimentation users were in some way constrained in the adoption of

Figure 5. Increase in OpenOffice.org usage. On the X-axis there is the week of the project; OpenOffice.org has been inserted during week 10; and the automatic association has been activated during week 23. In blue the percentage of opened files using OpenOffice.org is represented and in orange the percentage of average time devoted to OpenOffice.org among users that effectively used OpenOffice.org.



the new format, as they could not exchange the documents with the users not participating in the experimentation.

We also posed two questions to evaluate the impact on productivity, according to the GQM methodology.

a) Did the usage of OpenOffice.org caused a reduction in the number of documents used per day? We studied the correlation between the number of documents used each day and number of documents opened with OpenOffice.org. A negative effect on the usage of OpenOffice.org had to produce a negative impact on the usage of the office automation documents and a significant negative correlation between these two variables; that is, the more documents are handled with OpenOffice.org, the less they are globally handled. The correlation in question has been of -0.08, therefore we exclude that the usage of OpenOffice.org has reduced the number of documents handled daily.

b) Did the usage of OpenOffice.org caused an increase in the time devoted to each document? We studied the correlation between the time spent managing all the documents and the OpenOffice.org ones. A negative effect on the usage of OpenOffice.org has to create a significant positive correlation; that is, it should be evident that the more time spent with OpenOffice.org, the more time is spent globally managing documents, as OpenOffice.org required more time to accomplish the same tasks. This correlation has been determined in -0.04, therefore it has to be excluded that the usage of OpenOffice.org has increased the global effort to handle documents. The comparison with the control group confirmed furthermore that the evolution of the usage of documents among the test group and the control group has been consistent, excluding the presence of exogenous factors.

EX-POST ANALYSIS

At the end of the experimentation, the evaluation of the attitude towards OSS and in general the

evaluation of the project has been performed. We submitted one questionnaire to users in order to evaluate their attitudes towards OSS and the knowledge that was acquired after the transition. We submitted also the same questionnaire to the control group to ensure that no exogenous effects biased the results. The questionnaire was designated to answer to the following two questions:

- What is the user perception of OSS at the end of the experiment?
- Has the user modified his/her perception of OSS at the end of the experiment?

All figures of this section represent the ex-ante situation on the left and the ex-post situation on the right. In this way it should be easier to evaluate the change of users' attitudes.

The *first question* that has been submitted was whether the Open Source concept has become more familiar after the experimentation. The result in this case is quite obvious; at the end the users had a clearer idea of the concept of OSS. It may be surprising the initial number of users claiming to know OSS, but this is due to the preproject meetings with IT managers explaining the reasons of the experimentation.

The *second question* enters the heart of the matter, questioning about the perception of OSS. In this case an interesting phenomenon has been discovered. At the beginning one group had no opinion on OSS (almost half of the interviewed). At the end of the experiment, almost all users have an opinion: those that were positive maintained the same opinion and the uncertain were divided into three groups almost of the same size, those with a positive opinion, those with a negative one, and those that had no opinion. Nevertheless, at the end of the experiment only a small part of the participants had a negative opinion on OSS.

The *third question* focuses on the importance of the diffusion of the software in use. In this

Figure 6. Question 1 – How familiar are you with the expression Open Source Software? Possible answers: (a) very well, (b) well, (c) neither nor, (d) not well, (e) not at all.

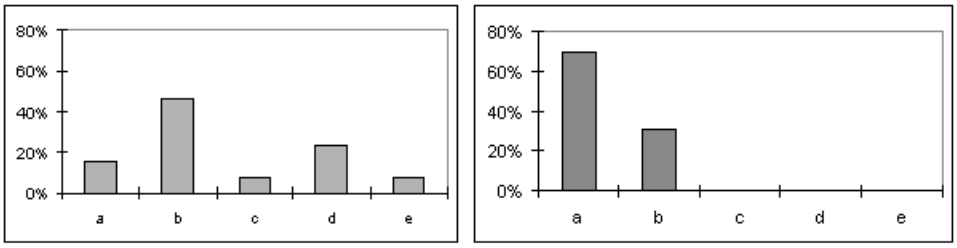


Figure 7. Question 2 – How do you perceive the expression Open Source Software? Possible answers: (a) as something negative, (b) as something positive, (c) neither positive nor negative.

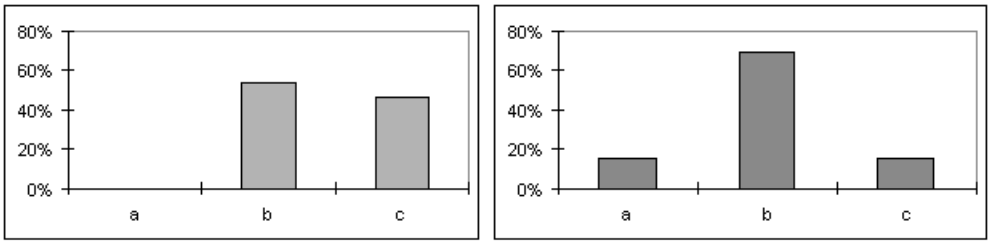

Figure 8. Question 3 - How important is it that the application you use is established and widely used? Possible answers: (a) very important, (b) important, (c) of moderate importance, (d) of little importance, (e) not important.

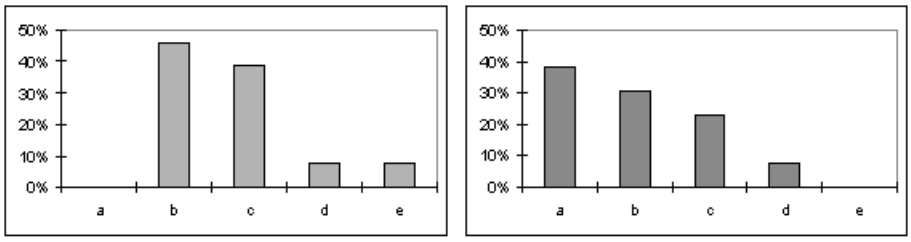

Figure 9. Question 4 – You are reluctant to give up the use of application software that you are using to in favour of an OSS alternative! Possible answers: (a) totally agree, (b) agree, (c) neither, (d) disagree, (e) totally disagree.

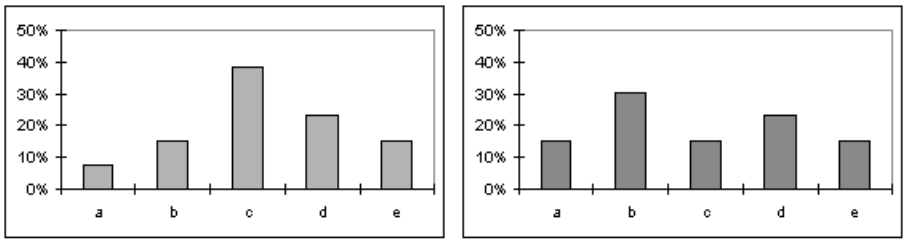

answer we have a strong movement towards a bigger knowledge; for example, the category "very important" has gone from 0 to almost 40%. The experimentation in the usage of OpenOffice.org has strongly increased the consciousness of the participants on the importance of the usage of well established software.

The *fourth question* poses the problem of the direct substitution and asks the user how much the user is reluctant to abandon the application in use in favour of an OS solution. In this case the user in favour maintained the same opinion, while reluctant people became more reluctant; also in this case users had a clearer idea of OSS after the experimentation. More than half of the interviewed users were still positive towards a possible transition.

The *fifth* and *sixth questions* present a slightly different nature. The aim is to find whether the experimentation changed the perception on the requirements of the software to be adopted and used. Question 5 focuses on the factors to consider when a new product is adopted and question 6 discusses the more important aspects of an efficient usage. In both cases the role of the training and support is evidenced as important, while other aspects as security, privacy, and availability of source code are considered less important. We can conclude that the effect of the OpenOffice.org introduction has increased the perception of the importance of the training. From one side, this can be obvious: the introduction of a new instrument requires always a training period, especially if it partially substitutes an old one. We must also point out that all the interviewed people had already performed their training with the office automation tools some time before, therefore such perception should already be present. It can be concluded that OSS has additionally stimulated the curiosity of participants, to the point to ask

Figure 10. Question 5 – How important do you find the following factors when you use a new IT-platform? Factors considered are: (a) support and training, (b) easiness of use, (c) interoperability, (d) source code available, (e) functionalities, (f) security, (g) privacy.

more questions about the tools used; such approach, if confirmed, can go in favour of people who claim that the adoption of OSS brings more "shared" knowledge.

The *last question* proposed before and after the experimentation is a sort of summary and deals with the motivations that the user would have to use OSS. It is interesting to note that near OSS supporters a new group emerged also absorbing neutral users towards a more negative opinion.

Some questions about the overall evolution of the migration have been submitted to users at the end of the project. Two questions are interesting for our evaluation of the migration, both related to the functionalities of OpenOffice.org and the possible full migration to the new solution proposed. We must point out that the experimentation has been performed with version 1.1.3 of OpenOffice.org; the latest release would, probably, obtain better results.

Question 8 faces the problem of the choice between the two proposed solutions in a general way. It asks whether the functionalities offered by the two suites are equivalent. Some users answered that Microsoft Office offers more functionalities than OpenOffice.org 1.1.3. In some way, the surprise may be that half of the users considered the set of functionalities offered equivalent.

Question 9 contextualises the problem. It tries to evaluate the impact of a possible substitution of Microsoft Office with OpenOffice.org. In this case almost all the participants in the test considered the migration as possible, even though the majority sustained later that this operation requires some effort and is not only a simple substitution.

A final evaluation of the experimentation has been performed on the number of files generated by the users adopting the new data standard supplied by OpenOffice.org. Table 7 contains a summary of all the different files created during

Figure 12. Question 7 – Which motivations do you have to use Open Source Software? Possible answers: (a) You believe it is right to support OSS initiatives, (b) You find that today's market dominance of a single software vendor is wrong, (c) other: specify, (d) I have no motivation to use Open Source Software.

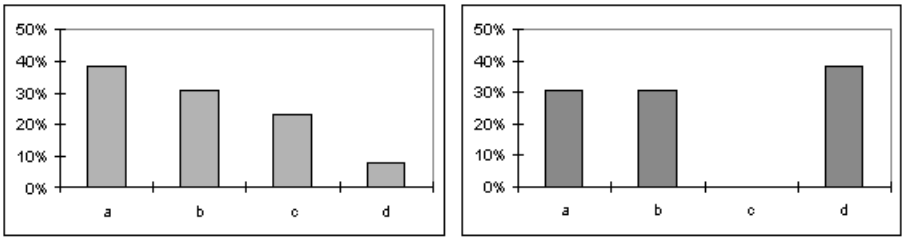

Figure 13. Question 8 – How do you evaluate the functionalities of OpenOffice.org with respect to the Microsoft Office ones? Possible answers: (a) widely superior, (b) superior, (c) equal, (d) inferior, (e) widely inferior.

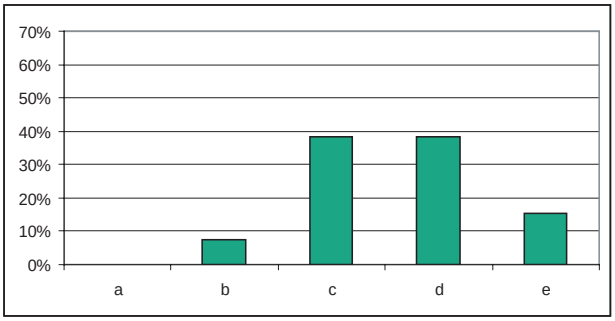

Figure 14. Question 9 – In this moment, if Microsoft Office is removed, are you still able to perform the same tasks? Possible answers: (a) yes, (b) yes but with some problems, (c) no.

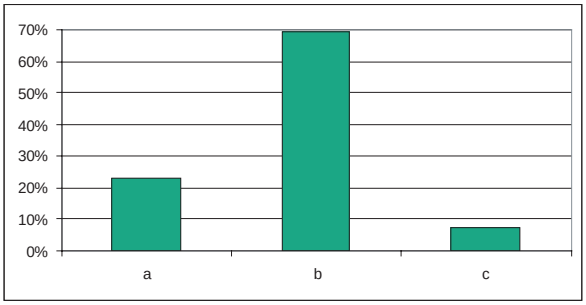

Table 7. Number of documents created during the experimentation

	Writer documents	**Calc documents**
Department 1	27	2
Department 2	223	34
Department 3	164	12
Total	414	48

the experimentation in the two different formats proposed by the OpenOffice.org suite for text processors and spreadsheets. Obviously this kind of static analysis represents only a small subset of the usage of the open solution, as users had also the freedom to open Microsoft Office proprietary formats using OpenOffice.org. For technical reasons FLEA could not be employed in this type of scan to give us more fine-grained data.

LIMITATIONS

This study represents the results of a single experience and such results cannot be systematically generalised, as the essential comparative aspect is missing. As already mentioned, the PA under exam has imposed some constraints on the selection of the sample. The office automation field, in particular, may not be fully comparable to other desktop environments where open source solutions are not as strong as OpenOffice.org. Furthermore, this study does not focus on a complete substitution of the old solution, rather on the evaluation of the coexistence of both solutions. A further step might be the evaluation of the effects deriving from a complete migration.

CONCLUSION

The migration to OSS described in this article has to be taken with care before generalising the results to other similar cases. In particular the migration has been restricted to the OpenOffice.org platform and to the PA field. The migration approach has been the more gradual as possible, maintaining the proprietary solution in parallel with the new one.

The results obtained from the experimentation have been encouraging for the introduction of OSS on the desktop-side. Data collected during the experimentation shows that the usage of the new platform increased during the whole period, reaching at the end 25% of the total office automation tasks. Proprietary software remained the preferred solution for users. The impact on productivity has been minimal also due to the similarities of the software considered. Users acquired a better understanding of OSS after the experimentation and tended to have, in general, a positive vision of the whole movement. Software used has been considered adequate for the transition, although a sort of lack of functionalities emerged from the opinions of the users. More recent releases of OpenOffice.org should solve these problems.

ACKNOWLEDGMENT

We acknowledge Dr. Hellmuth Ladurner for his precious help and support. Acknowledgments also go to all the users involved, participants in the experiment, technical personnel, and supervisors; without their constant effort and their availability, this study would not have been possible.

Chapter 4.14
An Empirical Investigation into the Adoption of Open Source Software in Hospitals

ABSTRACT

Open source software (OSS) has gained considerable attention recently in healthcare. Yet, how and why OSS is being adopted within hospitals in particular remains a poorly understood issue. This research attempts to further this understanding. A mixed-method research approach was used to explore the extent of OSS adoption in hospitals as well as the factors facilitating and inhibiting adoption. The findings suggest a very limited adoption of OSS in hospitals. Hospitals tend to adopt general-purpose instead of domain-specific OSS. We found that software vendors are the critical factor facilitating the adoption of OSS in hospitals. Conversely, lack of in-house development as well as a perceived lack of security, quality, and accountability of OSS products were factors inhibiting adoption. An empirical model is presented to illustrate the factors facilitating and inhibiting the adoption of OSS in hospitals.

INTRODUCTION

The open source software (OSS) phenomenon has become an important area of interest in information systems research due in part to the large and fast-growing number of OSS users and software products in a large variety of domains. OSS is already being adopted and used as a software platform in a number of fields other than

healthcare (Dedrick & West, 2003; 2004; Norris, 2004; Waring & Maddocks, 2005), and it has the potential to be equally promising for the hospital industry (Fitzgerald & Kenny, 2004). Studying OSS adoption in any domain can help reveal patterns and phenomena that are applicable to adoption in general, in addition to revealing insights into the domain being studied. In particular, the adoption and use of OSS in a hospital context remains a poorly understood phenomenon; only a handful of researchers have addressed the factors inhibiting or facilitating such adoption. Such an understanding is important in helping hospitals make better decisions about whether and how adoption of OSS could benefit them.

The first step in developing a better understanding is to explore the current state of OSS adoption, and the factors inhibiting and influencing it in hospitals. Such an exploration is the goal of this study. Once this current state is well described, it will be possible to seek answers to higher-level questions about the pros and cons, the costs and benefits, the advantages and disadvantages of OSS adoption in this domain, which is the second goal.

Therefore, the present study is of considerable interest for both practitioners and researchers. It will provide hospitals and healthcare organizations that are considering the adoption of OSS technologies with an understanding of how technological, environmental and organizational factors affect the adoption process. This way hospital IT practitioners, or others attempting to introduce OSS technology into hospitals, can prepare against the expected barriers and can utilize the facilitators for successful adoption. This research also provides scholars with an empirical model for better understanding facilitating and inhibiting factors, as well as providing the foundations for further research that may validate and expand on the empirical model in other healthcare organizations and other domains.

The main objective of this investigation was to explore and analyze the extent of OSS adoption in hospitals, along with the factors influencing or inhibiting this adoption process. Hospital IT managers were chosen to represent the hospitals' perspective on this topic. The following three questions guided this investigation:

1. What are the types and names of OSS products that hospitals choose to adopt?
2. What is the extent of OSS adoption for these products in hospitals?
3. What are the factors facilitating and inhibiting the adoption of OSS in hospitals?

To research these questions, a survey and interviews were used to acquire both breadth and depth of understanding. The purpose of the survey was to answer the first two questions—to explore and characterize the types of OSS products adopted in hospitals and to discover the extent to which these products have been adopted. The interviews were used to answer question three to attain a deeper understanding of the factors that are facilitating and inhibiting the adoption of OSS in hospitals.

In the following sections of this article, we first present the related work in this area. Then, we introduce the methodology for our survey and interview studies. After that, we present our data analysis and results. Then, we introduce our empirical model of the adoption of OSS in hospitals. Finally, we present our conclusions and the implications of our work.

LITERATURE REVIEW

Open Source Software Adoption in Healthcare

Over the past few years, a small number of researchers have focused on the study of the potential advantages and risks of adopting and implementing OSS in the healthcare domain. Prior research encouraged the adoption and use of OSS in healthcare organizations because of OSS's

potential to both enhance healthcare delivery and lower software acquisition costs (Carnall, 2000; Kantor, Wilson, & Midgley, 2003; McDonald et al., 2003; Valdes, Kibbe, Tolleson, Kunik, & Petersen, 2004).

OSS could potentially be more reliable and secure than proprietary software because its source code can be inspected and reviewed (Carnall, 2000). Past research introduced and extended the idea of OSS as a software development model that could definitively improve clinical and research software in the field of medical informatics (Yackel, 2001). A paper by Kantor, Wilson, and Midgley (2003) also presents the potential benefits that OSS could provide in the area of primary care. Kantor et al., also proposed that the adoption of OSS would reduce the excessive costs, the frequent turnover of vendors, and the lack of common data standards that are afflicting electronic medical records (EMR) systems in primary care.

More recently, McDonald, Schadow, Barnes, et al. (2003) also investigated the potential role that the OSS model of software development may have in the medical informatics area. They also described a number of OSS products that have been used in the medical informatics domain over the years, including: OpenEMed, a patient record system; OSCAR, a family practice office management and medical record system; as well as the internationally well-known VistA system, a computer-base patient records system (CBPR) developed in MUMPS (Massachusetts General hospital Utility Multi-Programming System) by the U.S. Department of Veteran's Affairs (Brown, Lincoln, Groen, & Kolodner, 2003; Longman, 2007). A more recent study by Valdes et al. (2004) also pointed out that OSS could be an effective solution for the problems that distress the healthcare industry such as high costs, business failures and barriers of standardization (Valdes et al., 2004). Other papers by Erickson, Langer, and Nagy (2005), Scarsbrook (2007) and Nagy (2007) supported the growth and adoption of OSS in radiology because OSS may significantly lower the entry cost for standards-compliant practices in the healthcare industry. They also proposed that OSS might allow rapid scientific advancement due to the sharing of information and software (Erickson et al., 2005; Scarsbrook, 2007). Other authors such as DeLano (2005) presented some reasons for the potential success of OSS predicting that the pharmaceutical research and development process may benefit from the OSS development model.

Open Source Software Adoption in Hospitals

A case study of OSS adoption was conducted at the Beaumont hospital in Ireland, where the IT department, under limited financial resources, made the decision to adopt OSS. Several OSS products were adopted and implemented successfully. The authors reported that there were important initial start-up and future operational costs when OSS products were preferred in the hospital (Fitzgerald & Kenny, 2004).

Another study by Glynn, Fitzgerald and Exton (2005) investigated the commercial adoption of OSS using an innovation adoption theory framework based on Tornatzky and Fleischer's (1990) model. They derived a framework that was then used to investigate the adoption process of OSS in the case of the Beaumont hospital (Fitzgerald & Kenny, 2004).

The OSS products and processes were also seen as promising in terms of enabling rapid evolution and proliferation of applications in the medical domain through their use of open standards and higher degrees of interoperability (Raghupathi & Gao, 2007). The authors argued that the development processes in the Eclipse project (http://eclipse.org) could improve scalability, prevent vendor lock-ins, and reduce costs in the medical information systems including electronic health record and clinical decision support systems.

Table 1. Main facilitators/inhibitors of OSS adoption

	Author(s)	**Major Factor Findings**	
		Facilitators	**Inhibitors**
Adoption of Open Source Software in Hospitals	**Fitzgerald and Kenny (2004)**	• Limited financial resources • Top management support • Software functionality • User's past experience	• Lack of support from vendors • Perception that OSS would threaten local proprietary software companies • Fear by users to become de-skilled
	Gynn, Fitzgerald and Exton (2005)	• Perception that the benefits of OSS outweigh its disadvantages • OSS-literate IT personnel • Top management support • Personal support for OSS ideology • Network externalities • The OSS champion example	• Perception of work under-valued if using OSS products • Having to change operating model to OSS • Fear by users to be de-skilled • Lack of OSS champion example • Lack of tolerance to technical problems with OSS • Favorable arrangements with proprietary vendors
	Holck, Larsen and Pedersen (2005)	• Limited financial resources • Pressure to upgrade IT systems • Top management support • User's past experience • Government support	• Lack of reliable procurement models ○ Legal (licenses) ○ Technical (functionality, security, usability) ○ Corporate and business policy (vendor, customer support, and software alliances)
Adoption of Open Source Software in Healthcare	Tomas Yakel (2001)	• Access to real-world systems • Reduction of bugs in medical systems • Reduction of software ownership and development cost	• Lack of a mature OSS beyond prototype phase • High level of technical expertise required for OSS • Proprietary mindset of the medical community • Technology complexity of the medical domain • Lack of OSS-IT personnel support, specifically for medical software applications
	MacDonald et al. (2003)	• Public policy encouraging that all software developed by the government must be released under an OSS license • Information mechanisms to disseminate to the community about OSS developments and benefits	• Medical software currently in use is proprietary software • Leadership and top management in healthcare is risk adverse • Elimination of in-house personnel due to outsourcing • Technology complexity of the medical domain
	Hogarth and Turner (2005)	• Reduction of software ownership and development cost • Disappearance of vendor lock-in • OSS adherence to standards for compatibility and data interchange	• Lack of OSS-IT personnel support, specifically for medical software applications • Technology complexity in the medical domain • Success of mainstream applications might not translate to clinical software
	Kantor et al. (2003)	• OSS can reduce EMR ownership and development cost • Disappearance of the vendor lock-in • OSS adherence to standards for compatibility and data interchange	

There are some recent studies focusing only on the managerial and technical barriers to the adoption of OSS (Holck, Larsen, & Pedersen, 2005). Past research on OSS and healthcare also proposed that OSS would reduce the number of bugs and failures in medical systems, as well as reduce their overall cost (Yackel, 2001). A study by Hogarth and Turner (2005) focused on creating a catalogue of existing OSS clinical projects and on determining metrics for their viability. The authors mentioned that many of the factors that are required to make a "successful and vibrant" OSS community within the mainstream software applications systems (e.g., Linux, Apache, etc.) may not necessarily be applicable to the clinical software applications systems.

Another study by Kantor, Wilson and Midgley (2003) presented a set of potential advantages that the adoption of OSS may provide with regards to lowering the resistance of hospitals to the adoption of electronic medical records (EMR). These included: 1) the potential of OSS to reduce EMR ownership and software development costs, 2) the removal of vendor lock-in, and 3) the adherence of OSS to standards for the compatibility and data interchange among systems.

In another study by Valdes, Kibbe, Tolleson, et al. (2004) dealing with the barriers to the proliferation of electronic health records/electronic medical records (EHR/EMR), the authors concluded that OSS is a viable solution to the barriers of high cost, business failure and standardization that the healthcare industry is facing when adopting EHR/EMR. The authors mentioned that, for example, interconnectivity problems are more easily solved when using OSS, since no technical information can be hidden. They also added that OSS can help alleviate the high costs associated with the adoption and implementation of EHR/EMR (Valdes et al., 2004). Although this article presents a good case for the adoption of OSS solving the barriers that EHR/EMR is facing, the authors do not support their case with empirical data.

In summary, even though we have witnessed a widespread, significant OSS research and industry adoption of OSS, there are still few studies on OSS adoption and use, especially in the hospital industry. Only a handful of researchers have addressed the factors inhibiting or facilitating OSS adoption in hospitals (Carnall, 2000; Kantor et al., 2003; Valdes et al., 2004; Glynn, Fitzgerald & Exton, 2005). Each of the aforementioned studies in this section found that top management support, limited financial resources, past experiences using OSS-like systems, and the flexibility to modify, combine, and tailor OSS are the most important facilitating factors for the adoption of OSS within a hospital scenario. The factors inhibiting adoption range from the fear of IT personnel becoming de-skilled by not using mainstream commercial applications, the lack of OSS-literate IT personnel, the lack of other successful OSS examples in the industry, to the lack of reliable procurement models for the adoption of OSS. Finally, many of the papers and studies reported are cases from European countries, with healthcare systems that are very different from that in the U.S. Table 1 presents only a summary of the facilitators and inhibitors shown to influence the adoption of OSS as found in the literature.

METHODOLOGY

A mixed methods design was used in this research to explore the extent of OSS adoption in hospitals as well as to investigate the influencing and inhibiting factors. The exploratory approach of this study is warranted by the fact that, as of yet, the adoption and use of OSS in U.S. hospitals has not been accompanied by any theoretical grounding or by empirical analysis that explains how or why OSS products are being adopted and used. That is, thus far, there are few existing conceptual frameworks to guide a research effort in this area. Similarly, there are no theoretical guidelines that have been

empirically evaluated to support a rigorous understanding of the complex factors that inhibit the adoption and successful implementation of OSS technologies in hospitals. For these reasons, a mixed methods approach using a grounded theory perspective was selected over a confirmatory or causal research design approach. Grounded theory is a systematic, qualitative research procedure used to develop an inductively grounded theory that explains a process, an action, or interaction about a phenomenon (Glaser & Strauss, 1967; Glaser, 1978; 1999; Creswell, 1994; 2005; Strauss & Corbin, 1998; Charmaz, 2006).

STUDY DESIGN

The data collection methods used in this research are a survey and interviews, allowing both breadth and depth of information concerning the adoption of OSS in hospitals. We focused on Baltimore, Washington and Northern Virginia (BWNV) area hospitals instead of a nationwide area. This allowed us to spend more time cultivating each contact from the target population through initial phone calls, and to obtain richer data in the form of personal face-to-face and telephone exchanges.

First, a survey was used to gather data from a wide variety of hospitals dispersed across a geographic area. This was done in order to explore and characterize the extent and the types of OSS products adopted by hospitals. Following the survey, semi-structured interviews were conducted in-person and by telephone with IT managers in order to attain deeper understanding of the factors that facilitate or inhibit OSS adoption in hospitals. Interviews are the quintessential qualitative method for data collection and one of the most widely used techniques for acquiring qualitative data in order to collect impressions and opinions about the particular research issue (Tashakkori & Teddlie, 1998; Patton, 2002).

The target population for the study consists of hospital executives, directors and managers that are involved in IT within BWNV area hospitals. Although we selected the BWNV area largely because of our own location, it is an appropriate choice because it is one of the most diverse areas in the U.S. socioeconomically, politically, and culturally. The survey sample was selected from the Healthcare Information and Management Systems Society (HIMSS) from their electronic mailing list database of chief information officers (CIO), chief technology officers (CTO), vice presidents (VP) (of information technology (IT), information systems (IS) and management information systems (MIS)), and directors and managers of other IT departments within hospitals. HIMSS was selected because it is a leading non-profit organization dedicated to improving healthcare through the application of information technology (HIMSS, 2006). This research takes a key informant approach that allowed the responses of the IT managers to represent those of the hospital being surveyed. The use of managers as key informants has been successfully applied in many IT studies that involve organizations (Huff & Munro, 1985; Gatignon & Robertson, 1989; Chau & Tam, 1997; Eyler et al., 1999; Goode, 2005).

SURVEY ADMINISTRATION

Prior to sending the survey invitation e-mail out, an attempt was made to contact each of the IT managers in the target population by telephone in an effort to encourage participation and receive a verbal commitment from them to complete the survey. After the initial telephone contact, an e-mail invitation letter was sent to the potential respondents. The survey link was appended to the bottom of the e-mail cover letter and upon clicking the survey link, the participant was directed to the online survey (Appendix A).

Descriptive statistics, such as frequency distributions, percentages, standard deviations, confidence intervals, Chi-square and Fisher's tests were computed in order to analyze the survey

results. Moreover, to ensure better reporting and complete description of our Web-based survey results, we applied a checklist of recommendations from the Checklist for Reporting Results of Internet e-Surveys (CHERRIES) (Eysenbach, 2004) (Appendix B).

INTERVIEWS

The interview population consisted of the subset of survey respondents who responded positively to a survey item that specifically asked if they were willing to share their thoughts and experiences in an interview. A total of 11 survey respondents initially agreed to be interviewed. All such respondents were sent an e-mail letter introducing the objectives of the interview and asking to schedule a meeting. By the end of this process, only five IT hospital managers ultimately agreed to be interviewed. The other six managers, for reasons unknown, chose not to respond to the many invitations by e-mail and telephone to participate and were unreachable to be interviewed. Each interview lasted 30-60 minutes and was conducted between January and May 2007. The interviews focused on the organizational, technological, and environmental factors that facilitated or inhibited the adoption of OSS at their hospitals (Appendix C). Before conducting each interview, the participant was briefed on the nature and purpose of the study. All the participants were asked for their authorization to be recorded during the interview and were asked to sign an informed consent.

The interviews were coded and analyzed employing grounded theory consistent with the systematic procedures recommended by Strauss and Corbin (1998), namely open coding, axial coding and selective coding. Coding is the process that dissects, differentiates, combines, and discovers concepts and relevant features from the data (Seaman, 1999). We developed concepts and categories emerging from the data using the line-by-line analysis as described by Straus and Corbin (1998) and Glaser and Straus (1967). The concepts and categories were generated by our analysis of the data and validated applying the constant comparative method. Each interview was treated as an individual case. NVivo® was used to assist the qualitative analysis process, to manage data, to store the interview transcripts, and to help in coding text (Bazeley & Richards, 2000).

RESULTS

Survey Results

This research finds that 23% (n=7) of the hospitals within the survey sample have adopted OSS. Conversely, 76% (n=23) of the hospitals indicated that they have not adopted any type of OSS. All of the hospital adopters of OSS reported having general-purpose products. Among them, only 57% (n=4) reported having adopted domain-specific products. Table 2 presents descriptive statistics profiling the hospitals in our survey sample.

Key findings from this research indicate that hospitals are adopters of both general-purpose and domain-specific products, but they have adopted general-purpose products to a greater extent than domain-specific products. General-purpose OSS adoption in hospitals clusters mainly in databases, desktop software, programming languages, and operating systems, as well as Web development tools and server products. Well-known OSS products such as MySQL, Linux, Apache, Firefox, PHP and Perl were the leading software products that hospitals selected to adopt. The scale used in the survey to indicate extent of adoption was adapted following Fichman and Kemerer (1997) and it ranges from unawareness (no knowledge of OSS), to awareness, interest (actively learning), evaluation/trial (acquisition and initiation of an evaluation or trial version), commitment (use for one or more deployment projects), limited deployment (regular, but still limited, deployment and use), and general deployment stages (a

stable and regular part of the IT infrastructure). The survey results show that the vast majority of general-purpose products are positioned from the evaluation/trial stages to the limited deployment stages. Well-known OSS products, for example, MySQL, Linux, Apache, and Perl, are in the limited deployment stages, whereas OSS desktop software applications, such as Firefox and Mozilla, are in the evaluation/trial stages. The extent of adoption of domain-specific products is lower than that of general-purpose products. The predominant adoption stages for all the domain-specific OSS products are awareness to interest. Domain-specific adoption occurs mainly in the telemedicine, electronic medical records, radiology, laboratory and pharmacy information systems products.

Furthermore, the results of the survey provide information about relevant contextual and structural characteristics of the hospitals that tend to adopt OSS. These characteristics may have a determinant effect on the adoption of OSS. First, the majority of the adopting hospitals are very large hospitals, with 500 beds or more. Second, these hospitals tend to have high annual revenue, more than $500 million. Third, hospital adopters

Table 2. Descriptive statistics of surveyed hospitals

Annual IT operating budget		
<2%	5	16.7
2.1-3.0%	15	50.0
3.1-4.0%	1	3.3
4.1-5.0%	5	16.7
5.1-6.0%	1	3.3
>8%	3	10.0
Type of IT personnel		
In-house	27	90.0
Outsourced	3	10.0
Number of in-house IT staff employed full time		
≤10	5	16.7
10-30	10	33.3
31-60	7	23.3
≥91	8	26.7
Years of experience of in-house IT staff		
≤2 years	1	3.3
2-5 years	6	20.0
5-10 years	15	50.0
≥10 years	8	26.7

of OSS have a propensity to have a large number of IT support staff. Finally, hospitals that have adopted OSS also tend to have IT budgets that are less than 3% of the hospital's total budget.

Interview Results

This study also identifies, through the interview data, key categories that facilitate and inhibit the adoption of OSS in the hospitals within the sample. The interview data reveal that hospital software vendors are the most critical factor influencing the adoption of OSS in hospitals. Further, hospitals rely heavily on software vendors for all of their IT solutions. The results also show that hospital software vendors enlarge their product lines and the services they provide to hospitals to include general-purpose and domain-specific OSS products. In addition, IT managers have a positive satisfaction level, in general, with the software vendor services and products, and, overall, have a good relationship with them. Table 3 presents a concise summary of the results of the interviews.

The majority of the hospital IT managers reported that lack of in-house development, and a perceived lack of security, quality, and accountability of OSS products were the most significant factors that inhibit the adoption of OSS in hospitals. IT managers also identified the lack of medical informaticians, patient-privacy protection and privacy legislation as major inhibitors to adopt OSS, particularly domain-specific products.

Based upon our findings (from both the survey and interviews), the following section presents an empirical model describing the factors facilitating and inhibiting the adoption of OSS in hospitals and the relationships between them.

ADOPTION OF OSS IN HOSPITALS: AN EMPIRICAL MODEL

We have used Strauss and Corbin's (1998) paradigm to develop an empirical model describing the adoption of OSS in hospitals, based on our data. This empirical model helps us to develop and propose connections between the factors that emerged from our findings. Figure 1 presents the empirical model that lays out the analysis of the factors that emerged from our results and the relationships between them.

The empirical model identifies temporal and inferential, rather than causal, relationships between the factors relevant to the adoption of OSS in hospitals. For example, the mix of causal conditions in a particular hospital at a particular point in time (as defined by the level of in-house development, the number of IT personnel, etc.) sets the stage and shapes what happens when an event occurs related to the core category (e.g., when a software vendor offers an open source solution to the hospital). This core category then directly influences the strategic actions (i.e., adoption or non-adoption of OSS) that lead to the consequences. The contextual factors and intervening conditions moderate and mediate the strategic actions that are employed to bring about certain consequences (Strauss & Corbin, 1998; Creswell, 2005). So, in terms of the symbology in Figure 1, an arrow from one construct to another cannot be interpreted to mean that the first construct in any way causes the second, but that the mix of factors and actions described by the first construct influence the mix of factors and actions described by the second construct in any particular instance. The constructs of the model are described in more detail below.

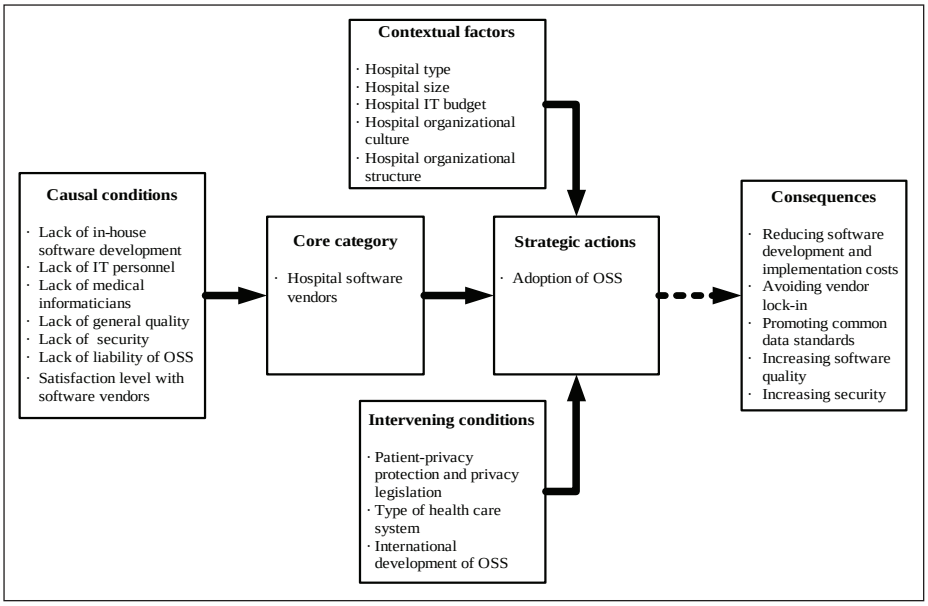
Causal Conditions

Causal conditions, as the term is being used in our empirical model, are factors that are identified as influencing the core category. There is evidence from our findings that all of these causal conditions have an influence on whether or not a hospital is open to an offer of OSS by a software vendor.

Table 3. Emerging code categories and subcategories of the adoption of OSS in hospitals

Core Categories	Subcategories
1. Hospital IT human resources	• In-house software development • IT personnel • Medical informaticians
2. Hospital regulatory landscape	• Patient-privacy protection and privacy legislation • Lack of liability/accountability provided by OSS
3. Hospital software vendors	• Software vendor providers of OSS • Satisfaction level with software vendors • New software business models
4. Hospital organizational factors	• Hospital organizational culture • Hospital organizational structure
5. Hospital technological factors	• Perceived lack of quality • Perceived lack of security
6. International development of OSS	• Labor cost and qualified programmers • Type of healthcare systems

Figure 1. Empirical model for the adoption of OSS in hospitals



The subject of technical personnel in hospitals came up often in our interview data (see "Interview Results" and Table 3). Hospital IT managers report that the lack of in-house development is the rule rather than the exception; hospitals do not develop their own software systems, and thus they depend on software vendors for all their IT operations and software needs. Managers also mentioned that much of their IT staff personnel are exclusively devoted to the on-site support of IT systems provided by vendors. The degree to which a hospital lacks in-house development activity, and IT personnel with technical development skills influences how dependent they are on their software vendors, and thus influences how they would react to the offerings of their vendors. Such a dependence would make a hospital more likely to accept a technology solution from a vendor that included OSS. A related causal condition is the lack of personnel who possess an amalgamation of medicine and information systems expertise and thus who would be able to develop and maintain software systems tailored to hospitals and healthcare organizations.

The perceived lack of general quality and perceived lack of security of OSS products are persistent themes that emerged from our data analysis (these are described under the core category "Hospital technological factors" in Table 3). As one manager commented "OSS is not going to have the same level of quality and not nearly the same level of documentation and rigor you can get from a corporate environment." Another IT manager opined that "the majority of the OSS are probably of inferior quality because they are just gifts that any research lab puts together and hands out from a couple graduate students." Managers also perceive OSS as a high-risk product when it concerns security. As one manager commented, "It is not the fact that the OSS won't be able to provide the functionality that we need in the hospital. The major concern is going to be how secure OSS is." Managers perceive OSS to be highly vulnerable to attacks from hackers or other parties, which may inhibit them from adopting OSS, even from a vendor. These quality and security factors will color a hospital's openness to a vendor's offer of an open source solution.

The lack of accountability of OSS providers is also a concern for the hospital IT managers we interviewed. Having a vendor that can be held liable or accountable if there is inadequate or insufficient quality or security of the software product strongly influences the decision to adopt products from software vendors. As one IT manager expressed: "the factor that caused us not to adopt OSS is the support and accountability that comes with writing a check to a commercial software vendor." The negative perceptions of quality, security and lack of liability reinforce the hospitals' dependence on software vendors.

Finally, our findings report that IT managers have a positive satisfaction level, in general, towards the products, support and services that software vendors provide in their hospitals, as noted in the interview results. This further reinforces the hospitals' dependence on software vendors.

In summary, these causal conditions all shape and impact the core category, that is, they influence what happens when and if a vendor offers a hospital a solution that includes OSS.

Core Category

The mix of causal conditions in a particular hospital setting sets the stage for the "core category," that is, the hospital software vendors. While our survey did not address the issue of software vendors, there was unanimous consensus amongst all the hospital IT managers interviewed that hospital software vendors play a pivotal role in the adoption process of OSS in hospitals, as discussed in the interview results. IT managers identify hospital software vendors who supply OSS products and services as the key facilitators for the adoption of both general-purpose and domain-specific OSS products. In terms of the empirical model presented in Figure 1, the actions of the software vendors is the trigger, or the gateway, that creates the situation where a hospital must decide to adopt or not adopt OSS. Such a decision does not even arise except through the actions of a software vendor, according to the findings of this study. As one manager commented, "hospitals are so dependent on vendors of hospital IT products that we are not in the position to kind of 'buck the rules' and go it alone for the adoption of OSS."

However, sometimes this decision is not even explicit. As one IT manager adopter of OSS expressed, "we don't have a conscious decision to adopt OSS because our hospital outsources a lot of our technical knowledge to vendors, so the adoption of OSS is coming throughout the vendor's decisions for the most part."

The hospitals' decision to adopt OSS from software vendors is linked to their belief that the OSS offered this way has "a professional level of quality control" that is greater than the OSS available from other sources, such as the Internet. As one IT manager who adopted vendor-supported OSS stated, "I am very happy using OSS because, for me, the best of two worlds is when vendors support an OSS solution. I am willing to pay for OSS, because I feel I have professional quality and control over the software."

Contextual Factors

Contextual factors are the "specific set of conditions (patterns of conditions) that intersect dimensionally at this time and place to create a set of circumstances or problems to which persons respond through actions/interactions" (Strauss & Corbin, 1998, p. 132). Our data, especially the survey data presented in "Survey Results", reveal that several contextual factors are expected to moderate the adoption of OSS in hospitals. The combined qualitative and quantitative results of this study provide evidence that the following contextual factors may facilitate or inhibit the adoption of OSS in hospitals: 1) hospital type, 2) hospital size, 3) hospital IT budget, 4) hospital organizational culture, and finally 5) hospital organizational structure. These factors are different from the causal conditions listed earlier, in that they are more general, static factors that

apply to the hospital as a whole and do not specifically form the hospital's attitude towards OSS, or towards the software vendor.

Depending on the hospital type (such as a stand-alone hospital versus a multi-hospital network, or a university hospital versus a private hospital, and so on), the importance of IT adoption within the hospital may differ. Different types of hospitals seem to have different requirements to adopt software. For example, a university hospital may allow experimentation with new software products while a private hospital in a multi-hospital network may not allow any type of experimentation. Such factors may have an effect on the adoption of OSS by hospitals. Hospital size is likely to be related to organizational characteristics such as slack in resources or a large professional workforce that can also have a positive effect on the adoption of OSS in hospitals. Hospital IT budget is another contextual factor that emerged in our study as a meaningful factor since hospitals with smaller relative IT budgets (with 3% or less of the total hospital budget) have a propensity to adopt OSS.

Other contextual factors within the hospital such as organizational culture and organizational structure can also have an effect on the adoption of OSS. As one manager commented, "the organizational design of the hospitals has a major influence on the adoption of software within the hospital, I don't want to use the word power structure, but it is almost the political landscape of the organization that influences the way we adopt any technology."

Our findings support the effect that all the aforementioned factors have on the strategic actions (i.e., adoption or non-adoption) as depicted in Figure 1 with regards to OSS adoption within hospitals.

Intervening Conditions

Intervening conditions are those conditions that "mitigate or otherwise impact causal conditions" (Strauss & Corbin, 1998, p. 131). The intervening conditions identified in this study included: 1) patient-privacy protection and privacy legislation, 2) type of healthcare system, and 3) international development of OSS. These intervening conditions are factors, external to the immediate hospital setting that may inhibit the adoption of OSS in hospitals. IT managers we interviewed (see Table 3) report that factors such as patient-privacy protection and privacy legislation may act as deterrents for the adoption of OSS in general, especially with regards to the domain-specific OSS products. For example, hospital IT managers were reluctant to adopt domain-specific OSS products because they perceived OSS as posing a threat to patients' privacy and confidentiality as well as to HIPAA compliance mandates. Consequently, we conclude that the aforementioned three intervening conditions also mediate the adoption of OSS in hospitals.

Strategic Actions

Strategic actions are "purposeful or deliberated acts that are taken to resolve a specific problem" (Strauss & Corbin, 1998, p. 133). The interaction outcome of the core category (hospital software vendors) with the contextual factors and the intervening conditions may result in a decision by hospitals to make full use of a technology—in this case OSS—as a plausible or implausible alternative to proprietary (closed source) or commercial software products.

Consequences

Consequences are the outcomes of the interaction of the core category with the contextual factors, intervening conditions and the strategic actions. The outcomes of this empirical model are closely aligned with the potential benefits of OSS claimed in the literature reviewed in literature section of this article. However, we can only speculate about the actual consequences, as that part of the model is beyond

the scope and objectives of this research. However, investigating the consequences of OSS adoption in hospitals is a vital area for future research.

IMPLICATIONS

Implications for the Literature

OSS has created a stir of interest in many disciplines ranging from computer science to sociology, and a growing body of literature has emerged to explain many aspects of OSS. However, no work has investigated the adoption of OSS in hospitals. The research presented here addresses this gap.

A number of respondents from the interviews noted that the lack of IT personnel and the lack of medical informaticians are inhibiting factors for adoption of OSS by hospitals. This is consistent with previous authors (Yackel 2001; MacDonald et al., 2003; Fitzgerald & Kenny, 2004; Hogarth & Turner, 2005; Waring & Maddocks, 2005) who have noted the importance of IT personnel with high levels of technical expertise required in order to deal with OSS applications and the technological complexity in the medical domain that needs personnel that understand both medicine and information systems.

In contrast to other studies claiming that the reduction of ownership and development cost is one of the main advantages of adopting OSS in healthcare (Yackel, 2001; Kantor et al., 2003; Fitzgerald & Kenny, 2004; Glynn et al., 2005; Hogarth & Turner, 2005; Holck, Larsen, & Pedersen, 2005), the findings from this research indicated that cost factors are not a core, important category for hospital IT managers when deciding to adopt OSS. The IT managers in our study were found to be more concerned about the quality, security and liability issues surrounding OSS than about the potential cost-benefit factors associated with the adoption and use of OSS. This finding also compares with a prior study by Goode (2005), which also noted that managers see software with high cost as an indicator of quality.

Prior research (Fitzgerald & Kenny, 2004; Glynn et al. 2005; Holck et al. 2005; Waring & Maddocks, 2005) has noted the importance of top management support for the successful adoption of technology within organizations. Our findings, by contrast, show that not only top management support is important to the adoption of OSS by hospitals, but clinical personnel within hospitals (e.g., physicians, nurses, etc.) also exert a significant influence on the decision to adopt not only OSS but any technology. Many IT managers recognized the political influence of these groups as a critical factor in how OSS would be used in the future, even before getting to the technology portion of the adoption of OSS by hospitals.

This study also shows that the hospital industry is a very conservative industry when it concerns adopting new technologies. Managers repeatedly indicated the "conservative aspects and risk adverse" behavior of the hospital industry to adopt not only OSS but also any new technology. This finding is consistent with MacDonald et Al. (2003) and Glynn (2005) who also pointed out hospitals' risk averse behavior when adopting IT.

Finally, our core finding about the central role of software vendors in the adoption decision in hospitals has some relationship to prior literature. Some existing studies have indicated that avoiding vendor lock-in is perceived to be an advantage of adopting open source (Carr, 2003; 2004; Fink, 2003; Kantor et al., 2003; Fitzgerald, 2004; Goldman & Gabriel, 2005; Goode, 2005). In contrast, in our study, the role of vendors emerged quite differently. The role of vendors as OSS adopters, who then transfer their adoption decisions on to their client hospitals, has not previously been described in the literature. This finding describes vendors as innovating the way they develop, distribute, support and maintain software systems within hospitals. Prior studies have not shown software vendors to be such key enablers of OSS in the hospital industry.

Implications for Future Research

This research is unique within the field of OSS and healthcare. That is, there is no study that has been published to date presenting an empirical model for the adoption of OSS in hospitals. This model, grounded in empirical data collected from surveys and interviews, identifies the factors and relationships facilitating and inhibiting the adoption of OSS in hospitals. This model provides the basis for future testing of the interactions among the key concepts proposed in this study. Furthermore, there are numerous significant issues for researchers, including ourselves. Our findings, while not highly generalizable due to the limitations of the study, provide sufficient grounding for future confirmatory studies.

In particular, a number of very interesting propositions or hypotheses are suggested by our empirical model, and by the survey and interview data. Future research aimed at validating these hypotheses would be a significant contribution to the field. Examples of such propositions include:

- **Proposition**: Adoption of OSS is more likely to be found in hospitals that have in-house technical staff with experience in software development, OSS, and/or with medical informatics.
- **Proposition**: Hospitals with an existing relationship with a software vendor who offers OSS solutions are more likely to adopt OSS. The likelihood increases with the degree of dependence on the vendor and the degree of satisfaction with the vendor.
- **Proposition:** The adoption of OSS in a hospital is more likely when there is a centralized IT strategy within the hospital.
- **Proposition:** The likelihood of a hospital's adoption of OSS is negatively correlated with the IT manager's perception of the general quality and security of OSS products.

To further validate propositions such as those above, as well as the whole empirical framework derived from this study, the following future research is planned:

1. Validation of the model by collecting data from a large sample of hospitals, either in the U.S. and/or internationally, would allow for further conclusions about the causal relationships and interactions suggested by our empirical model.
2. A case study in a hospital setting to analyze the consequences of the adoption and implementation of OSS.
3. Further empirical investigation into the relationship between hospital software vendors and adoption of OSS.

Implications for Practice

The present research provides a better understanding to hospital IT managers and practitioners about the extent of OSS adoption in hospitals in conjunction with the factors facilitating or inhibiting this adoption process. Hospitals and healthcare organizations that are considering the adoption and implementation of OSS technologies need to understand how technological, environmental and organizational factors affect the adoption process. This way IT hospital practitioners can prepare against the expected barriers and can utilize the facilitators for successful OSS technology adoption.

The first implication for practitioners is that, contrary to theoretical and anecdotal expectations about the cost-benefit advantages of OSS versus proprietary or commercial-based software, the findings from this research indicated that financial factors are not deemed to be a core concern for IT managers when deciding to adopt OSS. The IT managers in our study were found to be more concerned about the quality, security and liability

issues surrounding OSS. This implies that, when building a business case, or justification, for the adoption of OSS, the analysis must take into account issues related to quality, security, and accountability with at least as much prominence as cost-benefit issues.

The second implication for hospital IT practitioners would be to involve all the stakeholders within the hospital in the adoption decision-making; for this particular point, our finding indicated that physicians, nurses, and other clinical personnel are key stakeholders to address in the adoption process of not only OSS but any type of technology introduced to a hospital. Thus the receptivity to the idea and philosophy of OSS must be assessed with these stakeholders, and any ideas and concerns that might surface during the assessment must be documented and taken into account.

The third recommendation for hospitals that are considering OSS is that they can start adopting OSS with a small pilot project in order to test and experiment with the quality issues of interest, as well as the costs and benefits, of OSS to the hospital. In addition, it is very important to collect data and metrics from the pilot project and communicate the results to all the stakeholders, including vendors, within the hospital. It is important to mention that OSS is not "free," and never will be without a cost.

Another implication for practitioners who want to promote the use of OSS within the hospital and healthcare industry is for them to liaise with hospital software vendors and the OSS community. Coordinating with hospital IT vendors is important because, as our findings reported, any tendency towards adoption of OSS in hospitals is occurring because healthcare IT vendors are embracing, providing, and maintaining OSS products. Under this business model, hospital software vendors are not only offering the software to hospitals but also offering services for installation, customization, and maintenance of OSS applications, either domain-specific or general-purpose. Furthermore, there are good examples of software partnerships amongst IT businesses, open source communities, and researchers such as Eclipse and even Linux (Capek, 2005; Goldman & Gabriel, 2005; Zeller & Krinke, 2005) that can be replicated in the hospital and healthcare industry. Moreover, the hospital industry is probably the most influential and powerful industry operating today in the healthcare area. If this industry sees the benefits from OSS, then partnerships between IT businesses, OSS communities, and universities could result in research, development and promotion of OSS hospital products and policies that further the evolution of the OSS movement, as well as provide substantial benefits to the hospital industry. Therefore, such partnerships could be a potentially transforming development in promoting and adopting OSS in hospitals.

LIMITATIONS OF THE STUDY

Notwithstanding the important contributions of the current study, it has its own shortcomings. For example, our findings may not apply to the full spectrum of U.S. hospitals. This research is exploratory in nature, so that the design, data collection methods, and analysis were broad by design, and not intended for confirmation. This research also examined the adoption or non-adoption of OSS in a limited geographical area and over a particular time period, which makes any attempts to generalize the results across hospitals in the U.S. difficult without further empirical analysis and investigation.

Another limitation was the modest sample size of response in the survey (n=30) and interviews (n=5). Through the evolution of this study, it became clear that IT managers in the hospital industry in the BWNV area were less than enthusiastic about discussing and sharing information about open source adoption within their hospitals. Many attempts to influence a higher rate of response and interview participation were made, including initial contacts, follow-up contacts, reminders, and even

financial incentives. While the small sample size affects the ability to generalize results, it does not affect what was the intent of the study, to explore and identify relevant issues and factors for further study. However, it is important to mention that these are important limitations for any future similar study because of the unwillingness of the managers and executives to share their views on issues concerning IT adoption.

Finally, another limitation of this research is that the data appears not to represent all types of OSS products. While it was not the intent of the study, it is clear from the responses (in particular the types of OSS that survey respondents report adopting) that our respondents were referring primarily to large, enterprise-level OSS applications (e.g., database servers, Web servers, operating systems, etc.). This limits our ability to extend our findings to the entire spectrum of OSS products available to hospitals. It also limits our ability to compare the results of this study to prior research, which mostly addresses the adoption of smaller, stand-alone, download-and-install types of OSS applications.

CONCLUSION

This research identifies the factors that could lead to more effective adoption of OSS by hospitals. In addition, this research sheds light and broadens the understanding of OSS adoption within hospitals by offering to IT practitioners information on the extent of that adoption currently.

Finally, the insight gained from this research serves as a guide and foundation for future work to investigate more determinants of OSS adoption in hospitals and healthcare organizations. It is also the researcher's hope that this study will be the seminal stone to pave the way for future studies on OSS adoption and implementation in organizations, public and private, national and international.

ACKNOWLEDGMENT

The authors would like to thank Khaled El Emam, Medha Umarji, Roy Rada, Katherine Stewart Dongsong Zhang and Stephen Russell, as well as the anonymous IJHISI reviewers for their editorial insights. Additionally, we deeply appreciate the time, interest, and participation of hospital IT managers in the Baltimore-Washington area surveyed and interviewed in this study.

Open Source Software:
A Key Component of E-Health in Developing Nations

ORGANIZATION OF THIS ARTICLE

This article is organized around a number of sections. The introduction outlines the rationale of the article and deals with some aspects of open source software (OSS) that make it attractive for software development in the health domain for low-income countries. The methodology section then introduces the framework of assessment that is being used. The majority of this article describes a case study of a project run by the authors in Bhutan in the obstetric domain. Critical success factors for such a project are then analyzed and some conclusions are drawn. The discussion covers some of the issues that have arisen from this experience, and articulates some lessons learned.

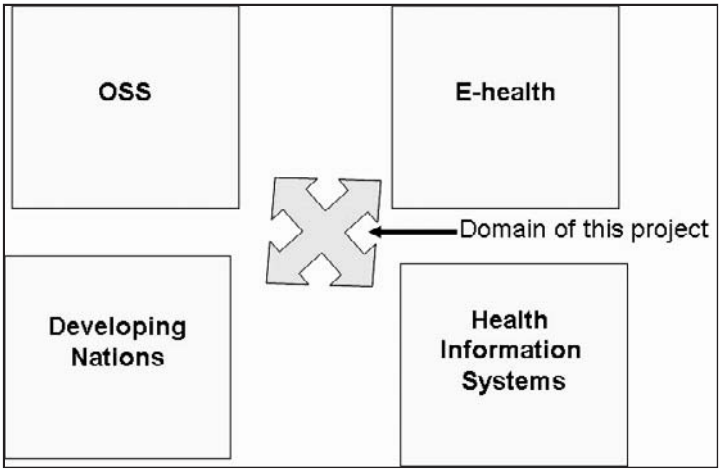
INTRODUCTION

This project deals with the intersection of a number of domains, as shown in Figure 1.

E-Health

E-health has become a popular term for the transformation of healthcare that has occurred through the use of electronic communications,

Figure 1. Research domains



in a conscious imitation of "e-business." E-health encompasses more than the traditional electronic health record. It involves the use of information and communications technologies in the widest sense, including telemedicine, Web-based health and mobile devices for healthcare. A definition has been proposed, after comprehensive analysis, in Pagliari et al. (2005):

E-health is an emerging field of medical informatics, referring to the organization and delivery of health services and information using the Internet and related technologies. In a broader sense, the term characterizes not only a technical development, but also a new way of working, an attitude, and a commitment for networked, global thinking, to improve healthcare locally, regionally, and worldwide by using information and communication technology.

This definition is actually adapted from a previous one in an editorial which discussed the scope of "e-health" (Eysenbach, 2001). The globalized and networked aspects are particularly important in our case study—the emphasis is on communication and collaboration rather than distance

Health Information Systems

Health information systems (HIS) often have three main objectives: to improve patient care, improve management and form part of a quality improvement program. However, these objectives—as described by Littlejohns, Wyatt and Garvican (2003), are not always achieved. As part of a HIS implementation there are often major changes to workflow and practice, large expenditures on hardware including computing and communications, and system integration, as well as software development, training and implementation. Failures occur in HIS development often due to a lack of understanding of the complexity of the project (Littlejohns et al., 2003). Interestingly, OSS appears to answer some of these issues by providing more stable—if less feature-rich—software, and providing a generally larger pool of developers and users than for proprietary software.

Open Source Software

Open source software (OSS) has gained very wide acceptance particularly in the Web server community. Projects such as Apache (Mockus,

Fielding, & Herbsleb, 2000) have involved large scale participation, and dominant market share. In the healthcare domain, Sourceforge.net lists 58 applications for download. Many of the applications are extremely specialized, but on the other hand, some like the Web Interface Repository server (WIRM), (Jakobovits, Rosse, & Brinkley, 2002) are effectively complete development environments. This article will argue that successful development and use of OSS in healthcare requires a number of critical "success" factors, and that these reflect both the nature of OSS projects in the wider world and particular aspects relevant to healthcare. OSS can be seen as part of a wider movement that has been characterized as innovation from the user community (Hippel, 2001). This emphasizes the point that OSS is not just "free" but also is able to be modified by the community that uses it.

DEVELOPING NATIONS AND THE CASE OF BHUTAN

Health information systems are important for developing nations as well as industrialized ones. A large review of the use of information technology in primary care in developing countries (Tomasi, 2004) identified five main areas of application—data processing in the healthcare system, decision support, electronic data transmission, electronic patient records and telemedicine. Many developing countries have low levels of trained clinical staff, and this can increase the load on secondary and tertiary providers. In order to audit their performance, and increase efficiency, electronic records and workflow systems can reduce the workload on the staff available.

Both of these aspects are particularly important for developing nations for a number of reasons:

- Developing nations have extremely limited health budgets, but the burden of disease on individual households can be very large. For example, up to 100% of household income being spent on end-stage care for AIDS patients in some nations in Africa (Russell, 2004).
- Developing nations often have a diverse mixture of groups within them, and it cannot be assumed that all citizens have a common language. Even when a common language exists, it may be spoken by a relatively small percentage of the world's population, and commercial development of software using that language may not be feasible.
- Infrastructure and resource constraints, in particular for network connectivity, may reduce the utility of high-performance systems routinely used in the west. For example, PACS systems involving transmission of large images via network connections may not be practical, but memory stick-based approaches may be feasible (Parry, Sood, & Parry, 2006).
- Open source approaches allow the development of expertise in multiple sites away from large commercial organizations. Therefore, they can encourage the upskilling of software developers in smaller centers. This expertise can be applied to the localization of standard packages and the development of a solid base for software support. In this aspect, both the development and the use of open source software can be beneficial in the education sector. Developing nations often have large and increasing numbers of young, educated people available for project development. OSS tools are attractive for teaching information systems development because of cost, wide availability of documentation and localized versions being available. For example, Debian translators are available in over 80 l language versions including Dzonga—the national language of Bhutan.
- Commercial software suppliers may be reluctant to sell advanced software packages in

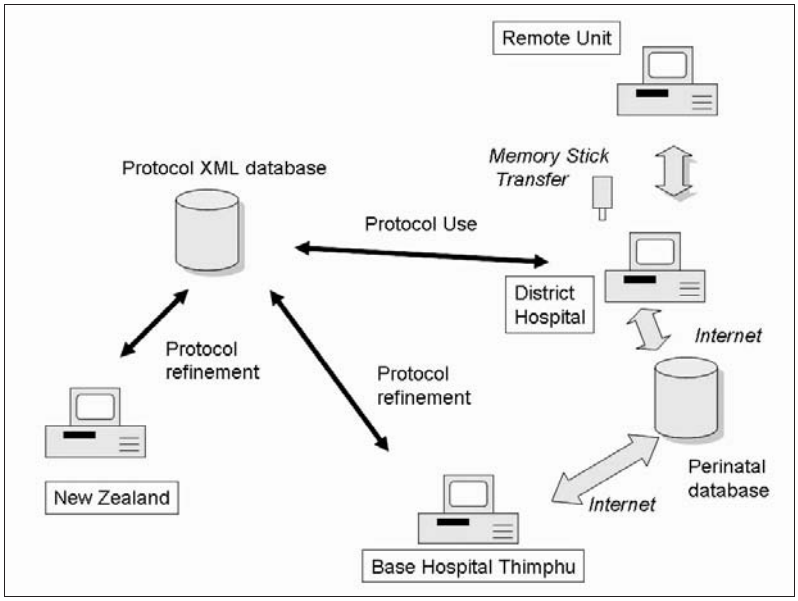
developing nations because of the difficulty of arranging support and the perceived threat of piracy.

- Developing nations' health systems often have a complex collection of groups working within them including governments, commercial organizations, local and international charities and international official organizations. The requirement for reporting and data analysis may well be more complex than in industrialized nations.
- Infrastructure developed to support call-center development or tourism, including Internet and telecommunications technology, is easily adapted to allow links between nations. Because OSS tools are supported via the Web, this approach avoids the reliance on expensive and out-of-date paper manuals and development kits. OSS's licensing structure allows cross-national projects to be completed much more easily.
- Mobile devices have particular promise for e-health in developing nations (Iluyemi, Fitch, Parry, & Briggs, 2007). Mobile OSS development is a particularly active area of research (Raento, Oulasvirta, Petit, & Toivonen, 2005).

The case study in this article deals with the intersection of a number of research domains, (Figure 1), which means that the choice of methodology for analysis may be challenging. There have been some recent papers on the use of OSS in health information systems, focused mainly on developed country applications (Kantor, Wilson, & Midgley, 2003; McDonald et al., 2003). Interestingly, these papers point out that the use of OSS in healthcare is not new and that although perhaps small-scale, this work has been consistently ongoing. However, these papers do emphasize the potential gains to be had by the use of 0SS in healthcare both in terms of health providers and also developers.

Because of the widely varying state of communications infrastructure in developing countries, western models of development which emphasize in-hospital systems linked by fixed line, high-capacity networks may not be appropriate. In the context of less developed countries, there have

Figure 2. Overall system plan



been a number of telemedicine projects, often concerned with communication from centers of excellence in western nations (e.g., Swinfen, Swinfen, Youngberry, & Wootton, 2005), or within developing countries (Deodhar, 2002), but a shared approach to development is vital (Wooton, 2001).

Methodology

In order to analyze a case study, some sort of framework of analysis should be adopted. The development project was actually quite complex with elements of telemedicine; knowledge management and information processing included in the overall design (see Figure 2).

A survey of telemedicine projects in India (Pal, Mbarika, Cobb-Payton, Datta, & McCoy, 2005) identified six critical success factors for telemedicine success; these were used as practical and simple measures that could be applied in this complex, yet small-scale project. The success factors identified were:

1. Set clear program objectives
2. Garner government support
3. Adapt user-friendly interfaces
4. Determine accessibility via telecommunications and Internet access
5. Implement standards and protocols
6. Measure cost-effectiveness and user satisfaction

The case study will deal with these areas, although the project is wider than a simple telemedicine project as it includes database development and integration with the audit system, along with Web-based protocols.

CASE REPORT: E-HEALTH SUPPORT FOR OBSTETRIC SERVICES IN BHUTAN

Bhutan is a small Buddhist kingdom located in the Himalayas, with a population of fewer than 700,000. Land transport is extremely slow because of the geography—for example it takes three days to travel across the country, a distance of around 300km. There is only one airport and no facility for helicopter transport. Seventy percent of the population live in rural areas with 30% more than a one-hour walk from the nearest road head. Bhutan has had major successes in increasing life expectancy and improving healthcare, but avoidable perinatal and maternal mortality and morbidity remains an issue. Current figures for Bhutan suggest an infant mortality rate of 67/1000 and a maternal mortality rate of 4.2/1000—compared with New Zealand's rates of 4/1000 and 0.07/1000 respectively (World Health Organization, 2006a).

Large numbers of preventable neonatal deaths continue to occur in the less developed countries. However, recent work has suggested (Darmstadt et al., 2005) that evidence- based interventions in antenatal and intrapartum care could reduce these rates by between 37% and 67%. These interventions are not complex and are relatively inexpensive. The overarching imperative is to ensure appropriate care for pregnant women that involves patient education and cooperation with antenatal and intrapartum services. Although there have been many studies on the use of e-health in obstetrics and perinatology and in less developed nations (Deodhar, 2002), there remains relatively little work on the evaluation of these systems. In particular, the outcome and integration

of these systems into existing structures, and the changes that occur because of their introduction have not been studied, although the 1 to 45 cost benefit ratio quoted in this study is impressive.

The World Health Organization has been running a "Making Pregnancy Safer" Initiative (World Health Organization) in order to reduce the level of neonatal and maternal mortality. Previous work in Bhutan had developed a protocol book for emergency obstetric care (EmOC). Other countries using EMOC have recorded improvement in outcomes, for example, Bangladesh (Islam MT, 2006) and Peru (Kayango et al., 2006). One of the major lessons learned in these trials was that a record of outcomes via a perinatal database, and the wide dissemination and use of protocols are vital for success. In general it is important that all health workers caring for pregnant women use health information that is based on clear evidence from rigorous studies (Tita, Stringer, Goldenberg, & Rouse, 2007). Surprisingly perhaps, the identification of appropriate procedures for dealing with high-risk patients has been shown to be effective in reducing the demand for interventions (Islam MT, 2006).

The Bhutanese Health System

Healthcare is free in Bhutan, and is delivered via a tertiary structure. The primary healthcare unit is the "Basic Health Unit" (BHU), of which there are approximately 170 around the country. These units do not always have medically qualified staff, but they run outreach and clinic services and usually a number of beds are available. Birthing services, run by nurses, are sometimes available. District health units (around 30) will have at least one generalist medical officer; some of these units have the capacity to perform caesarean sections and ultrasound scanning. There are three referral hospitals in the country which have at least one obstetrician and theatre services. The Jigme Dorji Wanchuck National Referral hospital (JDWNRH) in the capital has four obstetricians and is the tertiary referral unit for the whole country. Because there is no general practitioner service, patients have the opportunity to refer themselves directly to hospital-based consultants even in cases where primary care would be more appropriate. This and the paucity of qualified obstetricians, results in a large workload and the obstetricians are busy and often difficult to contact for advice. A current project is running to introduce the EmOC system to Bhutan, and the protocols are being integrated with these to provide seamless care.

Project Description

The aim of the project described in this article was to collaboratively develop a number of treatment and/or diagnostic protocols to allow the clinical staff to apply appropriate evidence-based care for the major problems that would be dealt with by a perinatal service. The role of the perinatal service is described in Mascarenhas, Eliot and MacKenzie (1992). Essentially, it provides care for mothers and babies from conception to birth, and aims to reduce the risks to mother and baby in this process, by appropriate intervention and monitoring. In addition to the staff applying the protocols in practice, the aim is to raise awareness of the issues that affect perinatal outcomes amongst others, for example, referring to clinicians. The development of a collegial editing and review process involving clinical staff in Bhutan and New Zealand was also seen as a vital part of the project. The project also included the development of a perinatal Web-based database to allow for more effective management of the service on a day-to-day basis and also allow for analysis of clinical performance.

OSS occurs in a number of places in the system. The perinatal database is written in PHP with a mySQL database engine. Web page development was done using open source tools, as was the XML protocol development. However, proprietary products were used for the operating systems and Web server software in Bhutan, along with the Linux/Apache

setup for the Web server in New Zealand. In addition, standard proprietary products were used to develop the protocols.

Review of Success Factors

Clear Objectives

The objectives of the project were identified in initial discussions and codified in the agreement signed between the stakeholders. The objectives included the development of a perinatal medicine service, continuing support for this service and standardization of treatment based on the best possible evidence. An additional objective was sustainability of the service. OSS supported this by allowing low- or no-cost technical documentation and development tools to be made available to local staff.

Government Support

The Royal Government of Bhutan (RGOB) is the sole supplier of healthcare in the kingdom. The RGOB runs a series of five-year plans which identify objectives and priorities as well as sources of funding. Plans developed by overseas providers are examined and extensive negotiation takes place to ensure that the country receives appropriate and sustainable help that is consistent with the RGOB objectives. This process began in the case of this project, two years before the initiation, when representatives of the funders—The Magee Family—met with other stakeholders including government representatives, clinical staff from New Zealand and Bhutan associated with the project, and UNICEF. This resulted in a project agreement that was signed off in a formal ceremony. The project composed a number of other elements including funding for hardware and training of clinical workers in the perinatal medicine area. Continuing involvement of the stakeholders has been a great asset to the project. The RGOB department of IT has been running a long-term project to support OSS and is getting closer to the development of a policy on its use (Bhutan Department of Information Technology, 2007).

Adapt User-Friendly Interfaces

The user interface adopted was a standard Web browser, whatever the source of the data—even locally stored protocols would display in a browser. The native protocols were stored as XML documents, which were then displayed in a human-readable format via a Web browser. XML was chosen for ease of updating—in that the editing

Figure 3. XML protocol fragment

```

  </Diagnosis>
</Root_Element>
```

process could alter content without a great deal of formatting issues and with the awareness that other display methods such as voice responses or mobile devices may be used in the future. As an open standard, XML is very well suited to this approach. The XML design is intended to be expandable and able to represent both diagnostic and therapeutic protocols.

A fragment of the XML representation is shown in Figure 3. The initial outline was based on the PubMED (may need to define this) schema, but simplified to remove excessive bibliographic elements. The XML documents identify the responses to particular diagnoses or symptoms which would be expected to be encountered commonly. The aim is to allow clinical staff, who may be at a remote site, to identify what emergency care is needed, whether the patient needs to be referred or transferred and the degree of urgency of that referral. Also, the protocol can identify what additional tests or procedures need to be performed.

Determine Accessibility

Although land transport is difficult, Bhutan is in the process of increasing the availability of Internet access. Apart from dial-up connections, there are microwave links and recently the international telecommunications union (ITU) e-post initiative (International Telecommunications Union, 2006) has recently been launched in Bhutan using very small aperture (VSAT) satellite ground stations for rural access to electronic communications, and this may be useful for rollout to remote areas. OSS tools are often very efficient in terms of file size, and machine footprint (use of processor time and memory) so they can be used in a wider range of scenarios than might be possible for the latest proprietary operating systems or applications.

Implement Standards

The protocols themselves were developed in a standard format (Table 1), and as seen above, implemented using XML. In addition to this, an attempt was made to standardize the production of the protocols so that candidate protocols from other sources would go through an editorial process and be routinely revised. This process was formally followed using paper-based systems, but electronic approaches allow instantaneous updating of the live protocol without fear of version control issues and also allow a trail to be kept of previous versions that can be linked to any events linked historically to the implementation.

Measuring Cost-Effectiveness and User Satisfaction

This aspect is perhaps the most difficult part of the project. As part of the process, proto-

Table 1. Major elements of the protocol document

Review Date	

cols will be regularly reviewed by stakeholders. In addition, a perinatal database is being implemented in order to record outcomes, and assess performance against that expected in the protocol, in particular, areas where the protocols are not being followed, and whether the protocols or behavior or both should be modified. It is hoped that improvements in the mortality and morbidity figures will also be noticeable, because of the currently relatively high rates of morbidity. Substitute measures, such as adherence to protocol may also be used. Finally, a rise in awareness of the general maternity service and increased access to it by women, only half of whom currently have an attended birth, would be expected to accompany improved outcomes among those who have contact with the perinatal service.

Lessons Learned

Integration of protocols from diverse sources was one of the major challenges facing the team. Protocols were sourced from the National Women's Hospital Auckland, New Zealand, the World Health Organization and EmOC protocols in Bhutan.

Collaborative review of protocols was extremely important, as buy-in from clinical staff is vital. However, the process of maintaining a common electronic repository was technically difficult as each of the reviewers tended to work asynchronously using paper copies. The final approach used was to produce paper prototypes and distribute them, collect back annotated versions and then combine them in a final Word document. This was then converted to XML. Development of the perinatal database was restricted by the very small numbers of users available to test and comment on the system, and a wide user community, which may only be available online, may well increase the quality and speed of development..

DISCUSSION AND FUTURE WORK

There are some general issues that affect e-health initiatives, and the use of OSS in the developing world, in particular, connectivity, computing resources and skills.

Connectivity

Less developed nations have generally much lower availability of fixed telephone lines. In addition, geographic, economic and governmental issues often conspire to make conventional dial-up access less common than in western countries. However, wireless and satellite solutions such as VSATS including the international telecommunications union (ITU) e-post initiative (International Telecommunications Union, 2006) are overcoming these issues. It is important to recognize that not every nation's infrastructure is developing in the same way, and many nations may leapfrog to wireless solutions without the use of landline-based solutions. However, high bandwidth solutions may not be appropriate for developing countries. One of the most successful e-health projects has been the Swinfen Project, currently expanding in Iraq (Swinfen et al., 2005). This project uses e-mail in a store-and-forward model, between clinicians in various countries. The prospects of advanced tele-presence approaches being effective in routine care seem slight because of issues concerning quality of service, bandwidth and reliability of connection. Even though the "trauma pod" and other projects financed by the U.S. Department of Defense are beginning to show results (Romano, Lam, Moses, Gilbert, & Marchessault, 2006), costs are likely to render this approach problematic in other contexts.

Computing

Devices such as the Simputer (The Simputer Trust, 2000) and the sub $100 laptop (OLPC, 2006) promise much cheaper access to computing power.

It should be emphasized that for e-health applications, the computing device can be fairly simple; indeed mobile devices may become the preferred means of access. Along with cost, the ability to survive rough treatment, extremes of temperature and humidity and long battery life—or even the use of clockwork power in the case of the sub $100 laptop—are more important in developing countries than in the organization for economic cooperation and development (OECD) member countries. Parts supply and transport cost can make the repair of computers extremely expensive. However, organizations such as global assistance for medical equipment (GAME) (http://www.global-medical-equipment.org/whatwedo.html) have established links between professional organizations in the developed and less developed world. These approaches move beyond the shipping of obsolescent equipment to an integrated and well-thought and sustainable out collaboration between donors and recipients.

Skills and Information

At present, consumer e-health is of limited usefulness in the developing world. Low levels of literacy and information literacy cause difficulties. However, the fact that the vast majority of Web resources are written in English and are U.S.-centric in terms of organization of healthcare, availability of drugs and medical devices and naming, makes even materials designed for health consumers in the OECD countries less useful for those in other nations. However, these issues are much less important when the provision of e-health services for medical professionals is considered. Adapting general principles to specific cases is a key skill of medical professionals. Indeed the traffic is not all one-way; less developed nation professionals often have skills that are no longer available in more developed nations. Collaboration in training of medical professionals, where trainees from different nations are exchanged, can improve the training in both systems. This can be supported by the use of e-health tools such as Web sites, e-mail and instant messaging.

Other skills required include the support of the e-health infrastructure in terms of technical support for computing devices and connectivity. Fortunately, the requirement of tourists from western countries for Internet connectivity, wherever they are, along with the burgeoning industries of call centers and 'off-shoring' of software development are providing a strong push for training in these areas.

OSS use in education and training allows nations with limited resources to devote more funding to the human side of education, as well as allowing projects that involve software localization to advance quickly. Open source clinical protocols may become important repositories of clinical knowledge allowing rapid development and input from experience, especially based on standard electronic forms.

Another important aspect of skill transfer and collaboration is the use of early warning networks for disease surveillance such as the Global Outbreak Alert and Response Network (GORAN) that played a very large part in the early detection of SARS (Heymann & Rodier, 2004). Such networks link health workers throughout the world and the transfer of information is by no means one-way.

There remains a dearth of well-controlled studies of e-health initiatives in developing nations, but the need for effective collaboration remains paramount (Wooton, 2001). However, there are a number of pointers to success:

1. The e-health system must be compatible with existing organizational and cultural structures. Some "western" assumptions do not apply in less developed nations and vice versa. For example, routine ultrasound examination in early pregnancy has not been shown to be effective in reducing mortality in a Cochrane review (Neilson, 1998). How-

ever, an environment where mortality due to unsuspected problems is much greater, and the availability of on-demand scans is lower, may give different results.

2. Collaboration and training between the professionals involved is vital. This applies to both clinical and technical staff. This may in fact be the area of greatest benefit.
3. Ingenuity is more important than technology. Store-and-forward e-mail may be of greater utility than tele-presence.
4. Open source technology is particularly suited to this area of work. Lower costs, availability of technical skills, greater range of customized languages and often lower technology requirements make open source approaches and especially Web-based open source tools particularly attractive.

FUTURE RESEARCH

Future work in this area will include greater use of multicenter collaboration, both within existing networks such as GORAN and GAME and outside them. Lower bandwidth costs, and easier access to high bandwidths will enable richer media to be used, such as tele-sonography via store-and-forward (Parry et al., 2006). Common health problems are starting to afflict north and south: aging populations, the rapid spread of new infectious diseases and chronic conditions. Common approaches to these issues, including the use of low-cost assistive technology, and offshoring of medical procedures such as radiology (Larson & Janower, 2005), may be controversial, but at least the discussion has started. There are enormous potential benefits in the development of e-health in collaboration with developing nations, and the benefit to the people of world may be immense. An additional benefit of the open source approach may be an increased ability for IT specialists in developed nations to assist people around the world. As virtually every nation now has a Web presence, the technical barriers to such collaboration are much lower than they were even ten years ago. It is hoped that further work will refine the system sufficiently to allow the software to be placed in a repository such as Sourceforge.net. Furthermore, it is hoped that such an approach will encourage increasing collaboration and development in this area.

ACKNOWLEDGMENT

This project would not have been possible without the generosity of the Magee family and the hard work of the representatives of UNICEF and the Royal Government of Bhutan. Staff of Jigme Dorji Wanchuck National Referral hospital, and Thimphu assisted in a very wide range of roles and continue to work on this project

Chapter 4.16
Patchwork Prototyping with Open Source Software

ABSTRACT

This chapter explores the concept of patchwork prototyping: the combining of open source software applications to rapidly create a rudimentary but fully functional prototype that can be used and hence evaluated in real-life situations. The use of a working prototype enables the capture of more realistic and informed requirements than traditional methods that rely on users trying to imagine how they might use the envisaged system in their work, and even more problematic, how that system in use may change how they work. Experiences with the use of the method in the development of two different collaborative applications are described. Patchwork prototyping is compared and contrasted with other prototyping methods including paper prototyping and the use of commercial off-the-shelf software.

INTRODUCTION

The potential for innovation with open source software (OSS) is unlimited. Like any entity in the world, OSS will inevitably be affected by its context in the world. As it migrates from one context to another, it will be appropriated by different users in different ways, possibly in ways in which the original stakeholders never expected. Thus, innovation is not only present during design and development, but also during use (Thomke & von Hippel, 2002). In this chapter, we explore an emerging innovation through use:

a rapid prototyping-based approach to requirements gathering using OSS. We call this approach *patchwork prototyping* because it involves patching together open source applications as a means of creating high-fidelity prototypes. Patchwork prototyping combines the speed and low cost of paper prototypes, the breadth of horizontal prototypes, and the depth and high functionality of vertical, high-fidelity prototypes. Such a prototype is necessarily crude as it is composed of stand-alone applications stitched together with visible seams. However, it is still extremely useful in eliciting requirements in ill-defined design contexts because of the robust and feature-rich nature of the component OSS applications.

One such design context is the development of systems for collaborative interaction, like "cybercollaboratories." The authors have been involved in several such research projects, developing cyberinfrastructure to support various communities, including communities of learners, educators, humanists, scientists, and engineers. Designing and developing such systems, however, is a significant challenge; as Finholt (2002) noted, collaboratory development must overcome the "enormous difficulties of supporting complex group work in virtual settings" (p. 93). Despite many past attempts to build collaborative environments for scientists (see Finholt for a list of collaboratory projects), little seems to have been learned about their effective design, and such environments are notorious for their failure (Grudin, 1988; Star & Ruhleder, 1996). Thus, the focus of this chapter is on a method of effective design through a form of rapid, iterative prototyping and evaluation.

Patchwork prototyping was developed from our experiences working on cybercollaboratory projects. It is an emergent practice we found being independently redeveloped in several projects; thus, we see it as an effective ad hoc behavior worthy of study, documentation, and formalization. Patchwork prototyping is fundamentally a user-driven process. In all of the cases where we saw it emerge, the projects were driven by user groups and communities eager to harness computational power to enhance their current activities or enable future activities. Additionally, the developers of the prototypes had no pretence of knowing what the users might need a priori. As a result, patchwork prototyping's success hinges on three critical components:

1. Rapid iteration of high-fidelity prototypes
2. Incorporation of the prototypes by the end users into their daily work activities
3. Extensive collection of feedback facilitated by an insider to the user community

In this chapter, we focus on how the method worked from the developers' point of view. It is from this perspective that the advantages of using OSS are most striking. However, one should bear in mind that the method is not just a software development method, but also a sociotechnical systems (Trist, 1981) development method: The social structures, workflows, and culture of the groups will be coevolving in concert with the software prototype.

REQUIREMENTS GATHERING IN COLLABORATIVE SOFTWARE DESIGN

Software engineering methods attempt to make software development resemble other engineering and manufacturing processes by making the process more predictable and consistent. However, software cannot always be engineered, especially Web-based applications (Pressman et al., 1998). Even when application development follows the practices of software engineering, it is possible to produce applications that fail to be used or adopted (Grudin, 1988; Star & Ruhleder, 1996). A major source of these problems is undetected failure in the initial step in building the system: the requirements-gathering phase. This is the

most difficult and important process in the entire engineering life cycle (Brooks, 1995).

In designing systems to support collaborative interaction, developers are faced with several complex challenges. First, the community of users for which the cyberinfrastructure is being developed may not yet exist and cannot be observed for one to see how the users interact. In fact, there is often a technological deterministic expectation that the computational infrastructure being created will cause a community to come into existence. Even in the case where there is a community to study, many of the activities expected to occur as part of the collaboration are not currently being practiced because the tools to support the activities do not yet exist. As a result, developers gain little understanding about how the users will be interacting with each other or what they will be accomplishing, aside from some general expectations that are often unrealistic.

Gathering requirements in such an environment is a highly equivocal task. While uncertainty is characterized by a lack of information, which can be remedied by researching an answer, collecting data, or asking an expert, equivocal tasks are those in which "an information stimulus may have several interpretations. New data may be confusing, and may even increase uncertainty" (Daft & Lengel, 1986, p. 554). Requirements gathering is one such situation in which the developers cannot articulate what information is missing, let alone how to set about obtaining it. The only resolution in equivocal situations is for the developers to "enact a solution. [Developers] reduce equivocality by defining or creating an answer rather than by learning the answer from the collection of additional data" (Daft & Lengel, p. 554). As Daft and Macintosh (1981) demonstrate, tasks with high equivocality are unanalyzable (or rather, have low analyzability; Lim & Benbasat, 2000), which means that people involved in the task have difficulty determining such things as alternative courses of action, costs, benefits, and outcomes.

RAPID PROTOTYPING

Rapid prototyping is a method for requirements gathering that has been designed both to improve communication between developers and users, and to help developers figure out the usefulness or consequences of particular designs before having built the entire system. The goal of rapid prototyping is to create a series of iterative mock-ups to explore the design space, facilitate creativity, and get feedback regarding the value of design ideas before spending significant time and money implementing a fully functional system (Nielsen, 1993). There are several dimensions to prototypes. One dimension is the range from low-fidelity to high-fidelity prototypes (see Table 1; Rudd, Stern, & Isensee, 1996). Low-fidelity prototypes have the advantages of being fast and cheap to develop and iterate. However, they are only able to garner a narrow range of insights. Perhaps the most popular low-fidelity prototyping technique is paper prototyping (Rettig, 1994). Paper prototypes are very fast and very cheap to produce. They can also generate a lot of information about how a system should be designed, what features would be helpful, and how those features should be presented to the users. However, paper prototypes do not allow developers to observe any real-world uses of the system, or understand complex interactions between various components and between the user and the system. Also, they do not help developers understand the details of the code needed to realize the system being prototyped.

High-fidelity prototypes, on the other hand, can simulate real functionality. They are usually computer programs themselves that are developed in rapid development environments (Visual Basic, Smalltalk, etc.) or with prototyping tool kits (CASE, I-CASE, etc). In either case, these prototypes, while allowing programmers to observe more complex interactions with users and to gain understanding about the underlying implementation of the system, are comparatively

Table 1. Advantages and disadvantages of low- and high-fidelity prototyping (Source: Rudd et al., 1996, p. 80)

	Advantages	Disadvantages
Low-Fidelity	• Lower development cost • Can create many alternatives quickly • Evaluate multiple design concepts • Useful communication device • Address screen layout issues • Useful for identifying market requirements • Proof of concept	• Limited error checking • Poor detailed specification to code to • Facilitator driven • Limited utility after requirements established • Limited usefulness for usability tests • Navigational and flow limitations • Weak at uncovering functionality- and integration-related issues
High-Fidelity	• Complete functionality • Fully interactive • User driven • Clearly defines navigational scheme • Use for exploration and tests • Look and feel of final product • Serves as a living specification • Marketing and sales tool	• More expensive to develop • Time consuming to create • Inefficient for proof of concept designs • Not effective for requirements gathering

slow and expensive to produce and iterate (Rudd et al., 1996). These costs can be offset somewhat by incorporating these prototypes into the development of the final system itself as advocated by RAD (rapid application development; Martin, 1991). However, critics of RAD methods are quick to point out the limited scalability of software built using source code from prototypes (Beynon-Davies, Carne, Mackay, & Tudhope, 1999). Typically low-fidelity and high-fidelity prototypes are used in succession, with developers increasing the fidelity of the prototypes as they develop the specifications. Due to their high cost, high-fidelity prototypes may only be built for a select number of designs generated by low-fidelity prototyping, which precludes the generation of a series of disposable high-fidelity proofs of concepts to test out alternative design ideas.

Another dimension to be considered in the prototyping discussion is scope. Software can be viewed as consisting of a number of layers, from the user interface to the base layer, which interacts with the underlying operating system or platform. Horizontal prototypes encompass a wide scope, spanning the breadth of a system but only within a particular layer (usually the user interface). Users can get a sense of the range of the system's available functions; however, the functionality is extremely limited. This can help both the user and the programmer understand the breadth of the system without plumbing its depths. Vertical prototypes, on the other hand, take a narrow slice of the system's functionality and explore it in depth through all layers. This allows users to interact with a particular piece of the system, and gives the programmer a detailed

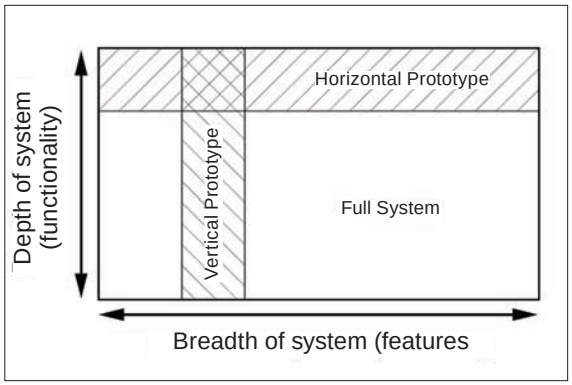
understanding of the subtle issues involved in its implementation (Floyd, 1984; Nielsen, 1993).

The high equivocality present when designing collaborative systems makes it difficult to apply rapid prototyping techniques effectively. Because users may not be able to articulate what they want or need, it helps to be able to collaboratively interact with high-fidelity systems in order to test them in real-world situations and see what requirements emerge. Without such an experience, it is unlikely that any feedback the developers get from the users, either through direct communication or observation, will be useful. Thus, low-fidelity prototypes are limited in their power to elicit requirements as the users have difficulty imagining how the system the prototypes represent will work, what it could do for them, or how they might use it. Also, since the majority of tasks involved in collaboration are quite complex and require multiple kinds of functionality to complete, the users need to be able to interact with the system as a whole and with considerable depth of implementation, thus requiring a prototype that is both horizontal and vertical.

The economics of developing high-fidelity prototypes that are both horizontal and vertical in scope, however, are problematic. Even if the developers were to build a series of high-fidelity, vertical prototypes, they would end up having built the equivalent of an entire system from scratch just to have a functionally sufficient prototype. Not only would it be expensive and time consuming, but the functionality and robustness would be minimal at best. Also, it is likely that the work would need to be discarded and replaced with something new since it is unlikely that the design would be correct on the first, second, or even third try. Thus, the typical methods of prototyping are not sufficient, either because developing all the code would be too expensive, or the prototypes that are developed do not have high enough fidelity.

The proliferation of production-scale OSS systems has created a vast field of growing, reliable, usable, and feature-rich programs, a large number of which support aspects of Web-based collaboration. These programs can be easily stitched together because the code is open and modifiable. Furthermore, they can be treated as disposable since one application can easily be discarded and replaced with another. This presents an opportunity for developers to rapidly build and evaluate a high-fidelity prototype of a collaborative environment comprising a patchwork of multiple open source applications. Such a prototype spans the breadth of a horizontal prototype and the depth of a vertical prototype within a single system.

Figure 1. Horizontal and vertical prototypes (Source: Nielsen, 1993, p. 94)



ORIGINS AND EXAMPLES OF PATCHWORK PROTOTYPING

Patchwork prototyping is a rapid prototyping approach to requirements gathering that was emergent from practice rather than designed a priori. We have been involved with several groups that were developing cyberinfrastructure to support collaboration, and in each group we observed ad hoc prototyping and development strategies

that were remarkably similar and that developed entirely independent of each other. Upon making these observations, we realized that there was a core process at work in each of these projects that could be abstracted out and described as a general approach to requirements gathering for developing cyberinfrastructure. Because patchwork prototyping evolved from practice, however, we believe that it will be much easier to understand our formal description of the approach after we describe some of the relevant details of our experiences. In this section, we describe two projects with which we were involved and the relevant dynamics of each project; in the following section, we describe the patchwork prototyping approach more abstractly.

Project Alpha: Building a Cybercollaboratory for Environmental Engineers

Project Alpha (a pseudonym used to preserve anonymity) was devoted to building a cybercollaboratory for environmental engineers. At the beginning, the project was intended to be a requirements-gathering project, and the goal was to build a functional prototype of the cyberinfrastructure that would be presented to the granting agency as part of a larger proposal. The effort was a success and now, more than a year after the project began, the prototype is being converted into a production-scale system. The cybercollaboratory prototypes were largely designed and built over a period of six months by a team of two developers, with significant contribution to the design by a team of around 12 to 13 other researchers (these researchers, plus the two developers, we call the design team), and some minor programming contributions by undergraduates employed by the project. By the end of the prototyping phase, there was a community of users that included 60 to 70 active users out of approximately 200 registered users, 10 of which comprised a core group of vocal users who provided significant feedback on the design.

The Project Alpha prototype was constructed on the Liferay portal server framework. In addition to using existing portlets, the developers also wrapped other OSS applications in portlet interfaces, enabling their rapid integration into the prototype. A number of different OSS applications were used, including the Heritrix Web crawler, the Lucene search engine, and the MediaWiki wiki system. Other applications were similarly integrated but were not necessarily publicly available OSS. Some were in-house applications developed by other projects for which the developers had source code. These applications were used to prototype data mining and knowledge management functionality in the cybercollaboratory.

The general process by which these tools were incorporated was very ad hoc. The development team might decide on prototyping a particular function, or the programmers might get some idea for a "cool" feature and would set about integrating the feature into the system. This approach had several unexpected benefits. First, minimal time was spent building portlets so that when a version of the prototype was presented to the design team, minimal effort was lost when particular features or portlets were rejected as being unsuitable. Second, it allowed the design team to choose between several different portlets that had essentially the same function but different interfaces (i.e., were optimized for different types of use). Third, it allowed the developers to easily switch features off when the interface for a portlet was too complex, or turn them back on if they were requested by either the design team or the active users. Fourth, the development community and the associated forums, mailing lists, and Web sites surrounding the OSS applications that were integrated into the prototype served as excellent technical support (Lakhani & von Hippel, 2002).

The fact that the prototype was fully functional was critical to its success in eliciting requirements. By using the prototypes over a period of 6 months, the users were able to incorporate them into their day-to-day work practices. This allowed them to evaluate the utility of the tool in various contexts of actual use. Without functionality, the developers feel that it would have been impossible to effectively gather requirements. However, it was also vital that the users communicate their experiences to the developers, both formally and informally. To this end, the developers conducted several surveys of the users, asking them about the prototype and features they found useful. The developers also used the prototype itself to solicit feedback. On the front page of the prototype was a poll asking users to vote for the features they liked the most. Additionally, on every page of the prototype was a feedback form that allowed users to send quick notes about the system as they experienced it. The users also communicated with the developers via informal means such as e-mail and face-to-face meetings. However, the most important method of obtaining feedback was that one of the PIs in the project acted as an intermediary, actively soliciting feedback from users as an insider to the community of environmental engineers. The PI position allowed the individual to receive more feedback of higher quality and honesty than the developers would have been able to collect on their own.

To illustrate the process in more detail, we describe how one particular piece of OSS was integrated with the cybercollaboratory. The developers wanted to allow users to be able to collaboratively edit documents in the system. The Liferay suite had a wiki system available that the programmers enabled; however, users found that tool to be too difficult to use, partly because of the unintuitive markup syntax of the particular wiki used, and partly because they had no tasks that clearly lent themselves to the use of such a tool. Later during the prototyping phase, some members of the design team wanted to demonstrate the usefulness of scenarios and personas in facilitating requirements gathering, and from prior experience suggested the use of a wiki. In response to this request and the prior difficulties in using the bundled tool, the developers installed MediaWiki on the server and added a link from the cybercollaboratory's menu next to the existing wiki tool pointing to the MediaWiki installation. No time was spent trying to integrate the Liferay and MediaWiki systems; each application had separate interfaces and user accounts.

One benefit of using the MediaWiki system was that it allows people to use the system without logging in, thereby mitigating the need to integrate authentication mechanisms. Users found the MediaWiki system easier to learn and use, and began using it exclusively over the in-built Liferay wiki. The developers then decided to embed the MediaWiki interface in the rest of the cybercollaboratory and wrote a simple portlet that generates an HTML (hypertext markup language) IFRAME to wrap the MediaWiki interface. Each step of integrating the MediaWiki installation took only minimal effort on the part of the developers (sometimes literally only a matter of minutes) and generated insights about the role and design of a collaborative editing tool in the cybercollaboratory. Among the design insights gained by the developers is that the tool should be easy to use with a simple syntax for editing. Also, the tool should support alternate views of the data, offering a unified view of all documents either uploaded to the site's document repository or created and edited on the wiki. The users were able to see how this tool could benefit their jobs, and that shaped the requirements of the tool. As a result of this process, the project is currently implementing a new collaborative editing component. This component will have features like integrated authentication, group- and project-based access control, and integration with other features (e.g., project views and wiki linking). Additionally,

the new collaborative writing component will deprecate redundant and confusing features like in-wiki file uploads.

Project Beta: Building Collaborative Tools to Support Inquiry-Based Learning

Project Beta is an ongoing research project aimed at designing and building Web-based tools to support processes of inquiry as described by John Dewey (Bishop et al., 2004). Initiated in 1997, the project has embraced a long-term perspective on the design process and produced a series of prototypes that support inquiry-based teaching and learning. In 2003 the project began exploring the development of tools to support collaborative inquiry within groups and communities. The current prototype is the third major revision of the collaborative cyberinfrastructure, with countless minor revisions on going. Throughout the project's life span, several generations of programmers have joined and left the development team. For a 30-month stretch, the majority of programming was sustained by a single graduate-student programmer. Between four and eight other researchers filled out the design team.

The prototypes are available for anyone to use, and the source code is also distributed under a Creative Commons license. To date, the prototypes have been used to support a large number of communities of users ranging from water-quality engineers to volunteers in a Puerto Rican community library in Chicago, from researchers studying the honeybee genome to undergraduates in the social sciences. There are numerous other groups using the system for any number of purposes. Given this scenario, it is practically impossible to design for the user community or any intended use.

The prototypes were developed in the PHP programming language on an open source platform consisting of Apache, MySQL, and RedHat Linux. In contrast to Project Alpha where the developers initially did very little programming and primarily used readily available tools, the developers of Project Beta spent considerable effort building an infrastructure from scratch, in part because the developers were initially unaware of relevant OSS. However, as the project progressed, several open source tools were incorporated into the prototypes including the JavaScript-based rich-text editors FCKEditor and TinyMCE, the phpBB bulletin board system, and MediaWiki.

To demonstrate the process in more detail, we describe how one particular piece of OSS was integrated with the prototypes. In the earliest version of the cyberinfrastructure, users expressed an interest in having a bulletin board system. The developers selected the phpBB system and manually installed copies of phpBB for each community that wanted a bulletin board; the bulletin board was simply hyperlinked from the community's home page. In the next iteration of the prototype, the phpBB system was modified to be more integrated with the rest of the prototype. Users could now install a bulletin board themselves, without involving the developers, by clicking a button on the interface. Furthermore, the authentication and account management of the bulletin board was integrated with the rest of the prototype, eliminating the need for users to log in twice. However, the full features of phpBB were more than the users needed. They primarily made use of the basic post and reply functions and the threaded-conversation structure. Users indicated that the overall organization of the board system into topics, threads, and posts made sense to them. In the most recent major revision of the prototype, the phpBB system was replaced by a simpler, more integrated homemade bulletin board prototype that supported these basic features. Had the development progressed in the opposite order (i.e., building the simple prototype first, then adding features), it is possible that developers could have wasted valuable time and energy prototyping features that would only be discarded later for lack of use.

GENERALIZED APPROACH TO PATCHWORK PROTOTYPING

Based on the experiences described above, we have outlined a general approach to building patchwork prototypes using OSS. While our experience has been primarily with Web-based tools, and this process has been defined with such tools in mind, it is likely that a similar approach could be taken with prototyping any kind of software. Like other prototyping methods, this is designed to be iterated, with the knowledge and experience gained from one step feeding into the next. The approach entails the following five stages:

1. Make an educated guess about what the target system might look like.
2. Select tools that support some aspect of the desired functionality.
3. Integrate the tools into a rough composite
4. Deploy the prototype and solicit feedback from users.
5. Reflect on the experience of building the prototype and the feedback given by users, and repeat.

For the most part, these steps are relatively straightforward. Making the first educated guess about what the target system might look like can be the hardest step in this process because it requires the design team to synthesize their collective knowledge and understanding of the problem into a coherent design. In this first iteration of the process, it is often helpful to use paper prototypes and scenarios, but their function is primarily to serve as communications devices and brainstorming aids. The high equivocality of the situation almost guarantees, however, that whatever design they produce will be insufficient. This is not a failure. It is an expected part of the process, and the design will be improved on subsequent iterations. The important thing is to have a starting point that can be made concrete, and not to spend too much time brainstorming ideas. It is essential not to become bogged down in controversies about how the software "ought" to look, but rather to put together a prototype and test it out with users in their everyday environments and let the users figure out what works, what does not, and what is missing.

Selection and Integration of Tools: The Benefits of Using Open Source Software

There are several important considerations to keep in mind when selecting the tools. On first glance, patchwork prototyping as a method does not require OSS; the same general process could theoretically be followed by using software that provides APIs, or by creating prototypes through adapting methodologies for creating production-scale software systems such as COTS (commercial off-the-shelf) integration (Boehm & Abts, 1999). However, using OSS confers several important advantages; in fact, we believe that patchwork prototyping is only now emerging as a design practice because of the recent availability of a significant number of mature, production-scale OSS systems.

Without access to source code, developers are limited in how well they can patch together different modules, the features they can enable or disable, their ability to visually integrate the module with the rest of the system, and their ability to understand the underlying complexity of the code needed to construct such systems on a production scale. High-profile OSS is often of high quality, which means that difficult design decisions have already been made. Given that it is built from the collective experiences of many programmers, less effective designs have already been tried and discarded. In fact, by using and delving into human-readable (compared to that generated by CASE tools, e.g.), open source code, the developers can get a grounded understanding

of how particular features can be implemented, which can enable them to better estimate development time and costs.

The Web-based nature of patchwork prototypes affords several ways of integrating the selected software into the prototype, ranging from shallow to deep. Shallow integration consists of either wrapping the tools in an HTML frame to provide a consistent navigation menu between the tools, or customizing the HTML interfaces of the tools themselves to add hyperlinks. Most open source Web applications use HTML templates, cascading style sheets, and other interface customization features, which make adding or removing hyperlinks and changing the look and feel very easy. The advantage of shallow integration is the ease and speed with which the developer is able to cobble together a prototype. A significant drawback to shallow integration is that each application remains independent.

Deeper integration usually requires writing some code or modifying existing source code. This may include using components or modules written for the extension mechanisms designed into the application or other modifications made to the application's source code. If the developers cannot find precisely what they are looking for, they can fashion the code they need by copying and modifying similar extension code, or, in the worst case, the developers will need to write new code to facilitate the integration. However, the amount of code needed is very little in comparison to the amount of code that would have been required of the developers building a prototype from scratch.

For any prototyping effort to be worthwhile, the costs of creating the prototypes must be minimal. OSS systems tend to be fully implemented, stand-alone applications with many features and capabilities that provide a wealth of options to play with when prototyping to elicit requirements. The minimal effort required to add features allows the programmers to treat the features as disposable: Because little effort was needed to implement them, little effort is wasted when they are switched off or discarded. That most OSS are free is also important, both for budgetary reasons and because the developers can avoid complicated licensing negotiations. Additionally, most OSS have very active development communities behind them with members who are often eager to answer the developer's questions in considerable depth, and do so for free, unlike the expensive technical support that is available for commercial products. All of this facilitates the requirements-gathering process because iterations of the prototype can be rapidly created with high functionality at minimal cost, and with minimal effort and emotional investment by the developers.

Deployment, Reflection, and Iteration

During the deployment of the prototype, future users integrate the cyberinfrastructure into their work practices for an extended period of time and explore what they can do with it collaboratively. The collection of feedback on user experiences allows requirements gathering that is not purely need based, but also opportunity and creativity based. By seeing a high-fidelity prototype of the entire system, users can develop new ideas of how to utilize features that go beyond their intended use, and conceptualize new ways of accomplishing their work. In addition, users will become aware of gaps in functionality that need to be filled, and can explain them in a manner that is more concrete and accessible to the developers.

When reflecting on the collected feedback, however, the design team must realize that the prototype does not simply elicit technical requirements; it elicits requirements for the collaborative sociotechnical system as a whole. The existence of the prototype creates a technological infrastructure that influences the negotiation of the social practices being developed by the users via the activities the infrastructure affords

and constrains (Kling, 2000). The design team must be aware of how various features affect the development of social practice, and must make explicit the type of interactions that are required but are not currently realized. By allowing the users to interact with the prototypes for extended periods, collecting feedback on their experiences, and paying attention to the social consequences of the cyberinfrastructure, a richer understanding of the sociotechnical system as a whole can

Table 2. Comparison of patchwork prototyping with other methods

Paper Prototyping	Patchwork Prototyping	COTS/API Prototyping
Speed		
Can iterate a prototype multiple times in an afternoon	Can iterate a prototype in less than a week	Can take weeks or months to iterate a prototype
Monetary Costs		
Cost of office supplies	Free, or minimal cost of licenses if in business setting	Purchasing and licensing software can be expensive
Availability of Materials		
Usually already lying around	Large number of high-quality OSS available for free download	Not all commercial systems have APIs
Functionality		
Nonfunctional	High	High
Accessibility		
Anyone can prototype systems using paper, including nontechnical end users	Requires skilled programmers to create patchwork prototypes	Requires skilled programmers to integrate commercial software
Interface		
Not polished, but can provide a consistent and/or innovative interface concept for consideration	Not renowned for excellent usability; assembled components may be inconsistent	Individual elements may be high quality and familiar; assembled components may be inconsistent
Flexibility		
High: can do anything with paper	High: can modify source to create any desired functionality	Low: restricted to what the API allows, which may be limited
Disposability		
High: little investment of time, money, emotions	High: little investment of time, money, emotions	Low: significant effort and money can result in high emotional investment
User Attachment		
Low: users can see it is rough and nonfunctional	Med. to High: upon using it, can get attached to the system unless iterated rapidly	High: cannot be iterated fast enough to avoid attachment

emerge. Thus, reflection is a process of attending to the consequences of the design for the broader sociotechnical system, and integrating those consequences into a holistic understanding of how the system is evolving.

Iteration is essential to the rapid prototyping approach. First, iteration allows for the exploration of more features and alternatives. This can uncover overlooked aspects of the system that might be of use. This can also reinforce the importance or necessity of particular features or requirements. Furthermore, iteration provides the users with a constant flow of new design possibilities, which prevents them from becoming overly attached to any single design, giving them the freedom to criticize particular instances of the prototype. Ultimately, it is impossible to reach complete understanding of the system given its evolving nature. However, by iterating the prototyping process, the design space may narrow, identifying a set of key requirements. At this point the design is not complete, but work on a flexible production-scale system can begin, and further exploration of the design space can be continued within that system.

STRENGTHS AND LIMITATIONS

Patchwork prototyping addresses two major problems that designers face when building new sociotechnical systems. First, it allows the design team to get feedback on the prototype's use in real-world situations. Users interact with the system in their daily activities, which focuses their feedback around task-related problems. In Project Alpha, when members of the design team started using the prototype, the feedback changed from general praise or criticism of the appearance of the interface to more detailed explanations of how particular functionality aided or inhibited task performance. Second, it reduces the equivocality of the design space. By creating a functional prototype, discussions change from being highly suppositional to being about concrete actions, or concrete functionality.

Integration into the real-world context is markedly different from other prototyping and requirements-capture methods. Paper prototypes are typically given to users in a laboratory setting (Nielsen, 1993), thus all the tasks are artificial. While this can give developers important design insights, the drawback is that prototypes can end up optimized for artificial tasks and not for real-world use. More expensive methods such as participatory design (Ehn & Kyng, 1991) and ethnography (Crabtree, Nichols, O'Brien, Rouncefield, & Twidale, 2000) try to incorporate real-world use into the design process, the former by bringing users into the design team, the latter by observing users in their natural work environment. However, when the technology that these methods were used to design is introduced, it inevitably changes the practices and social structures present in the work environment, often in a way that cannot be predicted. Patchwork prototyping overcomes these limitations by being cheap and by providing real-time feedback on both users' problems with the software and the effects the software is having on the broader work context.

The advantages of patchwork prototyping can be seen when comparing it to other prototyping techniques. In Table 2 we compare it to paper prototyping and to prototyping using COTS software. The advantages of patchwork prototyping are that it has many of the benefits of paper prototyping, including low cost and ready availability of materials, yet provides the high functionality of COTS/API prototyping; the effort needed to create the prototypes and the length of the iteration cycles lies somewhere in between. Thus, while we see the method as being yet another tool for developers and designers to have in their toolbox, in many ways, it combines the best of both worlds.

The patchwork prototyping approach is not without limitations, however. Despite our hope that the visibility of the seams between the ap-

plications would be interpreted by the users as an indication that the prototype is a work in progress, our experiences seem to indicate that the users still view it as a finished product due to the fact that it has real functionality. It is possible that such interpretations can be overcome through social means by emphasizing the fact that the system is a prototype to all users who are encouraged to test it. However, since none of the projects we participated in did this, we have no idea whether or not that would be sufficient. One thing that is clear, however, is that visual coherence between applications greatly facilitates the ease of use and positive perceptions of the system as a whole. In fact, in Project Alpha, it was realized that users need different views of the component modules and features depending on the context in which they access the applications, and in some of those views the distinctions between modules must be totally erased.

Patchwork prototyping requires highly skilled programmers to be implemented effectively. Programmers must have significant experience within the development environment in which the OSS applications are coded; otherwise, they will spend too much time reading code and learning the environment, and the speed of implementation will not be as fast. Also, OSS can have security vulnerabilities that can compromise the server on which they are hosted. Project Beta ran into this problem when multiple installations of phpBB succumbed to an Internet worm, bringing down the prototype for several days. Third, patchwork prototyping requires a long-term commitment by users, and a motivated facilitator who is able to convince the users to adopt the prototype and incorporate it into their work practices. The facilitator must collect feedback about the users' experiences. Without willing users and the collection of feedback, the prototyping process will likely fail.

FUTURE TRENDS

The use of patchwork prototyping is still in its infancy. The relative ease with which patchwork prototypes can be constructed means that the method itself affords appropriation into new contexts of use. For example, one of the biggest costs to organizations is buying software systems such as enterprise management systems. Patchwork prototyping offers a cheap and effective method for exploring a design space and evaluating features. Consequently, through prototyping, managers can be more informed when shopping for software vendors and can more effectively evaluate how effective a particular vendor's solution will be for their company (Boehm & Abts, 1999).

Because users have to integrate the prototype into their daily work practices, transitioning from the patchwork prototype to the production-scale system can be highly disruptive. One method of avoiding this is having a gradual transition from the prototype to the production-scale system by replacing prototype modules with production-scale modules. To do this, however, the prototypes must be built on a robust, extensible, modular framework because the latter component is not easily replaced. If this model is used, the system development process need never end. Prototypes of new features can constantly be introduced as new modules, and, as they mature, be transitioned into production-scale systems. As more developers and organizations support open source development, the number and availability of OSS applications will increase. As more modules are written for particular open source, component-based systems, the costs of doing patchwork prototyping will further decrease, as will the threshold for programming ability—perhaps to the point where users could prototype systems for themselves that embody specifications for software programmers to implement.

CONCLUSION

Patchwork prototyping is a rapid prototyping approach to requirements gathering that shares the advantages of speed and low cost with paper prototypes, breadth of scope with horizontal prototypes, and depth and high functionality with vertical, high-fidelity prototypes. This makes it particularly useful for requirements gathering in highly equivocal situations such as designing cyberinfrastructure where there is no existing practice to support because it allows future users to integrate the cyberinfrastructure into their work practices for an extended period of time and explore what they can do with it collaboratively. It has the benefit of allowing the design team to monitor the sociotechnical effects of the prototype as it is happening, and gives users the ability to provide detailed, concrete, task-relevant feedback.

Patchwork prototyping is an excellent example of how OSS can foster innovation. The affordances of open-source code and a devoted development team create opportunities to utilize OSS in ways that go beyond the functionality of any particular application's design. The cases presented here merely scratch the surface of a new paradigm of OSS use. Further research is needed to understand the specific features of technologies that afford such innovative integration.

KEY TERMS

COTS Integration: The process by which most businesses integrate commercial off-the-shelf software systems in order to create a computing environment to support their business activities.

Equivocality: The name for a lack of knowledge that cannot be mitigated simply by doing research or gathering more information. In an equivocal situation, decisions often need to be made, definitions created, and procedures negotiated by various (often competing) stakeholders.

Paper Prototyping: A rapid prototyping method for creating low-fidelity prototypes using pencils, paper, sticky notes, and other low-tech materials that can be quickly iterated in order to explore a design space. It is often used in interface design.

Patchwork Prototyping: A rapid prototyping method for creating high-fidelity prototypes out of open source software that can be integrated by users into their everyday activities. This gives users something concrete to play with and facilitates a collaborative process of sociotechnical systems development. It is ideal for highly equivocal design situations.

Rapid Prototyping: Rapid prototyping is a method that involves creating a series of prototypes in rapid, iterative cycles. Normally, a prototype is created quickly, presented to users in order to obtain feedback on the design, and then a new prototype is created that incorporates that feedback. This cycle is continued until a fairly stable, satisfactory design emerges, which informs the design of a production-scale system.

Sociotechnical System: Refers to the concept that one cannot understand how a technology will be used in a particular environment without un-

derstanding the social aspects of the environment, and that one cannot understand the social aspects of the environment without understanding how the technology being used shapes and constrains social interaction. Thus, one can only understand what is going on in an environment by looking at it through a holistic lens of analysis.

Uncertainty: The name for a lack of knowledge that can be addressed by obtaining more information, such as by researching an answer, looking it up in reference materials, or collecting data.

ABSTRACT

The chapter discusses the adoption and assimilation process of open source software as a new form of information technology. Specifically, the case reports a general positive attitude towards the widely used technology, the OpenOffice.org suite for office automation. Nevertheless, it shows the difficulties of the first early adopters to lead the innovation process and push other users. Different usage patterns, interoperability issues, and, in general, the reduction in personal productivity typical of the early phases of adoption are also remarked. The aim of this chapter is to give the reader an overview of the adoption process by means of the analysis of quantitative and qualitative data gathered during real world experimentation, and to shed some light on how empirical data can corroborate or challenge the existing literature about open source software and technology adoption.

INTRODUCTION

Open source software (OSS) and open data standards (ODS) have emerged in recent years as a viable alternative to proprietary solutions. There are many cases in which the adoption of OSS has proved advantageous for companies deciding to adopt it in replacement or in conjunction with closed source software (CSS). Unfortunately, at our knowledge, these studies often report only about server-side migrations or give very little empirical evidence of the benefits of the new solution. Among case studies that report success-

ful transitions on the desktop side we can surely mention as pioneers the Extremadura, Munich, and Vienna case studies (Marson, 2005; Landeshauptstadt München, 2003; Stadt Wien, 2004). All these cases have in common the intention of a large migration inside a single public administration (PA). Furthermore, the migration to OSS in all these cases has been already performed or is in the process of being deployed. We summarise the most famous deployments in Table 1, three are European, while one is U.S.-based.

One of the most remarkable deployments of OSS on the desktop side is surely the one of the Extremadura region in Spain, recently installing 80,000 Linux systems, 66,000 for the educational system and 14,000 for administrative workstations. The local administration even created their Linux distribution called gnuLinex[1]. According to their IT department, the savings have been of the order of €18M (Marson, 2005). Another case of success is the one of the city of Largo, FL (USA) where the migration has involved 900 clients; the savings have been estimated in $300,000-$400,000 (Miller, 2002). The migration of the city of Munich and the one of the city of Vienna are currently underway (Landeshauptstadt München, 2003; Stadt Wien, 2004). As the delay of the Munich migration seems to demonstrate, a transition to OSS is not a process to underestimate. There are also cases where the proprietary solution has been considered more convenient, like the city of Nürnberg, where according to their own migration study, the transition from Windows 2000/Office 2000 to Windows XP/Office XP was considered as €4.5M cheaper than the transition to Linux/OpenOffice.org (Stadt Nürnberg, 2004).

Another case of interest that emerged recently is the decision of the state of Massachusetts to abandon closed data standards (CDS) in favour of ODS, in particular to adopt the open document format for office automation documents exchange activities starting from January 2007 (Massachusetts State, 2005). According to the Organization for the Advancement of Structured Information Standards (OASIS) the purpose of the format is "to create an open, XML-based file format specification for office applications" (OASIS, 2005). Following this case and the increasingly requests coming from the European Commission to reduce e-government barriers, Microsoft decided to open the formats supported by its office automation suite in the upcoming months (Palmer, 2005).

The goal of this chapter is to provide an insight on two different experimental migrations to OSS inside European PAs. In particular, we don't consider a full migration, but the introduction of OSS in the office automation field. Throughout

Table 1. Large deployments of OSS inside public administrations

Region	Clients to migrate	Side	Distribution
Extremadura	80000	Desktop/ Servers	gnuLinex
Munich	14000	Desktop	Debian
Vienna	7500	Desktop	Wienux (Debian/ KDE)
Largo, FL	900	Desktop/ Servers	Linux KDE 2.1.1

a constant monitoring of the software employed, we derive some indications on software usage that can be useful to provide more information on the migration process and the adoption of OSS.

In the next sections, we will provide first an overview of the existing literature about technology adoption and then start reviewing the experimentation details providing background information about the two Public Administrations involved. The last part will be devoted to the discussion of the results.

Technology Adoption and Assimilation

Before entering the discussion about the experimentation and the migration performed, an overview of the existing literature about technology adoption and assimilation will be useful. This will also provide a framework in which the results of the experimentation will be inserted.

Technology adoption, diffusion and acceptance research bases its foundation on the early work of Everitt Rogers, in the book titled *Diffusion of Innovations.* Rogers (1995) interest lies in studying the diffusion process that characterises technology adoption. In his seminal work, technology adopters are categorised according to the phase in which they make the adoption decision. The main distinction is among innovators, early adopters, early majority, late majority, and laggards. In particular, the author models the diffusion as an S-shaped curve characterised by an initial adoption speed and a later growth rate. The claim is that different technologies will lead to different adoption patterns.

Interesting for our study are various factors that affect the level of technology adoption inside organisations, like the *organisational age* (Chatterjee, Grewal, & Sambamurthy, 2002), *organisational size* (Fichman, & Kemerer, 1997), *industry type* (Chatterjee, Grewal, & Sambamurthy, 2002; Fichman, & Kemerer, 1997), and *sophistication of the IT infrastructure* (Armstrong, 1999; Chau & Tam, 1997). To some extent, the evidence seems to report that organisations that are younger, larger and belong to certain industry types are more willing to invest and adopt new technology. The existence of a sophisticated IT infrastructure will also lead to an easier adoption path.

Furthermore, Fichman and Kemerer (1999) report two critical factors that influence the technology assimilation process: knowledge barriers and increasing returns. The first effect relates to the effort necessary to acquire the necessary knowledge and skills to properly adopt a certain technology. This effect leads to what are known as knowledge barriers (Attewell, 1992; Fichman & Kemerer, 1999). Being a new and still somewhat unexplored field, we think that OSS is subject heavily to knowledge acquisition barriers that can in some way hinder its adoption.

As a second macro-level phenomenon, the adoption of certain technologies is subject not only to supply-side benefits due to economies of scale (Shapiro & Varian, 1999) but also to a demand-side effect called increasing returns effect (Arthur, 1989). The effect leads to an increase of utility in adoption for each successive adopter, based on the number of previous adopters. Arthur (1989) goes further in this analysis, claiming that "[e]conomy, over time, can become locked-in by 'random' historical events to a technological path that is not necessarily efficient, not possible to predict from usual knowledge of supply and demand functions, and not easy to change by standard tax or subsidy policies" (p. 2). In this sense, it may not be possible to easily switch from a certain technology once a certain critical level of adoption has been reached.

Open source software and software in general is one of the goods that are particularly sensible to economies of scale, increasing returns and knowledge barriers. To understand fully the adoption process, all these effects have to be considered.

BACKGROUND INFORMATION

Experimentation on the migration to OSS in the office automation field has been performed in two different European public administrations (PAs). We will discuss briefly the background details of the two public administrations involved and for simplification purposes, we will refer to the first public administration as PA1 and the second as PA2.

PA1 is a large public administration, counting globally over 5,000 employees. The budget allocated for the ICT (information and communication technology) services is high, but the experience with OSS is still limited. The reason for the interest in a possible migration to OpenOffice.org and in general to other OS applications is threefold:

- Spare the money spent yearly to cover the license costs.
- Reduce the effort needed to handle the licenses.
- Provide a benefit to the local economy, by means of the adoption of OSS.

PA2 is composed by a large number of municipalities spread across the territory of its region. Nearly all the municipalities in the consortium are small and count on the average 50 desktop machines. The maintenance is performed remotely by the central IT (information technology) department. In this case, the budget available for ICT services in such small municipalities is low, but a great experience in OSS has been built in recent years, mostly based on server-side solutions. The objectives of a possible migration to OSS are the following:

- Reduce the costs of ICT services in the long term.
- Ensure the accessibility of generated documents also in the future, not relying on proprietary data standards.

To summarise the characteristics of the the PAs that took part to the experimentation, both share a similar organisational size, while differences exist in prior OSS experience and budget allocated for ICT services.

FOCUS OF CHAPTER

Experiment Design

The experimentation performed has involved the market leader Microsoft Office[2] and OpenOffice.org[3], an OSS suite offering ODS support. The decision to use these applications has been done in accordance with the relevance of office automation inside PAs (Drakos, Di Maio, & Simpson, 2003) and the guidelines given by IDABC (Interoperable Delivery of European eGovernment Services to public Administrations, Businesses and Citizens) for a gradual transition to OSS. One of the main suggestions is to "introduce applications in a familiar environment" (IDBAC Report, 2003, p. 23). The introduction of OpenOffice.org is seen as a necessary step for a successive complete migration to OSS.

To monitor the behaviour of users with both solutions, we adopted the PRO Metrics (PROM) software as a mean to collect and analyse software metrics and personal software process data (Sillitti, Janes, Succi, & Vernazza, 2003), software that permits to collect metrics on software usage in a non-invasive manner. It allows the collection of the measures of time spent on documents, name of the document and other useful information about the general software usage. To protect the privacy of the users several measures were taken in accordance with the local union representatives:

- Data collected has been encrypted by means of the strong AES algorithm (Pfleeger & Pfleeger, 2002).

- Usernames were randomly generated.
- Data of single users were not given to single PAs, the analysis presented has been only given in aggregated form and with the aim to provide an evaluation of the migration.

In Table 2, a comparison of both experimentations is performed.

The number of users involved in the experimentation has been equivalent, both PAs decided to install OpenOffice.org in order to evaluate the possible future migration. The suite has been installed on a large number of workstations in both PAs; however our study has been performed on a smaller subset of users. The total events that are reported in table refer to the smallest unit that the data collection software details; a single event refers to the application's window release of focus.

This number details the amount of data that have been collected during the experimentation. The maturity row refers to the situation in which the experimentation has been performed; PA2 was already in a more advanced state of technology adoption, offering the open solution for several months prior to the experimentation. As a last annotation, the details of username generation have been slightly different between the two installations, in PA2 the usernames have been generated on a per machine basis, different users working on a single workstation are mapped as a single entity. This will result in higher documents per day or time per day per single username compared to PA1, where the usernames map directly to a single user. Nevertheless, the results have not been influenced by this approach, since the common practice in PA2 is to have a single workstation per user.

The experimentation protocol followed the same schema in both experimentations:

- Installation of OpenOffice.org; the version of the suite installed is OpenOffice.org 1.1.3 in both PAs; various versions of the Microsoft Office suite were available on the target systems
- Installation of the PROM agent to monitor the software adoption level
- Training on the OpenOffice.org suite, mostly performed to show how to perform the same task in the new office automation environment
- A questionnaire on the attitude towards Open Source Software submitted to users
- Support provided to users by means of forums and hot-lines

Table 2. Comparison of both experimentations

	PA1	**PA2**
Users experimenting	1486	1475
Total OOo installations	~4000	~2000
Total MSO installations	~4000	~2000
Days	30	40
Total events	1518150	1435553
Maturity	Starting Ooo introduction	Already using Ooo
ID generation	Per user	Per machine

Methodology and Limitations

The methodology applied is mainly empirical; the analysis is based on quantitative data collected through a non-invasive software agent and on qualitative data collected by means of questionnaires. A full controlled experiment could not be performed, as it would not have been possible to control all exogenous factors that could affect the final results (Campbell & Stanley, 1990). For a controlled experiment, but on a more limited number of users during a migration to OSS (see Rossi, Scotto, Sillitti, & Succi, 2005). A comparison of the functionalities of Sun StarOffice Writer and Microsoft Office Word[4] can be found in (Everitt & Lederer, 2001). Also in this case the comparison is on a limited number of users, focusing on the functionalities offered by both solutions and how users could perform the same task. Researchers found that "[w]hile overall ratings for both products were comparable, participants were more comfortable and satisfied with Microsoft Word and found it easier to use than StarOffice Writer" (Everitt & Lederer, 2001, p. 2).

In the following sections we will perform first a comparison of the initial attitude of users towards OSS, the comparison of the two solutions by means of the quantitative data collected and in the end evaluate possible interoperability issues that can raise in case of a full migration.

Initial Attitudes Toward OSS

The experimentation has been supported by qualitative data coming from one questionnaire submitted to users; the aim of the questionnaire was to evaluate the attitude of the users towards OSS, as it can have a great impact on the successive acceptance of OSS. The questionnaire has been submitted in electronic format. We report here the results that may be interesting to evaluate the attitude of users before entering the experimentation. Data in this section refers to 282 users of PA1.

The first two questions related to the knowledge of OSS, in particular the familiarity with the concept and the general users' perception. The answers are represented in Figure 1.

Surprisingly, more than 60% of the users that filled the questionnaire depict themselves either as very familiar or fairly familiar with the concept. One of the reasons can be that users with more attitude towards OSS were the ones that filled the questionnaire earlier. The second question about the perception of OSS leads to a group of users neutral or positive towards the new concept; after the experimentation it is possible that users acquire a more sharp view on the subject; in this sense, we should expect at that point, neutral users to represent the minority.

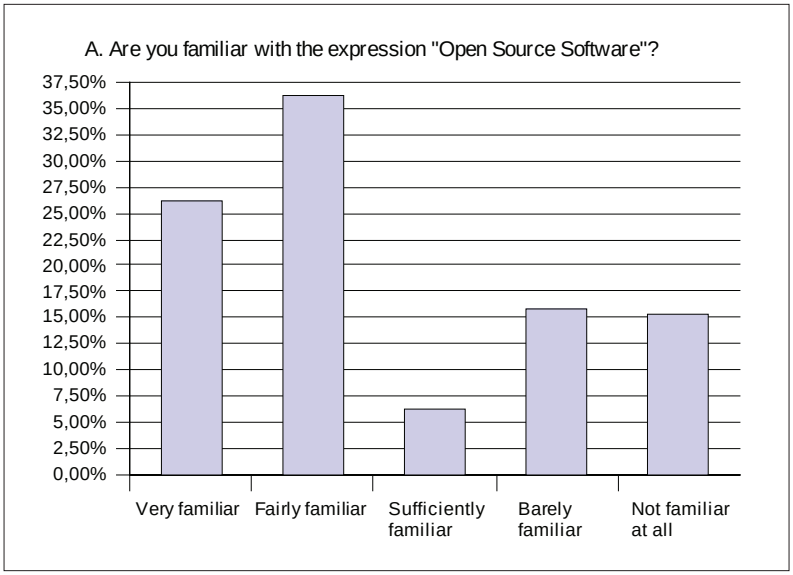
The third question in Figure 2 further investigates the knowledge of users in the field, we asked whether users know OS products and whether they can name at least one.

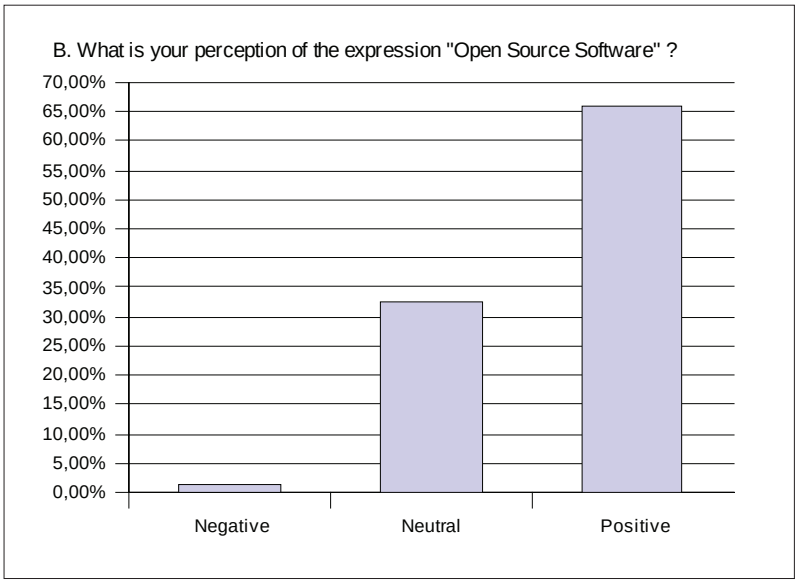
Not surprisingly, the majority of users report no application. The most known products are OpenOffice.org and the Linux operating system.

In showing the results of the remaining questions, we divided the users in two categories, users that had already an opinion on OSS and users that don't know the phenomenon. In this sense the first category consisted of all users considering themselves either as familiar or very familiar with OSS (see Figure 1, Question A) and naming at least one application (see Figure 2, Question C). For the reader's convenience, in the upcoming tables we named these groups OSS and non-OSS users. In Figure 3, the experimenters are questioned about the purchasing criteria of software in general, without particular reference to OSS.

In this case, users already with knowledge of OSS seem to be more aware of the customisation requirements of software inside PAs. The next two questions are related to a full migration to OSS. In Figure 4 users are posed in a situation of a generalized introduction of OSS and its effects on the organizational aspects of the PA.

Figure 1. PA1—Results of Question A





The results of Figure 4 are comparable across both groups: the majority of users consider the introduction of OSS as a chance of reorganization of the IT department of the PA. Furthermore, 15% of users consider the introduction as non important in terms of organizational impact. The last question in Figure 5 is very similar to the previous one, but this time is related to the impact of the migration on the single user.

Figure 2. PA1—Results of Question C and Question D

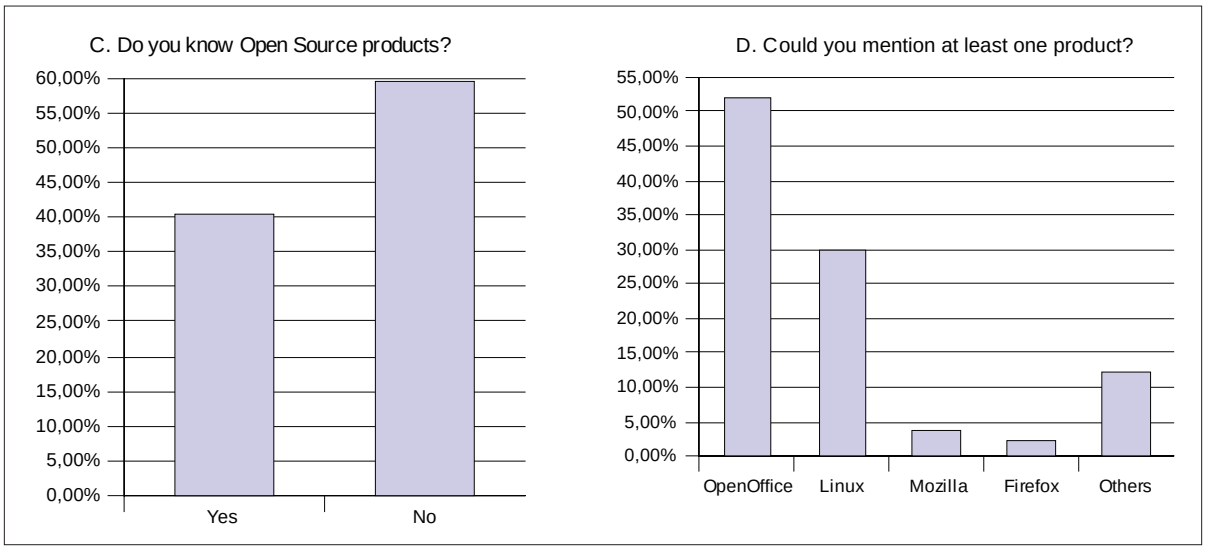


Figure 3. PA1—Results of Question E

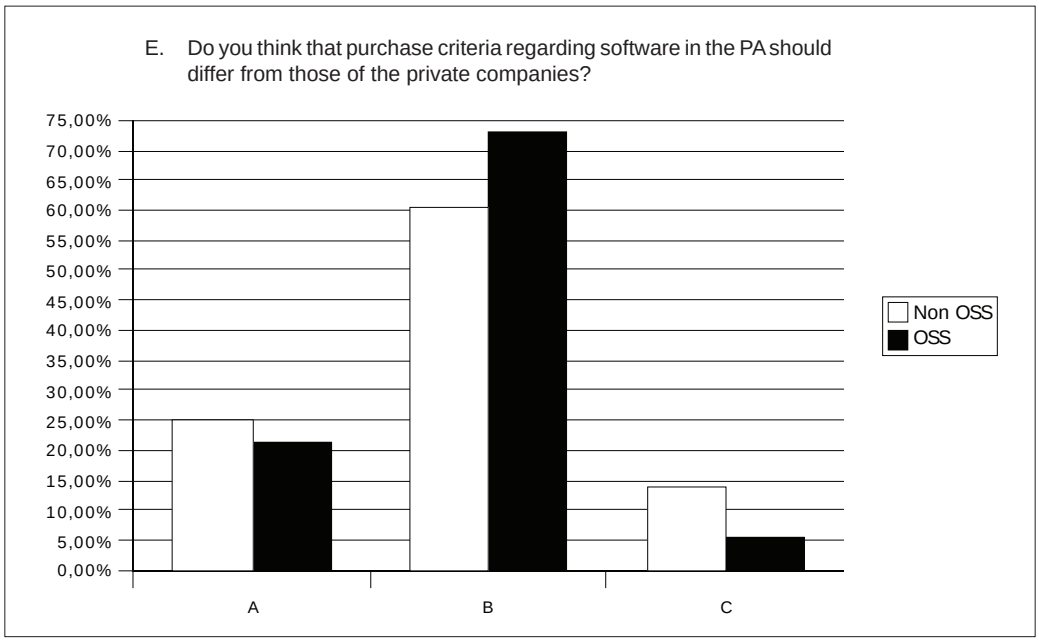
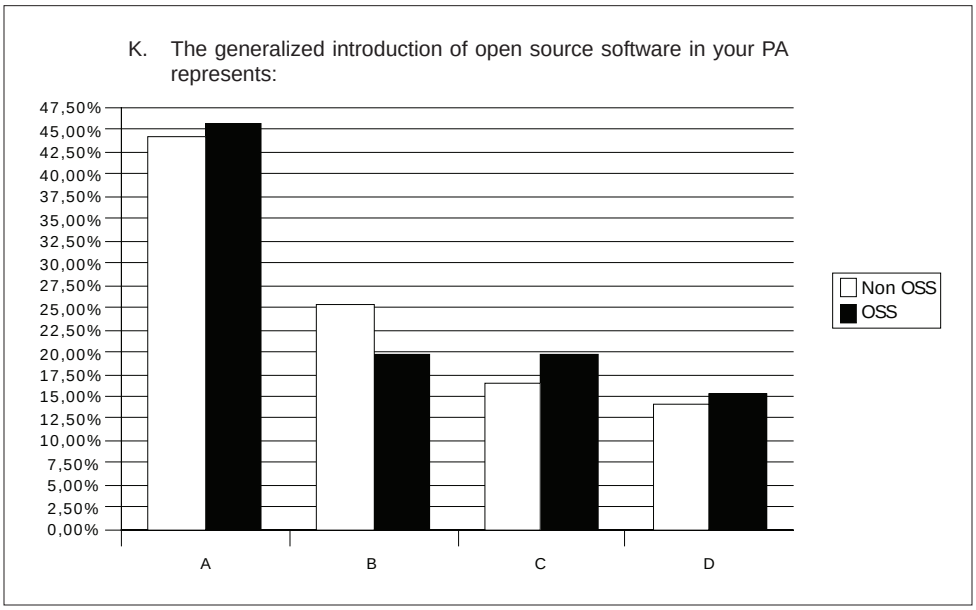


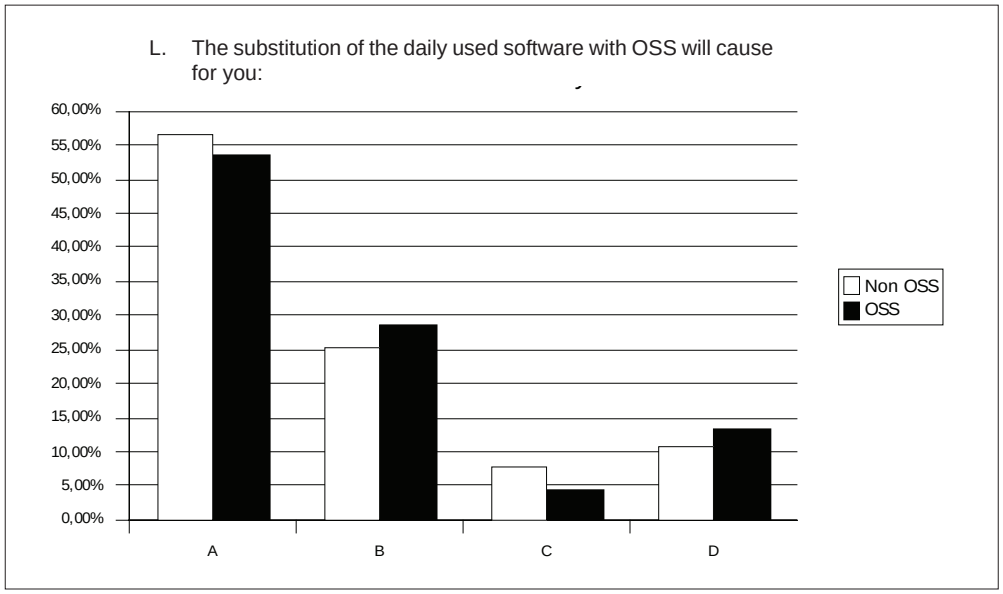
Note: Possible answers are (a) No, they should follow the same criteria; (b) Yes, they should take into account the peculiar needs of the PA; (c) I don't know.

Figure 4. PA1—Results of Question K



Note: Possible answers are (a) A chance for the reorganization of the IT structure; (b)A chance for the redefinition of the organizational structure in a wide perspective; (c) A further load of work for the single units; (d) The introduction will not be important.

Figure 5. PA1—Results of Question L



Note: Possible answers: (a) More work in the short run, but advantages in the long run; (b) More work in the short run and no advantages in the long run; (c) Less work; (d) More work.

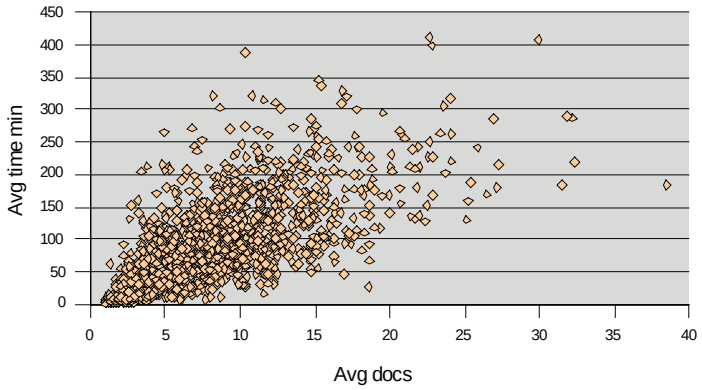
The results also in this case do not report a large difference between the two groups, more than half of the users are convinced that the substitution will have a negative impact on the workload in the short period, the advantages will be evident only in the long period. Users of the OSS group seem more conscious about the effort that a migration causes.

Overall the results of the questionnaires report users in general positive towards OSS. It would be interesting as an additional study to evaluate the impact of the experimentation on the users' attitude, to see how the perception of users changes after the influence of a full migration.

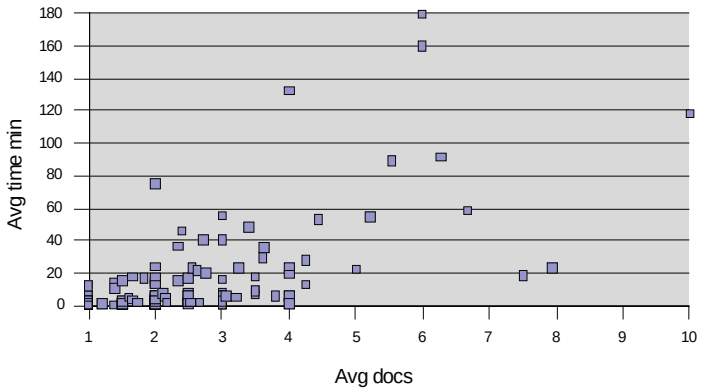
Comparison of the Solutions

Both softwares for office automation have been running during the whole experimentation, users were free to choose the solution more appropri-

Figure 6. PA1—Distribution of users across average documents (x-axis) and average time (y-axis)



(a) Microsoft Office documents handling



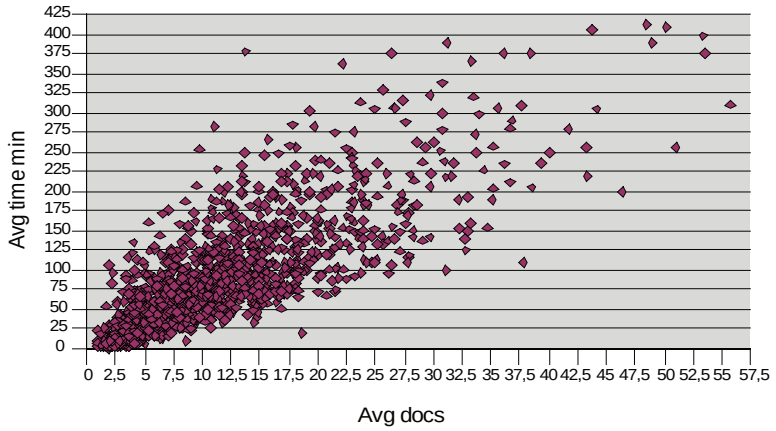
(b) OpenOffice.org documents

ate for the task to perform. A limitation on this decision was given by the large number of files already available in the original data format. More of these interoperability details will be analyzed in the apposite section.

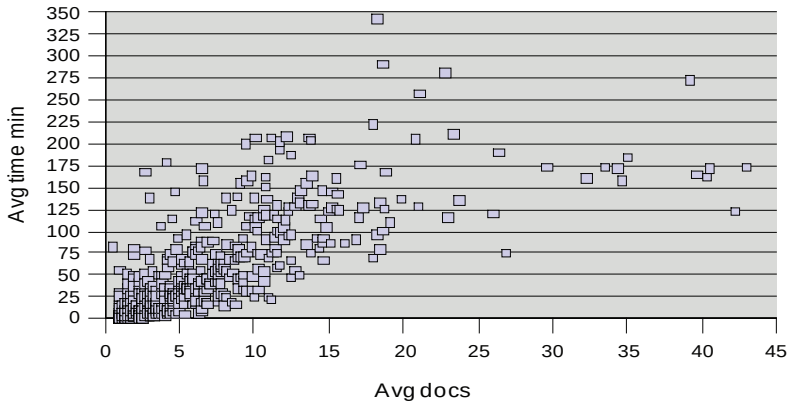
From the analysis performed, we observed that the average time spent with the new solution tends to be minimal in PA1, where the software has been introduced with the experimentation. In PA2 instead, where the solution has been installed for several months, daily average minutes per day tend to be above 50 minutes per user.

The events generated have been aggregated in two different kinds of measures, the average number of documents worked per day by each user during the whole period and the average time in minutes spent on the documents. In Figures 6 and 7 we see the mapping of each user for PA1 and workstation for PA2 in this space. In each figure on the left the mapping is for Microsoft Office,

Figure 7. PA2—Distribution of users across average documents (x-axis) and average time (y-axis)



(a) Microsoft Office documents handling



(b) OpenOffice.org documents

while on the right the mapping is for OpenOffice.org. Each point represents a user.

In PA1, 90% of all users lie in the space between 20 documents per day and 200 minutes per day spent using Microsoft Office. In PA2 90% of all clients lie between 24 documents and 240 minutes.

Regarding OpenOffice.org, 90% of PA1's users lie between four documents and less than 60 minutes of usage. In PA2, as we should expect, the usage is stabilized at higher levels, with the limit of eight documents and 135 minutes that encompasses 90% of the users.

From the temporal evolution of the software usage, we note that the software usage is constant in both PAs during the whole experimentation. This is due to the short time frame we are analysing. At this stage of the experimentation, the difference in usage of OpenOffice.org between the two PAs is clearly evident.

Furthermore, the distribution of users across time and documents gives a better idea of the grouping of users. As a further step, the application of clustering techniques in order to group users according to further variables and in accordance to their attitude, might also shed some lights on the usage pattern of the different applications (Duda, Hart, & Stork, 2001).

Functionalities

A further study on the functionalities[5] has been performed in both PAs, the goal was to gather information on how users evaluate the office automation application's features. Indeed, one of the major critics to OSS on the desktop-side, is its supposed lack of usability compared to CSS (Nichols & Twidale, 2003). The aim of this section is to evaluate the difference in functionalities usage between the two applications and whether from this distinction we can derive some indications about the usability.

In Figure 8, a first representation of the situation in PA1 is plotted. Users are mapped according to the average Microsoft Office functions per day (x-axis) and average OpenOffice.org functions per day (y-axis).

From the distribution of users in Figure 8, we can notice that users tend to use daily more functions in Microsoft Office. To further investigate this issue, we then compared both situations normalizing the functions used per time unit. To perform this operation, we set-up the following metric:

$$\frac{1}{n} \cdot \sum \left[\frac{\sum f}{t} \right]$$

Figure 8. PA1—Functions per office automation software

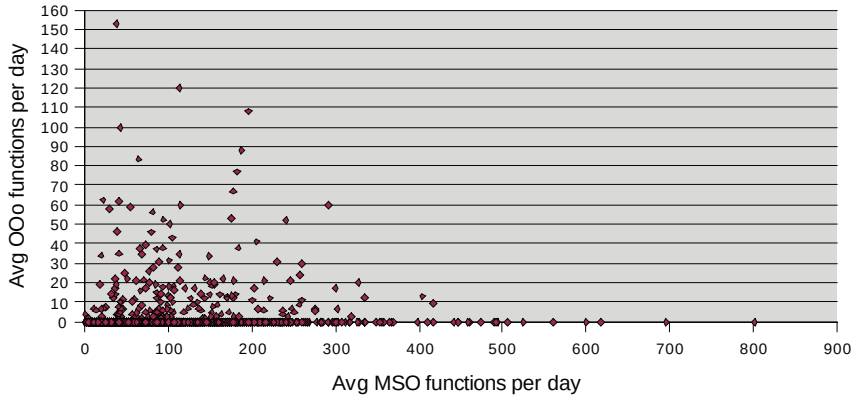


Table 3. PA1—Results of functions calling between Microsoft Office and OpenOffice.org

	MSO	OOo
Min	0,03	0.08
Max	5,45	5,45
Mean	0,41	1,71
Std. Dev	0,45	1,26

where f is a single function, t is the time spent on documents and n is the total number of users. By using the time we can compare the results among the two solutions. As a result of this formula, we get the distribution results shown in Table 3.

The number of normalised functionalities used is in general lower with Microsoft Office than with OpenOffice.org; an explanation can be the fact that users are more acquainted to shortcuts in order to perform certain operations. On the other side newcomers to OpenOffice.org have yet to acquire the necessary confidence in the functionalities offered.

These considerations cannot alone denote a possible usability problem of OpenOffice.org. However, they can indicate the difference in usage of the new technology introduced, a difference that will obviously reflect on users' productivity during the early phases of a migration.

FUTURE TRENDS

Interoperability Considerations

One of the strategies that a software vendor entering a market can exploit to emerge in a situation where users are in a situation of lock-in, is to provide higher compatibility with the standards already offered on the market. This strategy has its drawback in the fact that some performance of the application has to be sacrificed in favour of the compatibility, entering a mechanism of trade-off (Shapiro & Varian, 1999).

In this sense, OpenOffice.org offers compatibility also with the closed data standards of the Microsoft Office suite. It is interesting in the study proposed to see how users adopted this compatibility feature. To gain a measure of this interoperability issue, we computed as a first step the number of Microsoft Office proprietary formats documents opened by means of OpenOffice.org. Further data, as the time spent with the documents opened with this method and the number of users adopting the feature also add detail to this analysis.

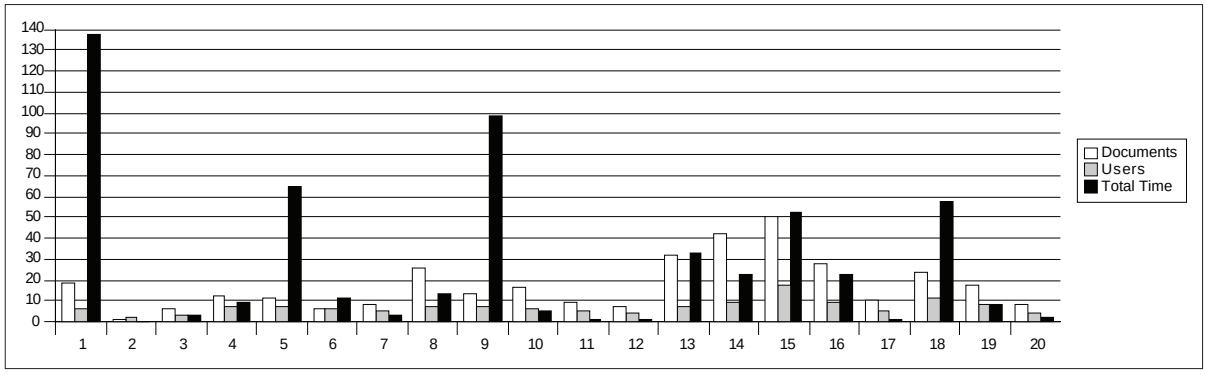
In Figure 9, data are reported for each day: the number of foreign documents opened per day (in white), the total time in minutes spent on the documents opened (in black) and the number of users adopting this solution at least once per day (in grey). The Microsoft Office formats considered are the ones handled by Microsoft Word, Excel and Powerpoint, namely files with doc, rtf, xls, and ppt extensions.

The results of this kind of analysis are not encouraging; probably one of the reasons is that users are not aware of this possibility. A minimal number of users is adopting this feature in his everyday work, to be precise only 10.90% of OpenOffice.org users (17 out of 156) with 6.76% of the global time spent in OpenOffice.org (nearly nine hours out of 138 hours). This last aspect seems to justify also that users tend to open documents of the foreign format for viewing purposes only; editing is seen as dangerous due to the different application used.

The same analysis is represented in Figure 10 also for the second PA. In this case we see that users more trained and adopting OpenOffice.org for a longer time have a clearer idea of the functionalities offered.

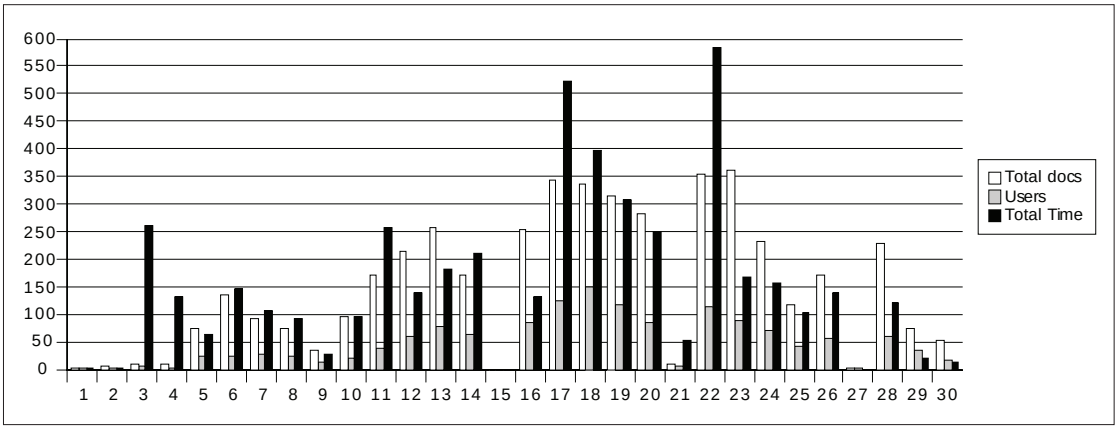
The same considerations of the previous group report that 57.46% of OpenOffice.org users (447 out

Figure 9. PA—Representation of the Microsoft Office documents opened by using OpenOffice.org



Note: For each day the figure reports number of documents (in white), users adopting this feature at least once in that day (grey) and the total time for the day spent in minutes on the documents after the opening (black). Extensions considered are .doc and .rtf (Microsoft Word), .ppt (Microsoft Powerpoint) and .xls (Microsoft Excel).

Figure 10. PA2—Representation of the Microsoft Office documents opened by using OpenOffice.org

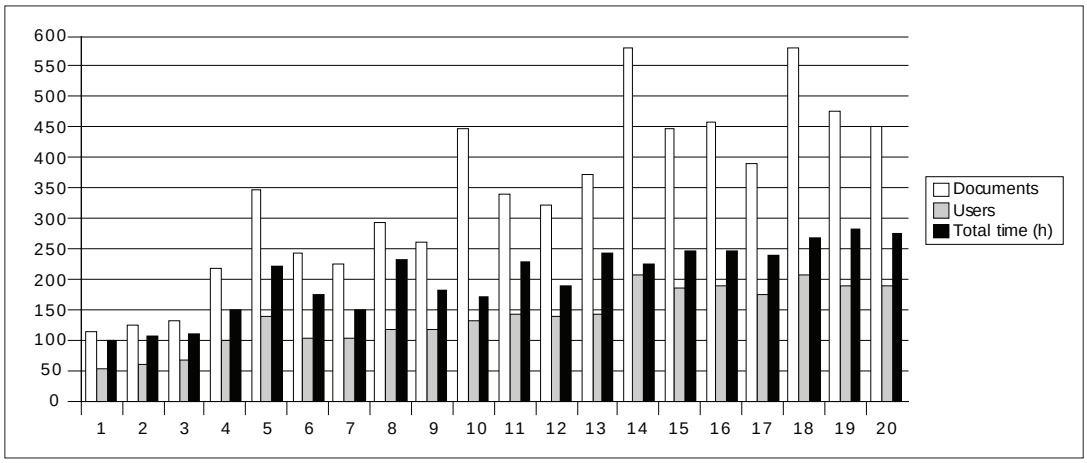


Note: For each day the figure reports number of documents (in white), users adopting this feature at least once in that day (in grey) and the total time for the day spent in minutes on the documents after the opening (in black). Extensions considered are .doc and .rtf (Microsoft Word), .ppt (Microsoft Powerpoint) and .xls (Microsoft Excel.)

of 778) used this feature, but only 2.26% of the time spent in OpenOffice.org (nearly 78 hour over 3.594 hours). In this case the result confirms that users are more aware of the interoperability features.

Another important interoperability issue in the migration in the office automation field is due to the different applications available in both suites. While Microsoft Office offers a small personal

Figure 11. PA1—Representation of the Microsoft Access documents handled by users



Note: For each day the figure reports number of documents (in white), users opening such a document at least once in that day (in grey) and the total time for the day spent in hours on the documents after the opening (in black).

database application called Access, OpenOffice.org in the version available to experimenters doesn't offer a comparable alternative[6]. In Figure 11 the use of Microsoft Access is reported, with number of documents (in white), number of users using the application in that particular day (in grey) and total time spent by all users in hours (in black). Time has been reported in hours to facilitate the reading.

What can be seen is that the software is still very used; nearly 30% of all Microsoft Office users used at least once the application during the experimentation period. If we consider only users employing it for a period greater than five days, the percentage drops to 15%. In this kind of analysis we cannot perform a comparison with PA2 as the software for data collection installed was not configured to collect this kind of information.

The results of this section report that a more focused training on the interoperability features offered by the OpenOffice.org suite can lead to a broader diffusion of the suite. It is still to understand the reasons of the lack of confidence in editing documents in the other application source format.

CONCLUSION

The results of both experimentations show that open source software (OSS) can represent a viable alternative to closed source software (CSS) even on the desktop side. The analysis was focused on four different levels of technology adoption, the level of the users' attitude towards OSS, level of adoption and usage of both solutions during the period, functionalities adopted and the interoperability issues. Where possible, all levels have been considered for both PAs that participated to the experimentation:

- The attitude was in general positive; users had a positive attitude before starting

the experimentation. However, we should expect a change of the attitude at the end of the experimentation. Neutral users will probably join the groups of enthusiastic or sceptics about OSS.

- The adoption and usage of both solutions has seen the predominance of the market-dominant Microsoft Office, although in the experimentation where OpenOffice.org was already introduced users started to use it in everyday work. This is due also to network effects in IT markets that have been exploited by the early adopter PA of our study (Katz & Shapiro, 1985). Implementing a strategy of documents exchange in the new format is a key decision to widen the diffusion of the new application. The results obtained show that the migration path will be more difficult in absence of a proper strategy of documents exchange.
- The analysis of the functionalities used has shown that there are different patterns between the groups of the two suites. The group of Microsoft Office users has more confidence in the software, performing their task mainly through shortcuts. Such a confidence is not present in OpenOffice.org users. The results cannot be used to evaluate the usability of OSS, however they do report the reduction in productivity that is typical of the early phases of software migration.
- The analysis on interoperability shows that there are still interoperability issues, mainly in the form of personal databases creation. Furthermore, users don't seem to evaluate positively the compatibility with the foreign format offered by OpenOffice.org. The strategy to increase the diffusion of the software by providing a greater level of compatibility with the existing data standards doesn't seem to provide the results expected.

Overall, the data collected have granted the possibility to evaluate the adoption levels of OSS inside two different PAs. In the cases reported, the initial levels of adoption are low and interoperability issues exist that can potentially hinder OSS adoption.

KEY TERMS

Assimilation: Passive adoption of a new practice or behaviour, generally resulting from participating in activities where such behaviour is used or is expected.

Data Standard: Denotes a standard to store data in information science. The most important classification is between open/closed data standards according to the publishing of the specification, although the exact classification is still controversial.

Deployment: Use of an item on a relatively large scale.

Lock-In: In economics, denotes a situation in which a consumer cannot change his buying decision without incurring in high switching costs. For example, a user may be bound to a certain software provider for the services offered, by switching to another provider he may incur in high switching costs to change his system infrastructure.

Network Effect: In economics, denotes a demand-side effect, by which the utility given to a certain good increases with the number of successive users adopting it. Information goods are a typical example of good that manifest this behaviour.

Migration: Transitioning from one particular software package to another.

Office Automation: The set of software necessary to provide the necessary integration between the information system and the standard office activities. The minimal set of instruments includes a word-processor, a spreadsheet, software for presentations, and a small personal database application.

Chapter 4.18
Open Source Software Adoption:
Anatomy of Success and Failure

Brian Fitzgerald
Lero – Irish Software Engineering Research Centre and University of Limerick, Ireland

ABSTRACT

Current estimates suggest widespread adoption of open source software (OSS) in organizations worldwide. However, the problematic nature of OSS adoption is readily evidenced in the fairly frequent reports of problems, unforeseen hold-ups, and outright abandonment of OSS implementation over time. Hibernia Hospital, an Irish public sector organization, have embarked on the adoption of a range of OSS applications over several years, some of which have been successfully deployed and remain in live use within the organisation, whereas others, despite achieving high levels of assimilation over a number of years, have not been ultimately retained in live use in the organization. Using a longitudinal case study, we discuss in depth the deployment process for two OSS applications – the desktop application suite whose deployment was unsuccessful ultimately, and the email application which was successfully deployed. To our knowledge, this is the first such in-depth study into successful and unsuccessful OSS implementation.

INTRODUCTION

Open source software (OSS) has elicited a great deal of research interest across a range of disciplines since the term was introduced in 1998. Much of this research, however, has focused *inward* on the phenomenon itself, studying the motivations of individual developers to contribute to OSS projects, or investigating the characteristics of specific OSS products and projects, for example. Far less has been done in looking *outward* at the process of OSS adoption and implementation in organizations. The need for rigorous research into this process is important for several reasons: Firstly, recent estimates suggest widespread adoption of OSS: A survey of public administrations in 13 European countries reported that 78% were using open source (Ghosh and Glott,

2005). Similarly, a large-scale survey in the US estimated that 87% of organizations were using open source software (Walli et al., 2005). However, these surveys did not distinguish between primary adoption (the initial decision to adopt at the organizational level) and secondary OSS adoption (the actual implementation process which involves adoption by individuals throughout the organization). Primary and secondary adoption have been identified as quite different scenarios (Gallivan, 2001; Zaltman et al., 1973). This distinction and the problematic nature of OSS adoption is readily evidenced in the fairly frequent (and somewhat controversial) reports of problems, unforeseen hold-ups, and outright abandonment of OSS implementation over time (e.g. Birmingham City Council (Thurston, 2006); Crest Electronics (Turner, 2005); Scottish Police (Niccolai, 2005), Newham Council (McCue, 2004).

Here we present the case of Hibernia Hospital, an Irish public sector organization, who embarked on the adoption of a range of OSS applications. Some of these applications have been successfully deployed and remain in live use within the organisation, whereas others, despite achieving high levels of assimilation over a number of years, have not been ultimately retained in live use in the organization. Using a longitudinal case study, we discuss in depth the deployment process for two OSS applications—a desktop application suite whose deployment was ultimately unsuccessful and abandoned, and an email application which was successfully deployed. To our knowledge, this is the first such study into successful and unsuccessful OSS implementation,although there have been several studies of OSS adoption (e.g. Lundell et al., 2006; Rossi et al., 2006; Ven et al., 2006; Zuliani and Succi, 2004).

As a starting point, we drew on Gallivan's (2001) process framework for studying secondary adoption of technology. This framework extends the classical diffusion of innovation theory of Rogers (1962-2003) by drawing on critiques of this theory (e.g. Fichman, 1992; Fichman and Kemerer, 1999; Moore and Benbasat, 1991). Our goal in this study was not to test a factor model of OSS deployment but rather to provide a rich description of the process of successful and unsuccessful OSS adoption in a single organizational context, with a focus more on theory development rather than theory testing.

Furthermore, researchers have identified a tendency in traditional innovation adoption research towards a pro-innovation bias (Fichman, 2004; Rogers, 2003). As a result, innovation is invariably seen as beneficial and positive for all participants, and, indeed, more has been written about successful adoption than rejection. Thus, our study here of the successful and failed adoption of OSS products can provide useful insights and contrasts which can contribute to theory development in this area.

The remainder of the paper is structured as follows. In section 2, we discuss the process model approach adopted here and present the conceptual framework we use in the study. Following this, section 3 discusses the research approach adopted. Section 4 presents the adoption process trajectories for both OSS applications in Hibernia. Following this, in section 5 we discuss this deployment using the framework derived in Section 2. Finally, the conclusions and the implications of the study for a theory of OSS deployment are discussed.

CONCEPTUAL GROUNDING

Process versus Factor Research Models

Process and factor approaches have been identified as alternative but complementary approaches to research (e.g. Markus and Robey, 1988; Mohr, 1982). Briefly summarising, factor research is concerned with identifying predictor and outcome variables. These are cast as independent and dependent variables and the research focus tends towards rigorous measurement of the variables

and statistical analysis of the relationship between them. The variables are assumed to be causally related with the predictor/independent variable accounting for variation in the outcome/dependent variable. However, such research cannot provide any in-depth explanation as to how and why the variables may be related (Newman and Robey, 1992). Process model research, on the other hand, seeks to elaborate the story of the underlying dynamics which reveals how and why outcomes are reached over time. In this study, given the lack of research on organizational adoption of OSS, successful or otherwise, a process model which could afford increased understanding of significant OSS adoption events was important.

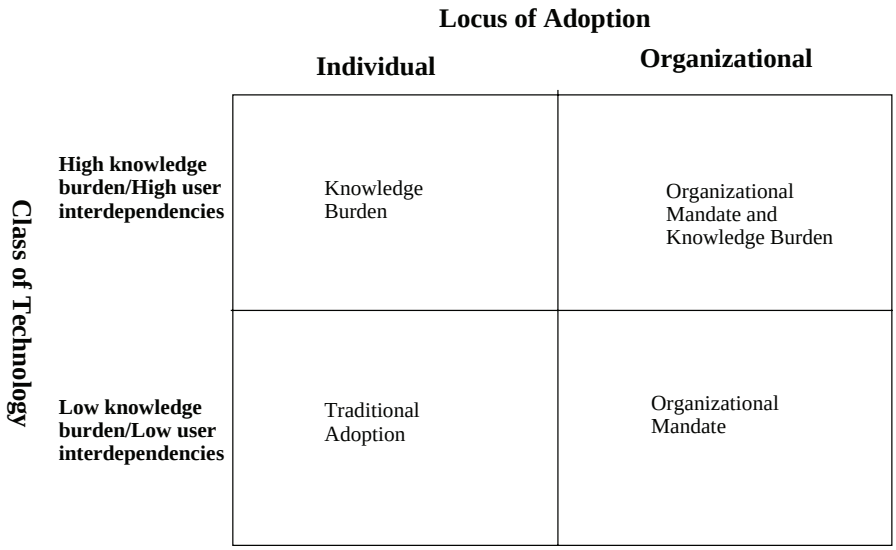
While process and factor models are acknowledged as complementary, researchers have warned against combining into a single model (Markus and Robey, 1988; Newman and Robey, 1992; Mohr, 1982). This argumentation is based on the fact that the models differ in form and operate a different model of causality. That is rather than a 'push type' causality of factor models where the levels of the independent variables cause the levels of the dependent variables, in the process model approach, outcomes are implied by preceding events—a 'pull-type' causality.

Notwithstanding this argument, several researchers have combined process and factor models to good effect (Gallivan, 2001; Sambamurthy and Poole, 1992; Shaw and Jarvenpaa, 1997). Indeed, combining factor and process models has been advocated when the focus is on understanding the adoption events and the factors that promote or constrain adoption outcomes (Gallivan, 2001; Shaw and Jarvenpaa, 1997). Therefore a somewhat hybrid model was followed here in that an overall conceptual framework of innovation adoption was identified, primarily as a conceptual lens to theoretically ground the study (Klein and Myers, 1999) and also as a means of bounding the study focus (Newman and Robey, 1992).

Innovation Adoption Research

In a review of technology diffusion research, Fichman (1992) proposes a 2x2 matrix of innovation adoption contexts where the axes are locus of

Figure 1. IT diffusion classification matrix (from Fichman, 1992; Gallivan, 2001)



innovation adoption (individual or organization) and class of technology to be adopted (low user interdependencies and knowledge burden versus high user interdependencies and knowledge burden). The model is presented in Figure 1.

Fichman argues that the assumptions underpinning traditional innovation adoption models hold best for the lower-left quadrant in Figure 1. In our study, we focus on organizational adoption of open source which is best characterised by organizational mandate to use the technology and also extensive knowledge required to overcome barriers to implementation and use. This is represented by the upper-right quadrant in Figure 1.

Such a characterisation of OSS as a technology subject to organizational mandate, high user interdependencies and high knowledge burden is justifiable for a number of reasons. Firstly, the OSS products that we focus on in this study include desktop and email application platforms. Both of these represent horizontal infrastructure systems in widespread use within organizations. As such they would be subject to the IT governance policy within an organization, and use of these systems would typically be organization-wide.

Furthermore in terms of knowledge burden, Fichman and Kemerer (1999) argue that IT assimilation may be hindered by knowledge barriers due to the learning required to obtain the necessary deep knowledge and skills to successfully deploy complex technologies. These knowledge barriers cause deployment to be a risky venture for an organization, but it may still undertake deployment so as to be in a position to avail of benefits at the appropriate time.

These issues are especially pertinent in the case of OSS. Given the fact that OSS is quite a new phenomenon, there is no well-established and codified base of knowledge that can guarantee successful deployment. OSS adoption represents a significant risk and a fundamental change in how software is acquired and maintained (Agerfalk and Fitzgerald, 2008). For example, there is usually no vendor to market an OSS product and verify that the product meets required functionality. Nor is there the automatic provision of the guaranteed maintenance contract that comes with the acquisition of proprietary software. These issues represent a considerable knowledge burden for organizations that embark on the process of OSS adoption.

A Conceptual Framework for the Innovation Adoption Process

Gallivan (2001) draws on a wide range of innovation adoption research, including Rogers diffusion of innovation, Davis' (1989) TAM model and, particularly the Theory of Planned Behavior (Ajzen, 1985) to propose a process framework specifically addressing secondary adoption and organizational assimilation of technology (see Figure 2).

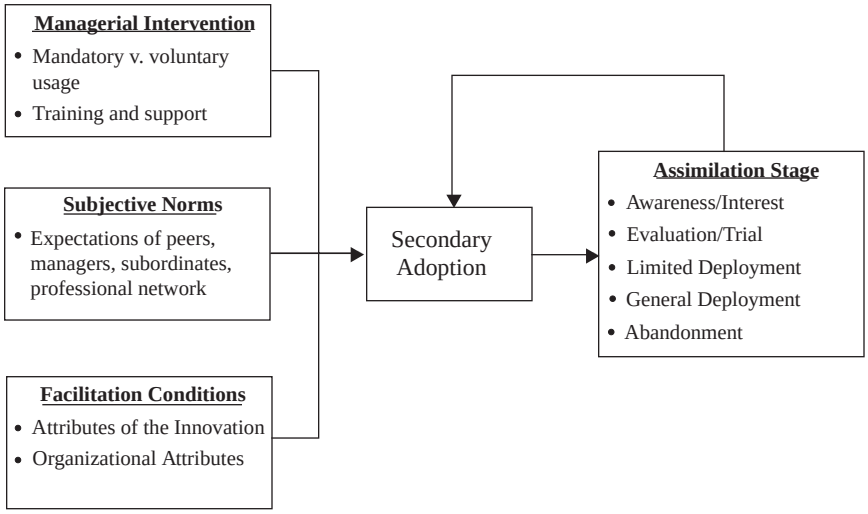
This framework operates at quite a high-level in identifying issues relevant to the IT adoption process. Here we briefly discuss the components of the framework and how they are relevant in an open source context. Later, we use this framework to structure our discussion of the deployment process for the various OSS applications in Hibernia.

Managerial Intervention

Managerial intervention refers to the actions taken and resources made available by management to expedite secondary adoption. Gallivan identifies issues such as voluntariness of adoption, training and support here. Voluntariness has also been proposed as a significant factor in other innovation research (Moore and Benbasat, 1991), and the issue of organizational mandate in relation to OSS adoption was discussed above.

Management support is undoubtedly critical for radical, high-risk initiatives such as OSS deployment since it contravenes the traditional model where ongoing support is legally guaranteed by a vendor. Indeed, management support

Figure 2. Secondary adoption process (adapted from Gallivan, 2001)



is likely to become even more important in the future as OSS adoption moves out of the domain of invisible infrastructure systems to more visible, high-profile applications.

Subjective Norms

Subjective norms have to do with individual beliefs about how relevant peers and co-workers expect them to behave in relation to the technology. This can lead to greater effort to learn about and adopt an innovation or even cause abandonment of a technology. This issue has resonances with attributes of the innovation, such as compatibility and image, discussed below.

From a values and norms perspective, the ideology represented by OSS may have significant implications. The importance of ideological values has been illustrated in several studies of OSS. For example, Stewart and Gosain (2006) identify how adherence to an overarching OSS community ideology facilitates team effectiveness. Similarly, the protracted and heated dispute over several years among the Linux kernel development community concerning the use of a proprietary version control system (BitKeeper) represented an ideological crisis for many in that community, and certainly influenced the choice of adoption and non-adoption of the technology (Shaikh, 2006).

Facilitating Conditions: Attributes of the Innovation and Organization

Much prior research on innovation adoption has focused on attributes of the technology and the organization. Rather than discuss exhaustively the range of attributes that have been identified, a number of attributes are briefly presented here and we discuss how they are relevant to an OSS context.

Attributes of the Innovation

Rogers (2003) identifies five key perceived attributes of an innovation that influence the outcome of the adoption process:

- **Relative advantage:** the extent to which an innovation is perceived as being better than its precursor.
- **Compatibility:** the degree to which an innovation is perceived as being consistent with the existing values, norms, needs and past experiences of potential adopters.
- **Complexity:** the degree to which an innovation is perceived as difficult to understand and use.
- **Trialability:** the degree to which an innovation can be experimented with.
- **Observability:** the degree to which the results of an innovation are visible to others.

In short, Rogers suggests that innovations will diffuse more quickly and successfully when they are readily trialable, of high relative advantage, compatible with the status quo, not too complex to use, and where use is readily observable to others. These attributes have been confirmed in many studies. Additional attributes, such as image and voluntariness, have been identified (Moore and Benbasat, 1991), and indeed some attributes have been found to overlap—relative advantage and compatibility, for example (Moore and Benbasat, 1991; Carter & Belanger, 2006). While Rogers' work is applicable to innovation in general, in the specific category of IT adoption, the technology assessment model (TAM) has been proposed by Davis (1989) with two central attributes—perceived usefulness and perceived ease of use. These are subsumed by the Rogers attributes of relative advantage and complexity respectively.

These attributes are readily apparent in the context of OSS. In terms of relative advantage, compatibility and complexity, for example, many OSS products have been purposefully designed to replicate proprietary counterparts. There should therefore be a sense of familiarity thus mitigating adoption problems in relation to these attributes. On the other hand, the observability of OSS use is less obvious due to the strategy of replicating proprietary software. For example, it is very difficult to tell the difference between MS Word, Excel and Powerpoint and the respective OpenOffice counterparts, Writer, Calc and Impress, merely by looking at users working online on these applications.

Given that acquisition of OSS products is usually extremely straightforward, often as simple as a zero-cost download from a web site, trialability is greatly facilitated in the specific case of OSS. Indeed, many OSS implementations up to now have been deployed by technologically-literate IT personnel who have not sought organizational approval to acquire the products.

In Rogers's work, image is considered to be subsumed in relative advantage, but Moore and Benbasat concur with previous studies which have shown image to be a separate factor (Tornatzky and Klein, 1982). Image is defined as the degree to which an innovation can enhance one's image or social status. This has emerged as a complex issue in relation to open source. Studies of the motivation of OSS developers reveal that the intrinsic satisfaction of belonging to a meritocratic community where talented developers can progress to become core developers is a powerful force (e.g. Kuk, 2006; Lakhani and Wolf, 2006). Similarly, from a user perspective, public administrations, particularly in Europe, have been enthusiastically seeking to deploy open source, seeing it as a positive initiative which frees them from the constraints of a proprietary software industry. However, other reports have found that developers do not necessarily embrace open source (Zachary, 2003), and equally, from a user perspective, there may be resistance to the use of open source products (van Reijswoud, 2005).

Organizational Attributes: Absorptive Capacity

Fichman (1992) recommends that theoretical frameworks of traditional innovation research be complemented by additional perspectives, including absorptive capacity (Cohen and Levinthal, 1990). Absorptive capacity refers to an organization's ability to recognise the value of new information, absorb it and subsequently leverage it productively. An absorptive capacity perspective has been used by Daniel et al. (2006) to study OSS development group performance in relation to knowledge acquisition and transfer. However, absorptive capacity certainly seems relevant for OSS adoption more generally. The ever increasing number of OSS applications appearing in the marketplace represents a significant knowledge challenge to be overcome—for example, the knowledge of what applications exist, which ones are most viable, how well they are supported, what functionality they offer, how they may be integrated with other OSS or proprietary applications. Indeed, developers in the past have referred to the "exhilarating succession of problem-solving challenges" when installing OSS products (Sanders, 1998). Furthermore, given that there is no tried and tested roadmap indicating a clear series of steps to guarantee successful deployment, organizations cannot expect to have the type of lengthy experience with OSS deployment that could guarantee success. Thus, the process of OSS implementation is clearly one where absorptive capacity may play a crucial role.

Secondary (Individual) Adoption Process

Gallivan suggests this component to address the details of the organizational implementation process whereby individuals throughout the organization adopt the innovation. This is taken to include when and how the innovation is adopted, what obstacles are encountered and how these influence the outcome and the degree of organizational assimilation.

Level of OSS Assimilation

Given that technology acquisition and deployment represent different assimilation events, the level or degree of assimilation can be viewed as a staged process from awareness/interest through to general deployment. The following, adapted from Fichman & Kemerer (1997), indicate the range of OSS assimilation levels experienced over time in Hibernia.

- **Awareness/Interest:** Key decision makers in organization aware of OSS and actively committed to learning more
- **Evaluation/Trial:** Organization has acquired specific OSS products and has initiated evaluation or trial
- **Limited Deployment:** Organization has established a program of regular but limited use of OSS products
- **General Deployment:** Organization is using OSS products for at least one large and mission critical system
- **Abandonment:** Organization has discontinued live use of OSS products

RESEARCH APPROACH

At a high level, research epistemologies may be classified as positivist, interpretivist or critical (Chua, 1986), although Klein and Myers (1999) recognise that classifying individual research studies is not always straightforward. To the extent that positivist research involves quantifiable measures, formal hypothesis testing and the pursuit of statistical generalization, this research study is not primarily a positivist one. Likewise given that critical research seeks to elucidate the negative and discriminatory conditions inherent in the status quo, this study does not follow a criti-

cal approach. Interpretivist research assumes the social construction of reality through language and shared meanings, and explicitly recognises the importance of a deep understanding of the context in all its inherent complexity. This research is largely compatible with these assumptions and our epistemology is thus closest to the interpretivist one. However, this classification should be tempered with our use of a high-level conceptual framework to ground the research, and to which we also link our findings. Nevertheless, Klein and Myers (1999) recommend the use of a conceptual framework in interpretivist research for such a purpose.

We sought to develop a rich understanding and insight based on a deep analysis of a single case context—what has been termed a "revelatory case" (Yin, 1994). This is also relevant given that there are undoubtedly political and social factors at play in IT assimilation (Fichman & Kemerer, 1999), which are difficult to elucidate in survey research, for example. Also, by definition postal surveys usually only elicit information from a single key informant (or perhaps two) in an organisation. Thus, there is merit in investigating the view of multiple stakeholders in a particular case context, particularly for the complex secondary adoption process (Fichman, 1992; Gallivan, 2001; Rogers, 2003). Also, just as quantitative research highlights findings that are of greatest statistical significance, in qualitative research, the aptness of a respondent's quote can memorably highlight the essence of the research.

Given that the OSS implementation process in Hibernia was not uniformly successful, we chose to focus on two example implementations—the desktop application suite which was unsuccessfully deployed and the email suite which was successful, thus representing 'extreme cases' (Miles and Huberman, 1994). Both applications are broadly similar—they are applicable to users throughout the organization, and there are strong proprietary alternatives in each case. Furthermore, by limiting our study to a single case context, certain factors are controlled to some extent—organizational attributes, for example. This makes it easier to isolate the salient elements influencing the success or failure of the process.

Data Collection and Analysis

In terms of data collection, a number of sources were drawn on (see Table 1). Over a three-year period, a series of formal face-to-face interviews, and more informal telephone interviews and meetings, were conducted with IT staff, key users and relevant management. In addition, interviews were conducted with external consultants from local firms who provided technical support for Hibernia's OSS implementation, and also with external experts who were familiar with overarching IT policy issues in the hospital sector. Formal interviews were generally of one to two-hour duration. These interviews were complemented by comprehensive reviews of documents and presentations, and fortnightly project workshops of half-day duration over a 12-month period. Furthermore, in the context of a collaborative funded research project between the author's university and Hibernia, there was prolonged and extensive access and interaction with the relevant personnel. Thus, clarification and refinement of emergent issues happened frequently through informal interviews and meetings with key personnel.

While the initial primary adoption of OSS in Hibernia was a straight-forward organizational decision, it soon became obvious that the secondary adoption of specific OSS applications by individuals throughout the organization would not be straightforward. Given this, we drew on the conceptual framework (Figure 2) which had been specifically designed to investigate secondary adoption (Gallivan, 2001). Data analysis occurred over two phases. Firstly, all the data gathered over the entire duration of the study was analysed from the high level perspective of the conceptual framework. Examples of issues which related to managerial intervention, subjective

Table 1. Data sources

Activity	Criteria
22 interviews in Hibernia and with relevant external experts	Interviews with 17 IT staff, OSS users and management in Hibernia over the period Feb 2003 to Nov 2006 Interviews with three consultants from three local organisations providing support to Hibernia (Feb 2004, Jun 2004) Interviews with two Government and Health Board personnel about general OSS implementation policy issues in the health sector in Ireland (Nov 2004 and Jun 2005)
Fortnightly half-day workshops	In context of a joint research project, half-day OSS implementation workshops held fortnightly in the period Mar - Dec 2004
Informal meetings/interviews	Frequent informal interviews/meetings with relevant staff refine/clarify issues in the period Feb 2003 to Nov 2006
Project Documentation	Various reports and presentations relevant to the OSS implementation process
Feedback presentations	Findings were presented at three workshops attended by relevant staff

norms, organizational attributes, and attributes of the innovation were identified. Following this, in a second coding phase, the specific details which underpinned the high-level constructs were identified thereby elaborating the high-level constructs of the framework. The method of constant comparison (Glaser and Strauss, 1967; Miles and Huberman, 1994) was used here as both cases of successful and unsuccessful OSS deployment were also drawn on to help isolate the most salient issues.

While generally guided by an interview protocol which specified the specific topics of research interest, interviews were conducted in a reflexive manner, in that it was accepted that responses to certain questions could stimulate new awareness and interest in particular issues which could then require additional probing. This strategy is also recommended by Eisenhardt (1989) who labels it "controlled opportunism". This probing was also a feature of the informal interviews and meetings which followed the formal interviews.

Reliability and Validity Issues

Research reliability is concerned with the consistency with which research results can be replicated. A frequent criticism of interpretivist research is that due to its subjective nature, replication is problematic. While acknowledging that interpretivist analysis would not expect all researchers to interpret the findings in exactly the same way, it is important that the research process be transparent and accessible to others. To help address research reliability, Yin (1994) recommends the use of a case study database and protocol. This strategy has been operationalised in other interpretivist case studies (e.g. Kirsch, 2004)

and we followed a similar approach here. A case study database was established which contained the raw field notes, transcribed interviews, and coding of this data according to our conceptual framework. The case study protocol specifies the criteria for selecting the case applications, the choice of whom to interview, and the interview protocol in terms of broad interview questions.

Research validity is concerned with whether the actual research in practice matches what it purports to be about. In interpretive research this is primarily concerned with the "truth value" of the research (Miles and Huberman, 1994).

Construct validity deals with the extent to which the constructs as operationalized relate to the research phenomenon being studied. In this study, given the lack of research on OSS adoption, and our goal of theory development, construct validity was important. Yin (1994) describes three tactics to deal with construct validity: the use of multiple sources of evidence, the establishment of a chain of evidence, and key informants reviewing draft findings. In this case, the collection of data on the same phenomenon from multiple interviewees both within and external to Hibernia, together with information gleaned from project documents and presentations, helped address the multiple sources of evidence criterion. In relation to the chain of evidence criterion, this was addressed through the establishment of a case study database, the rigorous analysis and coding of data according to the conceptual framework, illustration of the theoretical constructs with quotes from interviewees who fulfilled a variety of roles in the implementation, and the process description of the deployment trajectory over time. Finally, key informant review and feedback was addressed in several workshops in the context of a joint research project on OSS implementation in Hibernia, and also several draft reports and presentations on the topic were reviewed by Hibernia staff.

External validity is concerned with the extent to which a study's findings can be generalised. One of the limitations of this study might appear to be the fact that it is based on a single case and thus there is limited scope for generalization. However, Lee and Baskerville (2003) identify a fundamental and long-standing misapplication of generalization whereby researchers have solely focused on statistical sampling-based generalizability from a sample to a population, and have sought to overcome the perceived problem of attempting to generalize to other settings beyond the current one. Following this conventional model, researchers have suggested increasing sample size or number of case study organizations, but Lee and Baskerville argue cogently for the ultimate futility of this flawed strategy. They propose an overarching framework that proposes four distinct categories of generalizing, only one of which corresponds to statistical sampling-based generalization. One of the other categories in their framework, that of generalizing from empirical description to theoretical statements, is more applicable to our research study. This view of generalizing from thick description to theoretical concepts, specific implications and rich insight is also recommended as a strategy by Walsham (1993) and Klein and Myers (1999, p.75) who argue for such a theoretical link as being key to distinguish "interpretive research…from just anecdotes". In this study, the findings were analysed and integrated using the theoretical framework derived from Gallivan (2001).

OSS ADOPTION IN HIBERNIA HOSPITAL

Hibernia Hospital, which began as a merger of two of the oldest hospitals in Ireland, operates in a public sector environment, employing around 3,000 staff directly, which would make it quite a large organization by Irish standards. Similar to many other organizations worldwide, Hibernia's IT budget had undergone a significant contraction since 2000 in the wake of the increased budget

in the lead up to the Y2K. For example, in 2003, Hibernia faced an overall budgetary shortfall of €17 million. Further compounding this issue, was the fact that Hibernia would face an annual expenditure in the region of €1 million just to achieve compliance with the licensing conditions in the proprietary software products in use. It was clear that this level of funding would not be available. Thus, Hibernia was faced with the choice of either reducing the overall level of service to cope with cost restrictions, or embarking on some radical innovation in implementing less costly alternatives. Consequently, it began to investigate what could be found in the open source market-place. The IT staff in Hibernia undertook an extensive phase of desk research into various OSS products over a six-month period. The quality of the exchanges on SourceForge and Slashdot were sufficient to convince the IT Manager that OSS was worth investigating further. Some direct experimentation with downloaded OSS programs was then sufficient to convince him that the risk involved was acceptable.

StarOffice Desktop Suite

StarOffice is available from Sun Microsystems who were also the driving force behind OpenOffice. Some proprietary software is bundled with StarOffice, which prevents it being offered on the same terms as the pure open source, OpenOffice, with which it shares a common code base. Hibernia decided to implement StarOffice, as Hibernia could then purchase support from Sun. This was considered important to mitigate the risk in embarking on a radical new initiative such as OSS deployment.

In February 2002, Hibernia began the roll-out of Sun's StarOffice 5.2 desktop suite. This deployment was very problematic for users and the technical staff. However, this was felt to be largely due to problems in that version of StarOffice. In September 2002, StarOffice 6.0 was deployed with some support from Sun. However this was also troublesome. The IT Manager wanted to pursue a thin client strategy based around the concept that all applications should be downloaded from the network where practical. The StarOffice package was initially loaded onto a single Linux server, but this became overwhelmed, and it was then clustered to sustain a dual server strategy. Despite this, users continued to lose network connections in an unpredictable fashion. This inevitably increased frustration and tension amongst the entire workforce who were dependent on these tools. The IT Manager conceded that:

"we stuck with the network solution too long. It was only after a series of ferocious encounters with users—and with my own staff—that I recognised that we had to shift".

StarOffice was reinstalled on the desktop instead for those who wanted it, which did improve the situation somewhat according to technical staff, In November 2003, Hibernia installed StarOffice 7.0. This solved many of the existing problems, to the extent that the IT Manager could report that there were no open bug reports in Hibernia for StarOffice 7.0. Nevertheless, the users' perception of the StarOffice system appears to have been damaged irreparably.

Further compounding the problems was the fact that when Hibernia started StarOffice implementation in 2002, there was very little by way of training material. Thus, a lot of material had to be prepared internally which increased the workload for IT staff and trainers.

Even though the move to StarOffice was mandated, not everyone was obliged to migrate. The CEO, although a committed supporter who mandated the move to OSS, did not become a StarOffice user. In addition to this, Hibernia comprises many largely autonomous units which behave independently and raise research funds to support their activities. Across these units about 120 users chose to ignore the overall move to StarOffice. Typically, these users had sufficient

funds to remain independent of central IT support. However the IT Manager informed them that this would have consequences in that they would have to assume responsibility themselves for ensuring that the hardware which they use is upgraded, and provide resources for future maintenance upgrades, etc.

Email Platform

Prior to the move to OSS, Hibernia's email system was a proprietary one with a 500-user license limit. This limit had been reached and the IT Manager had to refuse recurring requests for new email accounts. Hibernia initially adopted the SuSE eMail application which was an open source email platform supported by Novell following acquisition of SuSE Linux. Given that there was no upper limit on the number of user email accounts with the SuSE eMail application, Hibernia sought to satisfy increased user demand for extra email accounts. However, when it reached about 700 user email accounts, the SuSE eMail system became prone to frequent problems of hanging and crashing. Hibernia had paid a consultant a once-off fee to implement the SuSE application initially. As with StarOffice, Hibernia sought to establish a support contract for SuSE eMail with Novell. However, the IT Manager reported that Novell at the time did not appear to be interested in offering an ongoing support contract for SuSE eMail. In the absence of a solution to the problems with SuSE eMail, Hibernia began to look for an alternative open source email platform. A multi-product open source email platform was established, comprising the Postfix mail transport agent, OpenLDAP directory access protocol service, SpamAssassin mail filter, and the SquirrelMail email client. After some initial teething problems with integration, this mixed architecture emerged as an extremely stable and scaleable email solution. Given that there were no license-imposed constraints on the number of users, Hibernia initiated a policy whereby all staff were entitled to an email account. Hibernia's IT staff were also able to add functionality to re-route emails to mobile phones and user PDAs. This, together with the impressive filtering capability of SpamAssassin, caused the email platform to be received very favourably by the general user base. At present, Hibernia supports more than 3,000 email accounts. Also, the system scope has been expanded to incorporate certificate-based external email access for about 350 authorised users. Overall, the IT Manager believes that "it would be unthinkable and completely unacceptable" to revert to a 500-user license again.

DISCUSSION OF OSS ADOPTION IN HIBERNIA HOSPITAL

Here we discuss the different implementation trajectories for both open source applications within Hibernia using the conceptual process framework derived above.

Managerial Intervention

Mandatory versus Voluntary Usage

As already mentioned, the decision to move to OSS was given full support by the CEO, largely on the basis that there was no other choice given the cuts in the IT capital budget. Thus, the use of StarOffice was seen as mandatory. This had significant negative implications. Firstly, as the Secretary Manager put it:

> We did not think that StarOffice had been given to us as a bonus. Rather we felt that Microsoft Office had been taken away.

However, even in the case of StarOffice, as already mentioned, a number of users who had sufficient resources were able to opt out of the migration. Also, one department who dealt primarily with fund-raising from external stakeholders

argued for the need to remain with the proprietary system due to having to liaise with these external agencies who solely used proprietary software.

On the other hand, this issue of mandatory usage did not arise in the case of the email platform suite. Hibernia was offering an additional service in terms of email access to those who sought it and who had not been able to get email access in the past. Thus, the email platform was implemented in the context of voluntary user demand rather than there being any perception of mandatory usage by management.

Training and Support

The Secretary Manager was critical of the process by which StarOffice was initially implemented. There was no effective buy-in process in her opinion. A small pilot group which included just one secretary comprised the initial trial. This was inadequate given that the most active users of StarOffice would be the cohort of secretaries in Hibernia. The Secretary Manager suggested that

StarOffice was sold as the same thing as Microsoft Office. A two-page brochure was provided and it was suggested that no training would be needed really.

However, even though StarOffice and MS Office are largely functionally equivalent, menus are constructed differently and terminology is slightly different. Thus, commonly-used options such as Print Preview or Track Changes are labelled differently or are in different sub-menus, with different key-stroke short-cuts. This contributed to a greater feeling of unfamiliarity and incompatibility than is probably warranted given the similarities between the applications.

Given these problems with the deployment of earlier versions of StarOffice, a widespread training and awareness program was created to ensure that the user community could be briefed on the new features in StarOffice version 7.0. While this could certainly address user perceptions in relation to issues of complexity, relative advantage and compatibility, it was not enough to overcome the very negative perceptions associated with StarOffice in Hibernia—this despite the fact that Hibernia have no unresolved problem reports for StarOffice 7.0.

While there was no specific training or extra support in the case of email, any differences between the original proprietary application and the subsequent OSS application have not been perceived as problematic. However, since the user base from email climbed from 500 to over 3,000, the vast majority of the users did not have an existing email application in their work context which they had learned and now needed to unlearn. Also, the fact that there are no alternative email applications elsewhere in Hibernia with which unfavourable comparisons could be drawn helps to minimise this as a problem.

Subjective Norms

In the case of StarOffice, the user base perceived usage as mandatory for those who did not have the resources to maintain an alternative. This led to feelings of resentment which were quick to emerge when problems became apparent. Interestingly, rather than being seen as renegades who failed to comply, the departments and users who were able to remain on the proprietary platform were envied by their colleagues. The Secretary Manager described it:

You meet people and hear that they are using Microsoft, and immediately you ask them how they managed to do that.

One of the key complaints from the administrative staff in Hibernia who moved to the StarOffice platform was that they feared being de-skilled

in relation to their employment prospects if they didn't have skills in popular proprietary applications. In fact, users readily admitted that they would have preferred not to have switched from the proprietary desktop systems to OSS. Additionally, there was further resentment in some quarters to the move to OSS systems, in that some staff appear to feel somewhat 'short-changed' and believe their work is under-valued if they are asked to use OSS systems which cost less that those being used by their counterparts in hospitals elsewhere using proprietary systems.

Attributes of the Innovation

The discussion above identified several innovation attributes that have been found in previous research to influence innovation adoption. Here we discuss the ones most salient to the OSS adoption in this study—image, relative advantage, trialability and observability.

Image

Perhaps the most significant issue for StarOffice was the fact that it quickly gained a negative image, and despite improvements in newer versions of the software, this negative image persisted. One user admitted that when StarOffice was proposed, there was a widespread perception that this was a cheap and antiquated package from "Jurassic Park" which would have limited functionality. This user was genuinely surprised to hear that StarOffice was a modern application which was actively being developed. This negative view was confirmed by an Informatics Nurse who suggested that StarOffice ran into "bad publicity from the outset".

There was a fairly widespread perception within Hibernia that it is prone to disadvantage due to its being on the North side of Dublin, an area traditionally perceived as being disadvantaged (at least by those who are from there), and that StarOffice was just another example of this disadvantage working against them. Indeed, in typical Northside Dublin fashion, users have coined the succinct and disparaging term, "Star Bleedin' Office", to refer to the system.

Significant in this perception was the fact that no other hospital in Ireland had chosen to implement an open source desktop. The Secretary Manager suggested that the budget-cutting rationale behind the implementation of StarOffice caused it to be perceived as a "poor man's Microsoft", and as a result there was a pre-conceived expectation that it would be problematic.

The negative effect of StarOffice was even suggested to underpin an increased level of absenteeism and stress-related sick leave, according to the Occupation Health department. While, there was no rigorous analysis of employee absences to support this, there was a belief that the stress of moving to StarOffice had been a factor in many stress-related and work leave/absences. It will be interesting to see if the level of stress-related absences also increases when Hibernia revert to a proprietary platform.

The StarOffice image has become quite notorious within Hibernia, to the extent that at meetings to discuss new IT projects, managers have been heard to express the hope that it would not be "another StarOffice". Also, the negative image of StarOffice extended beyond Hibernia. One user described emailing an attachment, which had been saved in StarOffice's proprietary format by default, to a colleague externally. This colleague couldn't open the attachment, and emailed a response saying that the attachment was in that "StarOffice gobbledy-gook".

In sharp contrast, the email platform has no such similar baggage of negative image. While there were problems during the implementation of SuSE eMail, these were quickly overcome when an alternative email system was implemented. Also, these problems only manifested themselves when more than 200 additional users had been given email access. Thus, there was no sense in which the user service had been disimproved in

any way. This has resonances with the relative advantage issue discussed next.

Relative Advantage

Clearly, the initial problems with StarOffice caused users to perceive their original proprietary system as better. There were several problems, particularly with Impress, the StarOffice equivalent of MS PowerPoint. An Informatics Nurse described it:

"I have seen people crying because of Impress. One day I was working on a presentation which I was due to give at 8:30 the following morning. At 5:30pm I checked it and it had become just one blank sheet. I had to go home and recreate it from memory in PowerPoint".

Interestingly, the Informatics Nurse also recalled losing several chapters of her thesis when using MS Word in the past, but there was a sense in which she felt less vulnerable about that. The IT Manager also recalled giving a seminar on OSS at an IT conference attended by several hundred delegates, and his Impress presentation stalled. It was not a happy experience, and certainly, the software which supports people publicly presenting, is not one where problems will be tolerated to say the least. This issue is interesting since only a very small number of actual users would need to deliver presentations, and thus the problems experienced due to the use of Impress were not all that widespread overall. Nevertheless, users seemed to very readily empathise with the negative scenario of problems with a public presentation.

While StarOffice and MS Office are more or less equivalent functionally, there are some differences, and these were were cited in some cases as a reason for not migrating to StarOffice. For example, the Finance Department cited the row number limit in StarOffice Calc which is less than that of MS Excel, as a reason for not migrating.

However, when things settled, particularly following the installation of StarOffice 7.0, a number of benefits became evident in the OSS solution. For example, one of the benefits has been the capacity of StarOffice to exploit its in-built XML capabilities. This is a very powerful feature of the application which enables documents to be structured in such a way that processing logic is built into different sections of the document, i.e. an on-line HR form request, for example, which is then automatically routed to the HR department for processing. This is a significant new feature and provides additional functionality over what was previously offered in Hibernia's proprietary desktop applications.

Also, the StarOffice suite contained an option to create PDF output, which was not available in the MS Office implementation in Hibernia. This was mentioned as a positive benefit by several interviewees. While the Impress application was clearly the most notable problem point, there was support for the other StarOffice applications. Indeed, an interviewee expressed a distinct preference for StarOffice's Calc over MS Office Excel spreadsheet software. However, such perceptions did not scale into an overarching perception of the relative advantage of StarOffice over the proprietary system it replaced.

In the case of email, Hibernia was able to satisfy additional requests for email accounts, thus offering an improved service. While there were significant problems around the use of SuSE eMail, these were very short-lived as Hibernia was able to overcome them quite quickly by implementing an alternative OSS email suite. Again, these problems only occurred after more than 200 additional email accounts had been added, so there was no real perception that the OSS system was operating at a disadvantage. This option of replacing StarOffice was not possible, and even though the problems were ironed out in subsequent installations of StarOffice, it was still perceived as StarOffice and viewed with suspicion.

Also, there were differences with the StarOffice scenario in that users were not aware of al-

ternative email applications in simultaneous use in other departments. Furthermore, users did not typically have an alternative email application at home, which was frequently the case where MS Office was installed on home computers.

Trialability

Trialabilty was a very salient issue in Hibernia's OSS deployment. At the initial stage, Hibernia's IT staff were able to download and experiment with several OSS applications of potential interest. Given the budget situation, the fact that this was a zero-cost exercise was important. Also when Hibernia experienced problems with the SuSE eMail implementation, IT staff were again able to experiment with a range of alternative OSS email applications and quickly implement a very successful and scaleable email solution.

This mode of OSS implementation has continued. When selecting an online e-learning system, Hibernia trialed a number of OSS e-learning systems before selecting the one which appeared to meet their needs best.

Interestingly, this easy trialability appears to have implications for the training and support process in that there was less attention paid to it. If it had been a high cost initiative it would certainly have had a higher profile within the organization and, as a consequence, more attention would have been paid to implementation issues such as pilot testing, training and support. The IT Manager summarised the dilemma:

"If you have a product which costs €1 million—it may seem appropriate to spend €500K on consulting. However if the product costs nothing—then spending €500K somehow seems to be a more difficult decision to take—yet the saving is still €1 million".

Hibernia have learned this lesson and, for example, created a more comprehensive user awareness and training package to support the implementation of StarOffice 7.0.

Observability

Rogers suggests that the extent to which results of an innovation are observable to others will affect its rate of diffusion. However, given that Hibernia wanted to achieve as smooth a transition as possible, the goal was to minimise and downplay the observability of the differences between StarOffice and MS Office to try ensure they would be perceived identically. This is often not difficult in an OSS context since applications have typically been designed to replicate the functionality of proprietary systems. Thus, rather than trying to publicly triumph the use of StarOffice as progressive and something to be enthusiastically yearned for, the emphasis was on downplaying the issue of observability. Given the negative image that has come to be associated with OSS in Hibernia, there is a conscious move to not identify IT applications as open source. Thus, the issue was not highlighted in the case of the email application. Similarly, when Hibernia implemented an OSS e-learning system subsequently, the fact that the systems being trialed were open source was deliberately downplayed as much as possible.

Organizational Attributes: Absorptive Capacity

Hibernia's absorptive capacity in relation to open source adoption was extremely important. The IT Manager accepted that the initial roll-out of StarOffice had been poorly conceived, and Hibernia had learned from that for subsequent implementations of OSS. Clearly, there was an element of risk in proceeding on the OSS path, since ongoing product support would not be provided in the usual way. Thus, there was a need for a complete rethink of the support strategy. In the past Hibernia had always purchased support

from a competent third-party provider. While with OSS this option still existed to some extent, there was a significant difference in expectation associated with OSS, as support was essentially derived from a series of bulletin boards, complemented with external consultancy initially until Hibernia became competent.

Also, it helped that a number of key staff—particularly in the computer operations department—rapidly adapted to the new OSS environment, and the IT Manager described the operations team as the "leaders in the overall adoption of OSS". The bulk of the overall OSS search selection and implementation was actually carried out by the hospital staff. This necessarily involved a process of learning/experimentation. As the staff confidence and familiarity with OSS products grows, the learning cycles were correspondingly shortened. It also helped that Hibernia already had a strong experience of UNIX applications to draw on. So the transition was not as radical as it would have been if staff experience was simply based on GUI-enabled systems administration. In the words of the Linux Systems Administrator, "We are not afraid of the command line interface".

Evidence of increased absorptive capacity in relation to open source is readily evident in the email application deployments. When Hibernia encountered insurmountable problems in relation to the open source SuSE eMail application, IT staff quickly sourced an alternative suite of email applications. This integration of an entire suite of disparate open source email applications into a single integrated email platform represented a significant technological challenge, from identifying suitable applications in the first place, to integrating them into an overall working application.

CONCLUSION

Table 2 summarises the differences in the deployment process for both the OSS desktop and email applications within Hibernia. Rather than elaborating the individual issues here, we will focus more holistically on interaction among the framework elements, as this had a significant influence on OSS implementation. Following this we discuss the implications of the study for research and practice, and discuss the limitations of the study.

Firstly, we focus on trialability and absorptive capacity as these served primarily to facilitate OSS adoption in this study. Trialability of OSS ensured that Hibernia could experiment with OSS applications in the first place and be reasonably confident that the OSS applications available could meet their needs. Also, when problems occurred as in the case of the initial OSS email implementation, an alternative could be found which solved the problem. However, while trialability certainly facilitates the primary adoption of OSS, it is absorptive capacity which ensures that the best OSS candidates are selected and successfully integrated and implemented, thereby facilitating successful secondary adoption.

However, other interlinked elements, such as voluntary versus mandatory adoption and image of the innovation, manifest themselves in such a way as to impede the assimilation of OSS within Hibernia.

Firstly, by being perceived as mandatory due to the necessity of cost-cutting, the adoption of StarOffice was inevitably perceived as reactive. Then when it emerged that some 'more privileged' users could opt out of the move, this two-tier scenario significantly contributed to the negative image bestowed upon StarOffice. When problems occurred, these served to fuel a disproportionately negative perception of StarOffice, despite the fact that it offered certain extra functionality, and that a steady state with no open bug reports was eventually reached following the implementation of StarOffice 7.0. Interestingly, the email application shared a similar deployment trajectory in that it too faced problems initially, which likewise were subsequently overcome, and also there were

Table 2. OSS deployment within Hibernia

	StarOffice Desktop	Email Platform
Managerial Intervention		
- Mandatory v voluntary usage	Usage seen as mandatory for those who could not afford to maintain proprietary alternative.	Access to email application provided upon request, thus usage not perceived as mandatory.
- Training and support	Differences between OSS and proprietary systems downplayed. Low level of training initially using in-house developed material.	No specialised training necessary. No incumbent proprietary system to unlearn.
Subjective Norms		
	Mandatory usage for users who could not afford to maintain proprietary led to StarOffice being perceived as inferior. Staff fear of being deskilled if using OSS, and also that work undervalued if using 'cheap' OSS.	More than 2500 additional users requests for email accounts were satisfied. Thus, uniformly perceived as beneficial.
	Those who opted out of the move to StarOffice envied rather than resented.	Also no alternative email system with against which unfavourable comparisons could be drawn.
Innovation Attributes		
- Image	StarOffice seen as cheap and antiquated "Jurassic Park" option for the disadvantaged. Widespread negative image of StarOffice both within and external to Hibernia.	Email access seen by many as a new privilege which hadn't been available in the past.
- Relative Advantage	Problems and instability led to StarOffice being perceived as inferior. Impress problems particularly cited. Benefits of StarOffice not widely appreciated.	Email a new application for the majority, thus no relative comparison. Also, problems with intermediate SuSE email quickly resolved, and new functionality (routing of email to PDAs) appreciated.
- Trialability	Trialability important, but limited due to lack of alternative OSS desktop suites.	Trialablity critical as Hibernia experimented with a number of OSS email applications.
- Observability	StarOffice and MS Office appear identical on casual observation. Thus, OSS usage is not readily apparent and observable.	Downplayed due to negative image associated with OSS. Not a major issue as no alternative email application in use to compare against.
Organization Attributes		
- Absorptive Capacity	Important as OSS represents new model of software acquisition, implementation and support. Prior learning evident in implementation of StarOffice 7.0.	Very relevant in this case as the first OSS email application had to be replaced by a suite of individual OSS email applications in a novel mixed architecture. High knowledge burden in selecting right applications to include in this architecture and configuring to work successfully together.

advantages in the OSS email system over the original proprietary system. However, the critical difference appears to be that the move to email was not seen as a top-down mandate, rather users could request an email account. Furthermore, there was no cohort using an alternative system who might be perceived as privileged.

The issue of observability was interesting in the Hibernia OSS adoption process. It would not be obvious at a casual glance wthether a user was using StarOffice or MS Office. In the case of email, the fact that the vast majority of users got access to email for the first time within Hibernia would have highlighted the observability issue, in that users were emailing who had not done so before. Thus, this was quickly evident and led to more requests for email accounts. However, due to the negative image of open source that arose from the StarOffice experience, Hibernia sought to downplay the fact that proposed applications, such as e-learning, were open source.

Implications for Research

The study identifies several issues and streams of research which could be further elaborated. To our knowledge, it is the first rigorous analysis of successful and unsuccessful OSS adoption. Our focus on a single case context is also noteworthy as certain important factors inevitably differ across organizations in a multiple case study context, thus making it more difficult to interpret the actual influence and role of individual elements. The study illustrates how a hybrid process variance model can shed light on the innovation adoption process, and in particular, illustrating the complex interaction between the various elements.

The link between trialability and actual deployment of OSS was significant in this study, particularly in the case of email. This also seems to be borne out in OSS adoption more generally. Onetti and Capobianco (2005) report a case study of a software company who offered both traditional proprietary and OSS products. The company found that the ratio of prospects who eventually become actual customers was markedly higher in the case of OSS. Funambol found that in contrast to its traditional sales process for proprietary software, when contacted about OSS products, the prospective customers had already downloaded and actually trialed the OSS product, and were far more likely to become customers paying for support. This altered the business flow from "sales push" to "user pull" (Onetti and Capobianco, 2005).

The Hibernia study also supports the contention by Fichman (1992) and Gallivan (2001) that innovations which involve organizational mandate and high knowledge require the integration of new metaphors and constructs into the research model. The high knowledge burden in successfully deploying OSS supports the view that absorptive capacity is an important issue, and this facet could be further elaborated to potential good effect. Another potentially promising perspective identified by Fichman (1992) is that of critical mass theory (Markus, 1987). This was clearly an issue in this study as the cohort of users who opted out of the move to StarOffice served to weaken the critical mass, whereas the increased number of users who received email accounts worked in the opposite direction.

The critical mass issue is linked to the issue of network externality effects. Some technologies become more valuable through the increasing returns to adoption that arise from the incremental contribution of other adopters. The basic argument is that for some technologies, the potential benefits are greatest when the entire ecosystem of users, suppliers and mediating institutions are in place to fully leverage the deployment of the technology. These increasing returns can arise through positive network externality effects (Katz & Shapiro, 1986), which are readily apparent in OSS, as the phenomenon is fundamentally predicated upon drawing sufficient voluntary interest from a worldwide network of talented hackers with complementary skills to produce industry-

quality software products (Feller et al., 2008). Furthermore, the commercial business model of open source is frequently based on creating a lucrative service and support market by leveraging the zero purchase cost to create a large base of potential customers.

It is also abundantly clear that in the case of OSS a focus on secondary adoption is important. As already mentioned, estimates of OSS adoption by organizations vary greatly. However, it is certainly the case that there could be a marked gap between the initial acquisition of OSS and its eventual large-scale secondary adoption by a critical mass of individual users. Indeed, the essential characteristics of OSS render it very prone to such an assimilation gap: The widespread media coverage leads to high awareness of the concept, while its zero cost results in a very low barrier to initial acquisition. However, the newness of the phenomenon, the manner in which it transgresses traditional software support options, and the lack of any tried and tested approach which could guarantee successful implementation—these all serve to exacerbate the potential assimilation gap between initial acquisition and widespread adoption.

Again, related to this are two elements which were found to be extremely influential in this study—voluntariness of adoption and image of the innovation. While these factors have been identified in some prior research (e.g. Moore and Benbasat, 1991), the issues, and in particular the inter-relationship between them, have not been studied in detail. Voluntariness of adoption is linked to critical mass as organizational mandate can decree that a technology be universally adopted. However, this has implications for how the innovation will be perceived especially by those who feel compelled to use it, thereby affecting the image of the innovation. Furthermore, in previous research, image is assumed to have a positive effect—the use of the innovation is expected to be image-enhancing. In this study, it was certainly the case that innovations are not always seen as conveying a positive image and universally welcomed by those who are expected to use them—the fear of deskilling and the perception of work being undervalued, for example, This has resonances with Fichman's (2004) critique of the dominant paradigm which typically assumes that technology innovation is universally welcomed and perceived as beneficial by all stakeholders. This was certainly not the universal perception from the outset in Hibernia.

Implications for Practice

The study also has a number of implications for organizations who are embarking on OSS adoption. At a higher-level, an open question in prior research has been whether IT implementation should follow a 'big bang' or phased approach, as successful implementations have been reported with both approaches (Fichman, 2004). This is also an open question for OSS migration with researchers recommending both 'big bang' approaches (Ven et al., 2006) and phased pilot approaches (Zuliani and Succi, 2004). The findings of this study would support the 'big bang' approach for each individual OSS application, primarily to avoid the situation where opting out of migration is seen as the preserve of those more privileged, thereby creating image and relative advantage problems subsequently.

This is also related to the issue of whether an organization treats OSS adoption as a mandatory or voluntary initiative. If mandatory, then it is important that OSS is not perceived as a low-cost 'second-rate' alternative, thereby relegating it to an inferior status which individual adopters seek to avoid.

Trialability is more or less a given in OSS, thus ensuring that the initial experimentation with OSS is facilitated. However, the zero cost trialability of OSS should not cause organizations to downplay the importance of implementation issues such as pilot tests, training and support. Also, in the absence of any comprehensive ven-

dor support and marketing, absorptive capacity becomes critical. Identifying potential OSS solutions in the first place is not a trivial issue. Generally, there are no vendors who can answer questions on the suitability and functionality of the software or provide details on reference implementation sites. Similarly, porting OSS to new platforms and integrating OSS systems with other proprietary and OSS systems is far from trivial, as is ongoing support. In this study, some expert consultancy was sourced locally to help with initial implementation issues, but these abilities were acquired in-house over time.

Limitations of Study

One of the possible limitations of this research is that it is a single case study, although we would argue that this should be tempered by the fact that this also afforded an in-depth insight into the process, and also allowed for the keeping constant of potentially confounding factors. Of more importance perhaps is the fact that the organization is a public sector one, and there could be important differences in the OSS adoption process for organizations in other industry sectors.

Also, this study focused on desktop and email applications, both of which are highly visible mass-market applications with strong market-leading proprietary alternatives. By contrast, less visible back-office infrastructure applications such as servers running Linux, Apache, Samba, and the like, may operate differently. Our experience would suggest that the OSS is already dominant in that sector. Similarly, the Hibernia experience would suggest that OSS can be a perfectly acceptable solution for niche applications such as e-learning, particularly when these systems are introduced without having any incumbent system to replace.

Overall, one can conclude that OSS is a very viable alternative for organizations. The main problems arise in the implementation process, rather than arising due to problems of a technical nature, as the latter are usually ironed out very quickly. Indeed, the acid test is perhaps the fact that despite any problems with StarOffice, Hibernia operated effectively as a hospital throughout this period.

ACKNOWLEDGMENT

I would like to acknowledge in particular the helpful feedback from Geoff Walsham, and also the suggestions of the Editor and two anonymous reviewers. This work has been financially supported by the Science Foundation Ireland (SFI) award to Lero—the Irish Software Engineering Research Centre, and the EU FP6 project OPAALS and EU FP 7 project NEXOF-RA.

Chapter 4.19
Media Centric Knowledge Sharing on the Web 2.0

Marc Spaniol

Yiwei Cao
RWTH Aachen University, Germany

ABSTRACT

The success of knowledge sharing heavily depends on the capabilities of an information system to reproduce the ongoing discourses within a community. In order to illustrate the artifacts of a discourse as authentic as possible it is not sufficient to store the plain information, but also to reflect the context they have been used in. An ideal representation to do so is non-linear storytelling. The Web 2.0 in its "bi-directional" design therefore is an ideal basis for media centric knowledge sharing. In this article we present a novel solution to this issue by non-linear storytelling in the Virtual Campfire system. Virtual Campfire is a social software that allows a modular composition of web services based on a Lightweight Application Server in community engine called LAS. Hence, Virtual Campfire is capable of fully exploiting the features of the Web 2.0 in a comprehensive community information system covering web-services for geo-spatial content sharing, multimedia tagging and collaborative authoring of hypermedia artifacts.

INTRODUCTION

The development of information systems for communities of practice (Lave & Wenger 1991; Nonaka & Takeuchi 1995; Wenger 1998) in different application domains is a challenging issue for several reasons. Principles like legitimate peripheral participation, group knowledge, situated learning, informality and co-location have to be taken seriously in the design of the community engine. For

that reason, the community engine has to reflect the social learning processes taking place, which differ from community to community. Even more, the information systems need a careful design of the digital media and the related communication/collaboration tools in order to reflect the discursive hypermedia knowledge contained in text, pictures, videos etc. Furthermore, communities are usually not able to express their needs in the very beginning of information system usage. Thus, the communities have to gain experiences "on their own" while applying the technologies in use. In addition, multimedia technologies and the Web 2.0 are rapidly developing, thus creating new requirements on hardware and software. In combination with a trend for multidisciplinary work and research novel approaches for flexible, evolving, adaptable, and interoperable community engines are required. Social software for technology enhanced learning therefore need to reflect the nature of the underlying community processes and their discourses. Consequently, the question is: How to design and orchestrate community information systems in order to fully exploit the features of the Web 2.0?

In order to meet these requirements we have developed in recent years a Lightweight Application Server [LAS] for community information system, which is capable of supporting communities by multimedia services on the basis of the multimedia content description interface MPEG-7. On top of it, Virtual Campfire is a community information system that allows a modular composition of web services for media centric knowledge sharing on the Web 2.0.

In this paper we first introduce a theoretical framework for working and learning in media-supported communities of practice. After that, we introduce concepts of knowledge sharing on the Web 2.0 and explain how these technologies help to create, manage and share knowledge in communities. Then we present Virtual Campfire and its core modules in a scenario of non-linear multimedia storytelling. Here, our social software is applied in a community of professionals for cultural heritage management. The paper closes with a summary and an outlook on further research.

A MEDIA CENTRIC KNOWLEDGE MANAGEMENT THEORY

Snow differentiates between two different trends in collaboration and learning within scientific communities (Snow 1959). First, the 'linear type' of learning that is goal-oriented and transmission-centered. This means, old information in scientific communities is being replaced by new one as soon as this appears. Second, there is a 'non-linear type' of learning. This type is media centric and reflects the nature of the ongoing discourse. It doesn't replace old information but keeps it and might be applied in a different context later on. Here, information is not simply transmitted for learning, but it is presented based on the underlying theory in use. Our collaborative research center on "Media and Cultural Communication" (cf. http://www.fk-427.de) has given us a detailed insight into the importance of proper media support in knowledge sharing. The description and [loose] classification of medial artifacts is probably the most important part of the methodological perception process to make social software work. This means that a continuous perception of activities in communities of practice is necessary for them in order to gain new knowledge. The question therefore is: How to resemble working practices in communities of practice by means of social software?

A media-specific theory developed in the center helped us understand digital media support for discourses in the cultural sciences. It is based on the following three media operations (Jäger & Stanitzek 2002; Fohrmann & Schüttpelz 2004):

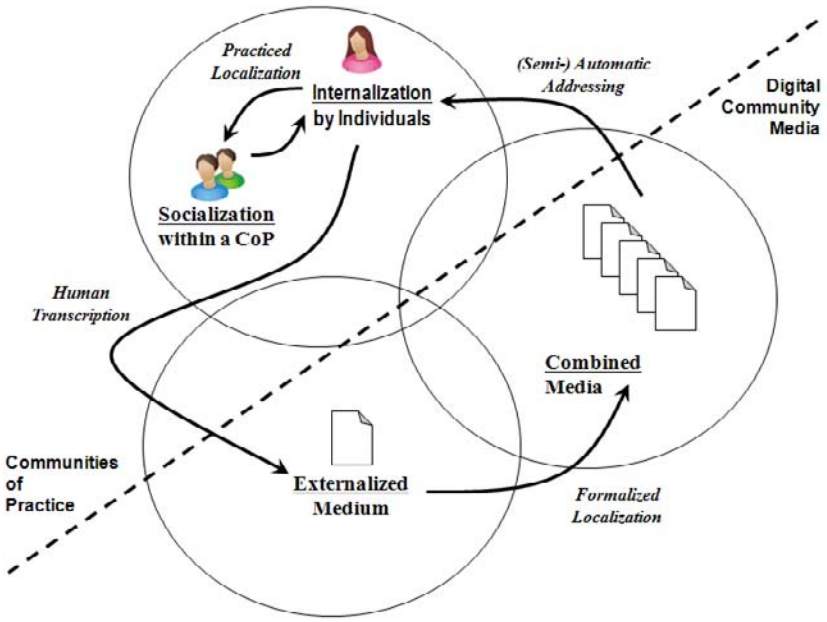
- *Transcription* is a media dependent operation to make media collections more readable.

- *Localization* means an operation to transfer global media into local practices. We distinguish between *formalized localization* within information systems [in digital community media] and *practiced localization* [in communities of practice] among humans.
- The term of *[re-] addressing* describes an operation that stabilizes and optimizes the accessibility in global communication.

In the following, we will now synthesize these media specific operations with learning processes of communities of practice. The result is a media centric re-formulation of the previously introduced media operations on knowledge creation and social learning processes adopted from Nonaka and Takeuchi (Nonaka & Takeuchi 1995) and Wenger (Wenger 1998).

Figure 1 brings together both approaches in media centric theory of learning and in communities of practice. It combines the two types of knowledge, tacit and explicit knowledge (Nonaka & Takeuchi 1995; Polanyi 1985), and the process within knowledge creation and learning processes with the media theory developed in our collaborative research center including its media specific operations [*transcription, formalized* as well as *practiced localization*, and *[re-] addressing*]. In the upper section we focus on actions performed by humans. Starting with an individual who has internalized some media-specific knowledge there are two ways to communicate with others. On the one hand, there is an option to present this information to others by human-human interaction in *practiced localization*, which allows the content's socialization within the communities of practice and vice versa which is equivalent to the development of a shared history. On the other hand, individuals may also perform a *human transcription* of their knowledge by generating new medial artifacts. This operation brings us into the lower section where digital community

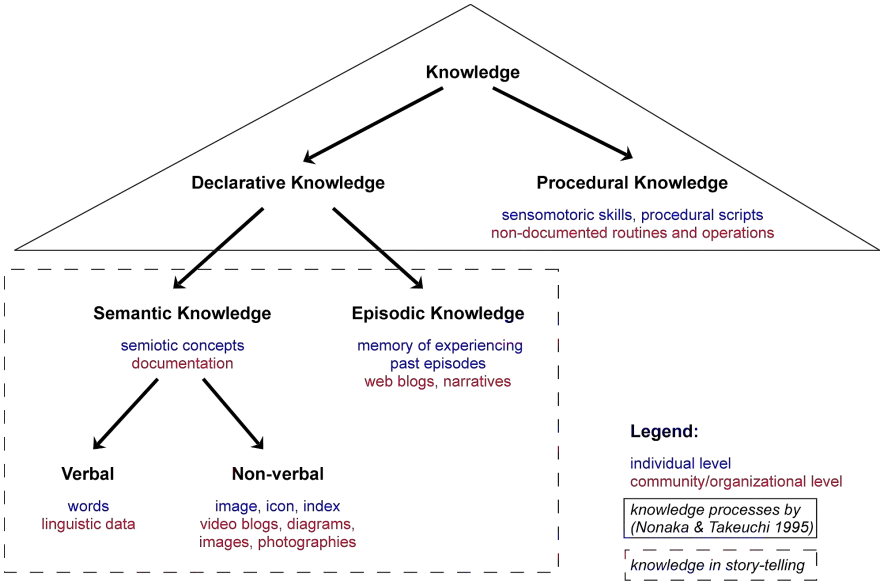
Figure 1. Media centric theory of learning in communities of practice



media are processed. The externalized artifacts of an individual are now further processed by the information system. This is done by *formalized localization* of the medial artifacts. In contrast to its high-level transcription by an individual, here, a technical computer supported recombination of medial artifacts takes place. As a result, the set of medial artifacts from various data types are combined within the information system. The final *[semi-] automatic addressing* closing the circle is the context depending presentation of the medial artifacts or a cross-medial concatenation. From then on, the process might be repeated infinitely oscillating between tacit and explicit knowledge on the epistemological axis and between individuals and the communities of practice on the ontological axis.

In order to make knowledge sharing a success for any kind of community of practice, independent of size or domain of interest, a generic community engine for social software is needed. That is exactly the point where social software is being applied in order to support the *formalized localization* process. While the previous media centric theory is based on the distinction between tacit or procedural and explicit or declarative knowledge, the importance of storytelling becomes visible after a further distinction between semantic and episodic knowledge (Tulving 1978; Ullman 2004) has been undertaken. In Figure 2 we depict a hierarchy of knowledge types with examples on the individual and community level. While semantic knowledge represents semiotic and conceptual knowledge such as documentation in organizational charts, business process definitions and so forth, episodic knowledge is knowledge about experiences such as episodes and narratives, e.g. war stories. This distinction is also being debated. Nevertheless, our claim is that a combination of semantic and episodic knowledge can be used more effectively in organizations. While situational context may be lost by external-

Figure 2. Individual and community/organizational levels of knowledge processing [Adapted from (Nonaka & Takeuchi 1995) with refinements on declarative knowledge done by (Ullman 2004)]



izing stories, outreach and impact of stories may be enhanced by this process. Documentation as a means of semantic knowledge can further be classified as verbal [linguistic data] and non-verbal [e.g. visual image, video, and diagram].

The Digital Storytelling Association [DSA] defines storytelling as follows: "Digital Storytelling uses digital media to create media-rich stories to tell, share and to preserve. Digital stories derive their power through weaving images, music, narrative and voice together, thereby giving deep dimension and vivid color to characters, situations, and insights" (DSA 2002). This illustrates that storytelling can be used not only for entertainment, but also for sharing knowledge. It intertwines semantic knowledge, i.e. already reified concepts of communities stored as documents, by linking it with the narrative experiences gained from episodic knowledge (Tulving 1978). Thus, storytelling can be seen as an approach to developing learning histories (Roth & Kleiner 1999) by creating knowledge hyper stories (Royrvik & Bygdas 2002). Consequently, storytelling is an important aspect for knowledge sharing and learning in communities of practice (Wenger 1998). Therefore, telling, sharing and experiencing stories are common ways to knowledge creation in communities of practice.

However, in the Web 2.0 (O'Reilly 2005) the power of storytelling has not been fully explored, yet. Particularly the opportunities of social software in combining contextualized knowledge with multimedia support in stories, is thus far marginally exploited. For that purpose we will introduce the key concepts of the Web 2.0 in the following.

KNOWLEDGE SHARING ON THE WEB 2.0 – THE POWER OF STORIES

While the Internet in general and the especially the web is assumed to be one of the really big media revolutions like the invention of book printing by Gutenberg in the 15th century, the wheel is still spinning. After only roughly 15 years of existence, the now so-called Web 1.0 is replaced by the Web 2.0, a term coined by Tim O'Reilly. Projects like Wikipedia let users become knowledge prosumers [consumer and producer "in parallel"] of wikis, replacing old-fashioned content management systems in organizations. Interoperability between content and services is realized by syndications tools [RSS]. In order to highlight the differences between the "new" and the "old" Web paradigms, we introduce the core Web 2.0 knowledge management presented in O'Reilly's seminal article (O'Reilly 2005). We will not repeat all features of the Web 2.0 here, but put forward the power of stories for knowledge sharing on the Web 2.0.

Participation instead of publishing. "Data are the new Intel Inside" is one of the slogans in the Web 2.0 (O'Reilly 2005), but communities get even more focus than data itself does. From del.icio.us, flickr, youTube, to mercora which are collections for bookmarks, photos, videos and music, the communities can subscribe to or rank the bookmarks' masters, photographers, video makers or DJs. Thus, social networks are built up to get a bundle of information instead of a single piece of information. In the information world, one can get whatever information he wants, when he finds the right community. Social navigation, social recommendation and social filtering techniques are even more important in a multimedia web, while classical information retrieval techniques deliver only limited support. Remix (cf. http://www.manovich.net/IA/index.html) of existing content is a technique which can easily be applied on existing Web 2.0 multimedia repositories like flickr and youTube. In the fact, digital storytelling can only happen within communities of story tellers and the audience. Storytelling as a community activity is based on participation, not necessarily similar to classical storytelling approaches but more to a many-to-many approach.

Syndication instead of stickiness. Lately, Web 2.0 is also featured as a kind of attitude with which people handle the web. More and more web sites support RSS instead of placing a button labeled with "Set this page to your home page". It has become natural and a kind of fashion to integrate third-party web services like google, yahoo and del.icio.us etc. Web services and syndication will be even more important in ubiquitous contexts when learners need support based on their location, their connectivity, their device capabilities and their usage context. Content has to be adapted to the various unreliable or unpredictable contexts of the learners instead of delivering the same content to every learner in every situation. For storytelling this implies more possibilities but also more care about media sets for stories. We already know that the narratives for mobile TV are much shorter than narratives in home TV where story parts e.g. in telenovelas are told in half hour rhythms. But based on adaptation strategies we have to prepare different media sets and even different narratives (Franz & Nischelwitzer 2004) for telling the same story in a different context.

Wikis instead of content management. Control freaks are worrying about the principal openness of the new social software applications like many wikis, but it turned out that participation is increased just by those low barriers. Even if inappropriate content is uploaded or created or existing content is modified or even vandalized, the communities have some self-repair strategies in place which are more flexible than any technological approach to protecting content. When these repair strategies do not work anymore, the community may have a problem by itself and will disappear eventually. This openness accepts various types of multimedia. It is possible to reuse multimedia, which takes advantage of well-rated community media. Open standards are widely employed but also here simple standards are preferred over complex ones. Storytelling in the Web 2.0 will depend on community strategies to maintain their media. Stories will evolve over time, but even the disruption of stories by other users has to be dealt with by the communities in the Web 2.0.

Folksonomies instead of taxonomies. Web 2.0 often uses tagging technologies to categorize multimedia content. For multimedia content-based retrieval techniques are of limited use, since they only work efficiently enough on a limited amount of materials, and even with large collections, only a limited number of retrieved materials has a high ratio in terms of precision and recall. Tags can inform multimedia retrieval and vice versa. Even if users misuse tagging and create false or misleading tags for multimedia content, content based retrieval techniques can be used to validate retrieval results based on simple keyword search. Multimedia and Web 2.0 technologies have to converge for storytelling on the Web 2.0. We need tagging technologies for retrieving interesting stories but we also need some kinds of emergent semantics for multimedia stories which are based on the content.

Contextualized Storytelling. Digital media allows fast creation, sharing and consumption of interactive content. What makes digital media most suitable for storytelling is the ability to recombine various media types, making stories more effective and interactive. Web-based systems are the ultimate step in the evolution of storytelling by making interactive multimedia contents not only available 24/7, but also allowing community-wide distribution.

As demonstrated in the concepts above, the Web 2.0 allows more and more knowledge to be created, managed and shared by communities themselves. Because Web 2.0 technologies were not intended specifically for digital storytelling, many challenges are raised by the readiness of communities to accept these technologies. However, already on the "classical" Web the power of storytelling was well recognized. There exist a lot of virtual communities like Fray.com (cf. http://fray.com/is/) whose content is solely

built of personal stories shared by the community members. Software like MemoryMiner (cf. http://www.memoryminer.com/) is capable of facilitating the authoring of digital stories even for non-experienced computer users. In oral history research web archives like the shoa archive (cf. http://www.shoahproject.org/) or the Densho project (cf. http://www.densho.org/) were created to preserve generational knowledge. In the context of corporate learning storytelling is also known and used (Nonaka & Takeuchi 1995; Davenport & Prusak 1998, Brown & Duguid 2000). A very comprehensive collection of resources is available on the Internet (cf. http://tech-head.com/dstory.htm). For the sake of clarity, we will now introduce and compare existing storytelling and analyze their capabilities for knowledge sharing on the Web 2.0.

Storytelling Environments Reviewed

There are many software tools and models for storytelling available on the Web. However, most of them are commercial products and do not incorporate any Web 2.0 methodologies. Even more, most of them aim at creation of fiction instead of sharing knowledge. Our overview will focus on these systems that are most suitable for sharing semantic and episodic knowledge in communities.

Dramatica is a comprehensive framework suitable to create multimedia stories (Phillips and Huntley 2001). However, it does not allow any kind of non-linearity. In Dramatica a story represents a particular model called the "story mind". It is left to the creativity of the authors to express their episodic knowledge as a linear story so that dedicated aspects of the story are filled with content. Dramatica is also capable of supporting semantic knowledge. Because of its mostly individual conception, Dramatica does not provide many Web 2.0 features.

Adaptive Digital Storytelling [Adaptive DST] is a computer-based form of narration that tries to integrate basic principles of narratives and dramatic art into interactive digital stories (Franz and Nischelwitzer 2004). Adaptive DST subdivides episodic knowledge into selected- and must-phases, and specifies their interdependencies. Another key concept in Adaptive DST is the option to manipulate the story a-priori. Here, a variation of a story can be generated based on pre-defined tags used to specify the level of information a user wants to obtain. Based on a 4-ary classification scheme users can select from a superficial to a fine-grained story adaptation. Thus, non-linearity is only supported to a certain extent. The existing "core story" might not be changed completely in its outcome, but might be altered depending on the user's interest in the topic. While the concept is applicable to knowledge sharing on scholarly level, in general, it is doubtful that such a labor-intense, and mostly unguided creation process might be applicable in a community, or at a larger scale. Even more, Adaptive DST does not support collaboration features for Web 2.0 technologies.

Storylining Suspense and **Story Engine** are closely related systems for the creation and consumption of non-linear multimedia stories. While Storylining Suspense is an approach to a new authoring method for interactive storytelling (Schneider et al. 2003), Story Engine is used to capture episodic knowledge by narrating interactive non-linear stories [e.g. created by Storylining Suspense] (Braun 2004). The focus in Storylining Suspense is on authoring of non-linear stories based on a set of morphological functions defined by Vladimir Propp (Propp 1958). These functions are mapped within the system based on a scene model thus creating variants of a story based on the underlying model and the user's interaction. Additionally, there are options to store semantic knowledge about multimedia contents, but it is left open, whether these contents are available only to support the creation process or will be accessible upon consumption as well. Thus, despite their client/server structure, Storylining Suspense

and Story Engine are suited only on a limited scale for multi-authoring and, consequently, the Web 2.0.

Hypermedia Novel [Hymn] is a new storytelling approach that extends the classical narration concept of Graphic Novel (Heiden et al. 2001). Hymn is a modular concept that allows the creation and consumption of hypermedia stories. The main concept of Hymn is the so-called narration module which can be accessed by an authoring tool. A narration module captures the episodic knowledge and stands for a scene within a story. These modules may be linked with other narration modules thus defining the story graph. Because of its openness in creating and sharing knowledge Hymn incorporates Web 2.0 methodologies. Despite its clear graph oriented narration structure, Hymn does not seem to apply any theoretical concepts. The "Hymnplayer" is a conventional web-browser using the Java Media Framework. Here, different media might be visualized but there is currently no support to store and retrieve semantic knowledge within media related metadata.

Table 1. Storytelling environments and methodologies compared

		Dramatica	Adaptive Digital Storytelling	Storylining Suspense & Story Engine	Hypermedia Novel	Digital Storytelling Cookbook and Travelling Companion [DSC]	Movement Oriented Design [MOD]	Storytelling in Virtual Campfire	
Story concept		n.a.	Must & should dependencies	Morphological functions	Extended Graphic Novel	Community "heuristics"	Motivation, Exigency and Structure	Motivation, Exigency and Structure	*Adopted from MOD*
Semantic Knowledge		Verbal & non verbal	Available	Available	n.a.	n.a.	Verbal & non verbal	Verbal & non verbal	
Episodic Knowledge		???	Linear	Linear & non-linear	Linear & non-linear	n.a.	Linear & non-linear	Linear & non-linear	
Product Type		Commercial	Viewer: Public Editor: Commercial / Proprietary	???	Viewer: Public Editor: ???	Not implemented	Not implemented	Research	
Validation		Advices only	n.a.	Automatic consistency checks	n.a.	Not implemented	Not implemented	Automatic validation of MOD compliance	
Web 2.0 features	Creation	Individual	Individual	Individual	Community wide	Not implemented	Not implemented	Community wide	
	Sharing	n.a.	Proprietary Webserver	Integrated Story Engine	Proprietary Webserver	Not implemented	Not implemented	Affiliated Community Webserver	

The **Digital Storytelling Cookbook and Travelling Companion** [DSC] is considered to be a handbook for the creation of digital stories based on the "heuristics" gathered in a community of users associated with the center for digital storytelling (Lambert 2003; Center for Digital Storytelling 2005). For that purpose, the DSC breaks down episodic knowledge of digital stories into subcomponents and gives practical advices how to make stories out of user experiences. Besides some practical advices on how to find ideas about stories there are seven theoretical elements specified which should be fulfilled in a good story. However, there are no concepts described suitable to process media related semantic knowledge. On the technical level, the DSC only gives hints on how to use proprietary software. A common technical platform to create and share stories has not yet been developed. For that reason, DSC can not be considered as Web 2.0 software. In general, the DSC is suitable to support digital storytelling in various areas of application without going into details.

The **Movement Oriented Design** [MOD] paradigm (Sharda 2005) is a new methodology for the creation of linear and non-linear multimedia stories. Its core idea is to bring different theories, models and tools under one roof. Thus, it integrates features from Dramatica (Phillips and Huntley 2005) as well as the Aristotelean Poetic (Aristotels 2000). The result is a novel methodology and formalism in order to create multimedia stories by combining three facets of stories: Motivation [verbal and non-verbal knowledge], Exigency [semantic knowledge] and Structure [episodic knowledge]. Thus, the MOD methodology is a comprehensive framework for the creation of non-linear digital stories. However, a prototypical implementation is missing yet. Consequently, MOD can not be considered as a Web 2.0 implementation.

In the previous subsections we have introduced several implementations and methodologies applied in the area of storytelling. As we have pointed out, current approaches are not suitable to combine Web 2.0 features with a comprehensive methodological concept to process **semantic** and **episodic knowledge**. Table 1 gives a condensed overview on these approaches by highlighting their key features. For the sake of a comparison among these features, our approach of a Storytelling in Virtual Campfire, which contains the theoretical concepts of MOD [cf. (Spaniol et al. 2006) for details], is included. Thus, Virtual Campfire is a social software that allows a modular composition of web services for media centric knowledge sharing. We will now introduce the core modules in a scenario of non-linear multimedia storytelling applied in a community of professionals for cultural heritage management.

VIRTUAL CAMPFIRE – SOCIAL SOFTWARE APPLIED

Despite the huge number of social software on the web, users face many problems when trying to apply these technologies for more sophisticated means of knowledge sharing than the simple tagging of pictures (e.g. http://flickr.com/) or exchange of bookmarks (e.g. http://del.icio.us/). However, what is really needed is to orchestrate services like these in an arbitrary manner. Therefore, our approach here is to go one step further by making multimedia contents available to others by interoperable multimedia metadata standards like MPEG-7 (ISO 2003; Kosch 2003). In order to allow community members browsing multimedia artifacts, collections and thus any kind of hypermedia, we use MPEG-7 for the capturing of explicit knowledge. For the purpose of combining interoperability and server side computations, Virtual Campfire is based on Lightweight Application Server [LAS] for MPEG-7 Services in community engines. Thus, we will first introduce the basic concepts of LAS before describing the core services applied in Virtual Campfire.

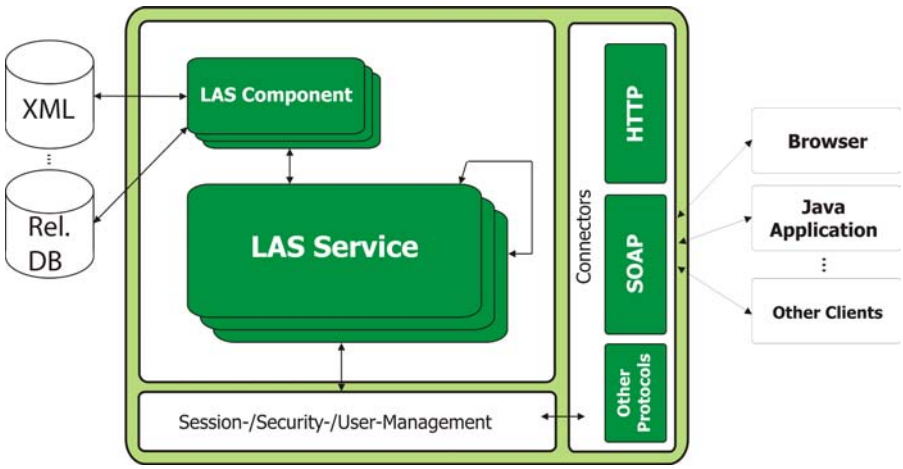
LAS: A Lightweight Application Server for Social Software

LAS is a platform independent Java implementation of a lightweight middleware platform for service oriented architectures [SOA] developed at our chair for the purpose of providing network services which can be shared among various tools supporting the work of communities in practice. The LAS Java API and its concepts are used to build the server's functionality and thus allow arbitrary server extensions by three basic element types: Connectors, components and services. Figure 3 shows a simplified diagram of the LAS architecture and the interrelations between server elements described in the following. A connector realizes the server side for client-server communication using a particular protocol, e.g. HTTP or SOAP. Components encapsulate functionality for common tasks shared by services or other components. Services define the actual functionality that LAS offers to its clients. Public service methods are available to clients through one of the connectors inside a session context. Service methods can be invoked by clients using a connector client for any of the available communication protocols [HTTP/SOAP]. Access to service methods as well as to arbitrary secured objects is controlled on server side by an internal security management that is based on users, groups and roles. Access rights can be defined on different levels of granularity, i.e. per-service, per-service-method or per-method-signature. Therefore, a client simply connects to the LAS using one of the available connector clients and invokes LAS service methods remotely, possibly involving secured objects.

Semantic Zapping Services: Exploration of Multimedia Contents

Semantic Zapping Services in Virtual Campfire tries to bridge the gap between "folksonomy-style" high-level semantic knowledge about multimedia and purely technical low-level content descriptions. These services are intended to support collaboration in communities by the exchange of multimedia contents and their low and high-level semantic descriptions. In order to ensure interoperability among the contents described multimedia

Figure 3. Simplified LAS architecture



metadata standards are being incorporated. In this aspect, the Dublin Core [DC] metadata standard (Dublin Core Metadata Initiative 1999) has been a step forward, as it is an easy to understand and concise method for media annotations. Nevertheless, DC is not suitable for temporal and media specific annotations of multimedia contents. For that reason, we try to overcome these limitations by a combination of the loose classifications in DC with more sophisticated description elements for time based media in MPEG-7. Thus, our Semantic Zapping Services are based on an excerpt of the extensive MPEG-7 multimedia metadata standard. Even more, we provide services for a semi-automatic conversion from DC to MPEG-7 while an affiliated FTP server is used for an automated up- and download of multimedia artifacts by the community to the common repository. Consequently, the Semantic Zapping Services of Virtual Campfire allow the community members to search and browse for multimedia contents described by MPEG-7.

Collaboration Services: Authoring of Multimedia Contents

Externalization of knowledge in Virtual Campfire is supported by annotating, tagging and sharing multimedia contents within the community. Contrary to a conventional categorization system, multiple concepts are used for one piece of information. Other than Flickr.com [cf. http://flickr.com) all metadata generated in Virtual Campfire is MPEG-7 compliant and generated using MPEG-7 LAS service methods. For that purpose, Virtual Campfire offers two types of tagging: keyword- and semantic tagging (cf. figure 4). Keyword tagging enables users to assign a set of plain keywords to an image like it can be done in Flickr. From the technical point of view,

Figure 4. Keyword and semantic tagging of multimedia contents

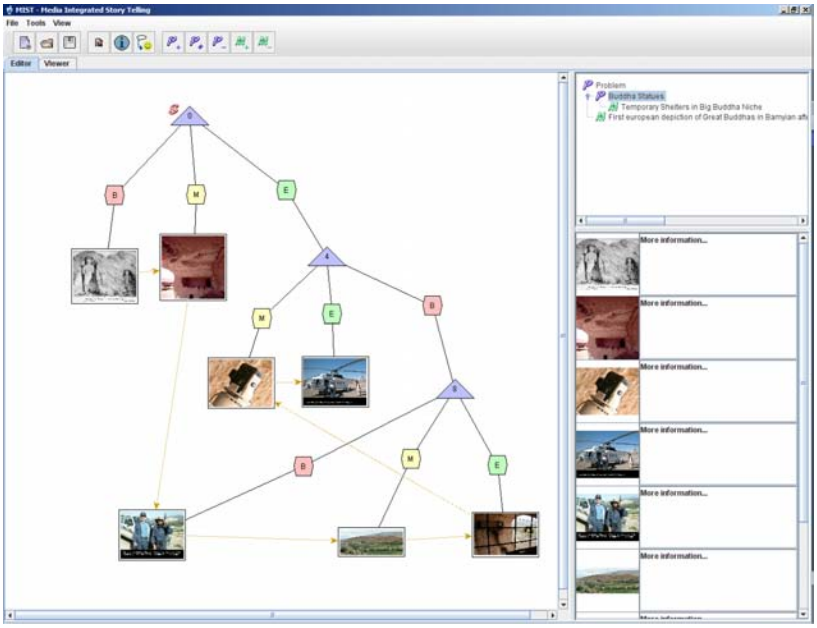
keyword tagging is covered by the methods of MultimediaContentService. Semantic tagging goes a step further by allowing users to define semantic entities and to assign semantic entity references to an image. These are more expressive than plain keywords, because they carry additional semantics. For example one could not derive from a plaintext keyword "Buddha", that it describes an agent, while for semantic tagging, "Buddha" has been modeled as a semantic entity of type agent. Semantic entities are defined using methods of SemanticBasetypeService. Semantic references are assigned to images using methods of MultimediaContentService.

Similarly, retrieval is based on the multimedia descriptions. For retrieval by plain keyword tags users can formulate keyword search expressions as propositional logic formulae using keywords as atomic propositions. For example, the keyword search expression "Buddha and Bamiyan and not(Destroyed or Taliban)"would retrieve all images having been assigned the keywords Buddha and Bamiyan, but none of the two keywords Destroyed or Taliban. The above concepts are transferable to the more expressive semantic tagging, which can be easily realized on the basis of the MPEG-7 services.

Storytelling Services: Re-Contextualization of Episodic Knowledge

For re-contextualization of episodic knowledge Virtual Campfire provides dedicated Storytelling Services. In order to help even an "untrained" user in creating useful stories (from a structural point of view), the MOD paradigm is being applied as a theoretical basis (cf. Section 3). For that purpose two dedicated user interfaces are available for the Storytelling Services: An editor and a player. The editor allows users to create new or edit already existing multimedia stories. The player is used for

Figure 5. A non-linear story created in Virtual Campfire



the consumption of existing multimedia stories. Besides the explicit knowledge contained in the multimedia contents themselves the high-level semantic tags are accessible. These contents can thereafter be temporally arranged as they depend on a certain context they belong to. When creating a story the author can now create paths covering different problematic aspects along the contents. Thus, the problems addressed depend on the path selected and lead consequently to different results in a story. Figure 5 shows the editor consisting of three main elements [from left to right]: Storyboard, plot and semantic annotations. The plot in the middle represents the declarative knowledge captured in a story. It is rendered as a tree hierarchy, which allows the further decomposition into sub-problems. In addition, problems addressed in a multimedia story can be linked to related multimedia contents. The storyboard on the left hand side shows a visualization of episodic knowledge as paths between content elements. In addition, the decomposition of stories according to MOD paradigm into begin (B), middle (M), and end (E) is shown. Finally, on the right hand side, additional semantic annotations can be added to any multimedia element. Thus, users may express verbal-knowledge being associated with non-verbal knowledge.

CONCLUSION AND OUTLOOK

With the further development of the Web 2.0 and social software (in particular) digital storytelling becomes a central knowledge sharing and learning technology again. Especially, in situations where direct interaction is not possible, the new social software application offers the possibility to share multimedia materials in a community-centered style. Like the creation of new knowledge is a discursive and multistage process, the user requirements are rapidly changing and several new features need to be integrated into community information systems. In contrast to existing implementations the methodology and architecture Virtual Campfire is more flexible to assess the community needs over time and to integrate the community members in the development process. Even more, the multimedia services of Virtual Campfire based on MPEG-7 provide interoperability and exchangeability of learning contents. Thus, the usage of LAS simplifies the community support process for the communities of practice drastically and on the same time offering more influence on the development process. However, the direct support of computer scientists and community designers is still needed. In future, graphical editing support for community web sites could leave even more responsibility on the community side.

Another topic of ongoing research is the assessment and analysis of stories. Since the stories are created by communities we need community-centered assessment tools beyond the level of simple rating tools. Our stories are related to a problem-solving space created by a hierarchical presentation of problems. Non-linear digital stories components have to cover at least all sub-problems in the problem space. This can be tested automatically by some algorithmic approach while the emotional movement of learners and their problem-solving skills are much harder to test. This is clearly interdisciplinary research which can be performed in an organizational or psychological framework.

ACKNOWLEDGMENT

This work was supported by German National Science Foundation (DFG) within the collaborative research centers SFB/FK 427 “Media and Cultural Communication”, within the research cluster established under the excellence initiative of the German government “Ultra High-Speed Mobile Information and Communication (UMIC)” and by the 6th Framework IST programme of the EC through the Network of Excellence in Professional

Learning (PROLEARN) IST-2003-507310. We thank our colleagues Nalin Sharda and Georgios Toubekis for the inspiring discussions. In addition, we thank our students D. Renzel, H. Janßen, M. Pienkos, P. M. Cuong, D. Andrikopoulos and A. Hahne for the implementation of the Virtual Campfire services.

Chapter 4.20
Towards an Integrated Model of Knowledge Sharing in Software Development:
Insights from a Case Study

Karlheinz Kautz
Copenhagen Business School, Denmark

Annemette Kjærgaard
Copenhagen Business School, Denmark

ABSTRACT

This article adds to the discussion on knowledge management (KM) by focusing on the process of knowledge sharing as a vital part of KM. The article focuses on the relationship between knowledge, learning, communication, and participation in action, and the role of social interaction and technical media in the knowledge sharing process. We develop an initial theoretical framework of knowledge sharing on the basis of a literature study. Drawing on an empirical study of knowledge sharing in a software development company, we discuss what supports and what hinders knowledge sharing in software development. Finally, we use this knowledge to improve the theoretical framework.

INTRODUCTION

The KM literature is extensive, but the discussion on how to manage knowledge in organisations is far from over, and new proposals as well as lessons learned are continually being suggested. However, the published literature, especially in the information systems field, is largely grounded in a view that considers knowledge as an objective commodity which can be collected, represented symbolically and processed like information (Dahlbom & Mathiassen, 1993; Tsoukas, 1998). The literature consequently shows a certain preoccupation with information technology (IT) and technical solutions while it reflects a limited view of individual and organisational knowledge-related processes (Swan, Scarbrough, & Preston,

1999). The practice of KM is frequently reduced to the implementation of new IT-based systems, and important organisational aspects, in particular human and social issues, are overlooked. There are, however, exceptions in the literature which reviews KM success and critical success factors (Jennex & Olfman, 2005, 2006). Like Kautz and Thaysen (2001), those who emphasise the important but not privileged role of IT provide a balanced discussion of technical issues related to KM.

This article takes this debate into account and is based on a broader perspective of knowledge and KM. Our focus is on understanding especially the process of knowledge sharing as a vital part of KM and on the relationship between knowledge, communication, and participation in action through either social interaction or technical media in the knowledge sharing process.

By studying the knowledge sharing process in a Danish software development company, we provide an insight into how developers draw from organisational memory (Walsh & Ungson, 1991) to share knowledge in a learning context. We discuss the use of social interaction and technical media in the communication process and provide conclusions on how different forms of knowledge are shared through the two types of media.

Our focus is primarily on the role of people in the knowledge sharing process, but we also include empirical findings on how people use technology to share knowledge.

The article is structured as follows. The next section introduces the concepts of knowledge, learning and communication which inform our understanding of knowledge sharing. The third section presents our research approach and setting. Our empirical findings are described in the fourth section and discussed in the fifth section. Finally in the sixth section, we present our conclusions and the challenges for future research.

THEORETICAL BACKGROUND

We begin by exploring the concepts on which we build our initial theoretical understanding in order to present how we utilise them in this study. Knowledge sharing is a bilateral process in which knowledge is exchanged between individuals and groups (Comas & Sieber, 2001). Knowledge is the outcome of a complex process, a part of which is the gathering and processing of information. This has been described by Kolb (1984) and others as a learning process. Learning is significant for the attainment of knowledge, and thus also for the sharing of knowledge. Information is communicated among people with the aid of a shared language, body language, and actions (Fiske, 1990; Nielsen, 1994) and participation in action and practice builds the foundation for learning (Wenger, 1998). This happens through social interaction and in some cases with the aid of technical media (Thompson & Walsham, 2001). Communication and participation in action are thus also significant for the sharing of knowledge. In the following we revisit the concepts of knowledge, learning communication, and participation in action and their relationship and importance for knowledge sharing in more detail.

Knowledge

Many definitions of knowledge have been presented in the literature. Although they differ in scope and orientation, they seem to agree upon the fact that knowledge is a complex multifaceted concept which can be understood from different perspectives (Cook & Brown, 1999; Kautz & Thaysen, 2001). From a hermeneutic perspective, knowledge is not a commodity which can be collected under controlled conditions and bought or sold on a market (Dahlbom & Mathiassen, 1993). On the contrary, it is subjective enlightenment, a personal property which is grounded in human cognition of things and relations in the world

(Nielsen, 1994) and it affords actions (Cook & Brown, 1999).

Nonaka (1994) and Nonaka and Takeuchi (1995) build their model of the dynamics of knowledge creation with its conversion processes socialisation, externalisation, internalisation, and combination, which is a prerequisite for knowledge sharing according to Polanyi (1966), in particular under his concept of tacit knowledge. However, the commonly used sharp distinction between explicit knowledge which can be captured and codified into manuals, procedures, and rules and is easy to disseminate, and tacit knowledge, which cannot be easily articulated and thus only exists in people's hands and minds, and manifests itself through their action, has not been made by Polanyi (Stenmark, 2000). As Stenmark argues, Polanyi (1966) sees explicit and tacit knowledge as intrinsically interrelated and mutually constituted, and views tacit knowledge as the backdrop against which all understanding is distinguished. All knowledge thus has a tacit dimension, and tacit knowledge is the cultural, emotional, and cognitive background of which humans are only marginally aware. This is supported by Tsoukas (1996), who argues that explicit and tacit knowledge are inseparably linked, and that they cannot be treated as two separate types of knowledge.

Against this background, the mechanical conversion model as a background for knowledge creation and sharing appears to be an inadequate description of the underlying processes. We follow Cook and Brown (1999), who apply the concepts of explicit and tacit knowledge in the form originally intended by Polyani (1966). Acknowledging the codifiable nature of explicit knowledge which can be transmitted through formal, systematic language, and tacit knowledge, which is rooted in action and difficult to formalise and communicate, they do not promote one distinct kind of knowledge as an ideal for knowledge. Instead they emphasise the importance and necessity of different forms of knowledge. They distinguish between explicit and tacit knowledge, but also between individual and group knowledge, thereby creating four basic knowledge forms: (1) explicit individual, (2) explicit group, (3) tacit individual, and (4) tacit group knowledge. They see these four forms as distinct forms of knowledge all with equal standing. All four forms are relevant to describe and understand knowledge and knowledge sharing in organisations. In addition to the four knowledge forms, Cook and Brown introduce the concept of knowing, which is the part of an action or practice which deals with the way knowledge is used in interaction with the social and physical world. Sharing their broader perspective on knowledge, our theoretical framework includes three dimensions of knowledge based on Cook and Brown's (1999) work: explicit/tacit knowledge, individual/group knowledge and knowledge/knowing.

We thus understand explicit knowledge as knowledge which is codifiable and can be expressed directly through language. This means that explicit knowledge is structured and ordered such that it can be described and discussed through speech, scripts, drawings, and other signs and symbols. Tacit knowledge is knowledge which cannot directly be codified, but which can (only) be expressed indirectly through language and action. Tacit knowledge is a "feel" or sense for something or "to be able to do something without being able to explain why" (Brown & Gray, 1995, p. 78). Tacit knowledge is not hidden or inaccessible—tacit knowledge simply cannot be codified or expressed directly.

Individual knowledge is knowledge held by an individual that is applied in the individual's actions, while group knowledge is knowledge held by a group and applied in the group's actions. Group knowledge is created through the cooperation of the group's members and is part of the group's practice (Brown & Gray, 1995). Group knowledge includes knowledge about how the group works, its social rules, the group's memory about earlier actions, and knowledge about the group's tasks.

Not necessarily all members of the group possess the whole group's knowledge; it is the group as a whole that possesses the group's knowledge, and it is the group as a whole that applies this knowledge (Cook & Brown, 1999).

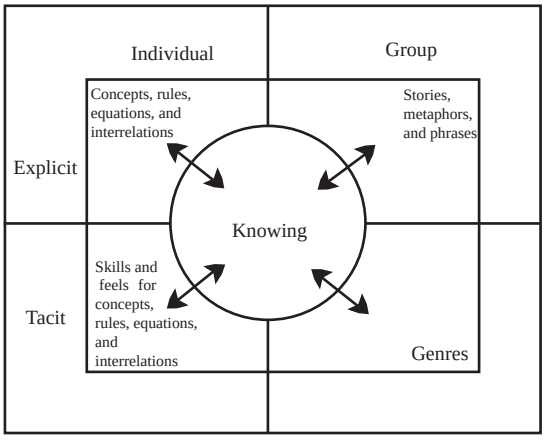
Each of the four types of knowledge presented by Cook and Brown (1999) is associated with a set of knowledge forms (see Figure 1). Explicit individual knowledge is expressed in concepts, rules, equations, and interrelations. This is, for example, knowledge in the form of concepts about the design of a product or a specific procedure to follow. Tacit individual knowledge can be expressed in a person's skills in applying tools or routines for the performance of a particular task (Comas & Sieber, 2001). Explicit group knowledge consists of shared stories about previous successes or failures and of metaphors used for establishing a common understanding of a problem or a task. And finally, tacit group knowledge is related to organisational culture in the form of genres which guide the thoughts and actions of organisational members.

The four types of knowledge can be seen as constituting organisational memory in different forms. According to Walsh and Ungson (1991), organisational memory is both an individual and organisational level construct. Although the definition of organisational memory is far from uniform, it is generally agreed upon that organisational memory consists of mental and structural artefacts which have a consequential affect on performance (Walsh & Ungson, 1991). In its most basic sense, organisational memory refers to stored information from an organisation's history which can be brought to bear on present decisions.

We have knowledge to carry out an action, but at the same time we can have knowledge independently of whether we carry out the action or not. Knowledge is something we possess irrespective of action. Thus knowledge is a tool which can be used in action, but which in itself is not action. The four forms of knowledge created by the dimensions of explicit—tacit and individual—group are thus not sufficient to describe the knowledge which is expressed through practice (Cook & Brown, 1999).

Every time someone carries out an action, a combination of many different types of knowledge is used. Each type of knowledge contributes to the action in a way in which the other types cannot. The

Figure 1. Types of knowledge related to knowing based on Cook & Brown (1999)



part of the action which focuses on the application and combination of explicit and tacit knowledge in interaction with the social and physical world is referred to as "knowing" by Cook and Brown (1999). As they put it, "Knowing is to interact with and honour the world using knowledge as a tool" (p. 389). Knowing has a focus on how we use our knowledge in practice. Knowing is not something we have, but something we do, and therefore a part of the actual action.

Figure 1 shows the different forms of knowledge related to the process of knowing.

Having argued for a three-dimensional understanding of knowledge, we now focus on the concept of learning and how this contributes to our understanding of the knowledge sharing process.

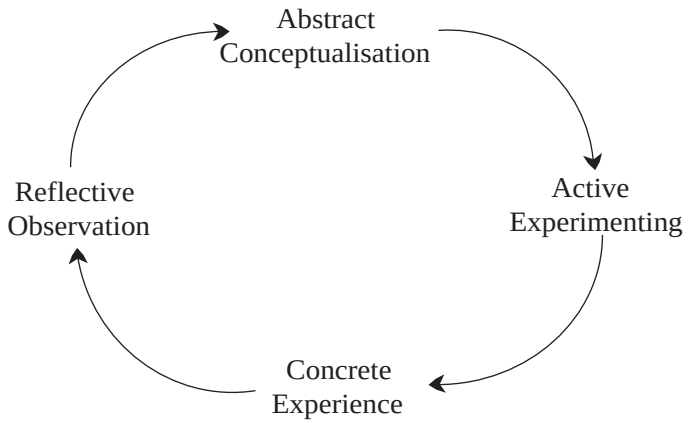
Learning: Knowing as a Learning Process

Learning is the process in which we acquire knowledge based on the communication of information and the participation in action. The learning process is thus an antecedent of having knowledge and is important for the sharing of knowledge.

Kolb (1984) has developed a theory of learning according to which learning is based on experience, and takes place through learning cycles. The learning process is a cognitive process in which individuals process new information or actions on the background of existing information or actions. In this process—depicted in Figure 2—information called abstract conceptualisation is obtained though speech and script, or indirectly through action and practice, when it is called concrete experience; thereafter information is processed actively through active experimenting or reflectively through reflection and/or observation. This means that abstract concepts and concrete experience are tested actively in practice or are reflected upon. The result of this process is new knowledge.

This learning theory can be related to Cook and Brown's (1999) understanding of knowledge and knowing (Comas & Sieber, 2001). A mutual interplay exists between knowledge and knowing: knowing means that we use our knowledge in new ways, or that we make use of our knowledge in new ways through practice, and thus discover new interrelations or gain a new understanding of our knowledge. Kolb's (1984) learning cycle, which is based on experiential learning, complements

Figure 2. Kolb's (1984) learning cycle



Cook and Brown's comprehension of knowing, as it can explain those aspects of knowing which deal with the creation of new knowledge. Comas and Sieber postulate that the four different stages of the learning process indirectly reflect the presence of different states of knowing, and argue that moving through the cycle contributes to what Cook and Brown have called productive inquiry.

There is, however, a difference between the four types of knowledge and how they relate to learning. The learning process depends on the types of knowledge involved, but also on different ways of learning (Nielsen & Kvale, 1999). This is a part of our theoretical framework and it will be discussed next.

The concept of scholastic learning describes the (part of) learning which takes place through verbal and textual instruction detached from practice (Nielsen & Kvale, 1999). This comprises the communication of information which represents explicit knowledge, and as such, concepts, rules, equations, and interrelations are acquired through scholastic learning. This involves learning through concrete institutionalised education, for example, through courses, seminars, or literature studies, but also through verbal and textual instruction among colleagues at the workplace.

Learning of tacit knowledge occurs through active participation in practice as well as general learning in day-to-day life. Wenger (1998) presents a social theory of learning in which participation in practice forms the basis for learning. When people work closely together, share a practice, a vocabulary to talk about the practice, and an understanding about the practice, tacit knowledge in the form of skills, proficiency, routines, and shared genres is more easily shared (Wenger, 1998; Wenger & Snyder, 2000). Practice learning takes place in communities of practice which are particular areas of activity or bodies of knowledge which a community has organised itself around. It is a joint enterprise inasmuch as it is understood and continually renegotiated by its members who are linked to each other through their involvement in common activities (Wenger, 1998).

Over time, a community of practice builds up an agreed set of communal resources, a shared repertoire which consists of tangible as well as intangible aspects such as procedures, politics, rituals, and values (Wenger, 1998; Wenger, McDermott, & Snyder, 2002).

While scholastic learning is primarily about receiving, processing, and "absorbing" information, practice learning is primarily a question of becoming part of a community (Brown & Gray, 1995).

Individual learning can occur through scholastic as well as practice learning, and it is an individual's learning of explicit and tacit knowledge. Individual learning denotes the acquisition of knowledge which an individual (him/herself) uses in and for his or her actions. An example is knowledge in the form of concepts about the design of a product, or skills in the application of tools or routines for the performance of particular tasks (Comas & Sieber, 2001).

Group learning is learning of tacit and explicit knowledge on a group level. Group learning can also occur through scholastic as well as practice learning. Through group learning, the group acquires knowledge which it uses for its actions. This comprises knowledge in the form of rules for how a task is to be solved, shared stories about successes and failures, routines for how the group distributes tasks, and genres for particular meetings and documents.

Communities of practice (Lave & Wenger, 1991; Wenger 1998) are a prominent example of group learning, being groups of individuals who work together over a period of time. The individuals in these groups may carry out the same job or cooperate on a shared assignment, but they do not have to be a formal or identifiable group (Brown & Gray, 1995). Individuals in communities of practice are bound together through a shared practice and understanding of this practice, and

they develop shared knowledge about the practice (Brown & Gray, 1995).

Communication and Active Participation in Action: Knowledge Sharing Through Social Interaction or Technical Media

Knowledge sharing is a process in which knowledge is exchanged between individuals and groups (Comas & Sieber, 2001). The access to and exchange of information is necessary for the acquisition of knowledge (Kautz & Thaysen, 2001), and communication is therefore important for the sharing of knowledge.

We take as a starting point Fiske (1990), who argues that communication can basically be understood as the exchange of information. Fiske relies on Lasswell's (Severin & Tankard, 1997)—Who (says) What (to) Whom (in) What Channel (with) What Effect—and Shannon and Weaver's (1949) rather general and simplistic models of communication, but emphasises that the communication process takes place with the aid of a shared oral and written language, body language, or action. In this model a sender or communicator chooses, combines, and presents data in such a way that it represents the information which he or she wants to communicate. A receiver recognises and takes information in by interpreting the transmitted data on the background of existing knowledge, other information, context, culture, and the rules and pragmatics of the language.

Communication can take place as a dialogue, meaning that the roles of sender and receiver change continuously during the communication, or as a monologue, in which case the roles of the sender and the receiver are fixed throughout the communication session. The roles of sender and receiver of information in the communication process can be held by individuals and by formal or informal groups. Formal groups are groups which are linked to business processes or organisational units and which have been defined by an organisation's management (Brown & Gray, 1995). Informal groups are groups which are connected with informal business processes or built by people who congregate outside or across the formal organisational units.

The differences between how individuals or groups exchange knowledge have an impact upon how and which information can be communicated. Information can not only be found in speech, but is also expressed through body language and action. An individual can obtain information which is embedded in actions and body language by participating in someone else's work. This means that information has different formats, is more or less structured, and is stored in different ways, which all have an influence on how information can be communicated.

Knowledge sharing takes place through inter-subjective and/or technology-facilitated communication (Thompson & Walsham, 2001). Inter-subjective communication takes the form of social interaction, while technology-facilitated communication comes about through technical media. There is a difference between which type of information can be most suitably exchanged and provided through social interaction and technical media (Thompson & Walsham, 2001).

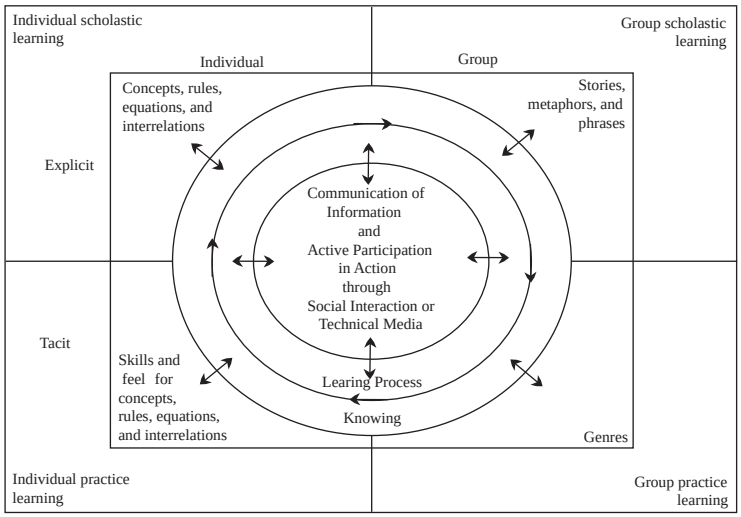
Social interaction as the exchange of information face-to-face between people comprises, for example, formal or informal meetings, verbal presentations, and teaching sessions. In social interaction, information is communicated through speech, body language, or actions; hence, social interaction enables the exchange of information linked to both explicit and tacit knowledge (Nielsen & Kvale, 1999). Explicit knowledge can be codified, and it can thus be expressed verbally (or textually) in a shared language. Tacit knowledge cannot be codified and it can therefore not be expressed verbally or textually; body language and actions are thus important for the learning of tacit knowledge (Nielsen & Kvale, 1999). This

indicates that social interaction is suitable for the communication of complex, less structured, and nonformalised information because it provides different possibilities for communicating a message. This happens through the application of a combination of a shared language and speech, body language, and actions which can supplement each other. Social interaction in itself cannot store information, and thus the storing of the exchanged information through social interaction is dependant on the individuals' or the group's capability to "store" across time and place.

Technical media are technologies, especially information and communication technologies, which support the exchange of information in the whole or in parts of the communication process. These can, for example, be telephones, databases, electronic documents, or e-mails. Technologies can "transport" communicated information between the involved parties and simultaneously support the storage of data (Thompson & Walsham, 2001). Technology thereby provides the possibility of making information available across time and space. Technology can also contribute to changes in the format or structure of information in the form of categorisation of documents, composition of document indices, or conversion of analogue sound to a data file. This improves the communication in relation to a situation where technology is not applied.

Technical media are suitable for the communication of codified information (Thompson & Walsham, 2001) as most technical media are based on verbal and textual communication. Some technologies, such as video, can also reproduce information expressed through body language and action. Technical media are suitable for well structured, well defined, and formalised information such as technical specifications or measurement results. Technical media primarily support the communication of information related to explicit knowledge, and they can only indirectly, and to a limited extent, support communication of information related to tacit knowledge (Thompson & Walsham, 2001). Different strategies are used to access that information depending on the type of

Figure 3. An integrated model of knowledge, learning, communication and participation in action



knowledge and the background of those who use the medium (Smolik, Kremer, & Kolbe, 2005).

An Initial Theoretical Model for Knowledge Sharing

In summary, in this section we have presented our understanding of knowledge, learning, communication, and participation in action as constituting knowledge sharing via different types of media. In Figure 3 we have integrated these concepts as a step towards a unified model of knowledge sharing.

In the model, learning occurs through scholastic or practice learning, and the learning process is the process which determines how individuals and groups acquire different types of knowledge through the communication of information and participation in practice. The model thus shows how knowledge, organisational memory, and learning are related, and how they influence each other as prerequisites for knowledge sharing. We will use the framework to analyse the relationship between ways of learning and types of knowledge as prerequisites for knowledge sharing in our case organisation, and take it up again later and discuss it in relation to our findings, which resulted in a refinement of the theoretical framework.

We use this model to discuss our empirical findings. In the next section we present the research approach and setting of our empirical study of knowledge sharing in software development as a prelude to the presentation of the findings in the *KNOWLEDGE SHARING IN THE CASE ORGANISATION* section.

RESEARCH APPROACH AND SETTING

The ontological and epistemological assumptions of our work are informed by the interpretive paradigm. The objective of our research was to study and understand the organisational members' knowledge sharing processes within their work and organisational context. In line with Andersen (1999), we chose a case study approach in order to study the process of knowledge sharing in its organisational context. To ensure the validity of our work we largely followed Klein and Myers's (1999) seven principles for interpretive field research and Eisenhardt's (1989) seven steps for case study research.

Given the resources available to our study, we concentrated on a single case study of knowledge sharing in a large Danish IT company. This approach might be criticised for only generating a local empirical theory which might not be generalisable, but as argued by Hughes and Jones (2003), it contributes to the existing body of knowledge by providing a detailed account of empirical findings. By limiting the study to a single organisation, we were able to examine the case in more detail to understand more thoroughly the interrelationships of separate data, which was our research objective.

The research setting was a Danish subsidiary of a global provider of telecommunication systems. At the time of the study (in 2002), the Danish subsidiary was 23 years old and it had been acquired by the American parent company 6 years earlier. The company's customers are fixed network, mobile network and cable operators who reside in more than 80 countries.

The Danish subsidiary concentrates on the development of new products. The company's products consist of hardware and embedded software which provide the product functionality and management software to access, calibrate, and monitor the products' functions. This is mirrored in the organisation of the company's research and development (R&D) department, which consists of three divisions (access, calibration, and monitoring) which perform the detailed specification and actual development tasks. In addition, the company has a product management department; a product planning and specification department; and a finance department. The company has 420

employees of whom 180 are directly involved in product development.

In agreement with company management and also because of resource restrictions, we agreed to focus our investigation of the knowledge sharing process on one organisational unit—the division of embedded software. The embedded software division consists of some administrative staff, a manager, three project leaders, two team leaders, and 27 staff members. With its position between different departments and divisions, embedded software appeared to be most appropriate and representative for our purpose in light of the resources available for the investigation.

The company was interested in participating in our research study due to increased competition in the market, they had decided to focus on employees' knowledge, learning, and communication both within and across the organisational units with the aim of increasing productivity and quality in the product development process.

The product development process is organised in programmes consisting of projects. The company has about three large and 5-10 minor programmes running at any one time, consisting of multiple projects of varying length from 6 months to 2 years. The projects are typically carried out in and by the different divisions. The company's development process can be characterised as product-oriented, sequential, and document focused. The process consists of an analysis and design phase, a development phase, a test phase, and a product installation and introduction phase.

A planning team consisting of experienced employees from different departments is responsible for the overall definition of a programme. A so-called core group of project leaders and technical experts performs a feasibility study and produces product and document reviews at the end of each development phase. Finally, a core team which consists of the project leaders of the different divisions in R&D is responsible for conducting and completing the actual projects and products. The development work is performed by the individual divisions and their developers and is coordinated by the project leaders in and across the three divisions and beyond.

The developers in the division were our primary unit of investigation. Within the category individuals and groups within the division under investigation, we differentiated between developers in the division, developers who worked on the same tasks, developers who shared a two-staff office, project groups, subproject groups, informal groups, and experience (exchange) groups. Individuals and groups related to other units were roughly distinguished into individuals in other divisions and departments affiliated with the same project or product, other departments and divisions in the Danish subsidiary, or individuals and groups in other countries.

We collected data through 13 semi-structured interviews with eight developers, our primary group of interest, and one project leader in the unit under investigation. We also interviewed four employees from other divisions and departments. We also performed one group interview with management personnel and two one-workday-long observations where we followed a member of management and a developer. Finally, we have included secondary material in the form of the different kinds of documents used in the organisation.

All interviews were taped, and a summary listing relevant issues from each interview was written. During and after the interviews we produced rich pictures inspired by the Soft Systems Methodology (Checkland & Scholes, 1990) to depict our understanding of the situation with regard to knowledge sharing in the organisation. These rich pictures constructed the basis for the data analysis and were so useful that we only had to return to the tape recording for further consultation in one case.

To analyse the data we used a combination of common sense interpretation, inspired by the Soft Systems Methodology, and theoretical interpretation which related the data to our theoretical

framework (Andersen, 1999). For all interviews and observations we identified and coded sensible units of expressions. These statements were then linked to one or more categories which we deduced from our theoretical framework, and by comparing all statements within each category and across categories, a number of recurring subjects emerged, and over 100 issues critical for knowledge sharing in the case organisation were identified. The three main categories, which will also be used in the subsequent in-depth description, were (1) knowledge sharing through social interaction, (2) knowledge sharing through technical media, and (3) (the) different kinds of knowledge (which are) shared.

This allowed for an in-depth understanding and discussion of knowledge sharing in the case organisation, revealing what kind of interaction and which media provide possibilities for sharing different kinds of knowledge. It also revealed what impact the identified issues had on the sharing of knowledge, and it ultimately led to a refinement of our theoretical framework.

KNOWLEDGE SHARING IN THE CASE ORGANISATION

We explore the case study to identify how the software developers draw upon organisational memory to share knowledge. As part of our research question, we investigate how knowledge sharing in software development unfolds in social interaction and via technical media. Our findings provide some interesting insights on these matters and present a more detailed account of the kinds of knowledge which are shared. Another interesting finding concerns how and when the developers rely on formal or informal contacts in the knowledge sharing process. Finally, the findings show a difference in the unfolding of the knowledge sharing process according to individual or group action.

When we refer to knowledge sharing as unfolding through social interaction, we relate to the subjects' knowledge sharing through formal interaction in formal meetings, informal interaction in informal meetings; seminars and courses; presentations; exchange of experience groups; personal networks; and in the offices shared by two or more people.

When we refer to knowledge sharing as unfolding through technical media, we cover the subjects' knowledge sharing by the use of the organisation's document handling system (DHS), the file server, the error reporting system, the version control system, the project management system, e-mail, electronic discussion groups, Internet, intranet, video, whiteboards, paper documents, and literature.

When we refer to kinds of knowledge, we cover the subjects' shared knowledge of technical specifications (particularly requirement specifications and design documents); general project information and technical standards; information about who knows what about previous projects or old products; and information about technical problems and improvement of products.

We then provide a more detailed analysis of how knowledge sharing unfolded between individuals and in and between groups, and what kinds of knowledge are shared. We identify critical issues related to each of the categories and provide some suggestions regarding how some of these issues can be solved. As limitations of space preclude a full description of our analysis, we have chosen two subjects from each of the categories to illustrate our findings.

Knowledge Sharing through Social Interaction: Formal Meetings and Personal Networks

Social interaction in the case study took place through formal meetings and personal networks which are now discussed.

Formal Meetings

The members of the case study organisation participate in various formal meetings dealing with the communication of the status of projects and problems through verbal and textual communication. These formal meetings provide the opportunity for the acquisition of explicit individual and group knowledge. Explicit individual knowledge is shared in the form of coordination, communication of status, and discussions of tasks. Explicit group knowledge is shared in the form of (communication of) management attitudes and opinions; definition of rules; and (communication of) stories about good and bad projects. The formal meetings are also used as "pathfinders" to those developers who hold individual knowledge about, for example, concepts and rules, or who have specific skills. In this way the formal meetings provide the individuals with the possibility of obtaining knowledge about where they can obtain further knowledge. Active participation in formal meetings also provides the opportunity for acquisition of knowledge about the genres which are related to formal meetings and the acquisition of individual skills about how meetings are run.

The following issues were identified in relation to the formal meetings:

- **The information communicated through project meetings is arbitrary.** This shows that the developers are not sure that the information they need, or which would be helpful to them, is communicated through meetings. It contributes to the project meetings having less value for the developers, and it indicates that the developers are not sure about the genres which are related to formal meetings, or that they lack skills to utilise formal meetings. The study does not provide any evidence that the developers are trained to use formal meetings. The developers therefore communicate to a higher degree through informal meetings which are "held" as the need for particular information arises, or through personal networks. Information about the same subject is thus communicated through many different forms of social interaction and through different technical media. This in itself does not have to be a problem as a certain amount of redundancy increases the chance that everyone will receive the desired or necessary information, but it is problematic when it confuses the developers.
- **There are no project meetings between divisions, and coordination across divisions rarely happens in formal meetings.** These issues indicate that communication between the divisions is generally poor, and that it is limited to taking place through the project leaders' personal networks. This reinforces the organisational divide between the developers in the different divisions and creates a barrier which does not support communication or insights into other developers' work. The communication and the exchange, which happen across the departments and is necessary for the developers, instead comes about through personal networks or written information. The communication between divisions is much more difficult than within a division because one has to be much more precise, as the developers cannot assume that the receiver of their information has the same background knowledge.

Personal Networks

Personal networks are personal relationships between the developers. These are used to communicate information and to instruct each other. Communication of information through personal networks is verbal and textual and provides the opportunity for scholastic learning of explicit knowledge. This is true for both individual and explicit group knowledge because personal networks are directed towards communication of concrete

problems, discussions of different possibilities for solutions, and informal education of the individual developer. This knowledge takes the form of concepts and rules related to projects, products, and other technical matters which the developers need for the performance of their work. Good and bad experiences are communicated for this purpose, and phrases are used which are defined by the groups in the organisation. This happens, for example, through informal meetings, which are the links for, and which make the networks visible. The developers communicate information through informal meetings, and at the same time they can identify other developers' personal networks and thereby build and extend their own personal networks.

The developers become actively involved and participate in each others' practice through personal networks, and in so doing they have the opportunity to acquire the genres which are related to personal networks. In addition, the networks give the developers the opportunity to acquire skills in how personal networks can be used, and skills related to the topics which are communicated. This happens, for example, through the two-staff offices, which facilitate the developers' participation in the same practice. It is common practice in the company that an experienced developer shares an office with a less experienced developer to help him or her to achieve skills and learn genres. This includes helping the less experienced ones by pointing them in the right direction when it comes to searching for information. This occurs in communication about how things work, and where what information can be found, as well as in the form of stories and rules related to work in the divisions.

The following issues were identified in relation to personal networks:

- **The poorer the formal meetings and the technical specifications, the more the developers use their personal networks.** This shows that personal networks are pivotal for communication in the division because many other forms of social interaction and technical media are not adequate and detailed enough for the developers to communicate all the desired or necessary information.
- **The developers gain a "feel" through the personal network for what is important and whom they should go to in order to prioritise resources and tasks.** These issues show the importance of the personal networks; they bind other forms of social interaction and technical media together, and they satisfy the need for communication which is not covered through other social interactions and technical media.
- **Developers depend on personal networks, which are strongest within the division, but more experienced developers have networks which span divisions.** This issue shows that the developers are dependant on their personal networks to be able to perform the work for which they need information from previous projects. This dependency on the personal networks and on the most experienced developers can be problematic when the developers, who have comprehensive knowledge of previous projects and old products, leave the organisation and take their knowledge with them.
- **Personal networks save time**. This shows that personal networks are faster to use than searching in documents. The developers can find what they are looking for faster through their personal networks than through other forms of social interaction or technical media.
- **A good personal network takes time to build.** These issues show that personal networks are created through the developers' daily work, and that a good network takes many years to build up. This is because the developers work on the same projects and

with the same colleagues over a long period of time. This contributes to those developers who have broad and comprehensive networks having a lot of information at their disposal, while others with lesser networks have less information. This indicates that not all developers have comprehensive personal networks, which results in less communication of information and less opportunity for the acquisition of new knowledge for these developers.

Some Conclusions on Knowledge Sharing through Social Interaction

The analysis of the examples of social interaction shows that social interaction through verbal and textual communication provides the possibility for scholastic learning of explicit knowledge. Beyond this, the active participation in action in the form of social interaction provides the opportunity to acquire those genres which are related to social interaction and the acquisition of the individual skills for how social interaction can be applied, and the skills related to the topics and themes which are communicated. The investigation shows that the individuals and groups in the investigated division communicate through social interaction, and social interaction thus provides the opportunity to share knowledge in the division.

This finding is interesting, as the analysis also shows that social interaction is not facilitated in a structured way, and that formal forms of social interaction in general are not prioritised. This creates problems, as the developers are uncertain about which information is communicated through which type of social interaction, and the findings show that this results in a high degree of arbitrariness with respect to which information is communicated through which form of social interaction, for example, in courses, presentations, experience groups, or personal networks.

Knowledge Sharing Through Technical Media: The Document Handling System and the File Server

In our case study company, documents used to share knowledge are stored on two kinds of technical media: the DHS and the file server.

The Document Handling System

The DHS provides the opportunity for textual communication. By far the largest part of all technical specifications, analysis documents, and project-related documents is stored in the DHS. This comprises feature plans, functional and object models, and iteration plans, but also how-to documents, technical standards, and presentations. The documents are used by the individual developers in their work as they describe what and how something should be or has been done. The documents are also directed towards groups as they provide the framework and the scope for the groups' collective work. The verbal and textual communication through the DHS offers the opportunity for individuals and groups to acquire explicit knowledge.

Active participation in the form of interaction with and use of the DHS provides the possibility for the developers to gain skills in use of the system to acquire the genres related to it. This comprises which documents are stored in the system, how the documents are structured and categorised, how search functions are applied, and how keywords and indices are linked to documents.

- **Not all documents are stored in the DHS, and as a consequence not all necessary documents are accessible to all developers.** This issue is related to the fact that the DHS is regarded as being for documents which are directly related to projects or the product development process. Other documents

which do not comprise formal or project-defining information, such as descriptions of "private" ideas for solutions, experience or general descriptions of problems, are often stored on other media, among others the file server. Only what the individual developer thinks has to be version-controlled is stored in the DHS. The developers have to search for information in many places and to supplement information from the DHS with information from, for example, the file server or their personal networks. This indicates that developers need to have a good overview of the information and have to make an extra effort to gather the quantity and the quality of information they need for their work.

- **The DHS is slow and hard to use, the search functions are poor, and distribution lists are not used to the necessary degree; it is difficult to find the right documents; there is a lack of abbreviations and designations, and the information structure in the system is strictly hierarchical.** These issues indicate that the actual functionality and the information structure in the DHS hinder the developers' use of the DHS and the communication of information. This limits the developers' chances of sighting all documents and finding all relevant information for a particular task. The strict information structure does not mirror the individuals' and the groups' problem-oriented way of working. Communication of information in the DHS is based on the partition between projects and divisions instead of being based on the structure of the working processes, problems, and solutions.
- **Not all departments are equally engaged in using the system.** This issue reinforces and even increases the problems related to the developers' limited possibilities of accessing all documents and finding all relevant information for a particular task. Although the DHS is the official place for storing and distributing documents, some departments use other technical media, for example databases for technical specifications.
- **Many developers use the system only to the extent to which it has an impact on their communication with other divisions, or when demanded as part of the formal work process.** This indicates that some divisions provide their documents to developers in other divisions only to a very limited extent, and that the division only has an insight into other divisions' documents to a limited extent. The lack of insight into each others' work makes the communication of information across divisions difficult and hinders the sharing and exploitation of explicit knowledge. In the case where the use of the DHS is bypassed to the advantage of other technical media, this also has an influence on the acquisition of tacit knowledge related to the use of the DHS, especially the individual skills related to using the DHS for the storage of technical specifications. This is also true of the acquisition of genres related to the DHS. Information about genres is communicated though the documents in the DHS. When the same information is communicated through different forms of social interaction and technical media, meaning that different genres are used for the same themes, this can lead to a situation where the same information gains different meanings.

The File Server

The file server is primarily used for informal documents such as technical notes, proposals for technical designs, intermediate and temporary versions of documents, standards, product de-

scriptions, third party documents, and so forth, which are not directly or ultimately related to the projects or the product development process. Apart from these documents the file server also contains binary files in the form of programs and video recordings. This shows that the file server is used for textual and verbal—in the form of video recordings—communication, which provides the opportunity for acquisition of explicit knowledge related to the information that is stored on the server. Interaction with and use of the file server provides the opportunity for the developers to acquire skills in the use of the file server and genres related to it. These are implicitly determined by the developers and deal, for example, with which documents and files are to be stored on the server; how they are and should be structured; and which search functions can and should be applied.

The following issues were identified in relation to the file server:

- **The file server is used to store files which should be stored in the DHS.** This problem is related to the fact that the DHS is regarded as being for documents which are directly linked to the projects or to the product development process. Nevertheless, some older documents have not been transferred to the DHS and are stored on the server. This includes, for example, own ideas and experiences; technical notes; proposals for technical designs; designs; intermediate and temporary versions of documents; standards; product descriptions; third party documents; and so forth, which are not directly or ultimately related to the projects or the product under development. This indicates that information which relates to the same subject is stored and communicated through different technical media: for example, own experience and proposals for technical designs are stored on the file server, while technical specifications related to the same product are stored in and communicated through the DHS. This results in a situation where the developers have to gather information from different places, depending on whether the information is categorised as formal or informal, or whether the information relates to newer or older products. This means that the developers must have a good overview of the information and extra time to gather the necessary quantity and quality of information. As information has an impact on the learning process and ultimately the acquisition of knowledge, the use of the file server hinders the sharing of explicit knowledge, as it functions as a ragbag and as it provides the opportunity to store information in places other than the DHS.
- **The developers' and the divisions' use of the file server is very different.** Some developers never use it; others use it often or store and find much useful information there. The divisions also structure files differently on the server, and this is an obstacle to the sharing of knowledge. The different use of the file server makes the communication of information through this technical medium look arbitrary and dependant on individuals. The different use of the file server holds the risk that the developers do not communicate the same information, and thus that the information accessible to the other developers becomes different. There is a risk that those developers who do not use or do not have knowledge of the information on the file server do not acquire knowledge of the same concepts or stories. This then decreases their later capabilities to act. The developers' different uses of the file server lead to differences in the extent to which the developers acquire skills related to the file server and knowledge of the file server as a genre. This includes skills related to

the use of the file server to store and work with technical standards or the handling of video recordings or other binary files on the server. It also includes the genres related to the file server, for example the form in which information in a technical standard is communicated through the medium.

- **It is difficult to find information on the file server; the developers have to know where the information is stored to find it.** The problem with access to information on the file server is emphasised by this issue. This is due to the fact that the file server has limited search functions which only cover searching based on file names, and that the directory structures and naming are very "anarchistic." This means that the developers have to have considerable knowledge of the file server and its contents to be able to search for information there. Information about the file server is communicated through personal networks, but the personal networks take a long time to build up and seldom cross division boundaries. It is thus difficult for new employees and developers in other divisions to find relevant information on the server.

Some Conclusions on Knowledge Sharing Through Technical Media

All these issues deal with access to information. As information is the basis of the developers' acquisition of knowledge, access to and gathering of information are necessary for the acquisition and sharing of knowledge. The analysis shows that the issues identified in relation to the developers' use of technical media to communicate have a negative influence on the sharing of knowledge between individuals and groups in the company division which was investigated.

Sharing Different Kinds of Knowledge: Technical Specifications and Information about "Who Knows What"

Finally, we shift focus from communication of information and participation in action through social interaction or technical media and emphasise what kinds of knowledge are actually shared, and we concentrate here on technical specifications and on information about "who knows what."

Technical Specifications

Technical specifications comprise feature plans; device transport and management specifications; overview and detailed function and object specifications; and hardware specifications. They are the basis for the acquisition of explicit knowledge, and the developers actually use specific technical specifications for product development. The technical specifications are directed towards the individual developer's work and at the same time define the rules and phrases for the collective, joint, and shared development work. They thereby form the basis for the sharing of explicit knowledge between individuals as well as groups.

The developers, who have been in the division for a long time, can understand and use technical specifications better than others. This indicates that through their daily work, the developers acquire skills and genres in utilising technical specifications. Active participation in action provides the opportunity for the acquisition of tacit knowledge. This means that the developers' use of technical specifications contributes to their skills in utilising technical specifications. Their skills related to the topics that the technical specifications deal with, and provide possibilites to the acquisition of genres that are related to technical specifications.

However, not all developers understand the documents equally well. When they do not under-

stand the documents they contact the developers who originally produced the documents and ask them what they were trying to describe and express. This shows that the developers need certain skills and knowledge of the applied genres to be able to use the information which is provided in the technical specification.

The following issues were identified in relation to the use of technical specifications:

- **The developers find it difficult to gain an overview of what has been agreed on, and which of the changes in the specifications have been carried out; changes are sometimes carried out before they are agreed upon and approved; not all changes are documented and reviewed.** These problems show that communication about changes or updates to specifications and documentation is sometimes difficult or defective. Acquisition of knowledge is based on the information which the receiver obtains. Access to and exchange of information is thus necessary for the acquisition of knowledge. The developers' different and nonupdated information basis therefore has an impact on the explicit knowledge they acquire, and ultimately on their possibilities of action.
- **The change management tool is not used to receive information on updated technical specifications; the document handling system is sometimes bypassed and e-mail is used instead.** These issues show that the communication of these documents and information on updated technical specifications takes place through many "routes" and different technical media. This indicates that the developers are not secure in and certain about the genres which are connected to these technical media, for example, the specifications are communicated through the DHS, but updates to these documents are communicated through the error reporting system, while both types of information should be communicated through the DHS.
- **Sometimes feature plans are not finished when a project starts, which results in guessing and rough estimates; there is no possibility of tracing all features through the whole product development process including the final test of the product.** These issues indicate that the quality of the information which the developers use in their work is insufficient. As noted earlier, access to and exchange of information is necessary for the acquisition of knowledge, and when information is not available, acquisition of knowledge is impeded or hindered.
- **The hardware specifications are difficult for the developers in the division to understand.** The hardware division uses different standards and a different version of the control system; hardware specifications are formulated in a 'slangy' way and are not written in pedagogical form; the schedule seldom leaves the developers an opportunity to dig deeply into the hardware specifications.

These issues also indicate that insufficient information, and information which is difficult to understand, as well as lack of time, hinder the sharing of explicit knowledge and the developers' possibilities of action.

Information on "Who Knows What"

Information on "who knows what" includes information about which employees and colleagues have which skills, and knowledge about projects, products, and technologies. As this information is directed towards the individual developer's seeking of information and simultaneously defines rules for who the developer should turn to, this information is the basis for explicit individual and group knowledge.

Active participation in action provides the possibility of acquisition of tacit knowledge. This means that the developers' utilisation of personalised knowledge contributes to the skills in utilising these skills and in skills to actually find the colleagues in question, and to the acquisition of the genres which are related to the skills and to these people. The study shows that the developers use a lot of time finding out who knows what, and that they do not always succeed. The developers find that knowledge about who knows what comes with time, when they become familiar with other developers.

The following issues were identified in relation to knowledge about "who knows what":

- **Many developers lack insight into who has what information and skills; the developers often only know the skills of those they work or have worked with in projects.** These issues show that many developers have limited knowledge of their associates. However, for development of the technical skills it is important to know whom to ask in the organisation, while formal education is less important. The lack of knowledge of colleagues can thus have a negative impact on the access to and communication of information, and ultimately on knowledge sharing, as the developers do not have an overview of what information can be found where, and this is even more problematic given that it is most important to know who to ask as part of the development of the skills which the developers require to perform their tasks.
- **The project leaders know who has knowledge; the division's "catalogue of competences" has become too voluminous to be updated; it is difficult to find information about who works in which project.** These issues show that the project leaders are prominent as those who know who has what knowledge. The overview over who has what information and which skills, and therefore the access to other people's information and capabilities, depends on a relatively small number of people. The division's catalogue of expertise is no longer updated, and therefore is of very limited help in this respect. The developers instead use their personal networks to obtain this information. The difficulties in localising information and skills of other developers are reinforced through the fact that the developers have difficulty finding overviews of who works in which project.
- **The developers do not know what other developers and colleagues need to know.** At the same time as they do not find desired or necessary information, the developers do not know what others need to know. This hinders the distribution of information to developers who might benefit from it.

Some Conclusions on Sharing of Different Kinds of Knowledge

In summary, the analysis of technical specifications and information about "who knows what" as exemplars of different kinds of knowledge shows that the identified issues can be detrimental to the sharing of knowledge in the case organisation, as this knowledge is difficult to find, and in part also hard to understand. The developers instead use their personal networks to acquire the knowledge they need. However, as personal networks take time to build, this solution works best for those employees who have been with the company for long time.

DISCUSSION

The study has shown that the integrated model can explain the relationship between the communication of information, participation in action, the learning process, and knowing the different

types of knowledge. It thus presents an appropriate basis for a detailed understanding of knowledge sharing. The empirical data provide examples of how different forms of knowledge are shared in social interaction and by using different media.

Our study shows that when there are problems with the communication of information such as missing information, poor access to information, or poor quality of information, this determines the extent to which explicit knowledge can be acquired. Similarly, if active participation and learning in practice are hampered or function poorly, this determines the extent to which tacit knowledge can be acquired.

Our work is based on the assumption that a number of different dimensions and perspectives have to be taken into account in order to create a comprehensive understanding of the knowledge sharing process.

Other authors such as Cook and Brown (1999); Comas and Sieber (2001); Kolb (1984); and Nielsen and Kvale (1999) only deal with the relationship between two dimensions such as communication of information and knowledge, or knowledge and learning, or they consider and describe the dimensions as different perspectives on knowledge sharing. We take all these different dimensions and perspectives into account.

Cook and Brown (1999) identify types of knowledge and knowing which can exist in an organisation and the relationship between them. They consider knowing primarily as productive inquiry. They do neither relate them to the concept of learning or to the importance of communication of information. Comas and Sieber (2001) discuss managing knowing by describing the relationship between experiential learning and knowing. They argue that managing knowing can be described as an experiential process, and they thus emphasis knowing primarily as a learning process. They do not, however, draw on the importance of what precedes this process, namely communication of information, and the actual situation in which learning takes place. Kolb's (1984) learning cycle also concentrates primarily on the learning process with a focus on individual learning which ignores the group dimension of learning and knowledge. Kolb also emphasises how information is gathered and processed in the learning process, but does not deal with what happens before in the form of communication of information. He thus ignores the problems which can arise when obtaining information.

Nielsen and Kvale (1999) identify scholastic learning and practice learning as well as the explicit knowledge and tacit knowledge to which these ways of learning contribute, but they do not clearly deal with the individual and group dimensions of knowledge and learning. We take all these issues into account.

Finally, our understanding of communication is distinct from the original models (Fiske, 1990) by being explicitly directed towards our focus on knowledge and learning processes, and by viewing communication not as a technical, decontextualised process, but as a social process which takes place in a context. We thus emphasise the concepts of social interaction and technical media instead of the technical term *channel,* and we do not use the terms *sender* and *receiver,* but stress the concepts *individual* and *group* in relation to communication.

In summary, our theoretical framework thus contributes to research within the field of knowledge sharing by integrating different areas related to knowledge sharing.

The theoretical framework does however not clearly show how communication in the form of verbal and textual communication and active participation in practice contribute to the acquisition of knowledge through scholastic and practice learning. Kolb's (1984) learning cycle can contribute to many types of knowledge. His learning cycle and the different types of knowledge focus on the individual's learning and the related cognitive process which, Kolb argues, can be dominated by a particular way of learning and type of knowledge. How far multiple learn-

ing cycles can take place simultaneously in the same situation is not evident from Kolb's theory. Comas and Sieber (2001) describe the relationship between experience or experiential learning and knowing, but they do not take a position on either, whether or if so, how many learning cycles take place at one time. Cook and Brown (1999), however, argue with respect to the relationship between tacit and explicit knowledge that these are separate types of knowledge, but that one is or can be used as support to acquire the other. We now provide examples from our study and discuss how different types of knowledge contribute to the acquisition of other types of knowledge, how this can be conceptualised as multiple learning cycles, and the consequences this has for our framework.

The Relationship Between Individual and Group Knowledge

A number of developers in our study explained that they discussed technical problems and solutions with other developers using, for example, personal networks and experience groups. We found that the developers had a shared repertoire of phrases for particular types of technical specifications. This indicates that the developers' individual explicit knowledge about, for example, how technological solutions are specified contributes to the group's use of phrases concerning technical specifications, and thus to explicit group knowledge, about specific types of technical specifications.

We also found that the developers primarily store formal documents, that is, documents which are a defined part of the development process or which are somehow related to projects and products, in the DHS. These documents are placed in a strict hierarchical structure which is ordered according to departments, products, and/or projects. This indicates that the developers' skills—tacit individual knowledge of skills and "feel" for which documents should be stored in the DHS, and where—contributes to the genre, tacit group knowledge with respect to which documents are communicated through the system and how they are communicated.

The study also showed that new developers are trained in use of the system through courses and apprenticeship learning. This indicates that the genre tacit group knowledge related to the DHS contributes to the development of the individual developer's skills in relation to the use of these genres. Figure 4 depicts these relationships.

The Relationship Between Explicit and Tacit Knowledge

The relationship between explicit and tacit knowledge is depicted in Figure 5. A number of the

Figure 4. The relationship between individual and group knowledge

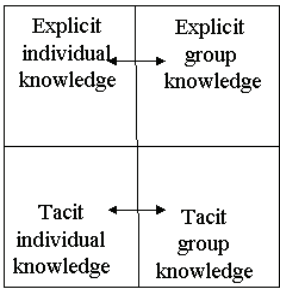


Figure 5. The relationship between explicit and tacit knowledge

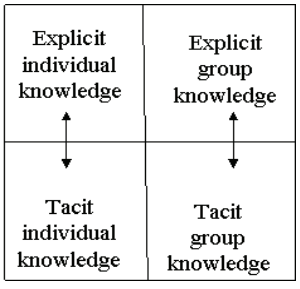


developers said that on the basis of books, presentations, and courses they use their understanding of concepts and interrelations to experiment in practice and thereby acquire new skills. This indicates that the individual developers apply explicit knowledge in practice—practice learning which contributes to the acquisition of tacit knowledge in the form of skills. The study also shows that developers who are experts in a particular field tell other developers about how a specific task should be carried out. This can happen through presentations, experience groups, and personal networks, thereby giving other developers the opportunity to gain explicit knowledge about the action related to solving the task in question. This indicates that the developers reflect upon their tacit knowledge and explicate related actions and activities, which they communicate to other developers through scholastic learning.

The study also shows that the project management system which was previously used to plan projects is now only used for general project planning and time registration. According to the respondents it ought to be possible to extract estimates for new projects directly from the system, but because the projects are dissimilar, these estimates are hard to use. We also found that some developers had ceased to register time in the system. This indicates that stories—explicit group knowledge—about the deficiencies of the project management system make the developers interpret the information which is communicated through the system in an unfavourable way. They have thus developed a concept of the system which has become tacit group knowledge. The study also shows that the developers reflect over their use of the document handling system as a form of communication in the company which only functions poorly. This contributes to stories among the developers about how their work is made cumbersome by the system, and that necessary documents are hard to find. This shows that the groups reflect on their tacit knowledge and explicate actions related to this knowledge which contribute to the acquisition of stories and phrases in the groups related to the use of genres.

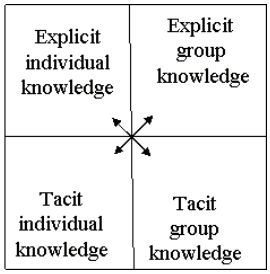
The Relationships between Tacit Individual and Explicit Group Knowledge and Explicit Individual and Tacit Group Knowledge

The relationships between tacit individual and explicit group knowledge and explicit individual and tacit group knowledge are depicted in Figure 6.

We observed how one developer, through use of his skills, developed a browser tool which other developers found useful. It became part of the development toolbox and contributed to the stories and phrases which the members of this group of developers told about useful tools. This shows that developers, through their skills and thus their individual tacit knowledge and its explication in related actions, contribute to the group's stories and phrases, and thus their explicit group knowledge.

The study also provided examples of how success stories about how to solve a specific task were sometimes transformed into how-to documents, for example how to program in C, which other developers could use to acquire new skills. This indicates that a group's stories enter into

Figure 6. The relationships between tacit individual and explicit group knowledge and explicit individual and tacit group knowledge



individual practice learning which contributes to the development of the individual group member's skills, in this case C programming.

Our findings show that the developers' understanding of the importance of standards for the development work makes them perceive what is communicated as a standard as being specifically important. This indicates that concepts or rules related to the use of a particular form of communication contribute to the development of genres. The study also shows that when developers observe others communicating, they gain knowledge about how, for example, one conducts a presentation or a formal meeting. This indicates that the developer's acquaintance and application of genres contributes to the developers' individual understandings of the concepts, rules, and interrelations which are related to genres.

Knowing as Multiple Learning Cycles

We have shown above how different types of knowledge contribute to the learning of different types of knowledge by drawing from our case study to show how the developers have knowledge which they apply to acquire new knowledge. Figure 7 summarises the relationship between the different types of knowledge and indicates a cyclic connection between them.

The various and different learning situations can also be understood as multiple cycles which can take place simultaneously—in other words, the developers constantly use knowledge to learn in order to create new knowledge. How this relates to the different types of knowledge is shown in Figure 8.

Figure 7. The relationships between different types of knowledge

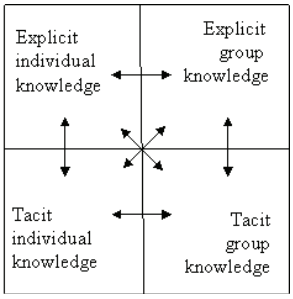


Figure 8. The relationships of different types of knowledge as multiple learning cycles

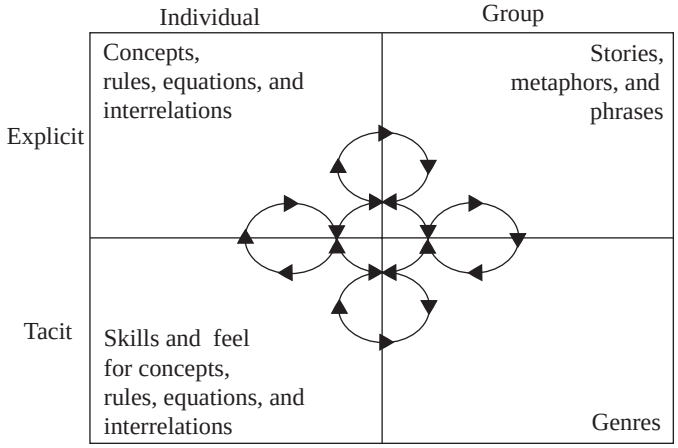
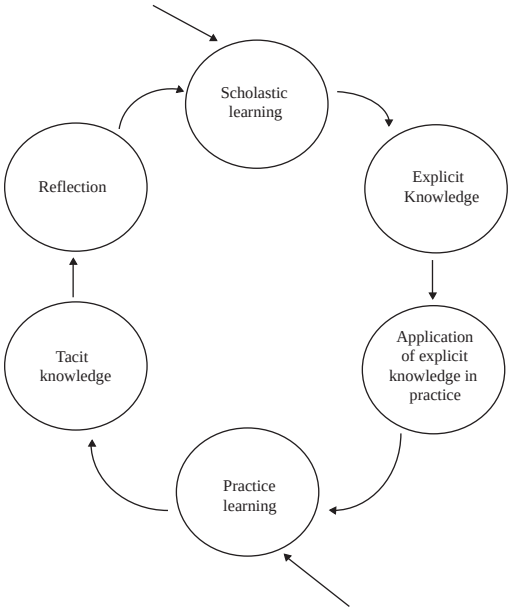


According to Cook and Brown (1999), learning is a process in which an individual or a group processes new information on the basis of existing knowledge which can then be used as a basis for action. The result of the learning process is new knowledge. Following Kolb's (1984) understanding of the learning process and the relationship between different ways of learning and different types of knowledge as expressed in our initial theoretical framework, and relating and comparing these to the relationship of different types of knowledge illustrated as multiple learning cycles and summarised in the preceding paragraph, the following becomes evident:

Tacit knowledge is acquired through practice learning, but when, for example, the developers explain how a task is solved, they reflect upon tacit knowledge. The situation where a developer explains to other developers what he or she has done is scholastic learning. It is not the tacit knowledge itself which becomes explicit through scholastic learning, but the developers acquire new explicit knowledge. This is not the same as being able to solve a particular task. If other developers want to achieve the same tacit knowledge, this can only happen through practice, that is, they themselves must apply the explicit knowledge in practice and participate actively in carrying out the task.

Explicit knowledge can contribute to the acquisition of tacit knowledge through application in practice and through participation in practice learning. At the same time, tacit knowledge contributes to the acquisition of explicit knowledge through reflection and participation in scholastic learning. Tacit knowledge and explicit knowledge thus supplement each other through reflection and application in practice (see Figure 9). This can be understood as a detailed description of knowing as a learning process. Taking scholastic learning as a starting

Figure 9. Learning of explicit and tacit knowledge through scholastic and practice learning



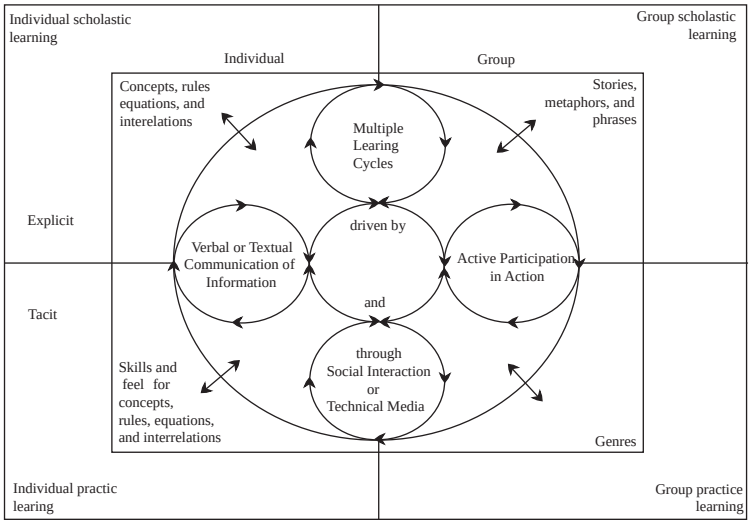
point, explicit knowledge will always precede an eventual acquisition of tacit knowledge. Taking practice learning as a starting point, tacit knowledge will always precede an eventual acquisition of explicit knowledge. It is a question of whether one starts with scholastic or with practice learning.

The Consolidated Model

The overall relationship between participation in action, communication, learning, and knowledge as the starting point for our theoretical framework was illustrated in Figure 3. On the basis of the study, we have brought together and integrated the theoretical framework's models for knowledge, learning, communication and participation in action, and amended them with the evidence for multiple learning cycles explained previously. As a result, the theoretical framework and the study's outcome can be presented in a model of sharing knowledge, where communication consists of verbal and textual communication and active participation in action. Learning comprises learning through scholastic learning, practice learning and multiple learning cycles, and knowledge consists of explicit and tacit individual and explicit and tacit group knowledge.

The model for the sharing of knowledge shows that verbal and textual communication of information through social interaction and/or technical media contribute to individual and group scholastic learning, which thereby contribute to explicit individual and group knowledge. The model also shows that participation in action through social interaction and/or technical media contributes to individual and group practice learning, which thereby contribute to tacit individual and group knowledge. The model for the sharing of knowledge shows in addition how multiple learning cycles and knowing contribute to the acquisition of knowledge.

Figure 10. The consolidated model



CONCLUSIONS AND FUTURE RESEARCH

In the research presented here, we have applied Cook and Brown's (1999) multiple forms of knowledge to an empirical example in software development, emphasising how these forms of knowledge are shared in communication via social interaction or different types of technical media.

Our work resulted in a model of knowledge sharing which can be used to understand and ultimately improve knowledge sharing in practice. Although some concrete advice for improving knowledge sharing could be derived from our analysis, the theoretical framework and our study do not describe how the results of the analysis and identified areas for improvements can be transformed into concrete organisational or technical improvements, or which strategies organisations should use to improve the sharing of knowledge. Furthermore, we do not include concrete guidelines for the design of information technology and technical media.

Problems related to the technical media lead to limited access to and quality of information. The developers in the case organisation thus use or supplement them with social interaction or other technical media which enable them to gain access to the information or actions which are a prerequisite for their learning processes, and the acquisition of knowledge which is necessary for them to carry out their tasks. How an optimal balance between social interaction and technical media might look has to be decided from case to case, and is again not part of our framework, but it could be constructed with the aid of Hansen, Nohria, and Tierney's (1999) work on codification and personalisation strategies. In this context it is necessary for future research to investigate the relationship between the different types of knowledge in more detail in order to clarify how this relationship can be used to improve the sharing of knowledge.

Finally, the study shows that personal networks play a specific role in the sharing of knowledge, as they link other forms of communication together and compensate for the information which is not communicated through these other forms of communication. The framework does not explain all phenomena related to personal networks with regard to knowledge sharing, and future research based on the framework should thus aim to extend the framework in this respect.

ACKNOWLEDGMENT

Chapter 4.21
Digital Library Structure and Software

Cavan McCarthy
Louisiana State University, USA

INTRODUCTION

Digital libraries (DL) can be characterized as the "high end" of the Internet, digital systems which offer significant quantities of organized, selected materials of the type traditionally found in libraries, such as books, journal articles, photographs and similar documents (Schwartz, 2000). They normally offer quality resources based on the collections of well-known institutions, such as major libraries, archives, historical and cultural associations (Love & Feather, 1998). The field of digital libraries is now firmly established as an area of study, with textbooks (Arms, 2000; Chowdhury & Chowdhury, 2003; Lesk, 1997); electronic journals from the US (D-Lib Magazine: http://www.dlib.org/) and the UK (Ariadne: http://www.ariadne.ac.uk/); even encyclopedia articles (McCarthy, 2004).

BACKGROUND

Digital libraries require appropriate presentation and careful logical organization to make them easily accessible, but arrangements typical of Web systems are inadequate for them. The classic Web structure, where random links can be created between any pair of pages, is not appropriate to highly organized data. The other classic arrangement is the tree or directory structure often found in computerized systems, where the user starts from a "trunk" or "root directory" and goes to a branch, then a subdivision of that branch. This is effective for individual images, but is inadequate for navigating sequential pages, as in a digital library system presenting lengthy texts. Before discussing the different software solutions available, it is useful to review the principle types of digital material currently offered by digital libraries.

DIGITAL LIBRARY MATERIALS

At this time digital library resources can be divided into three categories: images, texts and other resources:

Images

Image access is used for individual visual resources, such as photographs, posters, drawings, etc. The classic procedure uses a series of three types of image. Scanning produces a high-quality archive image, which is then used to generate an access image, for general public use. Finally, a small thumbnail image is produced, for quick reference (Boss, 2001; Lee, 2001). In more detail:

Archive Image

A high-quality image, scanned directly from the original, destined for long-term preservation. Normally an uncompressed TIF (Tagged Image File Format) image is used here; TIFs offer the highest quality images and a resolution of 600 dpi (dots per inch) is standard. As scanning is an expensive operation, which exposes original materials to possible damage, the archive image will be carefully preserved. It must always exist at the system level, but is not necessarily available to the end-user. TIF files occupy significant server space and imply lengthy download times. Another factor is that some DL will want to sell their own hard-copy prints of quality images.

Access Image or Working Image

A quality image, adequate for consultation and serious study by digital library users. This is normally a high-quality JPG (Joint Photographic Experts Group) image, generated from the archival TIF. JPG files are widely used on the Internet and offer quality spatial and color reproduction and a high compression ratio. For DL purposes JPG images will often be generated at a resolution of 300 dpi; a size of 640x480 pixels is also common.

Thumbnail Image

A small reference image, which gives the user a general idea of the Access image, before downloading that image. Typically a medium to low quality JPG, generated from the Access image, but about one-tenth of its size, and commonly produced at a resolution of 72 dpi. GIF format (Graphic Interchange Format) can also be used for thumbnails (Arizona, 2000; Western, 2003).

Text

Multi-page text documents, such as books, or journal articles require special procedures. Numerous options are possible and the principle alternatives for input, simple text presentations and pagination will be examined in turn; the earliest procedures will be discussed first.

Text Input

Manual keyboarding was originally adopted by Project Gutenberg, the first significant text-oriented digital library (http://promo.net/pg/), founded in 1971. This is a laborious process which severely limits productivity, and is now rarely used.

OCR (Optical Character Recognition) software is now routinely used to scan text into digital libraries. OmniPage Pro (http://www.scansoft.com/omnipage/) or the Russian software ABBYY (http://www.abbyy.com/) are frequently cited in the digital library context. OCR text requires careful revision, because even 99.99% accuracy means that there will be one mistake every couple of pages, but only a person fully conversant with the literature will be able to identify errors at this level. Many digital library texts are older books whose ornate type faces or soiled pages can generate additional OCR errors.

Simple Text Presentations

"Plain-vanilla" ASCII texts were the original basis of Project Gutenberg (http://promo.net/pg/). These TXT files can be used by a variety of computing platforms, but are suited to a word processing, rather than an Internet environment.

HTML text is now firmly established for textual work in digital libraries, including Project Gutenberg. All Internet users are familiar with HTML, files need not be much larger than TXT files, it is easy to present crisp black text on white background, text size can be quickly adjusted on computer screens, HTML can be indexed, readers can easily take extracts from the text, and, within the constraints of ethics and plagiarism, manipulate them and insert them in other documents.

The entire text, without page divisions, is normally delivered by Project Gutenberg as an ASCII or HTML file. Entire chapters or lengthy blocks of text are supplied by other digital libraries, such as Bartleby.com (http://www.bartleby.com/), another pioneering system, which has been offering free copies of classic books since 1963.

Disadvantages of HTML are that it does not necessarily communicate the original text in an integral manner: the "look and feel" may be different, transcription errors may occur and it may not accurately reproduce a combination of text and images.

Paginated Text

Pagination is typical of the traditional book, and most sophisticated digital library software now creates easily-navigated page-by-page sequences. The reader wants above all to go to the next page, also to go back a page when necessary, using appropriate icons or buttons.

JPG images reproduce individual pages exactly, without scanning or transcription errors, making them suitable for research. JPGs are widely used on the Internet and are easy to generate, download, and print; they are also appropriate for mixed text and images. But small size text, older typefaces and brown, mottled or foxed paper may reduce legibility, while readers cannot easily take extracts from a JPG document.

Adobe Acrobat's PDF (Portable Document File) format offers advantages similar to JPGs, such as quality reproduction of the original in relatively small files, excellent enlargement of the text and easy combination of text with images. Content producers can adjust the security settings within Acrobat to constrain the end user's interaction with the document. The digital library needs to purchase Adobe Acrobat (http://www.adobe.com/products/acrobat/main.html) to create PDFs, but end-users can easily download the free Adobe Reader.

Digital libraries offering access to texts therefore have two principle possibilities, text, typically delivered in HTML, or page images, which typically use JPGs. In fact, these are not alternatives, they are complementary approaches. The image offers a reliable reproduction of the text, while HTML may be easier for the end-user. Intellectual property and copyright issues may also impact the decision to present either HTML text or images. Even if only images are made available to the end-user, it will be necessary to create a text version in order to generate an index. Word-by-word indexing is a major advantage offered by digital libraries, which cannot be matched by traditional libraries.

For examples of sophisticated paginated access, browse the 8,500-volume Making of America collection from the University of Michigan at http://www.hti.umich.edu/cgi/t/text/text-idx?tpl=browse.tpl&c=moa&cc=moa. This uses DLXS software, discussed in more detail below. The Digital Quaker Collection (http://esr.earlham.edu/dqc/) contains full text and page images of over 500 Quaker works from the 17th and 18th centuries, generated using eXist software (see below for details).

The three-level imaging sequence, Archive, Access, and Thumbnail, described in Image ac-

cess above, is of lesser relevance to text systems. It is still possible to use TIF format to produce the Archive copy, because this creates a high quality preservation file in a non-commercial format. But the TIF will rarely be available to the reader in a text-based system. TIF files are slow to download and text, even with images, can be reproduced adequately using JPGs or PDFs. Thumbnail images of a series of book pages will normally appear identical to the reader, thus adding little to the digital library, and are therefore often omitted.

Location within physical books is not a problem; it is easy to see when half the text has been read, or to flip back to the table of contents. In digital books readers need a clear indication of location in relation to the text as a whole, via page numbering or by a link to a table of contents or chapter list. If the text has notes or references, it will be necessary to link to them, then jump back to the main text. It will also be necessary to link to a full bibliographic citation.

Other Resources

Collections of maps and aerial photographs need to offer spatially-oriented access, so that users can pan or zoom. For an example, see the collection of 50,000 old aerial photographs of the State of Georgia, USA, at http://dbs.galib.uga.edu/gaph/html/. Collections of 3-dimensional objects may need to be viewed from various angles. See http://www.lunaimaging.com/insight/featuretour/multiview.html for an example using Luna Imaging software (discussed in more detail below). Sound and moving images are still relatively rare in digital libraries, for examples see History and Politics Out Loud: a searchable archive of politically significant audio materials from NorthWestern University, USA (http://www.hpol.org/) or the Internet Archive at http://www.archive.org/movies/index.html.

Metadata

Digital resources need to be adequately described. Historical photographs, for example, are only useful if location, date, subject, etc., have been identified and input to the system. This additional information is known as metadata and must be added by trained professionals. There are various types of metadata:

- **Descriptive metadata:** creator, title, subject, etc.
- **Structural metadata:** information on the internal organization of the digital resource, such as the chapters in a book.
- **Administrative metadata:** management information, including technical information, such as scanning resolution, hardware and software used, also rights management information and restrictions on use.

Access

Initial access to a digital library is through a gateway, which needs to be attractive and easy to use. Many digital libraries, especially those sponsored by educational institutions, offer free and immediate access to their materials. Commercial digital libraries, such as e-journal and paid e-book collections, embed security procedures, such as IP recognition or password control, into their gateways. Once in the digital library, the user is normally offered a choice between browse and search access.

- **Browse access** or directory-based systems take the user to a menu of choices, such as an alphabetically organized list of authors or titles, a categorized list by subject, geographic location, specific collection, etc. Menus can be nested, subdividing broad subjects. This is the easiest access to orga-

nize (it can even be created manually), and is offered by almost all digital libraries, normally from the opening page.

- **Search access** involves software, which is used to create an index. The user queries the index via a search box, usually a prominent feature of the digital library.

See, for example, The American Memory collections of the Library of Congress, which offer both browse access (via a "Collection Finder") and search access prominently from the opening page (http://www.memory.loc.gov).

Boolean search (AND, OR, NOT) is common in digital libraries. For a sophisticated search of the documents of the Chicago Women's Liberation Union, see http://cwluherstory.master.com/texis/master/search/?q=CWLU&s=SS&cmd=Options. This uses indexing software from Master.com (http://www.master.com/texis/master/app/home.html). A help file will often be available, to familiarize the user with search techniques, which can vary considerably between systems. The State Library of New South Wales offers a good example at http://www.sl.nsw.gov.au/search/guide.cfm. The user will also want to know exactly what is being searched: is it the full text of the document? Or the text of the document, but excluding common words? Or the search may be limited to metadata elements, such as author, title and abstract. This is not always clearly stated. Whatever the parameters, the use of a computer-produced index implies a higher level of automated support than the browse or directory systems cited previously. Search access is therefore not quite as common as directory access.

Efficient retrieval implies both types of access. These are also the principal options for retrieving information from the WWW: browse access is available from directory-based systems such as that which forms the basis of Yahoo! and the Open Directory, while search is offered by search engines, such as Google.

DIGITAL LIBRARY SOFTWARE

It is possible to create small-scale digital collections by hand, using standard HTML editing or open-source software. But, due to the complexity and variety of the field, purpose-designed software is now in common use. In alphabetical order, principle options are:

CONTENTdm Digital Media Management Software Suite

A high-performance storage and retrieval software for multimedia collections which is rapidly gaining acceptance (http://contentdm.com/index.html). Developed at the University of Washington, it is offered to libraries, museums, and nonprofit archives by OCLC, the major supplier of bibliographic data to libraries (http://www.oclc.org/contentdm/default.htm). Collections relevant to regional studies include the Louisiana Digital Library (http://www.lsu.edu/diglib) and Early Las Vegas from the University of Nevada, Las Vegas (http://www.library.unlv.edu/early_las_vegas/index.html).

DLXS

Offered by the University of Michigan Digital Library eXtension Service. It is a comprehensive suite of software tools, especially suited to indexing and presenting multi-page documents (http://www.dlxs.org/). It has already been mentioned as the basis for Michigan's The Making of America collection with approximately 8,500 books and 50,000 journal articles from the antebellum period through reconstruction (http://www.hti.um ich.edu/cgi/t/text/text-idx?tpl=browse.tpl&c=moa&cc=moa). A further 3,000 books are in the Wright American Fiction collection 1851-1875 (http://www.letrs.indiana.edu/web/w/wright2/).

DSpace

A "Durable Digital Depository," designed to capture, distribute and preserve the intellectual output of universities and similar institutions (http://dspace.org/). A joint project of MIT Libraries and the Hewlett-Packard Company, the original DSpace can be searched at https://dspace.mit.edu/index.jsp; full-text is in PDF. An open-source software, DSpace can be freely downloaded from http://sourceforge.net/projects/dspace/ (Atwood, 2002; Carnevale, 2003).

eXist

An open source XML database created in Germany (http://exist.sourceforge.net or http://exist-db.org/). It was used for one of most ambitious digitization projects of recent years, The Proceedings of the Old Bailey, 1674 to 1834 (http://www.oldbaileyonline.org/). This offers access to the largest body of texts detailing the lives of non-elite people ever published, accounts of over 100,000 criminal trials held at London's central criminal court.

Greenstone Digital Library Software

An open source software suite, developed in New Zealand at the University of Waikato (http://www.greenstone.org/). It automatically creates organized collections of digitized documents with a standardized interface, with automatic full-text indexing, listing of titles, etc. (Witten & Bainbridge, 2002). It handles large collections of documents, in a variety of formats, works on a server or desktop, and exports to CD-ROM. It is used for the New Zealand Digital Library (http://www.nzdl.org/), notable for humanitarian and UN collections in a variety of languages and scripts, including Chinese and Arabic. It is distributed free under GNU Public License, and can be downloaded from http://www.greenstone.org/english/download.html. All texts in Project Gutenberg can be searched via Greenstone at http://public.ibiblio.org/gsdl/cgi-bin/library.cgi?a=p&p=about&c=gberg.

Hyperion Digital Media Archive

A tool for organizing, full-text indexing, storing and accessing of non-book holdings in a digital format (http://www.sirsi.com/Sirsiproducts/hyperion.html). It was produced by Sirsi, a Huntsville, Alabama, company which supplies automated cataloging and circulation systems to libraries of all types. An important application is the Civil Rights in Mississippi Digital Archive of resources on race relations, created by the University of Southern Mississippi (http://www.lib.usm.edu/~spcol/crda/).

Insight Image Management and Delivery System

Produced by Luna Imaging, a joint enterprise of the J. Paul Getty Trust, California, and Eastman Kodak (http://www.luna-imaging.com/). This high quality imaging software, notable for its powerful zoom capability, is used for works of art, photographs and maps. An example is the David Rumsey Historical Map Collection (http://www.davidrumsey.com/), which features over 8,000 maps and won a Webby Award in 2002.

Olive ActivePaper Archive Software

Permits historical newspapers to be scanned from the originals, or from microfilm, creating fully searchable digital collections. Readers are able to click on any article, photograph or advertisement, which is then enlarged and presented in a separate window. For a sample, see the Missouri Historical Newspapers Collection (http://newspapers.umsystem.edu/archive/Skins/Missouri/navigator.asp). OCLC, the major supplier of bibliographic data to libraries, offers Olive to libraries (http://www.oclc.org/middleeast/en/olive/about/); Olive

Software is a Denver company (http://www.olivesoftware.com/home.html).

FUTURE TRENDS

The following future developments can be forecast with confidence:

- **More standardization:** the current period is one of experimentation, but standardized solutions will rapidly become established. Cross-system searching and access will be major considerations in the future.
- **More access to audio, film and video:** resources are still thin in this area, but more sophisticated software and increased bandwidth will make much more material available.

CONCLUSION

Digital libraries will have a bright future in a world which is ever more reliant on electronic access to information to guarantee social integration, progress and the end of the digital divide. The increasing availability of special purpose software will facilitate digital library production. Open source software such as Greenstone, which is available free of charge, will be of great value for regional community digitization projects.

KEY TERMS

ASCII: American Standard Code for Information Interchange-Codification system used to convert simple text to computer readable form.

Digital Library: Provides the resources, including the specialized staff, to select, structure, offer intellectual access to, interpret, distribute, preserve the integrity of, and ensure the persistence over time of collections of digital works so that they are readily and economically available for use by a defined community or set of communities (Waters, 1998).

JPEG: Joint Photographic Experts Group-Specification for reproduction of digital images, widely used on the Internet.

Metadata: Data about data,surrogates or descriptions of data, key words or codes used as systematic keys to the content of digital objects, such as Web pages or digital images.

OCR: Optical Character Recognition-Software that recognizes text and converts it to a form in which it can be processed by computer.

PDF: Portable Document Format-Method of document reproduction, generated by Adobe Acrobat Systems, notable for quality reproduction of both text and accompanying images.

TIFF: Tagged Image File Format-High quality image reproduction format, typically generates large files used for archival purposes.

Chapter 4.22
Comparing Four-Selected Data Mining Software

Richard S. Segall
Arkansas State University, USA

Qingyu Zhang
Arkansas State University, USA

INTRODUCTION

This chapter discusses four-selected software for data mining that are not available as free open-source software. The four-selected software for data mining are SAS® Enterprise Miner™, Megaputer PolyAnalyst® 5.0, NeuralWare Predict® and BioDiscovery GeneSight®, each of which was provided by partnerships with our university. These software are described and compared by their existing features, characteristics, and algorithms and also applied to a large database of forest cover types with 63,377 rows and 54 attributes. Background on related literature and software are also presented. Screen shots of each of the four-selected software are presented, as are future directions and conclusions.

BACKGROUND

Historical Background

Han and Kamber (2006), Kleinberg and Tardos (2005), and Fayyad et al. (1996) each provide extensive discussions of available algorithms for data mining.

Algorithms according to StatSoft (2006b) are operations or procedures that will produce a particular outcome with a completely defined set of steps or operations. This is opposed to heuristics that according to StatSoft (2006c) are general recommendations or guides based upon theoretical reasoning or statistical evidence such as "data mining can be a useful tool if used appropriately."

The Data Intelligence Group (1995) defined data mining as the extraction of hidden predictive

information form large databases. According to The Data Intelligence Group (1995), "data mining tools scour databases for hidden patterns, finding predictive information that experts may miss because it lies outside their expectations."

Brooks (1997) describes rules-based tools as opposed to algorithms. Witten and Frank (2005) describe how data mining algorithms work including covering algorithms, instance-based learning, and how to use the WEKA, an open source data mining software that is a machine learning workbench.

Segall (2006) presented a chapter in the previous edition of this Encyclopedia that discussed microarray databases for biotechnology that included a extensive background on microarray databases such as that defined by Schena (2003), who described a microarray as "an ordered array of microscopic elements in a planar substrate that allows the specific binding of genes or gene products." The reader is referred to Segall (2006) for a more complete discussion on microarray databases including a figure on the overview of the microarray construction process.

Piatetsky-Shapiro (2003) discussed the challenges of data mining specific to microarrays, while Grossman et al. (1998) reported about three NSF (National Science Foundation) workshops on mining large massive and distributed data, and Kargupta at al. (2005) discussed the generalities of the opportunities and challenges of data mining.

Segall and Zhang (2004, 2005) presented funded proposals for the premises of proposed research on applications of modern heuristics and data mining techniques in knowledge discovery whose results are presented as in Segall and Zhang (2006a, 2006b) in addition to this chapter.

Software Background

There is a wealth of software today for data mining such as presented in American Association for Artificial Intelligence (AAAI) (2002) and Ducatelle (2006) for teaching data mining, Nisbet (2006) for CRM (Customer Relationship Management) and software review of Deshmukah (1997). StatSoft (2006a) presents screen shots of several softwares that are used for exploratory data analysis (EDA) and various data mining techniques. Proxeon Bioinformatics (2006) manufactures bioinformatics software for proteomics the study of protein and sequence information.

Lazarevic et al. (2006) discussed a software system for spatial data analysis and modeling. Leung (2004) compares microarray data mining software.

National Center for Biotechnology Information (NCBI) (2006) provides tools for data mining including those specifically for each of the following categories of nucleotide sequence analysis, protein sequence analysis and proteomics, genome analysis, and gene expression. Lawrence Livermore National Laboratory (LLNL) (2005) describes their Center for Applied Scientific Computing (CASC) that is developing computational tools and techniques to help automate the exploration and analysis of large scientific data sets.

MAIN THRUST

Algorithms of Four-Selected Software

This chapter specifically discusses four-selected data mining software that were chosen because these software vendors have generously offered their services and software to the authors at academic rates or less for use in both the classroom and in support of the two faculty summer research grants awarded as Segall and Zhang (2004, 2005).

SAS Enterprise Miner™ is a product of SAS Institute Inc. of Cary, NC and is based on the SEMMA approach that is the process of Sampling (S), Exploring (E), Modifying (M), Modeling (M), and Assessing (A) large amounts of data. SAS

Enterprise Miner™ utilizes a workspace with a drop-and-drag of icons approach to constructing data mining models.

SAS Enterprise Miner™ utilizes algorithms for decision trees, regression, neural networks, cluster analysis, and association and sequence analysis.

PolyAnalyst® 5 is a product of Megaputer Intelligence, Inc. of Bloomington, IN and contains sixteen (16) advanced knowledge discovery algorithms as described in Table 1 that was constructed using its User Manual by Megaputer Intelligence Inc. (2004; p. 163, p. 167, p.173, p.177, p. 186, p.196, p.201, p.207, p. 214, p. 221, p.226, p. 231, p. 235, p. 240, p.263, p. 274.).

NeuralWorks Predict® is a product of NeuralWare of Carnegie, PA. This software relies on neural networks, According to NeuralWare (2003, p.1):

"One of the many features that distinguishes Predict® from other empirical modeling and neural computing tools is that is automates much of the painstaking and time-consuming process of selecting and transforming the data needed to build a neural network."

Table 1. Description of data mining algorithms for PolyAnalyst® 5

Data Mining Algorithm	Underlying Algorithms
1. Discriminate	1. (a.) Fuzzy logic for classification 1. 1. (b.) Find Laws, PolyNet Predictor, or Linear Regression
2. Find Dependencies	2. ARNAVAC [See Key Terms]
3. Summary Statistics	3. Common statistical analysis functions
4. Link Analysis (LA)	4. Categorical, textual and Boolean attributes
5. Market and Transactional Basket Analysis	5. PolyAnalyst Market Basket Analysis
6. Classify	6. Same as that for Discriminate
7. Cluster	7. Localization of Anomalies Algorithm
8. Decision Forest (DF)	8. Ensemble of voting decision trees
9. Decision Tree	9. (a.) Information Gain splitting criteria (b.) Shannon information theory and statistical significance tests.
10. Find Laws	10. Symbolic Knowledge Acquisition Technology (SKAT) [See Key Terms]
11. Nearest Neighbor	11. PAY Algorithm
12. PolyNet Predictor	12. PolyNet Predictor Neural Network
13. Stepwise Linear Regression	13. Stepwise Linear Regression
14. Link Terms (LT)	14. Combination of Text Analysis and Link Analysis algorithms
15. Text Analysis (TA)	15.Combination of Text analysis algorithms augmented by statistical techniques
16. Text Categorization (TC)	16. Text Analysis algorithm and multiple subdivision splitting of databases.

NeuralWorks Predict® has a direct interface with Microsoft Excel that allows display and execution of the Predict® commands as a drop-down column within Microsoft Excel.

GeneSight™ is a product of BioDiscovery, Inc. of El Segundo, CA that focuses on cluster analysis using two main techniques of hierarchical and partitioning both of which are discussed in Prakash and Hoff (2002) for data mining of microarray gene expressions.

Both SAS Enterprise Miner™ and PolyAnalyst® 5 offer more algorithms than either GeneSight™ or NeuralWorks Predict®. These two software have algorithms for statistical analysis, neural networks, decision trees, regression analysis, cluster analysis, self-organized maps (SOM), association (e.g. market-basket) and sequence analysis, and link analysis. GeneSight™ offers mainly cluster analysis and NeuralWorks Predict® offers mainly neural network applications using statistical analysis and prediction to support these data mining results. PolyAnalyst® 5 is the only software of these that provides link analysis algorithms for both numerical and text data.

Applications of the Four-Selected Software to Large Database

Each of the four-selected software have been applied to a large database of forest cover type that is available on the same website of the Machine Learning Repository at the University of California at Irvine by Newman et al. (1998) for which results are shown in Segall and Zhang (2006a, 2006b) for different datasets of numerical abalone fish data and discrete nominal-valued mushroom data.

The forest cover type's database consists of 63,377 records each with 54 attributes that can be used to as inputs to predictive models to support decision-making processes of natural resource managers. The 54 columns of data are composed of 10 quantitative variables, 4 binary variables for wilderness areas, and 40 binary variables of soil types. The forest cover type's classes include Spruce-Fir, Lodgepole Pine, Ponderosa Pine, Cottonwood/Willow, Aspen, Douglas-Fir, Krummholz, and other.

The workspace of SAS Enterprise Miner™ is different than the other software because it uses icons that are user-friendly instead of only using spreadsheets of data. The workspace in SAS Enterprise Miner™ is constructed by using a drag-and-drop process from the icons on the toolbar which again the other software discussed do not utilize.

Figure 1 shows a screen shot of cluster analysis for the forest cover type data using

SAS Enterprise Miner™. From Figure 1 it can be seen using a slice with a standard deviation measurement, height of frequency, and color of the radius that this would yield only two distinct clusters: one with normalized mean of 0 and one with normalized mean of 1. If different measure of measurement, different slice height, and different key for color were selected than a different cluster figure would have resulted.

A screen shot of PolyAnalyst® 5.0 showing the input data of the forest cover type data with attribute columns of elevation, aspect, scope, horizontal distance to hydrology, vertical distance to hydrology, horizontal distance to roadways, hillshade 9AM, hillshade Noon, etc. PolyAnalyst® 5.0 yielded a classification probability of 80.19% for the forest cover type database.

Figure 2 shows the six significant classes of clusters corresponding to the six major cover types: Spruce-Fir, Lodgepole Pine, Ponderosa Pine, Cottonwood/Willow, Aspen, and Douglas-Fir. One of the results that can be seen from Figure 2 is that the most significant cluster for the aspect variable is the cover type of Douglas-Fir.

NeuralWare Predict® uses a Microsoft Excel spreadsheet interface for all of its input data and many of its outputs of computational results. Our research using NeuralWare Predict® for the forest type cover data indicates an accuracy of 70.6% with 70% of the sample for training and 30% of

Figure 1. SAS Enterprise Miner™ screen shot of cluster analysis

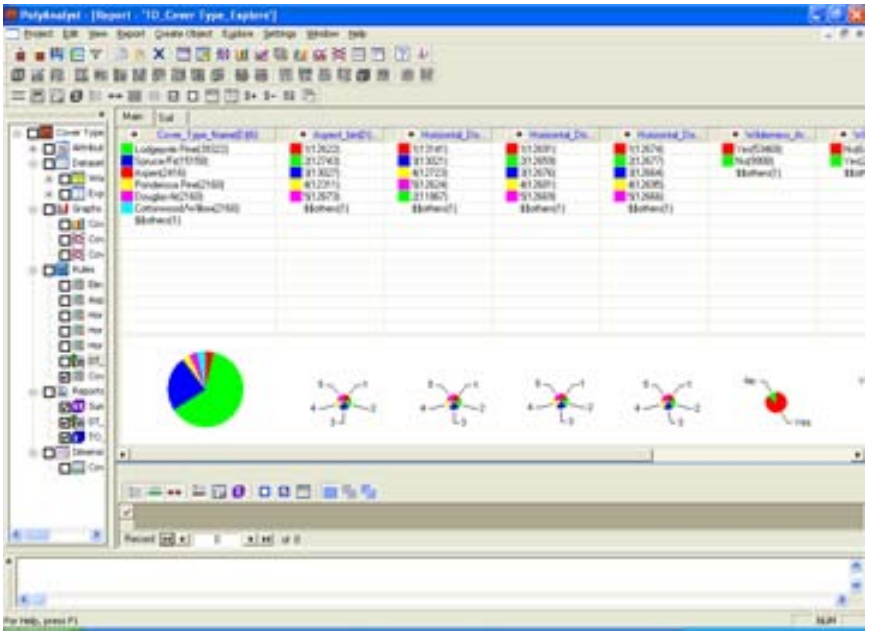

Figure 3. NeuralWare Predict® screen shot of complete neural network training (100%)

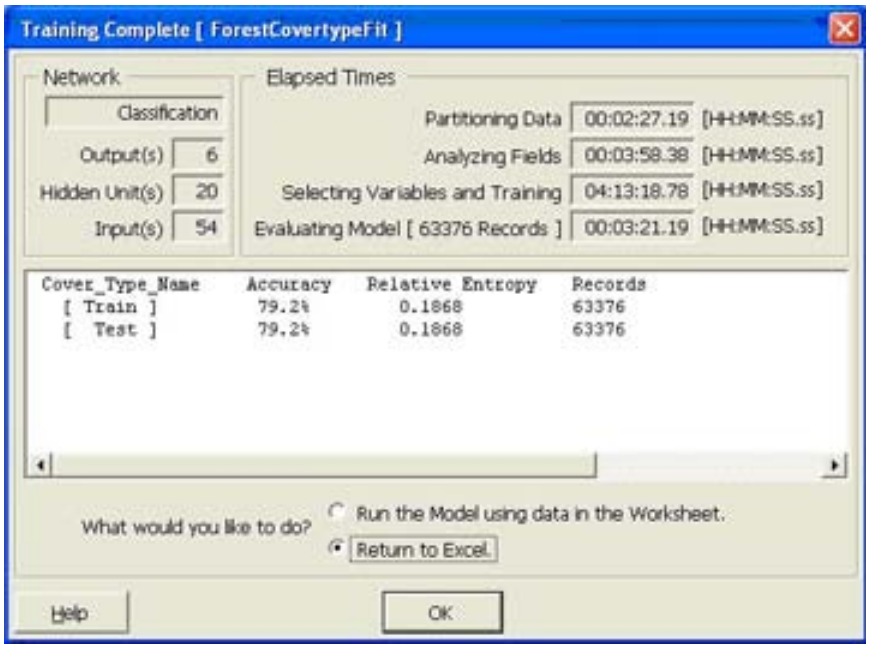

Figure 4. BioDiscovery GeneSight® screen shot of hierarchical clustering

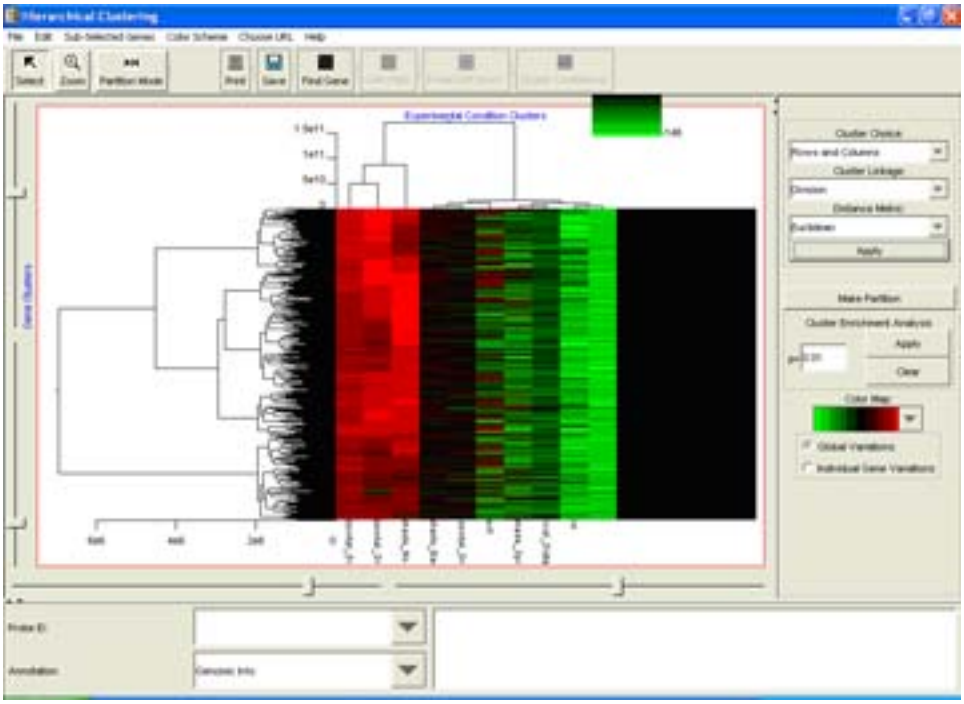

the sample for test in 2 minutes and 26 seconds of execution time.

Figure 3 is a screen shot of NeuralWare Predict® for the forest type cover data that indicates that an improved accuracy of 79.2% can be obtained using 100% of the 63,376 records for both training and testing in 3 minutes 21 seconds of execution time in evaluating model. This was done to investigate what could be the maximum accuracy that could be obtained using NeuralWare Predict® for the same forest cover type database for comparison purposes to the other selected software.

Figure 4 is a screen shot using GeneSight® software by BioDiscovery Incorporated. That shows hierarchical clustering using the forest cover data set. As noted earlier, GeneSight® only performs statistical analysis and cluster analysis and hence no regression results for the forest cover data set can be compared with those of NeuralWare® Predict and PolyAnalyst®. It should be noted that from Figure 4 that the hierarchical clustering performed by GeneSight® for the forest cover type data set produced a multitude of clusters using the Euclidean distance metric.

FUTURE TRENDS

These four-selected software as described will be applied to a database that already has been collected of a different dimensionality. The database that has been presented in this chapter is of a forest cover type data set with 63,377 records and 54 attributes. The other database is a microarray database at the genetic level for a human lung type of cancer consisting of 12,600 records and 156 columns of gene types. Future simulations are to be performed for the human lung cancer data for each of the four-selected data mining software with their respective available algorithms and compared versus those obtained respectively for the larger database of 63,377 records and 54 attributes of the forest cover type.

CONCLUSION

The conclusions of this research include the fact that each of the software selected for this research has its own unique characteristics and properties that can be displayed when applied to the forest cover type database. As indicated, each software has it own set of algorithm types to which it can be applied. NeuralWare Predict® focuses on neural network algorithms, and Biodiscovery GeneSight® focuses on cluster analysis. Both SAS Enterprise Miner™ and Megaputer PolyAnalyst® employ each of the same algorithms except that SAS has a separate software SAS TextMiner® for text analysis. The regression results for the forest cover type data set are comparable for those obtained using NeuralWare Predict® and Megaputer PolyAnalyst®. The cluster analysis results for SAS Enterprise Miner™, Megaputer PolyAnalyst®, and Biodiscovery GeneSight® are unique to each software as to how they represent their results. SAS Enterprise Miner™ and NeuralWare Predict® both utilize Self-Organizing Maps (SOM) while the other two do not.

The four-selected software can also be compared with respect to their cost of purchase. SAS Enterprise Miner™ is the most expensive and NeuralWare Predict® is the least expensive. Megaputer PolyAnalyst® and Biodiscovery GeneSight® are intermediate in cost to the other two software.

In conclusion, SAS Enterprise Miner™ and Megaputer PolyAnalyst® offer the greatest diversification of data mining algorithms.

ACKNOWLEDGMENT

The authors want to acknowledge the support provided by a 2006 Summer Faculty Research Grant as awarded to them by the College of Business of Arkansas State University. The authors also want to acknowledge each of the four software manufactures of SAS, Megaputer Intelligence,

Inc., BioDiscovery, Inc., and NeuralWare, for their support of this research.

KEY TERMS

Algorithm: That which produces a particular outcome with a completely defined set of steps or operations.

ARNAVAC: An underlying machine language algorithm used in PolyAnalyst® for the comparison of the target variable distributions in approximately homogeneously equivalent populated multidimensional hyper-cubes.

Association and sequence analysis: A data mining method that relates first a transaction and an item and secondly also examines the order in which the products are purchased.

BioDiscovery GeneSight®: A program for efficient data mining, visualization, and reporting tool that can analyze massive gene expression data generated by microarray technology.

Data Mining: The extraction of interesting and potentially useful information or patterns from data in large databases; also known as Knowledge Discovery in Data (KDD).

Link Analysis (LA): A technique used in data mining that reveals and visually represents complex patterns between individual values of all categorical and Boolean attributes.

Link Terms (LT): A technique used in text mining that reveals and visually represents complex patterns of relations between terms in textual notes.

Market and transactional basket analysis: Algorithms that examine a long list of transactions to determine which items are most frequently purchased together, as well as analysis of other situations such as identifying those sets of questions of a questionnaire that are frequently answered with the same categorical answer.

Megaputer PolyAnalyst® 5.0: A powerful multi-strategy data mining system that implements a broad variety of mutually complementing methods for the automatic data analysis.

Microarray Databases: Store large amounts of complex data as generated by microarray experiments (e.g. DNA)

NeuralWare NeuralWorks Predict®: A software package that integrates all the capabilities needed to apply neural computing to a wide variety of problems.

SAS® Enterprise Miner™: Software that that uses an drop-and-drag object oriented approach within a workspace to performing data mining using a wide variety of algorithms.

Symbolic Knowledge Acquisition Technology (SKAT): An algorithm developed by Megaputer Intelligence and used in PolyAnalyst® 5.0 that uses methods of evolutionary programming for high-degree rational expressions that can efficiently represent nonlinear dependencies.

WEKA: Open-source data mining software that is a machine learning workbench.

Chapter 4.23
Dimensions of UML Diagram Use:
A Survey of Practitioners

Brian Dobing
University of Lethbridge, Canada

Jeffrey Parsons
Memorial University of Newfoundland, Canada

ABSTRACT

The UML is an industry standard for object-oriented software engineering. However, there is little empirical evidence on how UML is used. This article reports results of a survey of UML practitioners. We found differences in several dimensions of UML diagram usage on software development projects including; frequency, the purposes for which they were used, and the roles of clients/users in their creation and approval. System developers are often ignoring the "use case-driven" prescription that permeates much of the UML literature, making limited or no use of either use case diagrams or textual use case descriptions. Implications and areas requiring further investigation are discussed.

INTRODUCTION

The unified modeling language (UML) emerged in the mid-1990s through the combination of previously competing object-oriented analysis and design (OOAD) approaches (Booch, 1994; Jacobson, Christerson, Jonsson, & Overgaard, 1992; Rumbaugh, Blaha, Premerlani, Eddy et al., 1991), along with other contributions to modeling complex systems (e.g., Harel, 1987). Control over its formal evolution was placed in the hands of the Object Management Group, which recently oversaw a major revision to UML 2.0. The UML became widely accepted as the standard for OOAD soon after its introduction (Kobryn, 1999) and remains so today (Evermann & Wand, 2006). A large number of practitioner

articles and dozens of textbooks have been devoted to articulating various aspects of the language, including guidelines for using it. More recently, a substantial body of research on the UML has emerged, ranging from proposals for extending the language (Moore, 2001; Odell, Van Dyke, & Bauer, 2000) to ontological analysis of its modeling constructs (Evermann & Wand, 2001a, 2001b) to analysis of the language's complexity (Siau & Cao, 2001, 2002; Siau, Erickson, & Lee, 2005) and experiments that evaluate various aspects of the effectiveness of UML models (Burton-Jones & Weber, 2003, Burton-Jones & Meso, 2006).

The UML was not developed based on any theoretical principles regarding the constructs required for an effective and usable modeling language for analysis and design; instead, it arose from (sometimes conflicting) "best practices" in parts of the software engineering community (Booch, 1999; Booch, Rumbaugh, & Jacobson, 1999). This resulted in a language containing many modeling constructs, which has thus been criticized on the grounds that it is excessively complex (DeJong, 2006; Dori, 2002; Kobryn, 2002). But, at the same time, the UML has also been criticized for lacking the flexibility to handle certain modeling requirements in specific domains (Duddy, 2002). As a consequence, the UML has evolved to allow for the definition of "profiles" that have enabled domain specific languages (Cook, 2000; DeJong, 2006).

While the UML is intended to be "largely process-independent," some of the key originators recommend a use case-driven process (e.g., Booch et al., 1999, p.33). A majority of UML books since then have endorsed this view, and most contain at least some further prescriptions for applying the language in modeling (Larman, 2005; Schneider & Winters, 2001; Stevens & Pooley, 2000). As would be expected with a best practices approach, their prescriptions sometimes differ. While some accept the original view that only use case narratives (or, more simply, use cases) be used to verify requirements with users (Jacobson, Ericsson, & Jacobson, 1994), others explicitly or implicitly indicate that other UML diagrams can be used for this purpose, for example activity diagrams "can be safely shared with customers, even those unfamiliar with software engineering" (Schneider & Winters, 2001, p.67).

There are also differences in guidelines for using the language, and use case narratives in particular (Dobing & Parsons, 2000). This is not surprising since the official UML 2.0 documentation provides no guidance on Narrative format, stating only that "use cases are typically specified in various idiosyncratic formats such as natural language, tables, trees, etc" (Object Management Group, 2005, p.574).

Finally, when the use case-driven approach is used, concerns have been raised about the potential communication disconnect (Dobing & Parsons, 2000) that can occur when use cases are the primary communication tool among analysts and the clients or users on the project team while class diagrams play that role amoung analysts and programmers. While use case narratives have been found to be the most comprehensible artifact for managers, users and domain experts, they are the least comprehensible for designers and programmers (Arlow & Neustadt, 2004) when they require knowledge of the organizational context that programmers do not have. Conversely, class diagrams are highly comprehensible by programmers, but not clients or users (Arlow & Neustadt, 2004).

In view of these issues, it would not be surprising to find a variety of practices followed by UML practitioners. We believe understanding current practice can make an important contribution to both theoretical and applied research on UML. From a theoretical perspective, understanding how the language is used can support or challenge theoretical analyses of UML capabilities and deficiencies (Evermann & Wand, 2001a, 2001b). From a practical perspective, usage patterns can inform best practices.

However, to our knowledge, only two surveys have addressed the extent to which UML diagrams are used in practice (Grossman, Aronson, & McCarthy, 2005; Zeichick, 2002), and neither examined why analysts choose to use some diagrams and ignore others. (We are defining "UML diagram" to include use case narratives, even though they are generally used to describe use cases in text form.) This is particularly surprising in view of the explosion of academic interest in UML. Our research seeks to address this issue by surveying UML use in practice.

Our objective was to study three key dimensions of UML diagram usage: how often each diagram was being used, the reasons why analysts chose to use or avoid them (emphasizing their role in facilitating team communication), and the roles of clients/users in their creation and approval. Such an understanding can also support the development of theory to explain observed usage patterns. From a practical point of view, understanding how the language is used can help support its evolution. For example, if certain parts of the language are not widely used or seen as useful, further research is needed to understand why this is so, and may lead to evolution or elimination of those parts.

RESEARCH METHODOLOGY

The research began with participation in a local UML user group, along with mostly informal interviews of about a dozen UML practitioners (none belonging to that user group and most in different cities) and some of their clients. Their approaches to using UML all differed to some degree from each other, some substantially. Some of the differences can be attributed to situational factors. For example, one project began with the database, and the associated class diagram, already in place. In other projects, analysts took a use case-driven approach and relied on someone else to do the class diagram later. Some clients wrote most of the use cases themselves, while others reviewed them.

The level of use case modeling varied, even in systems of roughly the same size, from a small number (less than 20) of relatively short use cases to much larger sets of detailed use cases and scenarios (usually defined as paths through a use case illustrating its application to particular instances) that attempted to capture very complex rules and regulations. The use of other UML diagrams depended on the analyst's knowledge of how to use them, client requests (e.g., one client insisted on at least one activity diagram for every use case), system domain, and other factors. Some learned the UML by starting with only a few of the diagram types while others took a more ambitious approach and attempted to use them all.

To get a broader picture of UML usage, a Web survey was developed based on the preliminary interviews and a literature review. The survey contained 38 questions, many with multiple parts (e.g., a list of possible reasons for not using a particular UML diagram). Both the survey and this article use UML 1.5 terminology, such as "collaboration diagrams" rather than the newer "communication diagrams." The original survey was first reviewed by colleagues and then pretested with two people involved in the interviews and one who had not been. Minor wording changes were made to several questions as a result. The pretest data were retained because the changes made were consistent with what these subjects had in mind.

The survey was intended for the population of analysts familiar with object-oriented techniques and UML in particular. To obtain a sample of such analysts, the OMG was contacted and they agreed to support the project. Their members were informed by email of the survey and the OMG endorsement. A link to the survey was also provided from the main OMG Web page. OMG members were encouraged to share the link with others using the UML in their organizations. Subsequently, an invitation to participate in the survey

was posted to the comp.object Usenet newsgroup. No participation incentive was offered. Some limitations of this approach are discussed later. However, other researchers in this area (e.g., Johnson & Hardgrave, 1999; Grossman et al., 2005) have used similar methods due to the difficulty of finding more representative samples.

RESULTS

Almost 2,700 hits on the survey site were recorded during the survey period from March 21, 2003 to March 31, 2004. About half (1,369) provided no response to any item. After eliminating these responses along with test data, minimal responses, meaningless or invalid responses, and inappropriate respondents (primarily students), there were 284 usable responses. While these criteria are difficult to define precisely, invalid responses were easily identified in practice based on either meaningless numerical entries (e.g., 1 for all entries including budget, number of classes, etc.) or comments that showed the response was not serious. Any response that had meaningful comments was included, no matter how incomplete. The 284 analyzed responses either contained data on UML diagram usage (182) or reasons why the UML was not being used (102). Of the 182 analysts using UML diagrams, most (171) responded that they were using the UML while 11 indicated they were using some UML diagrams in conjunction with other modeling approaches.

Demographic Data

The survey gathered some data on respondent experience in IT, but did not ask about age, gender or nationality. Table 1 shows that respondents have a wide range of experience in the IT field, reporting up to 45 years and 200 projects. UML experience is understandably less. In all cases, the minimum value reported was zero except for years of experience in IT (two years) and all IT projects (three). While respondents report more project experience with UML than other object-oriented approaches, it represents less than a quarter of their projects and about a third

Table 1. Respondent experience in years and projects

	Mean	Median	Max	Std Dev	N
Yrs Experience IT	15.1	14.0	45	9.2	96
Yrs Experience OO Prog	8.4	7.5	25	5.1	95
Yrs Experience OOAD	7.4	6.0	25	4.7	95

No. of UML Projects	6.2	4.0	51	7.0	168
Other OO Projects	4.0	2.0	50	7.6	127

Table 2. "Typical" project sizes

	Budget (in thousands)	**Person Years**	**Lines Of Code**	**Use Cases**	**Classes**
Mean	5,342	57.5	478,910	88	1311
Median	1,000	6.5	50,000	35	150
Maximum	75,000	3 000	5,000,000	800	25,000
Std Dev	12,000	297	1,050 000	137	4 215
N	71	118	64	75	95

of their years of experience. The figures reported for years of experience with OOAD include both UML and non-UML experience.

The survey also asked in what type of industry the respondent was primarily employed, either as a direct employee or as a consultant. Respondents could select only one industry. Of the respondents using the UML who provided their industry type, 47 percent were in software development, 13 percent in financial services, and 8 percent each in education, aerospace and defense, and health care and pharmaceuticals. About 44 percent also indicated they were associated with their industry through a consulting firm.

The survey asked respondents, "How large are the typical object oriented and/or UML projects you have worked on?" Table 2 shows the results, with budgets in U.S. dollars (with euros and Canadian dollars taken at par). The use cases and classes measures reflect both the size of the project and the extent to which these diagrams were used and exclude responses where they were not used at all. The inclusion of a few very large reported project sizes skewed the means, so the medians are also reported.

Overall UML Diagram Usage

Table 3 shows the relative usage of UML analysis diagrams, with our results compared to others (Grossman et al., 2005; Zeichick, 2002). To keep our survey to a reasonable length, we only asked about use case narratives and UML diagrams covering system structure and behavior that are used to document system functionality. This excluded the object diagram, which is closely related to the class diagram, and the component and deployment diagrams, used in application architecture modeling. Respondents were asked, "What proportion of the object-oriented/UML projects that you have been involved with have used the following UML components?" The five-point usage scale was: None, <1/3, 1/3 – 2/3, > 2/3 and All. The question asked about diagrams used in projects rather than personally by the respondent because the initial interviews found that team members often specialized in one or a few diagrams (e.g., focusing on use case narratives or the class diagram).

Although UML is often presented as being used with a use case-driven approach in the

Table 3. UML diagram usage

UML Diagram	Usage[1]	Never Used (percent)	>2/3 usage (percent)	>1/3 usage (percent)	G[2] (percent)	Z[3] (percent)
class	4.19**	3	73	87	93	75
use case diagram	3.56**	7	51	72	NA	89
sequence	3.51	8	50	75	89	75

, Significantly different from use case narrative mean, ** p<=0.01, * p<0.05 (t-test)*

UML literature, and in particular by the unified process (Jacobson et al., 1999), only 44 percent of respondents report that use case narratives are used in two-thirds or more of their projects. Over a third of the respondents say their projects never use them, or use them less than a third of the time (15 percent and 22 percent, respectively). Class diagrams were the most frequently used, with 73 percent of respondents using them in two-thirds or more of their projects. Use case narratives were ranked fourth, behind sequence diagrams and use case diagrams. Only three percent of respondents report that their projects never use class diagrams, while collaboration diagrams have the highest non-usage rate of 25 percent. The number of respondents to this question varied from 152 (Statechart) to 172 (class diagram).

Our results are reasonably consistent with other studies (Table 3), except for a much lower use case narrative usage in our study compared to Grossman et al. (2005) and a possibly related lower use of use case diagrams than in Zeichick (2002). In all three studies, collaboration diagrams were found to be the least frequently used. The differences may be attributable to question wording; for example, Grossman et al. (2005) simply asked if the diagram was being used rather than in what percentage of projects. The usage data in all three studies are based on respondents rather than projects. Due to the low correlations (maximum of 0.2) between UML experience and diagram usage, weighting usage by the respondent's number of UML projects increases the averages only slightly.

Most projects made only partial use of the seven UML diagram types studied (Table 4). Of the 135 respondents who reported project usage levels for all seven UML diagrams studied, 51

Table 4. Number of UML diagram types used

UML Diagram Types Used	>1/3 Projects (percent)	>2/3 Projects (percent)
0	6	13
1	4	14
2	8	13
3	10	23
4	21	16
5	16	10
6	19	3
7	16	8

percent reported that five or more of them were used in at least a third of their projects while 21 percent reported five or more used in at least two-thirds of their projects.

Usage rates of the different UML diagram types were all positively correlated with each other, from an r^2 of 0.64 between use case narratives and use case diagrams to 0.16 between use case narratives and Statechart diagrams. Thus, there is apparently no general tendency for projects to use certain diagrams at the expense of others (which would result in a negative correlation). For example, given that sequence diagrams and collaboration diagrams are "semantically close" so that "only minor visual information may be lost" when transforming one to the other (Selonen, Koskimies, & Sakkinen, 2003, p.45), one might expect to find that projects use either the collaboration diagram or the sequence diagram but not both. However, among our respondents, usage of the two was correlated at 0.38 ($p < 0.01$). There were 24 respondents (out of 153) who reported that all their projects use collaboration diagrams and 19 of the 24 reported always using sequence diagrams as well.

In contrast, of the 50 always using sequence diagrams in their projects, 18 used collaboration diagrams less than one-third of the time (and 11 of these never used them). While 87 respondents reported a higher usage level for sequence than for collaboration diagrams, only 12 reported the opposite. Analysts clearly prefer using sequence diagrams but many apparently value depicting the same information in different ways for different purposes. Their isomorphic nature also means that sequence and collaboration diagrams share underlying data, so the incremental cost of producing both (after committing to either one) is low with some UML tools.

UML Diagram Usage Patterns

The survey collected demographic data about respondents, their organizations, use of tools, and types of systems being built. Not all respondents completed these sections so the sample sizes for this analysis are somewhat smaller. Differences that are not reported were statistically insignificant.

Organization Size

There are a number of significant positive relationships between organization size measures and the use of UML diagrams. Comparing organizations above to those at or below $10 million in annual revenue, the former are significantly more likely to use use case narratives ($p=0.001$), use case diagrams ($p=0.02$) and sequence diagrams ($p=0.02$) and they use an average 4.75 diagram types compared to 3.65 for smaller organizations ($p=0.01$). Comparing usage by organizations with 50 or more IT employees to those with fewer, the former are more likely to use sequence diagrams ($p=0.01$) and activity diagrams ($p=0.03$). However, those with more employees use only slightly more use case narratives and total number of diagram types. Both points used to divide the samples were chosen to create roughly equal subsamples so they are somewhat arbitrary. Moreover, the two size measures are not independent ($r=0.72$).

Project Size

Larger projects might be expected to make wider use of UML diagram types, but this is generally not the case. A similar analysis using the five project size measures (Table 2) found that respondents reporting larger than average budgets reported more use of use case narratives and more diagram types used over a third of the time ($p<0.05$). Larger projects based on person-years also reported greater use of use case narratives ($p<0.05$). However, no other comparisons were significant.

UML Tools

The availability of UML tools is also related to the use of UML diagram types. Those with tools are significantly more likely to use class diagrams ($p=0.02$) and sequence diagrams ($p<0.001$) with usage levels higher for all remaining diagram types as well (none significant). Respondents from larger organizations might be expected to have better access to tools and they do, but only slightly so this does not explain why larger organizations are using more diagram types. Correlations between the organization size measures (annual revenue and number of employees) and spending on tools are also low (0.25 and 0.29, respectively, neither significant) even though tool cost is typically partly dependent on the number of installations.

Organizational UML Usage

Overall usage of the UML in an organization could affect practices within individual projects. For example, analysts (and presumably organizations) could begin learning the UML by focusing on a subset of diagrams (Ambler, 2002, pp.46-47). The survey data do not permit any direct testing to determine whether individual analysts are taking this approach. However, respondents from organizations using the UML in 40 percent or fewer of their projects use an average of 2.4 diagram types two-thirds of the time or more. Those from organizations using the UML in over 40 percent of projects average a significantly greater ($p = 0.02$) 3.3 diagram types and are also making significantly ($p = 0.03$) more use of sequence diagrams (3.84 usage level compared to the 3.51 average in Table 3 and 3.23 level for those using the UML 40 percent of the time or less). Usage levels of all the remaining diagram types are very similar to those reported in Table 3 for both groups.

Respondent Experience

There are generally weak relationships between respondent experience and their projects' UML diagram usage. Experience measures (Table 1) were correlated with use of each UML diagram type (Table 3). The strongest relationships involved Statechart diagrams and years of experience in object-oriented analysis and design (0.45, $p<0.01$) and years of experience with UML (0.35, $p<0.01$). Class diagram usage also correlated significantly ($p<0.01$) with these two experience measures at 0.36 and 0.40 respectively, and with years of object-oriented programming (0.31). No other correlations between experience measures and diagram type usage exceeded 0.30 (and thus they explained less than 10 percent of the observed variance).

Industry

The survey provided 15 possible industrial classifications, with all but one receiving 12 or fewer responses (insufficient to be useful in analysis). The 46 respondents working in the software development industry, who do not always have identifiable clients in the same sense as those working in other organizations, had somewhat (but not significantly) lower use of use case narratives, sequence diagrams and activity diagrams.

In our initial informal interviews, consultants were always described (by themselves and by others) as enthusiastic proponents of use case

narratives and the use case-driven philosophy. While we expected similar results from the survey, instead consultants reported lower use case narrative usage than non-consultants (but not significantly, p=0.07). However, consultants were significantly more likely (p=0.04) to use collaboration diagrams.

System Type

Respondents were asked to indicate the application area(s) in which their systems were being built. The seven choices (with the number of responses in parentheses) were e-commerce (90), administrative (71), embedded (36), manufacturing (28), customer relationship management (26), data mining (21) and mobile commerce (17). There were also 58 who provided "other" categories, although many used this option to further describe one of the existing categories. Building software tools (6) was the most common selection not listed in the survey.

Use case narratives were used most by those developing customer relationship management (3.57) and e-commerce systems (3.48), and least by those developing embedded systems (2.64). (The numbers shown use the same five-point scale as in Table 3.) T-test significance levels were 0.01 and 0.001, respectively, after excluding respondents who selected both the system types being compared. However, embedded system projects had the highest reported usage of sequence diagrams (3.56), while customer relationship management had the least (2.14) ($p<0.005$). Activity diagrams were used most in development of manufacturing systems (3.12) and least in embedded (2.58), but this difference was not significant.

Respondents were also asked to identify the proportion of their object oriented/UML projects that would be consider new systems, complete replacements of existing systems, or enhancements to existing systems. Most entered percentages that totaled 100, but others entered the number of each type and these were converted to percentages. There were 154 usable responses, averaging 56 percent new, 20 percent replacement and 24 percent enhancements. Table 5 computed the usage of each UML diagram (computed as in Table 3) for those who reported at least 50 percent of their projects were of that type; there were 96 responses for new systems, 23 for replacement projects and 34 for enhancement projects. (Some responses were split 50/50 between two types and were counted twice while others were split

Table 5. UML diagram usage by project type

UML Diagram	New System	Replacement System	Enhancement of System
class	4.19	4.82	4.38
use case diag	3.62	3.90	3.56
sequence	3.55	3.95	3.43
use case narr	3.08	3.82	3.23
activity	2.99	2.95	2.69
statechart	2.87	2.75	2.63
collaboration	2.59	2.95	2.45

more evenly among all three types and were not counted at all.) Most notable is the greater use of class diagrams and use case narratives when developing replacement systems.

Information Provided by UML Diagrams

There are a number of reasons for using multiple diagram types to describe system functionality, beginning with the possibility that different diagrams convey different information. To investigate this, the survey asked which diagrams provide new information beyond that contained in use case narratives. The use case narratives were chosen as the benchmark because a use case-driven approach had been endorsed by much of the early UML literature. Both the interviews and a literature review (Dobing & Parsons, 2000) showed that use case narratives varied widely in level of detail, so simply knowing that use case narratives are being employed does not answer the question of how much information they contain. In contrast, the level of redundancy across other pairs of diagrams is largely determinable from their syntax. The question used a five-point scale from "No New Info" to "All New Info," with "Some New Info" as the midpoint (3). This item was only seen by those whose projects had used both use case narratives and the other diagram in question so there were fewer respondents, from 89 (collaboration diagram) to 125 (class diagram).

Table 6 shows that the diagram of highest value for conveying new information not already contained in the use case narratives was the class diagram, with a score of 3.51 on the five-point scale, and 86 percent of respondents believe it offers at least some new information (at least 3 on the 5-point scale). The use case diagram was least useful in providing additional information, which is not surprising given its role is to depict the use cases and their relationships to actors and to each other.

Stronger relationships were expected between the belief that a UML diagram provides additional information beyond the use case narrative and the usage level of that diagram. For activity diagrams, the correlation was 0.42 ($p<0.01$). However, other correlations of this type were all weak (i.e., none exceeded 0.30, so none explained more than 10 percent of the variance).

There was also a strong correlation (0.77) between the beliefs that collaboration and sequence

Table 6. New information (not in use case narratives) from UML diagrams

UML Diagram	New Information[1]	Some – All New Information (percent)
class	3.51	86
use case	2.42**	48
sequence	3.37	78
activity	2.89**	63
statechart	3.38*	79
collaboration	2.98**	67

[1] *New information is measured on a scale from 1 (No New Information) to 5 (All New Information)*

*,** *Significantly different from class diagram mean,* ** *p<=0.01,* * *p<0.05 (t-test)*

diagrams provide new information beyond use case narratives, the highest correlation found among all pairs of diagrams. This could be attributed to the isomorphic relationship between collaboration and sequence diagrams (i.e., that they convey similar information but in different ways).

Role of UML Diagrams

Table 7 examines reasons for including each UML diagram in a project, with the focus on communication within the project team. Each respondent who reported using a particular diagram at least a third of the time was asked about four possible purposes. As expected, use case narratives had the highest score for "Verifying and validating requirements with client representatives on the project team" at 4.00 (on a 5-point scale). The use of other diagrams for this purpose was higher than expected, based on interview responses and our review of the UML literature. These high levels of client involvement show that use of the more technical diagrams of the UML is not limited to the technical members of the development team. The survey also included a single item that asked, "How successful has the UML been in facilitating communication with clients?" The items used a five-point scale from Not to Very Successful. The mean was 3.28 with 25 percent choosing the lowest two levels.

Of those respondents who reported using a particular diagram at least a third of the time, Table 8 shows the percentage who rated them from "Moderately Useful" to "Essential" for four different purposes. The results show higher than expected levels of usefulness for all UML dia-

[2] Specifying system requirements for programmers

[3] Documenting for future maintenance and other enhancements

[4] Clarifying understanding of application among technical members of the project team

grams in "Verifying and validating requirements with users." Only Statecharts, at 49 percent, were under the 50 percent level.

The other three purposes listed are more related to communication within the project team, among analysts, programmers and maintenance staff. For these three purposes, the class diagram was considered most useful with the use case diagram least useful (but all diagram types were rated as at least "moderately useful" by over 60 percent of respondents). As noted earlier, the use case diagram provides an overview of the project while programming tends to focus on implementing particular functionality. In Table 8, the usefulness levels reported for sequence diagrams are all significantly higher ($p<0.01$) on the three project team communication measures than those for the isomorphic collaboration diagram.

These reported levels of client involvement with the full range of UML diagrams exceed those generally recommended in the literature and, in particular, seem inconsistent with the dominant use case-driven philosophy. Concerns have been raised about a potential disconnect that could result from relying on use case narratives when working with clients and class diagrams when working with technical team members (Dobing & Parsons, 2000). The survey results confirm that use case narratives are indeed the primary diagram for communication with clients and class diagrams for communication within the technical members of the team. However, all diagrams received at least "moderately useful" ratings from over 50 percent of respondents across all forms of communication (Table 8), except using Statechart diagrams for communication with clients which was 49 percent. In particular, use case narratives are widely used among the technical members of project teams. This suggests that the disconnect problem may well have been addressed in practice, if not in the UML literature.

Table 9. Reasons for not using some UML Diagrams (% responses)

UML Diagram	Not well understood by analysts	Not useful for most projects	Insufficient value to justify cost	Information captured redundant	Not useful with clients	Not useful with programmers
class	50	13	13	25	25	25
sequence	32	23	36	14	23	23
use case narrative	29	26	37	29	11	26
use case diagram	32	32	42	19	29	42
statechart	35	42	28	12	28	33
activity	48	23	35	35	14	25
collab'tion	27	32	24	49	29	24

Those who reported that their projects used a particular diagram less than a third of the time (including not at all) were asked why they were not using it more often. There were fewer respondents for these questions, ranging from only 8 for class diagrams to 59 for collaboration diagrams. Table 9 shows the percentage of respondents who selected each possible reason. Respondents were encouraged to select all reasons that applied so row totals exceed 100 percent. A lack of understanding by analysts was the primary factor among the few not using class diagrams (50 percent). Similar concerns were expressed by 48 percent of respondents about activity diagrams. Leading concerns for the remaining diagrams were over how useful they are (Statechart), their value (sequence and use case diagrams and narratives) and the degree of redundancy (collaboration, presumably with respect to sequence diagrams).

Client Participation

Client participation has long been considered crucial to successful system development. The survey asked about the client's role in relation to each of the UML diagram types being studied. Respondents were able to select more than one (e.g., they could report that clients helped to develop use case narratives, reviewed some or all of them upon completion and had formal approval authority). The results are summarized in Table 10. For example, 76 percent of respondents who used use case narratives reported that clients were involved in their development. When UML diagram types are ranked on the level of client participation, the order is very similar (with only class and collaboration diagrams transposed) to "comprehensibility" rankings for managers, users and domain experts (Arlow & Neustadt, 2004, p.91).

The results show that clients were most likely to be involved in developing, reviewing and approving use case narratives and the use case diagram. Of the remaining diagrams, activity diagrams are probably the easiest for clients to understand and almost half the analysts report some involvement by clients in their development, consistent with the comment above by Schneider and Winters (2001).

Table 10. Client participation

UML Diagram	Develop (%)	Review (%)	Approve (%)	N
use case narr	76	63	54	78
use case diag	57	69	46	77
activity	47	60	19	57
sequence	37	52	16	87
class	33	53	20	103
collaboration	38	48	13	48
statechart	28	36	20	61

While clients were less likely to be involved in developing the class diagram, just over half were involved in reviewing this widely used diagram. The wide range of client involvement practices in our interviews and survey results is not unexpected given that most organizations have relatively limited experience with the UML.

Not surprisingly, clients were least likely to be involved in developing or reviewing Statechart diagrams. The fact that about one quarter to a third were involved in these tasks may reflect the technical sophistication of some clients in the survey sample, since the composition of OMG membership includes many large companies in the computer industry.

Respondents were also asked about possible difficulties that had occurred which "could be attributed to the UML." They could check any or all of the five categories listed. User interface concerns were checked most frequently (36 percent), followed by roles and responsibilities of particular users (21 percent), security (18 percent), data requirements (18 percent), and system capabilities and functionality (13 percent).

Respondents Not Using the UML

Some limited analysis was also done based on the 102 responses from those not using the UML. Software development was also the largest organization type for this group (31 percent) with education second (25 percent). These respondents were less experienced than the UML practitioners (averaging 8.1 years IT experience and 16.3 IT projects vs. 15.1 years and 27.0 projects for UML practitioners). The sample selection method suggests this group is probably more knowledgeable about the UML (and more interested in it) than the average non-practitioner. The primary reasons given by those not using the UML or any object-oriented approach were a lack of people familiar with the UML (51 percent) and a lack of suitable projects (16 percent). Of those whose organizations were using an object-oriented approach but not the UML, 55 percent cited a lack of people familiar with the UML while 23 percent said they had no suitable projects, 17 percent said it was too complex, 17 percent said it was not yet standardized or accepted and 15 percent indicated

their tools were not compatible with the UML. Respondents could select more than one answer so the percentage total exceeds 100 percent.

DISCUSSION AND RECOMMENDATIONS

This is the first survey we are aware of investigating not only how but why UML diagrams are used or not used in systems analysis. We found variations on all three of the major dimensions studied, including frequency of use for each diagram type, the purposes for which they were being used, and the role of clients/users in their creation and approval. While the UML is "unified" in that it brought together elements from disparate modeling notations, considerable variations remain in its use that are somewhat inconsistent with the notion of the UML as a "unified" language in the sense of implying coordinated and cohesive use of diagram types within a development project. Moreover, we found that use of only a subset of UML diagrams on a project is widespread. The data also show a variety of reasons why certain UML diagrams are not used.

The findings of this research can be useful in a number of ways. First, information on UML use can provide valuable input in the evolution of the standard. For example, on the issue of complexity, the language could be simplified by eliminating collaboration diagrams. Based on our findings, collaboration diagrams are used less often, deemed to be less useful, and appear to offer little additional value in relation to sequence diagrams. Statechart diagrams are also used less often than most and seem to be less useful most of the time, but are rated highly for providing new information in some situations (e.g., real-time systems) and have low redundancy. Admittedly, both these diagrams also have some strong supporters. As one interview subject said about Statecharts, "When they are useful, they are very useful."

Second, some projects do not follow a use case-driven approach with over a third of the respondents saying they use them less than a third of the time. At the same time, there is limited empirical evidence to support the proposition that use case narratives are a more effective way to communicate with clients than are the other UML diagrams. Research is also needed to determine an appropriate level of granularity and level of detail for use case narratives.

Third, more attention may be needed on the issue of how clients or users can be better prepared to participate in development and review of artifacts beyond use case narratives. We found that the use of diagrams other than use case narratives among clients or users was higher than expected based on the extant prescriptive literature on 'how to use' the language. The UML practitioner literature generally seems to assume that UML diagrams, except for use case diagrams and narratives, are too complex or technical to be understood by clients. However, our results show that clients frequently approve, review, and even help develop all of the UML diagrams. The views of clients and intended users of systems on the usability and usefulness of UML have received little attention from researchers (including this study). Nor has much consideration been given to how to prepare clients for this level of involvement.

Fourth, research is needed to understand which UML diagrams can best facilitate communication between clients and analysts, particularly as the use of the UML to support agile modeling grows (Ambler, 2002). In addition, work might be needed to modify these diagrams (e.g., by simplifying or otherwise changing the syntax and grammar of the diagram type) to enable them to support communication and verification more effectively.

Fifth, as noted earlier, 36 percent of respondents agreed that they had experienced "difficulties … [with user interfaces] that could be attributed to the UML." User interfaces have become much more complex over the past decade

with the use of both visual programming and Web environments, complicating development using any methodology or notation. Based on accompanying comments, respondents would welcome better ways to integrate user interface design with UML modeling. One approach is to distinguish between "system" and "essential" use case narratives (Constantine & Lockwood, 1999), where essential use cases are independent of technology (and user interfaces) while system use cases include these details. Currently, the UML has no standards for use case narratives (OMG, 2005) or system use cases in particular, which might explain why many respondents experienced user interface issues that they could attribute to the UML. Another approach is to use prototyping or other screen design tools in conjunction with the UML. One respondent noted that, "It is easier for clients to understand the functionality of software through user interface sketches" while another said that clients had difficulty validating use case narratives "without any draft of the [user interface]." The principle that system analysis should be technology independent long precedes the development of the UML and is widely accepted among leading writers in the field but, as several respondents pointed out, some difficulties can arise when applying this principle in practice. Another respondent noted difficulties in creating a vocal interface, pointing out that not all interfaces are purely visual. There are some very interesting research opportunities in this area.

Respondents provided fewer comments on other difficulties with the UML. Concerns about security are to be expected but no suggested solutions were mentioned. One difficulty with database design is that many respondents were using a relational, rather than object-oriented, DBMS. Difficulties identifying the "roles and responsibilities of particular users" suggest that there may be problems mapping the UML "actor" to specific individuals or job descriptions. There are some strong parallels with this issue and user interfaces; at least some clients prefer to work with more concrete designs that clearly show who does what rather than with more abstract approaches that take a higher level view. More research is needed on how clients can more effectively validate designs.

Finally, there have been numerous attempts to evaluate UML from a theoretical standpoint including assigning ontological semantics to UML constructs (Evermann & Wand, 2001a; Opdahl & Henderson-Sellers, 2001) and assessing the complexity of the UML (Siau & Cao, 2001, 2002; Siau et al., 2005). In cases such as these, theoretical conclusions can be substantiated or refuted by empirical data on usage. To illustrate, some UML constructs appear to have no ontological counterpart and such constructs may not be suitable for conceptual modeling (Evermann & Wand, 2001a). We then might expect that diagrams that have more such constructs would be less useful and less used in conceptual modeling. In terms of this study, this would correspond to less use of such diagrams/constructs for verifying and validating requirements with users. Our study did not examine use at the level of constructs within diagrams, but future empirical studies might do an analysis at that level of detail (perhaps for a single diagram type).

SURVEY RESPONDENT CHARACTERISTICS: PROFILE AND LIMITATIONS

Given the lack of any defined population of UML practitioners from which to obtain a random sample, we chose to survey primarily OMG members and those who use its Web site. This may have produced biased responses. However, given that the goals of this research were to examine how UML practitioners (the target population) were using the language, rather than the extent to which it is being used in software development in general, the participation of the OMG seemed appropriate. While respondents may not

be representative of all UML practitioners, they can be considered leading edge adopters. UML experience was naturally low when this survey was conducted, with medians of five years and four projects. As such, respondents might not be typical of the eventual set of UML practitioners (which could become the majority of system developers if object-oriented system development and the UML become more widely accepted). Based on other research in technology adoption, albeit in different areas (e.g., Brown & Venkatesh, 2003), early adopters might approach the UML quite differently from those who come later.

In addition, there are some obvious limitations with using a convenience sample. The number of people who received or read the invitation to participate is unknown because of the possibility of it being forwarded. Visitors to the OMG site need not be members, so the results should not be considered as a survey of OMG's membership even prior to inviting readers of the comp.object Usenet newsgroup. It is also likely that some people found the survey through search engines, since the survey was, for some time, the top result of a Google search on "UML survey." Despite the lack of control over respondents, reviewing the comments and contact information suggests that the group as a whole does belong to the target population and are reasonably diverse on a range of demographic measures. Moreover, whether they worked for OMG member companies or found the survey by other means, the respondents clearly were very interested in the UML, and can reasonably be considered leading edge practitioners. Whether respondents are representative of the target population of all analysts who use the UML is unknown.

A majority of respondents opted to remain anonymous so they could have submitted two or more responses, but there was no reason for them to do so and there are no obvious patterns of duplicate responses. It is also conceivable that results could be skewed by heavy participation by a single organization. However, responses came from a wide variety of organization types and sizes and there were no bursts of unusual activity levels. Among those who did provide an email address, no company domain had more than one response except for email providers (15 from Yahoo! accounts, five from Hotmail, etc.). So there is no evidence to suggest the results were manipulated by any individual or group.

The survey took a use case-driven approach, consistent with a majority of the books written on the UML up to the time of this survey. However, only 44 percent of respondents reported using use case narratives in at least two-thirds of their UML/object-oriented projects. Measuring the value of the information provided by different UML diagrams by comparing them to use case narratives therefore seems insufficient and new measures are needed.

The measures used for project size were also problematic. Low numbers of classes and use case narratives used in some "typical" projects probably reflect limited usage of those diagram types rather than the real size of the project, and many projects are not using them at all. Some unrealistically low budgets (which were coded as missing data) were perhaps intended to be in thousands of dollars while others appear to exclude salaries. On the other hand, some larger budgets might have included training and tool acquisition costs that do not reflect project size. Lines of code is commonly used as a measure of project size, and was used here because of its simplicity. However, respondents may or may not have included shared code, comments, etc. and programming style can also affect code size. Low correlations among these size measures also suggest a lack of reliability. Budget and number of classes correlated at 0.65 while person-years and lines of code correlated at 0.44 (both with $p<0.01$). But the next largest correlation is only 0.25.

Measures of user/client involvement have a long history in the IS literature. This survey measures only the perspective of IT professionals rather than the clients themselves. In the earlier

interviews, there were several cases of strong disagreement between the clients and analysts on their roles and even on appropriate use of some UML diagram types. There can also be differences in what 'client' means across different organizations and situations. Are clients those sponsoring the system or does this term also include the intended direct users? Some external consultants might view the IT Department that hires them as the client, while those developing commercial software may have certain types of clients in mind but have limited interaction with them.

CONCLUSION

The UML has rapidly become the de facto standard for object-oriented systems development. However, this survey suggests there is no standard approach to using the UML within a group of arguably leading edge practitioners. There is considerable variation in use of diagrams across projects and in the role clients/users play in the development of UML models. Clearly, in view of the popular interest in the UML, further research is needed to better understand UML use in order to gain insight on how it can be effectively used to support systems development. The results of this survey suggest several aspects of UML adoption and use that need to be studied.

ACKNOWLEDGMENT

The authors would like to thank the Object Management Group, and Richard Soley in particular, for their support of our research. Thanks also to Dinesh Batra and other anonymous reviewers for their helpful suggestions and comments. Funding for this research was provided by the Natural Sciences and Engineering Research Council of Canada.

Chapter 4.24
Enterprise Resource Systems Software Implementation

Ganesh Vaidyanathan
Indiana University, USA

ABSTRACT

Enterprise resource planning systems are complex yet single, integrated software programs that runs off a single database so that the various departments can easily share information and communicate with each other. The integrated approach can have a tremendous payback if companies implement the software correctly. This chapter illustrates the implementation steps as followed by major corporations in the United States, and provide an insight into the practical implementation issues. A business case for such systems is introduced in this chapter as well. The chapter provides seven ERP issues and elaborates these issues in the context of implementation. The implementation details during conceptualization, design, implementation, go-live, and operation stages are provided with a note to practitioners on ERP implementation.

INTRODUCTION

Enterprise resource planning (ERP) software attempts to integrate all departments and functions across a company onto a single computer system that can serve all those different departments' particular needs (Koch 2002). Each of those departments typically has its own computer system optimized for the particular way that the department does its work. But ERP combines them all together into a single, integrated software program that runs off a single database so that the various departments can more easily share information and communicate with each other. That integrated approach can have a tremendous payback if companies install the software correctly.

Typically, when a customer places an order, that order begins a mostly paper-based journey from in-basket to in-basket around the company, often being keyed and re-keyed into different departments' computer systems along the way. These activities cause delays and errors. Meanwhile, no

one in the company truly knows what the status of the order is at any given point because there is no way for the finance department, for example, to get into the warehouse's computer system to see whether the item has been shipped. ERP can replace the old standalone computer systems in accounting, human resources, manufacturing, and warehouse with single unified software. This results in integrated software that is linked together so that someone in finance can look into the warehouse module to see if an order has been shipped. Most vendors' ERP software is flexible enough to install certain modules without buying the whole package.

Enterprise systems that encompass all departmental processes can often be complex and interdependent. Highly interdependent technology solutions such as ERP are used by firms to enhance the efficiency and ease of in-house capabilities. The use of ERP is characterized by high levels of task interdependence (Sharma and Yetton 2003). To implement such highly complex and interdependent systems is often a daunting process. Implementing an enterprise-wide application like an ERP system to help run a business is a costly and complex process and is like implementing a civil engineering endeavor or sizable construction project (Hawksworth 2007). A certain amount of planning, discipline and wisdom are required to complete implementation on schedule to meet the requirements of a firm.

Many of the current ERP literature share implementation experiences from various companies. While some of them attempt to explain why the ERP implementation is difficult and what needs to be done to achieve desirable results, others present various models of implementation stages and different implementation methodologies (Moon, 2007). The contributions of this chapter to researchers and practitioners include:

a. Illustration of the implementation steps as followed by major corporations in the United States, and
b. Provision of an insight into the practical implementation issues, and
c. Introduction to a business case for ERP systems.

This chapter details the implementation issues of ERP systems and provides an insight into the practical aspects of such implementation. The next section provides seven ERP issues and elaborates these issues in the context of implementation. The following section describes ERP software and the ERP implementation scheme during conceptualization, design, implementation, go-live, and operation stages of implementation. The chapter concludes with a note to practitioners on ERP implementation.

WHAT CAN ERP DO?

ERP is an enterprise software package. With ERP, it is possible to keep track any transaction in an enterprise in real-time. ERP allows managers to process business information more effectively to support sound decision making. ERP solutions cover all of the core operations necessary to run successful small and midsize businesses, including accounting and banking, customer and vendor management, purchasing and sales, logistics and production, as well as reporting and analysis.

The benefits of ERP systems have been researched extensively in literature. Gefen and Ragowsky (2007) examined associations between the business characteristics of manufacturing firms and their perceived benefits from ERP system investments at both enterprise and a specific IT module level and found that the perceived value for ERP investments was consistently better explained at the specific IT module level. Ranganathan and Brown (2006) found that ERP projects with greater functional scope (two or more value-chain modules) or greater physical scope (multiple sites) result in positive, higher shareholder returns. ERP systems replace com-

plex and sometimes manual interfaces between different systems with standardized, cross-functional transaction automation (Hendricks et al., 2005). Information integration using ERP can replace functionally oriented and often poorly connected legacy software, resulting in savings in infrastructure support costs (Hendricks et al., 2005). Other business benefits include:

- **Improved productivity:** ERP engages and connects users within and beyond the enterprise, including customers, suppliers, and partners. An intuitive, role-based portal environment gives the system wide access to a single, consistent view of the business. Higher levels of efficiency and collaboration may be achieved and as a result firms can respond to new competitive threats, and proactively meet customer needs.
- **Increased insight:** ERP improves decision-making by giving managers a clear understanding of activities across functions. They can retrieve the right information at the right time to address problems and pursue new opportunities.
- **Enhanced governance:** ERP provides comprehensive functionality for corporate governance, enabling the firm to comply with Sarbanes-Oxley and International Accounting Standards. ERP also integrates corporate reporting, analysis, and compliance with underlying business processes and transaction systems.
- **Improved flexibility:** ERP provides a scalable and adaptable solution that seamlessly integrates end-to-end processes with the ability to add other external solutions that may include customer relationship management, supply chain management, and product life-cycle management.
- **Reduced costs:** ERP enables firms to manage IT costs by leveraging the investments they have already made.
- **Increased visibility:** ERP solutions provide real-time visibility across the entire enterprise, so firms can streamline their supply chain, bring products to market faster, get more out of procurement, and eliminate duplication of effort.

ERP IMPLEMENTATION ISSUES

Companies that install ERP do not have an easy time of it. To implement ERP right, the ways that they do business need to change and the ways people do their jobs need to change too. And that kind of change does not come without pain. The important thing is not to focus on how long it will take but rather to understand why the firms need ERP and how they will use it to improve their business.

Cost

Meta Group recently did a study looking at the total cost of ownership (TCO) of ERP, including hardware, software, professional services and internal staff costs. The TCO numbers include getting the software installed and the two years afterward, which is when the real costs of maintaining, upgrading and optimizing the system for business are felt. Among the 63 companies surveyed (Ketbi et al. 2002)—including small, medium and large companies in a range of industries—the average TCO was $15 million (the highest was $300 million and lowest was $400,000). The nature of ERP implementations are such that there are usually unforeseen and unexpected occurrences that increase the overall costs (Al-Mudimigh et al., 2001). In summary, the cost of implementing ERP remains quite high (Wu et al., 2007).

Schedule

The criticality of schedule and budget overruns as risk factors in ERP implementation projects has

been rated to be high by all companies regardless of their size (Laukkanen, 2007). The time and effort to implement is likely to be underestimated in the case of implementing ERP systems. ERP systems come in modules and do not have to be implemented entirely at one time; many companies follow a phase-in approach in which one module is implemented at a time. Some of the most commonly installed modules are sales and distribution (SD), materials management (MM), production and planning, (PP), and finance and controlling (FI) modules. The average length of time for a "typical" implementation is more than a year and can use more than 150 consultants. Corning, Inc. rolled out ERP in ten of its diversified manufacturing divisions in five to eight years (Stedman 1998). The length of implementation is affected to a great extent by the number of modules being implemented, the scope of the implementation (different functional units or across multiple units spread out globally), the extent of customization, and the number of interfaces with other applications.

Customization

ERP packages are very general in nature and need to be configured to a specific type of business. The customization is very tedious and takes a long time, depending on the specific requirements of the business. Customized development can provide a better fit with the operational procedures of a firm, yet often results in a system that is more risky to implement and more complicated to maintain and upgrade (Gebauer and Lee, 2008). An ERP system like SAP is so complex and general that there are more than 8000 switches that need to be set properly to make it handle the business processes in a way a company needs. The more customization needed, the longer it will take to roll out the software and the more it will cost to keep it up-to-date. The length of implementation time could be cut down by keeping the system "plain vanilla" and reducing the number of "bolt-on" application packages that require custom interfaces with the ERP system. However, the downside to this "plain vanilla" approach may or may not completely match business requirements.

Some companies undertake costly customizations to automate its processes on its ERP system—only to learn that the "plain-vanilla" version of the software performed certain functions much better. Companies even pull the plug partway into an ERP project because of functional or even philosophical problems. A technological mistake often made in SAP implementations, says Graham McFarlane, director of Western Management Consultants, is that organizations modify the software more than they should, rather than modifying their business processes (Hilson, 2001). The Military Sealift Command (MSC) successfully implemented Oracle's ERP solution. One rule they cite for achieving ERP success is that agencies must find an ERP package that mirrors their business practices as closely as possible, then resolve to implement the package without significant modifications. MSC managers made a key decision to minimize the risk of ERP implementation by taking a "vanilla" approach. They committed to installing the software as it was packaged, without any modifications. The MSC put together 1,000 requirements the optimal software would fulfill. There were only 11 areas where their processes didn't match the software and the commander made the decision to modify MSC processes to fit the Oracle software (Dean, 2001).

Management Commitment

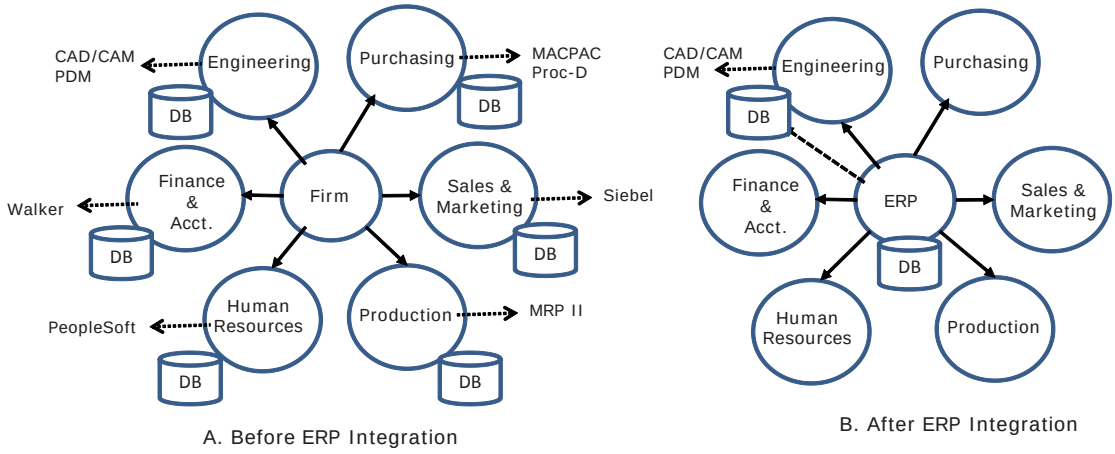
Management commitment for information systems (IS) projects has been researched extensively (Aloini et al., 2007, Aladwani 2002, Ravichandran and Rai 2000). They found empirically that management commitment this work can make human, monetary, and other important resources available for the IS project leading to a conducive and superior problem solving environment as well as

increase the likelihood of IS product quality and efficiency. Top management must consider the strategic implications of implementing an ERP solution (Davenport 1998). Management must also ask several questions before embarking on the project. Does the ERP system strengthen the company's competitive position? How might it erode the company's competitive position? How does ERP affect the organizational structure and the culture? What is the scope of the ERP implementation -- only a few functional units or the entire organization? Are there any alternatives that meet the company's needs better than an ERP system? If it is a multinational corporation, the management should be concerned about whether it would be better to roll the system out globally or restrict it to certain regional units? Management must be involved in every step of the ERP implementation. Handing over the ERP project to the IS department may result as a risk to the entire company's survival because of the ERP system's profound business implications. The top management must not only fund the project but also take an active role in leading the change. The success of a major project like an ERP implementation completely hinges on the strong, sustained commitment of top management. This commitment when percolated down through the organizational levels results in an overall organizational commitment. An overall organizational commitment that is very visible, well defined, and felt is a sure way to ensure a successful implementation (Bingi et al., 1999).

Integration

The system integration between existing information systems and ERP system is a technical problem which might complicate the entire ERP project (Liang and Lien, 2007). Firms have amassed multiple software that are either legacy systems or current add-ons. Different functions of the company have bought or developed different applications and are used to the software. Figure 1 illustrates before and after ERP implementation software integration in a business. Various functions of the firm and possible software associated with each one of the functions and how ERP can be integrated with some of the software are shown in the figure. Some of this software can be replaced

Figure 1. Integrated ERP software in a firm



by the newly proposed system and some of them can be integrated into the software. The databases (DB) of individual software, for instance product data management (PDM) database, can be integrated with ERP database as well. In this case, ERP serves as a backbone, and all the different software are bolted on to the ERP software. There is third-party software, middleware, which can be used to integrate software applications from several vendors to the ERP backbone. Middleware vendors concentrate only on the most popular packaged applications and tend to focus on the technical aspects of application interoperability rather than linking business processes. Many times, organizations have to develop their own interfaces for commercial software applications and the homegrown applications. Integration software also poses other kinds of problems when it comes to maintenance. It is a nightmare for information systems group to manage this software whenever there are changes and upgrades to either ERP software or other software that is integrated with the ERP system.

Until the end of 1996, for example, Dell Computer Corp. planned to roll out SAP's full R/3 suite, but it stopped after implementing only the HR modules. Jerry Gregoire, who joined the company as CIO that year, saw that a single software monolith would not be able to keep pace with Dell's extraordinary corporate growth—the company grows by a billion dollars every six to eight weeks. Instead Gregoire designed a flexible middleware architecture to allow the company to add or subtract applications quickly and selected software from a variety of vendors, including Glovia International LLC, to handle finance and manufacturing functions (Slater, 1999).

Reengineering

Reengineering existing business processes to the best business process standard is one of the activities in ERP implementation. ERP systems are process oriented; therefore only in a process-based organization they can completely express their integration potentiality (Guido and Pierluigi, 2008). ERP systems are built on best practices that are followed in the industry. One major benefit of ERP comes from reengineering the company's existing way of doing business. In this case, all the processes in a company conform to the ERP software and as a result the cost and benefits of aligning these processes with an ERP model could be very high. Since ERP systems such as SAP were built on a foundation of process best practices, it is probably easier and less expensive to change processes to adapt to SAP than the other way around. Many companies have reported good success from combining a SAP implementation with a reengineering project (Bingi et al., 1999).

The concept of reengineering traces its origins back to management theories developed as early as the nineteenth century. The purpose of reengineering is to make all of a firm's processes the best-in-class. In reengineering, there is one best way to conduct tasks.

Initiatives like Business Process Reengineering (BPR) and ERP promise radical improvements in relatively short periods of time. Processes, organization, structure and information technologies are the key components of reengineering. In implementing ERP, both business processes and information technology are combined into integrated software. This automates business processes across the enterprise and provides an organization with a well designed and managed information system. Companies like IBM, Texas Instruments, American Express, Johnson & Johnson, Chrysler, Ford, Shell oil and many others have achieved major reengineering successes. Many organizations have successfully implemented ERP systems and reported huge benefits. Yet many research studies estimate that at least 90 % of ERP implementations end up late or over budget and several failure stories are cited (Jarrar et al., 2000).

Consultants and Other Resources

Consultants are most often used as implementation partners at two to ten times the cost of the ERP software for the initial implementation (Karimi et al., 2007). The client, the management, must be involved in the consulting recruitment process. Simply trusting the consulting firm or not understanding what the consultants know is a risk. The more layers between the project manager and consulting company, the more the consultant's rates are reduced means that the consultants are willing to work for the lower rate and are usually the least knowledgeable.

SAP: ERP SOFTWARE

SAP the company was founded in Germany in 1972 by five ex-IBM engineers. SAP stands *for Systeme, Andwendungen, Produkte in der Datenverarbeitung* which - translated to English - means *Systems, Applications, Products in Data Processing.* SAP AG is now the third largest software maker in the world, with over 17,500 customers (including more than half of the world's 500 top companies). There are more than 50,000 installations of SAP, in over 120 countries, with more then 10 million users! SAP today is available in 46 country-specific versions, incorporating 28 languages including Kanji and other double-byte character languages. SAP R/3 is delivered to a customer with selected standard process turned on, and many other optional processes and features turned off. At the heart of SAP are about 10,000 tables which control the way the processes are executed. Configuration is the process of adjusting the settings of these tables to get SAP to run the way companies want it to. Functionality included is truly enterprise wide including: Financial Accounting (e.g. general ledger, accounts receivable etc), Management Accounting (e.g. cost centers, profitability analysis etc), Sales, Distribution, Manufacturing, Production Planning, Purchasing, Human Resources, Payroll, etc.

SAP is an integrated client/server software application. The features of SAP are as follows:

- Centralized database (ORACLE)
- Planning functions like Material Resource Planning
- Reporting functions
- Business workflow to simulate the business
- Development workbench that uses a language called ABAP (Advanced Business Application Programming)
- Implement Management Guide (IMG) used to configure the system
- An integration of finance, accounting, production planning, logistics, sales, material management, plant maintenance, human resources, etc.

SAP Database

The SAP repository or the data dictionary serves primarily as a tool to enter, manage, delete and evaluate company information. The rules for structuring this information are consistent with the concepts of the relational data model using tables and fields. The data repository is active at all times and therefore the information is always up-to-date and available to all authorized users at all times. The SAP repository is built on a table structure. A database most often contains one or more tables. Each table is identified by a name (e.g. "Customers" or "Orders"). Tables contain records (rows) with data. As shown the Figure 2, there are four different tables for configuration, control, master data and transaction data. System configuration tables are tables that define the structure of a system. An example of this type of table is one that defines the peripherals such as printers. To customize the system, the other three tables are used. Control tables define

Figure 2. SAP table structure

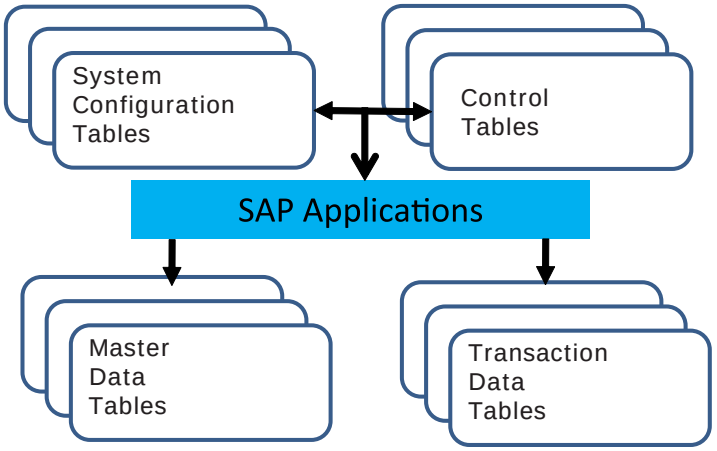


Figure 3. SAP modules

FI (Financial Accounting) • General ledger • Book close • Tax • Accounts receivable • Accounts payable • Consolidation • Special ledgers	**CO (Controlling)** • Cost elements • Cost centers • Profit centers • Internal orders • Activity based costing • Product costing	**MM (Materials Management)** • Requisitions • Purchase orders • Goods receipts • Inventory management • BOMs
SD (Sales & Distribution) • RFQ • Sales orders • Pricing • Picking • Packing • Shipping	**CA (Cross Applications)** • WF – workflow • BW – business warehouse • Office – for email • Workplace • Industry solutions •CRM, PLM, SRM, APO etc	**PP (Production Planning)** • Capacity planning • Master production scheduling • Material requirements planning • Shop floor
AM (Asset Management) • Purchase •Sale •Depreciation •Tracking	**HR (Human Resources)** • Employment history • Payroll • Training • Career management • Succession planning	**QM (Human Resources)** • Planning • Execution • Inspections • Certificates

functions that guide the users their activities. For example, a control table might be designed such that a material master data is entered before a purchase order is accepted. Control tables contain the structure or the process of the company. These tables contain data such as which plants are related which products, which sales organizations are related which products, etc. Master data tables

define customers, vendors, materials, equipment, etc. Customer master data might include customer name, address, contact information, etc. This table might also be related to other tables that represent the location of warehouse or repair shops that support the customer. Transaction data table represents the daily operations data such as sales orders, invoices and shipments. SAP modules are shown in Figure 3.

Business Case for ERP Implementation: IT Strategy

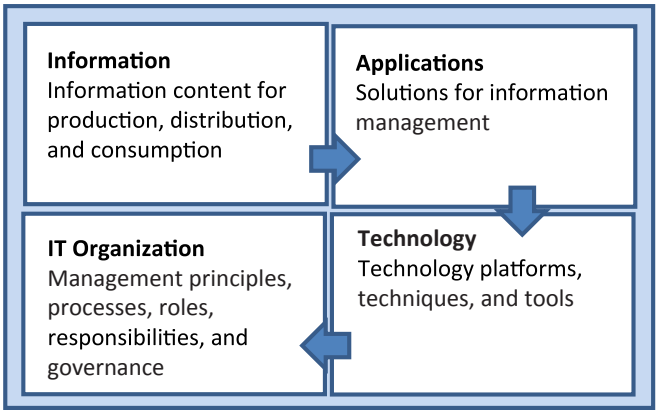
Companies implement ERP for many reasons. Y2K (Year 2000) was a costly fix for many companies and many of them resorted to ERP as a strategy as an easy, less costly to fix the Y2K problem. However, these companies found out that the reality was that ERP takes more time, more difficult to install, and cost as much if not more. As a result of the cost and time involved with the ERP implementation, a business case is needed. The thought process of IT department in many of the organizations can be generalized as below in Figure 4 (Norris et al. 1998). Figure 4 shows the four main components in this thought process. Information is gathered to be consumed and this information is managed by applications. The applications have to be created and managed by technology. Technology has to be managed by IT organization with its roles and responsibilities, and governance. As Norris et al. (1998) points out IT organizations need to answer the following questions on information:

1. What is the information?
2. Where does this information come from?
3. How do we create information from data?
4. How does information get distributed?
5. How does information get consumed?

The answers the above questions lead to the software applications. This is the level that users of IT and developers of IT deal with most of the time. Here the following questions need to be answered:

1. What applications does the company currently use to collect, collate, compute, and transform to useful information, store, distribute, and retrieve data?

Figure 4. IT thought process in a company (Adapted from Norris et al., 1998)



2. Is there a better application software available to carry out these tasks in a more efficient, less time-consuming, less resource-consuming and less expensive way?
3. Is there software available as Complete-Off-The-Shelf (COTS)?
4. By using this software, could the company redirect resources into other areas of the business in which it can establish and maintain competitive advantage?

Then the decision on hardware begins especially on technology platforms, techniques, servers, tools, etc. Each company has a different perspective on each one of these objects. For example, SAP is platform independent and has as a company provided an open-architecture presence which is an advantage for corporations. Finally, the questions to be answered for the IT organization are as follows:

1. What management principles will govern IT organization?
2. What processes for system development, operations, support and maintenance are used?
3. What are the roles and responsibilities of all the individuals in the organization?
4. What is the relationship as in power structure between the IT organization and the business units?

This thought process need to be followed before the implementation of SAP which will ensure smooth implementation. Once an IT strategy has been developed, and once an ERP solution is determined to be right, a company is ready to build a business case. Business case involves analysis of cost and benefits and determining the payback period for the expenses incurred for the implementation and getting the approvals from leadership.

Norris et al. (1998) shows how the complexity of the implementation, as well as the project risk and cost, increases as a company moves out on the continuum of the degree of business process change and up along the continuum of organizational change. As the level of business process change is increased, the level of organizational change necessary to carry it out must also increase. The key to successful implementation is assertive control over the project's scope and over the degree of business process changes to be undertaken. Clear objectives and justification (Weston, 2001), evaluation and selection (Van Everdingen et al., 2000), alignment between the ERP package and business strategies and requirements (Somers and Nelson, 2003) as part of the business case are critical to the success of implementation. To build a cost-based business case for ERP, firms need to extract savings that depend on ERP alone from the total savings to be had from ERP together with other sources. Wagle (1998) proposed five steps that include:

1. Create a base case of year-by-year savings from cost cuts that could be made without the ERP system in place.
2. Create an ERP case of year-by-year savings that could be made with ERP. This should include savings that do not depend on ERP as well as those that do.
3. Subtract the base-case savings (step 1) from the ERP-case savings (step 2) on a year-by-year basis, and calculate the net present value (NPV) of the residual cash flow. A positive NPV will indicate that the firm should probably proceed with the deployment of ERP.
4. If step 3 produces a positive NPV, conduct a sensitivity analysis to ensure that the business case is strong enough to withstand slippage and cost overruns.
5. Back-allocate all ERP system deployment costs to individual business units so that they can factor them into their planning. Ensure each unit is held responsible for producing the promised savings.

To summarize, the following factors need to be considered for the business case:

1. The decision must be driven by the business considerations, not merely the desire for new technology
2. Firms need to extract savings that depend on ERP alone from the total savings to be had from ERP together with other sources
3. ERP system will not solve business process and organizational dynamic problems.
4. ERP implementation cannot be delayed until the company is able to use to its fullest ability.

SAP IMPLEMENTATION STEPS

Botta-Genoulaz et al. (2005) in their survey of research literature note that recent research is on ERP post-implementation issues, customization of ERP projects, and the sociological issues of ERP systems, and return on investment of ERP systems. Implementation should depend on the size of the company (Mabert et al., 2003) and industrial sector (Wu and Wang, 2003). The roadmap to ERP or SAP is shown in the figure 5. The roadmap consists of five key functions that include:

- Project Preparation
- Business Blueprint
- Realization
- Final Preparation
- Go Live and Support

Each one of these functionalities has various steps. The following figure shows the implementation steps for enterprise software. The design and implementation phase consists of the following functionalities:

- Establishing hardware and SAP settings
- Establishing the key master data

Figure 5. SAP implementation roadmap

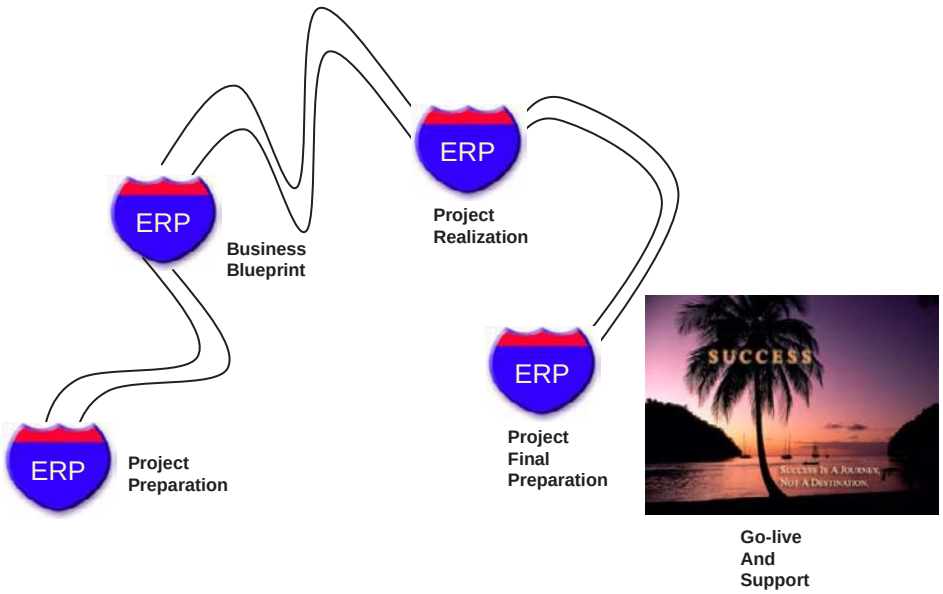


Figure 6. SAP implementation model

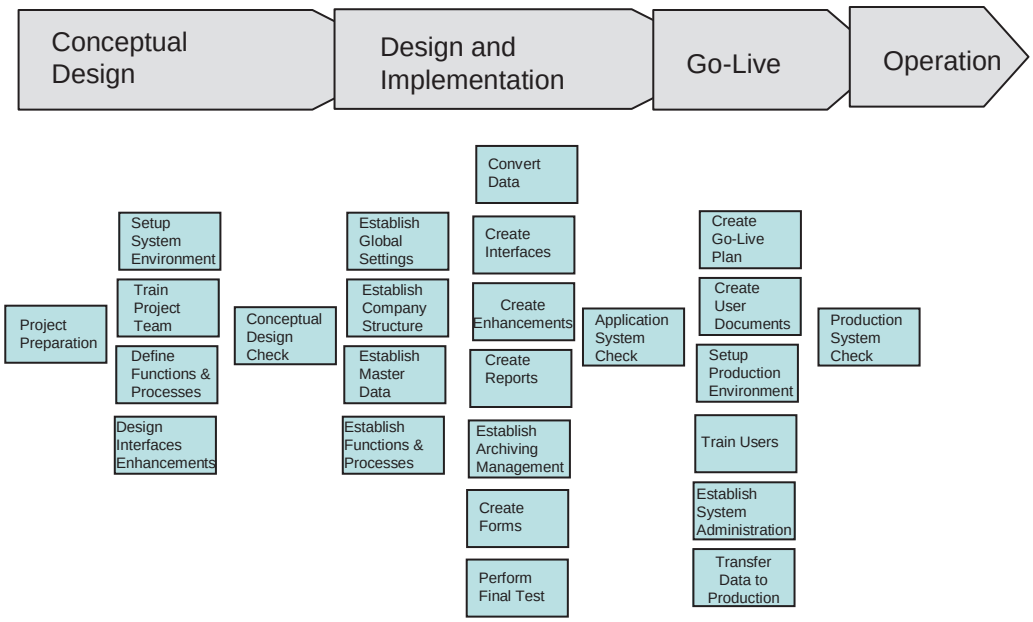

- Establishing the processes and functions inside the organization
- Implementing Reports, Interfaces, Conversions and Enhancements (RICE)
- Testing the system
- Training the users
- Go-Live
- Post production maintenance and support

The reason that ERP system implementations are time-consuming and costly is because of the complex nature of the implementation and the dynamics of the implementation involving with the organization. The basic functionalities described above may be expanded and is shown in Table 1.

Project Preparation

The purpose of this activity is to start detailed planning for the project. There are many basic issues to resolve at this early stage to ensure the project's success. The principal elements that determine how the ERP project is accomplished will be established in this phase. These activities set the groundwork for project kickoff, and provide a baseline of information to be referenced throughout the implementation. For all project team members to operate in an effective manner, it is necessary that project standards and procedures are established at the beginning of the project, and then communicated to all team members. Project planning is an ongoing cycle and should be constantly refined. Even when the project plan is created, it must be made clear that project planning is a continual, rolling process. As the project progresses, fewer revisions are necessary. In the SAP Business-to-Business Procurement system, requirement coverage requests for non-production materials or services are directly processed further, and purchase orders are placed. If data is missing for purchase orders, the Materi-

als Management functions are used to complete them. The follow-on documents for the purchase orders are also created in the SAP Business-to-Business Procurement system (confirmation, goods receipt / service entry and invoice). This phase also includes defining end user training and

documentation strategy. This includes analyzing and developing the training and documentation strategy with the overall implementation strategy and project plan.

The results of this activity are:

- Project Plan (Work Plan, Budget Plan, Resource Plan).
- Project management standards and procedures.
- ERP implementation strategy.
- Approved project organization
- Configuration standards
- End user training and documentation strategy
- Testing strategy
- Post-implementation support strategy
- Design of the company's system landscape, including its setup and maintenance strategy
- Official start of the project, presentation of the input mentioned above, explanation for any issues or questions about the project from the kickoff meeting participants.
- All project team members have attended Level 1 courses and have an introduction to ERP, navigation skills, and knowledge of major integration points of the system.
- The formal sign-off of Phase 1.

Business Blueprint

The purpose of this activity is as follows to create the Business Blueprint, which is a detailed documentation of the results gathered during requirements workshops. Furthermore, the Business Blueprint documents the business process requirements of the company. This phase also establishes a proper cycle of project management activities to ensure that the implementation project is on target. It determines all project planning, controlling and updating activities. It also identifies where changes in the relationship between business processes and the organizational structure need to be managed, in consultation with departmental management. The same work package is also in the subsequent phases. It is also defined now what content the customer needs, what user populations and needs that content will serve, and how the content will be structured. Also, definitions of enhancement contexts that customers need to create and maintain their own materials are completed. In general, the idea is to start with a single context and then create additional contexts based on the first one. The relationships between enhancement contexts are called enhancement chains. Description of processes and sub-processes that are particular to the following business processes such as training management, performance assessment, and web content management are also completed in this phase. At this time, all user master records with roles and responsibilities along with authorizations for the project team members are also created.

The business process definitions create the Business Blueprint. In case of a rollout most of the company requirements should already be determined and mapped to the corresponding ERP software settings. The Business Blueprint serves as the conceptual master plan, and eventually becomes a detailed written document. This document shows the business requirements in detail, and serves as the basis for organization, configuration and, if necessary, development activities. End User Requirements Document, Current Data Warehouse and Information Access Environment Document, Master Data/Transaction Data Requirements Document, Data Mapping Document, Data Access Recommendations Document, and Data Management Requirements Document are also completed.

The outputs of this activity are:

- Regularly scheduled project status meetings
- Updated Project Plan
- Definition of end user roles and responsibilities
- Quality Reviews

- Content Requirements document, which identifies user populations, existing information, and new information requirements.
- A business blueprint
- The technical infrastructure (network, system, and front-end environment) is documented
- A signed Business Requirements Analysis Document to include Completed business process questions, Completed CI template, Completed KPI template

Realization

The purpose of this phase is to implement business and process requirements based on the Business Blueprint. The objectives are final implementation in the system, an overall test, and the release of the system for production (live) operation. The project team also receives relevant knowledge. All testing is completed in order to implement the completely functional system

RESULT

The outputs of this activity are:

- Implementation of all necessary enhancement contexts, enhancement releases, and enhancement context chains
- The data extraction is configured.
- Configured and tested ERP system.
- Tested programs to migrate into the QA environment
- ERP system meets the business application requirements as defined in the Business Blueprint.

Project Final Preparation

The purpose of this phase is to perform the established cycle of project management activities to keep the implementation project on target. This determines all project planning, controlling and updating activities, and identifies changes between business processes and the organizational structure. Project management and consulting management must work closely together to guarantee that the project stays on schedule. Also, technical and performance tests will be conducted to verify that the production environment is ready and can be supported for productive operation. These tests should be performed in the actual production environment or in an environment that closely represents the actual environment. At this time, the move from a pre-production environment to live production operation will be done. In addition, it is important to monitor system transactions and overall performance. During the process of going live, there are two critical periods. In the first few days, the team must execute the production support plan and check the results. Any issues or problems that occur in this period must be resolved as quickly as possible. Following the first few days of live operation, monitoring issues for the long term, particularly with reference to system performance, capacity and functions should be addressed.

The results of this activity are:

- All roles and responsibilities defined with proper backups in place
- All procedures and responsibilities documented and signed off
- The entire technical infrastructure is tested and validated, including failure scenarios and disaster recovery.
- The configuration of the system and the procedures defined for the technical environment are tested and validated.
- A stress test is carried out successfully. Its result determines the validity of the planned go-live date.
- All ERP system aspects and support organization is approved, and the production system is released.

- The output of this activity is the formal sign-off of Phase 4.

CONCLUSION

A brief ERP implementation procedure using the SAP implementation documentation as well as issues regarding ERP implementations are detailed in this chapter. ERP implementations in the recent years have raised a number of questions regarding its success. Many companies regard ERP as their one and only savior and many others despise that ERP as a single system has brought them to their knees. Regardless, many more companies, small to medium size companies in particular, are beginning to invest in ERP. An industrial practitioner from such small to medium companies needs to understand how to implement ERP. This study provides the necessary tools and background for the industrial practitioner to implement not only ERP systems but implement the next generation of enterprise applications as well.

KEY TERMS

Customization: Customization refers to modifications to the original software that is typically not supported by the software vendor and those needed by the customer because of their unique business processes.

Enterprise Resource Planning (ERP): Software systems for business management that integrates functional areas such as planning, manufacturing, sales, marketing, distribution, accounting, finances, human resource management, project management, inventory management, service and maintenance, transportation, and e-business.

Enterprise Systems: Enterprise systems are software that provides solutions to an integrated business organization.

Implementation: Implementation consists of defining a project, putting together project teams, reengineering of existing business processes, customizing the software to reflect new business processes, testing the software in organizational environment such that the software is usable for the organizational users.

Integration: ERP software integration is the process of integrating ERP systems with other enterprise information resources or systems within an enterprise.

Management Commitment: Management commitment is direct participation by the highest level executives in a specific and critically important aspect or program of an organization.

Chapter 4.25
Teaching Operations Management with Enterprise Software

R. Lawrence LaForge
Clemson University, USA

ABSTRACT

Enterprise systems technology is used to enhance the teaching of operations management through development and operation of a virtual manufacturing enterprise. An ongoing, real-time simulation is conducted in which operations management issues in the fictitious factory must be addressed on a daily basis. The virtual manufacturing enterprise is integrated into an operations management course to facilitate understanding of the dynamic and interrelated nature of operations planning and control in a complex manufacturing environment. Enterprise software supports the primary learning objective of understanding how operations management decisions affect customer service, capacity, inventory, and costs.

INTRODUCTION

This chapter presents an approach to teaching operations management (OM) with enterprise systems technology. The approach described here is based on the premise that the topics taught in operations management courses are dynamic and interrelated. Therefore, the teaching and learning of operations management should address not only the content of each specific topic, but also the dynamic interrelationships among the topics.

The integration of OM topics is extremely difficult to accomplish in a traditional classroom setting. There are several excellent OM textbooks available in the market, and they generally provide information needed to study the content of OM topics such as aggregate sales and operations planning, master production scheduling, material planning and control, capacity planning and control, and production activity control. However,

textbooks are a static medium that cannot capture the dynamic interrelationships between and among the topics. The topics in an OM textbook must necessarily be presented in sequential fashion organized by chapter or unit, and conventional testing typically focuses on the content (issues, concepts, tools, techniques) related to each topic. True insights into the connections among the topics are extremely difficult or impossible to glean from even the best textbooks.

As an example of the interrelationship of operations management issues, consider the topics of aggregate planning and production activity control. Aggregate sales and operations planning deals with the company's overall strategy for meeting anticipated demand of broadly-defined product families over a planning horizon of 12-18 months. Production activity control, on the other hand, deals with day-to-day (or hour-to-hour) scheduling and sequencing issues for internal shop orders to make component parts or assemblies needed for specific products. The two topics are at extreme ends of the continuum and are invariably covered in completely different sections of the typical OM text, but they are in fact highly interrelated. While we might be tempted to seek sophisticated algorithms and models to help with complex scheduling issues that occur on a daily basis, it may be that our day-to-day scheduling issues are the result of poor overall planning at the product family level.

The previous argument suggests that conventional classroom lectures, textbook readings, and end-of-chapter exercises are *necessary* but *not sufficient* to gain insights needed to understand operations management. This chapter describes an ongoing project in which the desired synergy is addressed by the introduction and use of enterprise-wide system (ES) technology in the operations management classroom.

The objectives of this chapter are to raise the level of awareness regarding the need for active learning approaches to operations management, to describe in detail an approach to teaching OM with enterprise technology, and to discuss lessons learned that may be of benefit to other scholars and teachers interested in this approach.

BACKGROUND

The practice and teaching of operations management has been impacted significantly by advancements in information technology (Manetti, 2001; Rondeau & Litteral, 2001). The development of material requirements planning (MRP) systems in the 1970's revolutionized thinking about how to manage materials in a manufacturing environment. This provided an alternative to economic lot size models that assumed that demand for all inventory items was independent, and it promoted more of a systems perspective to materials management. This was followed by manufacturing resource planning (MRPII) systems that provided additional functionality related to capacity planning, limited financial analysis, and "what-if" planning. More recent enterprise resource planning (ERP) systems aim to link together the various functional areas of operations, accounting, finance, customer relationship management, and human resources. ERP systems can be enhanced with advanced planning system (APS) modules for obtaining near-optimal scheduling, manufacturing execution system (MES) modules for shop floor control, and/or supply chain management (SCM) modules designed to integrate planning and execution with suppliers and customers.

A key aspect of this evolution is integration. Organizations have made significant investments in hardware, software, and training to install, maintain, and use enterprise-wide systems designed to better integrate their activities (Hitt, Wu, & Zhou, 2002; Mabert, Soni, & Venkataramanan, 2000). It is logical to assume that collegiate schools of business would also value, and seek to achieve, higher levels of integration in the topics taught in the curriculum (Cannon, Klein, Koste, & Magal, 2004; LaForge & Busing, 2000).

In operations management, the objective of topic integration could be pursued in two ways. One way is to seek greater insights into the interrelationships of topics taught in a given OM course. Another way is to focus on the impact of operations management decisions on other functional areas in the organization such as accounting, finance, marketing, and human resources or on inter-organizational issues with suppliers and customers. That is, the goal could be integration within a given course and/or integration across courses. This chapter provides details on the first approach, which has been implemented under the assumption that one must achieve a high level of understanding of operations management issues before assessing their impact on other areas. However, the chapter also includes a discussion of efforts to achieve "across course" integration, which builds on the application of enterprise software in the operations management course described next.

THE OPERATIONS MANAGEMENT COURSE

The section describes an operations management course that has been enhanced by the use of enterprise software. The course is an advanced, undergraduate course in operations planning and control taken by primarily by management majors at Clemson University. The course topics are aggregate sales and operations planning, master production scheduling, material planning and control, capacity planning and control, and production activity control. The textbook used in the course is a primary study reference for the *Certified in Production and Inventory Management* (CPIM) examinations offered by APICS — The Society for Operations Management. Traditional classroom activities such as textbook readings, lectures, end-of-chapter exercises, and testing of content are involved.

A primary learning objective of the course is to understand and appreciate the dynamic interrelationships among the course topics. As discussed earlier, the traditional classroom activities are necessary to establish content knowledge of each major topic, but do not address the integration of the OM activities in a meaningful way. The issue of integration of OM topics in the course is addressed in the same way that a manufacturing company would address the issue of integration of key OM activities in its facilities — through the introduction of information systems technology. The technology is used to create and operate a virtual manufacturing enterprise in which the OM issues under study are carried out simultaneously on a daily basis. The virtual manufacturing enterprise is the focal point for active learning opportunities that address the integration issues and learning objectives. Table 1 shows details from the course syllabus regarding the body of knowledge and learning objectives.

In the following section, the virtual manufacturing enterprise is described in terms of four components necessary to create and maintain it. This will be followed by a detailed description of how the virtual enterprise is used to address the learning objective.

The Virtual Manufacturing Enterprise

The virtual manufacturing enterprise can be described by the four components shown in Figure 1. These elements consist of the body of knowledge, manufacturing database, enterprise software, and enterprise information. The following sections explain the four components of the virtual manufacturing enterprise and address key issues in developing each component.

Body of Knowledge

The most important component of this approach to teaching operations management is a clear

Table 1. Syllabus information for the OM course

Management 402
Operations Planning and Control
Clemson University

NATURE OF THE COURSE:

This course examines important concepts and procedures involved in managing the operations of a business enterprise. All class meetings take place in the Manufacturing Management Laboratory. This laboratory provides access to a realistic simulation of a business operation utilizing a state-of-the-art enterprise resource planning (ERP) system that is widely used in industry.

Students will study important concepts, issues, and procedures of an operations planning and control system, and then put this knowledge to work in a virtual manufacturing enterprise that is supported by the ERP system. Class meetings will be a combination of lecture and student participation. The basic concepts and procedures will be presented through instructor lecture, reading assignments, and class/homework exercises. The concepts will be reinforced through "hands on" experience with the ERP system and the virtual enterprise. Particular attention will be paid to the interaction of planning/control activities, and how decisions made at one level of the planning process affect output and performance at lower levels.

A model manufacturing company — Orange Office Products — is used to illustrate many of the topics in the course. Orange Office Products is a fictitious manufacturer of office furniture equipment that was developed specifically for use in this course. The database for Orange Office Products has been installed on the ERP system, providing live information about products, inventory levels, plant capacity, manufacturing orders, purchase orders, and much more.

Orange Office Products is an ongoing, real-time simulation of a manufacturing operation. The database changes daily to reflect the activities of the company. Students in Management 402 will observe and participate in many of these important operations management activities.

MAJOR TOPICS IN THE COURSE:

1. Overview of Planning and Control Systems
2. Material Planning and Control
3. Production Activity Control
4. Aggregate Sales & Operations Planning
5. Master Production Scheduling
6. Capacity Planning

OBJECTIVES OF THE COURSE:

Students who complete this course should be able to:

1. Explain the basic components of an operations planning and control system;
2. Understand the interrelationships among planning and control activities in a business operation, and their impact on customer service, inventory, capacity, and costs.
3. Develop, apply, and interpret the results of basic procedures for inventory planning, capacity management, shop floor control, aggregate production planning, and master scheduling;
4. Understand and appreciate the importance of operations management and the role of information technology in modern planning and control systems.

continued on

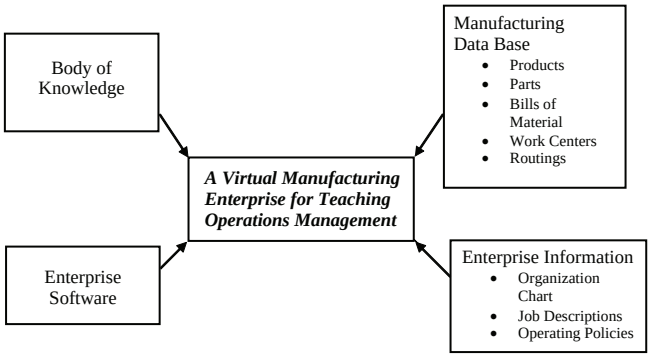
Table 1. Syllabus information for the OM course (continued)

OBJECTIVES OF THE COURSE:

Students who complete this course should be able to:

1. Explain the basic components of an operations planning and control system;
2. Understand the interrelationships among planning and control activities in a business operation, and their impact on customer service, inventory, capacity, and costs.
3. Develop, apply, and interpret the results of basic procedures for inventory planning, capacity management, shop floor control, aggregate production planning, and master scheduling;
4. Understand and appreciate the importance of operations management and the role of information technology in modern planning and control systems.

Figure 1. Components of the virtual manufacturing enterprise



statement of the body of knowledge to be taught. All other components of the virtual manufacturing enterprise, and all other activities, should be undertaken with the objective of addressing or supporting the body of knowledge in some way. This is important because without a clear statement of the body of knowledge, one may fall into the trap of teaching what a software package does rather than teaching what the curriculum says. As shown in Table 1, the body of knowledge for the OM course described here consists of concepts, issues, and tools for performing the previously-mentioned topics of aggregate sales and operations planning, master production scheduling, material planning and control, capacity planning and control, and production activity control.

Manufacturing Database

The database provides needed details of products, parts, bills of material, routings, work centers, customers, and suppliers. These details are essential for developing a realistic enterprise model capable of capturing the issues in the body of knowledge. While realism is needed, this does not mean that the database must consist of hundreds of products and thousands of parts. Realism in the database can and should be achieved through complex interrelationships among the elements, not through sheer size. Experience here suggests that size of the database is not as important as well conceived connections among the elements.

An original database for a fictitious manufacturing enterprise was created for the operations management course in this project. The decision to create an original database, rather than use sample data provided by the software vendor, was made to allow complete control over the size of the data set and the interacting components that result in operations management issues addressed in the course.

The fictitious manufacturer produces metal-based office furniture products. This environment was chosen because the products are common items that are easy to conceptualize for students with little or no practical experience in operations management. The database contains technical descriptions of five standard office furniture products that are manufactured in a make-to-stock environment: (a) three-shelf adjustable book case, (b) three-drawer file cabinet, (c) two-drawer work desk, (d) standard desk chair, and (e) one-shelf credenza. In addition to manufacturing details, a chart of accounts and other financial information were created to facilitate use of the virtual enterprise in accounting and other business courses, as discussed later in the chapter.

The inventory portion of the manufacturing database consists of 45 total items, including the five finished products. Twenty-two of the items are manufactured in house, while 23 are purchased from suppliers. The manufactured items typically consist of metal parts (handles, frames, brackets, shelf units, etc.), while the purchased items include raw sheet metal, hardware, paint, packaging materials, wooden parts, and accessories.

Bills of material were created to link the items needed to make each product. These documents are multi-level in nature, reflecting a process that flows from purchased materials to manufactured parts to assemblies to final products. Several items are common to different products, including handles, shelf units, and a major drawer assembly.

The manufactured items in each bill of material are made in a production facility consisting of nine distinct work centers. A routing file was created for each manufactured item that identifies the work center sequence required and the standard setup time and standard run time per unit for processing the item. Multiple operations are required to make each manufactured item. Defined shift lengths dictate the available capacity of each work center.

The database supports the body of knowledge by being small enough to allow manual calculation and tracking of some issues, but large enough to capture complex interrelationships impacted by operations management decisions. The major challenge in creating the manufacturing database was establishing parameter values (routing steps, standards for setup times and run times, work center capacities, planned lead times, etc.) that result in shop loads that introduce meaningful operations management issues to students. Capacity planning modules in the enterprise software assist in this issue by providing projected workloads for a given configuration of parameter values, facilitating adjustment of planning parameters as necessary. Development of the database is an ongoing activity, allowing the introduction of new parts, revised routings, adjusted planned lead times, and various other issues.

Enterprise Resource Planning Software

Introduction of enterprise resource planning software into an academic course obviously requires an answer to the following question: What software should be used? In this context, software should be viewed as the enabling technology that allows issues in the body of knowledge to "come to life" in a dynamic and realistic way. The functionality needed in the software is defined by the body of knowledge. Ideally, software selection should focus on systems that implement generally-accepted methods to address and integrate issues under study. That is, the software should be consistent with the methods described in the text and established in the curriculum. What the software does is give life to the issues and help create a dynamic and meaningful context for studying them.

Realistically, other issues come into play in the software selection decision. Costs associated with hardware, implementation, training, and maintenance must be considered. With the budget constraints and limited technical support that exist at many universities, these issues must be carefully weighed to ensure that the system can be sustained. However, the compatibility of the software with the body of knowledge must be the overriding consideration. It would be indefensible to introduce a software system into the curriculum simply because it was available or easy to maintain without regard to the value it adds to pre-established learning objectives for the subject matter in the course or curriculum. The teaching approach should not be software specific.

Fortunately, there are many software options available that are consistent with generally-accepted practices in operations management. In addition, many software vendors have special pricing arrangements, or make free donations of software and support, for educational institutions using their products in the curriculum. Over the twenty years in which the project described here has been under development, four different software systems, each from a different vendor, have been utilized.

Current enterprise software system support for this project comes from the Microsoft Dynamics Academic Alliance. This alliance not only provides software, but also support, training, and opportunities to interact with faculty at other institutions. Specifically, the activities in the virtual manufacturing enterprise are supported by the Manufacturing Series of Microsoft Dynamics GP 9.0. The system runs on a Dell PowerEdge Server 2600, with the client applications available through the Clemson University network to smart classrooms and laboratories throughout the campus.

Enterprise Information

This component of the virtual manufacturing enterprise refers to a description of the enterprise in sufficient detail to establish the context in which the simulated company operates. This background information is important for students to get the feel of a realistic enterprise. In addition to background information on the company, this material also includes defined roles in the virtual manufacturing enterprise that relate to the body of knowledge, as well as policies and operating procedures. Details of this information will be presented later in the chapter.

OPERATING THE VIRTUAL MANUFACTURING ENTERPRISE

The virtual enterprise is operated in a continuous, real-time mode without regard to the starting and ending dates of academic terms. The calendar in the enterprise system is maintained so that the factory is closed on academic holidays and other "down time" in the academic calendar. However,

the database is never reset back to initial conditions. In this manner, the virtual manufacturing enterprise is, in every sense, a going concern.

Daily decision making and transaction processing are required in the virtual manufacturing enterprise just they are in a real company. The virtual factory operates in real-time mode in that daily decisions must be made on matters related to accepting customer orders, shipping products, updating operating plans, managing materials, allocating capacity, and implementing scheduled work activity. A number of random events can be incorporated into the virtual factory that must be considered in the daily decision making, such as actual customer demand, vendor performance, and unexpected down time in work centers. Daily transaction processing is required to report all decisions, activities, and events affecting the virtual enterprise and keep the database up to date. Each day materials and products are moving through the virtual factory from receipts of raw materials, and processing of manufacturing and customer orders. At any time that an inquiry is made into the information system, the user sees current dates related to all activities. In short, the system is live and operated on a day-to-day basis.

The previous operational decisions were made to achieve the realism needed for meaningful active learning tasks that capture the dynamic interrelationships among the operations management topics taught in the course. Without such realism, only static inquiries into the system would be possible. While important to achieving the learning objectives of the course, this realism comes with a price. There is an "overhead" associated with operating the virtual enterprise in the form of instructor or graduate assistant time needed to perform the daily decision making and transaction processing necessary to keep the database current. To minimize the overhead of the daily routine, all activities are periodically evaluated to ensure that they add value with regard to accomplishing the learning objectives.

New features or issues that could be incorporated into the operation of the virtual factory are considered by weighing the potential value added to student learning against the additional overhead required to implement and maintain the new feature. For example, should routines be added to introduce uncertainty into all activities of the factory (e.g., processing times, lead times, customer demand, machine availability), or will uncertainty in final customer demand introduce enough uncertainty to create a meaningful scenario? In this project, uncertainty in final customer demand suffices, but that may not necessarily be the case in other situations with more experienced students in graduate programs, or in courses with different learning objectives.

USING THE VIRTUAL ENTERPRISE TO ACHIEVE THE LEARNING OBJECTIVES

The virtual enterprise is integrated into the operations management course in two ways that are described in detail in the following sections. First, activities are described for integrating the virtual factory into routine class activities. Next, a major project is described in which selected students assume managerial roles in the virtual enterprise and participate in daily decision making and transaction processing.

Class Activities Using the Virtual Manufacturing Enterprise

Students in the operations management course are seated at a work station and have access to the live ERP system during all class sessions. This enables the instructor to enhance traditional classroom instruction with the live system, providing a meaningful context for the course topics. The virtual manufacturing enterprise enhances, but does not replace, traditional classroom activities

such as lectures, discussion, and problem solving. After basic concepts and methods for a particular topic, such as material planning, have been addressed, students access data in the live system to explore key issues within the context of the virtual enterprise.

There are generally three objectives in using the virtual factory and enterprise software in the manner described above to enhance traditional classroom instruction: (1) identifying key concepts or issues, (2) verifying outputs of planning functions, and (3) understanding dynamic interrelationships.

Identifying Key Concepts or Issues

This provides a meaningful context for key concepts in the text that might appear to students to be abstract, and it facilitates more meaningful discussion of the issues. Rather than memorize a concept or definition, students have an opportunity to see practical implications of the issue. For example, material planning activities in the MRP module of the system rely on user-supplied parameters referred to as planned lead times. Memorizing the definition of "planned lead time" is one thing, but coming to grips with the fact that MRP-based planning cannot begin until we enter these numbers, understanding what one must do to establish reasonable values for this planning parameter, and realizing the implications of using "bad" numbers are much more valuable lessons for operations management students.

Verifying Outputs of Planning Functions

This enables students to test their knowledge of planning methods with live data in the ERP system. With a carefully constructed database that is realistic in connecting the various elements but small in size, students can manually verify some outputs of the system. For example, the MRP record for a purchased item in the database may show a planned order release on the current date for certain quantity of the item. This means that we should launch a purchase order today to the supplier of the item for the specified quantity. Without the planned purchase order, we will not have sufficient quantity of the item to meet projected requirements for the item in the future. While most ERP training would focus on the transaction processing necessary to create and release the purchase order, the focus here is on the planning logic that resulted in the order recommendation in the first place. Why is the system telling us to do this?

Operations management students who have studied the basic logic of material requirements planning should be able to answer the above question by accessing relevant data from the live system (current master production schedule, bills of material, planned lead times, available inventory, and open orders), and applying the same MRP logic used to work end-of-chapter problems in the text. Successful completion of this exercise goes beyond simply accessing information in a computer system — it requires knowledge of how that information has been generated and, therefore, provides insights into the usefulness and potential limitations associated with the information. Further, because the virtual factory operates on a real time calendar and is updated daily, students can test their skills repeatedly since the numbers are constantly changing with new conditions in the factory.

Understanding Dynamic Interrelationships

This is a key learning objective and is facilitated by the live system in which the various operations planning and control activities are taking place simultaneously. Some key links between planning activities can be examined in classroom sessions in which changes are introduced into the system.

Table 2. Using the virtual manufacturing enterprise for class activities

Identifying Key Concepts and Issues

Using the live system to access data and discuss issues related to:

- Importance of planned lead times
- Impact of ordering policies
- Importance of inventory record accuracy
- Meaning and use of "floor stock"
- Impact of standard queue times in scheduling
- Differences between backward and forward scheduling

Verifying Outputs of Planning Functions

Applying standard methods in the textbook to verify data in the live system related to:

- Projected available inventory
- Available to promise
- Order recommendations in material requirements planning (MRP)
- Rescheduling messages for open orders
- Operation due dates for scheduled manufacturing orders
- Projected work center loads

Understanding Dynamic Interrelationships

Using the live system to assess cause-and-effect relationships, such as:

- Changes in the material plan needed to accommodate a special customer order
- Capacity needed for a change in the master production schedule
- Effect of reducing planned lead times on shop capacity
- Impact of shop downtime on meeting the master production schedule
- Effect of reducing setup times on shop capacity
- Impact of different scheduling approaches in the shop
- Material planning actions needed to overcome scrap on the production floor

For example, a change in the master production schedule of a finished product could be made during a class session to accommodate an unusually large customer order. This in turn will trigger a series of changes in material plans, capacity needs, and work center schedules that are explainable, tractable, and predictable. Working through these changes gives students insights into the dynamics of operations management that are not possible in a traditional setting. These are extremely important insights that help students understand trade-offs involved in balancing customer service objectives with inventory and capacity issues.

Table 2 provides additional examples of the use of the virtual manufacturing enterprise and ERP system to enhance class activities.

Class Project in the Virtual Manufacturing Enterprise

In the first half of the semester, all daily decision making and transaction processing necessary to run the virtual factory are done by the instructor and graduate assistant assigned to the project. During this period, students in the operations management course are engaged with the enterprise system through the class activities described above, but are limited to inquiry capabilities and have no decision making or transaction processing authority in the system.

At approximately mid semester, selected students take an active role in the daily management of the virtual enterprise as part of a course project. In the target OM course, selection is based on student performance, motivation, and career interest. Participating students perform all project activities during special laboratory hours held outside of the normal class meeting time, and must agree that a formal assessment of their performance in the project will become their final examination grade in the course. In this manner, the participants substitute an active learning project that addresses all course concepts for the traditional cumulative final examination.

The student roles relate to the body of knowledge in the course. The three major roles related to the target course are master production scheduler, inventory planner, and work center manager. Multiple students can occupy each of these roles at the same time. In addition, roles are defined for the plant manager, materials manager, and production manager. The plant manager role is performed by an assigned graduate assistant with significant work experience in operations management, while the materials manager and production manager are undergraduate students enrolled in a special independent study course who completed the target operations management course in a previous semester (and therefore previously served as master production scheduler, inventory planner, or work center manager). Brief job descriptions of each of these key roles are provided in Table 3.

The student roles require content knowledge of operations management topics acquired through traditional classroom activities. It is for that reason that assigned student roles go into effect near the midpoint of the semester, at which time the student team replaces the instructor and graduate assistant in the daily decision making and transaction processing necessary to keep the system live and current.

Enterprise policies are published that provide general guidelines for student activity in the virtual manufacturing enterprise and specific rules for assigned roles. General policies apply to all student participants and deal with communication and reporting responsibilities. Rules for specific roles place requirements and responsibilities on students as they deal with unexpected situations in performing their assigned duties. For example, work center managers may schedule overtime in their assigned work center in a given day, but only if they submit a request at least one day in advance with appropriate justification and receive approval from the plant manager. Master production schedulers may make any changes in the master schedule they feel necessary, but changes in the

Table 3. Key OM roles in the virtual manufacturing enterprise

Plant Manager (graduate assistant) Responsible for all activities of the Virtual Manufacturing Enterprise. **Materials Manager** Coordinates activities to provide material needed to meet the master production schedule. Monitors material needs and order status, anticipates problem situations, and coordinates activities to solve problems in a timely fashion. Serves in a supervisory position and does not perform daily transactions related to materials management. **Production Manager** Coordinates shop floor activities required to meet the master production schedule. Monitors work in process, order priorities and capacity at each work center. Anticipates problem situations and coordinates activities to solve problems in a timely fashion. Serves in a supervisory position and does not perform daily transactions related to shop activity. **Master Production Schedulers** Develop and maintain the master production schedule for assigned end items. Receive and enter customer orders, adjust master schedule quantities as needed to meet demand and finished goods inventory targets, receive completed finished goods into inventory, process sales shipments to customers, and track customer service levels. Responsible for all decision making and transaction processing related to the master production schedule. **Inventory Planners** Initiate and monitor actions to obtain needed assemblies, components, and materials to meet the master production schedule. Responsible for all decision making and transaction processing to order, schedule/reschedule dues dates, and receive assigned inventory items. **Work Center Managers** Responsible for managing assigned work centers to meet manufacturing plans. Manage work center capacity, establish and execute daily job schedules, and coordinate operations with related work centers. Responsible for decision making, transaction processing, and reporting requirements in the assigned work area.

very near term must be justified in writing since these changes affect material and capacity plans that have already been implemented. The master production schedulers must be able to explain the impact of changes they propose. These and other policies force students to use the information system to plan ahead, anticipate problems, and communicate with each other.

During the second half of the semester, all decision making and transaction processing are conducted by the student team. Factory conditions resulting from these decisions provide the data used in the classroom activities during the second half of the semester as described in the previous section.

Weekly factory performance metrics are computed and posted in a public place so that factory performance can be viewed by all students and observers, whether or not they are direct participants in the project. These metrics include total sales shipments, customer service level (percent of customer orders shipped on time and complete), overtime hours worked in the facility, work in process inventory, finished goods inventory, and total inventory. Factory performance for several previous semesters is available so that students can see their performance relative to previous classes and to periods in which the instructor and graduate assistant were managing the factory. The formal performance assessment of each student at the conclusion of the project includes both individual performance and factory performance.

Project results continually show that successful management of the virtual factory requires more than simple content knowledge of operations management tools and techniques presented in textbooks. The dynamics of the virtual enterprise require students to deal with uncertainties and ambiguities, to make decisions in real time, and to coordinate their activities and understand how their roles and operations management decisions are interrelated. Successful completion of the project requires not only technical competence in operations management and expertise in using enterprise software, but also teamwork, communication, and leadership.

Overall Effectiveness of the Approach

There are a number of indicators that the use of enterprise software to teach OM as described above is effective. Three indicators discussed below include the success of former students, continuing support from the business community, and external recognition from academic and professional societies.

Student participants in the project have been well received in the job market, and many report that their hands-on experience with enterprise systems was a major factor in attracting interest from potential employers. Many former students hold positions of major responsibility in manufacturing firms, and have supported the program through donations and testimonials.

In the twenty years that the project has been under development, over $1.5 million in hardware, software, and support services has been donated by industrial partners and supporters. The project began in the mid 1980s with assistance from IBM, who provided MAPICS II software running on an IBM System 36 minicomputer. The project evolved with later versions of MAPICS designed for the AS400 series of IBM computers. Various software packages such as JOBSCOPE and FACTOR have been donated and utilized in the manufacturing simulation as the project evolved. Recent support from Microsoft Business Solutions has facilitated more of a total enterprise approach that integrates the virtual factory with accounting courses at Clemson, as described in the "Future Trends" section below. This continuing and evolving industrial support is an indicator of the relevance of the approach, and has enabled the project to stay on the cutting edge of information technology.

The project has also received significant external recognition through formal awards

from academic and professional societies and business organizations, including the Decision Sciences Institute, the Academy of Business, and Microsoft Business Solutions, as well as special recognition from the Carnegie Foundation for the Advancement of Teaching and the Council for the Advancement and Support of Education (CASE). In addition, instructors in the project have won numerous teaching awards from campus student groups.

FUTURE TRENDS

Integration of topics in the business curriculum is likely to be more important in the future as firms continue to rely on enterprise systems to link activities and processes internally and with external suppliers and customers. Enterprise systems are a potentially important resource for collegiate schools of business because they facilitate meaningful integration in the curriculum. As the operations management project described in this chapter continues to evolve, efforts have been undertaken to utilize the virtual manufacturing enterprise in other business courses as well.

The first step in this process involves various accounting courses at Clemson University. Daily operational decision making and transaction processing in the virtual manufacturing enterprise generate accounting data that are examined and processed in a number of different accounting courses. Introductory accounting courses use the ongoing live model to illustrate business events that are discussed in accounting texts, while intermediate accounting students work on financial problems that occur in the virtual enterprise and develop accounting adjustments as needed. This provides opportunities for accounting instructors to address issues involving asset purchases, accounts receivable write-offs, mortgage loan amortizations, and other problems, all in a dynamic environment created by the virtual manufacturing enterprise.

A logical extension of these activities is the development of courses that combine teams of management, accounting, and other business students working together to manage the virtual enterprise. This type of across-course integration could be the wave of the future in business schools, and it will likely blur the boundaries between traditional courses in functional areas of business such as operations, accounting, finance, marketing, and human resources. Such activities require careful planning to ensure that the body of knowledge in each functional area is clearly identified, the learning objectives are clear, and student participants have sufficient content knowledge to engage in their assigned role in the virtual enterprise and benefit from the experience. The enterprise system technology to accomplish this is readily available — the challenge is for business schools to develop meaningful ways to employ it.

CONCLUSION

An approach to teaching operations management has been presented in which enterprise software brings to life key issues in managing the production operations of a business. A key feature of the approach is the realism created by using enterprise software to operate the virtual factory in an ongoing, real-time mode in which various operations management issues related to customer service, inventory, scheduling, and capacity occur simultaneously. The approach provides a way to enhance understanding of operations management topics, as well as a vehicle for students to better understand the integration of operations management with other functional areas of business such as accounting, finance, and marketing. An important by-product of the approach is the hands-on experience students receive with enterprise software that is widely used in the business world.

Section V
Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of software applications. Chapters introducing this section analyze open source software communities, while later selections discuss organizational modeling and the analysis of user interfaces. The inquiries and methods presented in this section offer insight into the implications of software applications at both a personal and organizational level, while also emphasizing potential areas of study within the discipline.

Chapter 5.1
Open Source Software Communities

Kevin Carillo
Concordia University, Canada

Chitu Okoli
Concordia University, Canada

INTRODUCTION

Open source software (OSS) development has continued to appear as a puzzling and enigmatic phenomenon and has drawn increasing attention as its importance has grown. Relying upon an alternative way to develop and to distribute software, open source communities have been able to challenge and often outperform proprietary software by enabling better reliability, lower costs, shorter development times, and a higher quality of code (Raymond, 2004). Behind the software is a mass of people working together in loose coordination, even portrayed as a rowdy marketplace (Raymond, 2001, p. 1):

No quiet, reverent cathedral-building here—rather, the Linux community seemed to resemble a great babbling bazaar of differing agendas and approaches … out of which a coherent and stable system seemingly emerges only by a succession of miracles.

More precisely, the people behind open source projects have been defined as: "Internet-based communities of software developers who voluntarily collaborate in order to develop software that they or their organizations need" (von Krogh, 2003, p. 14). In contrast to the sacred cathedral-like software development model that gave birth to most commercial and proprietary systems, such bazaar-like communities seem to have based their success on a pseudo-anarchic type of collaboration and developers' interaction (Raymond, 2001). However, in spite of the apparent disorganization of these bazaars, a closer look distinguishes common values and norms that rule them, specific roles that can be identified, similar motives shared by people, and practices that follow patterns. This article highlights key aspects of what forms the communities that support these projects.

Definition of Open Source Software

The basic definition of OSS as expressed by the Open Source Initiative (www.opensource.org) goes beyond the notion of free code. It encompasses broader issues such as distribution and licensing that stipulate free exchange and modification rights of source code (OSI, 1997):

- Free redistribution of source code
- Free redistribution of compiled (binary) programs
- Derived works must be permitted
- Integrity of the author's source code
- No discrimination against persons or groups
- No discrimination against fields of endeavor (e.g., commercial and military uses must be permissible)
- Mandatory distribution of open source license
- License must not be specific to a product
- License must not restrict other software's licenses
- License must not restrict redistribution to a particular delivery technology

A BRIEF HISTORY OF THE OPEN SOURCE PHENOMENON

During the 1960s and 1970s, scientists and engineers in academic and corporate laboratories freely shared, exchanged and modified the software they produced. However, by the early 1980s, software was increasingly shifting from its original shared nature to becoming increasingly commercialized, with licenses that forbade the free sharing of source code. In 1983, Richard Stallman left MIT to found the Free Software Foundation (FSF) with the principle aim of defining and diffusing legal mechanisms and conceptual principles of "free software" (Hars & Ou, 2001; West & Dedrick, 2001). "Free" here refers to freedom, the liberty to do whatever desired with the software. Hence, free software in the open source sense is distinct from "freeware", which is software sold at no price. In fact, one of the explicit rights given to users of "free software" is the right to sell it commercially. It is noteworthy that most OSS is freeware (provided at no charge), but most freeware is not open source (the source code is not provided, and users are forbidden from modifying the program code even if they could).

Stallman's publication of the GNU Manifesto (1985) allowed him to communicate his ideological insights about the nature of software (von Krogh, 2003), and he convinced developers to join him in the GNU Project, whose primary goal was—and still is—the creation of a Unix-like free operating system. ("GNU" is a recursive acronym meaning, "Gnu's Not Unix".) Accompanied by the continuous improvements of networking capabilities and of the Internet, this major step signaled the beginnings of open source practices organized through the formation of virtual communities. In 1989, the Free Software Foundation released the GNU General Public License (GPL) in order to ensure the preservation of certain freedoms in the copies and derivative works of a piece of software. The GPL assures these freedoms via the copyleft mechanism, which permits free copying, modification, and distribution of software, with the condition that any distributed derivative works explicitly accord others the same rights.

In 1991, Linus Torvalds, a 21-year-old Finnish programmer, created Linux, a kernel for a Unix-based operating system that uses the operating system tools created by the GNU Project. Since then, this multi-user/multitasking platform has met tremendous success and is known for being powerful, fast, efficient, stable, reliable, and scalable (Edwards, 1998). In 1999, a survey estimated that the GNU/Linux operating system (popular known simply as "Linux") was the operating system of more than 30% of Internet server sites. A recent release of the kernel (Linux 2.2.10) credits 190 key developers, though the total number of

contributors was estimated to be around 1,200 (Dempsey, Weiss, Jones, & Greenberg, 2002; Stewart & Ammeter, 2002).

In 1998, Bruce Perens and Eric Raymond of the Open Source Initiative pointed out that the mistrust of many traditional firms towards the GPL was in Stallman's term "free", which is not very a attractive idea to the business world (von Krogh, 2003)—conventional wisdom says that you get what you pay for. Thus, they tried to refocus what they rebranded as the "open source" software movement by primarily focusing on the economic and engineering superiority of the "open source" approach to software development, in contrast to FSF's more philosophically antagonistic approach towards "source-hoarding". In response to their positive marketing, the term "open source" has become the preferred terminology for this approach. Other major open source projects have followed Linux's success, including the Apache Web server (started in 1995) and the Mozilla Internet suite project (started in 1999 when Netscape released its Communicator suite as open source; Mozilla released the Firefox Web browser and Thunderbird e-mail client at the end of 2004).

PROFILE OF OPEN SOURCE COMMUNITIES

Lee and Cole (2003, p. 51) defined a virtual community as "a cyberspace supported by computer-based information technology, centered upon communication and interaction of participants to generate member-driven contents, resulting in a relationship being built up." OSS development communities have been defined as groups of loosely connected programmers, who use the Internet as a medium for collaboratively developing, improving, and disseminating software (O'Reilly, 1999), and are recognized as a particular genre of virtual community (Ljungberg, 2000) and as virtual organizations (Crowston & Scozzi, 2002), which are characterized by: group members with a shared interest or goal; geographical distribution; and use of information and communication technology to communicate and manage interdependencies (Ahuja & Carley, 1998). They have been classified as communities of transaction (Hagel & Armstrong, 1997) and as "task- and goal-oriented" communities; that is, "communities striving to achieve a common goal by way of cooperation" (Stanoevska-Slabeva & Schmid, 2001).

Ideology and Values

One of the main emphases in OSS communities is the social interaction among participants through electronic communication. Rheingold (1993, p. 5) defines virtual communities as "social aggregations that emerge from the Net when enough people carry on public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace". This definition highlights the creation of relationships among people. As a consequence, the participants of an OSS community share a set of common values, and they adhere to the same ideology: the OSS culture.

The most commonly accepted view of OSS communities' culture has been proposed by Raymond (2001) in his landmark paper, "The Cathedral and the Bazaar", where he characterizes it as a "gift culture", as opposed to an "exchange culture". Exchange cultures are based on scarcity whereas gift cultures rely on abundance. Raymond argues that in gift cultures, social status is determined "not by what you control, but by what you give away". Bergquist and Ljungberg (2001) have empirically demonstrated that such giving values and behaviors enable social relationships to be created and maintained in virtual environments. Assuming any ideology is a common set of shared norms, values and beliefs among the members of a community, Raymond's view of OS communities can be characterized by the features listed in Table 1 (Stewart & Gosain, 2001).

Table 1. Ideologies and values of open sources software communities (Stewart &Gosain, 2001)

Norms	▪ Taboo against forking projects ▪ Distributing changes without cooperation of moderators frowned upon ▪ Removing a person's name from project history, credits or maintainers list is not done without explicit consent
Values	▪ The best craftsmanship wins ▪ All information should be free ▪ You don't become a hacker by calling yourself a hacker—you become a hacker when other hackers call you a hacker ▪ Non-trivial extensions of function are better than low-level patches and debugging ▪ Work that makes it into a big distribution is better than work that does not
Beliefs	▪ With enough eyeballs all bugs are shallow ▪ Practice is better than theory
Ideologues	▪ Stallman ▪ Raymond
Language, Symbols	▪ "Distros" ▪ "Suits" ▪ Free Software Foundation ▪ Copyleft ▪ Open source licenses
Narratives	▪ The Halloween Papers ▪ The Cathedral and the Bazaar ▪ Slashdot, Freshmeat, Sourceforge

Furthermore, another dimension that may be added to the OSS ideology is the hostility towards commercial software. The intensity varies from one community to another one, from a fundamentally hostile view of commercialized software (almost universally expressed towards Microsoft Corporation, currently the largest commercial software enterprise) to a moderate view that accepts the symbiotic nature and coexistence of open source and proprietary software (Ousterhout, 1999).

An organizational culture approach elicits further insights about the rules governing OS communities. Schein's (1984) framework posits that the culture of organizations can be understood by examining their artifacts, values and core assumptions. Sharma et al. (2002) have applied this

framework to OSS, with the results summarized in Table 2.

Researchers in the area of virtual communities have pointed out the overall importance of trust. For instance, Carver (1999, 114) affirms, "People are drawn to virtual communities because they provide an engaging environment in which other people … create an atmosphere of trust and real insight". Trust is considered as a core assumption of the OSS ideology, considering that core developers need to work closely with one another as they implement different but interrelated code segments (Sharma et al., 2002). As a result, it was found that trust among group members in OSS project groups plays an essential role in facilitating development success (Stewart & Gosain, 2001). Thus, OS development processes have to be managed through trust-based relationships in order to ensure OSS project success and quality.

Participants' Profiles and Roles

It has been common to characterize OSS community members as anarchistic crackers operating on the fringes of society, a stereotype that has been soundly dispelled by recent surveys (Fitzgerald, 2004). Several surveys have identified consistent traits among OSS community members. Over 95% of members are male. The average age is around 30, with a majority of people between 20 and 30. 20% of members are students and over 50% of people have IT jobs. Most developers have a bachelor's (or equivalent) degree, many have a master degree, and under 10% have a PhD degree (Ghosh, Glott, Krieger, & Robles, 2002; Hars & Ou, 2001; Lakhani, Wolf, Bates, & DiBona, 2002).

OS developers tend to participate in a limited number of projects—an average of just two or three each (Dempsey et al., 2002). Developers modify the program source code and make important decisions concerning any future development. Non-developers are valuable in reporting bugs, and in suggesting feature enhancements. Although it is common to think of OSS participants as willing, independent enthusiasts, on deeper analysis it is evident there is a certain kind of hierarchy inherent in any project (Glass, 2003).

CONCLUSION

OSS communities are an important type of virtual community today, where members convene online with the common goal of producing software that is valuable both to developers and for the general public. While most OSS communities do not explicitly restrict membership (except perhaps to

Table 2. OSS organizational culture (Sharma et al., 2002)

Artifacts	▪ Electronic communication
Values	▪ Altruism ▪ Reciprocity ▪ Gift Giving ▪ Reputation ▪ Fairness ▪ Shared risks and ownership
Core Assumptions	▪ Trust ▪ Loyalty

the inner core of developers), they are particular in their membership criteria, which by its nature requires considerable skills in computer programming and software development. However, as we have discussed, there is also plenty of room for non-developer user members who contribute ideas and directions valuable to projects, such as identifying bugs and suggesting new features. As the open source movement continues to grow both as a software development methodology and as a philosophical/social/political approach to intellectual property, OSS communities will have an increasingly important role in the software industry.

KEY TERMS

Free Software: An earlier name for open source software, emphasizing the liberties given to end users and developers of derivative works. There is no requirement that the software be distributed at no charge; thus, distinct from freeware.

Freeware: Software provided at no charge to the user. Might be open source or proprietary; that is, the developer only permits redistribution and use, with no modifications permitted. In fact, most open source software is freeware, but most freeware is not open source.

GNU General Public License: The first and still the most radical open source software license, created for the GNU Project. Requires that all derivative works be equally free (in the open source sense); that is, all derivative works must provide the full source code and must permit free use, modification, and redistribution.

GNU Project: (Stands for, "Gnu's Not Unix") Established by Richard Stallman in 1983 under the auspices of the Free Software Foundation. Its goal was, and still is, to create an open source Unix-based operating system. This goal was realized in 1991 by Linus Torvald's creation of Linux.

Linux: A Unix-based open source operating system designed for Intel-based microcomputers. The kernel was created in 1991 by Linus Torvalds, and it was added on to the GNU Project to form what is properly called the GNU/Linux operating system.

Mozilla Project: A project formed in 1998 when Netscape released its Internet tools suite for open source development. Released its flagship Firefox Web browser and Thunderbird e-mail client at the end of 2004. The Sunbird calendar component is currently under development.

Open Source Software: Software whose source code is liberally made available for use, modification, creation of derivative works, and redistribution.

The Cathedral and the Bazaar: Paper by Eric Raymond (most recent version in 2001) that contrasts the "Cathedral" software development approach of a closed hierarchy (e.g. for proprietary software and most open source software such as the earlier GNU Project) with the "Bazaar" approach of loose collaboration with light centralized moderation (as was used for the Linux and Fetchmail open source projects).

Chapter 5.2
Beyond Development:
A Research Agenda for Investigating Open Source Software User Communities

ABSTRACT

Open source software has rapidly become a popular area of study within the information systems research community. Most of the research conducted so far has focused on the phenomenon of open source software development, rather than use. We argue for the importance of studying open source software use and propose a framework to guide research in this area. The framework describes four main areas of investigation: the creation of OSS user communities, their characteristics, their contributions and how they change. For each area of the framework, we suggest several research questions that deserve attention.

INTRODUCTION

In recent years, the open source software (OSS) development movement has captured the attention of both information systems practitioners and researchers. The "open community model" is one that involves the development and support of software by volunteers with no or limited commercial interest. This model differs from proprietary software development, and with other open source business models such as corporate distribution, sponsored open source and second-generation open source (Watson, Boudreau, York, Greiner, & Wynn, in press). The open community model is appealing to many because of its application of community principles of governance over commercial activities (Markus, Manville, & Agres, 2000; von Hippel & von Krogh, 2003). By describing open source as a "movement," we

reflect the broader excitement about the implications of community governance processes in a knowledge economy (Adler, 2001).

Open source has rapidly become a popular area of study within the information systems (IS) research community, as evidenced by the appearance of special tracks for OSS within conferences and special issues of journals. For example, the Americas Conference on Information Systems sponsored an "Open Source Adoption and Use" minitrack, and the Hawaii International Conference on System Sciences offered a minitrack on "Open Source Software Development." On the journal side, *Management Science* invited submissions to a special issue on "Open Source Software" in 2004. Also, *Journal of Database Management* announced a special issue on "Open Source Software."

Although these calls for OSS research do not limit contributions, the vast majority of the research conducted so far has focused on OSS development rather than use (Fitzgerald & Kenny, 2003). The interest in open community development reflects a desire to explain the counterintuitive practice of treating commercially valuable products as public goods rather than proprietary products for sale. Likewise, the development and maintenance of complex software products by communities of expert volunteers has piqued interest into the incentives for developers. As a consequence of the primary focus on OSS development, little research has yet been conducted on OSS use, especially by non-technical users.

The neglect of OSS use may be attributed to two false assumptions about OSS projects. First, it is known that people often become OSS developers because they intend to use the product being developed. To echo Raymond's (2001) frequently quoted expression, OSS developers are users with an "itch to scratch," so they are willing to devote time and expertise to develop software solutions to their own problems as users. Thus, it is commonly assumed that there is no distinction between OSS developers and users (Feller & Fitzgerald, 2000). Following this line of argument, we might conclude that no special research agenda for OSS use is needed because OSS use is redundant with OSS development.

However, this argument and its underlying assumption can be challenged on the grounds that OSS use by technically experienced developers differs from OSS use by technically naïve users. Verma, Jin, and Negi (2005) argued that technical developers and non-technical users have very different interpretations of OSS's ease of use. Non-technical users may experience difficulty in using OSS products because OSS developers are motivated to improve functionality rather than usability (Nichols & Twidale, 2003). Thus, even though all OSS developers are likely also to be users, the distinction between developers and non-technical users remains important.

The assumption can also be challenged by statistics showing the rapid rise in the number of OSS users, the vast majority of whom have no interest or capability to contribute to modifications of the source code (Fitzgerald & Kenny, 2003). For widely distributed OSS such as Linux, it makes no sense to assume that more than a small percentage of users could possibly become developers (von Hippel & von Krogh, 2003). Clearly, users vastly outnumber developers in larger OSS projects. As OSS development becomes increasingly targeted toward productivity and entertainment applications, the relative proportion of non-technical users can be expected to increase.

The second assumption dissuading research on OSS use is that the OSS movement is unique solely because of the way software is developed, but that its use is similar to any other type of software. Given the abundance of IS research that is focused on the adoption and use of software applications, one might assume that no special research program is needed for OSS use.

This assumption can be challenged by examining some differences between OSS and proprietary software. Users of OSS are typically confronted by a fundamentally different type of technical

support than that found with proprietary software. Rather than relying on a vendor's customer support, users of OSS generally need to search for community resources for help for installing, learning and using their freely acquired software. OSS users are likely to receive such help through participation in user groups or mailing lists that are supported by volunteers, similar to the communities supporting OSS development (Golden, 2005; Lakhani & von Hippel, 2003; Raymond, 2001). Given these distinctive features of OSS products and support, we do not agree with the assumption that OSS use is the same as proprietary software use.

These arguments justify research into OSS use. In this article, we adopt a community perspective on OSS use, which is explained in the following section. We then present a framework that includes four main areas of investigation: *creation* of OSS user communities, their *characteristics*, their *contributions* and how they *change*. For each element of the framework we pose several research questions.

A COMMUNITY PERSPECTIVE ON OSS USE

The term "community" was introduced into the English language in the 14th century from Latin to refer to a group of people living in a common geographical location. Between the 17th and 19th centuries the meaning of community was extended to describe people who shared common characteristics, interests or identities – even if they were not geographically close (Cole, 2002; Williams, 1973). As the 21st century begins, people have grown more accustomed to participating in virtual communities that are enabled by Internet technology and the World Wide Web (Rheingold, 2000). Virtual communities differ from colocated communities by offering a wider range of options for participation and by allowing community size to grow, unconstrained by physical space. As Cole (2002) noted, virtual communities can be more heterogeneous: "each [community] is unique in the combination of institutional arrangements, educational content, forms of Internet communication, and participant goals that it embodies" (p. xxvi). Moreover, individual members may tailor their virtual communities to satisfy personal preferences (Wellman, 2001).

The power of collaboration within geographically dispersed communities is demonstrated by the making of the first edition of the *Oxford English Dictionary*, one of the earliest examples of an open community project (Watson, Boudreau, Greiner, Wynn, York & Gul, 2005). The dictionary, which took about 70 years to complete, was compiled primarily from definitions submitted by thousands of volunteers fluent in the English language. In his book, *The Professor and the Madman*, Winchester (1998) reported that an insane American prisoner became the most prolific contributor to the original compilation of the *Oxford English Dictionary*. This story illustrates two principles that also sustain modern OSS communities: everyone is welcome to contribute regardless of personal circumstance, and value can be produced through community effort.

OSS development largely depends upon the ability of developers to contribute as members of virtual communities (Markus et al., 2000; Lakhani & von Hippel; 2003; Raymond, 2001). Given that much OSS development transpires in online communities, we expect that OSS use also relies on virtual communities for software acquisition, implementation, maintenance and support. For example, Lakhani and von Hippel (2003) suggested that successful OSS projects were capable of delivering high quality field support – mundane but necessary tasks – to users through voluntary effort. Field support primarily involves experienced users answering questions posted by novice users through an archived mailing list. Indeed, a highly organized system of OSS user groups has grown around major OSS products. Taking Linux user groups (LUGs) as an example,

in July 2005 there were 846 registered LUGs in 108 countries, including 299 in the United States (http://www.linux.org/groups).

Despite the importance of electronically mediated interaction within OSS communities, we do not assume that OSS user communities are exclusively virtual. Indeed, one of the naïve assertions about OSS development is that software can be developed by a community of complete strangers who interact only through electronic media. To the contrary, experienced OSS participants have opportunities to attend conferences and regular meetings held in physical places. For example, the O'Reilly Open Source Convention and LinuxWorld Conferences are popular venues for OSS developers to meet and exchange ideas. Research on Linux user groups (Jin, Robey, & Boudreau, 2006) reveals that the Silicon Valley LUG holds face-to-face meetings at least monthly and organizes InstallFests, where new users can bring in their computers and allow experienced volunteers to install Linux, diagnose problems and repair configurations. The LUG of Davis, California, sponsors a Linux Emergency Relief Team, staffed with experts who may even travel to users' homes to service their Linux systems (Jin et al., 2006). According to Moen (2003), LUGs are vital to the Linux movement, taking on many of the same roles that a regional office does for a large organization:

LUGs' role in Linux advocacy cannot be overestimated, especially since wide-scale commercial acceptance of Linux is only newly underway. While it is certainly beneficial to the Linux movement each and every time a computer journalist writes a positive review of Linux, it is also beneficial every time satisfied Linux users brief their friends, colleagues, employees, or employers.

The following research agenda focuses on questions about the creation, characteristics, contributions and change in OSS user communities. There is no direct empirical rationale for dividing the agenda into these four categories because research on OSS user communities is just beginning. Rather, the research agenda reflects a progression through different phases of an OSS community over its life cycle. Creation is the beginning, characteristics describe the makeup of the community, contribution describes the major functions performed, and change describes later growth. The four phases are associated with different kinds of issues, which we offer as researchable topics. Because the life of a community is not biologically limited, our agenda shows that communities may repeat the cycle as they change.

The agenda is proposed at a high level due to the novelty of the phenomenon and the paucity of existing research efforts. By restricting our attention to a community perspective, we purposefully omit consideration of individual and organizational influences on OSS use. However, we believe that a community perspective on OSS research is valuable because it has played such a prominent role in research on OSS development.

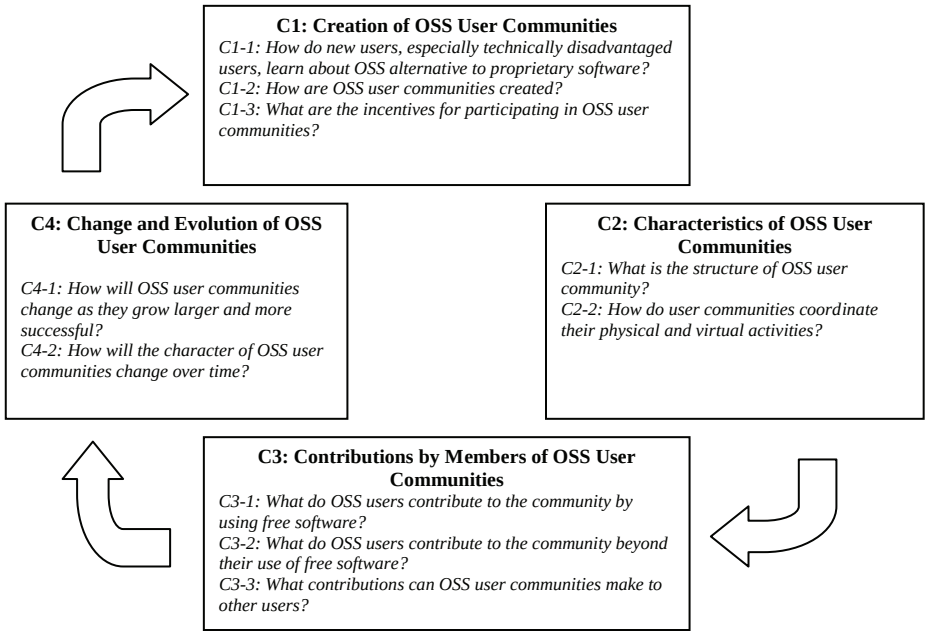
A RESEARCH AGENDA

Figure 1 identifies the four main areas where research into OSS user communities should be undertaken: creation (C1), characteristics (C2), contributions (C3) and change (C4). As shown, these areas are related sequentially, beginning with creation. It is also shown that change not only completes the cycle but potentially begins a new cycle.

C1: Creation of OSS User Communities

The creation of an OSS user community requires potential members to learn about OSS as an alternative to proprietary software and in-house development, to engage in community activities and to respond to incentives for starting or joining

Figure 1. Research areas



a user community. The research questions below address these three important issues.

C1-1: How do new users, especially technically disadvantaged users, learn about OSS alternatives to proprietary software?

This issue is interesting because, compared to proprietary software, open-community software projects lack specialized teams to market the product and to promote it through mass media. Although the notion of gift culture is well established within the OSS development community, users are likely to be suspicious of the opportunity to receive software as a free gift. Although OSS has made news headlines and gained immense exposure on the Internet, a nontechnical user would still be expected to have difficulty installing and using a new operating system such as Linux. Indeed, many new users are introduced to OSS through personal friends, whom they trust and rely upon for support when they encounter problems. The role of the broader OSS user community in introducing new users to OSS products stands as an important research question.

C1-2: How are OSS user communities created?

Creating and sustaining a software user community requires resources such as meeting places, newsletters, and Web hosting services. Traditional software user groups are often sponsored by vendors, who provide considerable benefits to both users and themselves (Buckner, 1996). On the one hand, users may benefit from discounted prices negotiated with the vendors and the chance to suggest improvements in the software's next release. On the other hand, vendors receive a low cost marketing opportunity and obtain feedback on the usability of their products.

Because software vendors are rarely involved in open-community OSS user groups, their creation depends on a group of enthusiasts sharing the same passion for the software. These enthusiasts

may be among the original developers, motivated to increase the software's user base. Alternatively, these enthusiasts may be pure users who believe in the principles behind OSS, therefore promoting its use and maximizing the benefits of their own use. Large companies may also be the principal instigators of OSS user groups. If an OSS product is used extensively within a company, creation of a user group for that product provides free training opportunities for the company's employees. Large technology companies with a stake in an OOS product may also support OSS user groups indirectly by providing meeting space or donating Web hosting services. Companies providing such support may enhance their reputations within the OSS community, which in turn may improve their opportunities to recruit talented new members.

Although we acknowledge that OSS user groups are important components of OSS communities, the creation of other community components should not be overlooked. Special interest groups and forums may be established by universities, government agencies and other organizations. Although their activities may be less visible to the public, they may generate additional resources, such as training provided by the sponsoring organizations.

C1-3: What are the incentives for participating in OSS user communities?

Because users may obtain OSS freely, with no obligation to contribute to development, their use of the software is likely to be based primarily on cost and quality considerations (Fitzgerald & Kenney, 2003). The incentives for community participation, however, differ from the incentives for using OSS (Wang, 2005). For developers who incur substantial private costs by investing their own resources into development, incentives include not only the ability to use the software but also benefits related to reputation and learning. It is conceivable that users may also obtain such benefits, gaining reputations as skilled implementers who are helpful to novice users.

It has been argued that the true benefit for using open source software goes beyond its low initial cost and involves a user's long-term control over information technology. By contrast, users of proprietary software become dependent on software that remains inside the vendor's black box. With no ability to change the source code, users of proprietary software lose control and subject themselves to a monopoly relationship with their vendor (Moen, 2000). OSS may provide an incentive by restoring the user's control.

It is also likely that OSS user groups offer more value than user groups organized by proprietary software vendors. Vendor-sponsored user groups often charge membership fees and use their meetings to promote new products. These commercial interests may interfere with the activities of OSS user groups. For the more technically inclined, OSS user groups offer solutions in the form of code modifications that address specific problems of individual users. By contrast, vendors are more likely to avoid solutions involving code modification and focus on software configuration or settings, which may or may not solve the user's problems. As stated by Moen (2003), OSS user groups are ready and willing to modify source code on the spot:

Traditional groups must closely monitor what software users redistribute at meetings. While illegal copying of restricted proprietary software certainly occurred, it was officially discouraged – for good reason. At LUG meetings, however, that entire mindset simply does not apply: Far from being forbidden, unrestricted copying of Linux should be among a LUG's primary goals.

Outside geopolitical forces could also provide powerful incentives for OSS user community participation. When a U.S. company refused to develop a Portuguese language version of its software for a company studying rain forest

biodiversity in Brazil, the Brazilians turned to an inexpensive OSS solution. The OSS software not only delivered the functionality that the company needed, but also provided all prompts in the Portuguese language (Hall, 2002). Consequently, the Brazilian government became a strong advocate of the OSS movement, as explained by a Brazilian representative at the LinuxWorld 2004 conference:

The question is . . . how the universities can have better tools to teach their students, how government can save millions or billions of dollars each year and still be able to use all kinds of technology. Our government decided that OSS is a good idea; it is something to be supported. In fact, we are the biggest user of OSS in Latin America. We have something around now, eight or ten million users of OSS.

Understanding the creation of OSS user communities requires attention to many issues pertaining to users learning about OSS products; the creation of specific mechanisms, such as user groups, to support user activities, and incentives for wide participation. Because these issues are raised at the community level of analysis, answers cannot be obtained by looking at individual decisions to join and contribute to user communities. Studies of OSS user communities may draw insights from OSS development communities, but it should not be assumed that use is the same as development. For these reasons, our research agenda focuses specifically on the creation of OSS user communities.

C2: Characteristics of OSS User Communities

Like all communities, OSS user communities are likely to be differentiated by the roles that different members play. It is also important to recognize the relationships between user and developer communities. Indeed, it may be desirable to consider users and developers as subcommunities within an OSS project. The questions below address issues related to the characteristics of OSS user communities.

C2-1: What is the structure of an OSS user community?

An OSS community is built around a specific OSS project, with shared interests of improving and using the software. As more people become interested in using the software, the community grows and differentiates into various roles. For example, Ye, Kishida, Nakakoji, and Yamamoto (2002) defined eight roles in OSS communities: (1) project leader, (2) core members, (3) active developers, (4) peripheral developers, (5) bug fixers, (6) bug reporters, (7) source code readers and (8) passive users.

Although helpful in defining the characteristics of an OSS community, the roles defined by Ye et al. (2002) appear most suitable as a description of an OSS development-oriented community (Jin, Verma, & Negi, 2005). Of the eight roles identified, only the last three include users, while the first seven describe developers. According to Jin et al. (2005), an OSS development-oriented community is "exclusively dedicated to develop, support, and maintain a single or multiple open source project(s)" (p. 16522). An OSS user-oriented community, by contrast, is typically created by users for users to "promote the use of OSS products" (Jin et al., 2005, p. 16523). The primary activities of OSS user-oriented communities are attracting new members to adopt OSS products and educating existing members about the best use practices for OSS products. Linux user groups are excellent examples of OSS user-oriented communities. Other examples include the perl mongers community, BSD User Groups, and MYSQL User Groups. While developers could be involved in an OSS user-oriented community, the roles that its members play would differ from those played in an OSS development-oriented community.

Based on our participation in various LUGs, the following roles of OSS user oriented community are evident: (1) founder/officer, (2) meeting and facilities coordinator, (3) public relations officer, (4) Installfest coordinator, (5) mailing list/Web site administrator, (6) face-to-face meeting attendees and (7) mailing list subscribers.

Depending on the size of a particular user-oriented community, some of these roles could be combined and performed by one person. An important issue deserving research attention is the way members assume these roles and the relationships among the various roles. Such research could contribute to more effective designs for community structure.

C2-2: How do user communities coordinate their physical and virtual activities?

Given that OSS development communities operate both physically and virtually, it is an important question to understand how they use these different arenas of community life. Theories of virtual organizing have pointed to the possibility for virtual and physical activities to reinforce, complement, compensate and produce synergies with each other (Robey, Schwaig & Jin, 2003). At one level, OSS virtual activities allow developers to access and modify source code, access necessary archives, and interact through mailing lists, Internet Relay Chat channels, and Web logs. At another level, OSS physical activities are important for forging social ties and clarifying communications (Jin et al., 2006). Moen (2003) emphasized that LUGs' socializing function was effective for members to become acculturated into the Linux user community:

By "socializing", here I mean primarily sharing experiences, forming friendships, and mutually-shared admiration and respect. In other words, acculturation turns you from "one of them" to "one of us." ... LUGs are often much more efficient at this task than are mailing lists or newsgroups, precisely because of the former's greater interactivity and personal focus.

Besides the socializing benefit from face-to-face meetings, physical activities like InstallFests can be effective for advanced users to tailor their help to new users' particular needs. Because new users bring their computers to InstallFests, OSS experts can demonstrate software installation, diagnose problems, and even conduct hands-on training individually with new users.

Understanding the characteristics of OSS user communities requires attention to the roles played by members and the mechanisms for coordinating community action. Again, such matters cannot be undertaken from an individual or even small group perspective. The virtual nature of OSS user communities makes their potential size practically unlimited. Yet, research on the characteristics of OSS communities needs to understand their virtual nature without losing sight of the importance of their face-to-face, physical activities.

C3: Contributions by Members of OSS User Communities

In the OSS development literature, much is made of the voluntary gifts donated by skilled designers for the creation of a public good (Fitzgerald & Kenney, 2003). Indeed, communities are likely to fail if such contributions are not made. The following questions are posed with the same issue in mind for the OSS user community.

C3-1: What do OSS users contribute to the community by using free software?

If contributions are not made by users, OSS users assume the status of free riders who simply take from the community without paying back. Paradoxically, free ridership by OSS users is actively encouraged rather than discouraged. Because the

number of OSS users is a measure of a project's success, users are not pressured to contribute as developers do (von Hippel & von Krogh, 2003). Indeed, their most important contribution may simply be their use of the OSS product.

For example, one of the goals of the Firefox team (a popular OSS Internet browser) is to acquire ten percent of the browser market share. According to one of the team's leaders, "It really doesn't matter how great your technology is. If nobody's using it, then you are not achieving that mission of bringing back choice" (personal communication, 2005). Although most users may never contribute toward product improvement, they are valuable to the success of the Firefox project because their usage adds to Firefox's market share. Indeed, some software projects have found an OSS strategy to be an effective solution for acquiring a customer base before pursuing more commercial objectives. Onetti and Capobianco (2005) found a positive correlation between the number of downloads generated on a Sourceforge OSS project site and the number of new clients interested in purchasing the product's commercial license. As more users download and use an OSS product, the more credible and successful the project becomes, potentially attracting even more new users.

C3-2: What do OSS users contribute to the community beyond their use of free software?

As Raymond (2001) pointed out, some of the most successful OSS projects are created by the most talented software developers. Because the OSS community tends to attract people with extensive technical backgrounds, there is a risk that resulting products would reflect the "geek" culture and be less useful to ordinary users. For example, the user interfaces of OSS tend to be command-line driven, making their installation and configuration technically demanding. It is conceivable that less technical users might contribute to development by making OSS projects easier to install, configure, use and maintain.

In the case of the Firefox browser project, project leaders not only encouraged contributions from nontechnical users but also valued them as vital assets to the project's success. Instead of contributing code, nontechnical users contributed artistic skills to design the logo and images, marketing skills to help spread the word about Firefox, and even monetary contributions to help place an advertisement in *The New York Times* (McHugh, 2005). Whether such participation would be welcomed on other projects remains uncertain, so the issue presents a good research opportunity to study the impact of less technical users on the development process.

C3-3: What contributions can OSS user communities make to other users?

Fitzgerald and Kenney (2003) reported an interesting case of an Irish hospital using OSS software for a number of internal operations. Although the hospital's IT staff had no intention of ever contributing modifications to the software's source code, they had begun to offer the applications, which they had tailored for themselves, to other health care organizations free of charge. In this manifestation of community spirit, one user was giving back to the community of other users. The study suggests that users may add further value by making OSS programs fit specific industry needs. While these contributions may not earn great reputations, they may provide value for the user community. Future research is warranted on the practice of users making vertical applications more useful for other users, in contrast to the traditional focus in OSS development on horizontal infrastructure systems (Fitzgerald & Kenny, 2003).

Studying contributions is important because communities are held together by such contributions. The research questions posed above guide these potential research opportunities.

C4: Change and Evolution of OSS User Communities

It is clear that OSS user communities are new phenomena that have only become significant economically in the last half decade. We expect the nature of OSS communities to change, perhaps rapidly, as software development and use practices evolve. This, in turn, will affect the creation of new communities, as our cyclical representation in Figure 1 suggests. The following questions address the evolution and change of OSS user communities.

C4-1: How will OSS user communities change as they grow larger and more successful?

Although core developers initiate and contribute the major portion of source code (e.g., 80% in the case of the Apache project (Mockus, Fielding, & Herbsleb, 2002)), the largest growth in community size comes from supporting roles like bug fixers, bug reporters and users. Core developers may even recede in importance as a project stabilizes and does not require major revision. Thus, users may assume more prominent stature in mature communities, partly from their endorsement of a particular OSS project.

Communities are sensitive in the longer run to the free ridership phenomenon because attempts to control free ridership involve increased monitoring costs that eventually outweigh the rewards from contributions (von Hippel & von Krogh, 2003). Because free ridership is viewed positively in OSS development communities, it would be useful to study whether growth will strengthen the community or whether growth can ultimately erode feelings of community solidarity. In other words, will the trust that characterizes a community form of governance (Adler, 2001) disappear as community size increases?

One could also argue that size may not be the most important factor promoting community change. The expansion of low cost communication channels allows OSS users to reach out globally and stay connected. Thus, the cost of monitoring members could remain low despite growth. In addition, increasing user community size could distribute monitoring costs across more members. Simultaneously, community trust could be reinforced at more local levels through the events and social activities discussed earlier. These potential effects of changing size could be studied as part of a research program on community change.

C4-2: How will the character of OSS user communities change over time?

As OSS communities grow and prosper, commercial interests may be expected to appear and taint the gift culture characterizing open communities. Firms such as RedHat emerged quickly to create value by improving software distribution and by adding supplementary services such as installation, support and training. JBoss promoted its application server software as "professional open source," charging users for the expertise and services of key developers (Watson et al., 2006). User groups associated with these and other commercial open source companies may come to resemble proprietary software user groups more than the open communities described earlier. Such changes would potentially affect the character of OSS user communities currently operating under volunteer arrangements.

Although user communities affected by commercial open source companies may lose free access to developer expertise, ultimately less experienced users may benefit more from subscribing to paid services at different levels of support. In addition, companies like JBoss have operated community forums in which independent developers can still contribute free advice. In such cases, commercial and noncommercial interests co-exist in the community. One benefit to the commercial interest is that community forums become fertile recruiting grounds for

new developers. As a JBoss representative at the JavaOne 2005 conference explained:

There are individuals on our forums that don't work for us. They answer questions. We actually try to get a ranking system of who answer the most questions, so it gives us an idea of who we can hire for support. So the forums might turn into a recruiting ground for us.

As the interests of commercial software developers and open source communities become reconciled, the line between the OSS user community and closed source user communities may blur. As more enterprises adopt Linux, for example, users have become more interested in running both Linux and Windows platforms (Adelstein, 2004). The OSS user community could attend to the needs of these ambidextrous users by addressing issues related to usability, hardware and software compatibility.

Alternatively, OSS user communities may try to preserve their character to some degree. For example, although the Firefox team had little marketing budget, they tapped into the resources of the OSS community to launch a promotional campaign. They were able to raise $200,000 from about 10,000 donors in 10 days to pay for a two-page print advertisement in *The New York Times*. In addition, the Firefox team worked closely with international OSS communities to achieve the simultaneous launch of Firefox in 14 languages. Firefox's experience illustrates that communities can remain powerful without having to co-opt commercial interests.

Although the nature and direction of change in OSS user communities cannot be predicted with certainty, it seems inevitable that changes will come, probably rapidly. However, there are probably no easily identifiable drivers of community change. Researchers investigating change in OSS user communities should approach this area with an appreciation for the complexity of organizational and institutional change. This recommendation lies beyond our present scope, but it remains an important consideration.

CONCLUSION

The framework offered in this article is designed to stimulate a new direction in OSS research, one that focuses primarily on software use rather than software development. Although development has attracted the bulk of research interest to date, many important issues pertain to OSS use. OSS users far outnumber OSS developers, and as OSS products become more popular, the number of OSS users will continue to increase. We have identified many of the issues that make OSS different from the use of proprietary and in-house developed software and posed our research questions accordingly. Our research agenda emphasizes the community perspective that has attracted such interest in OSS development research. We believe that many valuable insights can be generated by a focus on OSS user communities.

Beyond the present agenda, we may speculate on the impact of OSS user communities as a model for industries besides software. Although market research and customer relationship management are time-honored ways for companies to feel the pulse of their customers, the phenomenon of OSS user communities suggests that a more active role for customers might be valuable. For example, Threadless.com holds a weekly competition, in which anyone who wishes can upload T-shirt artwork to the company's Web site. Online shoppers can then vote for their favorite designs. Threadless.com prints the winning graphics on limited-edition t-shirts, which are available for purchase at the Web site. Winners are awarded cash or store credits. By 2005, threadless had attracted over 40,000 design submissions (Luman, 2005). This experience offers innovative ideas for community participation in electronic commerce.

In conclusion, the study of OSS user communities offers the potential to learn not only

about OSS projects but also about communities in general. The research agenda proposed in this article suggests many avenues for investigating OSS user communities. Given that there is little extant research on any of the questions raised in this article, our objective is to stimulate thinking about important research areas rather than to summarize findings. Hopefully, the IS research community will begin systematic investigation of the research questions posed here.

Chapter 5.3
Social Network Structures in Open Source Software Development Teams

Yuan Long
Colorado State University-Pueblo, USA

Keng Siau
University of Nebraska-Lincoln, USA

ABSTRACT

Drawing on social network theories and previous studies, this research examines the dynamics of social network structures in open source software (OSS) teams. Three projects were selected from SourceForge.net in terms of their similarities as well as their differences. Monthly data were extracted from the bug tracking systems in order to achieve a longitudinal view of the interaction pattern of each project. Social network analysis was used to generate the indices of social structure. The finding suggests that the interaction pattern of OSS projects evolves from a single hub at the beginning to a core/periphery model as the projects move forward.

INTRODUCTION

The information system development arena has seen many revolutions and evolutions. We have witnessed the movement from structured development to object-oriented (OO) development. Modeling methods, such as data flow diagram and entity relationship diagram, are facing new OO modeling languages, such as the unified modeling language (UML) (see Siau & Cao, 2001; Siau, Erickson, & Lee, 2005; Siau & Loo, 2006) and OO methodologies, such as unified process (UP). The latest development includes agile modeling (see Erickson, Lyytinen, & Siau, 2005), extreme programming, and OSS development. While many of these changes are related to systems development paradigms, methodologies, methods, and techniques, the phenomenon of OSS development entails a different structure for software development teams.

Unlike conventional software projects, the participants of OSS projects are volunteers. They are self-selected based on their interests and capability to contribute to the projects (Raymond, 2000). In addition, the developers of OSS projects are distributed all around the world. They communicate and collaborate with each other through the Internet, using e-mails or discussion boards.

Therefore, effective and efficient communication and collaboration are critical to OSS success. However, little empirical research has been conducted to study the underlying interaction pattern of OSS teams, especially the dynamics of the social network structures in OSS development teams. To fill this gap, this study examines the evolvement of social structure in OSS teams. The study contributes to the enhancement of the understanding of OSS development, and provides foundation for future studies to analyze the antecedents and consequences of social networks in the OSS context.

The remainder of the paper is structured as follows. First, prior studies on social network structures in OSS teams are reviewed. Second, theories related to social structure and social network theory are discussed. Third, the research methodology is presented, and the research results are reported. Next, discussions of the results, the limitations, and the implications are provided. The paper concludes with suggestions for future research.

LITERATURE REVIEW

The phenomenon of OSS development has attracted considerable attention from both practitioners and researchers in diverse fields, such as computer science, social psychology, organization, and management. Because of the multifaceted nature of OSS, researchers have investigated OSS phenomenon from varied perspectives. For example, focusing on technical perspective, researchers studied issues such as OSS development methodology (e.g., Jørgensen, 2001) and coding quality (e.g., Stamelos, Angelis, Oikonomu, & Bleris, 2002). Based on social psychology, researchers investigated individual motivation (e.g., Hann, Robert, & Slaughter, 2004), new developers (Von Krogh, Spaeth, & Lakhani 2003), the social network (e.g., Madey, Freeh, & Tynan, 2002), and the social structure (e.g., Crowston & Howison, 2005). In terms of organizational and managerial perspective, researchers examined knowledge innovation (e.g., Hemetsberger 2004; Lee & Cole 2003, Von Hippel & von Krogh, 2003) and the governance mechanism (e.g., Sagers 2004).

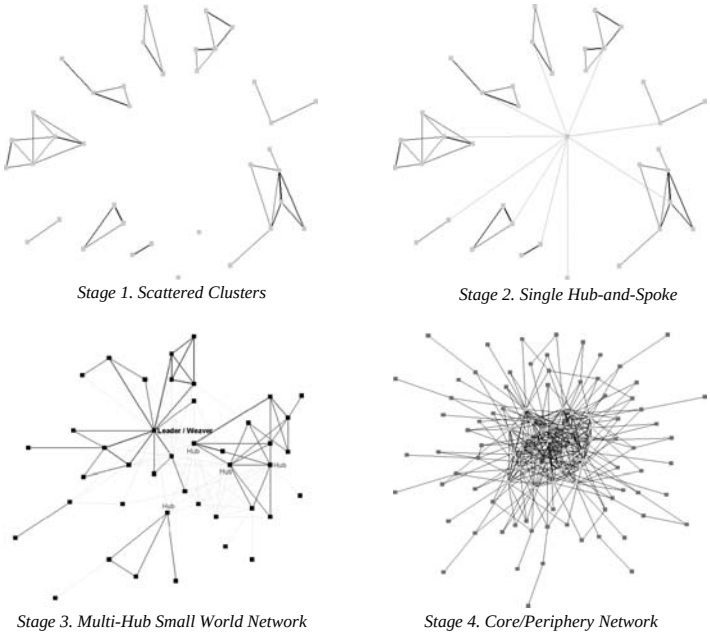
An OSS development team is essentially a virtual organization in which participants interact and collaborate with each other through the Internet. Compared to conventional organizations, the structure of virtual organizations is decentralized, flat, and nonhierarchical (Ahuja & Carley 1999). However, some researchers challenge the belief (e.g., Crowston & Howison 2005; Gacek & Arief, 2004;; Mockus, Fielding, & Herbsleb, 2000; Mockus, Fielding, & Herbsleb, 2002; Moon & Sproull, 2000). They argue that the social structure of OSS projects is hierarchical rather than flat, like a tree (Gacek & Arief, 2004) or an onion (Crowston & Howison, 2005). The social structure of OSS teams directly influences the collaboration and the decision-making process and further affects the overall performance of the teams as well as individuals' perception of belonging and satisfaction. Therefore, one wonders what form of social structure might be present in the OSS development and what type of structure will emerge—centralized or decentralized, hierarchical or nonhierarchical, onion-like or tree-like, or a combination of the above depending on certain specific situations?

A social network, as stated by Krebs and Holley (2004), is generally built in four phases, each with its own distinct topology (as shown in Figure 1).

1. scattered clusters,
2. single hub-and-spoke,
3. multihub small-world network, and
4. core/periphery.

Most organizations start from isolated and distributed clusters (Krebs & Holley, 2004). Then an active leader emerges and takes responsibility for building a network that will connect the sepa-

Figure 1. Four phases of social structures (from Krebs and Holley 2004)



Stage 1. Scattered Clusters

Stage 2. Single Hub-and-Spoke

Stage 3. Multi-Hub Small World Network

Stage 4. Core/Periphery Network

rate clusters. However, this single-hub topology is fragile. With more participants entering the group, the leader changes his/her role to a facilitator and helps to build multiple hubs, which is stage three. The core/periphery model, the last stage, is the most stable structure. In the core/periphery model, the network core encompasses key group members who are strongly connected to each other, while the periphery contains members who are usually weakly connected to each other as well as to the core members. With the general network building phases in mind, one can argue that OSS projects may follow the same four stages (i.e., scattered clusters, single hub-and-spoke, multihub small-world network, and core/periphery model). But is that true for OSS projects? How does the social structure of OSS teams evolve over time?

Our research addresses the following two questions:

1. What is the social structure of OSS teams?
2. How does the social structure evolve over time?

THEORETICAL FOUNDATION

Social Structure and Social Interaction

Social structure, as suggested by Schaefer and Lamm (1998), refers to the way in which society is organized into predictable relationships. Social structure can be considered in terms of three aspects—actors, their actions, and their interactions. The social actor is a relatively static concept addressing issues such as roles, positions, and statuses. Individual actors are embedded in the social environment and, therefore, their actions are largely influenced by the connections between each other. Social interaction is generally regarded as the way in which people respond to one another. These interaction patterns are to some extent independent of individuals. They exert a force that

shapes both behavior (i.e., actions) and identity (i.e., actors) (Schaefer & Lamm, 1998).

Research on social interaction focuses on how individuals actually communicate with each other in group settings. These studies address issues such as the interaction patterns, the underlying rules guiding interaction, the reasons accounting for the way people interact, and the impacts of the interaction patterns on the individual behavior and the group performance. These issues begin by questioning what might be the interaction pattern in a specific social setting and that addresses our research question—understanding social interaction of OSS project teams.

Social Network Theory

Social network theory focuses on studying actors as well as their relationships in specific social settings. Network theory is analogous to systems theory and complexity theory. It is an interdisciplinary theory stemming from multiple traditional fields, including psychology, which addresses individuals' perception of social structure; anthropology, which emphasizes social relationships; and mathematics, which provides algorithms (Scott, 2000).

Based on the view of social network, the world is composed of actors (also called nodes) and ties between them. The ties can represent either a specific relationship (such as friendship and kinship) between a pair of actors or define a particular action which an actor performs. Different kinds of ties specify different networks and are typically assumed to function differently. For example, the ties in a family network are distinctive from those in a working network, and the centrality in the "who loves whom" network obviously has different meaning than the centrality in the "who hates whom" network.

Social network theory is based on the intuitive notion that the social interaction patterns are essential to the individuals who reflect them. Network theorists believe that how individuals behave largely depends on how they interact with others and how they are tied to a social network. Furthermore, besides individual behavior, network theorists believe that the success or failure of societies and organizations often depends on the internal interaction pattern (Freeman, 2004).

Besides the theoretical essence, social network theory is also characterized as a distinctive methodology encompassing techniques for data collection, statistical analysis, and visual representation. This approach is usually called social network analysis and will be discussed in the research methodology section. This paper draws on the social network theory to study the interaction pattern of OSS development project.

RESEARCH METHODOLOGY

Social Network Analysis

Social network analysis is used in our study to investigate the interaction pattern of the OSS development process. Social network analysis focuses on uncovering the interaction pattern of interdependent individuals (Freeman, 2004). Through a structural analysis of a social network diagram, a map depicting actors as well as the ties that connect them, social network analysis can reveal the patterns of relationships and the relative position of individuals in a specific social setting. This approach has been effectively used in organizational research, social support, mental health, and the diffusion of information (Freeman, 2004).

Social network analysis is used in our study for two primary reasons. First, the purpose of social network analysis fits our research objective. Social network analysis aims to analyze the relationship among a set of actors instead of their internal attributes. Our research aims to reveal the interaction pattern of OSS project teams. Therefore, social network analysis is helpful in answering our research questions.

Second, the rich interactive data extracted from OSS projects presents a "gold mine" for social network analysis. Social network analysis is grounded in the systematic analysis of empirical data. However, there is usually a lack of convenient and objective resources from which to draw the links (i.e., relationships) among actors. Most OSS projects have online mailing lists, forums, and tracking systems that are open to public, thus providing a rich set of longitudinal data. Based on these public data, researchers are able to capture input data sets for social network analysis.

Longitudinal Data

Because we are interested in studying how the interaction pattern of OSS projects evolves over time, cross-sectional observations of interaction networks are not sufficient. Cross-sectional observations of social networks are snapshots of interactions at a point in time and cannot provide traceable history, thus limiting the usefulness of the results. On the other hand, longitudinal observations offer more promise for understanding the social network structure and its evolvement. In this study, we extracted longitudinal data on OSS projects.

Case Selection

OSS projects were selected from the SourceForge[1], which is the world's largest Web site hosting OSS projects. SourceForge provides free tools and services to facilitate OSS development. At the time of the study, it hosted a total of 99,730 OSS projects and involved 1,066,589 registered users (This data was retrieved on May 4, 2005). Although a few big OSS projects have their own Web sites (such as Linux), SourceForge serves as the most popular data resource for OSS researchers.

Following the idea of theoretical sampling (Glaser & Strauss, 1967), three OSS projects were selected from SourceForge in terms of their similarities and differences. Theoretical sampling requires theoretical relevance and purposes (Orlikowski, 1993). In terms of relevance, the selection ensures that the interaction pattern of OSS projects over time is kept similar. Therefore, the projects that are selected have to satisfy two requirements. First, the projects must have considerable interaction among members during the development process. All three projects had more than 10 developers, and the number of bugs reported was more than 1,000. Second, since we are interested in the interaction over time, the projects must have a relatively long life. In our case, all three projects were at least three years old.

In addition to similarities, differences are sought among cases because the study aims to study interaction patterns of various OSS projects. Therefore, the three projects differ on several project characteristics, such as project size, project type, and intended audience. These differences enable us to make useful contrasts during data analysis.

The Table 1 summarizes the three projects with a brief description.

Data Collection and Analysis

Social network analysis can be divided into the following three stages (Borgatti, 2002).

1. Data collection. In this stage, researchers collect data, using surveys and questionnaires, or from documents and other data resources, and generate input data sets for social network analysis.
2. Statistical analysis. Based on mathematics algorithms, this stage generates network indices concerning group structure (such as centralization and density) as well as individual cohesion (such as centrality and bridges).
3. Visual representation. This stage employs network diagrams to show the interaction structure as well as the position of specific actors.

Table 1. Summary of three projects

		Net-SNMP	Compiere ERP + CRM	J-boss
Description		Net-SNMP allows system and network managers to monitor and manage hosts and network devices.	Compiere is a smart ERP+CRM solution covering all major business areas—especially for small-medium enterprises.	JBoss is a leading open source Java application server. After Linux and Apache, it is the third major open source project to receive widespread adoption by corporate IT.
Similarities	Bug reports (more than 1,000 bugs)	1,361	1,695	2,296
	Development duration (more than 3 years)	55 months (registered on 10/2000)	47 months (registered on 6/2001)	50 months (registered on 3/2001)
Differences	Software type	Internet, network management	Enterprise: ERP+CRM	J2EE-based middleware
	Group size (number of developers)	Small (14)	Median (44)	Large (75)
	Intended audience	Developers, system administrators	Business	Developers, system administrators

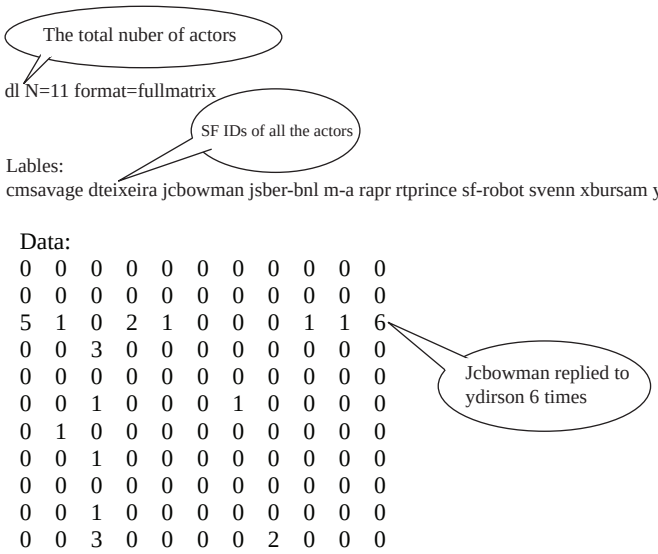
Note: Data was retrieved in April 2004 from SourceForge.net.

First is the data collection. The data were collected in April 2005 from SourceForge.net. Data were extracted from the bug tracking system of each project. We chose the bug tracking system as the primary data resource for three reasons. First, open source software is characterized as peer review of open codes. Raymond (1998) proposed the "Linus' law" in his well-known essay *The Cathedral and the Bazaar*— "Given enough eyeballs, all bugs are shallow." Therefore, the bug system can be viewed as the representative of open source spirit. Second, compared to other development activities, such as patch posting and feature request, the bug-fixing process is the most active procedure to illustrate the close collaboration between developers and users as well as among developers themselves. Finally, the bug tracking system provides rich data that record the interactive process.

A Web spider program, which is based on the work of Crowston and Howison (2005) with necessary revision, was used to download the bug tracking Web pages from the project Web site. After that, a Web parsing program was developed to analyze the Web pages. The interaction data was extracted from the bug tracking Web pages month-by-month, starting from the date the project was registered until the date the data was downloaded for this study. The output of this stage is a social matrix describing the interaction among users. Figure 2 shows an example of such a social matrix for an OSS project. In the matrix, each row or column represents a distinctive participant, which is identified by a unique SourceForge user identity. The values of cells indicate the degree of the interaction between each pair of participants, which is counted by the amounts of messages that participant A (i.e., row A) replied to participant B (i.e., column B).

Second is the statistical analysis. Our study focuses on two important and distinctive properties of network structure—group centralization and core/periphery fitness. Ucinet, which was devel-

Figure 2. An example of the social matrix for an OSS project



oped by Borgatti, Everett, and Freeman (2002), was used to calculate these two properties.

Group centralization, as suggested by Wasserman and Faust (1994), refers to the extent to which a network revolves around a single center. A typical case of centralized structure is a "star" network. Group centralization can be viewed as a rough measure of inequity between individual actors, and the variability and dispersion of the interaction pattern.

The other property is core/periphery fitness. It measures the extent to which the network is close to a perfect core/periphery structure. The core/periphery structure depicts a dense, connected group surrounded by a sparse, unconnected periphery. The opposite structure is clique, which represents a structure of multiple subgroups, each with its own core and peripheries (Borgatti, 2002).

Finally is the visual representation. We used Ucinet (Borgatti et al., 2002) to draw the interaction networks for each of the three projects.

RESEARCH RESULTS

Snapshots of the Three Projects

Monthly data were extracted from the bug tracking system of each project. To illustrate the trend of interaction pattern, we provide three snapshots for each project (see Figures 3-5)[2].

Table 2 summarizes the relevant network characteristics of each project. In addition to the group centralization and core/periphery fitness, we also report other network characteristics, such as density, average distance, and distance-based cohesion. Density depicts how "close" the network looks, and it is a recommended measure of group cohesion (Blau, 1977; Wasserman & Faust 1994). The value of density ranges from 0 to 1. Average distance refers to average distance between all pairs of nodes (Borgatti, 2002). Distance-based cohesion takes on values between 0 and 1—the larger the values, the greater the cohesiveness.

Looking at the statistical results and the network plots, we can observe the following.

First, the evolvement of interaction patterns of the three projects reveals a general trend. As

Table 2. Three snapshots for each project

		Net-SNMP	Compiere	JBoss
Group centralization (%)	1st.	9.420	15.624	4.931
	2nd.	3.071	2.294	4.45
	3rd.	2.316	1.288	4.12
Core/periphery fitness	1st.	0.674	0.774	0.485
	2nd.	0.654	0.796	0.477
	3rd.	0.651	0.765	0.501
Density	1st.	0.0235	0.0584	0.0073
	2nd.	0.0109	0.0610	0.0039
	3rd.	0.0072	0.0571	0.0026
Average distance	1st.	2.546	2.711	3.438
	2nd.	2.794	2.302	3.281
	3rd.	2.917	2.278	3.239
Distance-based cohesion	1st.	0.181	0.198	0.118
	2nd.	0.143	0.253	0.147
	3rd.	0.141	0.279	0.136

shown in the network plots (i.e., Figures 3-5), the interaction pattern develops from a centralized one with a single (sometimes dual) hub with several distributed nodes, to a core/periphery structure that has a core (a group of core developers) together with several hangers-on (periphery). Intense interactions exist within the core (among several core developers) and between each core member and his/her periphery. However, only loose relationships exist among peripheries. This pattern suggests a layer structure (i.e., core with its periphery) instead of a complete flat one with equal positions across all the members.

Second, although the interaction patterns of the three projects share some commonalities, their exact shapes are different. The shape of Net-SNMP (as shown in Figure 3) is more like a typical core/periphery compared to the other two. Compiere (as shown in Figure 4) keeps two cores, and the shape looks like a dumbbell. Jboss (as shown in Figure 5), which is the largest project among the three, maintains a more complex structure that shows multiple layers instead of just one core with the rest as peripheries (e.g., Net-SNMP)

Third, as time goes by, the group centralization decreases across the three projects, showing a trend that moves from a centralized structure to a decentralized structure irrespective of project sizes (The three projects with different project sizes are shown in Table 1), project types, and intended audience.

Fourth, the indices of core/periphery fitness of each project fluctuate slightly but maintain a relatively high value (larger than 0.5 on average). However, no observable trend was found across projects.

Fifth, since each project has a relatively large group (i.e., more than 100 actors including all the registered users), the values of density are relatively low with little variation. Therefore, density is not appropriate for comparing the projects.

From the snapshots, we observed the following trend. First, the OSS interaction network evolves into a core/periphery structure. Second,

Figure 3. Interaction patterns of Net-SNMP

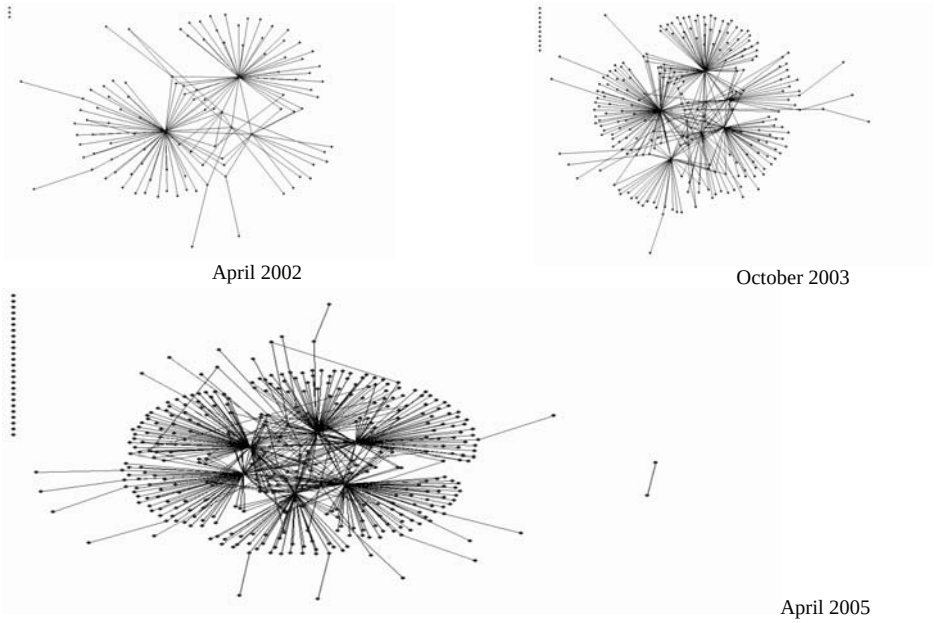


Figure 4. Interaction patterns of compiere CRM+ERP

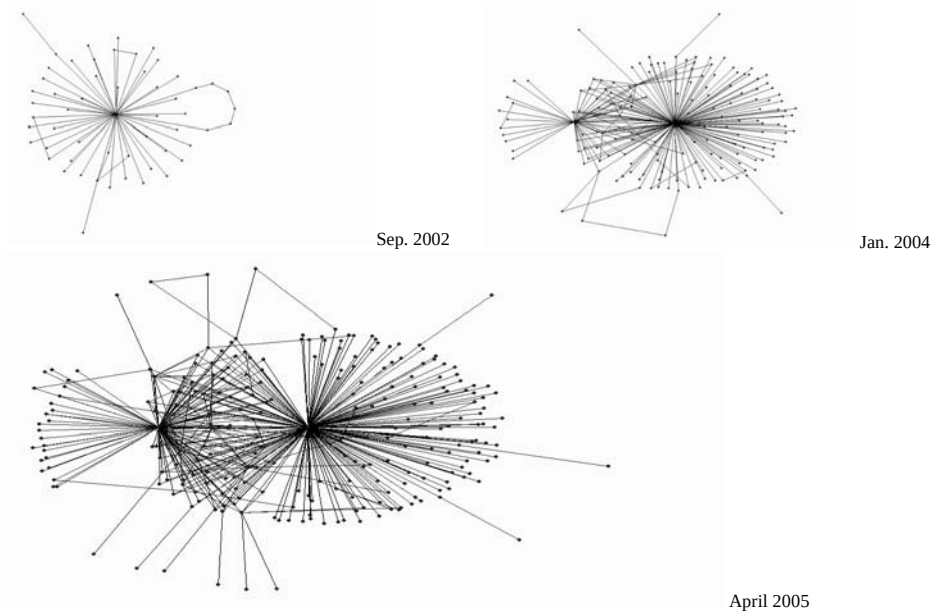
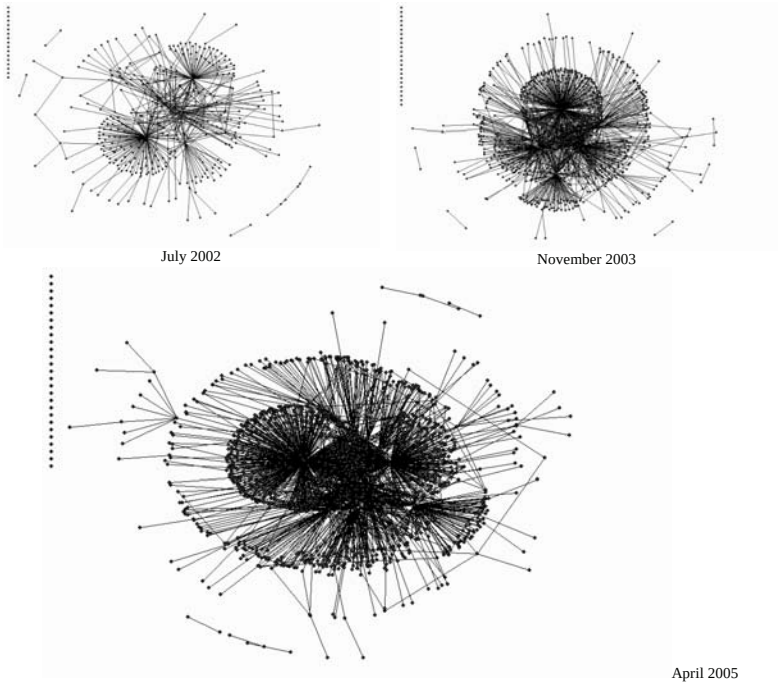


group centralization decreases over time. Third, core/periphery fitness stays relatively stable. To verify our observations, we used longitudinal data generated from the bug tracking systems to analyze the evolvement of interaction pattern (discussed in the following section).

Figure 5. Interaction patterns of JBoss



Group Centralization and Core/Periphery Fitness

Table 3 shows the values of both group centralization and core/periphery fitness over time based on the monthly interaction data. For each figure, the Y-axis indicates the social structure indices (i.e., group centralization or core/periphery fitness), and the X-axis reflects the time dimension.

Two primary observations can be made based on the statistical analysis.

First, the group centralization shows a decreasing trend across the three projects. This observation indicates that as OSS projects progress, the social network structure evolves from centralized to decentralized and then stabilizes. Also, the three figures suggest no substantial differences in the trend among the three projects.

Second, the core/periphery index is maintained at a relatively stable level for each project over time. In addition, the average fitness value stays relatively high for each project (larger than 0.5), indicating a closeness to a perfect core/periphery structure.

Besides a holistic view of network structure for OSS projects, the results also reveal other interesting findings. For example, by examining the core members over time, we found a relatively stable core for each project. The cores are usually project developers and administrators. This observation further demonstrates the existence of strong and stable core as well as loose hangers-on in OSS projects.

DISCUSSION

This research uses the longitudinal data of three OSS projects selected from SourceForge to study the social network structures of OSS teams. The purpose of this study is to investigate the evolvement of interaction patterns of OSS project teams.

Table 3. Group centralization and core/periphery fitness based on longitudinal data

	Group centralization	Core/periphery fitness
Net-SNMP		Compiere		JBoss		
The research results suggest a decrease of group centralization over time and a tendency of core/periphery structure in OSS project teams.

The network plots (as shown in Figures 3-5) indicate a layer structure instead of a flat one as suggested by earlier literature. The interaction pattern evolves from a single hub to a core/periphery structure. As the number of participants increases, a core with only one person (who may be the starter/initiator of the project) cannot satisfy the increasing requirements of development and communication. Therefore, other developers or active users join the core to serve as key members of the project. This results in a more stable structure, and the project is less dependent on a single leader.

With the growth of a software project, more people are attracted to the project. The original leader may not be able to solve all the technical problems encountered in the development process. Each key member has his/her specialty, is responsible for solving relevant problems, and has his/her own periphery in the network plot. Although there are multiple peripheries in the project, collaboration among key members in the project is vital. This phenomenon of distribution and collaboration can be viewed as a critical success factor of OSS development. And the evolvement is vividly demonstrated in our social network analysis.

In a way, the social structure of OSS projects is both centralized and decentralized. On one hand, it is centralized in the sense that there is a core that consists of key members. These key members are responsible for various issues encountered during the development process. On the other hand, it is decentralized in the sense that the decision or communication core is not concentrated on one or two members but a group of key members.

Like any other research, this research has its share of limitations. First, the cases were only selected from SourceForge.net. Although Source-

Forge is the world's largest Web site hosting open source software, there are also some other similar Web sites. Therefore, the total number of OSS projects in SourceForge cannot be viewed as the whole population. However, as we argued before, SourceForge is probably the best data collection site for this research.

Second, the bug tracking system was chosen as our data resource. The selection of bug tracking system as our research setting and data resource may have had an effect on the outcome and results. Besides the bug tracking forum, there are other forums that also provide space for participants to communicate with one another, such as mailing lists and feature requests. However, as we highlighted earlier, the bug systems are the most active forum, providing rich interaction data. The bug tracking systems also represent the spirit of open source software development. Examining the interaction data from other forums can be one of our research extensions in the future.

Third, because our research objective is to investigate interaction pattern, we chose projects that have a relatively large number of developers, a large number of bug reports, and relatively long history. Although we tried to involve different types of projects (i.e., different project sizes, project types, and intended audience), these three cases may not be representatives of OSS projects, for example, small projects with only one or two developers and few interactions. Increasing the sample size and including various types of OSS projects is one of our future research directions.

IMPLICATIONS AND CONCLUSION

This paper examines the interaction patterns of OSS teams. The research findings suggest that the interaction structure starts from a single hub and evolves to a core/periphery model. We argue that the social structure of OSS teams is both centralized and decentralized. It is centralized in the sense that there exists a relatively stable core that consists of a group of key developers. It is also decentralized because of distributed decision making among key developers and the broad collaboration between developers and users as well as among developers themselves.

The paper presents the evolvement of the social structure of OSS projects from a longitudinal perspective. It also provides empirical evidence of the change of interaction patterns from a single hub to a core/periphery model. Moreover, the paper utilizes social network analysis as the research method. This approach has been shown in this research as an effective tool in analyzing the social structure in OSS teams.

Social structure is an important variable for understanding social phenomenon. Open source software, with its open and unique nature, attracts researchers to ask a series of questions. For example, how do participants of OSS projects interact and collaborate with each other? What factors facilitate the interaction and the collaboration? And further, how does the collaboration affect project performance of OSS teams? Social network analysis is a good approach to investigate these questions. This research represents a pioneering effort in this direction.

Chapter 5.4
The Impact of Ideology on the Organizational Adoption of Open Source Software

Kris Ven
University of Antwerp, Belgium

Jan Verelst
University of Antwerp, Belgium

ABSTRACT

Previous research has shown that the open source movement shares a common ideology. Employees belonging to the open source movement often advocate the use of open source software within their organization. Hence, their belief in the underlying open source software ideology may influence the decision making on the adoption of open source software. This may result in an ideological—rather than pragmatic—decision. A recent study has shown that American organizations are quite pragmatic in their adoption decision. We argue that there may be circumstances in which there is more opportunity for ideological behavior. We therefore investigated the organizational adoption decision in Belgian organizations. Our results indicate that most organizations are pragmatic in their decision making. However, we have found evidence that suggests that the influence of ideology should not be completely disregarded in small organizations.

INTRODUCTION

The free software movement—led by Richard M. Stallman—has always taken an ideological, political view on software. Adherents to the free software movement advocate that all software should be free, in the sense that it should be free to read, modify, and distribute. The open source movement on the other hand was created in order to facilitate the introduction of free software in organizations and takes a more pragmatic stance in its efforts to market open source software (OSS). Previous research has shown that the open source movement is characterized by a shared, underlying ideology (e.g., Ljungberg, 2000; Bergquist & Ljungberg, 2001). Lately, an increasing number of developers are hired by commercial organizations to work on OSS projects. These developers may or may not share the OSS ideology. Nevertheless, many adherents to the open source movement still feel connected to the OSS ideology. Moreover, commercial organizations still need to find a balance between their commercial objectives and the

traditional values of the open source movement (Fitzgerald, 2006).

Many organizations have already adopted OSS, especially mature server software such as Linux and Apache. Research on the organizational adoption of OSS has shown that its use was frequently a bottom-up initiative, suggested by technical employees within the organization who are an adherent to the open source movement (Dedrick & West, 2003; West & Dedrick, 2005; Lundell, Lings, & Lindqvist, 2006). In some cases, decision makers could also be considered an adherent to the open source movement. These employees will take on the role of *boundary spanners* in their organization, bringing the organization in contact with new innovations (Tushman & Scanlan, 1981). West and Dedrick (2005) have found in their study on American organizations that although such employees try to ensure that an open source alternative is considered in the decision making, the final decision is made on pragmatic grounds (i.e., based on characteristics of the software such as cost, reliability, and functionality), and not based on ideological feelings towards OSS. The organizations included in their study are rather large,[1] which may have had an impact on their results.

We argue that it is useful to perform a similar study in a context in which there is more opportunity for ideological behavior. We expect that this might be the case in smaller organizations. In order to investigate whether decision making in small organizations is ideological, we have conducted 10 case studies in Belgian organizations to investigate the organizational adoption of OSS. The article is structured as follows. We will start by discussing the theoretical background of this study. Next, we will discuss our research design. Subsequently, we will present the results of our study, focusing on three organizations that used fairly ideological decision making. This is followed by a discussion of our findings. Finally, we will offer our conclusions.

THEORETICAL BACKGROUND

OSS Ideology

Numerous definitions have been proposed in literature for the term "ideology." Usually, the term is used in a pejorative meaning. Such use implies that an ideology is based on false beliefs of reality. Several authors however recommend against using such a perspective (e.g., Hamilton, 1987). The definition of ideology that we will use in this article is proposed by Hamilton (1987, p. 38):

"An ideology is a system of collectively held normative and reputedly factual ideas and beliefs and attitudes advocating a particular pattern of social relationships and arrangements, and/or aimed at justifying a particular pattern of conduct, which its proponents seek to promote, realise, pursue or maintain."

This definition is non-judgmental, and as a result we do not make any pronouncements with respect to the correctness of the beliefs, values, and norms that characterize an ideology. Hence, acting according to an ideology will not necessarily have negative consequences for the organization.

Previous research has described several ideological principles of the open source movement (e.g., Markus, Manville, & Agres, 2000; Ljungberg, 2000; Stewart & Gosain, 2006). This ideology has been shown to enhance the effectiveness of the OSS community (Stewart & Gosain, 2006). Stewart and Gosain (2006) identified a number of underlying norms, beliefs, and values of the open source movement (see Table 1). These norms, beliefs, and values are proposed as the tenets of the OSS ideology.

The tenets listed in Table 1 are used to describe the attitudes of developers within the OSS community. We argue however that some of the OSS beliefs and values (i.e., tenets 4–15 in Table 1) can also be shared by technical employees and decision makers in organizations. Hence, it is interesting to investigate whether decision mak-

Table 1. Tenets of open source ideology (Stewart & Gosain, 2006, pp. 294–295)

OSS Norms	OSS Beliefs	OSS Values
(1) *Forking*—There is a norm against forking a project, which refers to splitting the project into two or more projects developed separately. (2) *Distribution*—There is a norm against distributing code changes without going through the proper channels. (3) *Named Credit*—There is a norm against removing someone's name from a project without that person's consent.	(4) *Code Quality*—Open source development methods produce better code than closed source. (5) *Software Freedom*—Outcomes are better when code is freely available. (6) *Information Freedom*—Outcomes are better when information is freely available. (7) *Bug Fixing*—The more people working on the code, the more quickly bugs will be found and fixed. (8) *Practicality*—Practical work is more useful than theoretical discussion. (9) *Status Attainment*—Status is achieved through community recognition.	(10) *Sharing*—Sharing information is important. (11) *Helping*—Aiding others is important. (12) *Technical Knowledge*—Technical knowledge is highly valued. (13) *Learning*—There is a value on learning for its own sake. (14) *Cooperation*—Voluntary cooperation is important. (15) *Reputation*—Reputation gained by participating in open source projects is valuable.

ers who share these ideological ideas of the open source movement make an ideological—rather than pragmatic—decision. Although the study of West and Dedrick (2005) has shown that decision making on OSS is pragmatic, we believe that this may be different in small organizations. Some authors have pointed out that decision making with respect to IT in small organizations is often the responsibility of a single individual (Harrison, Mykytyn, & Riemenschneider, 1997; Riemenschneider, Harrison, & Mykytyn, 2003). We argue that the impact of the OSS ideology will be greater if a single decision maker—who can be considered an OSS advocate—is present in the organization. In such situations, the adoption decision may be ideological since personal traits and beliefs of the decision maker are more likely to impact the final decision than in larger organizations.

Mindful Innovation

Nowadays, many things require the attention of managers, making their attention a scarce resource (Hansen & Haas, 2001; Swanson & Ramiller, 2004). One of the consequences is that much innovation in organizations is actually driven by bandwagon phenomena, in which organizations mimic the adoption behavior of other organizations and do not properly evaluate alternatives (Abrahamson, 1991; Swanson & Ramiller, 2004). Recently, the bandwagon phenomenon has been framed into the broader context of *mindful innovation* (Swanson & Ramiller, 2004; Fiol & Connor, 2003). The concept of mindfulness originated in psychology and denotes a state of an individual involving: (1) openness to novelty; (2) alertness to distinction; (3) sensitivity to different contexts; (4) implicit, if not explicit, awareness of multiple perspectives; and (5) orientation in the present (Sternberg, 2000). Decision makers in organi-

zations who are mindful have a "watchful and vigilant state of mind" (Fiol & Connor, 2003). An organization that innovates mindfully with IT will therefore not take generalized claims about advantages for granted, but will critically examine their relevance and validity in the organization-specific context (Fiol & Connor, 2003). Mindless innovation, on the other hand, is characterized by "…acting on automatic pilot, precluding attention to new information, and fixating on a single perspective" (Fiol & Connor, 2003; Weick, Sutcliffe, & Obstfeld, 1999).[2] Such innovation may result in making premature decisions based on beliefs that do not necessarily accurately reflect reality (Butler & Gray, 2006). Hence, a dogmatic belief in the OSS ideology may lead to mindless adoption, in which no proprietary alternatives are considered.

Swanson and Ramiller (2004) note that boundary-spanning activities are important for mindful organizational decision making, in order to obtain information on the innovation. We argue that in the case of OSS, this information may be ideologically colored. As a result, the presence of boundary spanners in the adoption of OSS may actually lead to ideological (mindless) behavior instead, especially if decision makers share the OSS ideology. There are at least two factors that can facilitate ideological behavior in such context. First, decision structures in small organizations tend to be less formal (bureaucratic) than in large organizations. Fiol and Connor (2003) argue that underspecified decision structures may encourage further mindless behavior, if decision making was mindless to begin with. Second, Swanson and Ramiller (2004) point out that although personal mindfulness with respect to innovation does not necessarily equate to organizational mindfulness, it will definitely have an impact on it.

Ideology vs. Pragmatism

In order to investigate whether decision making in organizations exhibits ideological characteristics, we need to determine how ideological behavior can be identified. Based on the work of Stewart and Gosain (2006), we determine whether decision makers and other employees shared some of the beliefs and underlying principles (tenets) of the free and open source movements (see Table 1), *and* did not properly assess their relevancy for the organization. For example, proponents may argue that software should be free (similar to the views of the FSF), may have a negative attitude towards proprietary software, or may be convinced that OSS delivers software of a higher quality (Stewart & Gosain, 2006; Ljungberg, 2000). Consequently, decision makers may have a strong preference for using OSS, without (properly) considering proprietary alternatives. Such decision making may result in a less than optimal solution for the organization. In fact, decision makers are in that case rather mindless in their decision making. Mindless organizations will pay little attention to the organization's specifics or to studying new innovations. This will result in making decisions on "autopilot," using a single perspective (Swanson & Ramiller, 2004; Fiol & Connor, 2003). This means that the beliefs of the OSS ideology are taken for granted, without considering their suitability in the organization-specific context.

On the other hand, we consider an organization to be pragmatic in its decision making when the organization does not exhibit any of the tenets of the OSS ideology, or when decision makers do not take any claims of the OSS ideology for granted, but carefully examine their implications in the organization-specific context. Such organizations are mindful in their decision making. This means that decision makers base their decision on the characteristics of the innovation itself and consider how well the innovation fits within the organization. Pragmatic decision makers will probably consider both proprietary and OSS alternatives, outweigh the benefits of all alternatives, and choose the best solution based on factors such as cost and product features. In

this case, no favoritism towards using OSS should be present.

It must be noted that ideological and pragmatic decision making is not a black and white phenomenon. In practice, we expect organizations to exhibit some ideological and some pragmatic characteristics. This is consistent with Geuss (1994), who remarks that an ideology is generally not only composed of the beliefs and values that are shared by *all* members of a group. Consequently, not all adherents to the open source movement will share *all* values proposed by the OSS ideology. This is similar to the statement of Ljungberg (2000) who suggests that developers vary in their adherence to the OSS ideology. Hence, there are many shades of gray in this classification. In this article, we will discuss decision making in three organizations in our sample which clearly exhibited ideological behavior.

RESEARCH DESIGN

To investigate whether decision making is ideological or pragmatic, we studied the organizational adoption of OSS in Belgian organizations. In this study, decision makers were questioned about the reasons for using OSS and their attitudes towards the open source movement. Based upon the information obtained from these organizations, we were able to determine whether their decision making was either pragmatic or rather ideological.

Scope

We decided to focus mainly on the adoption of open source *server* software. We use the term open source server software to refer to both open source operating systems (such as Linux and FreeBSD) and other OSS for server use (for example, the Apache Web server or the Bind name server). This choice is motivated by the fact that this type of OSS is generally considered to be stable and mature, and is already in use by a significant number of organizations. A similar research approach has been undertaken by other researchers (e.g., West & Dedrick, 2005). On the other hand, we also gathered information on other OSS that was being used in the organizations (such as desktop software, development, and networking tools).

Methodology

We used the exploratory case study approach to study the organizational adoption decision on open source server software. The case study approach is well suited to study a contemporary phenomenon in its natural setting, especially when the boundaries of the phenomenon are not clearly defined at the start of the study (Yin, 2003; Benbasat, Goldstein, & Mead, 1987). We conducted a series of in-depth face-to-face interviews with informants from 10 Belgian organizations to identify the factors that influence the decision to use open source server software as well as their attitudes towards the open source movement. Organizations were selected from the population of all Belgian organizations and were sampled on the basis of two criteria: the size of the organization measured by the number of employees and the sector in which the organization operated. Organizations were only included in our sample if they were using open source server software at the time of our study. Informants within each organization were selected using the *key informant method*. Since the use of a single informant has been shown to give inconsistent results (Phillips, 1981), we tried to speak to both a senior manager (e.g., the IT manager) and a technical person (e.g., the system administrator) whenever possible.

The interviews took place between July and November 2005. An overview of the cases in our study is shown in Table 2. As can be seen from this table, the organizations in our sample are considerably smaller than those in the study of West and Dedrick (2005).[3] In each organization, we have

Table 2. Overview of the organizations in our study

Name	Sector	Employees	Informants	Extent of adoption
OrganizationA	Audio, video, and telecommunications	11	2	moderate
OrganizationB	Machinery and equipment	749	2	extensive
OrganizationC	Telecommunications	1346	1	limited
OrganizationD	Publishing and printing	31	1	extensive
OrganizationE	Food products and beverages	204	2	moderate
OrganizationF	Research and development	152	2	extensive
OrganizationG	Information technology	583	1	moderate
OrganizationH	Chemicals	4423	1	moderate
OrganizationI	Education	3303	3	limited
OrganizationJ	Publishing and printing	12	1	extensive

conducted a single interview during which all informants in the organization were present. The interviews were semi-structured, and the format was revised after each interview to incorporate new findings (Benbasat et al., 1987). In the first part of the interview, informants were asked to freely discuss their reasons for adopting OSS. In the second part of the interview, we probed for specific factors that were found relevant in previous studies, as well as the informants' perceptions of the free and open source movements. Each interview lasted 45-90 minutes, was recorded and transcribed verbatim. In order to increase the validity of our findings, informants were sent a summary of the interview and were requested to suggest any improvements if necessary. Follow-up questions were asked by telephone or via e-mail. The transcripts were coded and then further analyzed using procedures to generate theory from qualitative data, as described in the literature (e.g., Benbasat et al., 1987; Eisenhardt, 1989; Dubé & Paré, 2003). Various data displays were used to visualize and further analyze the qualitative data (Miles & Huberman, 1994; Eisenhardt, 1989).

EMPIRICAL FINDINGS

The dominant attitude towards OSS in seven organizations in our sample was pragmatism. These organizations did not exhibit any of the tenets of the OSS ideology, or their decision makers considered how the advantages of OSS could be realized in their organization. Consequently, these organizations could be considered pragmatic (and mindful) in their decision making with respect to the adoption of OSS. The most commonly cited advantages—and reasons for the adoption—of OSS were *cost* and *reliability*. In general, decision makers tended to consider both proprietary and OSS alternatives, and based their decision on the cost and functionality offered by the various alternatives. Some organizations even explicitly mentioned that they made a pragmatic adoption decision. These seven organizations did not have a preference for using OSS over proprietary software, except OrganizationB where a slight preference for OSS was present. Although they would accept a minor workaround in order to be able to use OSS, this effort should be limited. Or, as expressed by an informant:

We are not going to program around something, because we really want to use that [open source] component. But if there is a little workaround, we will certainly take it.

The other six organizations were quite agnostic about using OSS. One informant in OrganizationF expressed this as:

[The fact that the software is open source] does not really matter for a company.

Some of the technical employees who served as informants in our study had a background in OSS. Although some indicated that they did suggest the use of OSS when appropriate, they did not try to force its use and remained pragmatic. Nevertheless, many OSS development and networking tools (e.g., Nagios, Eclipse, and Maven) were being used by the organizations in our sample.

The results obtained from these seven organizations are quite consistent with the results obtained by West and Dedrick (2005). On the other hand, we observed a different behavior in the three very small organizations in our sample (OrganizationA, OrganizationD, and OrganizationJ) consisting of less than 50 employees. In those organizations, we were able to detect several characteristics of ideological behavior. In the remainder of this section, we will discuss these three cases in more detail.

OrganizationA

OrganizationA specialized in telecommunication devices. It originally started as a research and development company. Initially, all projects within the organization aimed to gather knowledge and experience in order to develop the initial product. Developers were free in their decision making on which products to incorporate into the final product. Consequently, decision making was significantly influenced by the personal experience of developers.

Our informants indicated that at the time of the organization's founding, many employees—including the organization's founders and the CIO—shared the same background, were very familiar with Linux, and shared the philosophical ideas of the open source movement. These employees had a "firm conviction" in OSS:

The firm conviction was coming from a number of people who said: 'It must be [OSS], we do not want anything else!'…The choice for using OSS was…just a conviction, rather than the result of a comparative assessment.

As a result, most software that was used in the organization was OSS. During package selection, no objective evaluation of (proprietary) alternatives was performed. Although some proprietary software was used, this was either on demand of a customer, or the software was eventually replaced by an OSS alternative.

The choice for OSS at that time was primarily motivated by the lower or non-existing license cost, the fact that there was more confidence in OSS, and the fact that OSS provides access to the source code. Our informants however admitted that these reasons were influenced by the philosophical view towards OSS and that this view on OSS dominated the adoption decision. They were for example aware that using OSS includes additional costs (e.g., packaging and updates), which makes it less clear whether OSS really offers a cost advantage. Such considerations were however not taken into account at that time.

Another factor that has influenced the decision is the avoidance of vendor lock-in. The open source movement generally depicts Microsoft as their common "enemy." This feeling was also present in the organization at that time. Vendor lock-in with Microsoft was feared, partly due to negative experiences in the past. The adoption decision appeared to be anti-Microsoft oriented. As expressed by one informant:

If you mentioned Microsoft, things exploded!

The organization also initiated its own OSS project. It consisted of a Java virtual machine for embedded devices. This project was started to try to benefit from the OSS community model (cf. tenets 4–15). This project was in fact quite successful, and the organization took the role of project maintainer. In the course of time, the project became less interesting for the community (as the product further matured) and participation of the community declined. The software is however still used in the organization's products.

As illustrated, the choice for using OSS was quite ideological in the early years of the organization. Interesting to note is that over the years, several employees of the organization who were adherents to the open source movement, and who advocated the use of OSS, left the organization. As a result, the choice for OSS became much more pragmatic. Another factor that may have influenced this evolution is that the organization finished its software products, gradually became less of an R&D organization, and other goals such as efficiency started to become more important.

At the time of our study, a slight preference for OSS still existed. One informant stated:

Our choice will in the first place go to open source or Linux, but less fanatical than in the past.

Furthermore, the organization seemed to be less willing to take risks in using OSS, or to invest additional effort to get OSS working. This was expressed by an informant as:

I think we are looking rather quickly towards open source products. But if it looks that it will deliver us more worries than it yields advantages, we will not doubt to use a commercial product.

Hence, the organization will only consider using OSS if the product complies with the requirements. The "firm conviction" that was present in the organization has now faded away. The choice for OSS is now mainly based on the potential cost advantages.

Nevertheless, it appears that the organization still felt connected to the principles of the open source movement. When asked whether the organization contributed back any modifications they made to OSS, one informant appeared to feel guilty about not contributing:

…we did contribute quite little, rather naughty, isn't it?

He further noted that the organization tried to participate in OSS projects in other ways, for example by filling in bug reports or by participating in mailing lists (cf. tenets 10–15).

OrganizationD

OrganizationD was active in the publishing and printing sector. The organization had a single person responsible for decision making on IT, and had no internal IT staff. The organization used OSS on a variety of systems (i.e., one Internet gateway, two file servers, and one intranet server). The organization also had 3 LAMP (Linux–Apache–MySQL–PHP) servers, running custom-developed software for time registration. Finally, three desktops were equipped with the Linux operating system in the offices, and an additional 11 PCs function as terminals for the time registration system. The main reason for choosing OSS was to reduce vendor lock-in and maximize the freedom of the IT infrastructure. Consequently, the decision maker investigated OSS solutions without considering proprietary alternatives. Other reasons for using OSS were an increased control over the software, cost advantages, and an increased flexibility. These factors are consistent with the advantages proposed by the OSS community. We were able to detect a few additional ideological characteristics, although they were not that strong.

Our informant indicated that his extensive personal experience with Linux influenced his decision to start using OSS within the organization:

Following [new evolutions] is not enough: you try out software, and free software has the advantage that it is much easier to try out. And of course, since you have tried it yourself, it did influence the [organizational] decision.

His decision to start using OSS within the organization was also influenced by some negative experiences with proprietary software in the past (including vendor lock-in). For example, some proprietary application the organization was using contained a bug which the vendor refused to resolve. As a result, our informant tried to remain in full control over his IT infrastructure. He therefore wanted to maximize the degree of freedom in the IT infrastructure, not only by using open standards, but by using OSS as well: "I wanted to go a step further: not only by using open standards, but also by using open source applications to have full insurance" (cf. tenets 5–6). He felt that by having access to the source code of OSS, he had maximum control over his applications.

The organization was remarkably committed to its pursuit of freedom. This commitment has moved the organization to start its own OSS project, namely a time registration system for employees. Existing software either did not satisfy all requirements, or was too expensive and did not allow for customizing the software. Hence, the software needed to be custom developed. The decision maker did not want to become dependent on an external organization—not even on the external programmer who develops the software. Instead of performing in-house development or closing an escrow agreement, the organization has chosen a different path. The organization has hired a programmer from an external organization to develop the software, and our informant decided to release the software under an OSS license (the GPL) to ensure that the software would remain completely free (cf. tenet 5). This way, the organization aimed to remain in control over the application, avoid vendor lock-in, and be allowed to make modifications to the software at a later time. The software is being developed as a cooperation between our informant (who is mainly responsible for the analysis) and the paid external programmer. It was the intention of our informant to eventually share this application with other organizations in the same sector. He strongly valued the ability to cooperate with other organizations, and hoped that he would be able to leverage the OSS development model (cf. tenets 4–15) and to receive comments, bug fixes, and maybe even new code submissions.

Interestingly, he was the only informant in our sample who deliberately used the term *free software*.[4] He preferred this term since—in his experience—the term OSS is misused by some vendors to refer to software of which the source code is available, but whose license is still proprietary and does not offer the same freedom as OSS licenses. He felt that the Dutch term for *free software* did not suffer from the confusion in English, and that it better articulated the spirit of the open source movement (cf. tenet 5).

OrganizationJ

The most prominent form of ideological behavior was found in OrganizationJ. Our informant was the IT and business manager of the organization, who was the only one responsible for the IT infrastructure. No internal IT staff was present. The complete IT infrastructure of the organization was based on OSS. This included two important servers: an intranet server running ERP software and an Internet server running the e-commerce site of the organization. Recently, all desktops in the organization were migrated from MS Windows to Linux. The desktops consisted of lightweight terminals which booted from a server. All appli-

cations ran on the server, which placed very low demands on the desktop itself. All administration could be performed on the server. The desktops were running the XFCE desktop environment and OpenOffice.org was used as the office suite.

Our informant had a technical background and was an experienced programmer. In fact, he developed his own e-commerce application and was currently rewriting his own ERP software. His personal experience with Linux dates back from 1999. Based on this personal experience, he decided to migrate his Unix-based server to Linux when he was experiencing difficulties with that server.

Similar to our informant in OrganizationD, the IT manager wanted to remain in control of his IT infrastructure (cf. tenets 5–6). Consequently, he tried to make exclusive use of open standards. Moreover, he stated that he only considered using OSS (except for one PC running Microsoft Windows on which specific banking software was installed that is unavailable for Linux). He also did not want to pay for software, hence he did not use any of the commercial Linux distributions.

Similar to the other two organizations, our informant indicated that his organization had bad experiences with proprietary vendors in the past. In fact, when migrating the server that ran the ERP software, the organization faced huge switching costs when transferring the software from the Unix-based system (developed by a small company) to Linux. He was also suspicious of proprietary software, because it could contain hidden features. This prevented him from having total control over the software. OSS was believed to be more secure, thanks to the availability of the source code: "I think there are thousands, ten thousands or millions of people who use and study it, so I don't have to worry" (cf. tenets 4 and 7).

As a result, he had a rule that proprietary software should not be used under Linux. Proprietary software was simply not considered as an alternative during decision making. This non-pragmatic decision making can be illustrated with two examples. First, the organization recently acquired a new printer/copier. Although the manufacturer provided drivers for Linux, they were proprietary; and the source code of the drivers was not provided. Consequently, the drivers were not installed on the Linux desktops. This means that default Postscript and PCL drivers were used. If specific features would be required, the IT manager stated that he would rewrite the drivers, based on the Postscript definition. He motivated his choice as follows:

Nothing is installed from which the source code is not available: I need control.…[The manufacturer of the printer] will probably have no bad intentions, probably, but nowadays you never know.

Second, when the IT manager decided that the ERP software needed replacement, he reviewed some OSS alternatives. One of the reasons why Compiere was not properly examined as an alternative, was that it required the Oracle database server.[5]

The IT manager also started a small OSS project. It consisted of a Perl module to create OpenOffice.org documents. He also indicated that he valued the OSS development model. Two important advantages of this model were the peer review process (see supra) and that it offers more continuity. Although his ERP software was using a graphical library that was maintained by a single person, he was not afraid of becoming too dependent. If the maintainer would quit, our informant was convinced that other people would take over the project. Otherwise, he would still have access to the source code of the library and make any required changes himself (cf. tenets 5 and 14).

DISCUSSION

As can be gathered from our findings, ideological or pragmatic decision making is not a binary

variable. Instead, decision making will exhibit both ideological as well as pragmatic characteristics, which places the organization's decision making on a continuum between both extremes. In practice, most organizations clearly use a pragmatic decision-making process with respect to the use of OSS. Nevertheless, we were able to detect rather ideological decision making in three small organizations in our sample. The degree of ideology varied between these three cases. A summary of the ideological characteristics in the decision-making process of these organizations is shown in Table 3.

Identifying Ideology

There were clear distinctions between the seven organizations that we labeled "pragmatic" and the three we identified as "ideological." First, within the three latter organizations, there was a clear push behind—or favoritism towards—using OSS. This was caused by the fact that decision makers were adherents to the open source movement and wanted to use OSS as much as possible, or even exclusively. Their personal experience and background was a major factor in this decision. The other seven organizations did consider OSS as one of the alternatives, but would not give preferential treatment to OSS.

Second, the tenets of the OSS ideology were only present in the three organizations. Among

Table 3. Ideological characteristics in the decision making of organizations in our sample

OrganizationA:
• Employees, including the organization's founders, shared the philosophical and cultural views of the OSS movement.
• A strong anti-Microsoft sentiment was present.
• Vendor lock-in was feared.
• The organization started its own OSS project to benefit from the OSS development model.
• All software that was used had to be OSS.
• The adoption decision was based on a "firm conviction" in OSS, not on an objective evaluation of alternatives.
OrganizationD:
• The IT manager strives to maximize the freedom in the IT infrastructure by using open standards and OSS.
• Extensive personal experience of the IT manager with Linux influenced the organizational adoption decision.
• The organization started its own OSS project to ensure that the software would remain totally free.
• Driven to OSS by negative experiences (including vendor lock-in) with proprietary software in the past.
• The IT manager uses the term "free software."
OrganizationJ:
• The IT manager does not want to pay for software, including application software.
• The switch to Linux was influenced by personal experience with Linux.
• All software that was used had to be OSS.
• Proprietary printer drivers were not used, even if this means that a work-around must be devised.
• Commercial software is not trusted because the source code is not available.
• Driven to OSS by negative experiences (including vendor lock-in) with commercial software in the past.
• The OSS development model is valued, because thousands of developers are reading the source code, correcting bugs, and ensuring the continuity of the project.
• The complete IT infrastructure was migrated to OSS.
• The IT manager started his own OSS project.

the tenets that were most prominently present were software freedom (tenet 5), information freedom (tenet 6), and cooperation (tenet 14).[6] These tenets are indeed central to the OSS ideology. The other seven organizations were rather agnostic about the values and beliefs of the open source movement and considered the OSS character irrelevant during decision making.

Third, several of the factors that influenced the adoption decision are consistent with the advantages put forward by the open source movement. Evidently, this is not sufficient to claim that these organizations shared the OSS ideology. However, there are indications (particularly in Organization A and Organization J) that the perceptions with respect to these adoption factors are influenced by the belief in the OSS ideology, and that their relevancy in the organization-specific environment were not or insufficiently evaluated. This indicates mindless decision making.

Finally, these three organizations were the only ones in our sample that initiated their own OSS projects. Organization A and Organization D clearly indicated that by starting their own OSS projects they wanted to try to leverage the OSS community model. This indicates a belief in the underlying principles of the open source movement (cf. tenets 10–15). If organizations would not be convinced of the advantages of the OSS development model, it seems likely that they would not initiate an OSS project and they would simply develop the software in-house. Nevertheless, principles such as sharing (tenet 10) and cooperation (tenet 14) were deemed quite important by the three organizations.

The previous four points demonstrate that the three organizations discussed in this article exhibited some form of ideological behavior. It is however not trivial to identify ideological tenets in organizations, since the ideas and beliefs of the OSS ideology are not explicitly formulated, as is often the case with ideologies (Hamilton, 1987). A second difficulty is that the presence of one of these characteristics by itself does not automatically lead to ideological decision making. A good example is the avoidance of vendor lock-in. All three organizations indicated having had bad experiences with proprietary vendors in the past and wished to minimize vendor lock-in. The desire to avoid vendor lock-in can be a pragmatic reason for choosing OSS. It may however also lead to a situation in which the decision maker—based on negative experiences with some vendors in the past—only wants to use OSS without considering proprietary alternatives, leading to an ideological position towards OSS. Similarly, the list of characteristics in Table 3 is not exhaustive, and there may be other indicators of ideological behavior. A third issue is that there may be "instances where actors, genuinely or otherwise, do not interpret their behavior in terms of any commitment to a set of beliefs but as simply pragmatic, but where it is clear to the observer that it is, in fact, in conformity with such a set of beliefs" (Hamilton, 1987, p. 21). Nevertheless, the evidence presented in this article and the impression of the decision makers obtained during the interview allowed us to identify ideological characteristics in the decision making of these three organizations. These characteristics had a clear impact on the adoption decision on OSS, resulting in a strong favoritism towards OSS. The attitude in these three organizations was fundamentally different from the other seven organizations in our sample.

Limitations

This study has a number of limitations. First, we used a qualitative approach consisting of 10 case studies. Although we have found that small organizations may engage in ideological decision making, a large-scale quantitative study could provide more insight into the generalizability of this result.

Second, we only included organizations that have adopted OSS. Future research may provide more insight into the attitudes of non-adopters. We can make a meaningful distinction between

two groups of non-adopters. On the one hand, there can be organizations that have considered using OSS, but decided not to adopt. The experiences of these organizations may provide more insight into the main drawbacks of using OSS. On the other hand, there are organizations that did not consider OSS as one of the alternatives. Such organizations may have negative perceptions towards OSS and did not further investigate them. For example, organizations may be convinced that OSS costs more in maintenance or is unreliable. Similarly, organizations may also have unverified ideas with respect to proprietary software. They may believe that using proprietary software is less expensive or may place more trust in a closed, proprietary software model. In the most extreme case, organizations may even only consider using software from one specific vendor. In either case, decision making will not be mindful, as not all alternatives are being considered.

Another interesting avenue for future research is to investigate whether decision making on OSS will become less ideological. Since the adoption of OSS is still a relatively recent phenomenon, less information is available on OSS than on proprietary software. It can be expected that as time passes, more information on an innovation becomes available, and decision makers will be able to make better informed choices. On the other hand, Swanson and Ramiller (2004) point out that later adoption can also be driven by diffusion itself, making later adoption not necessarily more mindful than early adoption.

A final topic for further investigation concerns situations in which the decision to start using OSS is triggered by the mere availability of OSS, rather than a concrete problem situation that gives rise to a search, evaluation, and decision-making process. This process resembles the *garbage can model* of decision making (Cohen, March, & Olsen, 1972). Hence, future research could investigate the applicability of this theory in situations in which decision makers share the OSS ideology.

CONCLUSION

The contribution of this article is that we were able to identify ideological characteristics in the decision making on OSS in very small organizations. This result further elaborates on the study of West and Dedrick (2005), who did not detect such behavior in their sample. We argue that while medium to large businesses are likely to be pragmatic in their decision making, the influence of ideological beliefs should not be completely disregarded in small organizations.

Although a minority of organizations in our sample has exhibited ideological behavior, it is remarkable that all three very small organizations in our sample—with a single decision maker—did to some degree. If that decision maker can be considered an open source advocate—which was definitely the case in OrganizationA and OrganizationJ—it is more likely that personal beliefs and values of the decision maker have an impact on the final decision making. Hence, the adoption decision with respect to OSS is more likely to be ideological. This is consistent with the observation of Fiol and Connor (2003) who argue that mindlessness in combination with the absence of formal procedures will further enable mindlessness. In larger organizations, decision making is more likely to be pragmatic, since there are more decision makers and procedures involved in the OSS adoption decision.[7] Ideological decision making is however not necessarily a static phenomenon. Since it appears that ideological decision making is closely related to a single decision maker, the situation may change if that person leaves the organization, or if other decision makers join the organization. This could be observed in OrganizationA.

The definition of ideology we have used in this article is non-judgmental. Consequently, we do not want to make any claims with regard to whether the organizations have made a wrong decision in choosing for OSS. We have found no evidence to suggest that the decision has had a negative impact

on the organizations. In fact, Organization A actually seemed to be able to innovate by using OSS and proved to be quite successful. On the other hand, it could be established that Organization A (at the time of founding) and Organization J were not sufficiently mindful in their decision. These organizations only considered using OSS and did not properly investigate alternatives. Such mindless behavior always entails the risk that the organization does not properly reflect on whether the innovation is suitable within the organization, resulting in a less-than-optimal solution for the organization (Swanson & Ramiller, 2004). A mindful organization that adopts OSS should not take the claims proposed by the OSS ideology for granted. Instead, it should investigate the implications of using OSS in the organization-specific environment. This is important since this situational context can be complex, rendering some claims irrelevant for the organization.

Swanson and Ramiller (2004) however point out that notwithstanding the risks, mindless decision making can have its merits for organizations. This can be the case when the rewards are likely to outweigh the risks, or when time limitations do not allow for a thorough decision-making process. Hence, mindless decision making can be a valid strategy for routine decisions and does not necessarily imply ideological decision making. However, we were able to exclude this possibility in the three small organizations in our sample by investigating the background of the decision-making process. In all three organizations, the adoption of OSS constituted an important change that concerned the replacement of existing proprietary software or the use of a new type of software. Therefore, no similar evaluation of OSS was previously undertaken, and decision making was indeed ideological.

ENDNOTES

1 These organizations had on average 41,885 employees (25,529 when only counting the unit studied in the organization).

2 The term "mindless" generally has a pejorative meaning, such as "unintelligent." In academic literature however, the term is used to refer to automatic or inattentive behavior (e.g., Swanson & Ramiller, 2004;

Fiol & Connor, 2003; Butler & Gray, 2006; Sternberg, 2000). We use the term "mindless" in the second sense. Hence, we do not wish to imply any negative connotations.

[3] The organizations in our case studies have on average 1,081 employees.

[4] Actually, the Dutch equivalent was used, namely "*vrije* software," which is similar in meaning as the French term *libre* software and refers to "freedom" rather than "free of charge."

[5] Other reasons were that it used Java (which the IT manager did not like very much), and the fact that he preferred using custom-developed software that fits his business.

[6] This may indicate that these organizations preferred to cooperate with other organizations within the same industry in order to extend their own capabilities, rather than to outsource development to an external firm.

[7] On the other hand, Fiol and Connor (2003) have noted that formal procedures may also lead to mindlessness (i.e., when decision makers follow procedures without critically considering them).

Chapter 5.5
Volunteers in Large Libre Software Projects:
A Quantitative Analysis Over Time

Martin Michlmayr
University of Cambridge, UK

Gregorio Robles
Universidad Rey Juan Carlos, Spain

Jesus M. Gonzalez-Barahona
Universidad Rey Juan Carlos, Spain

ABSTRACT

Most libre (free, open source) software projects rely on the work of volunteers. Therefore, attracting people who contribute their time and technical skills is of paramount importance, both in technical and economic terms. This reliance on volunteers leads to some fundamental management challenges: Volunteer contributions are inherently difficult to predict, plan, and manage, especially in the case of large projects. In this chapter we present an analysis of the evolution over time of the human resources in large libre software projects, using the Debian project, one of the largest and most complex libre software projects based mainly in voluntary work, as a case study. We have performed a quantitative investigation of data corresponding to roughly seven years, studying how volunteer involvement has affected the software released by the project, and the developer community itself.

INTRODUCTION

Volunteer contributions are the basis of most libre[1] software projects. However, the characteristics, and the way of working of volunteers, can be quite different from those of employees who are the main force behind traditional software development. Volunteers can contribute with the amount of effort they want, can commit for the time period they consider convenient, and can devote their time to the tasks they may prefer, if the context of the project makes that possible (Michlmayr & Hill, 2003). But even in this apparently difficult environment, many libre software projects have produced systems with enough quality and functionality to gain significant popularity. Therefore,

the fairly unstructured collaboration of volunteers has been demonstrated as a viable software development strategy, even if it is associated with certain challenges related to project management and quality (Michlmayr, 2004). In this chapter we explore how these voluntary contributions evolve over time in one of the largest libre software projects, Debian.

For our purposes, we will define volunteers as those who collaborate in libre software projects in their spare time, not profiting economically in a direct way from their effort. Volunteers can be professionals related to information technologies, but in that case their activity in the libre software project is not done as a part of their professional activity. Although the vast majority of participants in libre software projects comply with our definition, it is important to note that there are also non-volunteers, that is, paid people (normally hired or contracted), who produce libre software. German has studied paid employees from various companies in the GNOME project (German, 2004). He notes that they are usually responsible for less attractive tasks, such as project design and coordination, testing, documentation, and bug fixing. Also, "[m]ost of the paid developers in GNOME were, at some point, volunteers. Essentially for the volunteers, their hobby became their job."

The involvement of volunteers, of course, raises new economic and business model issues that have to be taken into account in commercial strategies around libre software. Collaboration from volunteers is difficult to predict, but if it is given, it may add value to a software system in very economic terms for a software company.

The structure of this chapter will be as follows. In the second section we discuss the nature and, in particular, the tasks performed by volunteers, paying special attention to those who contribute to Debian, the case study investigated in this chapter. Following this section, a set of research questions regarding volunteer participation will be raised. The primary goal of this chapter is to answer these questions based on quantitative data. The methodology for retrieving the quantitative data used in this study is first given. In this section, we also propose a number of measures that will allow us to answer the questions. The results we have obtained as part of this study will be presented and commented on in depth for the Debian project. Finally, conclusions, applicability of the methodology, and further research will be discussed.

THE DEBIAN PROJECT AND ITS VOLUNTEERS

Debian is an operating system completely based on libre software (Monga, 2004; O'Mahony, 2003). It includes a large number of applications, such as the GNU tools and Mozilla, and the system is known for its solid integration of different software components. Debian's most popular distribution, Debian GNU/Linux, is based on the Linux kernel. Ports to other kernels, such as Hurd and FreeBSD, are in development.

One of the main characteristics of the Debian distribution is that during the whole life of the project it has been maintained by a group of volunteers, which has grown to a substantial number. These individuals devote their own time and technical skills to the creation and integration of software packages, trying to supply users with a robust system which provides a lot of functionality and technical features.

Following our definition of volunteers, all maintainers in Debian are volunteers. Some employers of people who act as Debian maintainers in their spare time permit their staff to devote some of their time to Debian during work hours. Nevertheless, the majority of work by most Debian maintainers is performed in their spare time. In contrast to some projects, such as the Linux kernel and GNOME, there are no Debian maintainers who are paid to work on the system fulltime, even though a number of organizations have a com-

mercial interest in Debian and contribute varying degrees of manpower (and other resources) to the project. For example, a number of regions in Spain have their own operating systems based on Debian; HP made Debian more suitable for large telecom customers, and Credativ provides commercial services for Debian and similar systems.

There are several tasks that volunteers can do in Debian: maintaining software packages, supporting the server infrastructure, developing Debian-specific software, for instance, the installation routine and package management tool, translating documentation and Web pages, and so forth. From all these tasks, we will focus in this chapter on package maintainers, whose task it is to take existing libre software packages and to create a ready-to-install Debian package. Debian maintainers are also called Debian developers, although their task is really not to develop software but to take already developed software for the creation of a Debian package. This, of course, does not mean that a Debian maintainer may not develop and maintain software, but this is not usually the case: the original author (or developer), known as the 'upstream' developer, and the Debian maintainer, are usually, but not necessarily, not the same person.

Besides its voluntary nature, the Debian project is unique among libre software projects because of its social contract (Debian Social Contract, 2006). This document contains not only the primary goals of the Debian project, but also makes several promises to its users. Additionally, there are a number of documents Debian maintainers have to follow in order to assure quality, stability, and security of the resulting distribution. In particular, Debian's Policy document ensures that the large number of volunteers working independently will produce a well-integrated system rather than merely an aggregation of software packages which do not play together very well (Garzarelli & Galoppini, 2003).

There has recently been some interest in studying how the voluntary status of Debian members affects the quality of the resulting product. Managing volunteer contributors is associated with certain problems that "traditional" software development usually does not confront (Michlmayr & Hill, 2003). It is known that there are some intrinsic problems when the development process is carried out in a distributed fashion (Herbsleb et al., 2001). The situation in Debian and similar projects is even more complex because the development process is not only distributed but also largely based on volunteers. This can lead to certain challenges, such as the unpredictability of the level of their involvement (Michlmayr, 2004).

To some degree, the volatility of voluntary contributors can be limited by the introduction of more redundancy, such as the creation of maintainer teams. The creation of teams and committees for specific purposes, such as management, or for complex tasks has been already reported in other libre software projects (as for instance, German's work on the GNOME project [2004]).

RESEARCH OBJECTIVES AND GOALS

Related research has been very active in studying the static picture of a libre software project community over the last years, as can be seen from studies performed on Apache and Mozilla (Mockus et al., 2002), FreeBSD (Dinh-Trong & Bieman, 2005) or GNOME (Koch & Schneider, 2002), leading to models that discuss onion-like structures of libre software projects (Crowston & Howison, 2005). The main goal of this chapter is to introduce the time axis in these kinds of studies, focusing most notably on the contribution of volunteers.

We have therefore set up a list of research questions which we would like to answer for several large libre software projects. In the case of Debian, we have additional information that permits us to link the work done by a volunteer with a piece

of software, so we can, for example, study what has happened to packages from volunteers who have left the project. In the following, the set of questions that we are raising will be answered in detail for the Debian project.

The specific questions we aim to answer with this chapter are the following:

a. **How many volunteers does the project have, and how does this number change over time?** This will provide us with some basic data, useful when working with subsequent questions. When we started the study, we expected a steady increase of volunteers over time, as it is already known that the number of packages included in the system has been growing in that way (Gonzalez-Barahona et al., 2004). In addition, we will try to find out if the work ratio (measured as activity or output per developer) has increased over time or not.

b. **How many volunteers from previous releases remain active?** We want to measure the volatility of the volunteers in large libre software projects. That is, do volunteers join the project and work on it for short periods of time, or, on the contrary, do they stay for many years? Specifically, we want to calculate the half-life of contributors of the project. The half-life is defined as the time required for a certain population of maintainers to fall to half of its initial size. This figure could be easily compared with other libre software projects and, of course, with statistics from companies from software and other industries.

c. **What is the activity of volunteers who remain in subsequent releases?** Answering this question will allow us to know if "older" volunteers strengthen their contributions as time passes, contributing more to the project, or whether they become less active. There are two possible hypotheses one could propose. On the one hand, those volunteers who have been involved for a long time may be very experienced and therefore more efficient in their work than less experienced developers. On the other hand, young developers may have more time or energy to devote to the project and therefore contribute more. Both theories are possible and mutually compatible.

d. **What happens to packages maintained by volunteers who leave the project?** Our intention is to see if we can find a regeneration process in libre software projects that allows them to survive the loss of some of their human resources.
Since Debian maintainers are volunteers, they may quit the project at almost any time, leaving their packages unmaintained. There are two possible outcomes regarding the future of those packages: First, they can be taken over (adopted) by another maintainer. Alternatively, if nobody is interested in adopting them, they will eventually be removed from the archive and excluded from future stable releases. Such removals of unmaintained packages are part of Debian's Quality Assurance effort. Our intention was to know how this inherent characteristic of the voluntary contributors affects Debian, and how this is damped down by other (possibly new) maintainers.

e. **Are more "important" and commonly used packages maintained by more experienced maintainers?** It can be interesting to know whether packages which are considered crucial for the functioning of the system are maintained primarily by volunteers who have more experience. For this, we have considered the most used packages as the targets of the study. We have defined as crucial packages those which are usually installed on every system, as, for instance, the base system which in the case of the Debian GNU/Linux operating system is composed, among others, of the Linux kernel

and the GNU tools. This does not necessarily mean, of course, that crucial packages are more difficult to maintain than other packages, but as they are used by all users of the system and the rest of the software heavily depends on their proper functioning, these packages have to be maintained with special care. Data about the importance of each package will be obtained from the Debian Popularity Contest[2] that tracks how many people have installed a given package.

METHODOLOGY AND SOURCES OF DATA

Debian consists of four parallel versions (stable, testing, unstable, experimental) which can be downloaded from the Internet. The focus of this study is on the stable versions from Debian 2.0 onwards, up to version 3.1, which provide good snapshots of the history of the distribution. These releases comprise a period of time from July 1998 to June 2005. There have been releases of Debian before 1998 (Lameter, 2002), but they have not been taken into consideration for this study since the sources of data we have used in this study were not available for them. For each release, we have retrieved the corresponding Sources.gz file (see next section) from the Debian archive. We have then extracted information about packages and their maintainers from this file and stored the results in a database. After that, we performed some semi-automatic cleaning and massaging of the data that will be explained in more detail below. Final results were obtained through queries to the database, and correlations that have been implemented by another set of scripts.[3]

In addition to the analysis of official releases, we have enriched the findings by additionally taking a more fine-grained data source into account. While releases are only done occasionally, in the case of Debian with years between releases, uploads to the Debian archive are done on a continuous basis. We have analyzed the activity related to these uploads to clarify some of the findings of the paper on which this chapter is based (Robles et al., 2005). The estimations of the size of the releases have been done using a software that counts source lines of code and avoids double-counting the code included in various packages (this methodology is described in detail (Gonzalez-Barahona et al., 2001)), using previously published data (Gonzalez-Barahona et al., 2004), except for release 3.1, which was calculated specifically for this study. The data related to the importance of packages has been retrieved from the Debian Popularity Contest (see section on this topic).

Debian Sources File

Since version 2.0, the Debian repository contains a Sources.gz file for each release, listing information about every source package in it. Every source package contains the name and version, list of binary packages built from it, name and e-mail address of the maintainer, and some other information which is not relevant for this study. As an example, see an excerpt of the entry for the mozilla source package in Debian 2.2 below. It can be seen how it corresponds to version M18-3, provides four binary packages, and is maintained by Frank Belew.

```

Debian Popularity Contest

The Debian Popularity Contest is an attempt to map the usage of Debian packages. Its main goal is to know what software packages are actually installed and used. Information from the Popularity Contest is used by Debian, for example, to decide which software to put on the first CD.

The system functions as follows: Debian users may install the popcon package, which sends a message every week with the list of packages installed on the machine as well as the access time of some files which may give hints regarding the last usage of these packages. Of course, privacy issues are considered in a number of ways: Upon installation, users are explicitly asked if they want to send this information to Debian, and the server which collects the data anonymizes it as much as possible.

The resulting statistical information of all users participating in this scheme is publicly available on the Web site of the project. For every package, it includes the number of machines on which it is installed (inst), the number of machines which make regular use of that package (vote), the number of machines with old versions of the package (old), the number of recent updates (recent), the number of machines where not enough information is available (no-file), and the maintainer of the package. Below is an excerpt of the available data, in this case the top ten packages ordered by installations as of December 4, 2004. The first 66 packages are installed on all machines, with 6881 installations.

Debian Developer Database

From June 1999 onwards, Debian has held a database (http://db.debian.org) with data related to members of the project. Some information, such as the full name and user name, can be retrieved publicly through the Internet. This database also contains information about the digital keys used by a developer. Debian makes use of digital signatures through the use of the tools PGP (Pretty Good Privacy) and GPG (GNU Privacy Guard) to approve uploads to their software archive. The use of digital signatures provides two guarantees. First, the signature will show that the package comes from a trusted source, that is, from an of-

Table 1. Debian Popularity Contest statistics

10	ncurses-base	6881	56	143	6	6676	(Daniel Jacobowitz)

ficial Debian developer whose PGP or GPG key is stored in the Debian keyring and this developer database. Second, by verifying the signature on the package, it can be ensured that the package has not been tampered with during the process of uploading it to the Debian archive.

Package Uploads

While the main data source of this chapter is the Sources.gz files from the last official Debian releases, we have additionally taken uploads to the archive into account to answer some of the research questions with more detail. As mentioned above, Debian's archive is separated into various branches. The official releases are known as the stable branch, whereas Debian's development tree is known as "unstable." Even though it is said that the development tree is usually fairly stable, it is where major development occurs and as such, major bugs are introduced from time to time.

When an upload is made to unstable, a summary of the changes is automatically sent to a mailing list known as "debian-devel-changes." By extracting data from the archives of this list, the uploads made to the Debian archive over the last few years can be studied. The archive of this mailing list starts towards the end of August 1997. Because August is not complete, we use the data starting with September, since having data for full months allows for better comparisons. We then divided the whole time period into periods of three months each, leading to 34 periods which cover 8.5 years (102 months), from September 1997 leading up to February 2006. In total, slightly more than 181,500 uploads have been observed in this period, leading to a mean number of uploads of around 1,800 each month.

The method used to extract this information is as follows: first, the archives of the "debian-devel-changes" mailing list are downloaded from Debian. These are then parsed, leading to one message for each upload. These messages are signed by the developer's PGP or GPG key as described above. The information from these digital signatures is then used to map each upload to a unique user id corresponding to the developer who made the upload. The mapping from PGP or GPG key to user name is obtained from Debian's developer database and missing entries for old developers are manually supplemented. After this information is obtained, information about the developer (user name) and the date of each upload is stored in a database together with the message id from the posting stored in the archive.

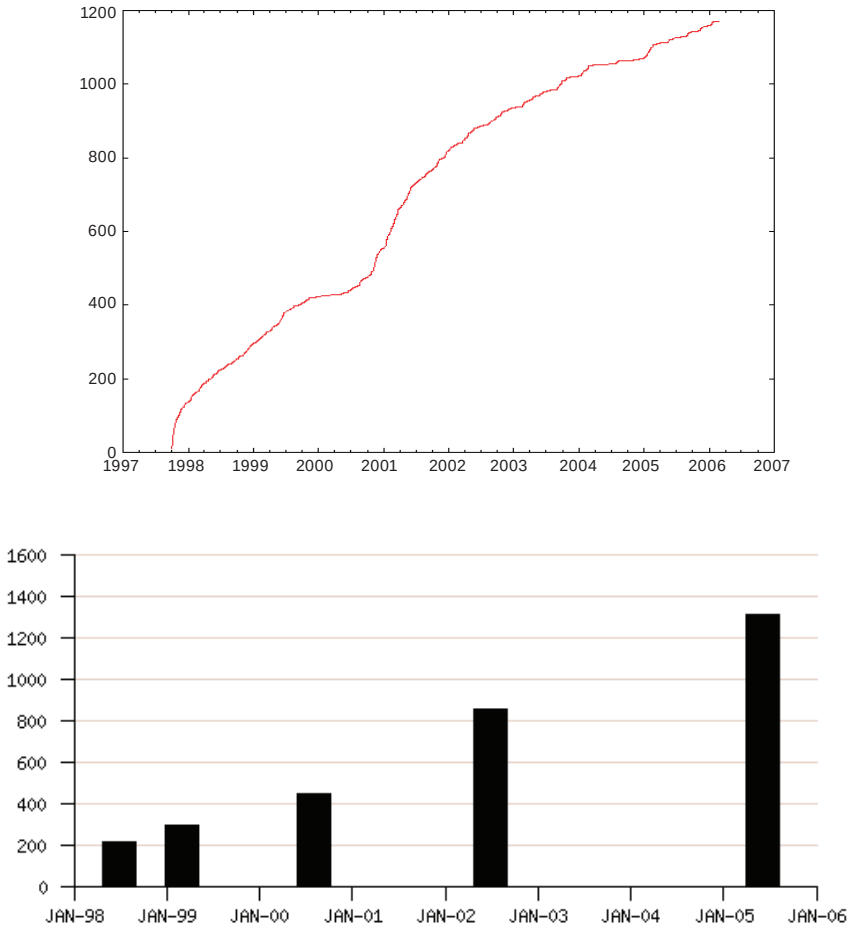
The extraction of this data leads to fairly precise results but there are some limiting factors. First of all, it is important to take into account that uploads are not a measure of effort. We use the data as an indication of activity of a developer but the information is not rich enough to give specific information about how much effort was involved with a specific upload. Second, for the last few years Debian had the concept of "sponsorship," whereby an official Debian developer would upload a package created by a prospective developer (who is not part of Debian yet and whose GPG key is therefore not recognized). In such cases, the main effort was done by the prospective developer but the signature shows the name of the official Debian developer. Since we are concerned with activity of developers and not with effort, this is not an obstacle but it has to be considered during the interpretation of the data. Finally, while the archive software used by Debian now sends automatic notifications of new uploads to the "debian-devel-changes" list, this was done manually in the past. Therefore, data from the past can be slightly unreliable. For example, we observed a number of messages which were not signed by PGP or GPG. Out of about 185,000, we have only detected about three thousand uploads for which no information about the developer could be extracted automatically. We believe that these are not significant and that data from uploads greatly enriches the findings from studies using the Source.gz file from official Debian releases.

EVOLUTION OF THE NUMBER OF DEBIAN MAINTAINERS

The information of the evolution of the number of Debian maintainers will provide us with some basic data useful when working with subsequent research questions. When we started the study, we expected a steady increase of maintainers over time, as it is already known that the number of packages included in the system has been growing linearly (Gonzalez-Barahona et al., 2004). In fact, we expected the packages-to-maintainer ratio to be nearly constant, since it seems reasonable to consider that volunteers devote similar amounts of effort over time, which would lead to a constant number of packages per maintainer.

Figure 1 shows on the left side the evolution of the number of Debian maintainers for the latest five stable releases. As we have expected, the number of Debian individual maintainers has been growing over time. Debian 2.0 (July 1998) was put together by 216 individual maintainers, while the number of maintainers for later releases are 859 for 3.0 (July 2002) and 1,314 for 3.1 (June 2005). This shows a growth of about 35 percent every year. The right side of the figure shows the cumulative

Figure 1. Number of maintainers over time. The left chart is based on Debian releases while the right one is based on continuous uploads.



number of developers who have made uploads to Debian (starting as of September 1997 and finishing with February 2006). This chart gives more precise information as to the growth over time but it does not include some information which the other chart captures. As mentioned above, only official Debian developers are considered and therefore the numbers are lower than in the chart on the left side which considers all maintainers of packages in Debian, regardless of their official status. The more detailed information the chart on the right conveys is very interesting, though. A remarkable stagnation of the growth can be observed. This is because the New Maintainer process, Debian's admission process, was stopped for several months at the end of 1999. The growth continues in the middle of 2000 and, interestingly enough, the pause in the admission of the developers did not have any significant effect on the overall growth of the project.

Based on the data from official releases, we have conducted a small statistical analysis; the results are shown in Table 2. The ratio of packages per maintainer (see column "Pkg/Maint") grows over time, contrary to our initial hypothesis. The growth of packages is actually bigger than that of volunteers who contribute to the project. There are some possible explanations for this finding. First, it is possible that improvements of the development tools or in the practices employed have led to an increase in the efficiency of developers. Second, due to increased interest in libre software, the development speed in general has accelerated and volunteers are more committed.

Interesting enough, the median does not vary (with the exception of Debian 3.0) over time in these last years. Half of the maintainer population does not have more than three packages to maintain. Furthermore, the mode shows that the most frequent situation is a maintainer who is in charge of one package. In brackets we can find the number of developers who actually maintain only one package, which is around one forth of the total population of Debian maintainers.

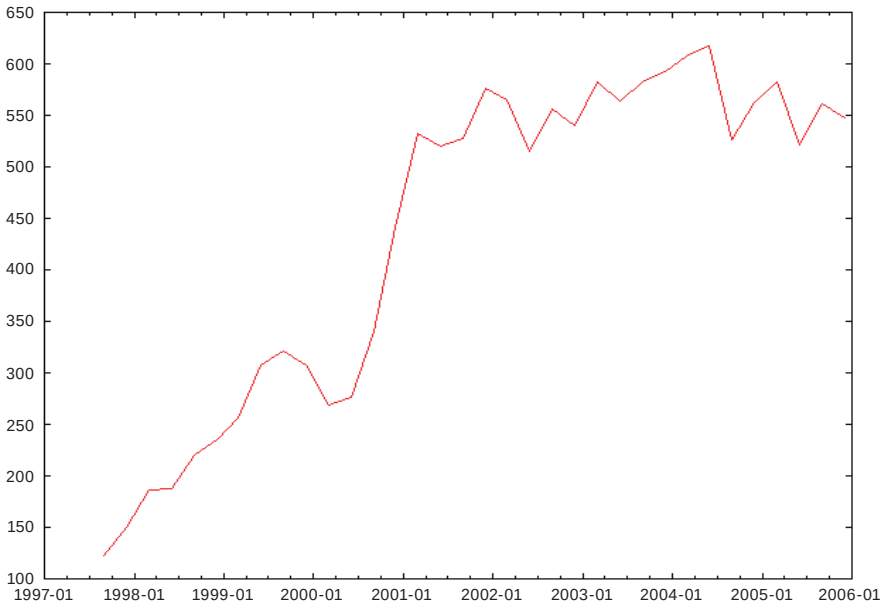
The next three values (the standard deviation, the Gini coefficient,[4] and the maximum number of packages maintained by a single maintainer) strengthen the idea that the distribution of work tends to be distributed in a more unequal way, with a small number of maintainers maintaining more and more packages while the number of packages the vast majority is in charge of does not change much. Compared to other libre software applications and, in general, to other studies which have looked at the distribution of work in libre software projects (Ghosh &d Prakash, 2000; Koch & Schneider, 2002; Hunt & Johnson, 2002; Mockus et al., 2002; Ghosh et al., 2002), we can see that, unlike other projects, Debian is far away from a Pareto distribution. In terms of the Gini coefficient, Debian shows values from roughly 0.5 to 0.6 while studies of the activity in CVS repositories of other projects have found Gini to be in the range between 0.7 and 0.9 (Robles, 2006).

Finally, in Figure 2 we see the number of individual developers making uploads to the Debian

Table 2. Statistical analysis of the growth in number of Debian maintainers

Date	Release	Maint	Packages	Pkg/Maint	Median	Mode	Std. Dev	Gini	Max
Jul 98	2.0	216	1,101	5.1	3	1 (52)	5.8	0.492	50
Mar 99	2.1	296	1,559	5.3	3	1 (76)	6.5	0.521	55
Aug 00	2.2	453	2,601	5.7	3	1 (122)	7.4	0.535	69
Jul 02	3.0	859	5,119	6.0	4	1 (208)	8.2	0.539	79
Jun 05	3.1	1,314	7,989	6.1	3	1 (386)	9.1	0.577	127

Figure 2. Mean number of developers making uploads per each three month period



archive for each three month period. A significant growth in the number of contributors can be seen in the first few years of the observed period. Since roughly the beginning of 2001, a fairly constant number of individuals makes contributions to Debian. There are about 550 unique contributors, even if they change over time.

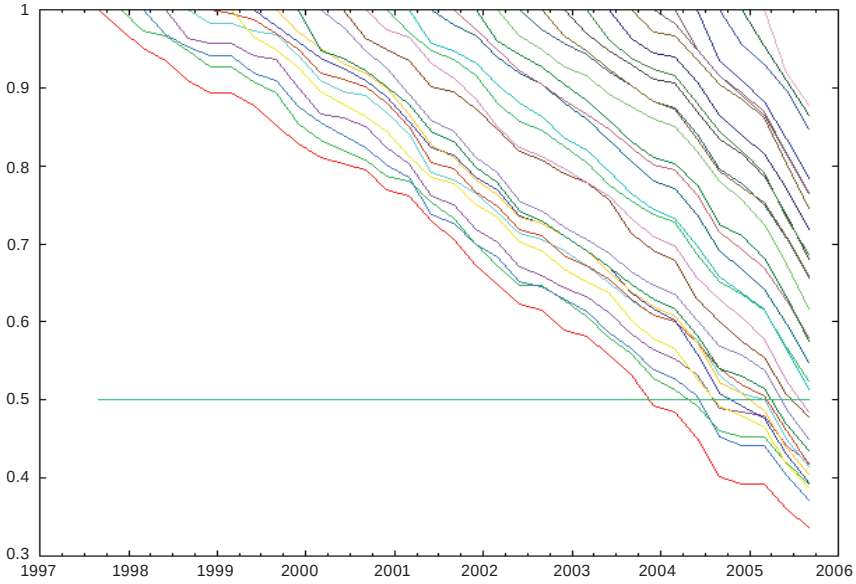
The first column gives the date of the release specified in the second one. "Maint" is the number of maintainers that maintain at least a package, "Packages" the number of total packages for that release, "Pkg/Maint," the mean number of packages per maintainer, "Median" the median number of packages, "Mode" gives the most frequent contribution in number of packages and in brackets the number of maintainers who contribute to it, "Std. Dev," the standard deviation of our sample," "Gini" the Gini coefficient, and "Max" the maximum number of packages that a unique maintainer is responsible for.

TRACKING REMAINING DEBIAN MAINTAINERS

At the time of the release of Debian 2.0 in July 1998 there were 216 voluntary developers contributing to Debian. We have studied how the involvement of these 216 contributors to Debian 2.0 has changed over time. Table 3 gives an overview of the number of contributors from the original group left at each release, as well as the number of packages maintained by them. As the figure shows, the number decreases steadily, with only 117 of the original 216 contributors (54.2%) still possessing ownership of a package in June 2005. Based on these figures, we concluded in a previous paper that the half-life value had not been reached after six and a half years and estimated that the half-life value would be around 7.5 years (or 90 months) (Robles et al., 2005).

Taking the more fine-grained information from uploads into account, we can now revise these findings. Taking package ownership as an indication for activity is error prone, since it

Figure 3. Half-life of Debian maintainers: How populations shrink over time. The horizontal line at 0.5 shows when a population reaches half-life



has been shown that a number of "maintainers" are actually inactive and do not maintain their packages (Michlmayr, 2004). It can take several months or longer until the situation is resolved, in particular if maintainers are busy but do not want to admit to themselves that they do not actually have enough time anymore. Uploads are therefore a much better measure in this case since they show activity. While this measure does not show the effort done by a maintainer it shows that they are still active, which is the question being asked here.

Based on data from uploads, we can see that as of the three-month period starting in June 1998, only 187 out of the original 216 contributors (which still possess packages in the release done in July 1998) are still active. Taking these 187 developers as the new population, we find that the group reaches their half-life in the periods between June and September 2004. This leads to a half-life value of less than 78 months (6.5 years). This is in line with the originally estimated value of 7.5 years, a slight over-prediction due to the fact that it takes some time until inactivity is reflected in the maintainer field of a package. The value obtained from this population is also in line with those obtained from other populations observed as part of the investigation of uploads to Debian, as can be seen in Figure 3. They all show a half-life of between 75 and 90 months.

It would be interesting to perform further analysis about which factors influence how long volunteers remain active. There is already evidence that some volunteers face feelings of burn-out (Hertel et al., 2003), but further studies into human-resource management and motivation in libre software projects could have positive effects on extending the half-life of volunteer contributions.

The number of packages for which these developers are responsible is also interesting. The initial number of packages maintained by the 216 contributors of Debian 2.0 was 1,101. The corresponding number of packages in Debian 2.1 (around nine months later) for the developers remaining rose to 1,351 and then to 1,457 for

Debian 2.2, where the maximum number of packages was achieved. Then it decreased to 1,305 for Debian 3.0, and in the last Debian version it had similar figures as in their first release, although now with half of the maintainers.

This data shows that there has been a continuous increase in the mean number of packages that maintainers are responsible for. While the number of packages per maintainer was slightly above five for the 2.0 release, this number has grown to nine packages per maintainer in release 3.1. It also seems that the mean value keeps on growing, although at a lower pace, and that it has a tendency towards a value around nine as we can see from the last two releases. Given the large amount of time between the last two releases, we can assume that this observed pattern is stable. We have already discussed possible explanations for this behavior with the data about the evolution in number of Debian maintainers (see Table 2).

Regarding the involvement of maintainers, we can see from the median that there is a general shift towards maintaining more packages, as the median value starts with three packages and raises up to five for Debian 2.2 and Debian 3.0. The mode, on the other hand, shows that the number of maintainers who only maintain one package decreases over time more quickly than the number of total maintainers (the total number of maintainers drops from 216 to 117, a drop of 46%, while the number of maintainers who maintain only one package decreases from 52 to 20, a 62% drop; this means that the number of maintainers with more than one package shrinks from 164 to 97, which is only 34% less, almost half of the drop for maintainers in charge of a single package). The cause for this may be twofold: On one hand those maintainers could have left the project, and on the other they could have gotten more involved in it by maintaining more packages. In any case, maintaining one package could be seen as a "hot" zone in which nobody stays for a long time and where a decision has to be taken: to get more involved in the project or to leave.

The standard deviation and the Gini coefficient give an idea of the distribution of work. Both values show that there is tendency to have a less equally distributed load of work. Of particular interest is the Gini coefficient, which starts at almost 0.5 and grows up to 0.574. The maximum number of packages that a single maintainer is in charge of grows consequently, from 50 packages in Debian 2.0 to 83 in Debian 3.1. It should be noted that the maximum number of packages of the first three Debian versions under study correspond to a different person than the last two.

INVESTIGATING MAINTAINER EXPERIENCE

In the previous paragraphs we tracked maintainers from Debian version 2.0 over time to see how their contributions evolved. In the following we are going to do the opposite; we will take the last Debian release (Debian 3.1) and will try to track when maintainers first started participating in the project. This will allow us to have a measure of experience in the project. Maintainers who entered in the same release will be grouped and analyzed together.

Figure 4 shows when currently active maintainers got involved in the project. For every maintainer of a package in the latest release, we have investigated in which release their first contribution can be found. In addition to the 117 developers who have made steady contributions since July 1998 (release 2.0), 55 participants got involved before Debian 2.1, and 106 arrived with Debian 2.2. In the last two stable releases, 384 and 652 new maintainers have been identified.

The evolution of the number of packages per maintainer given in Table 4 provides evidence about the impact of experience on the number of packages maintained. We can see that for the first three versions considered, the values range around 9.0 up to 11.5 packages per maintainer, while in the last two the number of packages

Table 3. Packages maintained by the Debian 2.0 maintainers

Date	Release	Maint	Packages	Pkg/Maint	Median	Mode	Std. Dev	Gini	Max
Jul 98	2.0	216	1,101	5.1	3	1 (52)	5.8	0.492	50
Mar 99	2.1	207	1,351	6.5	4	1 (38)	7.3	0.501	55
Aug 00	2.2	188	1,457	7.8	5	1 (33)	9.2	0.515	69
Jul 02	3.0	147	1,305	8.9	5	2 (20)	10.6	0.540	65
Jun 05	3.1	117	1,055	9.0	4	1 (20)	12.1	0.574	83

Figure 4. First stable release to which Debian 3.1 maintainers have contributed

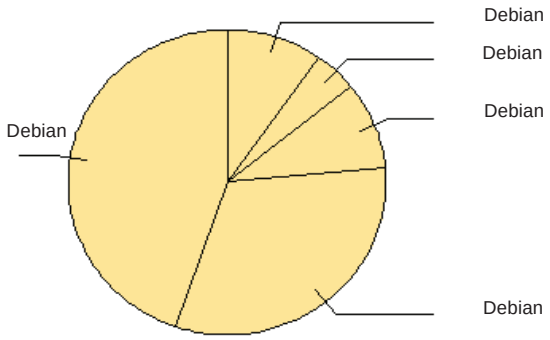


Table 4. First release as maintainer for maintainers in Debian 3.1

Date	Releale	Maint	Packages	Pkg/Maint	Median	Mode	Std. Dev	Gini	Max
Jul 98	2.0	117	1,055	9.0	4	1 (20)	12.1	0.574	83
Mar 99	2.1	55	631	11.5	6	5 (8)	15.1	0.544	81
Aug 00	2.2	106	1,008	8.8	6	1;2 (16)	9.7	0.515	55
Jul 02	3.0	384	2,835	7.2	5	1 (63)	9.5	0.511	121
Jun 05	3.1	652	2,221	4.0	2	1 (246)	7.4	0.570	106

is lower. In general, the tendency is that older maintainers have more packages than those who joined later. The exceptions are maintainers who joined with Debian 2.1. For this version, we can see a statistical distortion in the mode as it has a value of 5 while the values for all other versions is 1 (or 1 and 2 in the case of Debian 2.2).

With regard to the median value, we can see that it is also higher for more experienced maintainers, although in this case it is not that clear as we have seen with the mean number of packages. The different behavior of the last two releases is interesting: While Debian 3.1 has a median of two with many (up to 246) maintainers only in charge of one package, those maintainers who entered in Debian 3.0 and who are still active, have a median value of five and a smaller proportion of them maintain a single package. Again, this supports our previous conclusion that maintaining a single package is only a temporary situation.

The standard deviation of the sample does not give us much information in this case. Maybe it stresses the distorted behavior of Debian 2.1 with such a high value; interestingly enough it shows

that the data is more homogeneous as we come nearer to Debian 3.1. This is an expected effect, as "younger" maintainers should have a similar (smaller) involvement while "older" ones may vary more. Nonetheless, the Gini coefficient does not necessarily support this finding as the values show no clear tendency over time (the highest value is for Debian 2.0 followed closely by Debian 3.1). This is also the case for the maximum number of packages maintained by a single person which fluctuates from version to version without any predictable direction. In any case, we can see that very active maintainers enter any time in the project, some of them with a surprisingly high involvement. For instance, from July 2002 to June 2005 one new maintainer became in charge of 106 packages! Obviously, the effort needed for the maintenance of a package can vary widely. Further exploration is needed to estimate the effort associated with the maintenance of these packages.

PACKAGES OF MAINTAINERS WHO LEFT THE PROJECT

When maintainers leave the project, their packages become unmaintained (the Debian project uses the expression "orphaned"). These packages may be taken up by others ("adopted" in the Debian jargon), or they will not be present in the next stable release. In Table 5 the ratios and numbers of orphaned and adopted packages between any pair of the studied releases are shown.

The table should be read as follows: The first column shows the number of packages, 15, for which their maintainers have left the project (column "Orphaned") and that have been adopted, 14, by other (possibly new) maintainers (column "Adopted") from Debian 2.0 to Debian 2.1. This means that the percentage of orphaned packages that have been adopted is 93.3% (column "Adopt/Orph"), so in this case few packages got lost. The last two columns help situating the amount of orphaned packages we are talking about, giving the share of orphaned packages in comparison to the total number of packages for each release.

Looking at the rest of the rows in the table, we can see that the percentage of adopted packages is very high: more than 60% for all releases considered. This happens even for releases with a very high portion of orphaned packages (for instance, between version 2.0 and 3.1). In other words, even though maintainers who left Debian between July 1997 and June 2005 were responsible for 35.0% of the packages in Debian 2.0, 65.7% of these packages can still be found in version

Table 5. Orphaning and adoption of packages

Release 1	Release 2	Orphaned	Adopted	Adopt/Orph	Orph/Total1	Orph/Total2
2.0	2.1	15	14	93.3%	1.3%	1.0%
2.0	2.2	61	40	65.6%	5.5%	1.5%
2.0	3.0	231	171	74.0%	21.0%	4.5%
2.0	3.1	385	253	65.7%	35.0%	4.8%
2.1	2.2	47	31	66.0%	3.0%	1.8%
2.1	3.0	302	220	72.8%	19.4%	5.9%
2.1	3.1	516	332	64.3%	33.1%	6.5%
2.2	3.0	281	207	73.7%	10.8%	5.5%
2.2	3.1	685	433	63.2%	26.3%	8.6%
3.0	3.1	685	435	63.5%	13.4%	8.6%

3.0. We can thus affirm that Debian counts on a natural "regeneration" process for its voluntary contributors and that there is a high probability that the packages of a maintainer who leaves the project will be adopted by others.

Another interesting fact is that the ratio of adopted to orphaned packages is decreasing in later releases. This means that the number of orphaned packages grows more quickly than that of adopted, i.e., there are some packages missing in every new release. If a package is unmaintained and falls off the next release, it will probably not enter a future one. In this study we have only considered removed packages from maintainers who left the project, but it is likely that some software will also be abandoned by maintainers who still remain active and are therefore not covered by this study.

In any case, it should be noted that users are left unsupported when a package (maybe providing a unique functionality) from a previous release is not present in subsequent ones. It may therefore be beneficial to establish mechanisms to ensure that only packages which can be supported in the long term will not be introduced in the first place, or that at least that they be introduced only in a section of the Debian repository which is clearly marked as being less supported.

EXPERIENCE AND IMPORTANCE

We have used data from the Debian Popularity Contest (presented in detail in the section Debian Popularity Contest) to find out whether more "important' packages are maintained by more experienced volunteers. Table 6 shows the data corresponding to installations and use of packages by developers which are still in the project, and which were already present in the studied releases. In it we can see, for instance, that Debian 2.0 and 3.1 have 117 common maintainers, who are responsible for 1,091 packages which have been installed 1,305,907 times and 576,991 that are regularly used.

The CMaint column shows how many maintainers Debian 3.1 had in common with the release in the first column, while the CPkg shows the number of packages maintained by them. Columns Installations and Votes give the sum of the packages installed and voted (used regularly) for those packages maintained by common maintainers. The last two columns show the ratios of both to common maintainers.

If we take the number of installations per maintainer and the number of regularly used packages per maintainer ("Votes/Maint') we can answer the question we proposed in the section Research Objectives and Goals. According to our hypothesis, these ratios decrease over time, which would mean that more experienced volunteers maintain packages which are installed and used more often. In fact, this can be observed through all Debian

Table 6. Installations and regular use of packages

Release	CMaint	CPkg	Installations	Votes	Inst/Maint	Votes/Maint
2.0	121	1,091	1,305,907	576,991	10792.6	4768.5
2.1	176	1,722	1,584,413	673,236	9002.3	3825.2
2.2	290	2,730	2,217,199	885,448	7645.5	3053.3
3.0	683	5,565	3,923,753	1,405,322	5744.9	2057.6
3.1	1315	7,989	5,248,869	1,711,496	3991.5	1301.5

releases. An alternative (or complementary) explanation to our initial hypothesis is that many of the essential components of the Debian system were introduced in the first releases, and that new packages are mostly add-ons and software that are not installed and used that often.

CONCLUSION AND FURTHER WORK

We have conducted a quantitative study of the evolution of the Debian maintainership over the last six-and-a-half years. We have retrieved and analyzed publicly available data in order to find out how Debian handles the volatility of the volunteers who made it happen.

Some of the most interesting findings are:

- Both the number of Debian maintainers and the number of packages per maintainer grow over time.
- The number of maintainers from previous releases who remain active is very high, with an estimated half-life of around 6.5 years (78 months). Slightly less than half of the maintainers from Debian 2.0 still contribute to the current release after more than 7 years.
- Developers tend to maintain more and more packages as they gain experience in the project.
- However, this does not mean that maintainers who have been in the project for more time maintain more packages than newer maintainers. In fact, in the latest release, the highest packages per maintainer ratio is shown by those entering the project around the year 2000.

From these facts, it can be said that Debian maintainers tend to commit to the project for long periods of time. However, there is a worrisome trend towards a higher and higher ratio of packages per maintainer, which could imply scalability problems as the number of packages in the distribution increases, if the project doesn't admit a proportional number of developers.

Another issue on which we have focused is what happens to those packages that were maintained by developers who left the project. Most of them are taken over by other maintainers, so that we can state that a natural "regeneration" exists. Based on the data we have researched, those packages which are not adopted by other maintainers in the next release, and are therefore not present in it, are unlikely to be re-introduced in future releases.

Finally, we have also found that more experienced maintainers are responsible for packages which are installed more often and used more regularly.

In addition to the new insights gained in this investigation, we have proposed a number of further studies to elaborate on the findings of the present chapter. In particular, team maintenance and its impact on the quality of packages would be interesting to research. It is also not clear why there is an increase in the ratio of packages per maintainer. Possible explanations are that better tools and practices lead to more efficiency, or that with the success of libre software, new volunteers show more motivation and commitment, but more data is needed before these explanations can be conclusive.

From a more general point of view, this study explores the behavior of volunteers in libre software projects and provides some answers as to why these kinds of voluntary contributions are capable of producing such large, mature and stable systems over time, even when the project has no means for forcing any single developer to do any given task and when members may leave the project during important development phases. It is impossible to infer the behavior of volunteer developers just from the study of a single project, but given the size and relevance of the Debian project, at least some conclusions can be exposed as hypotheses

for validating in later research efforts.

One of them is the stability of volunteer work over time. The mean life of contributors in the project is probably longer than in many software companies, which would have a clear impact on the maintenance of the software (it is likely that developers with experience in a module are available for its maintenance over long periods of time). Another one is that volunteers tend to take over more work with the passing of time if they remain in the project: In other words, they voluntarily increase their responsibilities in the project. Whether this is because it is easier for them because of their experience, or because they devote more effort to the project, is for now an open question. Yet a third one is the stability of the voluntary effort when some individuals leave the project: Most of their work is taken over by other developers. Therefore, despite being completely based on volunteers, the project organizes itself rather well with respect to drop-outs, which is an interesting lesson about how the project can survive in the long term.

As a final summary, we have found that given that there are no formal ways of forcing a developer to assume any given task, voluntary efforts seem to be more stable over time, and more reliable with respect to individuals leaving the project than we had initially expected.

ABSTRACT

Source code management repositories of large, long-lived libre (free, open source) software projects can be a source of valuable data about the organizational structure, evolution, and knowledge exchange in the corresponding development communities. Unfortunately, the sheer volume of the available information renders it almost unusable without applying methodologies which highlight the relevant information for a given aspect of the project. Such methodology is proposed in this article, based on well known concepts from the social networks analysis field, which can be used to study the relationships among developers and how they collaborate in different parts of a project. It is also applied to data mined from some well known projects (Apache, GNOME, and KDE), focusing on the characterization of their collaboration network architecture. These cases help to understand the potentials of the methodology and how it is applied, but also shows some relevant results which open new paths in the understanding of the informal organization of libre software development communities.

INTRODUCTION

Software projects are usually the collective work of many developers. In most cases, and especially in the case of large projects, those

developers are formally organized in a well defined (usually hierarchical) structure, with clear guidelines about how to interact with each other, and the procedures and channels to use. Each team of developers is assigned certain modules of the project, and only in rare cases do they work outside that realm. However, this is usually not the case with libre software[1] projects, where only loose (if any) formal structures are acknowledged. On the contrary, libre software developers usually have access to any part of the software, and even in the case of large projects, they can move freely to a certain extent from one module to other, with only some restrictions imposed by common usage in the project and the rules on which developers themselves have agreed to.

In fact, during the late 1990s some voices started to claim that the success of some libre software projects was rooted in this different way of organization, which was referred to as the "bazaar development model," described by Eric Raymond (1997) and later complemented by some more formal models of nonhierarchical coordination (Elliott & Scacchi, 2004; Healy & Schussman, 2003). Some empirical studies have found that many libre software projects cannot follow this bazaar-style model, since they are composed of just one or two developers (Healy & Schussman, 2003; Krishnamurthy, 2002), but the idea remains valid for large projects, with tens or even hundreds of developers, where coordination is obviously achieved, but (usually) not by using formal procedures. These latter cases have gained much attention from the software engineering community during the last years, in part because despite apparently breaking some traditional premises (hard-to-find requirement studies, apparently no internal structure, global software development, etc.) final products of reasonable quality are being delivered. Large libre software projects are also *suspicious* of breaking one of the traditional software evolution *laws*, showing linear or even superlinear growth even after reaching a size of several millions of lines of code (Godfrey & Tu, 2000; Robles, Amor, Gonzalez-Barahona, & Herraiz, 2005a). The *laws* of software evolution state that the evolution of a system is a self-regulating process that maintains its organizational stability. Thus, unless feedback mechanisms are appropriately introduced, the effective global activity tends to remain constant, and incremental growth declines. The fact that several studies on some large libre software projects show evidence that some of these *laws* are disobeyed may be indicative of an efficient organizational structure.

On the other hand, the study of several large libre software projects has shown evidence about the unequal distribution of the contributions of developers (Dinh-Trong & Bieman, 2005; Koch & Schneider, 2002; Mockus, Fielding, & Herbsleb, 2002). These studies have identified roles within the development community, and have discovered that a large fraction of the development work is done by a small group of about 15 persons, which has been called the "core" group. The number of developers is around one order of magnitude larger, and the number of occasional bug reporters is again about one order of magnitude larger than that of developers (Dinh-Trong & Bieman, 2005; Mockus et al., 2002). This is what has been called the *onion* structure of libre software projects (Crowston, Scozzi, & Buonocore, 2003). In this direction, it has also been suggested that large projects need to adopt policies to divide the work, giving rise to smaller, clearly defined projects (Mockus et al., 2002). This trend can be observed in the organization of the CVS[2] repository of really large libre software projects, where the code base is split into modules with their own maintainers, goals, and so forth. Modules are usually supposed to be built maintaining the interrelationships to a minimum, so that independent evolution is possible (Germán, 2004a).

In this article, a new approach is explored in order to study the informal structure and organization of the developers in large libre software

projects. It is based on the application of well known social networks analysis (SNA) techniques to development data obtained from the versioning system (CVS). According to the classical Conway's *law*, organizations designing systems are constrained to produce designs which are copies of their communication structures (Conway, 1968). Following this line of reasoning, the relationships among modules will be studied, and the dual case of those among developers. Our target is the advancement of the knowledge about the informal coordination structures that are the key to understanding how these large libre software projects can work in the apparent absence of formalized structures, and where the limits are of those ways of coordinating and exchanging information. We have designed a methodology following this approach, and have also applied it to some well known projects. Although the aim of our approach is mainly descriptive, not proposing novel models for project evolution or agent behavior, just trying to describe in as much detail as possible the organizational structure of libre software projects, our work is illustrative of the power of the SNA techniques. To attain this goal, our approach is similar to that presented in Madey, Freeh, and Tynan (2002) and Xu, Gao, Christley, and Madey (2005): we consider libre software projects as complex systems and characterize them by using mathematical formalisms. As a result, some interesting facts related to the organizational structure of libre software projects have been uncovered.

The remainder of this article is organized as follows. The next section contains a basic introduction to SNA, and how we intend to apply its techniques to the study of libre software projects based on the data available in their CVS repositories. The third section specifies in detail the methodology for such a study, followed by the fourth section with a brief introduction to a set of classical social network analysis parameters. After that, the fifth section presents the main characteristics of the networks corresponding to the three projects used as case examples: Apache, GNOME, and KDE. This serves as an introduction to the more detailed comments on several aspects of those projects, presented in the sixth, seventh, eighth, ninth, and tenth sections. The final section offers some conclusions, comments on some related work, and discusses further lines of research.

APPLICATION OF SNA TO LIBRE SOFTWARE PROJECTS

The study and characterization of complex systems is a fruitful research area, with many interesting open problems. Special attention has been paid recently to complex networks, where graph and network analysis play an important role. This approach is gaining popularity due to its intrinsic power to reduce a system to its single components and relationships. Network characterization is widely used in many scientific and technological disciplines, such as neurobiology (Watts & Strogatz, 1998), computer networks (Albert, Barabási, Jeong, & Bianconi, 2000), or linguistics (Kumar, Raghavan, Rajagopalan, & Tomkins, 2002).

Although some voices argue that the software development process found in libre software projects is hardly to be considered as a new development paradigm (Fuggetta, 2003); without doubt, the way it handles its human resources differs completely from traditional organizations (Germán, 2004b). In both cases, traditional and libre software environments, the human factor is of key importance for the development process and how the software evolves (Gîrba, Kuhn, Seeberger, & Ducasse, 2005), but the volunteer nature of many contributors in the libre software case makes it a clearly differentiated situation (Robles, González-Barahona, & Michlmayr, 2005b).

Previous research on this topic has both attended to technical and organizational points of view. Germán used data from a versioning repository in time to determine feature-adding

and bug-correcting phases. He also found evidence for developer territoriality (software artifacts that are mainly, if not uniquely, *touched* by a single developer) (Germán, 2004a).

The intention of other papers has been to uncover the social structure of the underlying community. The first efforts in the libre software world are due to Madey et al. (2002), who took data from the largest libre software projects repository, SourceForge.net, and inferred relationships among developers that contributed to projects in common. A statistical analysis of some basic social network parameters can also be found by López, Gonzalez-Barahona, and Robles (2004) for some large libre software projects. Xu et al. (2005) have presented a more profound topological analysis of the libre software community, joining in the same work characteristics from previous papers: data based on the SourceForge platform and a statistical analysis of some parameters with the goal of gaining knowledge on the topology of the libre software phenomenon. This has also been the intention of González-Barahona, López-Fernández, and Robles (2004), where a structure-finding algorithm was used to obtain the evolution in time of the organization of the Apache project. Wagstrom, Herbsleb, and Carley (2005) propose to use the knowledge acquired from analyzing libre software projects with SNA for the creation of models that help understand the underlying social and technical process.

METHODOLOGY

The first problem to solve when using SNA is getting the information to construct the network to analyze. One especially interesting kind of data sources is the records maintained by many computer-based systems. For instance, Guimera, Danon, Diaz-Guilera, Giralt, and Arenas (2003) analyze informal networking on organizations using tracks of e-mail exchanges. Therefore, from the many kinds of records available about the activity of a libre software project, those provided by the CVS system where source code is stored have been the ones chosen. Those records offer information about who modified the code, and when and how, in many cases from the very beginning of the project, in some cases over a total period of time above 10 years.

The information in the CVS repository of a project includes an accurate and detailed picture of the organizational structure of the software, and of the developers working on it. When two developers work on the same project module, they have to exchange (directly or maybe indirectly) information and knowledge to coordinate their actions and produce a working result. It seems reasonable to assume that the higher their contributions to the module, the higher the strength of their informal connection.

Based on this assumption, a specific kind of social network has been considered, those called affiliation networks. They are characterized by showing two types of vertices: *actors* and *groups*. When the network is represented with actors as vertices, each one is usually associated with a particular person, and two of them are linked together when they belong to the same group. When the network is represented with groups as vertices, two groups are connected when there is, at least, one actor belonging, at the same time, to both groups. In our case, actors will be identified as developers, and groups as software modules. The "belong to" relationship will be in fact "has contributed to." This approach will result in a dual view of the same organization: as a network of modules linked by common developers, and as a network of developers linked by common modules. Similar approaches have been used for analyzing other complex organizations, like the network of scientific authors (Newman, 2001a, b) or the network of movie actors (Albert & Barabasi, 2002).

To finish the characterization of our networks, weighted edges are being considered. This means that it is not only taken into account whether a

node has some relationship with any other, but also the strength of that relationship. In our case, the weight will be related to the size of contributions to common modules (in the case of developers) and to the size of contributions by common developers (in the case of modules). It should be noted that from the methodological point of view, the use of weights is a major contribution of this article in comparison with previous works describing SNA techniques applied to libre software (Madey et al., 2002; Wagstrom et al., 2005; Xu et al., 2005). As we will see in this article, the use of weights is indicated as the distribution of work follows a very unequal distribution, in the range of a Pareto distribution[3] (Ghosh & Prakash, 2000). Our assumption at this point is that considering a link between two major contributing developers that equals the one between two random chosen developers, introducing an important bias in the results regarding the distribution of work observed in libre software environments.

Once we have identified how we want to use SNA for libre software projects, a well defined methodology is proposed in order to apply those ideas to any libre software with a public CVS repository. The process begins by downloading the relevant information from the CVS repository.[4] This information includes, for each commit (modification in a file in the repository): the date, the identifier of the developer (commiter), and the number of lines involved. Using all those records, the following networks are defined for characterizing the organization of the project:

- **Modules network.** Each vertex represents a particular software module (usually a directory in the CVS repository) of the project. Two modules are linked together by an edge when there is at least one commiter who has contributed to both. Those edges are weighted using a *degree of relationship* between the two modules, defined as the total number of commits performed by common commiters.
- **Commiters network.** In this case, each vertex represents a particular commiter (developer). Two commiters are linked by an edge when they have contributed to at least one common module. Again, edges are weighted by a *degree of relationship* defined as the total number of commits performed by both developers on modules to which both have contributed.

The definition being used for the *degree of relationship* is an attempt to measure the *closeness* of two vertices. The higher this parameter, the stronger the relationship between those vertices. In this sense, *cost of relationship* between any two vertices can also be defined as the inverse of their *degree of relationship*. In this sense, the *cost of relationship* defines a distance between vertices: the higher it is, the more difficult it is to reach one of them from the other. More formally, given a (connected) graph G and a pair of vertices i and j, we define the distance between them as $d_{ij}=\sum_{e\in P_s} c_r$, where e are all the edges in the shortest path P_s from i to j, and c_r is the *cost of relationship* of any of those edges.

Parameters

Once the networks are constructed based on the previous definitions, and the degrees and costs of relationship have been calculated for linked nodes, standard SNA concepts can be applied in order to define the following parameters of the network (the interpretation of the main implications of each parameter is also offered):

- **Degree.** The degree, k, of a vertex is the number of edges connected to it. In SNA, this parameter reflects the popularity of a vertex, in the sense that most popular vertices are those maintaining the highest number of relationships. More revealing than the degree of single vertices is the distribution

degree of the network (the probability of a vertex having a given degree). This is one of the most relevant characterizations because it provides essential information to understand the topology of a network (and if longitudinal data is available, the evolution of the topology). For example, it is well known that a random network follows a Poisson's distribution, while a network following a preferential attachment growth model presents a power law distribution (Albert & Barabasi, 2002). In our context, the degree of a commiter corresponds to the number of other commiters sharing modules with that committer, while the degree of a module is the total number of modules with which it shares developers.

- **Weighted degree.** When dealing with weighted networks, the degree of a vertex may be tricky. A vertex with a high degree is not necessarily well connected to the network because all its edges may be weak. On the other hand, a low degree vertex may be strongly attached to the network if its entire links are heavy. For this reason the weighted degree of a vertex, *w*, is defined as the sum of the weights of all the edges connected to it. The weighted degree of a vertex can be interpreted as the maximum capacity to receive information of that vertex. It is also related to the effort spent by the vertex in maintaining its relationships.
- **Clustering coefficient** (Watts & Strogatz, 1998). The clustering coefficient, *c*, of a vertex measures the transitivity of a network. Given a vertex *v* in a graph *G*, it can be defined as the probability that any two neighbors of *v* are connected (the neighbors of *v* are those vertices directly connected to *v*). Hence

$$c(v)=\frac{2E(v)}{k_v\ (k_v-} \qquad (1)$$

where k_v is the number of neighbors of k_v and $E(v)$ is the number of edges between them. The intuitive interpretation of the clustering coefficient is somehow subtle. If the total number of neighbors of v is k_v, the maximum number of edges than can exist within that neighborhood is k_v (k_v -1)/2 . Hence, the clustering coefficient represents the fraction of the number of edges that really are in a neighborhood. Therefore it can be considered as a measurement of the tendency of a given vertex to promote relationships among its neighbors. In a completely random graph, the clustering coefficient is low, because the probability of any two vertices being connected is the same, independently on them sharing a common neighbor. On the other hand, it has been shown that most social networks present significantly high clustering coefficients (for instance, the probability of two persons being friends is not independent from the fact that they share a common friend) (Albert & Barabasi, 2002; Watts, 2003).

  From an organizational point of view, the clustering coefficient helps to identify hot spots of knowledge exchange on dynamic networks. When this parameter is high for a vertex, that vertex is promoting its neighbors to interact with each other. Somehow it is fostering connections among its neighborhood. High clustering coefficients in networks are indicative for *cliques*. Besides, the clustering coefficient is also a measurement of the redundancy of the communication links around a vertex.
- **Weighted clustering coefficient** (Latora & Marchiori, 2003). The clustering coefficient does not consider the weight of edges. We may refine it by introducing the weighted clustering coefficient, c_w, of a vertex, which is an attempt to generalize the concept of clustering coefficient to weighted networks.

Given a vertex v in a weighted graph G it can be defined as:

$$c_w(v)=\sum_{i\neq j\in N_G(v)} w_{ij}\frac{1}{k_v(k_v-} \qquad (2)$$

where $N_G(v)$ is the neighborhood of v in G (the subgraph of all vertices connected to v), w_{ij} is the degree of relationship of the link between neighbor i and neighbor j (w_{ij}=0 if there are no links), and k_v is the number of neighbors. The weighted clustering coefficient can be interpreted as a measurement of the local efficiency of the network around a particular vertex, because vertices promoting strong interactions among their neighbors will have high values for this parameter. It can also be seen as a measurement of the redundancy of interactions around a vertex.

- **Distance centrality** (Sabidussi, 1996). The distance centrality of a vertex, D_c, is a measurement of its proximity to the rest. It is sometimes called *closeness centrality* as the higher its value the closer that vertex is (on average) to the others. Given a vertex v and a graph G, it can be defined as:

$$D_c(v)=\frac{1}{\sum_{t\in G}} \qquad (3)$$

where $d_G(v,t)$ is the minimum distance from vertex v to vertex t (i.e., the sum of the costs of relationship of all edges in the shortest path from v to t). The distance centrality can be interpreted as a measurement of the influence of a vertex in a graph because the higher its value, the easier for that vertex to spread information through that network. Observe that when a given vertex is "far" from the others, it has a low degree of relationship (i.e., a high cost of relationship) with the rest. So, the term $\sum_{t\in G} d_G(v.t)$ will increase, meaning that it does not occupy a central position in the network. In that case, the distance centrality will be low.

Research has shown that employees who are central in networks learn faster, perform better, and are more committed to the organization. These employees are also less likely to turn over. Besides, from the point of view of information propagation, vertices with high centrality are like "hills" on the plain, in the sense that any knowledge is put on them is rapidly seen by the rest and spreads easily to the rest of the organization.

- **Betweenness centrality** (Anthonisse, 1971; Freeman, 1977). The betweenness centrality of a vertex, c, is a measurement of the number of shortest paths traversing that particular vertex. Given a vertex v and a graph G, it can be defined as:

$$B_c(v)=\sum \frac{}{\sigma_{st}} \qquad (4)$$

where $\sigma_{st}(v)$ is the number of shortest paths from s to t going through v, and σ_{st} is the total number of shortest paths between s and t. The betweenness centrality of a vertex can be interpreted as a measurement of the information control that it can perform on a graph, in the sense that vertices with a high value are intermediate nodes for the communication of the rest. In our context, given that we have weighted networks, multiple shortest paths between any pair of vertices are highly improbable. So, the term $\sigma_{st}(v)$ /σ_{st} takes usually only two values: 1, if the shortest path between s and t goes through v, or 0 otherwise. So, the betweenness centrality is just a measurement of the number of shortest paths traversing a given vertex. In the SNA literature vertices with high betweenness centrality are known to cover "structural holes." That is, those vertices glue together parts of the organization that would be otherwise far away from each other. They receive a diverse combination of information available to no one else in the network and have therefore a higher prob-

ability of being involved in the knowledge generation processes.

High values of the clustering coefficient are usually a symptom of *small world* behavior. The small world behavior of a network can be analyzed by comparing it with an equivalent (in number of vertices and edges) random network. When a network has a diameter (or average distance among vertices) similar to its random counterpart but, at the same time, has a higher average clustering coefficient, it is defined as a small world. It is well known (Watts, 2003) that small world networks are those optimizing the short and long term information flow efficiency. Those networks are also especially well adapted to solve the problem of searching knowledge through their vertices.

Table 1 summarizes the various SNA parameters that have been presented in this section, their meanings, and the information they provide. These parameters, and their distributions and correlations will characterize the corresponding networks. From their study, a lot can be learned about the underlying organization and structure that those networks capture. An attempt to illustrate this is found in the following sections

Table 1. Summary of the SNA parameters described in this article, their meaning and their interpretation

Parameter	Meaning	Interpretation
Degree of relationship	Common activity among two entities (measured in commits)	How strong the relationship is
Cost of relationship	Inverse of the degree of relationship	Gives the cost of reaching one vertex from the other
Degree	Number of vertices connected to a node	Popularity of a vertex
Distribution degree	Probability of a vertex having a given degree	Topology of the network (Poisson or power law distributions)
Weighted degree	Degree considering weights of the links among vertices	Maximum capacity to receive information for a vertex. Effort in maintaining the relationships
Clustering coefficient	Fraction of the total number of edges that could exist for a given vertex that really exist	Transitivity of a network: tendency of a vertex to promote relationships among its neighbors. Helps identifying hot spots of knowledge interchange in dynamic networks
Weighted clustering coefficient	Generalization of the clustering coefficient concept to weighted networks	Local efficiency of the network around a vertex. Redundancy of interactions around a vertex
Distance centrality	Measurement of the proximity of a vertex to the rest	Gives the influence of a vertex in a graph. The higher the value the easier it is for the vertex to spread information through the network
Betweenness centrality	Number of shortest paths traversing a vertex	Measurement of the information control. Higher values mean that the vertex is an intermediate node for the communication of the rest. Vertices with high values are known to cover “structural holes”
Small world	Diameter (or average distance among vertices) similar but higher average clustering coefficient than random network	Optimizes short and long term information flow efficiency. Especially well adapted to solve the problem of searching knowledge through their vertices

by studying several cases on real libre software projects.

CASE STUDIES: APACHE, KDE, AND GNOME

Apache,[5] KDE, and GNOME are all well known libre software projects, large in size (each one well above the million of lines of code), in which several subprojects (modules) can be identified. They have already been studied from several points of view (Germán, 2004a; Koch & Schneider, 2002; Mockus et al., 2002). Here, they will be used to show some of the features of our proposed methodology for applying SNA to software projects.

The use of versioning systems is fortunately the case for most large libre software projects. Some approaches on how to gather information from versioning repositories, in particular CVS (Germán, 2004a; Germán & Hindle, 2006; Zimmermann & Weißgerber, 2004; Zimmermann, Weißgerber, Diehl & Zeller, 2005), have been presented, and are used in this study. Therefore, focus is set on what to do once that information is available, and not on how to gather it.

Tables 2 and 3 summarize the main parameters of both. In the case of commiter networks the GNOME case has been omitted.

By comparing the data in both tables some interesting conclusions can already be drawn. It may be observed, for instance, that the average number of commiters per module is greater in KDE (12.5) than in Apache (4.3), meaning more people being involved in the average KDE subproject. It can also be highlighted that the average degree on the commiters networks is in general larger than in the modules ones. This is especially true for KDE, which rises from a value of 21.4 in the latter case to 225 in the former. In the case of Apache it only raises from 14.2 to 31.1. Therefore, we can conclude that in those cases, commiters are much more linked than modules. The percentage of modules linked gives an idea of the synergy (in form of sharing information and experience) in a network as many modules have commiters in common. It can be assumed that this happens because of the technical proximity between modules. Regarding our case studies, KDE and GNOME show percentages near 30%, while the average Apache module is only linked to 8% of the other modules in the versioning system. So, Apache is specially fragmented in several module

Table 2. Number of vertices and edges of the module networks in the Apache, GNOME, and KDE projects

Project name	Modules (Vertices)	Edges		% of edges (avg)
Apache	175	2491	14.23	8.13
KDE	73	1560	21.37	29.27
GNOME	667	121,134	181.61	27.23

Table 3. Number of vertices and edges of the commiter networks in the Apache and KDE projects

Project name		Edges	Commiters per module	Avg Number of edges
Apache	751	23,324	4.3	31.06
KDE	915	205,877	12.5	225.00
GNOME	869	N/A	1.3	N/A

families that have no commiters in common. KDE and GNOME have a higher cohesion, while there is more dispersion in Apache.

In the following sections some specific aspects of all those networks will be studied, with the idea of illustrating both how the methodology is applied and which kind of results can be obtained from it.

DEGREE IN THE MODULES NETWORK

Table 4 shows that the number of modules for Apache (175), KDE (73), and GNOME (667) differ significantly. These projects are similar in software size (at least in order of magnitude), so the number of modules depends mainly on the various strategies that the projects follow when creating a new module. KDE has a structured CVS; applications that belong together are usually grouped into one module (so, for instance, there exists the *kdenetwork* module for many network applications or the *koffice* module for the various office suite programs). Apache has modules at the application level. Finally, GNOME follows a more *chaotic* approach, resulting in many more modules. Almost every application, even components (there are almost a dozen different GIMP add-ons with their own module) can be found to be a module in themselves.

The most popular characterization of network degree is the distribution degree $P(k)$, which measures the probability of a given vertex having exactly k edges. However, the representation of $P(k)$ in networks of a small size like ours is usually messy.[6] In these cases, the specialized literature prefers to use an associated parameter called the *cumulative distribution degree*, $CP(k)$, which is defined as $CP(k) = \sum_{k}^{\infty} P(i)$ and is usually represented in a log-log scale.

Table 4. Small world analysis for the module networks

Project name	<*d*> / <*rd*>	<*cc*> / <*rcc*>
Apache	2.06 / 1.47	0.73 / 0.19
KDE	1.31 / 1.11	0.88 / 0.65
GNOME	1.46 / 1.10	0.87 / 0.54

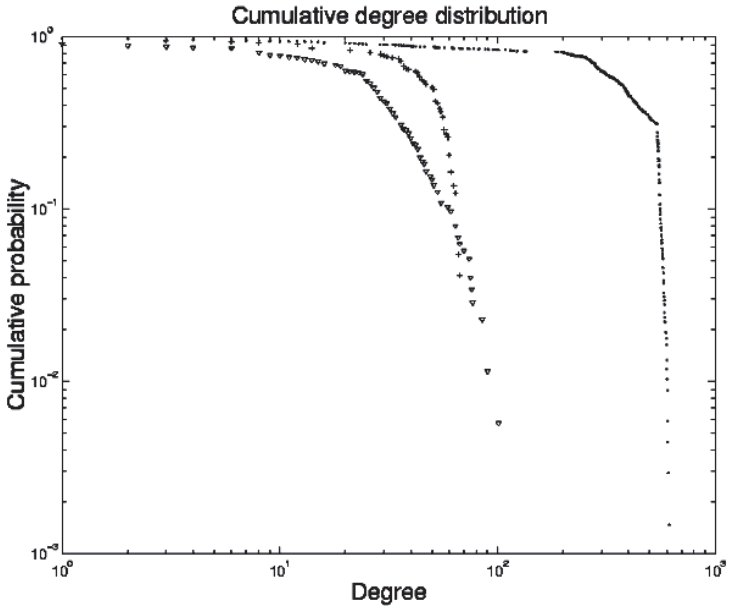
Figure 1 shows the cumulative distribution degree for our three networks. As it can be observed, all of them present a sharp cut off, which is a symptom of an exponential fall of the distribution degree tail. From a practical point of view, this means that none of our networks follow a power law distribution. This is quite a remarkable finding, because the specialized literature has shown that most social networks present power laws for this parameter. This implies that the growth of the network does not follow the traditional random preferential attachment law. Thus, it is difficult to come to any conclusions at this point; maybe by using a weighted network approach, as shown later, we could infer more information about the network topology.

Starting with the degree of the vertices, an analysis of assorts of the networks can also be carried out. The assorts measure the average degree of neighbors of vertices having a particular degree. For this reason it can also be called the *degree-degree distribution*.

Figure 2a represents this parameter for our networks. As can be observed, all three networks are elitist, in the sense that vertices tend to connect to other vertices having a similar degree ("rich" with "rich" and "poor" with "poor"). This is especially clear in the case of GNOME, where the curve approaches a linear equation with slope 1. Apache project deviates slightly from that behavior, showing some higher degree modules connected to other modules of a lower degree.

The previous analysis assumes unweighted networks. If weighted edges are considered now, similar conclusions are obtained. Figure 2b represents the cumulative weighted distribution degree of the networks. Comparing this picture with Figure 1, it may be remarked that the sharp exponential cut-offs have disappeared. This is

Figure 1. Cumulative degree distribution for Apache (▽), KDE (+), and GNOME (·)



especially clear in the case of GNOME, where the curve tail can be clearly approximated by a power law. The interpretation for this finding is that the growth of that network could be driven by a preferential attachment law based on weighted degrees. This means that the probability of a new module to establish a link with a given vertex is proportional to the weighted degree of that vertex. That is, the commiters of new modules are, with high probability, commiters of modules which are well connected (have high weighted degree) in the network. It should be noted that the use of weights has given a more realistic picture.

From Figure 1, it can be remarked that the sharp cut offs for Apache and KDE are close to each other. This means that the maximum numbers of relationships in both projects are similar. Nevertheless, observing Figure 2b, it can be seen that the KDE tail is clearly over the Apache tail. This fact implies that KDE weighted links are, on average, stronger than those of Apache. This can be quantitatively verified: we have calculated the average edge weight for the three projects obtaining 1,409.27 for Apache, 11,136.82 for KDE, and 7,661.18 for GNOME.

If multiplied, the average edge weight and the number of modules, the figures obtained are the total amount of commits performed by developers that contribute to at least two modules: 105,695 for Apache, 812,988 for KDE, and 5,110,007 for GNOME. This gives an idea of the modularity of the modules as a lower number of commits is indicative for developer work being more focused on a low number of modules. While the figures for Apache are not surprising (we have already noticed with previous parameters that is a high level of structure in the Apache project), the difference between KDE and GNOME is astonishing. The organization of the KDE CVS repository yields in more independent modules than the ones found in the one for GNOME.

(b) Cumulative weighted degree

CLUSTERING COEFFICIENT IN THE MODULES NETWORK

For the analysis of the clustering coefficient, we have represented its distribution in Figure 3a.

In Table 4 the average distance <*d*> among vertices are represented, together with the average clustering coefficients <*cc*> for our three networks and their equivalent random counterparts (<*rd*> is the random average distance and <*rcc*> is the random average clustering coefficient). As can be observed, the three networks satisfy the small world condition, since their average distances are slightly above those of their random counterparts; but the clustering coefficients are clearly higher.

As can be observed, the average random clustering coefficients for KDE and GNOME are very close to the real ones, due to the high density of those networks. This could be an indication of over-redundancy in their links. That would mean that the same efficiency of information could be obtained with fewer relationships (i.e., eliminating many edges in the network without significantly increasing the diameter or reducing the clustering coefficient). In this sense, the Apache network seems to be more *optimized*. To interpret this fact, the reader may remember that links in this network are related to the existence of common developers for the linked modules. It should be noted that redundancy is probably a good characteristic of a libre software project as it may lose many developers without being affected heavily. It may be especially interesting to have over-redundancy in projects with many volunteers, as in those environments, turnover may be high. Future research should focus on investigating whether over-redundancy is a good or bad parameter in the case of libre software projects. On the other side, how much of this redundancy is due to the taking of a static picture of the project should be researched; it may well be that the redundancy we have observed is the result of different generations of developers working on the same file in different periods of time.

Some interesting conclusions can also be obtained by looking at the weighted clustering coefficient. In Figure 3b we can observe the average weighted clustering coefficient as a function of the degree of vertices (the weighted degree-degree distribution). As we have already noticed, the KDE and GNOME networks have a similar local redundancy, which is higher than the one of Apache. High redundancy implies more fluid information exchanges in the short distances for the first two projects. Besides, the weighted clustering coefficient lowers with the degree in all cases, according to a power law function. We can infer that highly connected vertices cannot maintain their neighbors as closely related as poorly connected ones. This happens typically in most social networks because the cost of maintaining close relationships in small groups is much lower than the equivalent cost for large neighborhoods.

DISTANCE CENTRALITY IN THE MODULES NETWORK

The analysis of the distance centrality of vertices is relevant because this parameter measures how close a vertex is to the rest of the network. In Figure 4a, the distance centrality distribution for our three networks can be observed. They follow multiple power laws, making higher values of the parameter most probable. This is an indication of well structured networks for the fast spread of knowledge and information.

We can also analyze the average distance centrality as a function of the degree (average distance centrality-degree distribution), which is shown if Figure 4b. It can be observed that in all three cases the average distance centrality grows with the degree following, approximately, a power law of low exponent. This means that, in terms of distance centrality, the networks are quite *democratic*, because there is not a clear advantage of

Figure 3. Clustering coefficient distribution for Apache (∇), KDE (+) and GNOME (·). Average weighted clustering coefficient as a function of the degree of vertices for Apache (∇), KDE (+) and GNOME (.)

(b) Average distance centrality

well connected nodes compared to the rest. Curiously enough, the Apache and GNOME curves are quite similar, while the KDE one is clearly an order of magnitude over the rest. This could be an effect of the lower size of this network, but is also an indication of an especially well structured network in terms of information spread. So, even if KDE showed to be more modular as has been seen for a previous parameter, its structure seems to maximize information flow.

BETWEENNESS CENTRALITY IN THE MODULES NETWORK

The distance centrality of a vertex indicates how well new knowledge created in a vertex spreads to the rest of the network. On the other hand, betweenness centrality is a measurement of how easy it is for a vertex to generate this new information. Vertices with high betweenness centrality indexes are the crossroads of organizations, where information from different origins can be intercepted, analyzed, or manipulated. In Figure 5a, the betweenness centrality distribution for our three networks can be observed. In the same way, this was the case for distance centrality, as it grows following a multiple power law. Nevertheless, there is a significant difference between the distributions of these two parameters. Although the log-log scale of the axis of Figure 5a does not allow visualizing it, the most probable value of the betweenness centrality in all three networks is zero. Just to show an example, only 102 out of 677 vertices of the GNOME network have a nonzero betweenness centrality. So, the distance centrality is a common good of all members of the network, while the betweenness centrality is owned by reduced elite. This should not be surprising at all, as projects usually have modules (i.e., applications) which have a more central position and attract more development attention. Surrounding these modules, other minor modules may appear.

This fact can also be visualized in Figure 5b, where we represent the average betweenness centrality as a function of the degree. It can be clearly seen that only vertices of high degree have nonzero betweenness centralities.

COMMITER NETWORKS

The analysis of commiter networks draw similar conclusions to those shown for module networks, and therefore they are not going to be commented on in detail. For instance, the cumulative degree distribution for the two commiter networks is shown in Figure 6a, which has clearly the same qualitative properties than for this parameter for the module networks shown in Figure 1. The same holds true for the commiter cumulative weighted degree distribution depicted in Figure 6b, or for the average degree as a function of degree, depicted in Figure 7a, where it can be noticed how both networks maintain the elitist characteristic also observed in the case of modules.

An interesting feature of commiter networks can be seen in Figure 7b. The average weighted degree of authors remains more or less constant for low values of the degree. Nevertheless, in the case of KDE, it increases meaningfully for the highest degrees. The implication is that commiters with higher degrees not only have more relationships than the rest, but also their relationships are much stronger than the average. This indicates that authors having higher degrees are more involved in the project development and establish stronger links than the rest. At the same time, as we observed in Figure 7a, they only relate to other commiters that are involved in the project to the same degree as they are. If this behavior is found in other large libre software projects, it could be a valid method to identify the leading “core” group of a libre software project. On the other hand, the Apache project seems to promote a single category of developers, given that the weighted degree does not depend so clearly on the degree of vertices. It

may be also that because of the fragmentation of the Apache project in many *families* of modules, it is easy to developers to reach a point where they do not have the possibility to get to know more developers.

Table 5 digs into the small-world properties of commiter networks. As we can observe, both networks can still considered to be small world. The Apache case is especially interesting, because an increase in the average distance is observed. This characteristic plus the large value of the clustering coefficient may indicate that the network is forming cliques.

CONCLUSIONS, LESSONS LEARNED, AND FURTHER WORK

In this article an approach to the study of libre (free, open source) software projects has been presented, based on the quantitative and qualitative application of social networks analysis to the data retrieved from source code management repositories. Since most libre software projects maintain such repositories, and allow for public read-only access to them, this analysis can be repeated for many of them. However, given its characteristics, it will be most useful for large projects, well above the hundreds of thousands of lines of code and dozens of developers.

We have designed a detailed methodology which applies this SNA-based approach to the study of CVS data, and which can be automated. It starts by downloading the required information from CVS, and produces as an output several graphs and tables which can be interpreted to gain knowledge about the informal organization of the studied project. It is important to highlight a set of parameters in the output that are suitable for characterizing several aspects of the organization of the studied project, which makes it possible to gain a lot of insight on how a group of developers is managing coordination and information flow within the project. In addition, it has been shown that the introduction of weights in the relationships gives more realistic information about the projects under study.

It has also been shown how our methodology is applied to some important and well known projects: KDE, Apache, and GNOME. Although these studies are sketched just as case examples, some relevant results can also be extracted from them. For instance, it has been shown how all the networks that have been studied fulfill the requirements to be a small world. This has important consequences on their characterization, since small worlds have been comprehensively studied and are well understood in many respects. We have also not only found that the growth of the studied networks cannot be explained by random preference attachment (something that could be previously suspected). Moreover, it matches pretty well the pattern of preference attachment related to the weight (amount of shared effort) of links. Some other relevant results are the elitist behavior found in these projects with respect to the connectivity of modules and developers, which are indicators of an over-redundancy of links, and of a good structure for the flow of knowledge, and the absence of centers of power (in terms of information flux). All of these conclusions should be validated by studying more projects, and by analyzing with detail their microimplications before being raised to the category of characteristics of libre software projects, but that so far are good lines of further research.

There are some other studies applying similar techniques to libre software projects. For instance, Crowston and Howison (2003) suggests that large projects are more modular than

Table 5. Small world analysis for commiter networks

Project name	<*d*> / <*rd*>	<*cc*> / <*rcc*>
Apache	2.18 / 1.60	0.84 / 0.08
KDE	1.47 / 1.10	0.86 / 0.52

small ones. However, to our knowledge the kind of comprehensive analysis shown in this article has never been proposed as a methodology for characterizing libre software projects and their coordination structure. In fact, after using it in the study of some projects, we believe that it has a great potential to explore informal organizational patterns, and uncovering nonobvious relationships and characteristics of their underlying structure of coordination.

1 In this paper the term "libre software" will be used to refer to any software licensed under terms that are compliant with the definition of "free software" by the Free Software Foundation, and the definition of "open source software" by the Open Source Initiative, thus avoiding the controversy between those two terms.

2 Concurrent Version System (CVS) is the source code management (also known as versioning) system used in most libre software projects, although lately a new generation of tools, including for instance Subversion, are gaining popularity. In those projects, the CVS repository is usually freely readable over the Internet.

3 A Pareto distribution is known to be given when the 20% most active is responsible for 80% of the output.

4 For downloading this information we have used the CVSAnalY tool described in Robles, Koch, and Gonzalez-Barahona (2004).

5 Throughout this article, references to Apache cover all projects lead by the Apache Foundation and not just the HTTPd server, usually known as the Apache Web server.

6 Social network analysis has been applied to networks with hundreds of thousands, sometimes millions of vertices. In this sense, our network is of a small size even if we are handling large libre software projects.

This work was previously published in International Journal of Information Technology and Web Engineering, Vol. 1, Issue 3, edited by E. Damiani; and G. Succi, pp. 27-48, copyright 2006 by IGI Publishing (an imprint of IGI Global).

Chapter 5.7
Open Source Software Business Models and Customer Involvement Economics

Christoph Schlueter Langdon
Center for Telecom Management, University of Southern California, USA

Alexander Hars
Inventivio GmbH, Bayreuth, Germany

ABSTRACT

This chapter is focused on the business economics of open source. From a strategic perspective, open source falls into a category of business models that generate advantages based on customer and user involvement (CUI). While open source has been a novel strategy in the software business, CUI-based strategies have been used elsewhere before. Since the success of e-commerce and e-business, CUI-based strategies have become far more prevalent for at least two reasons: Firstly, advances in information technology and systems have improved feasibility of implementation of CUI strategies and secondly, CUI-based economics appear to have often become a requirement for e-business profitability. This chapter presents a review of CUI-based competition, clearly delineates CUI antecedents and business value consequences, and concludes with a synopsis of managerial implications and a specific focus on open source.

INTRODUCTION

Open source software applications and source code are developed cooperatively in an Internet-based peer-to-peer network or community of programmers (Hars, 2002). Some call the open source development process, therefore, also as peer-to-peer production (Wikipedia.org, 2006). The open source model has caught the attention of business strategists and financial analysts (and executives and shareholders of software firms), because open source developers devolve most property rights to the public, including the right to use, redistribute and modify the software free of charge. Some industry observers argue that this approach will emerge as the prevalent way to design and write software; others have been more cautious seeing open source as a niche model (Hars & Ou, 2001; *The Economist*, 2006).

Open source is new and old at the same time. It is a new concept in the software industry. However, the attractiveness of open source is rooted in mechanisms and economics that have fueled

business success in many other areas before. From a business strategy perspective open source fits into a broader category of business models based on customer and user involvement (CUI) that can provide superior economics.

A very visible example of this category of business models is Ikea, the Swedish furniture maker and retailer. Among consumers Ikea is known for its stylish yet affordable furniture. Among some business strategists and researchers Ikea is a prominent example of the economics of customer involvement, which has emerged as a key source of competitive advantage, particularly in the e-commerce area. Broadly speaking customer or user involvement describes a strategy that emphasizes engaging customers and user in business operations.

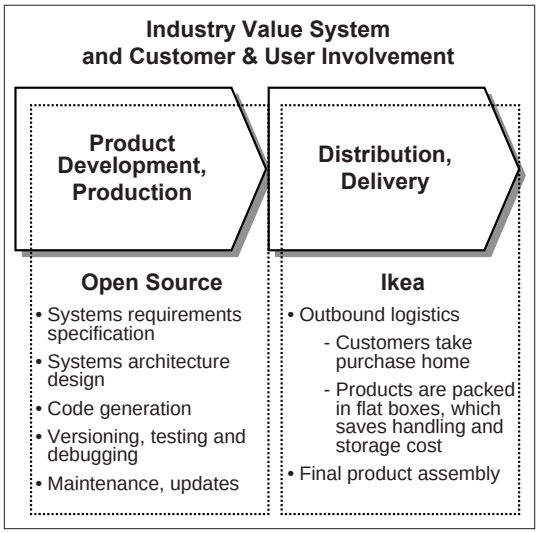
BACKGROUND

"Ikea Economics"

In the case of the Swedish furniture maker and retailer, Ikea, customer involvement is integral to doing business and creating economic advantage. Ikea customers are involved in business operations in that they pick their purchase off the Ikea warehouse shelf, drive it home and assemble it themselves.

Figure 1 depicts a two-tier industry system following Porter's value chain schematic (Porter, 1985). A product has to be developed, made, distributed, sold, and delivered. In the case of Ikea outbound logistics or delivery and final assembly are "outsourced" to the customer (see Figure 1). This saves Ikea cost compared to the competition that sells assembled pieces, which are bulky and, therefore, have to be home delivered. Furthermore, because Ikea furniture is assembled at the final destination, a customer's home, products can be shipped in flat boxes without negative space, which further saves handling and storage cost throughout the entire supply chain and channel system. But the advantage of customer involvement doesn't stop here with merely lower cost. Customer involvement economics can be an enabler of other economic advantages. In the Ikea example, the cost advantage due to customer involvement is used or leveraged by splitting savings with the customer, effectively lowering product prices, often below the price of the competition. The lower sticker price makes stylish design affordable for a larger market, which increasing Ikeas market potential. This larger footprint, in turn, allows Ikea to benefit from another economic advantage, the one that has been the main economic engine of mass production, namely scale economies. In other words, at Ikea customer involvement has worked as a starter to ignite an economies of scale engine. This combination of customer involvement economics and scale economies have helped Ikea become the world's largest furniture maker and retailer with 221 stores in 34 countries as of Spring 2006 (http://franchisor.ikea.com, 3/31/06). It also turned its founder, Ingvar Kamprad, into a multi-billionaire. *Forbes* magazine recently estimated Mr. Kamprad's fortune at $28

Figure 1. Open source and Ikea: Two examples of customer and user involvement



billion—trailing only Microsoft co-founder Bill Gates, U.S. investor Warren Buffett and Mexican industrialist Carlos Slim (Forbes, 2006).

Theory of Customer and User Involvement (CUI)

The literature defines customer involvement as the extent to which a customer is engaged as a participant in business operations, specifically in service production and delivery, including, for example, order processing and account management (Schlueter Langdon, 2003a, 2006). A first research construct has been developed and integrated into a broader theoretic model (see Figure 2; Schlueter Langdon, 2003a, 2006).

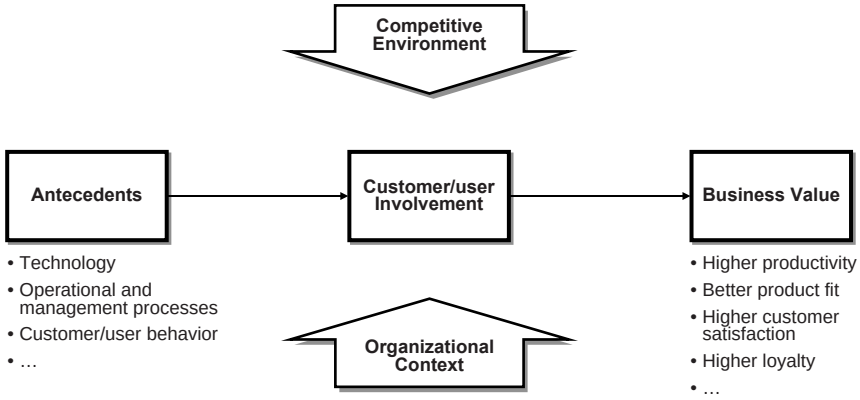
The customer involvement construct and its definition are rooted in several streams in the literature: "customer integration" and "customer relationship management" in marketing, "co-production" and "service encounter management" in service operations research, and "citizen participation" in the public policy literature.

In 1980, Whitaker introduced the notion of "co-production" in public service delivery in the field of public policy management (1980). At the same time Hakansson appears to have introduced the notion of a "customer integration strategy" within the context of marketing strategies in industrial markets, defining it as the ability to adapt to specific customer needs to increase business benefits (Hakansson, 1980, p. 370).

Brown, Raymond, and Bitner (1994) have first explicitly used the phrase "customer involvement" in their categorization of research on service encounters. Brown et al. divided research on service encounters into three primary types, the second of which is focused "on customer involvement in service encounters and the customer's role in service production and delivery" (1994, p. 34). Chase (1978) first discussed a customer's role in the service delivery process. This perspective has been expanded in the service operations literature to also consider the customer as a partial employee (Czepiel, 1990; Bowen, 1986; Kelley, Donnelly, & Skinner, 1990; Mills & Moberg, 1982; Mills & Morris, 1986).

In the marketing literature Sheth and Parvatiyar posited that "relationship marketing attempts to involve and integrate customers, suppliers, and other infrastructural partners into a firm's development and marketing activities. Such involvement results in close interactive relationships with […] customers […]" (Sheth & Parvatiyar, 1995, p. 399). Furthermore, "consumers are increasingly becoming co-producers. […] In many instances,

Figure 2. Theoretic customer and user involvement model



market participants jointly participate in design, development, production, and consumption of goods and services" (Sheth & Parvatiyar, 1995, p. 413). Gruen, Summers, and Acito (2000, p. 36) called this phenomenon "co-production."

The notion of customer integration is presented in the marketing literature as an extension of manufacturer-distributor relationships (Andersen & Narus, 1984, 1990). The theory base that underlies the marketing literature on manufacturer-distributor relationships and, therefore, the argument that customer involvement can enhance business value (see Figure 2) is a synthesis of exchange theory (Kelley & Thibaut, 1978; Thibaut & Kelley, 1959) and transaction cost economics (Williamson, 1975, 1985). Exchange theory states that parties transfer resources in relationships to enhance self-interest, while transaction cost economics reveals conditions under which certain organizational choices can maximize self-interest in the exchange relationship.

Specifically, the literature points to several consumer and seller benefits from tight customer integration. Lovelock and Young (1979) discussed the customer as source for increasing a service firm's productivity. Sheth and Parvatiyar (1995) indicate that consumers benefit from products and services that suit their needs better and sellers from higher customer satisfaction. Higher customer satisfaction in turn is positively related with customer loyalty and market share (Anderson, Fornell, & Lehmann, 1994; Anderson, Fornell, & Rust, 1997).

MAIN FOCUS OF THE CHAPTER

Customer and User Involvement and Business Value Categories

Since the success of the Internet in business, CUI-based strategies have become more prevalent. For one, advances in information technology and many open standards have increased information systems capabilities at lower cost to make CUI-based strategies feasible. For another, CUI economics are often required in the first place in order to make e-business operations profitable, because in electronic commerce companies have become expected to do more for less.

Analysis based on industrial organization theory clearly highlights this more-for-less dilemma. Tracking value chain activities, such as product search, reveals that the Internet-enabled change in the interaction between a consumer (demand side) and vendor (supply side) has led to an extension of the traditional value system (Schlueter Langdon & Shaw, 2000, 2002). In electronic commerce vendors are often doing more than in traditional commerce. Online vendors are supporting activities, which consumers have to perform manually in traditional channel systems. For example, instead of driving to multiple stores, walking up and down the aisles to search for a product and find a low price, shoppers can enter key words and at the push of a button, they can evaluate competing price quotes. Doing more is costly as online sellers resort to "softwarization," the wholesale automation of business transactions and processes using information systems (Schlueter Langdon, 2003b, 2003c). While labor cost may be saved, online vendors have to invest in the design, building and implementation of sophisticated information systems, and they continue to spend money on operations, maintenance and updates. The cost of selling goods online may be cheaper but consumers also expect lower sticker prices online. In order to turn a profit, online vendors often rely on CUI economics. Table 1 provides a systematic overview of major, generic CUI business value categories.

High customer involvement may allow for mass-customization of products and services using customer data or user profiles, which, in turn, may facilitate both—lower cost and higher revenue. To take a real-world example, Dell can leave customization of products (e.g., choice of microprocessor) and product bundling (e.g., PC

Table 1. Major, generic CUI business value categories

Cost	Revenue
Customer or user operates business process activities	
• Company saves employee time and expense • Likely higher fixed cost for IS that can be operated by many customers instead of a few employees only	• Goods can be purchased anytime and from anywhere -> Higher quality, better product fit -> Better customer data
Higher quality, better fit	
• Less inventory in entire channel system • Less slow moving and obsolete items • Less discounts	• Customer likes the feeling of being in control -> Higher customer satisfaction • Monopolistic competition pricing opportunities
Higher customer satisfaction	
• Lower churn saves customer acquisition cost • Positive word of mouth may save marketing expenses	• Higher loyalty • Higher lifetime customer value
Better customer data or "profiles" (behavior, wants and needs)	
• Data mining improves accuracy of targeting customers and saves marketing and sales cost • Lower marketing research cost	• Up-selling opportunities • Better next generation product • User lock-in and higher switching cost

with ink jet or laser printer) to individual preferences, which can increase up-/cross-selling opportunities and customer satisfaction (see Table 1). At the same time Dell can save inventory cost and write-offs, because customers trigger of manufacturing and assembly activities (see Table 1). Instead of Dell pushing products into the market, customers are pulling the product through the system, turning a made to stock system into a made-to-order flow.

CUI is not limited to specific industries, such as consumer products (Ikea and Dell). The auto industry has discovered CUI economics as a source of business advantage. For example, BMW, the German maker of luxury cars, has designed information systems so that European buyers can custom-design their own cars with any change possible until five days before production. As a result, 80% of European BMW buyers custom-design their vehicles and most last minute changes of orders are reportedly upgrades to bigger engines and more luxurious interiors, which tend to be more lucrative for the firm (*Business Week*, 2003). Another CUI example in the auto industry is the emerging area of vehicle relationship management (VRM). Automakers have begun to install black boxes into vehicles that often work similar to flight tracking devices in airplanes. The box is valuable in two ways. Firstly, it provides vehicle usage data, which is a function of vehicle model, the driver and its environment. Secondly, it provides a new, interactive channel system with every customer. The data and the channel can be exploited to better manage customer and vehicle relationships, hence VRM. Vehicle usage data can be exploited for diagnostics purposes to improve uptime. The new channel can be used to interact with customers to improve buyer satisfaction and loyalty. All it takes to unlock the value is user participation.

In the software industry open source software has emerged as an important implementation of CUI economics. Many applications are created by an open source community. Figure 1 illustrates that all essential software development activities of requirements specification, architecture design, code generation, debugging and testing as well

as ongoing maintenance are left to a community of users.

FUTURE TRENDS

Discussion and Managerial Implications

In open source software advantages accrue along all three major dimensions of business performance: cost, time and quality. Figure 3 reveals how an average IT implementation project using open source software compares with a project that is being built traditionally. Results are based on a convenience sample of expert assessments. The business value parameters have been defined at a very high level: cost measures project cost including maintenance, time measures initial implementation as well as downstream modifications, and quality rates the degree of excellence and customer satisfaction.

In terms of cost, open source saves at least the profit or profit margin associated with a brand name product, brand name systems integration service and brand name maintenance contract. (The software business "has an exceedingly high gross [profit] margin of 90%, [...] a net profit margin of 27%. This shows that its marketing and administration costs are very high, while its cost of sales and operating costs are relatively low (McClure, 2004).)

Open source can save time, because documentation is public and exposed to public scrutiny, just like the source code itself (Hars, 2002). Furthermore, customer support is not limited to a vendor's office hours or a particular maintenance subscription level but open source documentation and expertise tends to be available online and anytime.

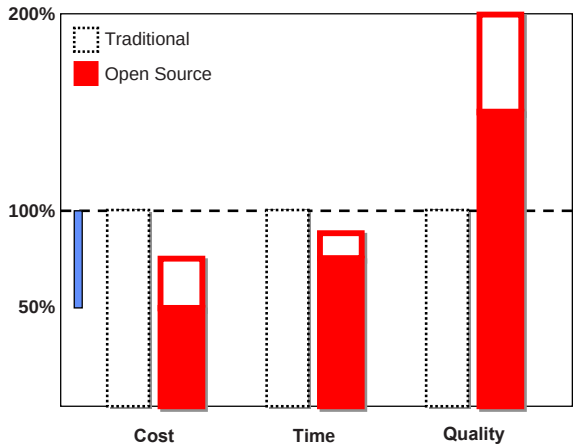
Quality can be better, firstly, because of transparency of the process and secondly, because of transparency of qualification and achievements of contributors (Hars, 2002). This mirrors a key lesson of a free market system, namely that transparency tends to increase buyer value. Also, problems are fixed when a problem exceeds users' willingness to cope and not when decided by a vendor's corporate strategy or business policy.

Figure 3 summarizes the assessment of our convenience sample of experts, which includes senior developers and architects, and information technology executives of Fortune 500 companies (chief information officers, CIOs, and vice presidents).

Figure 3 compares an open source implementation with a traditional, branded solution along the aforementioned and defined business value categories of cost, time and quality. Results reflect a consensus among our experts that open source software beats a traditional solution in any category. The extent of this advantage can vary. First, there is variability within each category. Consider cost: some experts see an OSS implementation at 50% of the cost of a traditional solution. Others see it more at 75%. Second, there is variability across business value dimensions. Higher quality appears to be the most significant advantage, followed by lower cost.

By nature, a high level comparison, such as the one presented in Figure 3, is constrained and

Figure 3. CUI business value assessment: The open source example

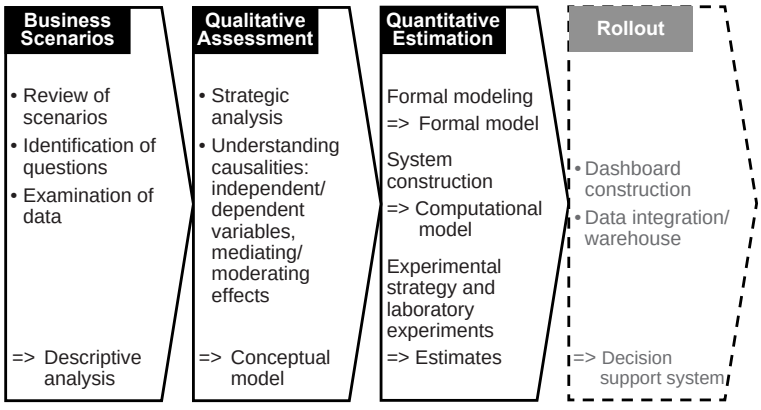


implications are limited. First, this comparison is limited to an implementation that utilizes open source software instead of a commercial package (e.g., installing, configuring, integrating, testing, and maintenance). It does not include the writing of application source code. Furthermore, the comparison is focused on situations in which open source is a true alternative. Second, the business value parameters—cost, time, and quality—can be interdependent and, therefore, difficult to isolate. For example, in order to speed up a project the quality of the code may be compromised; to save money less qualified engineers are used who need more time to write the code, and so on. Expert interviews were conducted in a way that such effect would be additive to the assessments presented in Figure 3. Third, an average project is considered and, therefore, results aim to reflect a *central tendency,* which is useful as a guideline but it obscures the variance in size and complexity of information systems projects. Furthermore, the distribution may be skewed and in this case average values can be easily misinterpreted.

It is understood that a specific evaluation would require a dedicated analysis in order to properly compare alternatives quantitatively. In order to conduct such analysis, a multi-step approach would have to be devised. Figure 4 depicts an exemplary business intelligence analytics schematic derived from research theory (Schlueter Langdon, 2005, 2007).

Central to any business value assessment—and open source is no exception—is the identification of a causal model that underlies everything that follows (see Figure 4, phase two: qualitative assessment -> conceptual model). A causal model represents the most relevant variables and a set of logical relationships between them. It prevents confusing cause and consequences. The business practice of jumping straight into a spreadsheet to calculate a conclusion is a common mistake. No patient would accept treatment without prior diagnosis. By the same token, any reliable and robust business value assessment requires careful separation of independent and dependent variables as well as moderating effects grounded in theory and best practice. While medical doctors are trained extensively to administer diagnosis-based treatment many managers jump straight to actions, often based on gut instinct only. If key variables and cause-result relationships cannot be clearly identified and delineated on a single sheet of paper then it is not plausible that jumping to some spreadsheet-based calculation would suddenly solve the problem.

Figure 4. Business model evaluation method



At the conceptual modeling stage for assessing CUI benefits it is important to:

- Understand under which circumstances customer involvement can create benefits:
  - What are specific customer involvement antecedents?
  - What are key moderating effects (see Figure 2)?
  - Avoid reinventing the wheel and instead use existing theory, best practice and literature in information systems, management and marketing, for example.
- Understand how to leverage CUI economics:
  - Can CUI be leveraged to generate other advantages (see Table 1)?
  - Would it take partners to increase advantages?
- Understand how an incumbent business model may become vulnerable to CUI-based competition from either old rivals or new entrants or both.

Once a model has been designed it can be implemented. Typically, this means constructing a spreadsheet (see Figure 4, phase three: quantitative estimation -> estimates). This is also an opportunity to verify measurements concepts before collecting the required data. Finally, results would have to be evaluated.

CONCLUSION

Aforementioned issues can only be exemplary. Experience suggests that it is often misleading to suggest a generic solution. The business model evaluation method presented in Figure 4 distinguishes between major analytical phases. It would have to be adapted, modified and specified for a given decision problem. However, while actual outcomes may vary, Figure 3 suggests that an open source solution may in any case be an economical choice. This outcome coincidences with the observation that brand name software vendors increase the attractiveness of products that compete with open source packages and/or even offer products in an open source way.

ACKNOWLEDGMENT

The manuscript has benefited from thoughtful suggestions and comments of the many contributors and anonymous reviewers of the Special Interest Group on Agent-Based Information Systems (SIGABIS) of the Association for Information Systems (AIS, www.agentbasedis.org). The authors particularly acknowledge discussions with and advice from Steve Davis, Omar El Sawy, Mark Hayes, Jörg Heilig, Bob Josefek, Ann Majchrzak, Steffen Neumann, Kim Spenchian, and Ed Trainor.

KEY TERMS

Business Intelligence Analytics: Summarizes models and methods used to analyze data for the purpose of helping executives make better, more precise decisions.

Business Model: Describes how profit is generated; captures business logic by separating independent/dependent variables and mediating/moderating effects.

Co-Production: Has evolved to describe a situation in which people outside paid employment, such as customers, contribute to business value-added.

Customer and User Involvement: Describes the extent to which a customer is engaged as a participant in business operations, specifically in service production and delivery, including, for example, order processing and account management.

Customer Relationship Management (CRM): A broad term to cover concepts, methods, and procedures, and enabling information technology infrastructure that support an enterprise in managing customer relationships.

IT Business Value: Captures the business value derived from investments in information technology components and systems. Generic IT business value categories include cost, revenue, and quality.

Peer-to-Peer Production: Describes work performed and organized through the free cooperation of equals.

Chapter 5.8
Investing in Open Source Software Companies:
Deal Making from a Venture Capitalist's Perspective

Mikko Puhakka
Helsinki University of Technology, Finland

Hannu Jungman
Tamlink Ltd., Finland

Marko Seppänen
Tampere University of Technology, Finland

ABSTRACT

This chapter studies how venture capitalists invest in open source-based companies. Evaluation and valuation of knowledge-intensive companies is a challenge to investors, and while many methods exist for evaluating traditional knowledge-intensive companies, the rise of open source companies with new hard-to-measure value propositions such as developer communities brings new complexity to deal-making. The chapter highlights some experiences that venture capitalists have had with open source companies. The authors hope that the overview of venture capital process and methodology as well as two case examples will provide both researchers and entrepreneurs new insights into how venture capitalists work and make investments.

INTRODUCTION

In the traditional view, the evolution of a technology-based new company is seen through separate consecutive stages. Business is based on creating tangible real assets; and in the end, the value of a company is also based on real assets. First, the technology is developed, which is followed by setting up the organization. Once the organization has reached a sufficient scale, internationalization is started. Finally, the value of the company is estimated with potential venture investment or through realization either through an initial public offering (IPO) or a trade sale.

However, due to the increased complexity of products and services, time-to-market tends to lengthen. In order to maintain sufficient resources until the company reaches profitability, external financing is needed. The time needed to turn a

company's cash flow positive varies considerably. A long product development phase and slow market penetration prolong the period of negative cash flow. Simultaneous internationalization drains resources at an even higher rate. Since start-ups do not usually have collateral to secure bank loans, equity financing is the most evident form of financing. Venture capital funding is usually sought in order to get business development support in addition to plain financing.

New business ideas are increasingly more knowledge intensive, driven in part by the application of ICT as an enabling technology across industrial sectors. Also, the nature of business has changed: times-to-market are faster, development stages are no longer consecutive but can be simultaneous or even skipped, and companies are born global. Distinct from yesterday's industrial companies, today's knowledge-intensive companies' values are not based on their real assets but rather on their intangible assets such as knowledge, networks, and brand. Needless to say, intangible assets are considerably more challenging to value. The previous is even truer in the case of open source software (OSS) companies, since part of their business (and value) relies on open source (OS) communities in which people contribute their time and knowledge voluntarily into projects. Contributions are real but take place without formal contracts or incentive mechanisms, and people can easily abandon the community.

Furthermore, OSS companies that build their businesses on OS products (e.g., Google, JotSpot) have huge savings in time and licensing fees; they get to market faster and cheaper. This sets even greater challenges for those valuating OSS companies. In theory, these free contributions should yield in higher valuations. On the other hand, the uncertainties involved should have the opposite effect.

The mission of this study is to compare traditional IT companies and their valuations and evaluations to those of OSS companies from the viewpoint of the venture capitalist. This is further divided into several subquestions:

- What are the special issues to be taken into account when evaluating OSS companies?
- Do venture capitalists assign a positive, negative, or no value to OSS companies and their communities when compared to traditional IT companies?
- Is there hype around OS?

Data for recent valuations of OSS and traditional IT companies were gathered from the VentureOne database. VentureOne (2005) is one of the leading venture capital research firms offering information on the venture capital industry. To better understand the investment decisions made and valuations paid for OS companies, and in order to get insights into what are the specialties in evaluation of OSS companies, two case studies were carried out. When designing the case study, based on the authors' initial understanding of the issues at hand, a pattern of interview questions was constructed. In addition to these semistructured interviews, data were gathered from publicly available sources. The interviewees were key managers of the case companies. Both of the cases present seed/early-stage venture capitalists that have been active in investing in OS companies. In addition, the case studies were backed up with several interviews with venture capitalists and entrepreneurs as well as feedback gathered from Internet online communities (for the questionnaire used, see Puhakka & Jungman, 2005).

BACKGROUND

Earlier Research on Evaluation and Valuation Theory

Venture capitalists evaluate their investment opportunities based on certain criteria. It is widely accepted that the three key investment decision

criteria are management team, market projections, and product (Tyebjee & Bruno, 1981, 1984; MacMillan, Siegel, & Narasimha 1985).

In addition, venture capitalists have preferences, such as a venture's stage of development, its location, its industry or technology, and size of the investment required, which vary among one another (Seppä, 2000). These criteria and preferences are related to evaluation of an investment opportunity: does the venture have potential? Is it worth our time and money? Does it fit our investment strategy? Venture capitalists base their evaluation on business plans, meetings with the entrepreneurial team, and various researches.

Only after positive results from evaluation is it time to think about the value of the company. The process of valuation resembles business negotiation. Herein, "valuation means the process of placing a monetary value on an investment opportunity" (Seppä, 2003, p. 6). Venture capital valuations are not as straightforward as public market valuations or share prices. "Because of the fluctuations in the supply and demand of venture capital, investment valuations are not always determined according to the rules of efficient markets" (Seppä, 2003, p. 11). Valuation also can refer to venture capital funds' periodic valuations of investments (Association Française des Investisseurs en Capital [AFIC], British Venture Capital Association [BVCA], & European Private Equity and Venture Capital Association [EVCA], 2005).

Valuation of high-tech companies by venture capitalists theoretically has been studied extensively (e.g., Lockett, Wright, Sapienza, & Pruthi, 2002; Seppä, 2003). The value of a new venture is derived by discounting predicted future cash flows to the present. The discounting factor depends on the probability of returns. Even if a company has significant potential future cash flows, the risk of failure decreases its net present value.

Different methodologies exist in the valuation, but all aim at answering the same question: what is the present value of expected future earnings or the exit value of a company? The methods fall into the following four categories (Lockett et al., 2002):

1. Liquidation value-asset-based methods
2. Discounted cash-flow-based methods
3. Options-based valuation methods
4. Rule-of-thumb valuation methods (comparator valuations)

The concepts of present value and net present value (NPV) form the basis for the valuation of real assets and investment decision-making. Essentially, the method makes a comparison between the cost of an investment and the net present value of uncertain future cash flows generated by the venture. There are at least four major steps in a discounted cash flow for a proposed venture.

First, assuming that the venture is all equity financed (i.e., all necessary capital is provided by the shareholders), forecasts are needed for what the expected incremental cash flows would be to the shareholders if the venture were accepted.

Second, an appropriate discount rate should be established that reflects the time value and risks of the venture, which, therefore, can be used for the calculation of the present value of expected future cash flows. The concept of present value includes the notion of the opportunity cost of capital. The appropriate discount rate, or the cost of capital, first must compensate shareholders for the foregone return they could achieve on the capital market by investing in some risk-free assets. It also has to compensate them for the risk they are undertaking by investing in this project rather than in a risk-free financial asset. Thus, the cost of capital is determined by the rate of return investors could expect from an alternative investment with a similar risk profile. Fortunately, the rich menu of traded financial assets provides venture fund managers with the opportunity to estimate the right price.

Third, based on the value additives of present values, the NPV of the venture is to be calculated.

Once the cash flow forecasts are finalized and the appropriate discount rate is established, the calculation of the venture's NPV is a technical matter. When all future cash flows that need to be discounted arrive at their present values, and by adding them to the present value of the necessary capital outlay, the NPV of the venture is achieved.

Finally, a decision has to be made whether to go ahead with the venture or not. As the company proceeds toward profitability, the likelihood of success grows, and the value of the company grows. Thus, it can be argued that every step a company takes toward its goals increases its value.

Exit valuations of technology companies are dependent on the prevailing market situation. Because the presumed exit valuation is the most important measure when considering the value of a company at the last venture capital round before an IPO, it is obvious that exit valuations have significant effects on valuations at all investment rounds, although the effect diminishes toward the founding stage. Due to dramatic changes in exit valuations (e.g., during 1999-2000), there has been a wide variation in valuations at various venture capital rounds as well.

Hype and Uncertainties Vitiate the Theory

Every now and then, things get out of hand. In the 1990s, it was argued that revenues and earnings were neither sufficient nor relevant ways to put value to emerging e-businesses or dot-coms that had no revenues and actually no existing mechanisms of extracting payments from customers. A way to assign value to a member in a Web community was proposed: a so-called "lifetime value of a customer" or a "price-to-eyeball multiple," an estimate of how much on average a customer would end up paying to a company (Valliere & Peterson, 2004).

Emerging OS companies face a similar challenge since part of their businesses (and values) relies on OS communities in which people contribute their time and knowledge voluntarily. Contributions are real but take place without formal contracts or incentive mechanisms, and people can easily abandon the community. The question rises how one should value community contributions like these. The International Private Equity and Venture Capital Valuation Guidelines (AFIC, BVCA, & EVCA, 2005) provide no aid on this. On the other hand, venture capitalists certainly have some views, since there are already several cases in which they have invested in OS companies.

Every venture capital (VC) investment is difficult to value due to the high degree of uncertainty in the performance. The valuation of OS companies is even more challenging, as there is yet neither history nor guidelines due to the uncertainties, for example, in the following:

- Profitability of business model
- Revenue streams
- Market acceptance
- Community commitment
- Competitive reactions
- Quality of software
- New General Public License (GPL) version in 2007

The list includes similar uncertainties that were involved in the dot-com bubble (Valliere & Peterson, 2004). Indeed, one can see the signs of hype in OS as well. Signs of hype surround certain companies (company hype), the OS market (market hype), and the activity of other investors as a group (investor hype) (Valliere & Peterson, 2004). In 2005, OS was getting increasing attention in the press, and venture capitalists were announcing OS strategies. However, it is too early to say whether this will lead to unreasonable valuations of OS companies.

MAIN FOCUS OF THE CHAPTER

Done Deals and Given Valuations

So far, the OS experience has not been a happy one for venture capitalists. According to the research firm VentureOne, some $714 million was invested in 71 OS companies in 1999-2000, and most of those projects collapsed (VentureOne, 2005). One of the biggest successes that is left of those experiences is RedHat Inc., which went public in 1999 and makes money selling enhancements and maintenance services to corporations using Linux OS operating systems. However, it still has some ways to go before reaching $200 million in revenues (RedHat, 2005) and is a relatively mild success with market value less than $5,000 million and earnings per share (EPS) of $0.33 (NASDAQ, 2005). So this is certainly no Google with market value just under $70,000 million (EPS $5.02) or eBay with market value just under $60,000 million (EPS $0.78) (NASDAQ, 2005) that aggressive venture capitalists often use as a reference as companies they want to fund as the "next big thing."

The biggest success so far with OS ventures, as they traditionally have been viewed, has been IBM's Linux service business that the company has grown as a separate emerging business opportunity unit and has managed to grow it from $0 to more than $2 billion in revenues in just 5 years. Still, there is no public record on how much IBM has invested in this venture to realize that growth (IBM, 2005).

Several studies have pointed out that Linux, Apache, and MySQL, for example, have reached the maturity in which the technology or code is comparable or even superior to the existing proprietary ones. Furthermore, for example, Firefox has managed to take the market by storm extremely quickly without any significant marketing budget. In other words, early evidence seems to point to the OS approach, at least some cases, as an efficient way to develop technology and take that to market. However, at least the experiences from the first round financings of OS companies indicate that it is not necessarily the best way to do business.

After a few years of trying to figure out whether money can be made by OS companies, the answer from venture capitalists seems again to be a reluctant yes. Twenty OS businesses raised $149 million in venture money in 2004 in the United States alone (VentureOne, 2005). There are no numbers available for the rest of the world, but in Europe, several investments took place. Looking at that total, it would seem that most of the investments are still on a seed or first-round level (compared to an average level on various rounds of realized investments); if distributed evenly among companies, the amount would be $7.45 million.

Case: BlueRun Ventures

BlueRun Ventures was originally launched as Nokia Venture Partners in 1998 with $150 million initial invested capital from Nokia Corporation. Even with money from Nokia, it was designed right from the start to act independently of its only investor. It raised a second fund of $500 million in 2000, which then already included other investors besides Nokia, such as Goldman Sachs.

In 2005, Nokia Venture Partners raised its third fund of $350 million and changed its name to BlueRun Ventures. Today, BlueRun Ventures has offices in nine locations globally and manages $1 billion making investments into IT, mobile, and consumer technologies at seed- and early-stage levels (BlueRun Ventures, 2005). In looking at OS investment opportunities, the key issue identified by BlueRun Ventures is a strong community close to the company. In their view, OS is a transformation force that is forcing a unit price down and the only realistic counterforce to big incumbent companies such as Oracle or BEA systems.

Still, they consider the market being at an early stage of deployment since after the bubble there have been no notable initial public offerings by OS companies. From the investment point of view, they consider two uncertainties in OS: the size of the market and the fragile business attachment of dealing with a community.

BlueRun Ventures has quite a bit of experience dealing with OS companies and has looked at about a hundred companies from 2002 to 2005. However, in early 2006, it had just completed its first investment in this space. Seed and early-stage investments are tricky, as typically there is very little or no historical numbers to look at. As the company's partner noted, it really is not a science but rather a very subjective opinion of opportunities. The questions are typically, "Do I like this opportunity? How much money is needed to make it happen? Does it fit with the funds strategy?" After that, the actual valuation is actually based on negotiations, which rely more on people skills than anything else (A. Kokkinen, personal communication, November 11, 2005).

From BlueRun Ventures' perspective, valuations in the long run should be the same for both traditional and OS startups. However, the nature of seed-investments is different since communities in a way have taken care of development that is typically done with seed money, resulting in a technology but not in protected intellectual property rights (IPRs).

As the market is still developing, BlueRun Ventures has not been able to identify any OS-dedicated venture funds, even though it expects several of those to be formed. A prerequisite for an OS fund may be that first there should be four to five initial public offerings, which would give enough evidence to the managers of funds in order to go to their investors and propose an OS fund (A. Kokkinen, personal communication, November 11, 2005). How this will turn out remains to be seen. Either OS will remain part of existing funds' investment targets, or OS-dedicated funds will be seen in the future. The latter would obviously result in more sophisticated ways of evaluating OS; otherwise, the competition for investors' money will continue to be played out between traditional software companies and OS companies in mutually accepted terms.

Case: Nexit Ventures

Nexit Ventures is a Finnish-based traditional venture capital company. It raised its Euro 100 million fund in 2000, which was later reduced to Euro 66.3 million. The investors are private institutions with 50% of their commitments outside Finland. The initial focus was seed and early-stage companies both in the Nordic and North America; later this was modified to early- and later-stage companies in the same geographical regions. The technology focus of mobile and wireless communication, from core components and enabling middleware to applications and services, has remained the same.

Nexit Ventures does not consider a pure OS company to be a viable investment opportunity. Rather, it sees the OS approach of collaborative effort to solve various issues to be an enabler for various things of potentially great value. For example, Apple's iPod makes it easy for consumers to utilize music downloaded from Web, whether the music is from legitimate sources or not. Still, the idea was that the closer one gets to the core of OS (the community), the harder it is to make money. Nexit Ventures considers OS be at every level of deployment from early adoption to maturity; it just is not always very visible, and there are legal uncertainties.

From Nexit Ventures' point of view, it is somewhat isolated in Finland about what is taking place globally (a bit paradoxical, as most things are said to take place on the Internet), and it has not yet seen a rise of OS-based businesses, often referred as Web 2.0 companies. There has been little discussion on the public media, especially compared to the United States. In the United States, where valuations are very high again,

due diligence in follow-up rounds is quite weak, according to Nexit Ventures, as there is pressure to do hard sought deals.

Regardless, looking at opportunities and valuating them, Nexit Venture's comments corroborate those of BlueRun Ventures. The markets for venture capital investments are imperfect and always will be. Therefore, the valuations are not made with transparent scientific methods but rather are results of negotiations. In other words, it can be argued that the potential of one's business idea opens the door to negotiations with the venture capitalist, but the valuation that will take place with the investment is determined "by one's skills as a negotiator, that are impossible to quantify or to break down into a scientific model" (A. Tarjanne, personal communication, November 30, 2005).

FUTURE TRENDS

It might be that in the end, the biggest successes to financing community come from and to companies that are not really OS companies as such but rather use OS components to build new businesses; for example, Google, which, like most Web companies, was built on top of OS). From $1 million initial seed capital in 1998 and an injection of $25 million growth capital in 1999, the company realized the value to its investors in 2004 by going public, and by spring 2005, it had surpassed the Finnish pride Nokia with more than $80 billion in market capitalization, compared to just less than $80 billion for Nokia (Google, 2005).

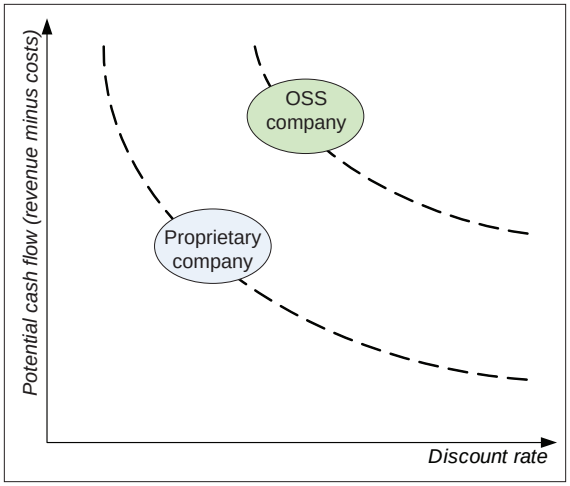
As stated earlier, lareg amounts of money are invested into OS businesses, and we expect dedicated OS funds to be formed in the near future. The key driver will be successful exits from OS investments. However, the first bets (i.e., seed round investments) to potential future successes have just been made, and how successful those will be can only be known in the coming years. Once we can get significant amounts of data, interesting quantitative comparisons can be made between investments in OSS and traditional IT companies.

CONCLUSION

Venture capitalists do not seem to put special value on OS companies. However, some of them recognize that there are distinctly different elements in evaluating OS companies. For instance, expected cash flows are likely to be bigger in businesses built on OS software than in similar traditional software companies, due to the savings, for instance, in licensing fees. Concurrently, the uncertainties in OS should increase the discount rate (see Figure 1).

In interviewing the selected experts and looking at the selected cases, it seems that rather than putting effort into further understanding valuation methodologies, entrepreneurs should seek help in learning better negotiation skills. However, in the academic world, more complex approaches have been taken in valuating a company. It might be

Figure 1. Potential cash flow and risk measured by discount rate of the companies using OS or proprietary software (Source: Adapted from W. Cardwell, personal communication, November 15, 2005)



appropriate to ask whether the academics are really serving the industries if these methodologies are not actually used by the people in the venture capital industry.

The good news for entrepreneurs looking to launch new OS ventures is that money is available, and investors are making their bets again on OS. Still, the basic dilemma remains: while the venture capitalist is looking to become a shareholder as cheaply as possible, the entrepreneur, of course, is trying to retain as much ownership as possible. This would not be an issue if there were a transparent, objective way to estimate the value of the venture. However, as one interviewee said, this is not likely to happen, as the venture capital market remains imperfect. Unfortunately, there are many unknown factors affecting the present value of a startup that have to be estimated, and thus, objectivity is hard to maintain.

ACKNOWLEDGMENT

The authors wish to express their gratitude to interviewed investors and other persons who have expressed their valuable opinions in various forums. An earlier version of this chapter (Puhakka & Jungman, 2005) was presented at the eBRF 2005 Conference in Tampere, Finland, September 26-28, 2005, and published in the *Conference Proceedings, Frontiers of e-Business Research (FeBR 2005).*

KEY TERMS

Evaluation: Subjective and qualitative assessment of an investment opportunity.

Proprietary: Belonging to or controlled by an individual or organization that has the ability to share that item (in this case, software code) with others.

Seed Company: Company in a stage of research, assessment, and development of an initial concept before reaching the start-up phase (FVCA Yearbook, 2004).

Startup Company: Company in a product development stage requiring further funds to initiate commercial manufacturing and sales (FVCA Yearbook, 2004).

Valuation: Process of placing a monetary value on an investment opportunity (Seppä, 2003).

Venture Capital: Equity investments made for the launch, early development, or expansion of a business (EVCA, 2005, www.evca.com).

This work was previously published in Handbook of Research on Open Source Software: Technological, Economic, and Social Perspectives, edited by K. St. Amant; and B. Still, pp. 532-540, copyright 2007 by Information Science Reference (an imprint of IGI Global).

Chapter 5.9
Open Source Software:
A Developing Country View

Jennifer Papin-Ramcharan
The University of the West Indies – St. Augustine Campus, Trinidad and Tobago

Frank Soodeen
The University of the West Indies – St. Augustine Campus, Trinidad and Tobago

ABSTRACT

This chapter presents issues that relate to developing countries' use of open source software (OSS) and the experience of these countries with OSS. Here the terms open source software (OSS), free/libre and open source software (FLOSS) and free software (FS) are used interchangeably. It describes the benefits of FLOSS including its superior quality and stability. Challenges to FLOSS use particularly for developing countries are described. It indicates that despite the greater benefits to developing countries of technology transfer of software development skills and the fostering of information and communication technology (ICT) innovation, the initial cost of acquiring FLOSS has been the key motivation for many developing countries adopting FLOSS solutions. It illustrates this by looking at the experience of a university in a developing country, The University of the West Indies, St. Augustine Campus in Trinidad and Tobago. Strategies for developing countries to benefit "fully" from FLOSS are presented including the implementation of formal organized programmes to educate and build awareness of FLOSS. The authors hope that by understanding some of the developing country issues that relate to OSS, solutions can be found. These countries could then fully benefit from OSS use, resulting in an increase in size of the global FLOSS development community that could potentially improve the quality of FLOSS and indeed all software.

INTRODUCTION

Open source software (OSS) is understood by many to mean software or computer programs where the source code is distributed and can be modified without payment of any fee by other programmers. The term OSS first came into use in 1998 and is attributed to Eric Raymond (Feller & Fitzgerald, 2002). The Open Source Initiative (OSI) has been formed to promote the use of OSS in the commercial world (www.opensource.org/).

The terminology related to software that is released with its source code and is modifiable and distributable without payment and then developed by a group of users or community can be confusing. For example the literal meaning of *open*

source implies access to the source code, without necessarily implying permission to modify and distribute. Also, the Free Software Foundation (FSF) (founded in 1985) which predates the OSI refers to these programs not as OSS but as *free software* (www.fsf.org/). The term *free software* was created by Richard Stallman where *free* refers to the freedoms to use, modify, and distribute the programs and does not have anything to do with the cost of acquiring the software. Therefore, *free* software does not necessarily mean *zero cost*, and *open source* does not just mean access to the source code.

The differences between free software and OSS have been well documented (Fuggetta, 2003). Stallman (2002) gives details about these differences at www.gnu.org/philosophy/free-software-for-freedom.html. What really then defines software as OSS? Generally, OSS is a software product distributed by license, which conforms to the Open Source Definition[1]. The best known of these licenses are the GNU General Public License (GPL) and the Berkeley Software Distribution (BSD) license. Unlike traditional commercial or proprietary software (e.g., Microsoft Word, Windows XP, or Internet Explorer), these licenses permit OSS to be freely used, modified, and redistributed. The source code for these programs must also be freely accessible.

The term *free/libre open source software* (FLOSS) is used to refer to both free and open source software and was first coined in 2002 by Rihab Ghosh in a study undertaken for the University of Maastricht (Ghosh, Glott, Kreiger, & Robles, 2002). Libre here is the French word for liberty making clear the *free* as in freedom and not free as in "no cost." It is also common to use the term FOSS (free/open source software) for such programs.

Many countries do not have the luxury of debating the philosophical differences between the OSS or free software movement and so are content to use the all encompassing term of FLOSS (see e.g., www.floscaribbean.org/). For the purposes of this discussion the terms Free Software, Open Source Software and FLOSS are used interchangeably[2].

The development of FLOSS has often been contrasted to that of proprietary software. FLOSS has primarily been developed by individuals who volunteer their time to work on FLOSS projects. Normally, modified versions of the source code are posted on the Internet and are available for free to anyone who wants to use or modify it further. Thus a community of developers is created all working on modifications, bug fixing, and customizations of the initial code. An extensive explanation and analysis of OSS development can be found in Feller and Fitzgerald (2002).

The number of open source software projects can be gleaned by visiting http://sourceforge.net/index.php where there are over a hundred thousand such projects registered to date. Thus, FLOSS is not a fad or fringe phenomenon. It is important to note that FLOSS has penetrated major markets in countries worldwide. Indeed, some open source products like Linux and Apache are market leaders globally, and major ICT companies like IBM, Sun, and Oracle have adopted the open source model (Bruggink, 2003). In some countries, governments have even made the decision to support the use of FLOSS (Brod, 2003; Evans & Reddy, 2003).

Because of its free cost and its freedoms, FLOSS should be an obvious choice for widespread use in developing countries. In fact, these countries should be virgin territory for FLOSS deployment. What do the developing countries themselves say and what has been their experience? This chapter presents the point of view and experience of developing countries with FLOSS.

BACKGROUND

Developing Countries

As is well-known, the term *developing country* applies to most African, Latin American, Caribbean, and Asian countries, as well as some countries in the Middle East and Eastern Europe. The definition of a developing country is generally based on that country's annual per capita income. Indeed, developing countries are most often defined following the World Bank classification (World Bank, 2006). According to the World Bank, the developing country's annual per capita Gross National Income (GNI) can range from:

- US$875 or less (low income)
- US$ 876-3,465 (middle income)
- US$ 3,466-10,725 (upper middle income)

Thus developing countries are not as homogeneous a group as some may think. Yet there are some common problems in all developing countries. For example, many such countries have unreliable electricity supplies (Ringel, 2004). Additionally, ownership of computers and access to the Internet is low when compared to developed countries (Table 1).

In simple terms, how useful is FLOSS without hardware or electricity or trained and skilled personnel? The vision of developing countries being able to leapfrog from the use of proprietary software into using FLOSS and benefiting from all its "freedoms" must be tempered with these realities (Steinmueller, 2001). This chapter presents many of these realities as they relate to FLOSS in developing countries. If the problems with FLOSS in developing countries could be solved, then such countries could fully participate in FLOSS development. This would increase the size of the global FLOSS development community thereby creating the potential for an increase in the quality of FLOSS and software in general.

Table 1. Telecommunications infrastructure for Internet access; comparison of selected countries for 2002 (Source: United Nations Statistics Division-Millennium Indicators [ITU estimates] from http://unstats.un.org/unsd/mi/mi_series_list.asp rounded to the nearest whole number)

Countries	Telephone Lines and Cellular Subscribers/100 Population	Personal Computers/100	Internet Users/100
Trinidad and Tobago	53	8	11
United Kingdom	143	41	42
United States	114	66	55
Singapore	126	62	50
Sweden	163	62	57
Venezuela	37	6	5
Brazil	42	8	8
Chile	66	12	27
China	33	3	6
Guyana	19	3	14
India	5	1	2
Nigeria	2	1	0

Benefits of FLOSS

The benefits of FLOSS are well-documented in the literature particularly by Raymond (2002). These benefits include:

- Free or small cost of acquisition; future upgrades are free
- Flexibility of its license vs. restrictive licenses of proprietary software; the General Public License (GPL) used to license most open source software is much more flexible than the End-User License Agreement (EULA) of proprietary counterparts, giving more freedom to users to customize and to install on as many computers as needed without incurring added costs
- Superior quality and stability of FLOSS; because the source code is open to full and extensive peer review, open source software is known for its superior quality and stability
- Effectiveness as a teaching tool vs. closed proprietary software; users of FLOSS learn team work; importance of intellectual property protection and ethical use of software in addition to programming skills (Rajani, Rekola, & Mielonen, 2003)
- Potential as a solution to the software crisis; the "software crisis" refers to "software taking too long to develop, costing too much, and not working very well when delivered" (Feller & Fitzgerald, 2000, p. 58)
- Reduces the dependence of public administration and international governments in particular on specific software providers (Fuggetta, 2003); according to Nolle (2004), internationally, where Microsoft is viewed with more alarm than it is in the United States, FLOSS is seen as a defense against U.S. and Microsoft domination
- Stimulates innovation; FLOSS encourages the mastering of the technology of software by enabling the development and expression of creativity in the modification of the software by its users
- Improves commercial software
- Develops and enables applications that leverage local knowledge; because it can be freely modified, FLOSS is easier to translate, or localize (Bruggink, 2003)
- Fosters the creation of local software industry and entrepreneurs; the potential exists for the creation of local companies and small businesses supplying services associated with FLOSS in training, support, customization, and maintenance (Ghosh, 2003; Rajani, et al., 2003)

FLOSS Challenges

There are those who question most of the stated benefits of FLOSS particularly its claim to be innovative (Boulanger, 2005; Evans & Reddy, 2003; Fuggetta, 2003). Those on the side of proprietary software suggest that FLOSS is less secure, not as high in quality, stable, or dependable as its advocates insist. The very model of development of FLOSS that results in its best qualities can also lead to concerns about lack of support (Lai, 2006), security, and possible intellectual property violations by incorporating FLOSS into proprietary software (Kramer, 2006).

Compatibility concerns are also common. For example, although most FLOSS runs on both Microsoft Windows and Mac OSX, some run only on the Linux operating system. FLOSS may not come with as complete documentation and ready support as proprietary alternatives. Fees may have to be paid for substantial technical support. It should also be noted that there are fewer trained people available to provide technical support since most ICT training programmes prepare students to work with the most commonly used proprietary software packages, such as those from Microsoft (Bruggink, 2003). Additionally, FLOSS may require more learning and training time as well as skill to deploy and maintain. Large scale

migration from proprietary software installations to FLOSS can be problematic, particularly if there is a lack of practical experience and support and ready information on migration issues (Bruggink, 2003; Van Reijswoud & Mulo, 2005).

Cost as the main driver for the adoption of FLOSS in developing countries cannot be ignored. Ghosh (2003) demonstrates this vividly by comparing license fees for proprietary software with the income per capita of selected countries. He concludes that in developing countries, "even after software price discounts, the price tag for proprietary software is enormous in purchasing power terms." This is further supported by the Free and Open Source Software Foundation for Africa (FOSSFA) (as cited in May, 2006) who report that countries in sub-Saharan Africa each year pay around US$24 billion to (mainly U.S.-based) software companies for the rights to use proprietary software.

Thus FLOSS provides an opportunity for developing country institutions to find cost effective solutions in many areas that could include electronic governance to online health and learning. But there is an even greater benefit of FLOSS to these countries. Following the old adage that it is better to teach a man to fish than to give him fish, there is some appreciation that OSS can be even more beneficial to developing countries because it can be a vehicle for technology transfer of software development skills, thus building local IT capacity and stimulating innovation (Camara & Fonseca, 2006; Ghosh, 2003). Yet, for many end-users and even institutions in these countries, the choice is not between FLOSS and proprietary software but between FLOSS and cheap pirated software. When faced with this choice there is very little incentive to consider FLOSS (Heavens, 2006).

Furthermore, limited Internet access and bandwidth may not allow regular interacting with FLOSS online communities for updates, documentation and help with problems (Heavens, 2006). In addition, jobs in the IT industry in these countries are often confined to large companies that place a high premium on skills in traditional proprietary software (e.g., Microsoft Certification and experience). Also for those uninformed about FLOSS in developing countries, there is much skepticism about its use since "free" is often equated with poor quality and expensive software with high quality and reliability. This is confirmed by Gregg Zachary (as cited in Fitzgerald & Agerfalk, 2005) in his personal communication about unsuccessful attempts to introduce FLOSS projects in Ghana.

Are these difficulties peculiar to some developing countries? As a contribution to the FLOSS debate it may be useful to present the experience of a major university in a developing country.

EXPERIENCE IN THE WEST INDIES

The University of the West Indies (UWI)

The University of the West Indies (UWI) was first established in 1948, as a college with a special relationship with the University of London to serve the British territories in the Caribbean area. There are three UWI Campuses, in three different West Indian islands: Mona in Jamaica, Cave Hill in Barbados and St. Augustine in Trinidad and Tobago.

FLOSS at the University of the West Indies – St. Augustine Campus

The St. Augustine campus of the UWI is located in the middle income developing country of Trinidad and Tobago. Rampersad (2003) gives a succinct description of FLOSS in Trinidad and Tobago and reports that "Proprietary software is used most in Trinidad and Tobago, and as such, Microsoft and its many applications have a strong grip on the IT market." The University of the West Indies just like other employers of IT personnel in Trinidad and Tobago places high value on

proprietary software certification (e.g., MCSE). Additionally, agreements have been made with computer manufacturers like Dell for the supply of computers campus wide and these are naturally shipped with proprietary software.

It is therefore not surprising that, like many similar developing country institutions, the UWI, St. Augustine campus has no formal institutional policy for the use or deployment of FLOSS. Individual IT personnel and other staff members at UWI who become aware of FLOSS solutions have tried using these in their various departments or units. The main motivation for this has been the cost of FLOSS versus proprietary software particularly when licensing per-seat costs are considered in deploying software in large computer labs. The FLOSS software used so far at the university is shown in Table 2.

Were the other vaulted outcomes of FLOSS use in developing countries experienced at the UWI? Modification of source code, customization, and so forth, implies that there exists a certain level of programming skills locally. In Trinidad and Tobago, practical computer programming skills are in very short supply and so FLOSS is sometimes seen as just a cheap alternative to the high cost of proprietary software, nothing more.

Also, as is the case with most developing countries, UWI has a small IT staff fully engaged at any time on a multiplicity of projects. There is often no time to invest in modifying source code.

Table 2. FLOSS used at UWI St. Augustine

FLOSS	Type
Linux	Operating System
Open Office/Star Office	Productivity Software
PHP, PERL	Middleware
MySQL	Database
Moodle	Courseware
DSpace	Institutional Repository
Apache	Web Server

A good example of how limited resources can affect the progress of FLOSS projects in particular is UWI, St. Augustine's Institutional Repository Project which is based on the open source DSpace software (www.dspace.org). The initial impetus for the implementation of an institutional repository at the UWI, St. Augustine campus was a need to expose the unique Caribbean resources housed in the West Indian collection of the library to the world via digitization.

DSpace was acquired in 2004 and was installed first on a test server at the UWI Main Library in early 2005. Yet the installation is still "ongoing" since it involves a steep learning curve for the staff charged with the technical implementation. Knowledge and skills in Linux, Apache, Tomcat, and Java programming required for a successful DSpace repository deployment are not readily available. Thus, progress on implementation of the repository has been slow (Papin-Ramcharan & Dawe, 2006). Like most developing countries which do not have in place a well developed IT infrastructure and highly skilled IT personnel, it has been found that the true total cost of ownership (TCO) of DSpace as a FLOSS institutional repository solution has been high.

FUTURE TRENDS

It seems clear that the initial cost of acquiring FLOSS has been the key motivation for many developing countries adopting FLOSS solutions. It is also clear that there are greater benefits that can be derived from FLOSS in terms of encouraging the development of local IT skills, the creation of jobs locally to support FLOSS, and the eradication of piracy of proprietary software. Independence from being hostage to a single proprietary vendor is also beneficial to such countries.

The benefits to a country and its citizens from FLOSS adoption can possibly be viewed along a spectrum. Some countries which are relatively new to FLOSS will take time to fully exploit its

potential, whereas those that are farther along will work on higher value FLOSS activities like customization. Eventually, developing country users could move from being just consumers of FLOSS to being equal participants in the global community by becoming initiators and creators of FLOSS projects (i.e., FLOSS developers). Further along the spectrum, local jobs and small businesses could be created to sell FLOSS support and maintenance services.

It also seems likely that for developing countries and others, there probably will never be a FLOSS-only or proprietary-only market. The future will be about choice, where both FLOSS and proprietary software will co-exist and decisions to acquire software will not be based on philosophy alone but follow the standard criteria used to select any software package.

CONCLUSION

The literature while emphasizing that FLOSS is obviously a cost effective solution for developing countries also extols its higher benefits. These include: its technology transfer potential, the creation of jobs, fostering of innovation and creativity, the reduction in piracy of proprietary software, the independence achieved from being hostage to a single proprietary vendor, and the ability to localize software products to local languages and conditions. These outcomes will not be achieved for most developing countries unless there are enhanced supporting mechanisms to foster FLOSS use. These can emanate from international agencies like those of the UN and World Bank whose interest lie (for example) in the sustainable development of developing countries. The mechanisms could include:

- Formal organized programmes to educate and build awareness of FLOSS in developing countries; this should not just be targeted to IT personnel but to common users, governments, and other decision makers
- International agencies working presently to upgrade ICT skills and infrastructure in developing countries should work closely with the FLOSS "movers and shakers" to ensure that training is provided in these countries on commonly used FLOSS with emphasis on programming skills.
- Sponsoring agencies that support nongovernmental organizations (NGO) or other community organizations should require that FLOSS be considered for use in their operations and projects.
- Procurement agencies of governments and other bodies should be educated about FLOSS so that it can be seen as a viable alternative when procurement decisions are made.
- Examination and other education bodies must be encouraged in an organized and targeted manner to change the computer studies and science programmes in these countries from being mostly Microsoft-centric to include the study and use of FLOSS.

KEY TERMS

Developing Countries: Developing countries are those that have an annual per capita income (Gross National Income [GNI]) between US$875 and US$10,725.

Free/Libre Open Source Software (FLOSS): Used to refer to both free and open source software making no distinction between them.

Free Software (FS): Computer programs that are not necessarily free of charge but give access to the source code and permit users the freedom to freely use, copy, modify, and redistribute.

Open Source Software (OSS): Software that meets the terms of the Open Source Definition (www.opensource.org/docs/definition.php). To be open source, the software must be distributed under a license that guarantees users the right to read, redistribute, modify, and use freely.

Proprietary Software (PS): Software that is normally owned by a company that typically restricts access to the source code to protect the company's intellectual property. The software is distributed as the "compiled" source code or executable code (the binary form of the program). Its use, redistribution, or modification is prohibited or severely restricted (e.g., Microsoft Word, Norton Antivirus).

Source Code: The list of instructions that make up a computer program written in a high level programming language (like C, Java or PHP) that humans can read, understand and modify.

Total Cost of Ownership (TCO): The full cost of deploying, maintaining and using a system (or software) over the course of its lifespan.

ENDNOTES

1 Open Source Definition, Version 1.9. Retrieved July 15, 2006, from http://www.opensource.org/docs/definition.php

2 It is important that FLOSS is not confused with terms like freeware and shareware. These terms are usually used to describe software which is available at no cost, but its source code usually is closed. Internet Explorer is one example of freeware that is proprietary.

This work was previously published in Handbook of Research on Open Source Software: Technological, Economic, and Social Perspectives, edited byK. St. Amant; and B. Still, pp. 93-101, copyright 2007 by Information Science Reference (an imprint of IGI Global).

Chapter 5.10
Open Source and Outsourcing:
A Perspective on Software Use and Professional Practices Related to International Outsourcing Activities

Kirk St.Amant
Texas Tech University, USA

ABSTRACT

This chapter examines the role of open source software (OSS) in international outsourcing practices that involve the transfer of knowledge work from one nation to another. Included in this examination are discussions of the benefits and the limitations of OSS use in outsourcing. The chapter also presents organization-specific and industry-wide strategies for effective OSS use in outsourcing situations. The chapter then concludes with a discussion of areas of international outsourcing where OSS might have important future applications or effects. The purpose of such an examination is to provide readers with the knowledge and the insights needed to make effective decisions related to the use of OSS in international outsourcing situations.

INTRODUCTION

International outsourcing now includes the distribution of knowledge-based work to employees in other countries. Much of this work, however, requires the use of software either to perform a task or to provide the technologies that allow clients and outsourcing providers to interact. Conventional "proprietary" software can, however, be prohibitively expensive to outsourcing employees in developing nations.

Open source software (OSS) might offer a solution to this problem, for OSS is often free to use and is relatively easy to modify or to update. Yet open source software also brings with it a new series of problems related to product consistency, user support, and digital piracy. While the relationship between outsourcing and software (particularly OSS) has been known for some time, it has received relatively little attention in terms of social and economic implications both for those who outsource work and for those who perform outsourced work. Knowledge of these issues, however, is essential to understanding both current and future outsourcing practices and the socio-economic development of nations that engage in outsourcing.

The purpose of this chapter is to provide readers with a foundational knowledge of how OSS use

could affect international outsourcing practices. After reading the chapter, individuals will understand the relationship between software and outsourcing practices in terms of the opportunities and the limitations it creates for client companies and for outsourcing employees in developing nations. This chapter also presents strategies organizations can employ to use OSS more effectively in international outsourcing situations. The chapter then concludes with an overview of how global computing and OSS use is poised for significant growth and the implications this growth could have for different organizations.

BACKGROUND

The Growth of International Outsourcing

In international outsourcing — or offshoring — situations, companies in one nation transfer the responsibility for completing a task to workers in another country (Bendor-Samuel, 2004). Originally, this transfer of responsibility focused on manufacturing and the production of physical products such as clothing or footwear. The global spread of online media, however, has given rise to a new kind of international outsourcing that involves the export of knowledge-based work. Known as business process outsourcing — or BPO — this practice encompasses everything from computer programming to call center staffing and medical transcription. While such BPO practices have existed on a relatively limited scale to date, they are poised to expand rapidly in the future.

The push to adopt BPO has to do with the perceived benefits related to such practices. Perhaps the most publicized of these benefits is savings related to the cost of skilled labor. Much of today's knowledge work is being outsourced to skilled employees in developing nations — employees who can perform most technical tasks for far less than what counterparts in industrialized nations would charge. For example, gaming developers in Russia earn roughly $100 U.S. a week, while middle managers in mainland China earn roughly $9,000 a year (Weir, 2004; Nussbaum, 2004).

Such wage-based savings, however, are not the only advantage related to offshoring. Rather, proponents of outsourcing note it also offers the benefits of

- Improved quality of service: Research indicates overseas outsourcing employees often provide better quality service than "domestic" workers who perform the same jobs (Reuters, July 182004; Farrell, 2004; Hagel, 2004). Certain call centers in the Philippines, for example, take 25% less time to handle incoming calls and receive higher rates of caller satisfaction than do U.S. counterparts (Hagel, 2004).
- Effective management practices: Because managers are paid less in developing nations, organizations can easily justify the use of more in-country managers to oversee outsourcing activities (Nussbaum, 2004; Hagel, 2004). This increase means managers have more time to answer employee questions and to provide employee training — factors that contribute to the improved quality of work or service perceived by many consumers (Hagel, 2004; Lewis, 2003; Hagel, 2004).
- Reduced employee turnover: Secure employment is often rare in many developing nations, and outsourcing jobs tend to be among the better paying ones. Therefore, outsourcing workers in developing nations tend to stay with employers for longer periods of time (Reuters, July 18, 2004; Farrell & Zainulbhai, 2004). As a result, these long-term employees tend to have more experience performing their jobs while reducing the need for and the cost of new employee training.
- Reduced production time: By using online media to distribute work to employees in

different nations and time zones, organizations can keep operations going 24 hours a day, seven days a week. Such continual production means that processes and products can be completed more quickly than if done exclusively in one country (Friedman, 1999; Baily & Farrell, 2004; Bierce, 1999; "America's pain," 2003).

- Increased access to international markets: In many developing nations, marketplace success is often a matter of knowing someone in that region (Rosenthal, 2001). Companies that provide outsourcing services can provide such an "in," as well as provide advice on how one should proceed with business interactions in a particular nation or region (Rosenthal, 2001).

The manifold benefits of offshoring have prompted many companies to adopt it as a part of their core business strategy. At present, it accounts for $10 billion U.S. in worth and engages the services of some 500,000 workers in India alone (Baily & Farrell, 2004; Rosenthal, 2004b). Moreover, some researchers believe offshoring will grow by 20% a year through 2008, and by 2015, some 3 million business processing jobs will be performed by outsourcing employees (Rosenthal, 2004b; Baily & Farrell, 2004). Some critics expect this number to be much higher and claim at least 5 million international outsourcing jobs will emerge in the next five to 10 years (Garten, 2004).

The perceived benefits of international outsourcing have resulted in such practices spreading to a number of countries and to a variety of industries. French companies, for example, have begun working with French-speaking developing nations such as Senegal and Morocco on a variety of outsourcing projects, and these relationships have met with good results (Reuters, July 18, 2004). Similarly, German firms have begun exploring outsourcing relationships with Easter European nations, while the Netherlands has begun using call centers located in South Africa where Dutch-based Afrikaans is spoken (Farrell, 2004; "Sink or Schwinn," 2004; Baily & Farrell, 2004; Rosenthal, 2004c). Additionally, markets in Spain, combined with the growth in the U.S. Spanish-speaking population, have meant more work is now outsourced to Mexico and to Latin America (Rosenthal, 2004a). Even India, the one time center for international outsourcing, is now outsourcing work to China and to Sri Lanka, where it can be done for less money (Reuters, September 2, 2004).

The majority of BPO practices, however, are reliant on software. Aspects related to software use can thus affect if and how organizations realize the advantages related to the offshoring of knowledge work. For this reason, decision makers in the public and the private sectors need to understand the differences between proprietary and open source software — as well as the limitations and advantages of each — in order to make informed choices related to international outsourcing. Only through such informed decision-making can organizations benefit from the advantages related to offshoring.

MAIN THRUST OF THE CHAPTER

Software, Cost, and International Outsourcing Activities

Software is essential to international BPO practices for two key reasons. First, it provides the mechanism for sharing materials and for interacting with others online (e.g., browsers and email systems). Without the software needed to engage with others quickly, easily, and directly via the Internet, many of the cost, time, and quality benefits associated with the international-outsourcing of knowledge work would not exist. Second, production-related software (e.g., Microsoft Word or Adobe Illustrator) is essential to performing most knowledge-based programming, customer

support, and IT tasks efficiently and effectively. Again, without the software needed to perform tasks, the time, cost, and quality benefits of international outsourcing cannot be realized.

Unfortunately, the makers of software products have traditionally produced proprietary programs that require individuals to purchase them in order to perform a given activity. The for-profit nature of proprietary software has, however, made it unavailable to large segments of the world's population — particularly in developing nations where high purchase prices are often associated with such materials (Warschauer, 2003). This restriction, in turn, affects online access and thus outsourcing activities in those regions.

One solution to this situation would be for companies to supply prospective international outsourcing providers with free or inexpensive software products that would allow them to participate in outsourcing activities. Such an approach, however, would contribute to a second major software problem — copyright violation. In many developing nations, copyright laws are often weak (if not non-existent) or governments show little interest in enforcing them. As a result, many developing nations have black market businesses that sell pirated versions of software and other electronic goods for very low prices (Balfour, 2005). Such software piracy reduces consumer desire to purchase legitimate and more costly versions of the same product, and thus affects a company's profit margins within that nation. In fact, global software piracy in 2004 accounted for some $33 billion U.S. in lost profits ("One third," 2005). Further compounding this problem is the fact that it is often difficult for companies to track down who is or was producing pirated versions of software products in order to stop that offender. Thus, while the distribution of cheap or free digital materials can help contribute to outsourcing activities, that same strategy can undermine an organization's ability to sell its products abroad. Open source software (OSS) can offer a solution to this situation.

Open Source Software and International Outsourcing

Software, in essence, is programming code — or source code — that tells a computer's operating system how to perform a certain action (Still, 2004). The source code of Microsoft's software program Word, for example, tells the related operating system how to transfer keystrokes into letters on a page and how to edit or to print that page. In theory, if an individual knows what programming/source code is needed to make a computer perform such activities, then that individual can simply retype that source code into his or her operating system, and the computer will respond as desired — the exact same way the original software would.

Accordingly, if and individual can see how someone else programmed software to work (see the underlying source code), all that person needs to do is copy that programming/source code, and he or she no longer need to buy the related software. Rather, that person can now achieve the same action on his or her own. For this reason, many software companies "close" their source code in order to prevent users from seeing the underling programming that allows the software to work (Still, 2004). In these situations, users need to work through an interface that allows them to activate certain commands indirectly within a software program's underlying source code. Closed software that prevents users from seeing the underlying code is know as proprietary software, for only the creator of that software is allowed to open or to see and to copy or to manipulate the underlying source code.

Open source software is a polar opposite in terms of access to source code/programming. That is, the developer of a piece of software creates it in manner that is "open" and permits any and all users to access, copy, and modify the underlying source that allows software to work (Still, 2004). A classic example of such open source programming is the HTML coding that allows Web pages

to be displayed on browsers. The coding of these pages is open for anyone to review and copy; all the user needs to do is view a page's underlying source code by using the "View source" — or related option — in his or her browser.

This openness means individuals do not necessarily need to buy open source software in order to use it. Rather, they can directly access and copy the underlying source code in electronic format, or they can re-code/re-type the programming code and create a free copy of the related software. Such openness also means individuals can alter the underlying source code to make a software program perform different functions. So, in theory, a copy of the underlying source code from one kind of software could be modified into a variety of programs — each of which performs a different task. Updating software, moreover, becomes a matter of copying new/updated code versus purchasing the newest version of a product.

In the case of international outsourcing, OSS can provide individuals with access to affordable software that allows them to work within outsourcing relationships. Moreover, the flexibility permitted by OSS means outsourcing workers could modify the software they use to perform a wide variety of tasks and reduce the need for buying different programs in order to work on different projects. As the software it is produced by the outsourcing employee and not the client, concerns related to copyright and proprietary materials are no longer stumbling blocks to outsourcing relationships. Thus, it is perhaps no surprise that the use of OSS is growing rapidly in many of the world's developing nations ("Open source's," 2003).

The Problems of Open Source Software in International Outsourcing

While the free and flexible nature of open source software allows it to contribute greatly to international outsourcing situations, OSS also brings with it limitations that could affect the success of BPO relationships. First, because OSS is open for the user to modify as he or she sees fit, it is easy for each individual to use the same programming foundation/source code to develop a different kinds of non-compatible software or other digital products. Such divergence is know as forking code, for each programmer can take a different "fork" in the programming "road," and such forking code has long been considered a major problem in OSS use (Still, 2004). These prospects for divergence mean international outsourcing situations are open to a variety of problems related to compatibility. Such problems include

- Employees might generate software or other materials that the related client company cannot use due to compatibility issues.
- Software products might not work as desired or work in unexpected ways/ways not compatible with the client company's intentions.
- Employees working on different parts of the same project might produce component parts that cannot be integrated into the same whole or do not work together correctly or as intended within that same whole due to compatibility issues.
- Addressing compatibility issues either among international work groups or between offshoring workers and clients could take more time and cost more than if the product had been produced domestically.

Thus, the freedom that allows one individual to operate software might also prevent others from making use of digital materials. Additionally, any or all of these factors could contradict the advantages of reduced cost, quicker production time, and increased quality that encourage organizations to use international BPO.

Some OSS companies, such as LINUX, have successfully addressed the problem of forking

code through focused oversight processes that govern programming practices (Hamm, 2005). The result has been successful and relatively stable software products that work effectively with other systems. The same kind of management, oversight, and standardization, however, becomes more complicated in an international outsourcing situation where a variety of employees can be working in different nations and different time zones

A second problem involves the kind of technical support available to OSS users — both outsourcing employees and consumers using OSS products. Because no individual or organization really owns an open source software product, there is often no formal or standardized mechanism for providing technical support to OSS users. Rather, technical support often comes in the form of a loose network of OSS programmers/developers who interact informally — and sometimes haphazardly — in online contexts such as chat rooms or listservs (Still, 2004). The idea is that a user who is experiencing software difficulty posts a query to one of these online forums and waits for a member of that forum to read the posting and respond to it.

A major problem in such an informal system is that technical support/answers are not readily available. Rather, individuals who experience "glitches" related to time-sensitive OSS projects could find themselves missing or offsetting deadlines as they wait for some random programmer to respond to a request for help. Unfortunately, such a response could take anywhere from minutes to days depending on who is reading what lists or who is posting when. In the fast-paced environment of global business, such delays could have a major effect on production schedules, profits, and access to international markets. These delays also counteract one of the key benefits of and reasons for using international outsourcing — quicker production times.

Equally problematic is the fact that such support systems are open for anyone to respond to, regardless of a person's technical skills or understanding of the situation (Still, 2004). Thus, the quality of the advice related to such a support system can be haphazard, inconsistent, or even wrong. Moreover, different individuals might offer varying suggestions/solutions to the same situation. Thus, requests for assistance could introduce the similar problem of forking/diverging source code into situations where different individuals encounter problems when working on the same project. As a result of these limitations, materials created using OSS could be incompatible, inconsistent, or even non-functional depending on the kind of "help" one received.

Finally, open source software creates interesting and often unintended problems related to copyright. Most proprietary operating systems (e.g., Microsoft Windows) and proprietary software programs (e.g., Microsoft Windows Media Player) work by opening digital materials loaded into a computer system. That is, Windows Media Player opens the video files on a DVD or the audio files on a CD so that individuals may view or listen to films or music stored on those DVDs or CDs. This approach means the individual is able to access materials while maintaining the copyright related to such items.

Open source software allows users to access the same kinds of files in a very different way. Rather than simply opening files located on a DVD or CD, OSS programs often automatically make a copy of such digital products, store that copy on the hard drive of the user's computer, and then open that copied file so the user can view or can listen to it (Zoellick, 2001). This automatic copying process, known as ripping, means that users of OSS materials automatically violate copyright just by trying to access or to use certain digital products. These unauthorized copies are available for anyone with access to the related computer — an important problem in outsourcing situations where more than one employee often uses the same terminal for work. Such ripped copies, moreover, can easily be replicated and

sold in black market exchanges — a situation of particular importance as such illegal activities are well established and difficult to monitor in many of the world's premier outsourcing locations (e.g., the People's Republic of China). As a result, the copyright — or piracy — problems OSS could solve in terms of misuse of proprietary software could affect different products should

- The original client company needs to provide outsourcing employees with proprietary digital materials in order to perform certain outsourced tasks.
- The original client company sells OSS products resulting from outsourcing work to different customers who can now use such products to make illegal copies of digital materials.

Thus, the use of OSS in BPO can be a double edged sword. Yet, the use of OSS in international outsourcing is a situation that must be addressed if organizations wish to succeed in the global business environment of the 21st century. For this reason, organizations must find ways to strike a balance between OSS's benefits and detriments in offshoring situations. Such a balance can be established through the development and the use of various organizational and industry-wide practices and policies.

Strategies for Using OSS Effectively in International Outsourcing

While OSS use in outsourcing creates a complicated situation, these complications can be addressed successfully through approaches that create standards for design and for use. What follows are ten strategies that can create an effective foundation for using OSS in international BPO.

- Strategy 1: Create a programming standard all outsourcing employees will use when working with OSS. By creating and sharing standards for how one should program with OSS, organizations that outsource activities can provide overseas workers with guidelines that impose consistency on the programming process. These guidelines would instruct outsourcing OSS users on what programming choices to make during different points in an overall process. Such instructions would help reduce the prospects of forking code and increase compatibility across employees.

Standards should also be created to address the coding of comments — or the bits of verbal explanation that appear within the coding of a program. These comments allow users and clients to know why a particular programming decision was made and to know the effects that decision could have on the operation of the related digital product. By creating standards for when and for how to create such comments, companies that use outsourcing create a built-in mechanism for reviewing materials produced by overseas workers. To make sure that such standards are followed by outsourcing employees, the related client company should suspend all or part of final payment until it has had time to review the final product, and its related comments, in order to confirm standards were followed. While such monitoring could initially slow production, as outsourcing employees become aware of the fact their work is being monitored, they will spend more time adhering to standards. In so doing, these employees will create a better product. Thus, over the long term, the time spent monitoring OSS processes would decrease while the quality of products would increase. The increase in quality resulting from such practices would therefore eventually offset any initial slowdown in production caused by the introduction of monitoring procedures.

- Strategy 2: Require outsourcing workers to identify themselves as OSS users and require those users to complete organiza-

tional training programs in standard OSS practices. Such identification and training — which can be completely online — would allow organizations to provide outsourcing workers with instruction in how to follow a particular organization's standards for OSS use and coding. It would also allow companies to identify which standards seem most problematic for individuals (via automatically reviewed online tests). Organizations could then provide follow-up online training to help individuals address their particular problem areas related to OSS. Initial expenses dedicated to the development and the delivery of such training can contribute to increased later profits in the form of more efficient, more effective, and more standard uses of OSS by outsourcing employees.

- Strategy 3: Develop an organizational support mechanism for helping outsourcing OSS users. To make sure that outsourcing employees using OSS get consistent and accurate answers to technical questions, organizations should develop their own OSS online support lists or Web sites. Such Web sites would be free access, but they would require individuals to enter a username and password (supplied by the organization) to gain access to such resources. Such a measure would cut down on non-employees taking advantage of this resource and thus diverting attention away from the help given to an organization's actual workers.

This resource would be staffed by employees who have a high degree of proficiency in OSS use, and these "help" persons would be "on call" 24 hours a day to accommodate queries from outsourcing employees in different nations and time zones. These help employees would also be given access to an online database of the kinds of projects being worked on by different outsourcing employees. Help workers could then use this information to determine the prospective problems (and related best solutions) affecting different outsourcing workers. Such help workers would also record all comments and suggestions in a central online database that would cross-reference those suggestions with the names of all outsourcing workers involved in the same project. Such cross-listing would allow other help providers to offer consistent advice (and germane suggestions) to all outsourcing employees working on a project.

- Strategy 4: Establish a peer-mentoring program for outsourcing workers who use OSS. The effective use of OSS in a business environment is part understanding programming processes and part understanding the culture and the goals of the organizations using those programs. For this reason, the more outsourcing workers know about an employing organization's culture, goals, and objectives, the more effectively they can use OSS to engage in processes or develop products that address those factors (Clement, 1994; Tan, 2000; Sandholm, 2004). That is, if the outsourcing employee knows how a given OSS product will fit into a company's objectives, that employee will have a better idea of how to program to meet those objectives (Clement, 1994; Tan, 2000; Sandholm, 2004). Similarly, if the outsourcing employee is aware of the importance of copyright and proprietary products to a company, that employee is less likely to make unauthorized copies — either inadvertently or intentionally.

By pairing outsourcing employees with a peer mentor from the client company, organizations provide such outsourcing employees with someone who can provide an introduction to the organization's culture and its objectives. This mentor could make the outsourcing employee feel more a part of the overall organization. Such a peer could also familiarize outsourcing employees with company standards for OSS use and copyright

policy (as well as the consequences for violating such a policy). In so doing, the mentor creates a mechanism for accountability, for the outsourcing employee is no longer a "faceless" worker who exists as a mere payroll number.

Such a peer mentor should also have a background in OSS so he or she can provide the outsourcing worker with advice on how to best address a particular programming/software situation. The mentor could similarly introduce the outsourcing employee to corporate training materials and support services and review programming work to check its quality. Work with such a peer mentor could be made an essential part of the training process associated with outsourcing workers. The mentor's evaluation of that worker's progress could likewise serve as an important resource when making the decision to continue using a particular outsourcing employee.

- Strategy 5: Create protocols for sharing or for forwarding work among international outsourcing employees. In many cases, work that is outsourced to one overseas employee is shared or forwarded to another international outsourcing employee working on the same process (Freedman, 1999). Within such contexts, effective information sharing is essential, for the more time it takes an individual to determine what a predecessor has done and expects that individual to do, the less efficient the international outsourcing process is. For this reason, outsourcing employees need to use a standard mechanism for listing what they have done/how they've used or programmed OSS so colleagues can understand this work.

Outsourcing employees also need to provide standard directions on how the recipient of that information should use OSS to continue with work on that project. By developing standards ways of reporting such information to colleagues, organizations decrease the chances that confusion or a programming inconsistency will occur. These comments should also be shared with/downloaded to a database controlled by the client company. This database can help organizations anticipate or backtrack to locate prospective problems related to OSS use in outsourcing. Such a database should also be accessible to any individuals providing help in such outsourcing situations. The information in this database could allow help providers to better understand and address prospective problems encountered by one of more of the outsourcing employees working on forwarded materials (Strategy 3).

- Strategy 6: Require all international outsourcing relationships to be long-term contracts. Many of the disaster stories associated with international outsourcing occurred because of short-term relationships (Goolsby, 2004). In such relationships, neither party feels particularly invested in the long-term success of the other, so the desire to conform to standards or respect copyright is low. Moreover, such short-term relationships often mean that the employment of the outsourcing worker ends just as he or she finally begins to understand and feel comfortable with a client's expectations. By requiring international outsourcing employees who use OSS to contract for longer times, client organizations can retain experienced employees who are accustomed to working according to a company's OSS programming guidelines.

Such long-term relationships also improve accountability in outsourcing, for outsourcing employees are more likely to conform to programming standards and to respect copyright if they wish to maintain long-term business relations with the client (Atwood, 2004). Thus, long-term contracts enhance accountability in international outsourcing situations. Within such long-term relations, client companies should conduct regular

audits of outsourcing employee work to make sure programming and comment guidelines are being followed and that the copyright of materials is respected.

- Strategy 7: Hire in-house (domestic) employees who are proficient in OSS or train in-house (domestic) employees to be proficient in OSS. Such employees will be essential to an organization, for they can serve as the peer mentors and the trainers of international outsourcing workers. They can also serve as the individuals who provide online support to outsourcing employees and as the individuals who will audit OSS work in long-term contract situations.

By having trained OSS employees in house, organizations can rapidly respond to a variety of OSS crisis situations, easily develop new OSS coding practices, and readily share information about new OSS processes. Organizations can also adapt mentoring, training, support, and auditing activities to conform to new computing and business developments. Finally, such in-house employees can help client organizations understand different developments in, successes of, and problems related to OSS when used in an international outsourcing context.

- Strategy 8: Develop a list of "copyright-friendly" outsourcing locations and refer to this list whenever considering international outsourcing. To protect materials from piracy, organizations need to make sure they send such materials to nations that will acknowledge and enforce copyright laws and treaties. Such laws and treaties would provide organizations with a method for stopping such piracy if it happens in another nation and provide a method of recourse for curbing sales of and profits made from pirated materials. For these reasons, organizations can benefit from regularly updated listings that overview what international outsourcing destinations offer the best copyright protections. Such listings should include the following information:
  - If a convention or a treaty on copyright protection exists between the nation of the client organization and that of the outsourcing employee; a sample listing of such copyright-based treaties involving the Unites States can be found at www.copyright.gov — the Web site for the U.S. government's Copyright Office
  - What laws a particular nation has to guarantee copyright protection and how enforceable those laws are, for some nations have copyright agreements that are either not enforced or enforced haphazardly (Doyle, 2004; Orr, 2004)
  - How the client organization should file a grievance or petition according to a particular convention or treaty, or according to the laws of a certain nation
  - With which government agencies — both in the client organization's own nation and the outsourcing employee's nation — such a grievance or petition should be filed
  - What actions to expect in response to filing such a grievance and if any losses can be recovered according to international agreements or national laws

By consulting such a listing in advance of distributing work to overseas outsourcing workers, companies can reduce the risks that copyright violations will occur through restricting the distribution of materials only to employees in nations that provide effective copyright protection.

- Strategy 9: Develop an industry standard for OSS use. While an individual corporate standard can address compatibility issues related to one organization, the OSS-based products created by that organization might be used by other companies within an overall

industry. At this level, the compatibility of OSS products again becomes an issue. To avoid compatibility problems across overall industries, the members of those industries should work together to develop an industry-wide standard for how to code, record comments, offer help, and record suggested solutions to programming problems. These standards could then be shared via an online database available to all members of a given industry. As computer programming practices are continually evolving, such a site should also have a "recent developments" section in which member organizations share new information and practices, innovations, or responses to previously unconsidered problems. Industry members should also meet regularly (annually or bi-annually) to share experiences and to update the related standards for OSS use in international outsourcing practices.

- Strategy 10: Establish and maintain an industry-wide database of individuals and organizations that have violated copyright or violated coding standards in international outsourcing relationships. Several outsourcing experts have noted that the fear of lost employment — and thus lost money — is one of the few ways to force international outsourcing workers to comply with industry standards and procedural (legal) guidelines (Atwood, 2004). The problem with international outsourcing is that an individual might violate the standards or the guidelines of one organization without fear. That is, individuals could think they can simply go to work for a different organization and that new employer would be unaware of an outsourcing worker's past. In this situation, the fear of reprisal through lost income remains low as the international outsourcing employee can easily move on to other clients.

To counter this practice, organizations within an industry should establish a list of outsourcing offenders who have either failed to conform to OSS programming guidelines or who have used OSS to violate copyright. The idea would be to create an easy-access registry (e.g., a Web site) in which companies could record the names of the outsourcing providers with which they worked.

Included in such a registry would be a listing of who the violator is, what the nature of the violation was, what the client did in response to this violation, and what results came from this action. Such a registry could help companies avoid working with "disreputable" outsourcing providers as well as offer effective strategies for addressing violations that occur in outsourcing relationships. These industry-wide registries mean that a large number of companies might now avoid "suspect" outsourcing providers and greatly affect their profits by creating a boycott situation. This fear of boycott could be a powerful incentive for outsourcing providers to abide by data processing practices required by client organizations (Atwood, 2004). Such a site should also allow users to provide a synopsis of the effectiveness with which they felt an outsourcing provider performed work.

For such a registry to be effective and open to the widest range of users, it should be online and allow users to perform internal searches for different outsourcing providers. It should also be updated regularly. Perhaps the best organization to oversee such a registry would be industry oversight bodies or the chamber of commerce or the Better Business Bureau in states where a large number of companies engage in international outsourcing.

These registries would need to provide users with effective instructions on how to report concerns and locate data on outsourcing providers. They would also need to provide different kinds of information to different companies depending on the size of the company (small business or multinational conglomerate) and the related industry.

Such registries could also be made effective by having frequently asked questions (FAQ) sheets or online help functions that facilitate use and provide information on how to address problems related to international outsourcing.

Each of the afore-mentioned strategies is crucial to maintaining consistency and protecting ownership in outsourcing situations involving OSS. This list, however, is by no means comprehensive. Rather, it is a starting point that addresses some of the more fundamental aspects of OSS use in international outsourcing. For this reason, organizations might wish to address new developments in or particular uses of OSS in international outsourcing relationships.

FUTURE TRENDS

At present, international OSS use might seem to be a peripheral topic related to a limited number of activities. Certain trends in business practices and international markets, however, indicate that organizations need to explore their OSS practices now, in order to prepare for and effectively address these trends.

The Projected Demand for Computing and IT Use in International Outsourcing

Among the areas expected to experience the greatest growth in BPO are finance, accounting, and medicine, and all of these areas of growth have one thing in common — data processing that involves computers and information technology. Many managers and bankers in the United States, for example, see international outsourcing as an effective way to address different accounting practices — particularly those related to information technology (IT). This push is in part due to the Sarbanes-Oxley Act of 2002 — section 404 of which requires chief executive officers and chief financial officers of public companies to review their internal controls over financial transactions ("404 tonnes," 2004). The costs and time associated with all of the data crunching related to such activities are massive,1 and IT could greatly help with the compiling of information and the coordination of related activities. One way to curb costs, maximize time, and focus on computing in processing would be to outsource such activities. After all, the outsourcing of accounting and of IT work is not new and could address a lack of needed and costly domestic employees in both IT and in auditing2 ("Relocating the back office," 2003). Given the costs related to such activities and the fact that more complex accounting practices are being outsourced, it seems reasonable to expect that some section 404 activities would be prime candidates for international outsourcing.

New U.S. healthcare legislation also seems poised to increase the international outsourcing related to IT work and data processing. The driving force behind this trend is the Health Insurance Portability and Accountability Act (HIPAA), which requires that all of an individual's medical information be placed in electronic format so it can be easily shared via computer systems (Goolsby, 2001b; Goolsby, 2001c). Under HIPAA, print medical records must be processed into a digital format — a task that is time consuming, costly, and monotonous — and maintained via an IT system for sharing such information. The projected result of such processing is massive IT costs for all health care organizations such as hospitals (Goolsby, 2001a; Goolsby, 2001c). These factors make HIPAA-related tasks, such as medical transcription and IT development and oversight, ideal candidates for international outsourcing. They also make the development and the monitoring of related IT systems prime areas for international outsourcing, especially as most healthcare providers are relatively new to such systems and their operations (Goolsby, 2001a; Salkever, 2004; "Sink or Schwinn," 2004). As so much of this financial and medical related work involves computers, it would be safe to as-

sume that some — or many — of the outsourcing employees working on such projects would be using OSS. For this reason, the development of standard OSS practices becomes essential, not only to achieving organizational objectives, but to meeting legal requirements.

The Value of OSS in International Marketing

OSS also has important implications for how businesses access markets in developing nations. Until quite recently, the majority of individuals within these regions had little or no access to the online environment. That factor of access, however, has changed markedly in recent years, due in large part to a mixture of public and private sector programs designed to increase global Internet use. In China, for example, the number of Internet users grew from 2.1 million in 1999 to a projected 96 million by the end of 2004, and some experts expect this number to balloon to over 200 million users by 2007 ("Wired China," 2000; "China's coming," 2004). In Africa, the United Nations and private companies have undertaken initiatives to increase online access across the continent, and Africa's number of dial-up Internet connections has grown by some 20% in the past two years while the sales of laptop computers remain strong in this part of the world ("Tapping in to Africa," 2000; Kalia, 2001; Reuters, 2002; "Laptop sales," 2004).

In Latin America, Brazil has seen its number of online users grow by 430,000 in recent months, and Global Crossings Ltd. has recently completed a project that uses fiber optics to give, "multinational companies the ability to communicate with Latin America as efficiently as with any other region" ("Active Internet users," 2004; "Tying Latin America together," 2001, p. 9). Additionally, the number of individuals going online in Eastern Europe is expected to climb from 17% to 27% by 2006, and laptop sales in the region remain strong ("IDC research," 2003; "Laptop sales," 2004).

As a result of these developments, companies can now use online media to market goods, supply, and services, and even sell and distribute digital products on an unprecedented scale in the developing world. This concept of scale, moreover, is no small matter, for the poor in many developing nations have a large combined purchasing power. The collective buying power of Rio de Janeiro's poorest residents, for example, is estimated to be some $1.2 billion ("Beyond the digital divide," 2004). The value of such aggregate overseas markets is perhaps the reason that certain companies have started developing online communication technologies that could provide the "less well off" citizens of the world with affordable online access ("Beyond the digital divide," 2004; Kalia, 2001). They have also begun developing inexpensive hubs for online access in nations such as India, Ghana, Brazil, and South Africa (Warschauer, 2003; "Beyond the digital divide," 2004).

Interaction via the Internet and the Web, however, requires the use of software (e.g., a browser) that allows a wide range of individuals to navigate the online environment. For this reason, the only way companies would be able to effectively tap these poorer overseas markets would be through the use of free or inexpensive open source software. If, however, each prospective consumer in developing nations used a different kind of OSS to interact online, then the ability of companies to tap those markets in a mass, and thus a profitable, manner is lost. The development of standards in OSS programming and use provides a mechanism for avoiding such problems. Moreover, by introducing such standards early on and to the more technologically savvy individuals engaged in international outsourcing, organizations can improve the chances that such standards will either "trickle down" or spread throughout an overall region. Thus, the development of international OSS standards has important financial implications that can extend far beyond international outsourcing.

CONCLUSION

International outsourcing offers a variety of cost, time, and quality advantages to those organizations that use it effectively. In relation to the international outsourcing of knowledge work, such effectiveness often involves access to and uses of software. While open source software can provide a distinct advantage in international outsourcing situations, such uses of OSS must be guided by both client companies and overall client industries. Fortunately, uses of OSS in international outsourcing are still relatively new. For this reason, organizations have some time to develop the standards, protocols, resources, and relationships essential to effective OSS use in outsourcing contexts. The ideas presented in this chapter provide the reader with a foundation for exploring such developments. By understanding, employing, and building upon these ideas, organizations can improve the success with which they engage in international outsourcing practices both today and in the future.

Chapter 5.11
How to Create a Credible Software Engineering Bachelors Program:
Navigating the Waters of Program Development

Stephen Frezza

Barry J. Brinkman
Gannon University, USA

ABSTRACT

This chapter presents a case study in the development of a Software Engineering (SE) Bachelor's Degree program. It outlines issues in SE program development, various means to address those issues, and explains how the issues were addressed in the initial and ongoing development of an undergraduate SE program. By using SEEK and SWEBOK as requirements sources to define what an undergraduate software engineer needs to know, the authors walk through the creation of a sample curriculum at a small, comprehensive university in the United States. Both the current and initial curricula are presented. The article discusses many items to consider in the process of planning and launching a new BSSE program, such as accreditation, curriculum guidelines, sources of information, and potential problems.

INTRODUCTION

Software Engineering is one of the newer engineering disciplines to emerge. Starting with the coining of the 'Software Engineering' term in 1968

(Naur, 1969), there has been continual growth in interest in software engineering education. Initially, these efforts were primarily at the graduate level, serving software engineering practitioners with undergraduate degrees in Computer Science, Computer Engineering or other related fields. In 1998, in recognition of the needs of bachelors-level computing graduates, the Computer Society of the Institute for Electrical and Electronic Engineers (IEEE-CS) and the Association for Computing Machinery (ACM) established the Joint Task Force on Computing Curricula 2001 (CC2001) to undertake a major review of curriculum guidelines for undergraduate programs in computing (Diaz-Herrera, 2004). This and other efforts (EA, 2007; CEAB, 2006; ABET, 2005) added official recognition of the need for the establishment of effective undergraduate programs preparing students to become software engineers.

The underlying assumption is that creating a new degree program for a relatively new discipline (Software Engineering), in a professional area (Computing) that already has several well-established disciplines (Computer Science, Computer Engineering, Information Systems, etc.) necessarily comes with a number of significant development risks. This chapter takes the form of an extended experience report, in the hope of presenting an overview of these risks, and practical means to mitigate them. This work is primarily based on the authors' experience in developing a software engineering undergraduate program leading to a Bachelor of Science degree in Software Engineering (BSSE) at a small comprehensive university in the United States (Frezza, 2006). Effort has been made to generalize this experience, and include questions and issues encountered in other SE program development efforts, as well as raising issues that may be more critical in other organizational settings.

ISSUES IN SE PROGRAM DEVELOPMENT

Developing a new undergraduate program, particularly one like Software Engineering that does not have long-established definitions can be (and for us was) a delicate business. Among the key stakeholders for a new SE program, the requirements for what belongs in such a major may not be well understood, or easily communicated. In all, our program development effort was similar to many of our software development experiences, in that the requirements management activities were significant, messy, and working to resolve them early proved worthwhile. Our undergraduate software engineering program, at the time of writing, has been developed, launched, gone through several on-going outcomes reviews, and we are currently preparing our first accreditation self-assessment.

Based on our reflection on the issues we encountered, and our post-design assessments, some of the key issues we've found in developing a new SE program include:

- **Organization:** Determining where the program is housed or sponsored within the institution
- **Vision:** Defining the style, or professional focus of the program
- **Accreditation:** Applying international and national standards to ensure program quality
- **Curriculum:** Designing the academic plan for students to meet or exceed the vision, and
- **Finding help:** Locating contacts to support program development

Organization

Determining where an SE program is housed is important to its success. The issue centers on

faculty ownership of the program, and administrative support for the students. Many SE programs are organized in the same academic housing as Computer Science programs, but this is not universally the case. At issue is the blend of CS, IS, and Engineering courses currently available, and ability to work with the faculty delivering these courses to be effective for the new program. While Software Engineering is normally classified as a computing sub-discipline, in many institutions computing disciplines may be in multiple departments scattered across multiple schools, or not. The character and ability of the various departments and schools to collaborate (*e.g.,* School of Engineering *vs.* School of Arts and Science, etc.) may not be easily navigated, and can delay program introduction.

The housing issue for a program is significant, as it can affect issues related to shared course content, accreditation, funding, hiring, tenure, and a plethora of other subtle and inter-related academic issues, not the least of which is the culture of the faculty leading the program. Mismatches can adversely affect program development, but more especially student learning and faculty retention issues.

While many programs are initially housed in an existing department structure, in several instances, sponsoring departments have been cross-department, or even cross-college arrangements. In some cases these more complex structures, created to launch the SE program, were later replaced. Factors that can affect complex administrative structures include growing enrollments, competition, budgets and funding, faculty issues and other sustainability factors. In some schools, the more complex structures proved workable, and have been maintained (e.g., Drexel). The common theme is the ability to gain sufficient institutional agreement for offering SE course and related program content.

In our case, this negotiation of where to house the program led to delaying the program launch by about a year. Our initial proposal was to run the new SE program with a systems orientation from the Electrical and Computer Engineering (ECE) department. What was at issue was the nature of software engineering – few faculty having significant experience beyond embedded software development, or exposure to the significant and world-wide efforts to define software engineering as a discipline (Bourque, 2000). Locating authoritative guidelines as to what a software engineering undergraduate program should include was significant to this negotiation. Even with these guidelines, identifying the nature of our new SE program, and where it should be developed/housed was by no means a simple process.

Addressing this housing issue led to several surveys and presentations, using materials from conferences (Diaz-Herrera, 2001), ABET program-specific criteria (ABET, 2005), the Certified Software Development Professional (CSDP) effort (McConnell, 1999; IEEE CS, 2001), SWEBOK drafts (Abran, 2004), and the SE2004 drafts (Diaz-Herrera, 2004) to define software engineering for students, faculty and administrators. In particular, SE2004, SWEBOK, and ABET proved to be the most useful, and served as authoritative guidelines for our proposal development. At the end of these discussions, even though the program proposal originated from our ECE department, the strong computing focus of the SE program was deemed more suitable to be housed in the Computer and Information Science (CIS) department offering our computer science (CS) and management information systems (MIS) degree programs.

As the CIS department was housed in the same school as ECE, no administrative objections were encountered. The new task was to redevelop the program vision and program details with a team of primarily CIS faculty in a way that would succeed when the new program was launched and managed from the CIS department.

The decision to house the program in a different department meant ECE relinquishing control on the proposal, the proposal champion working with a new department chair and new faculty partners. The benefit of this redevelopment work was the promise of building consensus around a shared vision from those who would ultimately deliver the program.

Vision

Following a well-documented SE best practice, identifying a coherent vision was a useful starting point, and our experience confirmed that it is a key factor for success in developing a Software Engineering undergraduate program. Within the vision for an academic program, one of the most fundamental issues is the judicious selection of the type, or character of the program that is desired. Notwithstanding other sources, at least six application models for software engineering have been identified (Jones, 2003):

- **Military:** Applications built according to military or US Department of Defense standards. This may include weapons systems, but also logistics and non-military systems that use military standards.
- **Systems:** Applications developed to control hardware devices such as computers, aircraft, telephone switches, and other physical devices and products, including embedded systems.
- **Commercial:** Applications for lease or sale to external customers, occasionally referred to as 'shrink-wrap' software. This category includes many personal computer applications, but also includes larger mainframe applications.
- **Outsourced:** Applications developed for a specific client company under a contract. Because of contractual obligations and the possibility of litigation, outsourced projects have some additional activities in comparison to in-house development.
- **Management Information Systems (MIS):** Applications built to control major business functions such as accounting, marketing, sales, and personnel. This category includes many traditional mainframe applications, but also the more recent client-server, multi-tiered and web-based applications.
- **End-user development:** Small applications that various kinds of knowledge workers—such as accountants, engineers, or project managers—build for personal use.

In developing a vision for a specific program, casting the nature of the program may be decided by other factors, such as faculty availability, skills, and influences from local and regional employers. These can, and should influence what a specific SE program graduate should be able to do. However, this 'local' approach can easily ignore the other external 'requirements' for a credible program.

There exist broad and relatively well-developed, and reasonably authoritative guidelines for what software engineers need to know (See the *Defining the BSSE Graduate* and *What Software Engineers Need to Know* subsections that follow). However, the context in which these skills are developed is also important, as these different application models have differences that can be significant in program delivery. These differences will typically show up in the determination of the content of required upper-level courses and elective courses.

Developing a vision is important in that the vision statement, once agreed to, serves as a useful guide in helping to sell the program to different academic and administrative stakeholders, as well as a useful reference during program design. Like most business exercises in vision, developing this as a shared vision, rooted in the realistic limitations of the organization will help reduce the risk of failure.

In our case, the decision to house the program in the CIS department led to a new shared vision for our SE program. The initial ECE-based proposal was based on a *systems* focus. With CIS faculty participation, the revised program proposal focused on delivering skills and knowledge for the *outsourced* and *MIS* categories. These represented trade-offs among the program developers, recognizing that the o*utsourced/MIS* view would have distinctly different courses and flavor from the *systems* view. While different from the initial vision, this was a vision that was both legitimate, and would work well within the exiting department and course structures then in place. The tradeoffs allowed the new proposal to parallel the CS program more closely, but with the recognition that software engineering concepts needed to be integrated into courses taken jointly by CS and MIS students. Ultimately, this has proven to be useful in our situation, as the integration of software engineering concepts into early courses was easily negotiated, and continues to be well received.

Accreditation

In the US and many other countries, the use of the term "Engineering" in a program or degree title is necessarily accompanied by the requirement for some form of national accreditation which serves to ensure program quality. In the United States, ABET, Inc. (ABET, 2007) is responsible for the specialized accreditation of educational programs in applied science, computing, engineering, and technology. In Canada, the Canadian Engineering Accreditation Board (CEAB), serves as the accreditation body for engineering programs (CEAB, 2006), while Engineers Australia (EA) is responsible for this service in Australia (EA, 2007). This is an important initial consideration for creating a new program, because the nature of engineering accreditation generally brings with it required documentation processes, criteria and even academic culture that may be foreign to the institution or sponsoring department. Taking the time to become familiar with the processes and documentation needed is important, and in some instances may require hiring consultants to review academic proposals.

At the time of writing, 13 such programs were accredited in the United States (ABET, 2006), 12 in Canada (CEAB, 2006), and 18 in Australia (EA, 2007). To give a sampling of the breadth of universities that have chosen this route, these universities are listed in Figure 1. In our case, the goal was to create a program that would warrant including Gannon University in the list.

While not all programs require national accreditation, international guidelines exist (such as SE2004) to help ensure the quality of Software Engineering undergraduate programs. In our case, accreditation was a process new to the sponsoring department, but not to the school. Experience in applying the ABET criteria was easy to find, and the use of the EAC accreditation criteria (ABET, 2005) and the related SE2004 volume served as significant drivers in assessing the quality of the program proposal. This validation of the curriculum development process was extremely valuable in describing software engineering to program stakeholders, and served as a very useful means of assessing changes to the program (Frezza, 2006). These processes as we applied them are described in more detail in the pages that follow.

Curriculum Development

Ultimately one of the most critical portions of the program delivery is the curriculum employed by the program. The curriculum development process includes the development of the program objectives, as well as courses and course objectives. In most institutions, these are developed within the framework of institutional standards, as well as existing computing, mathematics, engineering and other courses that would also be taken by SE students. This key issue is discussed in much more detail in sections which follow.

Sources of Help and Advice

As in most engineering endeavors, one of the most useful sources of development information comes from others who have developed similar products (Kelley, 1999). These resources are particularly useful for helping to understand issues, avoid issues, or also experience to resolve issues as they are encountered in your program development. This is also a significant source of external expertise that can be used to help validate the program, such as a 'blue-ribbon' or other external panel that can validate or provide guidance to program development.

In our case, finding help in the form of the Working Group on Software Engineering and Education, and the more recent Software Engineering Program Leaders Association (SEPLA) proved to be extremely useful for helping find and share materials to explain the SE profession to various constituents (faculty, students, administrators), as well as provide useful market data and comparison programs. Various SEPLA members also volunteered, and provided input on various program proposals. The SEPLA listserv is available at sepla@listserv.butler.edu.

In our experience, the faculty development wherein we used authoritative guidelines to define Software Engineering for ourselves was absolutely essential. The need for this education came initially in response to addressing our organization issues. Our Accreditation goal dictated that ABET criteria needed to be considered, but the more extensive international guidelines

Figure 1. Accredited software engineering related programs in the U.S., Canada, and Australia (current as of Sept. 2007)

US (*ABET*)	Canada (*CEAB*)	Australia (*EA*)
Auburn University	University of Calgary	Australian National University
Clarkson University	Carleton University	Curtin University of Technology
Embry-Riddle Aeronautical University, Daytona Beach	Concordia University	Flinders University
Fairfield University-School of Engineering	Lakehead University	Griffith University Nathan Campus
Florida Institute of Technology	McMaster University	La Trobe University (Bundoora campus)
University of Michigan-Dearborn	University of New Brunswick	Monash University
Milwaukee School of Engineering	University of Ottawa	Murdoch University
Mississippi State University	University of Waterloo	RMIT University

University of Texas at Arlington	Polytechnique	The University of Newcastle
University of Texas at Dallas		The University of New South Wales
		The University of Queensland
		The University of Western Australia
		University of Southern Queensland
		University of Sydney
		University of Technology, Sydney

(SWEBOK and SE2004) were more informative. The process of blending these viewpoints helped establish detailed 'requirements' for our BSSE program, as well as establish agreement on these requirements. This analysis work was crucial to the success of the program proposal process, and became central to developing the program outcomes, expectations, and ultimately its detailed design. Our particular blending is summarized in the *Defining the BSSE Graduate* and the *What Software Engineers Need to Know* sections that follow.

While the authoritative sources (ABET, SE2004 and SWEBOK) are all aimed at different target audiences, the definitions of software engineering they provide for these audiences are important. These definitions all speak directly to what the expectations would be for our BSSE graduates *after* the program was established, hopefully accredited, and they were well into their careers. Because the definitions were external, they carried significantly more weight than the viewpoint of any particular faculty member. These definitions, once blended, became central to developing the shared vision for our BSSE program as the program was developed, and has since continued to support outcomes assessment and program enhancement.

DEFINING THE BSSE GRADUATE

For the purposes of creating a quality, accreditable program, it is essential to define the desired knowledge and skills possessed by the BSSE graduates. One of the more useful forms for defining the desired knowledge and skills are the "outcomes" for the program. Outcomes relate to broadly defined skills, knowledge, and behaviors that students should acquire as they progress through the program (Wankat, 1993). If a graduate achieves all the program outcomes, this indicates that the student meets the program's stated educational objectives and is equipped to function as expected of a BSSE graduate.

To create an accreditable SE program, the program design must meet the established educational objectives and program criteria for a BSSE program. There are at least two primary sources for these objectives and criteria which define the minimal knowledge and skills for a BSSE graduate. In the US, the Engineering Accreditation Commission (EAC) provides two categories of objectives and criteria that apply to the design of engineering programs (ABET, 2005).The first category, the EAC Program Educational Objectives, is a broader set which applies to all engineering programs. The second category provides each engineering discipline a unique set of program criteria specific to the discipline.

While these objectives and criteria are definitive for accreditation in the U.S., they do not provide as much detail as the SE2004 guidelines (Diaz-Herrera, 2004). The difficulty is that when comparing the SE2004 Student Outcomes (Diaz-Herrera, 2004) with the related EAC Program Educational Objectives (ABET, 2005) and EAC SE Program Criteria (ABET, 2005), there are noticeable gaps among them (Frezza, 2006). However, the superset of related SE skills indicates that a program should provide at least the following outcomes (Frezza, 2006):

- Show mastery of the software engineering knowledge and skills, and professional issues necessary to begin practice as a software engineer
- Demonstrate the ability to appropriately apply science, discrete mathematics, empirical techniques, probability and statistics and relevant topics in computer science and supporting disciplines to the development of complex software systems

- Work as an individual and as part of a multidisciplinary team to develop and deliver quality software artifacts
- Reconcile conflicting project objectives, finding acceptable compromises within limitations of cost, time, knowledge, existing systems and organizations
- Design appropriate solutions in one or more application domains using software engineering approaches that integrate ethical, social, legal and economic concerns
- Understand professional and ethical responsibility
- Demonstrate an understanding of and apply current theories, models, and techniques that provide a basis for problem identification and analysis, software design, development, implementation, and documentation
- Demonstrate an understanding and appreciation for the importance of negotiation, effective work habits, leadership, and good communication with stakeholders in a typical software development environment
- Learn new models, techniques and technologies as they emerge and appreciate the necessity of such continuing professional development
- Obtain knowledge of contemporary issues
- Receive and internalize a broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context

These program outcomes, which arguably must be met for a U.S.-based program, provide a useful definition of what the BSSE graduate should know and be able to do. Although important for defining and continually improving program effectiveness, the outcomes by themselves don't provide adequate detail about the specifics for "software engineering knowledge and skills". What specifically should we teach students? What should the courses contain? SE fortunately has other sources that define more specifically what students must know and be able to do.

WHAT SOFTWARE ENGINEERS NEED TO KNOW

In order to craft a credible Software Engineering curriculum that also paves the way to students' success in the workforce, we need to understand what knowledge students are expected to possess. Not only does this include knowledge that students fresh out of college are expected to know, but also knowledge that these students after a few years in the workforce are expected to hold. There are two primary sources for these requirements, SE2004 (Diaz-Herrera, 2004) and SWEBOK (Abran, 2004), addressing aforementioned types of knowledge respectively.

- **SE2004 (Software Engineering 2004):** defines the body of knowledge that every software engineering degree graduate fresh out of college needs to know as the *Software Engineering Education Knowledge* (*SEEK*).
- **SWEBOK (Guide to the Software Engineering Body of Knowledge):** characterizes the contents of software engineering discipline, i.e., the knowledge needed for the practice of software engineering after four years in the workforce.

Both of these documents carry with them extended development processes and improvements. In addition, both development efforts included significant efforts to ensure that the documents, and thus the educational patterns that might emerge from them, were not US-centric. The SE2004 effort, in particular, has been translated into Russian to support curricular development efforts in Central and Eastern Europe (Pavlov, 2006). At the time of this writing, new curriculum

pilots based on SE2004 have been started in over 30 Central and Eastern European universities (Sobel, 2007).

SE2004

The Joint Task Force on Computing Curricula sponsored by the IEEE Computer Society and the Association of Computing Machinery Joint Task Force developed *Software Engineering 2004 (SE2004)* as curriculum guidelines for undergraduate degree programs in software engineering (Diaz-Herrera, 2004). SE2004 defines a detailed set of knowledge expected of a BSSE graduate as the *Software Engineering Education Knowledge* (*SEEK*). SEEK is designed as a guide to support the development of undergraduate software engineering education curricula.

SEEK defines 10 education *knowledge areas* (*KAs*), each of which is recognized as a significant part of the body of knowledge that every bachelors-level software engineering graduate needs to know. A short description for each of the ten knowledge areas defined by SEEK (Diaz-Herrera, 2004) are listed below:

1. **Software evolution.** "Software evolution is the result of the ongoing need to support the stakeholders' mission in the face of changing assumptions, problems, requirements, architectures, and technologies." (Diaz-Herrera, 2004)
2. **Software process.** "Software process is concerned with knowledge about the description of commonly used software life-cycle process models and the contents of institutional process standards; definition, implementation, measurement, management, change and improvement of software processes; and use of a defined process to perform the technical and managerial activities needed for software development and maintenance." (Diaz-Herrera, 2004)
3. **Software verification and validation.** "Software verification and validation uses both static and dynamic techniques of system checking to ensure that the resulting program satisfies its specification and that the program as implemented meets the expectations of the stakeholders." (Diaz-Herrera, 2004)
4. **Software quality.** "Software quality is a pervasive concept that affects, and is affected by all aspects of software development, support, revision, and maintenance. It encompasses the quality of work products developed and/or modified … and the quality of the work processes used to develop and/or modify the work products." (Diaz-Herrera, 2004)
5. **Software design.** "Software design is concerned with issues, techniques, strategies, representations, and patterns used to determine how to implement a component or a system. The design will conform to functional requirements within the constraints imposed by other requirements such as resource, performance, reliability, and security." (Diaz-Herrera, 2004)
6. **Software management.** "Software management is concerned with knowledge about the planning, organization, and monitoring of all software life-cycle phases." (Diaz-Herrera, 2004)
7. **Computing essentials.** "Computing essentials includes the computer science foundations that support the design and construction of software products." (Diaz-Herrera, 2004)
8. **Software modeling and analysis.** "Modeling and analysis can be considered core concepts in any engineering discipline, because they are essential to documenting and evaluating design decisions and alternatives. Modeling and analysis is first applied to the analysis, specification, and validation of requirements." (Diaz-Herrera, 2004)

9. **Mathematical and engineering fundamentals.** "The mathematical and engineering fundamentals of software engineering provide theoretical and scientific underpinnings for the construction of software products with desired attributes." (Diaz-Herrera, 2004)
10. **Professional practice.** "Professional Practice is concerned with the knowledge, skills, and attitudes that software engineers must possess to practice software engineering in a professional, responsible, and ethical manner." (Diaz-Herrera, 2004)

Each knowledge area (KA) is further divided into smaller modules called *units*. The left column in Figure 2 lists the SEEK knowledge areas in light grey shades, and the knowledge units (KUs) defined for each KA in italics.

Each knowledge unit defined in SEEK is further divided into *topics*. Some topics are designated as 'essential', and constitute the core knowledge which is considered required for anyone to obtain a software engineering undergraduate degree. In its current (2004) revision, SE2004 defines 240 topics as essential that software engineers graduating from credible programs need to know (Diaz-Herrera, 2004). A summary of the number of units, topics, essential topics, and contact hours for essential topics are listed in Table 1.

The topic-level detail outlined in Table 1 can be a two-edged sword for program design. With the rigorous application of the topic-level information, those developing new software engineering programs may well find that the credit hours needed to cover the 'essential' units would be well beyond the ability to offer a program within most University constraints. Similarly, this 'essential' detail can be too detailed for effective course planning, and can obscure what units are more essential than others, particularly in the context of making a program unique to an institution (Frezza, 2003). Conversely, the detail facilitates definition of what is meant by particular knowledge units, and thus strongly facilitates measuring the completeness of a program, and clarity in communicating what constitutes a BSSE degree.

Besides the undergraduate education knowledge defined by SEEK, we also need to know about what kinds of knowledge are needed for the practice of software engineering in the workforce. The guide to the Software Engineering Body of Knowledge (SWEBOK) does just that.

SWEBOK

The IEEE Computer Society established a baseline for the body of knowledge and recommended practices for the field of software engineering in the Guide to the Software Engineering Body of Knowledge (SWEBOK) (Abran, 2004). SWEBOK characterizes the contents of software engineering discipline, *i.e.* the knowledge needed for the practice of software engineering after four years in the workforce, into ten Knowledge Areas (KAs). Each knowledge area is further divided into subareas, and each subarea is further divided into topics and subtopics. The right column in Figure 2 lists the SWEBOK knowledge areas in light grey shades, and the knowledge subareas defined for each KA in italics.

The KAs for both SEEK and SWEBOK are highlighted in light grey shades in Figure 2. The double arrowed lines given in Figure 2 outline the similarities, the dashed lines outline partial coverage, while KAs without links indicate the differences between SEEK and SWEBOK KAs. As you can see from the figure, for the first six SEEK knowledge areas (KA) each has a very related KA in SWEBOK as indicated by the double arrowed lines. Typically the KA in SWEBOK has a broader coverage in topics than the corresponding SEEK KA. However, the SEEK knowledge units listed in light grey are not covered by its knowledge area's corresponding SWEBOK KA, but are covered by the SWEBOK KA to which it is linked with solid lines. For example, SEEK unit *Software Configuration*

Figure 2. SE2004 SEEK knowledge areas and units vs. SWEBOK knowledge areas and subareas

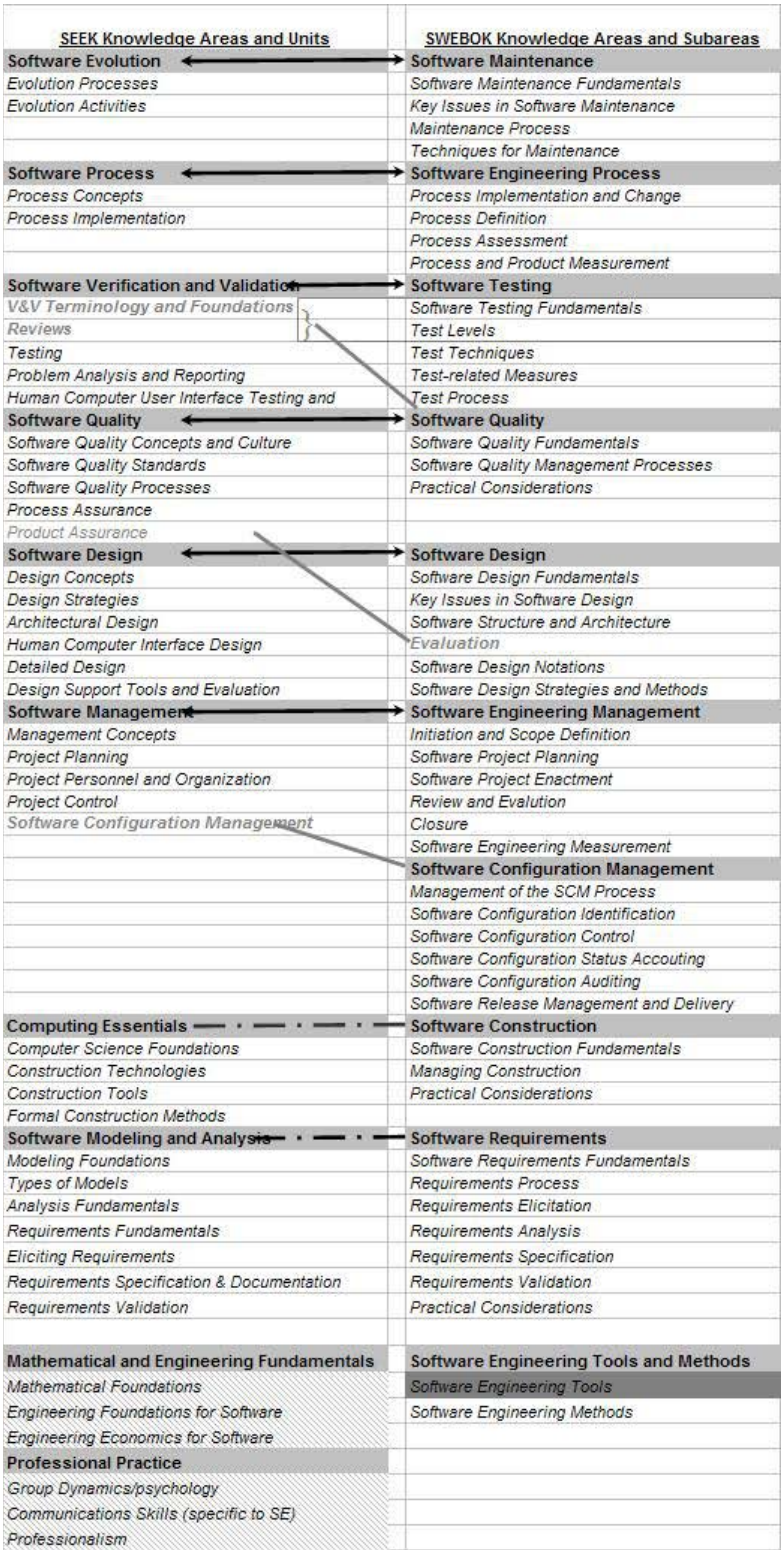

Table 1. Summary of SEEK knowledge areas, units and topics

SEEK Knowledge Area	Units	Topics	Essential Topics	Essential Contact Hours
Computing Essentials	4	42	37	172
Mathematical and Engineering Fundamentals	3	22	19	89
Professional Practice	3	17	17	35
Software Modeling and Analysis	7	42	33	53
Software Design	6	37	31	45
Software Verification and Validation	5	30	28	42
Software Evolution	2	13	9	10
Software Process	2	14	13	13
Software Quality	5	28	25	16
Software Management	5	31	28	19
Total	**42**	**276**	**240**	**494**

Management in *Software Management* KA is covered by SWEBOK *Software Configuration Management* KA. SEEK unit *Product Assurance* in *Software Quality* KA is covered by SWEBOK subarea *Software Design Quality Analysis and Evaluation* in *Software Design* KA.

In addition to the closely related SEEK and SWEBOK KAs mentioned above, two SWEBOK KAs, each having significant overlap with but only partially covering its corresponding SEEK KA, are shown in dashed lines. SWEBOK KA *Software Requirements* only covers requirements related units in SEEK KA *Software Modeling and Analysis,* while *Software Construction* covers construction related units in *Computing Essentials.*

Noticeable unit differences between SEEK and SWEBOK are highlighted in reverse diagonal shades. Both *Mathematical and Engineering Fundamentals* and *Professional Practice* SEEK KAs do not have corresponding SWEBOK KAs due to the educational nature and curricula development purpose of SEEK. As the SWEBOK focuses on the boundary of software engineering, hence non-software engineering-specific knowledge, such as the fundamental background required to acquire software engineering specific knowledge, was intentionally left out.

Another noticeable difference is in the SWEBOK *Software Engineering Tools and Methods* KA as highlighted in dark grey shades. The *Software Engineering Tools* subarea is embodied inside the *Software Evolution, Software Process, Software Verification and Validation, Software Quality, Software Design, Software Management, Computing Essentials, Software Modeling and Analysis, Mathematical and Engineering Fundamentals* and *Professional Practice* topics in SEEK, as highlighted in dark grey shades.

Both SEEK and SWEBOK define the specific knowledge and skills required of a software engineer. For undergraduate software engineering graduates fresh out of college, the knowledge they attain comes from the courses they complete in their curricula, hence curricula plays an important role in deciding what knowledge students will posses when they graduate. While both SEEK and SWEBOK are designed as a guide/foundation for software engineering curricula development, SEEK is especially designed for undergraduate software engineering curricula development with detailed topics defined, and an expectation

that accredited programs will reflect this set of knowledge and skills in their program.

SEEK provides description for each KA, but no descriptions are provided for the units and topics defined. This kind of set up could be hard for syllabus development as the contents which should be included for the name provided for units and topics could be open for interpretation. With no reference materials provided, it could be difficult for faculty to find suitable textbooks or materials to cover the desired topics. On the other hand, SWEBOK provides detailed description and interesting discussion for each KA, subarea, topic and subtopic defined as well as links to books and articles.

STARTING THE PROCESS

The practical process of developing a vision for a specific instance of a Software Engineering program includes a number of concerns to be addressed, such as focus, style, leadership, and the requirements derived from the institutional strengths, weaknesses and opportunities. The experience of the authors is that of developing a program within the context of existing computing and engineering programs within the sponsoring institution, so issues concerning the creation of new academic structures will only be by inference.

Project Leadership

The immediate starting point is necessarily one of leadership – who will lead the project to define and launch the program. While this may seem trite, clearly defining the academic stakeholders is critically important, as the risks of not involving appropriate representation from related academic departments early in the program development are real, and have proven to be stumbling blocks to SE program development. As with any successful project, establishing executive sponsorship at various levels is key, as is communication with the executive sponsors and other stakeholders. One mechanism for supporting ongoing validation, communication and development of the program is a steering committee.

An effective program development steering committee should follow effective patterns within the institution, and typically is formed from department chairs, experienced faculty, external advisors, and anyone else deemed appropriate to the institution. This committee, whether formal or informal in its makeup, should necessarily include persons who have the authority to formally propose a new program within the institution. In some cases, this process may require cross-college cooperation, and thus may also include either academic deans or their representatives.

The steering committee should at minimum approve program development decisions, but may (as in our situation) be significantly more active in the development of the program details. Among these, determining the expected style of the program was a significant set of decisions. For example, in our case, the deliberate choice was to not require co-ops, and to not focus on one particular SE style, such as embedded systems, but rather allow styles and domains to be student-selected via the use of technical electives.

In our development process, the project started with one faculty project leader, and eventually formed a development committee after the housing (which department) issue was settled. In the case of Butler University in Indiana, the housing department was clear, and they developed an external advisory board consisting of local software industry leaders which helped significantly in crafting the program and building internal credibility (Henderson, 2003).

Capitalizing on Institutional Strengths

Each educational institution has its own set of distinguishing characteristics, including things

like the faculty, teaching style(s), history, physical location, etc. Part of the success of a new program is its ability to realize these characteristics within the program in ways that strengthen the program, its appeal to students and its effectiveness for graduates.

In many cases, these institutional strengths are easily recognized, and involve institution-wide structures to support them. These structures can take on many forms: core curricula, freshmen sequences, service learning, marketing, development, alumni services, cooperative arrangements, etc. While many of these academic and non-academic features may also act as constraints, they are also what bring the institutions' unique stamp to the new program. Clearly identifying and celebrating these institutional strengths are significant for marketing the program, both internally and externally. Performing a formal Strengths, Weaknesses, Opportunities and Threats (SWOT) analysis may be useful.

One of the more common SE program development questions that hinges upon institutional strengths is that of requiring cooperative employment placements as part of the academic program. In some institutions, such as Rochester Institute of Technology (RIT) and Drexel University, this is an institutional strength, and is required of most programs. In other schools, required co-ops are common, and institutional support is readily available. Yet this is not the case in most institutions – neither the culture nor the academic structures support co-ops, so the decision to include a required co-op placement as part of the program design may involve significantly more cost to the program.

In our case, similar to that of Butler University, we developed our BSSE program in a 'liberal arts' institution, where the general education requirements included 36 semester hours of general education, and provides a significant institutional 'stamp' to the program. Similarly, there was no institutional support for required co-op placements, and despite the attraction of such an arrangement, it was deemed unfeasible by the development steering committee.

One of the more important institutional limitations to be negotiated is the availability of faculty resources; some institutions are very risk-adverse, and consequently are very reluctant to invest in new faculty positions for new programs until the enrollment proves the need. Other institutions are more accepting of risk, and are more tolerant of investment that will help distinguish a program, and ensure its early success.

In our case, after creating the initial academic plan, we projected the faculty resources needed to develop and sustain the new program. With an enrollment estimate, the request took the form of one new faculty member the year after the program launch, and another faculty member two years after launch if enrollment met or exceeded the estimates.

CURRICULUM CONSTRUCTION AND DESIGN

Students gain and build knowledge and skills from the courses they take while in college. Curriculum dictates what courses students in a specific program should take and the sequence of taking them. Hence curriculum plays an important role in determining what *knowledge and skills* students should possess when they graduate with a bachelor's degree. On the other hand, each course students take has a specific set of course objectives that students completing the course are expected to accomplish; curriculum also plays a determining role in what *program outcomes* will be achieved through the course outcomes. Furthermore, curriculum is the place where each institution showcases its strength, uniqueness and special program focus. So what courses should be included in an institution's BSSE curriculum? There is no one easy answer for that.

For the purpose of creating an accreditable program, where graduates meet or exceed expected

program outcomes, in our experience, there are several factors to consider during the curriculum design and construction process.

1. Institutional/university strength and constraints

Each university/educational institution has its unique set of characteristics as discussed in the *Capitalizing on Institutional Strengths* subsection. No matter what the characteristics are, some (such as faculty, teaching style(s) and co-op arrangement) are great for marketing as the unique strength of the institution while others (such as core curricula, co-op requirement and freshmen sequences) can be considered as constraints for curriculum development.

In our case, our university mandates 36 credit hours of general education which ensures that every graduate achieves the university outcomes (Frezza, 2003). Although the number of credits required is mandated, every program does have the autonomy of restricting course(s) that students can select from each category to better suit the needs of each program. Furthermore, our SE program does not have co-op requirement which opens up credit hours for curriculum. On the other hand, if a co-op arrangement is instituted by the university, the number of credit hours required for the co-op arrangement would be a constraint for curriculum design.

An area where this can be significant is that of total credit hours – in our case, the Computer Science and other Engineering programs all require over 130 semester credits, so this afforded a bit of room in creating courses for the SE program. Many schools have very specific credit constraints that can make this more difficult, e.g., in the United States, many schools have 128 credit limits for bachelors degree programs. As in our case, using related programs in the school (such as EE or CS) as patterns can prove to be effective. Many of the patterns these existing programs have, such as when they take general education courses, the patterns for lab courses and lab credits, the patterns for co-ops, the patterns for common and discipline-specific courses can prove to be useful. In our case we used the CS degree as the pattern, and reused as many of these courses as possible; by replacing some advanced mathematics courses with SE courses, this allowed us to create a program with essentially the same number of credit hours as the CS program.

2. SE program hosting department/college constraints

In addition to university/institutional constraints, program hosting department/college may have its own set of requirements (such as maximum reuse of faculty and existing courses offered, existing prerequisite structure, capstone project requirement, departmental outcomes, maximum number of credits required in a program) that need to be fulfilled.

In our case, the SE hosting department, CIS, expects the new SE program to be compatible with the existing CIS computing programs: computer science and management information systems. This is not only for the economic benefits of shared courses and faculty resources but also allows students to switch majors early in the program without much impact on required time to earn the degree (Frezza, 2003). Such a requirement leads to the mapping/compatibility analysis of existing CIS course offerings, prerequisite structure and the SE program vision. Since the SE program focuses on the *outsourced* and *MIS* categories, the CIS faculty felt the strong need of solid programming, systems, networking and computing background for SE students which in turn leads to the reuse of a great number of existing CIS courses. Specifically, SE and CS program students have almost identical courses for the first two years. However, such an arrangement also limits the number of credits available for Software Engineering specific courses that can be offered.

In addition, every CIS department graduate is expected to complete a capstone project and achieve a set of departmental outcomes. The capstone project, which integrates ethics and project management with a multi-disciplinary two semester long team project, mandates six credit hours of the senior year schedule. Although the set of departmental outcomes are not in the form of credit hours, it requires careful traceability analysis on the mappings of course outcomes to departmental outcomes. The analysis result could start the process of redefining current course content and outcomes, as well as creating new courses and the responsibility (assignment of departmental outcomes) of new courses.

3. Defined SE program outcomes

Besides the hosting departmental/college outcomes that need to be achieved, every SE program that hopes to be accredited should also fulfill the outcomes defined by its accreditation body. As discussed in the *Accreditation* subsection and *Defining the BSSE Graduate* section, every SE program needs to define its own set of program outcomes that can be related to the outcomes required by the accreditation body and specified in SE2004 (Diaz-Herrera, 2004). Both departmental outcomes and the defined SE outcomes will serve as targets for the courses designed into the BSSE curriculum.

In our case, we combined the generic CIS departmental outcomes with specific SE outcomes that then defined the BSSE program outcomes. A gap analysis was performed on the mapping of BSSE program outcomes to the eleven outcomes, the superset of ABET EAC, EAC SE and SE2004 outcomes, described in *Defining the BSSE Graduate* section. The result is shown in Table 2. The analysis goal was to make sure that every Gannon BSSE outcome maps to at least one generic SE outcome and every generic SE outcome maps to at least one Gannon BSSE outcome.

4. Outcomes to Courses: Applying ABET, SEEK and SWEBOK

The outcomes only convey what objectives should be achieved by the courses prescribed in a BSSE curriculum but not courses should be offered. One of the important goals in the design and construction of courses is to build up students' knowledge and skills through the curriculum. Both SE2004 and SWEBOK, described in *What Software Engineers Need to Know* section, define *Knowledge Areas* (KAs) and *topics* that are important to a software engineer. By identifying *Knowledge Areas* (KAs), *Knowledge Units* (KUs) and *topics* that need to be covered by courses, assigning them to courses, defining course outcomes, and mapping course outcomes to BSSE program outcomes, this not only ensures that every BSSE program outcome is covered by one or more courses, but also ensures that the important (essential) topics hand-picked by the SE program committee are covered by one or more courses. While most ABET program outcomes (A-K) and program criteria were well covered, issues regarding the minimal standards for science, mathematics, and the application of SE to some discipline needed specific inclusions in the program designs under consideration.

In our experience, SWEBOK proved to be invaluable in helping to define Knowledge Areas, subareas and topics to be covered by courses. Although SWEBOK is not designed specifically for undergraduate curriculum development and accreditation, we found it provided easy to understand, and more in-depth description of knowledge areas and topics than SE2004. In addition, it also provided useful references in building syllabi for new courses.

Since SE2004 SEEK and SWEBOK defined very similar *Knowledge Areas* (KAs), as discussed in *What Software Engineers Need to Know* section, it was not difficult for us to identify *Knowledge Areas* (KAs) that need to be

Table 2. Mapping of Gannon BSSE program outcomes to generic SE outcomes

Gannon Software Engineering (BSSE) program outcomes 2006-7	1. Apply problem solving strategies to software development	2. Interface with business and analytical professionals to solve software or systems development problems	3. Comprehend ethical decisions and their ramifications as professionals.	4. covered by courses in SE curriculum. SE2004 SEEK defined very detailed topics for each KA, more specifically topics that are designated as *essential* should be covered by an accreditable SE curriculum. In an ideal world, we should be able to assign every essential topic or even non-essential ones defined in SEEK to courses in our SE curriculum. In reality, we had to operate under institutional and departmental constraints; those are 36 credits of general education requirement, remaining compatible to existing CS and MIS programs (maximum reuse of existing CIS courses), six credits of capstone project, and 135 maximum credits for the SE program.

Our program development model started with using an existing program (in this case, Computer Science) as the basis for the formulation. Instead of assigning all essential and even non-essential SEEK topics, KUs and KAs to whatever courses that we imagined as important for SE curriculum, we started with mapping these topics, KUs and KA's to existing computer science courses, related discipline and general education course contents. After such a mapping exercise, we were able to find the topics, KUs, KAs and even BSSE outcomes not covered by existing courses. This enabled us to revisit existing course contents and outcomes, and even allowed us the opportunity to reshape or redirect the contents and outcomes of existing courses, as well as facilitate the discussion to remove courses to make room for SE courses.

The mappings created were managed in a spreadsheet, much like requirements traceability lists, and showed that the 'requirements' coverage was incomplete. So there remained the question of whether we could cover the rest of essential topics, KUs and KAs reasonably by redesigning existing course offerings or whether new courses should be designed to serve this purpose.

In our case, we were not able to reasonably cover most of the essential topics, KUs, KAs and even BSSE outcomes by redesigning existing courses. Seven new SE specific courses: *Software Engineering Seminar*, *Requirements and Project Management*, *Formal Methods in Software Development*, *Software Architecture*, *Software Testing and Quality Assurance*, *Human Interface Design and Maintenance*, and *Personal Software Process*, totaling 19 credits, were created and offered by the CIS department. The initial curriculum is presented in Figure 3, and the current (2007-8) curriculum is listed in Figure 4. Each SE student also needs to pick an application domain, consisting of nine credit hours of existing courses from various departments, to focus on. The math department also agreed to offer a new course – *Discrete Math 2* for our SE students. Even with the creation of these new courses, we still could not cover all the essential topics in SEEK due to the constraint of the maximum of 135 credits. The detailed examples of the mapping process can be found in (Frezza, 2003) and (Frezza, 2006).

Figure 3 presents the 135 credits initially proposed for the BSSE curriculum. These are organized by type, such as current Engineering and Computer and Information Science courses (51 credits), new Software Engineering courses (19 credits), Application Domain courses (9 credits), new and existing mathematics courses (15 credits), existing Science courses (8 credits), and existing liberal studies (general education) courses (36 credits).

5. New courses or reuse existing courses

In an ideal world where unlimited resources (faculty, budget, number of credits, etc.) are available, and no constraints are imposed for curriculum development, all new courses can be created specifically for an SE program. However, in reality, where multiple constraints exist and academic political issues are abundant, it's not always possible to create all the new courses a new SE program needs. In such a situation, a gap analysis on the mapping of existing course contents to SEEK topics, KUs, KAs and defined BSSE program outcomes could serve as the starting point for the discussion of redirecting current

course contents, negotiating whether and what new courses to create, and where and how to run the new courses.

The discussions about old, revised and new courses were at times heated – for example, a more 'systems' or 'engineering' flavor to the course would have introduced discrete mathematics in the context of digital design, and then followed up with formal discrete mathematics course to fill out the KA. However, the 'MIS' vision prevailed, (and the desire to parallel the Computer Science program closely), and a *Discrete Mathematics 1*, followed by a *Discrete Mathematics 2* combination was agreed upon, followed up by a *Formal Methods in Software Development* course, offered by our department. For each of these courses, appropriate KA's were assigned to the mappings, as well as the subproject of getting our colleagues in the Math Department to support the approach. Such tradeoffs were not insignificant, but were guided by the needs as expressed in the traceability spreadsheet. The spreadsheet framed the problem; our particular resolution to the program vision (information systems) and organization issues (CIS department) guided the debate.

Similar issues surfaced around addressing the 'Computer Organization' requirements within the Computing Foundations KU, which could be implemented with a 'microprocessors course' or a 'computer architecture course' – neither of which would come from our department. Here the traceability showed the need for, and coverage within the spirit and letter of the requirements – but a choice/decision needed to be made. In this case, the previous 'Discrete 1 vs. Digital Logic' decision drove the issue. Only the 'Computer Architecture' remained as a viable choice, both because of the desire to parallel the CS program, and the fact that the architecture course accepted the *Discrete Mathematics 1* course as a prerequisite – whereas the microprocessor course did not.

In our case, the seven new SE specific courses fell logically on the shoulders of the hosting department, CIS, due the focus and skills of the department and faculty. We were able to negotiate with Math department to offer the new *Discrete Math 2* course due to its strong mathematics content. For domain related courses, we decided to reuse existing courses offered by various departments to offer students more domain specific knowledge. Our current Software Engineering curriculum is presented in the Change Management section below.

Once the BSSE curriculum is developed, it is just a proposal – it serves as the guide and core for getting the agreement to launch the program, and ultimately for attracting students, staffing and running the courses that make up the program and continuing to improve the program to serve students' needs.

SELLING THE PROGRAM

During the early stages of conceiving and constructing the program, support must be obtained on several levels in order to reasonably proceed, and, ultimately, to launch a successful program.

Understanding the Student Market

One initial question which must be answered is whether there is and will be work for BSSE graduates. If this question is answered in the negative, there is little chance for program success since it will be extremely difficult to attract students to a program with bleak job prospects. According to the United States Bureau of Labor Statistics (U.S. Department of Labor, 2006a), computer software engineers in the United States held about 800,000 jobs in 2004. They are employed in a wide variety of industries, with employers ranging from startup companies to established industry leaders.

According to Bureau projections, computer software engineer will be one of the fastest-growing occupations through 2014 as businesses adopt

and integrate new computer-based technologies. Jobs openings will be created both through employment growth and from the need to replace workers who retire or otherwise leave the occupation. Consulting opportunities for computer software engineers also should continue to grow. Growth in the field will come from rapidly evolving technologies as well as new software needs driven by information security concerns.

With growing internationalization of software development, some countries will see more software development contracted out abroad. However, jobs in software engineering are less prone to being sent abroad because the occupation requires innovation and intense research and development. Most companies prefer to keep this function in-house whenever practical.

Since the BSSE is a relatively new major, it is often difficult to obtain accurate statistics which isolate the major. This is true when discussing starting salaries. Some basic information is available from the National Association of Colleges and Employers web site (National Association of Colleges and Employers, 2007) (more detailed information is available to members). This press release lists the average starting salary offer to recent bachelor's graduates in Management Information Systems/Business Data Processing as $46,966. The average offer for Computer Science graduates is listed as $52,177. The press release does not distinguish between types of job, nor does it list Software Engineering as a category of degree.

The United States Bureau of Labor Statistics (U.S. Department of Labor, 2006b), lists median salary data for computer software engineers in the United States, but the data is for the profession. As discussed below, most practicing software engineers do not have a degree in Software Engineering, so the data applies to anyone working as a software engineer, not just to those with a Software Engineering degree.

Given the promising employment outlook, a follow-up question is whether students are enrolling in BSSE programs. If we build it, will they come?

As with employment trends, it is difficult to obtain accurate enrollment statistics which apply specifically to the Software Engineering major. The Digest of Education Statistics, 2005 (National Center for Education Statistics, 2005), lists 163 students receiving a Bachelor's degree in Computer Software Engineering in 2003-04, while the 2004 Digest (National Center for Education Statistics, 2004), lists 121 students receiving a Bachelor's degree in Computer Software Engineering in 2002-03. These are the most recent official statistics generally available as of this writing. While these statistics indicate solid growth in the number of bachelor's degrees granted, the number of SE graduates is still extremely small when compared with the number of software engineers needed.

It is also difficult to obtain statistics for software engineering as a career preference. For example, the Post-Secondary Planning Survey Analysis, conducted by the National Research Center for College and University Admissions (NRCCUA) Career-Choice Preferences lists "Computer Sciences," "Information Technology," and several Engineering choices, but "Software Engineering" is not included as a separate choice (NRCCUA, 2007). The SAT survey of intended majors of college bound students in 2007 includes only the broad categories of "Computer and Information Sciences and Support Services" and "Engineering" (The College Board, 2007).

Based on the above numbers, it can be concluded that most practicing software engineers do not have a degree in Software Engineering, but rather in Computer Science or some other related discipline. The question is whether a traditional Computer Science degree program best prepares a student for today's typical software engineering jobs and future career need not be addressed; there is room for and need for both majors.

With promising employment and enrollment outlooks, a final general question is whether

the market is already flooded with new BSSE programs. The brief, simple answer is "no" (or at least it was in 2002 and still is at the time of writing).

In 2003, there were 21 known programs in the United States offering some type of bachelor's degree in Software Engineering, with more being proposed (Bagert, 2003). As of January 1, 2007, there are at least 34 known BSSE programs in the U.S. 13 of which are accredited by ABET (ABET, 2006). Based on these numbers and the projected need for Software Engineers, it seems that many more programs with a Software Engineering focus are needed.

Building Additional Support

Once these initial questions are answered, support to proceed must be obtained from several groups. First, the affected faculty must support the program. If housed in a Computer Science program, one adjustment will be a shift in the focus of some upper division courses. The basics of programming, database, networking, operating systems, and computer architecture will be taught in both majors. However, Computer Science majors will then study topics such as analysis of algorithms, comparative programming languages, compilers, and formal languages. Software Engineers, on the other hand, with study topics such as software design and test, software architecture, requirements, project management, quality assurance, and human interface design.

For some faculty, this will be an issue. It will be seen as a move from a set of courses with technical, well-defined content to a set of courses with a more subjective content. If co-located with a Computer Science program, the split in focus and teaching assignment for upper division courses may fall naturally along the strengths and interests of the faculty and be seen as a positive. If not, some accommodation will need to be made for and by the faculty. This can often be accomplished by judicious distribution of the core set of courses. Regardless of initial reaction, recent downward trends in enrollment in Computer Science programs should provide motivation for faculty to support a program which will likely lead to an increase in enrollment.

Once the faculty is behind the concept of a Software Engineering program, the university administration must be convinced that launching the program is a good idea. While there are several factors involved, the overriding issue with the administration is likely to be economic: will the new program make money or lose money? For a university, the business case will boil down to whether revenue from increased enrollment will offset increased costs. The overall impact of the program proposal was the creation and staffing of seven new courses in software engineering; if offered annually, as was the plan, this defined the need for a new faculty member. In our case, we developed our proposal to feature launching the program first, and then adding the new faculty member in the second year in order to offset the economic impact.

Cost increase can vary greatly depending on factors discussed in preceding sections. If the program is housed in a department such as Computer Science, there can be much reuse of courses and faculty. As such, there will likely be little additional cost when the program is first launched. As the program moves into its third and fourth years, new upper division courses must be developed and taught. Part of this cost can be shifted by eliminating or reducing the frequency of current courses which are under-enrolled. Other costs are more than offset by the increase in enrollment.

A further advantage to the university is the visibility of offering a cutting-edge program. This will help attract both students and faculty. It will also bolster the overall image of the university. In our case, adding the SE program led to a change in the CS+SE enrollment trends – what had been on significant decline grew slightly and stabilized.

Finally, to be successful, the program must be attractive to both students and their parents. One major point, of course, is that Software Engineering is a promising career. The field provides an adequate number of jobs and good salaries. A degree in Software Engineering provides the right skill set for a student entering the job market, and degree in Software Engineering distinguishes the graduate from a graduate with a Computer Science degree. This can be highlighted by the admissions department as well as in any marketing provided by the university. One criticism of adding Software Engineering was the question of impact on Computer Science enrollment. In our case, there has been an impact on CS enrollment (and MIS for that matter). We have 'lost' students to SE from these programs, but we also found many new students who would have otherwise not applied to the university. For our (rather small) program, this has been averaging about 50% for the four years we have accepted students to the SE program. Over this period, about half of the new students who join the BS-SE would not have joined the university. For our department, this has resulted in a slight decline in CS undergraduates, but more recently it has also seen an increase in CS applicants, as well as a qualitative difference in those students who join the CS program – they are increasingly joining because they are genuinely interested in CS topics and approaches.

Finally, the entry in the university catalog for the new program becomes more important than for more established programs. In addition to just being a listing of required courses and their content, the catalog entries server as a marketing tool. A good entry will highlight the potential of the career path, the promise of the department to the students to deliver the appropriate courses and material, and the commitment of the university to support the new program.

LAUNCHING THE PROGRAM

Based on the plan initially proposed to and then approved by the university (Frezza, 2003), Gannon was able to launch the SE major with little impact on courses or faculty for the first two years. Based on the assessment of Gannon's strengths and those of the various departments as well as a review of requirements imposed by the policies of both the university and college, the courses taken by SE majors in the first two years were already offered within the university. These courses consisted of Liberal Arts core courses taken by all Gannon students, CIS core courses already offered and taken by the CS and MIS majors at the university, and introductory science courses already offered to several majors. The only exception to this is the *Discrete Math 2* course taken second semester of sophomore year. The Math department was willing to develop and offer this course in the necessary time frame. By design, the first two years of the program had little immediate impact on course delivery or teaching load – only one new one-credit course was needed. Our internal goal of trying to reuse as many of the existing Computer Science curriculum courses and sequences as possible had the significant benefit of our being able to launch the program prior to searching for new faculty.

Adding New Faculty

Adding a new faculty member to the department proved to be significantly easy for our situation, as one of the proponents of the program (who was CSDP qualified), by mutual agreement, essentially transferred from the Electrical and Computer Engineering department. Finding a second qualified faculty member was not as easy. Finding a potential faculty member with a good academic

background, worthwhile industry experience, an appropriate commitment to teaching and scholarship, who fits in the university/department culture and has not already taken on a higher-paying job in industry is a tall order.

While our experience has been somewhat limited, some of the problem areas have included recruitment of junior faculty; getting the right match for credentials, experience and fit have proven to be difficult. The typical Computer Science Ph.D. may not have any interest in 'core' software engineering topics; whereas Ph.D.'s from Engineering or Information Science disciplines may not have any significant software development background. In any case, many typical Ph.D.s do not have either experience or education in SE 'special topics' areas such as project management, software maintenance or even requirements.

Additional issues abound when searching for seasoned faculty members – while they often have more project and teaching experience, they also have the potential for more (and more complex) issues in areas such as benefits and tenure. Such issues are often institutional, and flexibility may not be available.

Course Pilots

This particular facet of our program design did not eliminate the need for additional staffing, however. Based on our assessments, we would need a new faculty member in the second year of the program to teach the first round of the new SE courses, and if enrollment took off, in year three or four we would need another faculty member to help with the additional sections that would be needed in the introductory sequence. These points were very important to painting the financial picture to the university about the distribution of costs and risks in launching the program. Financially, the big impact would be in years two and four; academically, the real impact would begin in the third year of the program; a change-management plan was needed.

The plan was to hire a new (additional) SE-qualified faculty member in year two, and additionally to offer all of the new junior-level SE courses in advance. This latter plan was part of a (pedagogical) risk-management strategy so that the new faculty member and other department faculty members could pilot the new SE courses prior to the first wave of SE students entering the courses. The expanded department faculty would then offer each of the new SE courses one year in advance of the first wave of SE students – with three semesters containing significant piloting of courses.

For the fall (piloting semester five) of their junior year, SE majors were scheduled to take three upper division SE-specific courses: *Software Design and Test*, *Personal Software Process*, and *Formal Methods in Software Development*. Of these, only one was new, as *Software Design and Test* was already a course offered and required of our CS majors and *Personal Software Process* was offered to our 1st-year graduate students. Hence neither of these courses needed significant modifications for the undergraduate BSSE population. The *Formal Methods* course was a different story – it was new to our faculty and needed to be developed and offered. Finding educational resources and faculty development seminars to support this course proved to be difficult. Developing this course offering required identifying and making decisions on course topics, approaches, tools, methodologies and textbooks that would work for our students.

During the next spring (piloting semester six), the impact intensified. The SE majors were scheduled to take two more new courses in the following year, so *Requirements and Project Management*, and *Software Architecture*, which were developed and offered in their pilot forms, knowing the regular group of majors would register in the following year. This additional workload was covered by the new faculty member.

The third year of the program (pilot for Semester seven) required the development and offering

of two new undergraduate courses, both offered in the first semester: *Software Testing and Quality Assurance*, and *Human Interface Design and Maintenance*. These courses, along with the first regular offerings of the three fifth-semester SE-specific courses accounted for the additional time provided by the faculty hired at the beginning of the second year of the program.

In addition to the courses and faculty needed, two other factors needed to be considered. First, the university Admissions department needed to be involved in the process. The program needed to be advertised as much as possible, and admissions needed to understand the requirements for admission to the program. They also needed to place the incoming SE students in the proper courses for the freshman year.

Finally, the issue of transfer students, both internal and external, needed to be addressed. Since the program was phased-in over four years, for the first two years, we would be unable to accept upper division transfers (unless they were willing to stay an extra year) since the upper division courses were not available during those first two years. We did, in fact, accept one sophomore transfer the first year of the program and he was able to graduate with just one additional semester.

CHANGE MANAGEMENT

One important issue to address early in the program development is to plan for change. This begins with outcomes and measurement. We were fortunate that many of the processes that we required in this area were already largely in place. The CIS department already had outcomes defined for the CS and MIS majors and some measurement tools in place.

Further, the Electrical Engineering and Mechanical Engineering departments were ABET accredited. Concurrently with the launching of the SE major, the CIS department was preparing for ABET accreditation for the two existing majors, and the EE and ME departments were preparing to renew their accreditation. To aid in this process, an online course evaluation tool was prepared to gather information specifically required by the ABET process. (A university-wide course evaluation instrument had been in use for all courses for several years, but it did not gather all information required by ABET.) This tool was used from the beginning of the SE program.

Even though we are only about to begin our fourth year of the program, and the first time the senior level courses will be offered, we have already made changes to the program. First, we realized that we had a hole in coverage in the operating systems area. To address this issue within faculty time and budget constraints, we added the full Operating Systems course to the list of required courses. To make room, we dropped an Introduction to Engineering course which had only partial content relevant to our needs. We moved the relevant content into pieces of existing courses where they fit the best.

One of the core Liberal Studies requirements is a basic business course. Many of our majors chose either Microeconomics or Macroeconomics. After two years of the program, we saw an opportunity to provide a business course more directly applicable to the SE majors. As such, we co-developed a course (*Project Economics*) with the business school which provides basic economics theory as well as the application of the theories in a project setting. This course is now the designated business course for SE majors.

Our current Software Engineering Curriculum (2007-8) is listed in Figure 4. Diagonal shading indicates reused Computer and Information Science courses. The darker grey shading indicates new courses developed for the Software Engineering major by the Computer and Information Science department. One of the seven originally proposed new Software Engineering courses (See Figure 3), the *Software Engineering Seminar*, was offered two times and it was determined that the course was not serving the needs of our software

engineering students. Therefore, it was removed from the curriculum. As noted in a previous section, *Discrete Math 2* was developed by the Math department for our software engineering program. The remaining courses required for the software engineering major, including the application domain courses, are coded in Figure 4 as indicated by the shading key. These courses were already

offered by various departments within the university, with the exception of *Project Economics* discussed above.

CONCLUSION

This article does not address the relative merits of the education provided by a traditional Computer Science program compared with a Software Engineering program. It does seem that there is a need to provide the type of Software Engineering curriculum discussed in the article and that the curriculum can be provided along with, rather than instead of, a more traditional Computer Science curriculum. Programs have been and can be introduced at institutions with diverse size, diverse overall focus, diverse program style, and diverse strengths.

This article discusses many items to consider in the process of planning and launching a new BSSE program. Further, obtaining program accreditation is highly desirable, in some cases necessary. Understanding the steps required by the appropriate accrediting body to obtain accreditation is mandatory at some point in the program's lifecycle. Understanding the steps very early and accounting for them during program planning will help smooth the journey to accreditation.

Chapter 5.12
Facilitating eLearning with Social Software:
Attitudes and Usage from the Student's Point of View

ABSTRACT

This article explores how social software tools can offer support for innovative learning methods and instructional design in general, and those related to self-organized learning in an academic context in particular. In the first section, the theoretical basis for the integration of wikis, discussion forums, and Weblogs in the context of learning are discussed. The second part presents the results of an empirical survey conducted by the authors and explores the usage of typical social software tools that support learning from a student's perspective. The article concludes that social software tools have the potential to be a fitting technology in a teaching and learning environment.

INTRODUCTION

One major task of higher education is to train students for the requirements of their future work by applying and adapting their knowledge to specific workplace-related requirements and settings. Due to the ongoing pressure on enterprises to cut costs, the periods of vocational adjustment in a company will become shorter and shorter.

On the one hand, the rising pressure of innovation and fast-paced development in the economy results in increased demand for continuous employee training. On the other, growing global competition forces enterprises to use available resources very economically so that employee training is considered to be necessary and desired even though it is conducted under considerable time and cost pressure (Köllinger, 2002).

According to these goals, the settings of the education must be changed adequately: "While most of higher education still ascribes to traditional models of instruction and learning, the workplace is characterized by rapid changes and emergent demands that require individuals to learn and adapt in situ and on the job without the guidance of educational authorities" (Sharma & Fiedler, 2004, p. 543).

In the field of higher education, it has become an important goal to develop "digital literacy" and educate learners as competent users and participants in a knowledge-based society (Kerres, 2007), but it can be assumed that there is a new generation of students, the "digital natives," who are accustomed to digital and Internet technology (Prensky, 2001a, 2001b).

Oblinger and Oblinger (2005) characterize next-generation students (called "n-gen," for Net generation) as digitally literate, highly Internet savvy, connected via networked media, used to immediate responses, preferring experiential learning, highly social, preferring to work in teams, craving interactivity in image-rich environments, and having a preference for structure rather than ambiguity.

According to a study conducted by Lenhart and Madden (2005), half of all teens in the USA may be considered "content creators" by using applications that provide easy-to-use templates to create personal Web spaces.

Classical face-to-face learning is seen as rigid and synchronous, and it promotes one-way (teacher-to-student) communication. Thus, it is not surprising that more and more students are opting for Web-based education as a more flexible and asynchronous mode (Aggarwal & Legon, 2006).

The higher education system should provide answers to this new generation of students who enter the system with different backgrounds and skills. They are highly influenced by social networking experiences and are able to create and publish on the Internet (Resnick, 2002).

Educators and teachers therefore have to consider the implications of these developments for the future design of their courses and lectures.

In 2002, a new term, "social software," entered the stage to refer to a new generation of Internet applications. One focus of this new generation is the collaboration of people in sharing information in new ways such as through social networking sites, wikis, communication tools, and folksonomies (Richter & Koch, 2007).

Wikis, Weblogs, and discussion forums will play a central role in the new context, so the areas of application and possibilities will enlarge enormously. It can be assumed that this will also have considerable influence on learning and the usage of these instruments as learning tools.

This article presents the results of an empirical survey in order to highlight the benefits of the above-mentioned Web-based social software tools from the student's point of view; 268 first-semester students, all in the first term of their studies at Austrian universities from different study programs, took part in this survey. The students were asked to use one or more of these tools as a learning tool. Participation in this survey was voluntary.

The presentation of the results of this survey is divided into three parts: first, the use of the tools by the students (before they started their studies); second, the experiences the students had made with the tools during the study; and third, the potential future usage.

The article concludes with a discussion of the results of this survey in contrast with other empirical studies already published. Also, the limitations of this survey and ideas for further research are pointed out.

THEORETICAL FRAMEWORK

This part refers to the necessary theoretical background required for the following empirical study, especially the areas of social software and learning.

Social Software

The term *social software* emerged and came into use in 2002 and is generally attributed to Clay Shirky (2003). Shirky, a writer and teacher on the social implications of Internet technology, defines social software simply as "software that supports group interaction."

Another definition of social software can be found in Coates (2005), who refers to social software as "software that supports, extends, or derives added value from human social behaviour."

Users are no longer mere readers, audiences, or consumers. They have the ability to become active producers of content. Users can act in user and producer positions and they can rapidly change the position.

Nowadays the term *social software* is closely related to "Web 2.0." The term *Web 2.0* was introduced by Tim O'Reilly (2005), who suggested the following definition:

Web 2.0 is the network as platform, spanning all connected devices; Web 2.0 applications are those that make the most of the intrinsic advantages of that platform: delivering software as a continually updated service that gets better the more people use it, consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others, creating network effects through an "architecture of participation," and going beyond the page metaphor of Web 1.0 to deliver rich user experiences.

Web 2.0 technologies such as blogs, wikis, podcasts, and RSS feeds or discussion forums have been dubbed social software because they are perceived as being especially connected and allow users to develop Web content collaboratively and publicly (Alexander, 2006).

Until now, the Internet (Web 1.0) has one big disadvantage: It is easy to get information in it, but it is quite complicated and inconvenient to act as an author and take part in the development of content. Web 2.0 should enable all Internet users to actively take part in the further development of the Internet. Everyone should be able to contribute easily. The focus of Web 2.0 is on the behaviour of the user. It should empower people to communicate, collaborate, contribute, and participate.

This growing phenomenon is very interesting and ought to be examined carefully in order to understand how the Web is evolving and how this continuously regenerative cycle of performance and technological innovation empowers "learning by sharing" (Thijssen & Vernooij, 2002).

Based on the key principle of the architecture of participation, social software can be seen as part of Web 2.0. Wikis, Weblogs, and discussion forums are tools that are seen as social software applications and were selected for further research and the empirical study presented below.

Related Empirical Research

Institutions in the field of higher education have made efforts to introduce various IT-supported learning tools in the daily routine of students and lecturers (Aggarwal & Legon, 2006; Dooley & Wickersham, 2007; Duffy & Bruns, 2006; Evans & Sadler-Smith, 2006; McGill, Nicol, Littlejohn, Grierson, Juster, & Ion, 2005).

Published results of the usage of Weblogs in the Prolearn project (http://www.prolearn-project.org) have shown that a large majority of respondents considers personalization and adaptation of the learning environment as important and crucial factors. Learning should be individualized to become more effective and efficient. Personalization is a key element of the learning process, and specific problems need specific solutions as students differ greatly in their backgrounds and capabilities.

Learning materials are typically too general in order to cover a very wide range of purposes and personal learning needs. Compared to classical learning, personalization can be the most important added value that e-learning can offer. With it, education can be optimised and adjusted to various working conditions and needs because students have different goals, interests, motivation levels, learning skills, and endurance (Klamma et. al., 2006).

Chao (2007) explored the potential uses of wikis in the field of software engineering (38 participants), especially for software project team collaboration and communication. Overall, 25 students agreed and 1 student disagreed (2 were neutral) that the wiki is a good tool for project collaboration. Concerning the applications of wikis, more than 23 students found that a wiki is a good tool for maintaining a group diary, managing user stories (project requirements), and project tracking and reporting. While a majority of students found that a wiki is a good tool for updating a project plan, managing acceptance tests, tracking defects, and developing user documents, there were also a significant number of students who disagreed.

First results using wikis for collaborative writing (about 40 participants) also reported similar results. In this study, students used wikis to write articles partly together with the lecturer.

After early problems with using the software and writing contributions in the wiki, students were able to write articles by themselves or in teams. The motivation among students was on different levels, so the lecturer had to increase it during lessons. Other students, however, were highly motivated and were creating the content and adding them to the wikis (Bendel, 2007).

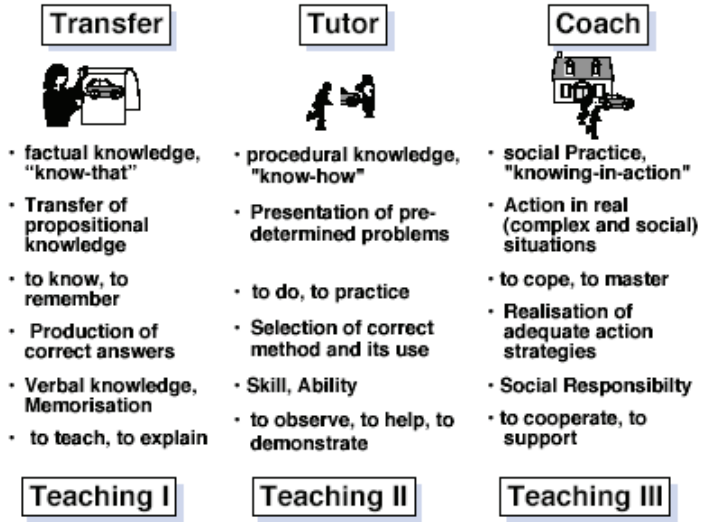
Constructivism and Learning: Presentation of the Learning Model

A constructivist point of view focuses on the learning process by looking at the construction of knowledge by an individual. As a consequence, there is a recommendation to align learning environments, especially in the academic context, and associated complex learning objectives with constructivist learning principles (Du & Wagner, 2005; Jonassen, Mayes, & McAleese, 1993; Tangney, FitzGibbon, Savage, Mehan, & Holmes, 2001). Learning is not seen as the transmission of content and knowledge to a passive learner. Constructivism views learning as an active and constructive process that is based on the current understanding of the learner. Learning is embedded in a social context and a certain situation (Schulmeister, 2005).

The constructivist approach shifts learning from instruction and design centered to learner-centered learning and teaching. The role of the educator changes from directing the learner toward supporting and coaching the learner.

Baumgartner (2004) has suggested three different prototypical modes of learning and teaching. These three different modes of learning and teaching can be neutral or specific so they can be applied across all subject domains. Therefore, each teaching model can be used to teach, for example, sociology subjects as well as to teach technical sciences. Learning can be portrayed as an iterative process that can subsequently be subdivided into different phases, which are summarized in Figure 1.

Figure 1. Prototypical modes of learning and teaching (Baumgartner, 2004)



In particular, these three different prototypical modes for learning encompass the following.

Learning and Teaching I: Transferring Knowledge

At the starting point, the learner needs to be provided with abstract knowledge to lay the theoretical foundations and to understand relevant signposts, road markings, and orientation points. This kind of factual knowledge is static and has little value by itself in real and complex situations. It merely serves as a shortcut to prevent pitfalls and to help to organize the student's learning experiences.

The knowledge of the student is based on knowledge possessed by the teacher. Students have to learn what teachers ask them to learn. The teacher has the responsibility to make the knowledge transfer as easy as possible.

Learning and Teaching II: Acquiring, Compiling, and Gathering Knowledge

In this section of the individual learning career, the student actually applies the abstract knowledge and gathers his or her own experiences. In order to limit the action and reflection possibilities, the learner interacts within a somewhat restricted, artificial environment, which is reduced in complexity and easy to control by the teacher. To provide feedback, the learning environment is designed to include relevant devices where students can deposit their interim products and teachers can inspect them.

The emphasis in this model lies on the learning process of the student. Teachers try to help the students overcome wrong assumptions and wrong learning attitudes, and assist in the reflection process of the subject domain.

Learning and Teaching III: Developing, Inventing, and onstructing Knowledge

Teacher and learner work together to master problems. This model includes problem generation and/or invention. The environment is constructed in such a way that it represents, at least in certain aspects, reality or reality in a constrained form. This model includes two-way communication on equal terms, using either linguistic representations or other adequate kinds of language.

Teaching III has strong links to constructivism. From a constructivist point of view, learning is considered as an active process in which people construct their knowledge by relating it to their previous experiences in complex and real situations in life. In their practical lives, people are confronted with unique, unpredictable situations whose inherent problems are not readily observable (Baumgartner, 2004).

Students should be enabled to invent new things, and produce or generate new knowledge. Consequently, learning and teaching at universities in most cases can be assigned to the requirements presented in Learning and Teaching II and III. In order to achieve this goal, a special learning environment must be provided.

Consequences for IT-Supported Learning and Teaching

Computer software can be used for all three models, ranging from programmed instruction (Learning/Teaching I) to problem-solving software (Learning/Teaching II), to complex simulations and/or so-called micro worlds (Learning/Teaching III). It is said that the inherent nature of the Internet brings the real world into the classrooms, and with its hyperlink structure it clearly advocates the model of Teaching III (Baumgartner, 2004).

The use of the Internet, especially through its social software, gains importance because it can contribute to exceed the limits of classical teaching models. By adapting learning and teaching models to the new technical possibilities, the roles of learner and teacher are becoming more indistinct because the learner can take a central part in the design and arrangement of the learning process (Kerres, 2006).

Systems that support learners with respect to the Learning Model III are called personal learning environments (PLEs). PLEs are mostly Web-based applications and are based on learning management systems (LMSs; Seufert, 2007).

PLEs are personal and open learning environments, and they are suitable for cross-linking content and people. Learners can use PLEs to manage individual learning progress. They are ideally available for lifelong learning and are supported by the following processes.

- setting up individual learning goals
- planning and controlling one's own learning concerning the content as well as the learning process
- combining formal and informal learning activities
- communicating with peers during the learning process
- establishing social networks or communities of practice
- using Web-based services, for example, syndication
- verifying the learning process with respect to the learning goals

Unlike an LMS, which is usually related to one special institution or to one special course, a PLE is focused on the individual learner. A PLE should combine a broad mixture of different resources and subsystems in a "personally-managed space" (Attwell, 2006).

In the previous decade, learning management systems were developed that moved toward enterprise-level applications, "but the wealth of new, user-friendly, tools in the Web 2.0 environment suggests that the all-in-one monolithic e-learning systems may be entering a phase of obsolescence by the ongoing development of the web" (Craig, 2007).

Social software applications have the potential to cope with these requirements (Brahm, 2007).

DESCRIPTION AND CLASSIFICATION OF SOCIAL SOFTWARE TOOLS

In the following section, three social software tools—Weblogs, discussion forums, and wikis—are described in more detail and the tools are compared. Students were able to select these tools during the empirical study.

Weblog

A Weblog, a compound of *Web* and *logbook*, usually just called "blog," is a Web site that contains new articles or contributions in a primarily chronological order, listing the latest entry on top.

Primarily, a Weblog is a discussion-oriented instrument especially emphasizing two functions: RSS feeds and trackback. RSS feeds, also called RSS files, can be read and processed for further use by other programs. The most common programs are RSS readers or RSS aggregators that check RSS-enabled Web sites on behalf of the user to read or display any updated contribution that can be found. The user can subscribe to several RSS feeds. Thus, the information of different Web sites can be retrieved and combined. Preferably, news or other Weblogs are subscribed to.

Trackback is a service function that notifies the author of an entry in a Weblog if a reference to this contribution has been made in another Weblog. By this mechanism, a blogger (person who writes contributions in a Weblog) is immediately informed of any reactions to his or her contribution on other Weblogs (Hammond, Hannay, & Lund, 2004).

Forum

A discussion forum or Web forum is a service function providing discussion possibilities on the Internet. Usually, Web forums are designed for the discussion of special topics. The forum is furthermore subdivided into subforums or subtopics. Contributions to the discussion can be made and other people may read and/or respond to them. Several contributions to a single topic are called a thread.

The application areas of the two instruments, Weblogs and forums, are quite similar. The most essential differences between Weblogs and discussion forums can be described as follows:

- A forum is usually located on one platform while many bloggers develop their own, individual environments. They connect their Weblogs via RSS feeds and trackback functions.
- Through the integration of RSS files and trackback functions, a discussion process can be initiated and continued, crossing the boundaries of the bloggers' own Weblogs without authors having to observe other Weblogs.
- Weblogs tend to be more people centered whereas forums are more topic focused. Through the use of Weblogs, learner-specific learning environments can be constructed without interfering with the learning environments of others (Baumgartner, 2004).

Wiki

A WikiWikiWeb, shortly called wiki, is a hypertext system for storing and processing information. Every single site of this collection of linked Web pages can be viewed through a Web browser. Furthermore, every site can also be edited by any person. The separation between authors and readers who write their own text, and change and delete it is obsolete as also third parties can carry out these functions (Augar, Raitman, & Zhou, 2004).

Learning Activities Supported by Social Software

The integration of different social software tools offers support in the following learning activities:

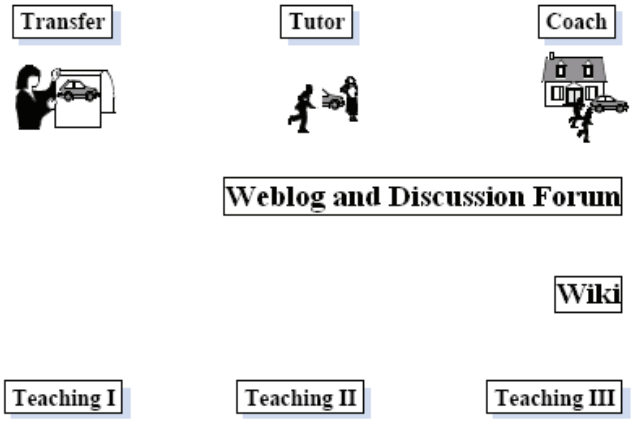
- Learning from different perspectives: The integration supports the exchange of ideas as well as finding like-minded people. Furthermore, social software tools simplify the process of establishing connections between people of the same or similar interests. Simultaneously, its open and expandable philosophy supports going beyond the thinking in groups (of a common interest) by supporting diversity and bringing together different perspectives and backgrounds (Efimova & Fiedler, 2004; Schulmeister, 2004).
- Synergies of self-organized and joint learning: Social Software tools provide a personal learning area for their authors. However, this does not force a general learning flow or learning style. Learners are not alone and can profit from the feedback of a community in order to examine and enhance the development of their own ideas (Böttger & Röll, 2004; Efimova & Fiedler, 2004; Fiedler, 2004).
- Digital apprenticeship: Through reading other wikis, forums, or Weblogs regularly, beginners are enabled to learn from experts. At the same time, they can actively participate in discussions beyond geographic or thematic borders (Efimova & Fiedler, 2004; Fiedler, 2004).
- Support for the development of the ability to learn (learning to learn): Through the publication of one's own thoughts and reflections, content is made available for assessment as well as for further development, thereby improving self-observation and self-reflection skills. The knowledge change of the learner will be improved (Baumgartner, 2005).
- Support for reflexive writing: The simple but efficient and rather robust encoding standard usually used in social software allows for the explicit modeling of content flows, feedback loops, and monitoring procedures of various kinds, thus supporting an ongoing reiterative process of explication and reflection (Fiedler, 2004).

Integration of Social Software Tools and the Learning and Teaching Modes

Baumgartner (2004) has integrated different types of content management systems in relation to the most suitable learning and teaching mode. He clearly states that the boundaries are overlapping and that every tool, in one way or another, could be used for every teaching model. Figure 2 presents the integration of the social software tools and the learning and teaching modes.

Weblogs and forums can be defined as discussion-oriented tools because the discourse and exchange of ideas related to a certain topic is the preeminent aim. Weblogs offer the possibility to support all three phases of the learning process. However, the main focus can be assigned to Modes II and III.

Figure 2. Prototypical modes and social software tool



Based on the multitude of interaction possibilities, wikis can be attached to Teaching III (Baumgartner, 2004). Additional functions were added to Weblog tools that go beyond the scope of the central use of Weblogs; for example, longer articles can also be stored. Through the creation of directories, a structured collection of links can be implemented.

Through the additional linking of Weblogs, wikis, and forums, there is the possibility to develop a personal knowledge collection (Kantel, 2003).

EMPIRICAL SURVEY

The purpose of this survey was to determine if the integration of Web-based social software tools (wikis, discussion forums, and Weblogs) are suitable to foster learning from the student's point of view.

Aim of the Survey and Methodology

Scrutinizing the possibilities and constraints of social software tools (wikis, discussion forums, and Weblogs) as personal learning environments, students at Austrian universities were asked to use one or more of the offered tools for their research, homework, and documentation purposes. In most cases, the collaboration of students was required to perform the assigned tasks.

The students were asked to use the tools for one course only during the winter term of 2006. Furthermore, there was no obligation for the students to use a tool at all; they were just encouraged to do so. Students were also offered the possibility to use two or three tools; the selection was up to the students.

The courses were organized as blended-learning courses so they included on-campus lessons and off-campus work in which the students could work face-to-face or using the social software tools.

More than 90% of the students attending the courses took part in this survey. In order to give the participants an impression of the functionality and usage of the tools, short presentations of the tools were made by an instructor before the students made their choice.

At the end of the testing phase—after 4 weeks of using the tools—selected students reported their experiences with the tools used. Students who had decided not to use the tools in the first place got an impression about the usage, advantages, and disadvantages of the tools from their fellow students. Following these short presentations, a

questionnaire was completed that provided the basic findings for further inspection and research.

A total of 268 first-semester students of different Austrian universities in five selected courses took part in this survey. The majority of the participants were between 18 and 20 years old. The portion of female students was about 17%.

According to a survey conducted by Seybert (2007) concerning gender differences in computer and Internet usage by young people (aged between 16 and 24), there is no gap between men and women in Austria. The proportion of women and men (in the relevant age class) that use a computer (almost) once a day is 72% the same. A study by Otto, Kutscher, Klein, and Iske (2005) indicates that there is a positive correlation between a formal educational background and the usage of the Internet in Germany: "Beside socio-cultural resources like family background, peer structures and social support in general, the formal educational background turns out to be the main factor for explaining differences in internet usage" (p. 219). As a consequence, for the analysis of the results of this survey, no distinction between male and female students was made.

Table 1 presents the distribution of the participants concerning the degree programs the students are attending.

For the further analysis of the results, no distinction according to degree programs will be made.

The questionnaire asked each participant questions about her or his subjective impression of the application of the tools. It included 5-point Likert scales for rating constructs such as eligibility, perceived quality, or enjoyment.

The study was conducted to find answers about the:

- usage of social software before the study started,
- selection of the offered tools,
- perceived quality of the contributions and the support for learning,
- applicability of the instruments to support communication and community building,
- correlation of the usage for private and educational purposes of the tools,
- fun factor in using the instruments, and
- potential future usage.

Table 1. Distribution of students regarding degree program

	Distribution
Management & Law	17%
Management & IT	31%
Management & Industrial Engineering	22%
Mechanical Engineering, Electronics	30%

The results of the study are presented in three parts:

- Part 1: Analysis of the usage of wikis, discussion forums, and Weblogs of the students before the study was started
- Part 2: Experiences made with the tools during the study
- Part 3: Potential future usage of the tools

Part 1: Tool Selection and Prestudy Usage

Due to the fact that the students could select the tools on their own, the Table 2 shows the results of this selection process.

According to Table 2, the combination of wikis and discussion forums is the most selected combination of tools (42.9%), followed by wikis only (23.1%) and discussion forums only (22.4%). In the end, only five students (1.9%) did not take part in the study; they did not select a tool, although they first had the intention to do so. Only one student used Weblogs only. Generally, Weblogs were not used very intensively by the participants.

Table 2. Tools selected by the students

	Percent	Number
Only one tool selected		
Wikis only	23.1%	62
Discussion forums only	22.4%	60
Weblogs only	0.4%	1
More than one tool selected		
Wikis and discussion forums	42.9%	115
Wikis and Weblogs	1.9%	5
Discussion forums and Weblogs	0.7%	2
Wikis, discussion forums, and Weblogs	6.7%	18
No tool selected		
No tool selected	1.9%	5

Table 3 shows the usage of the tools by the participants before they took part in the study. It indicates that wikis (76%) and discussion forums (78%) are currently the most widely used tools. Weblogs are only used by 11% of the asked students.

The results clearly show that the Weblog hype had not yet reached the surveyed students. Due to the fact that only about 11% of the students are currently using Weblogs, the results for this instrument are not published for the first part of the analysis. When it comes to the potential future usage of the instruments, Weblogs are taken into consideration again.

The following section presents the results for statements used in analyzing the usage in more detail.

Tables 4 and 5 present the current usage of the tools for private and educational purposes. First, the statement "I often use wikis or forums for private purposes" was presented.

Table 5 presents the results for the statement "I often use wikis or forums for educational purposes."

A huge majority (90%) stated that they use wikis for educational purposes and about two thirds (68%) used wikis for private purposes. Wikis are therefore more intensively used for

Table 3. Students already using the tools

	Wiki	Forum	Weblog

I slightly disagree	8%	24%
I disagree	1%	12%

educational purposes than for private purposes, whereas the usage of forums is exactly the opposite: They are more used for private purposes than for education.

The responses of the students concerning these statements were that wikis are foremost considered as a source of serious information, whereas forums are ideal for getting hints or clues to problems because of their privacy. Questions about computer problems, computer games, leisure activities, and so forth were mentioned. A repetition of this image can be identified when the disagreement with the statement is analyzed; 29% of the students do not or rarely use forums for private purposes compared to 36% for education.

Part 2: Experiences Made During the Study

This section presents the results of the study concerning experiences with the usage of the tools during the study.

Quality and Support for Learning

The following refers to statements concerning the quality of the contributions of wikis and discussion forums and their support for learning.

The results of the statement "The quality of contributions in wikis or forums is in general good" are presented in Table 6. The contributions of wikis are evaluated to be much better than those of forums.

The surveyed pupils had the opportunity to give reasons for their assessment concerning the quality of contributions via additional qualitative feedback. The following summarizes the addressed reasons.

One reason for the excelling grade for the quality of wikis is the "Wikipedian community." The term *wiki* is often seen as a synonym for the free online encyclopedia Wikipedia (http://www.wikipedia.org). Wikipedia is widely used for a great variety of tasks, including research on all topics needed for educational and private purposes.

In contrast to the good evaluation of the contributions of wikis, the open architecture of wikis was also mentioned. In most cases, this open architecture allows everyone to edit entries, which results in the uncertainty of whether the knowledge presented is correct or not. The quality of contributions in discussion forums was rated rather mediocre. Forums are primarily used for technical problems, especially computer-related problems; to get in contact with experts on certain topics, and to get information on online games.

The next statement, "The usage of wikis or forums leads to misunderstandings and confusion," is about the clarity of the contributions.

Only a minority think that the contributions are not clear and may lead to misunderstandings. In this case, wikis are also rated better than forums.

The next statements addressed the support of these instruments for learning. Table 8 summarizes the results for the statement "When reading contributions in wikis or forums, it is easier for me to acquire the learning contents."

More than half of the students express that reading contributions in wikis is helpful for learning, whereas only about 8% think that it is not helpful. Compared to forums, wikis were again much better evaluated, especially considering the big difference from the negative evaluations of forums.

Table 9 presents the learning support achieved by writing contributions. ("When writing contributions in wikis or forums, it is easier for me to acquire the learning contents.")

A different picture emerges in the statistics when comparing the evaluation of how writing an article or post supports the learning process. Here, forums take the lead when it comes to positive assessment. In both cases, there was a large number stating that writing is neither positive nor negative. The majority of the students read rather than wrote, while more students wrote in forums than in wikis.

Table 6. Perceived quality of contribution

	Wiki	Forum
I totally agree	38%	10%
I generally agree	52%	31%
Neither...nor (neutral)	10%	41%
I slightly disagree	2%	15%
I disagree	0%	4%

Table 7. Clarity of contributions

	Wiki	Forum
I totally agree	2%	4%
I generally agree	6%	18%
Neither...nor (neutral)	29%	37%
I slightly disagree	34%	27%
I disagree	29%	14%

Applicability for Communication and Community Building

The statement was formulated as follows: "Wikis or forums are appropriate to support communication."

The results clearly demonstrate that discussion forums are made for communication whereas wikis are rather seen as a kind of reference book or encyclopedia, as already mentioned above.

The results of the next statement, "Wikis or forums support the setup of communities," can be seen in Table 11.

Opinions about the applicability of wikis to establish a community is split. About 35% say that wikis are supportive of building a community compared to 25% who said that wikis do not support community building. The support of forums to build a community is rated much better: 50% indicated that forums are well suited to build a community. These results were to be expected because they confirm the nature of the instruments.

Fun Factor in Using the Instruments

In surveying whether students gain pleasure ("I enjoy using wikis or forums"), wikis again came out on top.

A majority enjoy using wikis (62%) and forums (56%). Considering the percentage of students who said that there is no ("I disagree") or little ("I slightly disagree") fun when using these instruments, wikis (6%) are much better rated than forums (18%).

Part 3: Potential Future Usage of the Tools

The third section of the empirical study deals with the potential usage by students who had not used the instruments before the study. Students gained knowledge and experiences by using the tools during the study by themselves or on the basis of the reported experiences made by their fellow students.

The first statement, "I will use wikis, forums, or Weblogs for educational purposes in the future," yielded the results in Table 13.

According to this study, wikis will have a bright future and will be used often for educational purposes, whereas forums will be used less often. About 54% of the surveyed students had the intention of using wikis more or less often in the future. About 16% did not think that they will use wikis often in the future and 30% are not yet sure if they will use this instrument.

The results for forums and Weblogs indicate no clear trend, but forums were rated slightly higher than Weblogs; 39% of the students stated that they can imagine using forums in the future for their education compared to 36% for Weblogs. At the other end of the scale, 45% did not have the intention to use forums (40% for Weblogs).

The statement "I will use wikis, forums, or Weblogs for private purposes in the future" leads to similar results.

Table 8. Reading contributions helps to acquire contents

	Wiki	Forum
I totally agree	23%	8%
I generally agree	36%	21%

I disagree	10%	6%

From this point of view, wikis are again the leading instrument, followed by forums and then Weblogs.

It must be said that the responses to this set of statements represented feelings, attitudes, and opinions about instruments that had not yet been used by the asked participants. The purpose of posing these statements was to gain insight into the mind-set in regard to these instruments.

DISCUSSION

The results clearly show that wikis are currently the most often used instrument and furthermore have the greatest potential as a tool for learning and knowledge management in the field of learning; these findings are in line with other empirical studies (Bendel, 2007; Chao, 2007).

Other studies (McGill et al., 2005; Nicol & MacLeod, 2004) report that a shared workspace helps to support collaborative learning; the possibility of being able to access and contribute to the development of resources at any time and from any location was especially appreciated by the students.

The survey at hand made a distinction between reading and writing contributions to wikis and discussion forums. The results show that 59% of students said reading contributions in wikis is helpful for learning (stating “I totally agree” and “I generally agree”) while only 21% stated that writing in wikis is helpful for learning. Reading contributions in forums helped 29% of the participants, whereas writing in forums was helpful to 26%. This survey supports the general statement that a shared workspace that supports a constructivist and learner-centered approach is helpful for learning.

The pedagogical value in the context of learning is described in several publications (Babcock, 2007; Hurst, 2005). Weblogs can foster the establishment of a learning and teaching environment in which students and teachers experience a greater degree of equality and engagement. Du and Wagner (2007) published results of a study

Table 12. Fun Factor in using the instruments

of an information systems undergraduate course (31 participants). This study indicated that the performance of students' Weblogs was a significant predictor for learning outcomes, while traditional coursework was not. Moreover, individuals' cognitive construction efforts to build their own mental models and social construction efforts to further enrich and expand knowledge resources appeared to be two key aspects of constructivist learning with Weblogs. According to this study, there is a potential benefit of using Weblogs as a knowledge construction tool and a social learning medium.

According to the survey at hand, Weblogs are not yet widely used, and their potential seems to be limited. It can be assumed that these limited prospects will change when the penetration of Weblogs into the daily routine of the students increase—for private as well as for educational purposes.

To avoid possible pitfalls about the application of these instruments in the context of learning, some social and psychological issues must be taken into consideration (Kreijns, Kirschner, & Jochems, 2003). Social interaction is essential for members of a team to get to know each other, commit to social relationships, develop trust, and develop a sense of belonging in developing a learning community. The size and the composition of the learning communities seem to be important factors in how interaction and communication within the learning community will take place (Dooley & Wickersham, 2007). There are also many unresolved issues, like the provision of the technology and the services, intellectual property rights and digital rights management, the security of data, access restrictions to the content, and information ethics (Attwell, 2006; McGill et al., 2005; Sharma & Maleyeff, 2003).

CONCLUSION

The aim of this contribution was to investigate the experiences of students using social software tools in the context of learning. Wikis, Weblogs, and discussion forums are typical social software tools and were used for this survey.

The results clearly show that wikis and discussion forums can support learning and collaboration. The usage of Weblogs in this study was limited and hence no statements about their applicability can be made. In order to assure a successful implementation of these tools, social and psychological issues must be taken into consideration as well.

The results of this study are the basis for the introduction of social software into education to help students set up individual learning environments. These learning environments should support lifelong learning.

There are likely to be other unplanned consequences of the intensive use of the Internet in general and social software especially. Further research is needed to explore possible problems and solutions.

The results of the empirical survey indicate that a long-term study in combination with the further development of social software tools may be promising.

Chapter 5.13
Continuous Curriculum Restructuring in a Graduate Software Engineering Program

Daniela Rosca

ABSTRACT

The development, maintenance and delivery of a software engineering curriculum present special challenges not found in other engineering disciplines. The continuous advances of the field of software engineering impose a high frequency of changes reflected in the curriculum and course content. This chapter describes the challenges of delivering a program meeting the needs of industry and students. It presents the lessons learned during 21 years of offering such a program, and dealing with issues pertaining to continuous curriculum and course content restructuring, the influence of the student body on the curriculum and course content. The chapter concludes with our recommendations for those who are seeking to create a graduate program in software engineering, with a special note on the situations where an undergraduate and graduate program will need to coexist in the same department.

INTRODUCTION

The objective of this chapter is to prepare those who are seeking to introduce a graduate program in software engineering (SE) for the challenges they will face. Towards that end, the lessons learned during 21 years of offering such a program at Monmouth University will be presented. As it will be demonstrated, the development, main-

tenance and delivery of a software engineering curriculum present special challenges not found in other engineering disciplines.

This chapter describes the challenges of delivering a program that meets the needs of industry and students in a highly dynamic field. The evolution of the curriculum induced by the domain's continuous advances and evolution in industry practice will be presented. The special meaning of continuous course content development in software engineering will be argued through issues pertaining to dated textbooks, ever-changing programming languages, operating systems, and software tools. The chapter will also present our experience in dealing with the diversity of the student body, and its influence on the curriculum and course content. The chapter will conclude with our recommendations for constructing a similar program, with a special emphasis on situations where an undergraduate and graduate program in software engineering will need to coexist in the same department.

BACKGROUND

Although software engineering was recognized as a field in 1968 at the NATO sponsored conference on the subject (Naur, 1968), it took universities and colleges a significant amount of time to respond to that fact. It was not until 1986 that Monmouth University (MU) started a graduate program dedicated to software engineering, which was offered by its Computer Science Department. In 1995 Monmouth created the first Software Engineering Department in United States. Now it is one of the pioneer universities offering a bachelor's degree in software engineering.

One motivation for creating a separate software engineering program and department was the awareness of the skills that industry would like students to have upon graduation, which are not stressed by most computer science curricula. These skills include teamwork, communications, time management, engineering problem solving, quantitative and qualitative process management, reuse, requirements management, system architecture, testing and project management.

As one of the few universities with extensive and comprehensive experience in offering software engineering programs, we have learned much about providing such a program. With more and more undergraduate software engineering programs appearing, we feel it is beneficial to other institutions for us to share the problems encountered and lessons learned over the past 21 years. A summary of the problems encountered and the lessons learned are presented here:

- **Continuous curriculum restructuring.** One can expect to revisit the overall curriculum of the program every four to five years, in order to accommodate changes in industry practice and educational expectations. This is reflected also in the historical investigation of the graduate software engineering curriculum reported in (Duggins, 2002).
- **Continuous course content restructuring.** It is critically needed due to the dynamics of the field. The continuous development of course content implies also a continuous development of course projects, and dealing with dated textbooks, ever changing operating systems, programming languages and software tools.
- **Hiring and retaining faculty.** The need for new faculty to have a record of sustained scholarly accomplishments and industrial experience enforces great restrictions on the number of available candidates, as it was also notified by Glass (2003). Retaining faculty is complicated by the fact that in addition to performing their normal teaching duties SE faculty must continually keep up with changes in the field as a whole.

- **Influence of the diversity of the student body on the curriculum and course content.** Issues raised by a diversity of educational backgrounds, employment status, educational goals, and communication skills introduce challenges that need to be dealt with by any software engineering program.

The remainder of the chapter discusses in detail the topics presented above. It begins with the presentation of the curriculum evolution over the history of our program. Then it discusses various issues involved in the continuous changes of the software engineering course content. The subsequent section outlines our experience in hiring and retaining the faculty, followed by a presentation of the student body influence of the diversity of the curriculum and course content. The chapter concludes with the presentation of our recommendations for those interested in starting a graduate program in software engineering, and future trends of the MU program. This discussion will emphasize the accommodation of an undergraduate and graduate program in software engineering in the same department.

CONTINUOUS CURRICULUM RESTRUCTURING

Over its short history, software engineering (SE) as a field has been a moving target. We have observed the introduction of the capability maturity model, the unified modeling language, personal and team software process, and corporate adherence to ISO Standards emerge as major forces within software engineering organizations. We have observed important changes in analysis and design with transitions from structured analysis and design ,to object-oriented analysis and design. Even the architectures being released today have shifted from client-server architectures to distributed architectures with the current trend being focused on service-oriented architectures.

A curriculum that addresses the skills and practices required by professionals in this field must continuously reinvent itself over time. The curriculum of Software Engineering changes with a frequency on the order of twice a decade as opposed to decades for engineering (Clough, 2005) and sciences (Stryer, 2003), in general. Just about every aspect of the software engineering curriculum is susceptible to change over a decade. In order to accommodate industry's needs and to keep pace with the advances of software engineering as a field, we have added or dropped courses, and added new tracks and programs. The decisions were made in the context of creating and maintaining a balance between the theory, technology and practical aspects of software engineering.

Changing the curriculum can not be performed in an ad hoc manner. We follow a well-defined process. First, the faculty discusses the need for change based on feedback from industry, students, and current publications. The acquisition of feedback is a continuous process that is assisted through an industry advisory board, alumni surveys, student exit interviews, student learning outcomes assessment, periodical evaluation of the program by an external reviewer who is a prominent figure in software engineering education, and attendance at professional meetings. We have established a set of learning outcomes that we monitor on a regular basis and we take into consideration when the need for a significant curriculum change is required.

Next, the program director writes a proposal identifying the new curriculum, and any additional courses that might be required. This effort includes writing a complete syllabus for each course that is introduced, modifying existing syllabi for courses

with significant content changes, and a justification for each course that is dropped.

The proposal is put forth to the faculty in the department for comments. Comments include challenges to the changes in course content and discussion of the overall package. The syllabi for the various courses may undergo several iterations.

Once the proposal is approved within the department, the proposal is sent to the chairs meeting within the school. Often times, changes to the software curriculum may require changes in the course content of other departments (e.g., computer science and the business school). If significant push-back arises from the other departments within the school, the proposal is reconsidered by department.

At the school chairs meeting it can be decided that a stronger business case is required. An external body typically develops this business case. It is either a survey developed by an independent firm, or by an external industrial advisory committee. The business case reflects the needs and state of industry, which will attract new students.

After the eventual suggestions for change are incorporated into the proposal, it is submitted to the university graduate studies committee. Here the curriculum is evaluated in terms of its consistency with the University Policies applied to graduate programs. This includes establishing maximum class sizes, the number of contact hours, assignment of lab fees, and other factors.

Next we present the evolution of the Monmouth University's Graduate Software Engineering Curriculum. This evolution shows a gradual transition from a software engineering program created inside a Computer Science department, towards a program with engineering courses that span the entire software lifecycle. It incorporates the results of a strong collaboration between academia and industry (Powell, 1997).

The Initial Curriculum (1986)

The initial software engineering curriculum at Monmouth University consisted of 30 credits, with 6 core courses and 4 electives (see Figure 1). The core courses covered in detail only the implementation (in Ada) and project management aspects of the software lifecycle, due to the limited availability of faculty with an appropriate background. The curriculum looked more like "a computer science curriculum with an engineering flavor" (Dart, 1997), covering classic computer science courses such as algorithms, operating systems, computer architecture and database management systems.

Students' practical training was accomplished in a 3-credit practicum course. This course consisted of a team project to develop a software system from initial requirements to the final, tested and documented product. The early curriculum was biased more on theoretical aspects (notice the heavy concentration on mathematical foundations of SE), with less exposure to specific SE technology and practice, as was very early recommended in (Ford, 1987).

1991 Curriculum Changes

This curriculum added a number of SE courses, including formal methods, formal specifications, software process and SE environments (see Figure 2). However, it still had a bias towards computer science, offering an artificial intelligence course, 4 courses of mathematical foundations and formal methods, and 4 courses in network technology, due to our geographic location in an area dominated by the telecommunications industry. It was similar to the First MSE model curriculum (Ardis, 1989a; Ardis 1989b) that recommended a set of 10-12 courses, which comprised 6 core courses, 3 or more electives and a two-semester practicum

Figure 1. 1986 curriculum

Core Courses
(6 Courses = 18 Credits)
SE 501 Mathematical Foundation of Software Engineering I (3 credits)
SE 505 Programming-in-the-large (3 credits)
SE 510 Computer Network Design (3 Credits)
SE 516 Software Engineering I (3 credits)
SE 518 Project Management (3 credits)
SE 525 System Project Implementation (3 credits)
Elective Courses
(4 Courses = 12 Credits)
SE 502 Mathematical Foundation of Software Engineering II (3 Credits)
SE 506 Programming-in-the-small (3 credits)
SE 509 Programming Languages (3 Credits)
SE 511 Protocol Engineering (3 Credits)
SE 512 Algorithms Design and Analysis (3 Credits)
SE 514 Computer Architecture (3 Credits)
SE 515 Operating Systems Implementation (3 Credits)
SE 517 Software Engineering II (3 Credits)
SE 519 Database Management (3 Credits)

Figure 2. 1991 curriculum

Core Courses
(6 Courses = 18 Credits)
SE 501 Mathematical Foundation of Software Engineering I (3 credits)
SE 505 Software System Design (3 credits)
SE 506 Formal Methods in Programming (3 credits)
SE 516 Software Engineering (3 credits)
SE 518 Project Management (3 credits)
SE 525 System Project Implementation (3 credits)

Elective Courses
(4 Courses = 12 Credits)
SE 502 Mathematical Foundation of Software Engineering II (3 Credits)
SE 503 Intro. to Computer-Communication Networking (3 Credits)
SE 509 Programming Languages (3 Credits)
SE 510 Computer Network Design (3 Credits)
SE 511 Protocol Engineering (3 Credits)
SE 519 Database Management (3 Credits)
SE 522 Software Engineering Environments (3 Credits)
SE 532 Software Process Quality (3 Credits)
SE 534 Formal Specifications of Software Systems (3 Credits)
SE 536 Fundamentals of Computer Security (3 Credits)
SE 538 Advanced Topics in Networking Topology (3 Credits)
SE 540 Introduction to Artificial Intelligence (3 Credits)

project. However, due to the lack of qualified faculty, the core courses offered were not able to cover the entire software lifecycle.

1995 Curriculum Changes

In 1995 the curriculum was substantially changed to include 36 credits, with 10 core and 2 elective courses (see Figure 3), in order to comply with the Software Engineering Institute model curriculum (Ardis, 1989) and the 1991 Computing Curriculum guidelines (Tucker, 1991; Ford 1991). That curriculum covered the entire software lifecycle in detail, by offering 3 new courses, specifically in requirements, implementation and reuse, and testing and quality. A former elective, software systems security, became a core course.

Having such a heavy core, this curriculum offered little flexibility for learning aspects of SE that students would be most interested in. Another major change was reflected in the introduction of several new courses that would form 6 credit elective specialization tracks: in distributed software systems, software management, information systems, and real-time systems. These tracks were introduced as a response to the needs and feedback from the local industry, and government collaborators (Powell,1997). The curriculum change was made possible by hiring faculty with both theoretical background and working experience in industry, supplemented

Software Management
SE 531 Software Organization Management
SE 532 Software Quality Management
Information Systems
SE 541 Information Systems Architecture
SE 542 Information Systems Engineering
Real-Time Systems
SE 551 Real-Time Software Analysis & specification
SE 552 Real-Time Software Design & Implementation

with a substantial help from adjunct faculty with expertise in specialized areas of SE.

1996 Curriculum Changes

In 1996 minor changes were made in the curriculum. It remained a 36-credit program, with 9 core and 3 elective courses, which offered a bit more flexibility than the previous program. The curriculum covered all the aspects of the software lifecycle. The capstone course was either a 3-credit practicum, or 6-credits of thesis research. The introduction of a thesis option was made possible by attracting faculty with the desire to engage in research activities.

1998 Curriculum Changes

The 1998 curriculum represented another major change by providing for much more flexibility in a 36 credit program, with 5 core, 5 elective courses, and a 6-credit practicum or a 6-credit thesis (see Figure 4).

The recognition of the importance of exposure to practical experience in a software engineering program has lead to the increase of the practicum project from 3 to 6 credits, and to the introduction of term projects in most of the courses in the curriculum. This is similar to the recommendations of the First MSE curriculum (Ardis,1989) of offering a two semester practicum and as much as 30% of the program be dedicated to project work.

The MU curriculum continued to follow the software life-cycle model, as opposed to the CMU Model (Garlan, 1995), which emphasized teaching "cross-cutting principles of software development" throughout the curriculum. As such, the CMU Model offered five core courses organized around modeling, methods of development, management, analysis and architecture. Also, they included a software development studio for the development of practice skills, during the entire duration of the program.

The 1998 MU curriculum has added a new course, The Process of Engineering Software, which largely follows Watts Humphrey's Personal Software Process (PSP) principles (Humphrey, 2005). The introduction of this course was justified by the need for graduates who are aware and have the necessary skills for predictably producing high quality systems, in a timely and cost effective manner, using reusable components as much as possible in their work. In spite of the hard work necessary for the manual input of the data for the various forms and templates involved in the PSP, students have given us very positive feedback about the usefulness of the principles learned in this course. For alleviating the clerical work related to the manual input of data, we created a semi-automated tool to support the PSP process (Rosca, 2001). This tool was the result of a two-semester practicum project of one group of students.

Two of the former core courses, mathematical foundations of SE, and principles of SE, have been transformed into preparatory (bridge) courses (see Figure 4). Together with three other programming courses the "bridge" program is offered for students with an undergraduate major other than computer science, computer engineering, electrical engineering, or information systems. After taking the 15 credit preparatory courses and a one-semester project course, students can receive a certificate in software development if they don't wish to pursue a Master's program.

The elective courses included in this curriculum were necessary for completing a chosen specialization track, such as organizational management, telecommunications, embedded systems, and information systems. These 15-credit tracks were much more comprehensive than their counterparts in the 1995 curriculum. They comprise courses from other disciplines such as business, electrical engineering and

computer science. However, students have been able to select elective courses across tracks if they didn't want to pursue a specialization. A brief description of the specialization tracks is given next.

The Organisational Management track prepares students to become software development managers or specialists in software process improvement. Topics of study include process improvement, quality management, organisational development and management, risk management and project planning and management.

The Telecommunications track prepares students to become specialists in telecommunications. Topics of study include networks, software systems security, and evaluation of telecommunications systems.

The Embedded Systems track prepares students to become specialists in embedded systems development. Topics of study include specification and analysis of embedded real-time systems requirements, design and implementation of embedded real-time software systems, performance evaluation of embedded real-time software systems, and development of real-time components.

The Information Management track prepares students to become chief information officers or specialists in information systems integration and development. Topics of study include information technology management, specification and analysis of information systems, evaluation of information systems, and development of information systems software components.

2002 Curriculum Change

In 2002, the only curriculum change was the addition of a new specialization track: the Management of Software Technology, offered in collaboration with the Monmouth University School of Business. The idea of this track grew out of the recognition that industry is outsourcing increasing amounts of software development. This track prepares students to be chief technology officers or specialists in the acquisition of software systems for businesses. Topics of study include assessing the impact that software can have on organizations, the development of requirements for system acquisition via purchase or outsourcing, the assessment of software technologies with regard to organizational needs, and implementing a controlled introduction of technology into an organization.

All the knowledge areas of the Software Engineering Body of Knowledge (SWEBOK) project (Bourque, 2004) can be identified in this curriculum.

CONTINUOUS DEVELOPMENT OF COURSE CONTENT

Technologically, the computing field has undergone significant changes that have forced alterations in the material taught within Software Engineering courses. Since the inception of our SE Master's program, we have witnessed the widespread adoption of Object-Orientation (along with massive changes in techniques and methodologies), the phenomenal explosion of the World Wide Web, the emergence of Java, and the move of security requirements from corporate to consumer platforms, just to name a few of these changes. Therefore, the material covered within a curriculum that addresses the technological understanding required by professionals in this field, needs to be continuously updated over time.

This problem emerges in several different forms. In particular,

- Continuous course content changes
- Dated textbooks

- Operating system/programming language biases
- Continuous development of course projects

Each of these areas is discussed in greater detail in the paragraphs that follow.

Course Content Changes

One can expect to have to revise course material every year. This is necessary to accommodate technological changes and to incorporate new industrial practices. For example, since the inception of our program we have changed the programming languages taught in class from Ada, to C++ and Java; in the requirements engineering course object-oriented analysis methods were added to the structured analysis methods (Rosca, 2000); in the design course a transition was made from structured design to object-oriented design, component-based design, and architectural design. In the testing course we have added segments on testing applications that are constructed using commercial off-the-shelf (COTS) components, using automated testing and test management tools. For project management more content was gradually introduced on the use of scheduling tools, such as MS project, risk simulators, like Risk+, and discussion of the use of buffer tasks in the planning of software development projects (McDonald, 2000). The burden of this continuous course creation or updating could be alleviated in the future by the curricular materials offered by the SWENET project (Lutz, 2003), created by the professionals in the SE community for the use of the community, at large.

The continuous revisions of course material constitutes a significant amount of work on the part of the faculty. In as little as three years, the changes within the field are significant enough that many courses have to be totally redesigned. The adoption of UML and its subsequent evolution has forced revisions in design diagrams, the vocabulary used to describe designs, and introduce new best practices.

Dated Textbooks

As technology changes and software engineering evolves, the ability of texts to keep up with these changes is severely stressed. An instructor will find himself or herself utilizing three or four texts in order to properly cover a topic area. Books will seemingly contradict each other, only because they were published two years apart. Often, a book that is only three years old will contain many concepts that have been already superseded or renamed. Many excellent textbooks have not been updated to use current representations, such as UML2, for example.

This forces faculty continuously research new and updated prints. The faculty has to take into consideration student feedback on the usefulness of the recommended textbooks. Some new textbooks might be already dated at the time of their publication.

Operating System/Programming Language Biases

Few topics seem to generate as much debate as the selection of which operating system (OS) or programming language should be the lingua franca for course work. It seems that everyone has an opinion or a realistic need to learn one environment over another. The selection of one environment over the other has significant impacts on the tools available for use by the instructor, the knowledge that the instructor has to bring into the classroom, and the equipment that must be maintained. In our case, over the years we have migrated from UNIX platforms, to Windows, and to dual-boot machines that run both Windows and Linux. Most of the students are familiar with both operating systems, since different instruc-

tors favor one OS over the other. They appreciate the flexibility offered by the dual-boot machines available in our labs.

The programming language debate is a little more problematic than OS preferences. Many of the students at the graduate level have jobs in which they work in C++, Java, or C#. The students often insist that the programming language that they use in the workplace be utilized in their courses. The problem is that choice of programming language can significantly impact what is appropriate content for a course. Designing C++ programs utilizes different patterns than those used in designing Java programs, since C++ programs must necessarily and explicitly manage memory. Historically, the choice of programming language has been made largely based on inputs from the market and external program reviewers. For example, at the time this paper was written, most courses use Java, with the exception of the real-time systems course which still uses C and C++.

Continuous Development of Course Projects

Faculty, students, and industry have universally recognized the need for hands-on experience (Ellis, 2000). Without practical training, students and industry complain that the material will be too theoretical and that graduates would have trouble applying the theory to real world projects. This has led us to incorporate projects into the majority of courses taught in the program, while maintaining a balance between the theoretical and practical aspects of the courses. The type of projects has changed over the years: we have started with stand-alone systems, to continue with distributed, web-based, service-oriented systems.

The program culminates with a two semester practicum, where students work in groups on all phases of a real-world project, starting with requirements elicitation, design, implementation, and testing. Unlike the course offered at University of Southern California by B. Boehm (Boehm, 2006), in our practicum there are no lectures, because it is assumed that students have already covered all software engineering core courses in the curriculum. Students need to follow a well defined software process, producing all the necessary documentation that covers the product life-cycle. Although the process is not prescribed by the instructor, as in (Germain, 2003), most of the students follow a heavy–weight type of process, such as UPEDU (Robillard, 2001). The students practice teamwork and communication skills, while working on a large-scale project proposed by a real client. The clients are either from our campus, or companies from the area surrounding the university. They are asked to provide comments and evaluate the deliverables, in addition to the instructor. The type of project proposals we get from the industry partners points us to areas that need to be covered by the curriculum.

The course/term projects are administered at the beginning of the semester, and have a couple of milestones spread along the semester. The instructors check the documents and/or software applications delivered at each milestone and provide feedback to the students. The instructors provide the project statements. The members of the project teams are either established by the students, when they are not new to the program, or when no preferences are expressed, the instructor makes the choices. The teams have the authority to choose their leaders, and the role of each member.

The introduction of projects into a Software Engineering course encompasses its own set of difficulties. While a simple program for shuffling cards may suffice to teach students about algorithms and data structures in a programming course, software engineering has to deal with much larger problems in order to demonstrate the value and need for an engineering process. The

result is that projects have to be big, but not so big that they cannot be performed within the confines of the course. Because the project has to be big, it has to be structured such that the students can incrementally develop it as the course unfolds.

As the course content, technology and available tools change, the course projects need to change too. We have found that the size issue can sometimes be addressed by partially completing the project before presenting it to the students. This might require the development of a set of requirements before introducing a larger project into a software design course, providing some economic or financial analyses before introducing a project into a software project management course, or developing requirements and code before introducing a project into a testing course. In any case such a strategy requires that the instructor spend significant time doing the background work and documenting the results of that work so that the students can make good use of it as they proceed with the next steps. This way the students are encouraged to concentrate on tasks for a specific project that are unique to the course in which the project is being used.

Hilburn (2006), who wants to develop a comprehensive case study along with education material that can be used throughout the curriculum, proposes another alternative. This way, students will use the output of one course project work in subsequent courses, and will be able to better understand the connections between the topics taught in different courses. Again, this approach requires more work for faculty while making it more difficult to adapt courses to technological advances.

DIFFICULTIES ATTRACTING AND RETAINING FACULTY

Software Engineers, even in difficult economic times, are a highly sought after commodity. It is extremely challenging for any software engineering program to both attract and retain their faculty, in USA or around the globe (Grant, 2000). We noticed that the stability of the faculty makes a program more attractive to prospective students.

It is very difficult to attract appropriate faculty, as it has been observed by Glass (2003). In particular, faculty members usually are acquired from computer science backgrounds and/or from industrial practice. The problem with faculty from computer science backgrounds is that their backgrounds are in computer science rather than software engineering. The problem with acquiring faculty from industry is that often they do not have documented credentials (a PhD degree) and a documented trace of their scholarly work.

With the need to continuously update course content and curricula, to keep up or advance the state of the field, the load on a faculty member in software engineering tends to be significantly greater than in some other academic areas. Given that it is very difficult to hire faculty with the appropriate academic and industrial backgrounds, many of the hires are often non-tenure track. We are very fortunate to be positioned in a strong high tech industry area, with a steady supply of teachers with a very good industry experience, who are seeking to augment their income, are between jobs, or are retired.

A real solution for the administration is to provide competitive salaries and support consulting or research activities. This enables faculty to make up any shortfalls in salary and keep abreast of the industry needs and practices. With respect to this issue, MU offers faculty one day a week to spend on research or consulting activities. Also, MU has been successful in hiring excellent faculty with a PhD degree in areas other than computer science, with a strong industrial experience in software development.

We are aware that this solution might not be easy to implement at many universities, therefore

we are suggesting another venue for attracting and retaining faculty: the creation of a research center or institute on campus. This way faculty with complementary expertise can collaboratively work on interesting, complex projects and create rich opportunities for research and publications. This allows faculty to keep current with the state of research and practice, feed this information into a curriculum that is up-to-date (Boehm, 2000), reduce the teaching load, and build a cohesive faculty community. MU has created the Rapid Response Institute, where faculty from the SE department works together with faculty and students from around the campus on research and applications for Homeland Security.

DIVERSITY OF THE STUDENT BODY

In the 21-year history of the software engineering program at MU we have observed increasing diversity within the student population. The diversity spans several dimensions: educational background, employment status, educational goals and native language. The successful program must address all these dimensions of diversity.

Educational Backgrounds

Consistent with the origins of the program, many students in the graduate program achieved undergraduate degrees in computer science. These students have strong programming skills, but very seldom have the engineering discipline that emphasizes understanding the problem to be solved, or the process to be followed. These students tend to immediately start coding once they receive a problem to be solved. Students asked on more than one occasion why it was necessary to design a program when they could write one faster.

We also have a large population of students that are coming into the graduate program from other engineering and non-engineering disciplines. These students usually are much more accepting of engineering processes, but have relatively weak programming skills and minimal knowledge about how computers function. To accommodate them we have had to incorporate a set of preparatory courses to provide the programming skills and computer knowledge necessary to succeed in the program.

Our program has already started receiving a new group of students. These students have undergraduate degrees in software engineering and already have a good understanding of engineering practices balanced with programming skills. At this point, our program had to address increasingly more advanced software engineering topics that may be beyond the knowledge of the other two groups of students. A detailed discussion of this topic is deferred to in the Future Trends section.

Employment Status

The employment status of students has significant impact on the program. It affects how long students are in the program, the effort that they put into assignments, their willingness to accept course material, and when classes are offered. It should be noted that (with a few exceptions) students entering into the program full-time usually find work at the end of their first year and become part-time students. The majority of our student population attends school part-time with full-time employment in the software industry. Most of our classes are offered in the early evening to accommodate them.

The fact that the average student is employed full-time and attends classes part-time means that they may be in the program for as long as 8 years. In fact, the population of students is much more stable than the curriculum. Some students have

graduated on curriculums that have been replaced twice since they enrolled in the program.

Employment in the software industry has significant impact on the willingness of some students to accept the concepts taught in the classroom. These students have already acquired work habits that are not consistent with best practices. Students often state that they don't perform a particular engineering practice at work and that they don't see a need for it. Of course, many of these same students talk about how their projects at work tend to be chaotic. Other students report the difficulties they've encountered in trying to practice in their conservative organizations what they've learned in class. Either case tends to undermine the instructor in presenting new material in the classroom. Here is one of the situations where the instructor's industrial experience plays an important role in both selecting the material to be taught and in responding to student concerns regarding the usefulness of the topics learned in the real world.

Employed students also tend to focus on what they immediately need to succeed in today's workplace. There is often an insistence on learning a product (such as Oracle or Sybase) rather than the concepts (i.e., database principles). This emphasis on skill rather than knowledge runs counter to the goals of the program that are the development of software engineers who can lead their organizations into the future. We have included some of these products into our classrooms, but the main goals of the courses remain to teach the engineering principles of the field, which can be applied to a large number of products.

Students who are not employed in the industry have problems prioritizing the material being taught or placing it in the context of delivering a product. If they are required to know C++, they assume that all employers develop code in C++. They are often surprised when they get a job and discover that they will have to learn a new programming language. Students are occasionally concerned that courses cover many different methods and approaches to achieve a given goal rather than emphasize one method. They have to be taught to understand that the knowledge and skill they acquire in school will have to blend into whatever organization they join, and that they need to engage in a lifelong learning process that is inevitable in this dynamic field.

Educational Goals

It would be nice if all students entered the program with the desire and goal of becoming a software engineer and delivering a specific kind of product. However, the educational goals of the students range from wanting to know all about software and engineering, to the other extreme where they only want to get the credentials that will allow them to earn a higher salary. Our student body appears to be driven by a small number of educational goals, as we were able to derive from their application packages, advising sessions and an alumni survey. These are:

- Get the business and process knowledge that will allow them to manage software projects and people.
- Get the skills and knowledge that will allow them to be more productive in their chosen career.
- Start a career in which they can have a significant income
- Get a job in the software field that does not involve a lot of coding.

The major impact of these goals concerns the subject areas that interest the student. We have had to tailor our curriculum to respond to these different goals. We find a significant fraction of the students are very interested in the process, project management, and organizational man-

agement courses. Others find that the courses on requirements and software testing give them an entry point into a part of the software business that does not appear to require major coding efforts. Finally, the courses that emphasize specific types of software systems (real-time, information, and embedded systems) attract those students that are interested in gaining the particular knowledge and skills that will allow them to master their chosen field of work.

Communications Skills

There is significant diversity among our students in terms of their communication skills. However, communication skills are critical in software engineering, being considered as important as the technical skills (Teles, 2003; Lethbridge 2000). The average software engineering student will probably produce more documents and make more public presentations than the average English major. Communications have to be precise, unambiguous, complete, logically sound and well structured. Oral presentations have to convey complex information under time constraints. Students have to learn to gauge how much information is to be conveyed. This requires that they judge what their audience can be expected to know and what must be presented. Although typical undergraduate general education programs attempt to teach these skills most students who enter our graduate program require additional coaching and training in this area.

International students are often at a disadvantage due to the fact that English is their second language. This affects their writing ability where a weakness in vocabulary often prevents them from expressing themselves clearly and succinctly. It also undermines their confidence in public speaking due to concerns about their command of the language and fears that others will not understand them because of their accents. It can also severely limit their participation in class discussions.

International students are not the only ones with problems in communications. Many of the students, particularly those with computer science backgrounds, are not used to writing technical documents. While they may be good at writing code, they often have difficulties in expressing themselves succinctly in a written document.

The most direct approach to dealing with significant changes in the student population has been to adapt the curriculum and individual courses to meet the changing needs of our students. Employed students are encouraged to express their perspectives on the material so that their experiences can be shared with students that have yet not entered the field. In some classes, programming assignments can be written in Java or C++ depending upon the student's choice.

Another change has been the incorporation of more term papers into course work to allow students to get greater experience in writing. Papers are graded on technical content, structure, adherence to topic, and on the use of language. Corrections are suggested and students have a chance to resubmit corrected work. With respect to verbal communications, students are required to make oral presentations of their term projects. This way, until they reach the capstone project, students would have had the opportunity to exercise their communications skills several times. We have also observed significant progress in the communication skills and self-confidence of students when we created multicultural teams, and encouraged informal peer-mentoring. As one of our external program reviewers observed, the oral communications skills of students significantly improved when they were repeatedly videotaped, and discussed the strengths and weaknesses of their recorded presentations with the instructor.

GUIDANCE ON STARTING AND MANAGING PROGRAMS

Based on the experience described above in starting and managing Monmouth University's software engineering program we would offer the following advice to academic departments that are considering a similar program:

1. Conduct research to determine the most current curriculum recommendations from the IEEE, ACM and other sources.
2. Find out, by participating in national groups and committees that develop those recommendations, what likely future changes might take place.
3. Enlist the academic institution's industrial advisory boards to determine how the general recommendations need to be tailored to suit the needs of local industry. The partnership with the local industry will bring multiple benefits, such as a good source of real world projects for courses, student placement for summer internships, industry guest lecturers for courses or a research seminar.
4. Form a Task Force with professors from both SE and CS departments to make sure the two departments will not conflict each other. Also invite an external reviewer who can offer concrete guidance, based on personal experiences in building such a program at another university.
5. Recruit full-time faculty who are competent to teach the required variety of courses and who have industrial experience in applying software engineering techniques in real work environments. Don't expect this to be an easy task. You might need to manage the program initially with significant help from part-time faculty.
6. Expect that the curriculum will need to change with time to accommodate both changes in the discipline as well as changes in the needs of local employers.
7. Define a set of students learning outcomes that you will continuously monitor, and use the results to evaluate the need for improvements.
8. Periodically seek accreditation from a national board, or at least solicit a thorough review from an external evaluator, who is a prominent figure in the field. These efforts will ensure the quality of your curriculum.
9. If you intend to advertise your program to international students, make sure that you educate student's expectations regarding the research oriented or practical training oriented nature of the program.
10. If you intend to offer the program over multiple campuses, or on-line, you need to secure the equipment, technology and instructors qualified and willing to teach distance learning courses. Don't expect this to be an easy task, the instructor's effort to teach these courses might be considerably higher than teaching face-to-face courses.

FUTURE TRENDS

Having looked at the past, it is now appropriate to look to the future for our program. In particular, we recognized a need for another set of changes. The introduction of an undergraduate software engineering program had profound consequences on the graduate program, forcing severe changes in its curriculum. The redesigned curricula should allow the new graduates of the bachelor's degree in software engineering to have the opportunity of extending their knowledge and skills to new frontiers. In particular, we believe that while in

the undergraduate program students should focus on the application level software development, at the graduate level they should focus on the enterprise and global levels. Also, we expect these students to show originality in the application of their knowledge and pursue research to push the boundaries of knowledge in the SE area of their choice (similar to the UK program reported in (Edwards, 2003)).

With this respect, in 2007 we modified our graduate program, such that the students with a bachelor's degree in SE will be required to take 5 core courses, 6 elective courses and a two-semester thesis. Up to 9 credits of core courses can be waived if equivalent courses have been completed as part of the students' Bachelor of Science in software engineering program. This would make our SE graduate program similar in structure to masters programs in electrical engineering, mechanical engineering, etc. throughout the United States (see Figure 5).

In particular, we moved a bridge course into a core course: former SE501 (Mathematical Foundations) is combined with former SE561(Formal Methods) into a new and augmented core course, SE561(Mathematical Foundations of Software Engineering). This course will include mathematical methods that a software engineer needs to master, such as graph theory, formal languages, logic, sets theory, etc.

Former SE565 and SE570, the requirements and design courses, have been changed to cover techniques at the global and enterprise levels of software development. Former SE575, the software verification and validation course, has been changed to cover verification, validation and maintenance techniques and tools. Former SE580 course will cover the team software process (Humphrey,1999) due to the recognition that the graduates will need to work in teams for most of their careers, and the feedback received from graduates.

We have also made some changes in the bridge courses of our curriculum by adding two bridge-courses, SE510 (Object-oriented Analysis and Design) and SE515 (Disciplined Software Development). We strongly believe that all our students should know the basic analysis and design methods by the time they enter the graduate program. This would allow us to teach advanced methods for software analysis and design in the corresponding core courses (SE565 and SE570), instead of spending a considerable amount of time teaching basic knowledge. Also, we are strong believers of the engineering principles emphasized by a disciplined approach to developing programs, such as the Personal Software Process (PSP). We would like all our students to be familiar with these engineering techniques at the individual level, to be able to leverage them at the team level in the software process core course (SE580). This course will also introduce principles of agile software development.

We removed Operating Systems Concepts (CS505) from the curriculum since the material was covered in several other software engineering courses. We revised SE504 (Principles of Software Engineering) to focus on structured analysis and design methods while presenting the breadth of software engineering principles. This emphasis would allow us to focus on the modern object-oriented methods in the core analysis and design classes.

In the electives courses, we added a course on Secure Web Services Design (SE611) to develop a sequence of courses on security, together with SE610 (Software Systems Security). This sequence will cover both the theoretical and practical aspects of software systems security, given the ubiquity of security issues in today's systems.

Another future trend that we believe will induce major changes in the way we deliver our program will be determined by the increas-

Figure 5. 2007 curriculum

Core Courses(5 courses = 15 credits)
SE561 Mathematical Foundations of Software Engineering
SE565 Software Systems Requirements
SE570 Software System Design
SE575 Software Verification, Validation and Maintenance

Electives(4 courses = 12 credits)
Choose two pairs of guided electives from among
SE601 Outsourcing: Specifications and Strategies
and SE602 Technology assessment

SE620 Network Software Systems I
and SE621 Network Software Systems II

SE625 Information Systems Architecture
and SE626 Information Systems Engineering

SE630 Real-Time Software Analysis and Specifications
and SE631 Real-Time Software Design and Implementation

SE637 Wireless Communications
and SE638 Communications Systems

SE650 Software Project Management
and SE651 Software Organization Management

Electives(2 courses = 6 credits)
Choose two guided electives from among
SE601,SE602,SE603,SE605,SE610,SE611,SE615,SE620,SE625
SE626,SE630,SE631,SE637,SE638,SE650,SE651,SE652,SE660,
SE698,SE699,CS514,CS517,CS533,BM565

Thesis (6 credits)
Two semester Thesis:
SE690A: Thesis Research
and SE690B: Thesis Research

ingly mobile characteristic of the majority of our students, whom are working full-time and take the courses part-time. To allow them maximum flexibility, we might need to change our delivery mode to include more distance learning, maybe in the way The Open University in UK does (Quinn, 2006). At the moment we are experimenting with offering "hybrid courses" that are a combination of a traditional, face-to-face delivery, and distance learning that uses online curricular materials. This delivery mode saves students the travel time to campus, and also allows them to keep up to speed when they travel for business. Students are required to come to campus every other week, to meet with the instructor for a face-to-face class. If their grade falls below a certain threshold, they are required to come to class every week. This is a new approach for us, and we don't have enough data yet for a thorough evaluation.

Another issue, that is beyond the scope of this paper though, is the awareness of the influence that the licensing of software engineers shall have on the design of the curriculum. However, the directions and discussions that are taking place

with regard to licensing have to be followed so that appropriate changes can be implemented in the curriculum.

CONCLUSION

This chapter has presented the main problems and lessons learned from one of the oldest programs in software engineering in the USA. The evolution of the graduate curriculum over its 21 years of existence has been shown as an example for other colleges and universities considering the addition of a software engineering degree. We expect this evolution to continue in the future, as the SE field is a constant moving target.

We have argued that the continuous update of the course content has a special meaning in software engineering, due to the dynamics of the field. With this respect, we have shown the impact of the advances in the field on the textbooks used, the need for continuous reevaluation of the chosen programming language, operating system, or software tools used in class.

The chapter has shown the difficulties we have experienced in attracting and retaining the faculty over the years, due to the need of the new faculty to have both a record of scholarly accomplishments and industrial experience. The emphasis here is on the conjunction of these two requirements, which sets great restrictions on the pool of available candidates.

We explained how various issues related to the diversity of the student body influence the curriculum and course content. As such, the educational backgrounds, employment status, educational goals, and communications skills of the student body are challenges any software engineering program has to solve.

Based on our experience in dealing with these problems, we have offered some recommendations for those interested in starting a similar program, with an emphasis on the curriculum and course content issues that arise where an undergraduate and graduate program in software engineering coexist in the same department.

As a measure of success of our continuous efforts to improve, we have seen the program enrollment increasing steadily over the years. This is not a reason to rest, since the SE field will continue to evolve, and we will have to respond to new challenges.

Chapter 5.14
The Influence of Computer-Based In-Class Examination Security Software on Students' Attitudes and Examination Performance

Lori Baker-Eveleth
University of Idaho, USA

Daniel M. Eveleth
University of Idaho, USA

Michele O'Neill
University of Idaho, USA

Robert W. Stone
University of Idaho, USA

ABSTRACT

Expectancy theory is applied to the use of software that secures the testing environment of in-class examinations. This security software prohibits students from viewing unauthorized material during an examination. The empirical study collected 60 student questionnaire responses completed after using the security software. These responses were used to develop measures for a model derived from expectancy theory. Using structural equation modeling, the model was estimated twice for two different variables. These dependent variables were student attitude towards the security software and the student's examination grade. The empirical results indicated that student attitudes were positively impacted by self-efficacy, outcome expectancy, and the software's ease of use. However, student grade was not influenced by any measures in the model. It is concluded that the security software is neutral with regard to student performance, while there are manageable actions faculty can take to positively impact student attitude towards security software.

INTRODUCTION

Declining technology prices and a drive to innovate in the learning environment create an opportunity to incorporate computer technology into the classroom. An example of these types of opportunities is the use of laptop computers to facilitate learning and classroom activities. The mobility of laptops provides a number of teaching and learning advantages. One such advantage that has not been fully explored is using laptops to evaluate and assess student examination performance by having students complete their examinations using laptops.

When using laptops on examinations, one challenge for instructors is how to provide a secure examination environment. A secure environment restricts students from accessing notes on their laptop hard drives or the Internet as well as prohibiting communication with other students via e-mail and instant messaging. Another challenge for both faculty and students is how to make sure that the technology has no impact on a student's grade. If a student takes an examination in a traditional way, using paper and a pencil, there may be test anxiety, poor handwriting or writing hand cramps, but the testing method (i.e., paper and pencil), does not affect performance on the examination. Using technology to automate the process of the examination provides advantages (i.e., typed text and no poor handwriting and hand cramping) but adds an additional dilemma, that is, what happens if the technology fails during the examination or if an inadvertent key stroke by the student leads to the loss of typed text? Furthermore, the laptop could crash, the power could go out forcing battery backup, or the software application could fail. All these events could affect student performance and the student's grade on the examination. It is important to know if using computer technology for assessment has an effect on this important outcome.

Another advantage of using laptops for examinations is to better prepare students entering the workforce. An important skill needed by today's graduates is confidence in technology ability. Confidence in one's ability can make the difference in a student being hired quickly for a management position or struggling to find an entry-level position. Any positive experiences using technology in novel environments can help build students' confidence levels regarding technology and its use. In other terminology, these students' confidence and its role in many behavioral and affective outcomes is described by self-efficacy and outcome expectancy (Henry & Stone, 2001; Jenkins & Garvey, 2001). In general, self-efficacy is the individual's perception of possessing the requisite abilities to successfully perform a specific task (Bandura, 1977; 1982; 1986). Outcome expectancy is a companion to self-efficacy reflecting the individual's perception regarding the result or gain from successful completion of these tasks. In this context, the expectations of self-efficacy and outcome expectancy provide a well-established theory by which to understand the impacts of laptop-completed examinations on student performance and attitudes.

The research presented below focuses on how the use of computers by students to complete examinations in a secure environment impacts their performance and attitudes as predicted by a model based on expectancy theory. The remainder of the article is organized into sections to present the details of this examination of self-efficacy theory and its impact on student performance. First, a discussion of the theoretical model based on self-efficacy theory is presented. Second, the methodology used in the research is discussed. Finally, the empirical results are examined followed by conclusions and directions for future research.

LITERATURE REVIEW

The model used to guide the use of laptops on examinations and the corresponding use of security

software is rooted in expectancy or self-efficacy theory. The theory (Bandura, 1982; 1986) links an individual's cognitive state to a variety of affective and behavioral outcomes, along with perceptions of future outcomes (i.e., loss of control, low self-confidence, low achievement motivation) (Staples, Hulland, & Higgins, 1998). Self-efficacy theory has in the past been used to explain user reactions to information technologies (Meier, 1985; Bandura, 1986; Baronas & Louis, 1988; Martinko, Henry, & Zmud, 1996; Potosky, 2002; Hasan, 2003; Havelka, 2003). Recent research on computer self-efficacy investigated the influence of demographic predictors (e.g., academic major, gender, computer-related experience) on business students' self-efficacy (Havelka, 2003). Significant differences in self-efficacy ratings resulted for information systems and economics majors compared to management majors and those who had greater than five years' experience working with computers. Gender differences did not result in reported self-efficacy differences.

According to self-efficacy theory, expectations in large part determine affect and behavioral reactions in numerous situations. Bandura (1986) further separated expectations into two distinct types, self-efficacy and outcome expectancy. An individual's belief that he or she possesses the skills and abilities to successfully accomplish a specific task represents self-efficacy. Furthermore, an individual's persistence to learn a task impacts his or her perceptions of future outcomes, which in turn influences self-efficacy. Outcome expectancy, on the other hand, is an individual's belief that by accomplishing a task, a desired outcome is attained. Self-efficacy and outcome expectancy have separate impacts on behavior and affect. However, self-efficacy typically has a larger effect than outcome expectancy (Bandura, 1986) and generally self-efficacy has a direct impact on outcome expectancy (Stone & Henry, 2003).

The work of Bandura (1982; 1986) was adapted for application to the adoption and use of information technology. Based on self-efficacy theory, four constructs are proposed as directly impacting self-efficacy and outcome expectancy in this environment of students using security software and laptops to complete examinations. These variables are watching others use the security software, direct experiences using this software, faculty support in its use, and ease of the security software's use. The resulting modified model used in this research is displayed in Figure 1.

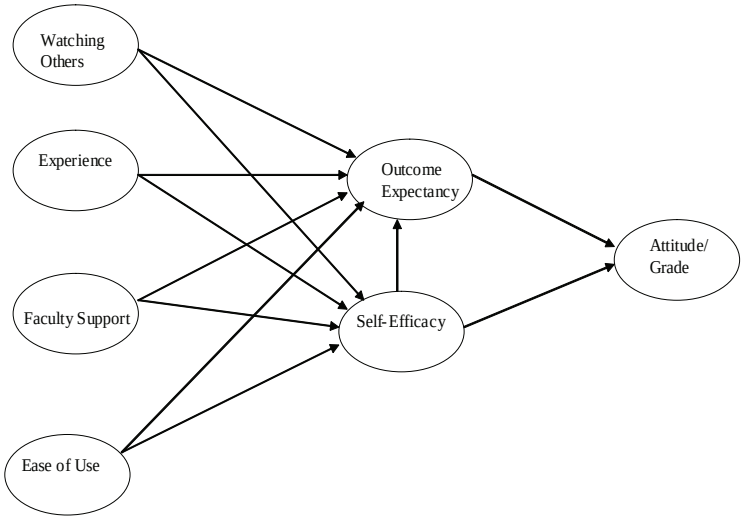
THE EMPIRICAL STUDY

A paper-and-pencil questionnaire was administered to students enrolled in what is commonly referred to in a business school as the 'Junior-level Business Core' or the 'Common Body of Knowledge' in order to collect the sample. This course is team taught by five faculty members. In two sections of the course, students completed an examination using their laptops and software that provided a secure testing environment. The security software allows students to use word processing documents and spreadsheet templates on the examination, but prevents students from performing other actions such as accessing hard drives, the Internet, and instant messaging, or e-mailing others in search of answers to examination questions. The examination was developed by the faculty in a manner that required students to review a spreadsheet template and respond to all examination questions by typing answers in a word processing document. This is because all the examination questions were essay questions.

Sample Data

A total of 107 students were enrolled in these two sections of the business core. There were 63 students enrolled in the morning section and 44 students in the afternoon section. The particular examination was administered during a common time to 98 students. Of the nine students who did not take the examination, five were excused due

Figure 1. The theoretical model



to illness and four had conflicts with the common time and were given the examination in a traditional hand-written format at another time and location.

The 98 students who used the security software to complete the examination were given the opportunity to complete the questionnaire five days following the experience, but prior to receiving their examination scores or grade. A verbal reminder to return the questionnaire was provided during class prior to the grade being released. No additional reminders were provided due to concerns over latency effect and attribution of examination performance; that is to say, no other reminders were provided due to the concern that too much time had elapsed between using the security software and the students responding to the questionnaire. In such a case, the students' responses might not reflect their immediate perceptions after using the software. Furthermore, if students received their examination grades before completing the questionnaire and if their grade was different than what they perceived as appropriate, they could attribute their unexpected performance, either better or worse, to the security software. Thus, limited in-class reminders to complete the questionnaire were made to hopefully obtain responses that best reflected students' true perceptions of the software. Furthermore, it was made clear that completing the questionnaire or not completing the questionnaire would have no impact on the student or their grade. Of the 98 students that took the examination with laptops, 62 students responded to the questionnaire, with 60 students fully completing the questionnaire, producing a 61% response rate.

Characteristics of the Respondents

The characteristics of the sample respondents are shown in Table 1. The average GPA of 3.06 appears high, but it is the case that all students enrolled in the course must have completed several qualifying courses and obtained a minimum GPA among these courses. These requirements prohibit some students, who tend to have lower GPAs, from enrolling in the course. The average age of the respondents was 22.2 years. Both genders were represented with 40% females and 60% males.

Table 1. Data characteristics

Characteristic	Sample	College Population	Test Statistic
			t-Statistic
Average GPA	3.06	2.98	1.25 [a]
Average Age (years)	22.2	21.6	1.68 [a]
			z-Statistic
Gender:			0.26 [b]
Female	40.00%	39.00%	
Male	60.00%	61.00%	
			Chi-Square Statistic
Major:			13.89 [c]
Marketing	28.33%	22.20%	
Information Systems	11.67%	12.60%	
Finance	11.67%	11.60%	
Management & Human Resources	16.67%	14.00%	
Production Operations Management	3.33%	5.60%	
Professional Golf Management	3.33%	0.70%	
Accounting	20.00%	16.20%	
Economics-Finance	5.00%	6.10%	
Other/Undeclared	N/A	9.00%	
Number of Observations	60	837	

[a] *t-Statistic = two-tailed*

[b] *z-Statistic = two-tailed*

[c] *df = 8*

The percentage of students in each major ranged from a high of 28.33% in Marketing to 3.33% in both Production Operations Management and the Professional Golf Management program.

Non-response Bias

For any research that depends on data collected using a questionnaire, non-response is a concern. To examine the possible presence of non-response bias, the sample characteristics were compared to the corresponding values at the college level. The logic of using the college demographics is that the students in the college form the population from which the sample was drawn. Any potential non-response bias would be reflected in differences in the demographics between the sample and the population. Table 1 also displays the demographic values for the college and the corresponding statistic testing the significance of the difference between the sample and the population values. All these tests were two-tailed and no meaningful differences between the sample and the population demographics were found at a 5% significance level. Based on the comparison of these demographic variables, it is concluded

Table 2. Items and measures reliabilities

Measures and Indicants	Cronbach's Alpha
Experience Using the Software	0.77
For each of the following factors, indicate the extent to which you agree or disagree that it helped your use of the software:	
Going through a short practice exercise with the software during class.	
Going through a sample exam during class.	
Watching Others Using the Software	0.90
Watching my teammates working on the software helps me understand how to use it.	
Watching my peers practice working on the software helps me successfully use it.	
Outcome Expectancy	0.85
I find it easy to recover from errors encountered while using the software.	
I find it easy to get the software to do what I want it to do.	
Helps me complete the exam faster.	
Ease of System Use	0.74
I often become confused when using the software.	
I make errors frequently when using the software.	
Attitudes Towards the Software	0.93
Completing exams using the software is the way I prefer to work on exams.	
I would like to use the software for all my exams.	
I wish all my classes would use the software on exams.	
Faculty Support	0.80
The faculty team:	
Encourages us to use the software.	
Seems to value the software.	
Self-Efficacy	0.89
I know enough to successfully use the software.	
I fully understand how to complete an exam using the software.	

that non-response bias does not present a problem for the sample.

MEASURES AND THEIR PSYCHOMETRIC PROPERTIES

The work of Stone and Henry (2003) was modified and adapted to develop the questionnaire items used to measure the constructs in the model. For all measures, students were asked the extent to which they agreed or disagreed with each of the items and were presented with the ordered answer choices of strongly disagree, disagree, neutral, agree, or strongly agree. The questionnaire was pre-tested by 11 students who had completed the course a year earlier and were familiar with the examination security software. Using the feedback from these students regarding the intent and readability of the questions, four items were deleted from the questionnaire.

Each measure used in the model and the questionnaire items forming them are shown in Table 2. Also shown in Table 2 are the Cronbach's

Alphas for each measure. These values ranged from a low of 0.74 for the measure ease of system use to a high of 0.93 for the measure attitudes towards the software. These values indicate that all the measures have acceptable levels of reliability and therefore satisfy composite reliability (Nunnally, 1978).

In order to examine the measures for the psychometric property of discriminant validity, a series of correlations were performed. Analyzing one questionnaire item at a time, the item was removed from its measure and correlated with its own modified measure and all other measures in the study. If the item satisfies discriminant validity, it correlates more highly with its own modified measure than with all other measures. The process was repeated for each questionnaire item in the model. This is the approach to evaluate discriminant validity proposed by Campbell and Fiske (1959). For this particular study, a total of 112 of these correlations were computed. Only one of these correlations violated discriminant validity. This violation was for an item measuring *Outcome Expectancy* that correlated more highly with a measure for Attitudes towards the Software. As a result, it is concluded that discriminant validity is satisfied (Campbell & Fiske, 1959). Based on the desirable composite reliability and these discriminant validity results, it is concluded that the measures used in the empirical study display satisfactory psychometric properties (Rainer & Harrison, 1993). As a result, we can be confident that the items and measures perform reasonably well in measuring the intended underlying constructs.

MODEL ANALYSIS

Because the model was relatively complex compared to the sample size, the questionnaire items were summed to form the measures of the model's constructs. The hypothesized paths among the measures were estimated using structural equations modeling as performed by covariance analysis of linear structural (CALIS) equations in PC SAS version 9.1. The estimation was done using maximum likelihood. Two models were estimated that differed only by the dependent variable. The model was estimated once using the dependent variable attitudes towards the software and once again using as the dependent variable student grade on the examination.

Summary statistics for the fit between the model and the data from the estimation of both models are reported in Table 3. The model using attitudes towards the software as the dependent variable had a goodness of fit index of 0.99 (adjusted for degrees of freedom it was 0.93). The root mean square residual was 0.02 while the chi-square statistic (four degrees of freedom) was 2.15 and insignificant at a 5% level. The normed chi-square statistic was 0.54. Bentler's comparative fit index was 1.00 while the incremental fit indexes ranged from 0.88 to 1.13. A couple of these values indicate an "over-fitting" of the model to the data, which is most likely due to the relatively complex model and small sample size.

For the model using student examination grade as the dependent variable, the goodness of fit index was 0.98 (adjusted for degrees of freedom it was 0.86). The root mean square residual was 0.04. The chi-square statistic (four degrees of freedom) was 4.03 and not statistically significant at a 5% level. The normed chi-square statistic was 1.01. Bentler's comparative fit index was 0.99 and the incremental fit indexes ranged from 0.48 to 0.99.

In summary, even though these statistics provided mixed findings regarding the goodness of fit between the model and the data, the values were sufficient to conclude the fit was acceptable (Hair, Anderson, Tatham,& Black, 1992). This acceptability judgment was based on the fact that more of these summary statistics meet the generally accepted cutoff values than not. Thus, the variations found in the data were consistent with those implied by the theoretical model, and

Table 3. Fit of the models

Statistic	Value
Goodness of fit index	0.99
Adjusted goodness of fit index	0.93
Root mean square residual	0.02
Chi-square (4 degrees of freedom)	2.15
Normed chi-square	0.54
Bentler's comparative fit index	1.00
Bentler & Bonett's non-normed fit index	1.13
Bentler & Bonett's normed fit index	0.98
Bollen non-normed fit index	0.88
Bollen normed fit index	1.02

Dependent variable: Attitudes toward software

Statistic	Value
Goodness of fit index	0.98
Adjusted goodness of fit index	0.86
Root mean square residual	0.04
Chi-square (4 degrees of freedom)	4.03
Normed chi-square	1.01
Bentler's comparative fit index	0.99
Bentler & Bonett's non-normed fit index	0.99
Bentler & Bonett's normed fit index	0.90
Bollen non-normed fit index	0.48
Bollen normed fit index	0.99

Dependent variable: Examination grade

it was concluded that the data "fit" the model reasonably well.

The estimated structural model using Attitudes towards the Software as the dependent variable is presented in Figure 2. Ease of system use had a meaningful impact on student attitudes through outcome expectancy. Self-efficacy had a direct impact on Attitudes towards the software as well as an impact through outcome expectancy. Results for the model using student grade as the dependent variable are shown in Figure 3. Neither self-efficacy nor outcome expectancy had meaningful impacts on the grade. However, ease of use and self-efficacy did have meaningful impacts on outcome expectancy.

DISCUSSION

The expectancy model was applied to students completing examinations in class using laptops loaded with software that provided a secure testing environment. The features of this security software were described earlier in the article. The intent of the research was to identify those actions impacting not only student attitudes towards the software, but also student performance on the examination as measured by grade.

The most interesting empirical result comes from comparing evidence from the two estimated models. Student attitudes towards the security software are positively impacted by self-efficacy and outcome expectancy, as well as ease of use via outcome expectancy. When the model was estimated using examination grade as the dependent variable, none of the other variables in the model had either a direct or indirect impact on this grade. The interpretation of these results is that the examination security software did not influence student examination performance as measured by grade and ease of use, self-efficacy, and outcome expectancy positively impacted student attitudes towards the software. The result is intuitively appealing because it indicates that students have positive attitudes toward the examination security software yet the software is neutral with respect to student examination performance.

CONCLUSION

The presented research examines an increasingly common situation in education, the use of computer-based examinations and the resulting need for software that secures the testing environment.

Figure 2. The model with student attitude as the dependent variable

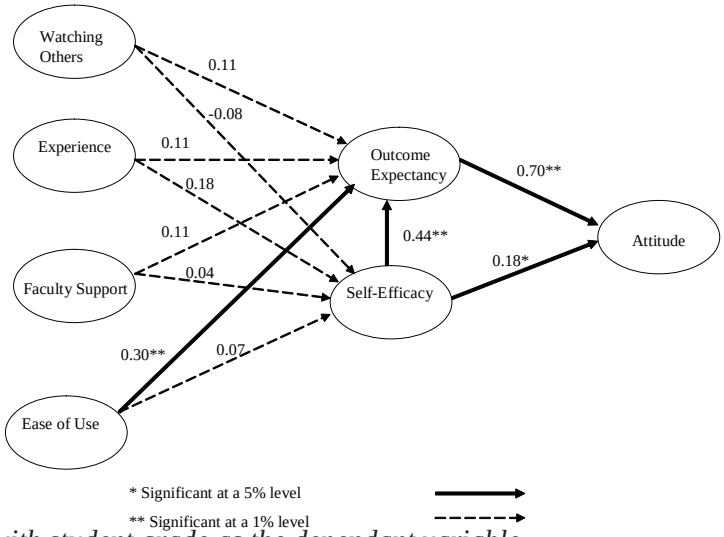


Figure 3. the model with student grade as the dependant variable

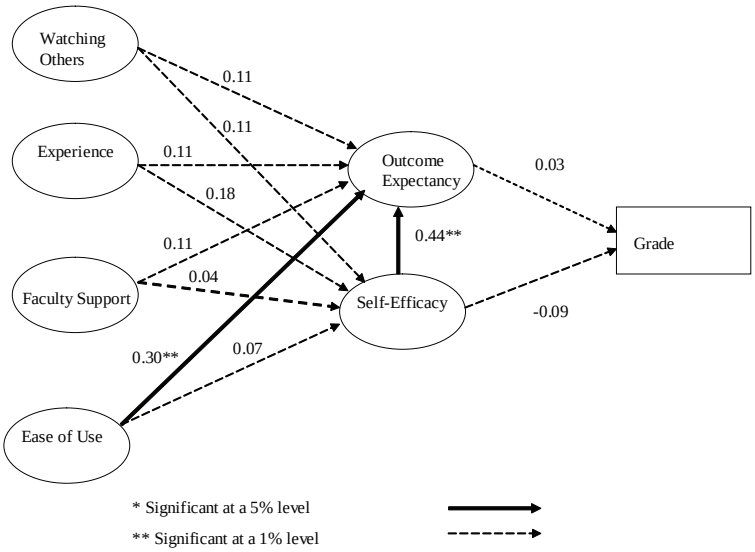

The empirical study shows student attitudes towards the software are positively influenced by several factors, yet student performance on the examination as measured by grade is not. The software providing a secure testing environment is neutral with regard to examination performance and yet student attitudes can be positively influenced. In a larger sense, these attitudes and the confidence from successfully using such software may translate into greater confidence regarding technology in general. As mentioned early, such skills may help these students secure an entry-level position upon graduation.

As more colleges and universities move toward mobile computing environments there will be additional opportunities to assess student performance using computer-based examinations. It is encouraging that student performance is not hindered by use of such software. Is this not what is desired from such software? The variables

positively impact student attitudes towards the software yet the software does not artificially help or hinder a student's performance. Future research in this area should look at other variables that may influence self-efficacy and outcome expectancy, as well as examine additional variables influencing student performance.

Chapter 5.15
Integrated Software Testing Learning Environment for Training Senior-Level Computer Science Students

Daniel Bolanos
Universidad Autonoma de Madrid, Spain

Almudena Sierra
Universidad Rey Juan Carlos, Spain

ABSTRACT

Due to the increasingly important role of software testing in software quality assurance, during the last several years, the utilization of automated testing tools, and particularly those belonging to the xUnit family, has proven to be invaluable. However, as the number of resources available continues increasing, the complexity derived from the selection and integration of the most relevant software testing principles, techniques and tools into an adequate learning environment for training computer science students in software testing, increases too. In this chapter we introduce a experience of teaching Software Testing for a senior-level course. In the elaboration of the course a wide variety of testing techniques, methodologies and tools have been selected and seamlessly integrated. An evaluation of students performance during the three academic years that the course has been held show that students' attitudes changed with a high or at least a positive statistical significance.

INTRODUCTION

In this chapter we present a complete methodology for software testing training in the context of a laboratory course for senior-level computer science students. The intent of this work is to provide educators with a set of guidelines to effectively

instruct computer science students on software testing. The goal is not only to incorporate specific software testing skills into students' curricula, but also to prepare the student with skills for independent lifelong learning on the topic. The designed course spans the whole software testing lifecycle, and includes teaching recommendations to address students' common difficulties and misconceptions, as well as techniques to evaluate Students' performance for every stage.

During three academic years (2003-2006, note that results for the ongoing academic year are not currently available) we have developed and improved a software testing learning environment that has been used to train senior-level students in the Department of Computer Science of Universidad Autonoma de Madrid (Spain). In this environment, students are instructed about the elaboration of the test plan, test cases design, testing automation by means of specific tools, reporting and interpreting test results and maintenance related issues. All of these tasks are carried out over a complete pre-existent software system that has been specifically developed for this purpose.

To evaluate the effectiveness of the approach we have carried out attitudinal surveys to students during the three years that the course has been offered. These surveys provided us with inestimable information about students' progress and perception on several aspects of the course. This information was used to find out which elements of the course were perceived by students as most useful, most difficult or most personally rewarding; and, of course, to improve the learning environment along the academic years. We have found that, thanks to their immersion in this testing environment, students understood the crucial importance of software testing across the software lifecycle. Also, they incorporated a complete testing methodology and a broad set of software testing tools into their previous knowledge.

The chapter is divided into the following sections: a background section in which previous work on the topic is discussed and compared to the proposed approach, a description of the software testing learning environment including teaching recommendations and a description of the students' performance evaluation method, an evaluation of the effectiveness of the approach and a final section with the conclusions and future work.

BACKGROUND

Due to the increasingly important role of software testing in software quality assurance, during the last years, the use of testing frameworks that assist the developer during the testing process, and particularly the use of those belonging to the xUnit family, has proven to be invaluable. The production of high-quality and bug-free software products and solutions has gained a crucial importance in the software development industry, always focused to meet the needs of its increasingly more demanding end-users. In the last few years, many software testing techniques and methodologies have emerged to address these challenges, some of them influenced by agile (Beck, K. et al., 2001) and particularly by Extreme Programming (XP) (Beck, K., 2000). These techniques provide a wide set of principles, practices and recommendations for all the tasks involved in the software testing process, from test case design to automation of functional tests. In this context, an overwhelming number of testing frameworks and tools have been developed and are available (many of them under open-source licenses) with the purpose of aiding the developer in testing every particular system aspect written in any programming language imaginable.

However, as the number of resources and techniques available continues increasing and demonstrating new benefits, the complexity derived from the selection and integration of the most relevant software testing principles, techniques and tools into an adequate learning environ-

ment for training computer science students in software testing, increases too. Though several interesting experiences have been reported, to collecting and integrating all of these continuously evolving sources of knowledge and experience into a methodology to effectively teach software testing, remains an unresolved issue. As we will see later on in this section, many experiences of taking software testing to the classroom have been reported. They are focused in a number of testing related topic like for example extreme programming, unit testing or pair programming. However, it seems like there have not been any experience of collecting and integrating the most relevant and successful techniques into the same course.

There have been numerous experiences bringing Extreme Programming principles to the classroom (Astrachan, O. Duvall, R.C. & Wallingford, E. 2001; Edwards, S. 2003; Kaufmann, R. & Janzen, D. 2003; Melnik, G. & Maurer, F. 2002; Mugridge, R. 2003; Müller, M. & Hagner, O. 2002; Müller, M. & Tichy, W. 2001; Reichlmayr, T. 2003; Shukla, A. & Williams, L. 2002; Tinkham, A. & Kaner, C. 2005) as well as other less specific like (Collofello, J. & Vehathiri, K., 2005) and (Astrachan, O., Duvall, R.C., & Wallingford, E., 2001). For example, in (Shukla, A., & Williams, L., 2002) a complete report of an undergraduate course on software testing focused on Test-Driven Development (also known as TDD and considered one of the most important aspects of Extreme Programming) is presented. The course was held during three academic years and, despite positive results in terms of students performance, a main problem was identified. The problem lies in the counterintuitiveness of TDD due to the fact that, according to this technique test cases need to be written before the code to test. This problem is especially significant in graduate and nearly-graduate students (for whom the course presented in this chapter is intended) who have already become established in the traditional "write the code and then test it" software testing strategy. In general, in the vast majority of these experiences a special need for coaching and support for students has been detected due to the novelty of the topic and the large number of new concepts it involves. For this reason we decided to design an integrated learning environment in which students' progress is monitored through individualized tutoring during laboratory classes and the use of a centralized software repository where they store the work as they progressively complete it. In this respect the adoption of pair programming as the collaborative paradigm for the course has brought us the possibility of taking advantage of the benefits it provides to students when facing radically new software development related concepts and scenarios.

Pair programming is a software development model at the core of XP and is a kind of "collaborative programming". It consists of two programmers (two students), working side-by-side at one computer collaborating on the same design, algorithm, code or test. One person is the "driver", i.e. has control of the pencil/mouse/keyboard and is writing the design or code. The other person, the "observer," continuously and actively examines the work of the driver identifying tactical and strategic deficiencies in it (Williams, L., Kessler, R. A., Cunningham, W., & Jeffries, R. 2000). Despite cases of study (Müller, M., & Tichy, W. 2001) where pair programming has been shown to suffer from some waste of time and from an unclear division of work, we have chosen pair programming as the collaborative model during the laboratory course due to the following reasons:

- Pair pressure: pair programmers put pressure on each other. This is a form of positive pressure that leads students to keep each other focused and on-task (Williams, L. A., & Kessler, R. R. 2000).

- Pair programming has been shown to be beneficial independent of the developers' experience (Cockburn, A., & Williams, L. 2001). Note that our students do not have experience in formal software testing.
- Pair programming improves the success and morale of the students and increases satisfaction in the process (McDowell, C., Werner, L., Bullock, H., & Fernald, J. 2003).
- Pair programming increases confidence in the programming solutions
- Students are much less reliant on the teaching staff. When one partner doesn't know/ understand something the other almost always does, therefore the teaching workload is reduced and lab consultation hours are very calm (McDowell, C., Werner, L., Bullock, H., & Fernald, J. 2002; Williams, L., & Kessler, R. 2000).Pair programming is much more productive when developers face unfamiliar problems than when facing familiar ones (Lui, K.M., & Chan, K. C.C. 2003). This is the case we are considering since students have no previous knowledge about the software system to test, nor experience using the testing tools introduced in the course.

THE SOFTWARE TESTING LEARNING ENVIRONMENT

The Course

The software testing course has been held during the second semester of the last three academic years (2003-2006) as a laboratory course in the senior-level Software Engineering subject at the Department of Computer Science of Universidad Autonoma de Madrid (Spain). At the beginning of the course students have intermediate Java programming skills and more than 100 hours of theoretical-practical software engineering training plus specific theoretical instruction in software testing fundamentals. This instruction comprised basically the following topics:

- Test design techniques: black box and white box.
- Integration strategies in structured programming languages: top-down, bottom-up, and sandwich.
- Integration strategies in object oriented programming languages.
- Test cases design.
- Testing across the software development lifecycle: unit, integration, system, acceptance, and regression testing
- Risk management during the test process.
- Test plan document elaboration guidelines.

Table 1 summarizes the most relevant features of the course.

The first day of the course students are grouped in pairs and informed about the work to do:

- Test plan documentation: scope, description of the integration strategy and techniques selected, assignment of responsibilities and resources, schedule, milestones, risk management, completion criteria, etc.
- Test development: test procedures, test scenarios, test cases and test source code.
- Test execution: execution of the software following the plans and reporting of failures and errors detected.
- Test reporting: final conclusions about the results obtained from the executed tests.

During the explanation teachers emphasize aspects related with the testing automation level, code coverage, test cases design and maintenance. Finally students are informed about the course evaluation procedures.

System to be Tested

A complete system has been developed by teachers with the sole purpose of being tested. The main advantage of this is that students have the same starting point what makes students' performance evaluation more straightforward. Due to the strict time constraints of the course as well as the broad software developing experience students acquired in previous years, we have not seen the necessity of spending time instructing students on development issues.

The developed system presents a very interesting set of features that makes the testing process very interesting from an educational point of view: multithreading, HTTP interface, file input/output, private methods, exception handling, XML documents generation and parsing, external configuration, etc. The system consists of 7 Java classes and about 1700 lines of code. However, no more than 200 lines shared out between a few selected methods are used for testing purposes. In order to delimit the range of results that can be potentially obtained from the testing process, as well as facilitating students' performance evaluation and making the testing process more rewarding, several failures affecting different parts of the system have been deliberately introduced. These failures have been carefully selected with the intention of being detected using different testing techniques and strategies: black box, white box (grey box), unit testing, integration testing, functional testing, etc. Note that for obvious reasons the different failures introduced vary each academic year.

The system to be tested is named Road Information Server (RIS) and its aim is to serve XML documents via HTTP containing information about roads: traffic flow, presence of accidents in the road, weather forecast, etc. This information is taken by this module from the output of a hypothetical system named Road Observation and Information Providing System (ROIPS) from a data file (note that the format of this file is the only thing students need to know about the ROIP system) that acts as an interface between both systems. The RIS system is continuously reading the data from that file and generating XML documents containing the information requested via HTTP (GET method) by the clients. Since the information is published using HTTP the simplest way to interact with the system is from a conventional browser (this feature enables students to easily interact with the system). Figure 1 shows the system to be tested and its environment.

Table 1. Summary of course details

Number of students	150 students divided into 5 groups with an average of 15 pairs of students and a dedicated teacher per group.
Qualification required	Last year undergraduate computer science students.
Programming language	Java JDK 1.5
Testing tools	JUnit 4.0, JFunc, HttpUnit, XMLUnit, JTestCase, JUnitReport, JUnitAddOns, and others.
Software configuration management tools	SVN 1.3 + TortoiseSVN
Software execution and deployment	Ant 1.6.5
Evaluation procedure	• Oral presentation. • Formal written report including the Test Plan, test cases design and test execution results and interpretation. • Software generated quality and completeness (only the software present in the repository is evaluated) • Practical examination.
Duration	8 Weeks

Elaboration of the Test Plan

Once the students understand the goals of the course and get familiarized with the system to test, they must start elaborating the test plan. This document is required to be formatted as a technical report, this point is the special interest because students are very close to finish their degree and need to be prepared for dealing with the document formatting standards used in the software development industry. This document must be realistic and include a schedule and milestones adjusted to the course length.

Unit Testing

Unit testing is one of the core practices of XP and consists of taking each class of an object oriented software system and testing it in isolation. Students are encouraged to select a bottom-up testing approach, i.e. testing the classes of the system first and then testing the sum of its classes. On such an approach, integration testing becomes much easier. Teachers also encourage students to put special emphasis on unit testing due to the following reasons:

- Unit testing implicitly involves a sort of documentation that provides students with a better understanding of modules, requirements and API's.
- Good unit tests are fundamental when doing regression tests.

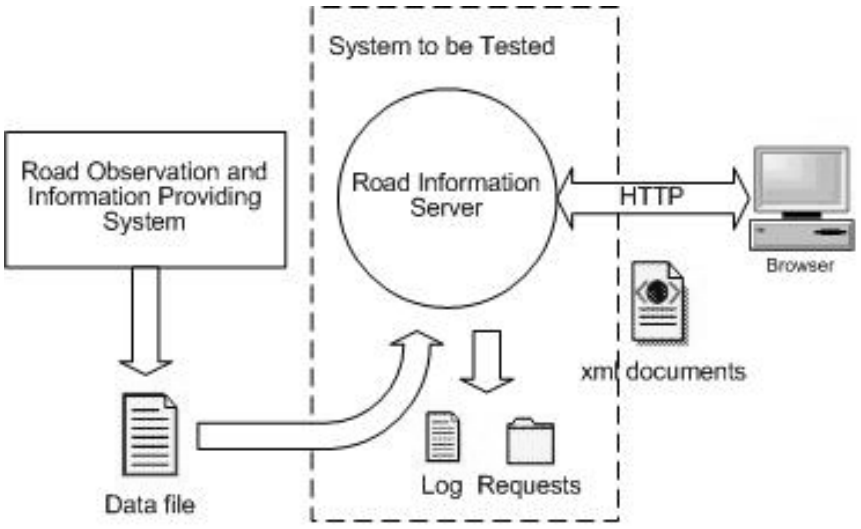
Since Java is the programming language selected for the course, the tool selected to assist the unit testing process can't be other than JUnit. Many issues concerning test cases design and the right way to test an object in isolation need to be covered for an in-depth understanding of unit testing. In the following subsections we describe these issues in detail, providing some teaching recommendations obtained from our experience holding the course. However, note that some aspects, like test cases design, are not uniquely correlated with unit testing.

Test Cases Design

The first step when doing unit testing is to design the test cases, black box and white box techniques are both suitable for this purpose. Black box consists of testing whether the output of a function or method, given certain inputs, conforms to its functional specification. White box consists of analyzing the source code in order to guide the selection of test data. In this respect, students need to have good enough Java programming skills to throughfully understand the execution flow present in the methods' source code. It is important to balance the pairs when creating them at the beginning of the course; students with less Java programming skills must be paired with the more experienced ones. Test data must be appropriately selected to achieve an adequate coverage over the code to test. Students have to decide which coverage (statement, edge, branch or path) to use when testing each method and justify the decisions made. Also, students have to create flow graphs for each method and depict on them special situations derived from exception handling when it is the case. Note that only 6 methods of the whole system are selected to be tested, so the workload is assumable.

We have encountered difficulties among students to understand and appropriately set-up the context in which a method for a given test case must be called. There is a trend to conceive a method as an execution entity which results are only determined by the input parameters regardless the context in which the method is invoked. This problem is especially notorious when designing test cases under the white-box perspective. For this reason we have selected some methods which results are strongly influenced by events like the presence of a file in the file-system or the inner-

Figure 1. Diagram of the system to be tested and its environment



state of the object in which the method is defined. Another important issue is to make students take into account all the factors involved in setting-up the method invocation context and to check all the observable results of its execution.

Testing in Isolation

Maybe the most difficult aspect when doing unit testing is to completely isolate a class from its collaborative classes. Usually an object makes use of other objects to carry out certain tasks beyond its own functionality. Obviously, the execution results (and so that the test results) of methods belonging to that object are going to be strongly determined by the inner-state of the object. Usually it is very difficult to set up domain state on such a way that it exposes the features to be tested. Even if we can do it, the written test will be probably very complex and difficult to understand and maintain. We can avoid these problems using Mock Objects (Mackinnon, T., Freeman, S., & Craig, P. 2000) that are a substitute implementation to emulate or instrument other domain code (in particular the collaborative classes). They should be simpler than the real code, not duplicate its implementation, and allow the developer to set up private state to aid in testing. Mock Objects are very useful, but to create them by hand may be tedious, therefore, students use a tool named JMock. JMock automatically generates the mock classes' source code from the original classes and presents a very intuitive interface with a very plain learning curve. In addition to the generation of the Mock Objects, a preliminary refactoring process is typically required, consisting in creating the factory methods in which the original objects will be replaced by mock objects. In the Source code listing 1, it is shown an example of a factory method that instantiates a collaborative class.

```
public class TargetClass() {
    protected CollabClass factory-
Method(){
    return new CollabClass();
   }
   ...
}
```

Source Code Listing 1

Following this procedure, it is possible to test objects that inherit from the target class and over-

ride the factory method to replace the instantiation of the collaborative object with the instantiation of the mock one. This can be seen in the Source code listing 2.

```
   public void testTargetClassMethod {
   // instantiation using mock objects
   TargetClass targetInstance = new Tar-
getClass() {
     protected CollabClass
      factoryMethod {
        return new CollabClass();
      }
     }
     // test something
   }
```

Source Code Listing 2

We have found that is very important to carefully select the code examples to which students must apply the Mock Objects technique so they can see a tangible benefit derived from its use. This way, applying Mock Objects becomes a very rewarding task rather than a nuisance. Otherwise they tend to consider the solution too complex in comparison to the problem to solve and it discourages them.

Testing Private Methods

Some TDD purists suggest that principles of encapsulation should never be violated for testing an object. Testing private methods (note that in the Java language as well as in other object oriented languages there are several access modifiers. In this respect, the qualifier private must not be interpreted literally but as "not belonging to the public interface of the class") means that you have to change your tests every time you change your private methods, and this becomes a barrier to refactoring and agile development. The reason is that, typically, private methods contain implementation details of the objects and therefore are more prone to suffer changes during the software maintenance process. We can consider, in the context of white-box testing technique, that a private method is implicitly tested by means of testing the public methods that use it. However, sometimes it is not easy to obtain an acceptable coverage following this strategy. In these cases we may need to test private methods directly, so we include such an exercise in the laboratory course. The problem here is that private methods can't be called outside the class where they are defined and obviously the test code can't belong to the class to test. The best solution is to by-pass the Java Virtual Machine (JVM) encapsulation mechanism by using the Java Reflection API. This can be done using the classes included in the `java.lang.reflect` package or by means of the JUnit-addons library (available under an open source license). As can be seen in the Source code listing 3, calling a private method with the later is straightforward:

```
   SomeClass returnValue = (SomeClass)Pr
ivateAccessor.invoke(
     instanceToTest,
     "methodToTest",
     new Class[]{ Class1, Class2},
     new Object[]{ param1, param2});
```

Source Code Listing 3

As a laboratory exercise, some private methods are selected; students must decide which of them should be tested and include the observed advantages and disadvantages of the decision taken in the documentation produced.

Testing Exceptions

Exceptions are a mechanism to handle unexpected or atypical situations during the execution of a program. Exception management code is responsible for the detection and handling of system conditions that could potentially lead to failure. As any other part of a software system,

they must be tested. However this is probably one of the aspects of an object oriented programming language, which testing procedure has never been covered in detail in the available bibliography. There are a few recommendations on the topic; even frameworks like JUnit provide helper tools. However, we have observed a lack of an in-deep analysis in which students can rely to successfully proceed in most of the possible scenarios.

When testing exceptions, students use to consider them as an `if-else` block of code, where the `if` corresponds to the `try` sentence and the `else` corresponds to the `catch` sentence. This way, the testing procedure would consist in defining two test cases, one for each possible execution path. Nevertheless, there are a fair number of non trivial questions that arise among students when taking this procedure to practice. Should all the exceptions be tested following the same procedure? Should all the potentially thrown exceptions be tested? If not, what is the criteria to decide which of them should not? In the rest of this section we will try to shed some light on these questions.

The goal is to verify that exceptions are generated only when it's due, following this consideration it makes sense to classify them as expected or unexpected. Note that this classification does not attend to the exception itself but to the nature of the test cases designed for testing it.

Expected Exceptions

Expected exceptions refer to test cases in which the method-under-test execution context is set-up so an exception must be thrown. Testing them consists of invoking the throwing method with "exceptional" data and checking that the exception is actually thrown via an assertion. Testing this kind of exceptions can be done in JUnit 4.x using the annotation `@Test(expected=ExpectedException.class)` when defining the test method. However, it presents a clear shortcoming, checking that the right exception has been produced is up to the framework and no extra verifications over the exception object itself can be done since it is not available in the test method. For simplicity and generality the procedure shown in the Source code listing 4 has been proposed to students:

```
public void testSomeMethod () {
  try{
            instanceToTest.
methodToTest(params);
   fail("An exception was expected");
  } catch (ExpectedException e){
    // Execution control must reach
here
  }
}
```

Source Code Listing 4

With these code sentences we ensure that a failure will occur if the exception `ExpectedException` is not raised when invoking the method to test with the adequate parameters. We have observed among students a common misconception of expected exceptions. Sometimes, they include some test cases in which the concept of expected exceptions is extended to "testing the Java platform". For example, test cases are written which result in a method invoked over a non initialized object that produces a `NullPointerException` raised by the JVM. This kind of test cases doesn't make any sense because testing the JVM is obviously out of the scope of the test plan.

Unexpected Exceptions

Unexpected exceptions correspond to those unpredicted situations for which the system can not suggest any solution. This kind of exceptions is easy to test since JUnit automatically catches exceptions thrown by test methods and report

them as errors (note the non trivial distinction between errors and failures in JUnit). While for unchecked exceptions (those who inherit from `RuntimeException`) nothing needs to be done, checked exceptions have to be declared in the throws clause of the test method definition.

```
   public void testSomeMethod () throws
SomeCheckedException {
     // test something
   }
```

Source Code Listing 5

Improving Maintainability

Nowadays, most of the activity and economic benefits of software enterprises come from maintenance related tasks. In fact, commonly in the vast majority of software projects, the maintenance life-cycle is much longer than the development one and so is the volume of resources dedicated to it. The interesting point here is that the larger the number of resources needed, the larger the potential for cost-effectiveness improvement and so must be the effort in teaching good practices on this topic.

During a maintenance stage in which the production code is being altered, regression tests need to be done with a very high periodicity and have to be as much automated as possible so they can be ran at a reasonable cost in resources. For this reason, it is necessary to train students in good testing practices that guarantee the production of not only maintainable test software but test software with a highly automated that can be effectively used in regression. In addition to some general recommendations, like minimizing the coupling between test code and production code and using auto-deployment scripts, students are trained in the use of an open source tool named JTestCase. This tool is very helpful assisting in the test cases design and execution tasks; it is basically a JUnit extension library that allows the test cases data to be separated from the test cases source code. This separation is provided by using XML data files to store test cases data in a very structured and readable fashion. To enhance maintainability even further, different XML files must be used to store test data belonging to different classes. JTestCase also provides the API methods required to load this data into memory from the test code during the testing process. The main advantages that led us to recommend students the use of this library are two:

- It is possible to enlarge the test cases data set with only adding a new test case description to the XML files, and without modify and having to recompile the test source code.
- Developers who design test cases data sets don't need to know about the source code of the methods to test. Therefore a clear separation between the test cases design and execution roles is established.

Nevertheless, this library also presents some drawbacks we needed to deal with when designing the laboratory exercises in order not to increase excessively their complexity. For example, storing the parameters data of the methods to test in the XML files when they are instances of complex data types or user defined classes, may result in a very complex and tedious task (because they are not directly supported by the syntax JTestCase provides). Although this problem may be overcome using the JICE library, we considered it does not worth the time students spend to learn a new tool.

Another recommendation we do is to use the XML documents generated as part of the test cases design documentation (XML files are readable by both humans and machines) and therefore avoid duplicated information that is always hard to maintain.

Reporting and Interpreting Test Results

Once the test cases execution has been carried out using the corresponding Ant script, a fair amount of information summarizing the errors and failures detected is generated. The correct interpretation and understanding of this information is a key issue to locate and solve adequately the software defects found during the testing process. JUnit includes support for the presentation of test cases execution results in textual (standard output in the command window) or graphical form. However, in real applications for which thousands of test cases are typically developed, these methods of presenting the information are unreadable and impractical. To cope with this problem we have instructed students in the use of the JUnitReport tool, which allows the generation of hypertext browsable documents in HTML format containing the execution results for every particular executed test case. This tool is able to merge the individual XML files generated by the <junit> Ant task, and apply a stylesheet on the final document. JUnitReport is provided with the Ant release as an additional task but installation of external third party libraries is required. One important thing to point out is that both <junit> and <junitreport> tasks must be written in different targets inside the Ant script so the test case execution and results reporting tasks are not interdependent.

Another fundamental topic that must be covered is the correct interpretation of the obtained results. Usually, JUnit makes a distinction between errors and failures, however, this distinction is artificial, unuseful and usually a source of misunderstandings among students. This distinction does not provide clear information about the source of the software defects found. While failures relate to assertion methods that have not been satisfied, i.e. defects in the production code, errors reflect unanticipated situations that occurred during the test cases execution and could be caused by both defects in the production code or in the test code. This issue must be covered at the beginning of the course when the JUnit tool is introduced.

Integration Testing

Integration tests are centered on the collaboration of classes in a system. Once the different classes have shown to work well in isolation, is necessary to verify that they also work well when combined. When doing unit testing over a target class, students do a little refactoring process to replace domain objects with mock objects through the use of factory methods. After that, mock objects must be replaced progressively by the original ones. This can be done straightforward using the approach presented in (Wick, M., Stevenson, D., & Wagner, P. 2008). Students have to replace the factory method of the original target class with a new factory method that returns the actual object with which students wish to integrate. Note that this approach allows a step-by-step integration, i.e. if we replace factory methods one by one, we are adding the original classes to the integration test one-by-one. In comparison with unit tests, integration tests are more difficult to implement due to the complexity of setting up the domain in the right state to test a specific behavior. In integration tests lots of objects are involved while in unit tests only a few mock objects, plus the target object, are involved. Moreover, mock objects state is very easy to set up comparatively. Due to these difficulties, we have found that students need extra support and instruction to make integration testing successfully.

Functional Testing

The final step is to make functional tests over the system as a whole. For this purpose students are provided with a brief Software Requirements Document in which, for example, the syntax of the HTTP requests served by the system and the format of the XML documents returned are

described. The goal is to make automated tests to verify that the system behavior meets the software requirements. Making functional tests from scratch over a distributed application with the only help of JUnit (note that despite its name JUnit is not exclusively attached to unit testing.) is a hard task. To cope with this difficulty we have introduced in the learning environment two interesting JUnit extension libraries (these two libraries as well as all the tools included in the learning environment described in this chapter are free-available open source tools) that facilitate this work: HttpUnit and XMLUnit. Note that despite their names, XMLUnit and HttpUnit are not unit testing tools but functional testing tools; nevertheless the "unit" prefix is an easy way to make these tools easily recognizable as belonging to the JUnit family. In one hand HttpUnit simplifies the interaction with a Web application by hiding all the HTTP protocol details from the developer. This tool basically emulates the functionality of a Web browser allowing the test code to navigate a Web application and retrieve its contents as a user would do by clicking links and reviewing documents using a conventional Web browser and the mouse. Once the test code is able to retrieve documents from the system, the next step is to validate the contents and structure of the documents retrieved to ensure they follow the specification contained in the Software Requirements Document. For this purpose, HttpUnit can be used in combination of XmlUnit. While the former is able to parse and validate the contents of HTML documents (like the title of the page, tables and forms present in it and even the correctness of the script code) the later is able to do XML documents validation.

Another interesting point when making functional tests is the possibility of allowing multiple failures, i.e. to allow more than one assert method to fail inside the same test method. JUnit typically stops the execution of a test method and continues with the execution of the next one when the first failure occurs. While this is convenient in the particular case of unit testing, in which after a failure happens the state of the object under test is potentially unpredictable, in functional tests is common to design a test case so it carries out a set of higher level operations that are often uncorrelated. In these cases, one failure may not affect the normal execution of the following operations and, since functional testing is usually a very time-consuming task, to be able to continue the testing process can save a lot of execution time. There is a specifically designed tool to overcome this drawback of JUnit when applied to functional tests, its name is JFunc and was also incorporated to the testing environment.

In the following points we summarize some interesting issues we have observed during the three academic years the course have been held.

- The process of incorporating functional testing tools to the course involves a relatively long learning curve if is not accompanied by the adequate examples and instruction.
- Once the tools are effectively applied to the functional testing process, students realize the simplicity of the test code produced and the extensibility and generality of the solution. After an initial guided research effort followed by a posterior independent research effort, they incorporate to their curriculum a set of state-of-the-art functional testing tools that clearly improve the quality and the level of automation of the tests, as well as are very helpful in regression.
- Sometimes students need extra support to distinguish between the aspects of a Web document that must be tested and those that must not. While the contents and organization of the information contained are important, aspects like presentation and Web design elements are obviously out of the scope.
- The system to test produces dynamic documents, this is an interesting point because some dynamic contents we deliberately in-

cluded, like time-stamps or auto-increment values, are by nature nearly impossible to test. In these cases, students are instructed to eliminate the validation of those values from the overall contents validation process.

Taking Advantage of Software Management Configuration Tools (SMC Tools)

Nowadays SMC tools are essential to track the evolution of the software under development and also represent the basic support for the collaborative work model of every software development team. For this reason, and in order to make the working environment as real as possible, we have considered a key issue to incorporate the use of a repository along the course. The version control system selected is SVN Subversion v1.3 (Subversion, 2000). This tool was originally created to replace CVS (Concurrent Version System) and presents some advantages over it, among them, its usage simplicity. Students interact with SVN by means of a Windows client named TortoiseSVN, which is integrated in the Windows Explorer contextual menu. The repository can also be accessed for reading purposes through a standard WEB browser using Apache authentication. Working with the repository using TortoiseSVN is a very easy task and only a few commands (import, checkout, commit …) and a basic knowledge about the work-cycle is necessary for students to get started. Each pair of students has a folder in the repository and a login/password to access it. The first day of the course students import the baseline software system to the corresponding work folder in the repository. At the end of every day in the course or after a major change has been made over the software contained in the local working folder, students are required to commit the changes to their personal folder in the repository. One common problem we have found is that some students can't clearly differentiate between software elements that must be stored in the repository (only those that evolve across the software life-cycle and can't be generated from others, as is the case of a .class file generated from a .java file) and those that must not. This concept is important because making a clear distinction between both kinds of elements prevents filling the repository with unuseful and redundant content and saves time in the interaction with it. For this purpose students are encouraged to define a "clean" task in the Ant script that allows deleting the compilation process results (binary files like .class and .jar) before committing to the repository.

The repository is also, indirectly, an excellent mechanism for teachers to track students' progress and detect misconceptions in the early stages of the course, when these problems are more likely to happen and easier to deal with. We will cover this topic in more detail in the next point.

Students' Performance Evaluation

Students' performance evaluation along the course is based on the following:

- Oral presentations in which each student explains and defends the decisions made and justify the obtained results. A key aspect is the adequate defense of the testing process completion criteria and the testing techniques and strategies selected. Also students are required to make suggestion about how to improve the learning environment and how other parts of the system that remain out of the scope of the test plan could be tested.
- A formal written report including the Test Plan, test cases design as well as test execution results and interpretation: The goal is to get students used to write formal documents as close as possible to those used in real-world software companies.
- Software generated quality and completeness: At the end of the course, the test software contained in the students' folder in the repository is examined and evaluated in terms of readability, completeness, level

of automation achieved, coverage over the production code, maintainability, etc. An existing tool designed for measuring the coverage achieved over the production code, which name is Cobertura (Cobertura, 2005), has been utilized for automatically measuring the coverage of students' generated test code and to compare it to the target coverage they described in the Test Plan. Another interesting point is the use of the repository to obtain feedback for evaluation purposes. By looking at the changes-log in the repository, it is possible to observe which versions of which software elements and when were committed to the repository. This is very helpful for evaluating up to which extent the schedule students wrote in the Test Plan was met. This is an important issue because a last-year computer science student must demonstrate enough experience to accurately estimate time and resources to accomplish a task.

- A practical examination, in which the student is tested on skills that indicate a good level of understanding and handling of the tools used. In this respect students use to perform very well and, when asked, they show to be very capable of applying the tools to new scenarios.

In the vast majority of the cases students performed very well in the oral presentations and in the practical examination. Interestingly some students went beyond the scope of the course and incorporated new tools to the testing process, like it is the case of performance analysis tools. However after carefully examining the change-log of the working folder in the repository for each pair of students, it seems like some of them have troubles estimating the time needed to accomplish each task. We attribute it to the lack of experience taking to the practice the testing techniques introduced. We expect to get better performance in this respect in the following.

The final results indicate that about 85% of students (as an average of the three years in which the course has been held) completed the course satisfactory, being the average grade 7.5 out of 10. This percentage is very similar to the number of students who actually completed all the exercises comprised on the course. This, lead us to the conclusion that the learning environment success is guaranteed whenever the teachers get students enough involved on it.

EVALUATING THE EFFECTIVENESS OF THE APPROACH

To evaluate the impact of the course on students learning and attitudes we carried out a series of surveys. Surveys took place at the beginning and at the end of the course that has been held during the last three academic years. Despite the voluntary nature of the surveys, 93% of an average of 150 students per year completed them. It is important to note that students knew that their answers to the questions would have no effect in their grades. The purpose of the surveys was to evaluate whether students attitudes over relevant software testing topics covered during the course, changed accordingly with our previously stated hypotheses.

The attitude evaluation survey was designed in a similar fashion to the one presented in (Sitaraman, M., Long, T.J., Weide, B.W., Harner, E.J. & Wang, L. 2001). The survey consists on 18 statements. Each of them must be marked by students with one of six choices: strongly disagree (1), disagree (2), moderately disagree (3), moderately agree (4), agree (5) and strongly agree (6); where the number in brackets is the score associated to each choice. Table 2 contains 6 of the 18 sentences that compose the attitudinal survey. Note that each sentence is labeled with a word ("positive" or "negative") that refers to the expected trend for the sentence's results when comparing surveys at the beginning and end of the course.

Table 2. Attitudinal survey questions and expected trends

1.	To put a special effort in ensuring the software design quality plays a fundamental role in facilitating the software testing process. (positive)
1.	Software testing is an effective and powerful way to increase software reliability. (positive)
1.	Software testing process starts when all the source code is written and it is always the last stage of the software development life-cycle. (negative)
1.	Software testing is a very time consuming process. (positive)
1.	Software testing is a very repetitive and tedious task; however, no special skills are required to get satisfactory results. (negative)
1.	The best results you can find out once the software testing process is done, is that neither errors nor failures were found. (negative)

Table 3. Summary of attitudes changes

Sentence	Before	After	Difference	P-Value	Significant?
1	3.3	5.1	+1.8	< 0.01	High
2	4.5	5.3	+0.8	0.02	Yes
3	3.9	2.8	-1.1	< 0.01	High
4	4.1	4.5	+0.4	0.2	No
5	5.1	2.3	-2.8	<0.01	High
6	5.3	2.6	-2.7	<0.01	High

Table 3 summarizes results from the sentences contained in Table 2. These results are obtained from 134 students of the course that was offered in the 2005-2006 academic year. The first column indicates the number of the sentence. The second and third columns indicate the average agreement scores for each sentence in the surveys taken at the beginning and at the end of the course respectively. The fifth column shows the P-value derived from one-sided paired t-tests on the raw data. These values are used to determine the statistical significance, which is contained in the sixth column.

CONCLUSSION AND FUTURE WORK

Looking at the overall results for the 2005-2006 course's surveys, we see that students' attitudes changed with a high or at least a positive statistical significance for 15 out of 18 sentences. Moreover, results associated to the sentences designed to evaluate the effectiveness of pair programming confirm initially stated hypotheses always with high statistical significance.

At the beginning of the course students are skeptical about the benefits of a formal software testing process when they realize the amount of work and time that such a process demands. However, we have found that the software testing environment presented here, change students' perception about the value of software testing to improve software reliability. Students see how to test an almost real application and we observe it really encourages them. During the years in which the course has been held, pair programming has demonstrated to be an effective collaborative work model, especially when two students with very different skills are grouped into the same pair. In this case, both members' skills converge to be at least equal to the higher one at the end

of the course. After the training, students work was evaluated in terms of completeness, effectiveness, maintainability and level of automation, results show that more than 85 percent of students performed above the required level. This evaluation also shows that students usually have difficulties when doing integration tests. They don't know how to start the integration and how to progressively select new classes to be added to the integration test. Coaching is much needed at this point. Final evaluations also show that students are generally satisfied with their work and consider the methodology experimented to be useful in the long term.

Our current work and intention for the future is to update and enhance the learning environment by incorporating into it the most relevant software testing related trends and techniques among those that are continuously arising in the software testing world. In particular, we are currently working to incorporate into the course testing of database access and new ways to identify test anti-patterns.

Chapter 5.16
European National Educational School Authorities' Actions Regarding Open Content and Open Source Software in Education

Riina Vuorikari
European Schoolnet (EUN), Belgium

Karl Sarnow
European Schoolnet (EUN), Belgium

ABSTRACT

This chapter provides an overview into policies in the area of e-learning that ten European countries, all members of European Schoolnet, have taken regarding open content and free and open source software (FOSS) to be used to support and enhance learning. Additionally, it elaborates on European Schoolnet's initiatives to support open learning resources exchange in Europe. European Schoolnet (EUN) promotes the use of information and communication technologies (ICT) in European schools, acting as a gateway to national and regional educational authorities and school networks towards Europe. A variety of actions have been initiated by a number of European educational authorities from analysis and feasibility studies to the development of educational software based on open source as well as open educational content.

INTRODUCTION

European Schoolnet is a network of 27 national educational authorities in Europe in the area of compulsory education (K-12). European Schoolnet provides insight into the educational use of information and communications technologies (ICT) in European schools for policy-makers and education professionals. This goal is achieved through communication and information exchange at all

levels of school education using innovative technologies, and by acting as a gateway to national and regional school networks.

In recent years, European Schoolnet and a number its members have, little by little, begun a trend towards awareness building, piloting, development, and the rolling-out of open source software programs for schools, as well as investigating open content as a possible addition to a more conventional content provision.

This chapter introduces some of these policy-level actions; however, it cannot be regarded as an exhaustive summary of policy initiatives in the field of ICT and education. There are two main focuses for the chapter, the policy initiatives and EUN initiatives.

First, the chapter introduces a number of emerging initiatives lead by ten EUN member countries in the area of open source and content for education. Initiatives are categorized in four main sections: awareness raising of Free Open Source Software (FOSS), development of LMS and learning platforms, promotion of the use of Linux on desktops and educational servers, and finally, the promotion of open content. The following countries are featured: Estonia, Spain, and Slovenia as an example of countries basing part of their policy initiatives and actions on open source development; Belgium's Flemish Community and the Netherlands, which run major campaigns to raise awareness of the FOSS issues; Ireland and Finland, as well as France, with smaller scale policy initiatives to familiarize schools with alternative solutions; and finally the UK and Lithuania carrying out feasibility studies with FOSS.

The second part presents two European Schoolnet's recent initiatives in this regard: Xplora, which promotes science education in Europe, and secondly, the EUN's Learning Resources Exchange, which promotes the use and reuse of educational content across Europe. The latter introduces the implementation of a digital rights management framework and briefs on the current development of a learning toolbox to support collaborative learning based on open source development.

BACKGROUND

European Schoolnet (EUN) was funded in 1996 with the mandate of the Council of the European Union. The members of European Schoolnet represent national and regional educational authorities such as the Ministry of Education (MoE) or National Board of Education. Its mission is twofold: on the one hand, EUN works closely with national and regional policy-makers and shapers by setting up special interest committees, involving them in transfer of best practices, and in e-learning research and development. On the other hand, EUN works directly with a large network of European schools through special online events organized in collaboration with a variety of stakeholders.

European Schoolnet is committed in following open standards in e-learning research and development that it conducts in the field, partnering up with different stakeholders from public, private, and industry partners. This has resulted in services that allow multiple players' access to the field. Furthermore, the use and development of open source software in education is becoming more of a concern in different EUN member countries, whereas the promotion of interoperable content-based services, such as federations of learning resources repositories, has long been in the centre of EUN's attention. It is important to note that the members of EUN all lead their own policies based on their national policymaking, and that EUN only has an advisory role for its members.

Apart from reporting on European Schoolnet's partners on their national initiatives, this review will also extend to other national policymakers whenever the information was made available. Mostly, this review relies on contributions from European Schoolnet's partners.

EUN'S MEMBERS ACTIONS IN THE QUEST FOR EDUCATIONAL OPENNESS IN SOFTWARE AND CONTENT

A number of European Schoolnet's partners have explicit roles in promoting the use and development of open source software as an alternative choice for schools. A review on a selection of partners acting upon this challenge is provided in this section presenting the Ministry of the Flemish Community, Education department in Belgium, Kennisnet in the Netherlands, Becta in the UK, Tiger Leap foundation in Estonia, the Ministry of Education and Sport in Slovenia, the National Centre for Technology in Education in Ireland, National Board of Education in Finland, and the Ministry of Education and Science of the Republic of Lithuania. Additionally, some development is reported from Spain and France.

The actions, initiatives, and policies that countries have undertaken in this regard vary throughout Europe. Table 1 presents the main action areas, which can be classified as following; awareness building and distribution of open source software for schools, feasibility studies regarding the deployment of open source software and/or open content, initiatives or pooling resources in the area of software development of learning management systems (LMS) and learning platforms, development or localization of GNU/Linux distributions for schools' use in native languages, and finally, in the area of open content. The list presented in this report does not cover equally all the European countries and is not exhaustive by any means; rather, it serves the purpose to highlight some of the good practices and initiatives.

Estonia: Tiger Leap Foundation (Tiigrihüppe Sihatusutus)

In 2004 in Estonia, the Tiger Leap Foundation (TLF) initiated a project for distribution and

Table 1. Main action areas of a number of EUN member countries in FOSS and open content

Country	Awareness building/FOSS distribution	Feasibility studies	Common development of software	Development of GNU/ Linux	Open content
Flemish Community of Belgium	x				x
Estonia	x		x	x	x
Finland	x				
France	x		x	x	
Ireland	x				
Lithuania		x			
Netherlands	x	x	x		
Slovenia	x		x	x	x
Spain	x			x	x
UK	x	x			

promotion of freeware in schools. The project aims at releasing a Linux distribution that is suitable for schools, preparing training materials, and training teachers. Furthermore, since the spring 2005, TLF only supports projects that will be released under general public license for the code; as for the content, a creative commons license will be required.

A number of Estonian educational open source software applications have been developed, with the financial support of TLF in collaboration with Tallinn University (TU). The development of virtual learning environment VIKO started in 2001. Schools do not have to set up their own server, VIKO is offered as a free service by Tallinn University. Furthermore, KooliPlone, a Plone-based content management system for school Web sites is developed in TU.

Another large-scale development of a learning management system, called IVA, was supported by Estonian Ministry of Education and Science, the Estonian Information Technology Foundation, and Hansapank, the largest bank in Estonia. IVA is also developed in TU, based on Zope and an existing educational platform called Fle3. It has Estonian, Russian, and English user interfaces, and is currently used by more than 2,000 users in TU.

Additionally, Estonia being a country representing a small market, the government has funded the translation of OpenOffice's spell-check program in Estonian.

Slovenia: Actions by the Ministry of Education and Sport

Slovenian Ministry of Education and Sport has a focus on three main areas providing basic tools, didactic tools, and promoting open source for teachers, headmasters, and pedagogical specialists.

To the category of providing basic tools, the Ministry includes Linux, OpenOffice.org, CMS, LMS, as well as some distance learning services. First of all, all new computers in schools, which are co-financed by the Ministry of Education and Sport, have a dual boot for Windows and Linux, and have OpenOffice.org installed for both operating systems. The Linux distribution is called Pingo and is provided in Slovene. Pingo has been developed by a local association, called Lugos, with the Fedora Linux 3 open source community in Slovenia. For the last two years, the Ministry of Education and Sport, the Ministry of Information Society and the (governmental) Centre for Informatics have financed the localization in Slovene language. Currently, a tender to co-finance the localization for the next two years is under preparation.

Another example of learning management and learning content management system that is available free of charge for academic institutions is E-CHO, developed by the Faculty of Electrical Engineering, University of Ljubljana. It enables simple course creation, extensive content management, and it supports entire learning process.

Secondly, in the area of basic teacher training, among other ICT skills, the programs include the use of Windows Office as well as OpenOffice.org. The Ministry financed an expert group that supports schools with open source software, such as some CMS and LMS, and support books have been distributed to schools about the use of Linux and OpenOffice.org. Moreover, the Ministry with National Education Institute and Center for Vocational Training promotes the use of open source software among teachers, headmasters, and didactic specialists.

As for didactic tools and open content, the Ministry finances teacher training in the area of open source didactic materials (i.e., open content). It has also co-financed some new open content didactic material on the Web for the use in classrooms, with some support given for teachers in training to use this material. As well, the Ministry will co-finance, in the future, creation of didactic material that is not open source, but can be used freely by schools.

To promote the use of open source and open content, the Slovenian Ministry of Education and Sports has started the portal OKO. This project is with the intention to make the introduction of open source and free educational software into education environments faster and more efficient. The OKO project was started in 2003.

Spanish Initiatives

Spain has had some regional policy initiatives to promote the use of open source, and especially Linux use, in school servers and desktop. Probably, the region of Extremedura is the best-known large-scale example in Spain, where the local information strategy is based on the use of free and open source software. The local authorities decided to boost development in the region, which is prone to high unemployment, by delivering over 150 000 cd-roms containing a localized Linux distribution, Linex, along with dedicated office software. It has been distributed in different ways. In Extremadura, schools are immersed into using Linux; it has been deployed on around 70,000 desktop PCs and 400 servers in schools. Some other communities in Spain who have decided to do so are at least Andalucia, Madrid, and Valencia. In two of them, the school's workstations are delivered with a dual boot configuration, so that the users have the option to work either on Linux or Windows, and can familiarize themselves with two different operating systems. In the community of Galicia, new computers to schools are delivered with Linux installed.

Belgium: The Ministry of the Flemish Community, Education Department

The Ministry of the Flemish Community, Education Department in Belgium has an explicit role in promoting the use of open source software as an alternative choice for schools. In 2004, the former minister of Education, Ms. Marleen Vanderpoorten, commissioned an advisory on the issue, which led to a vision and a proposed action plan.

In 2005, a large campaign was organized to introduce free and open source software in Flemish schools, aiming to highlight its educational possibilities. In this campaign, a publication, a CD, and an educational tools database were drafted and a conference was organized.

By means of the publication "free software in the education," a practical guide for the use of FOSS and open educational tools is spread amongst all schools. Besides general information on the "what and how" of FOSS, one finds descriptions of a number of interesting open source applications. In association with the educational portal Klascement, an educational tools database was developed for these applications. This is also the general campaign Web site. Moreover, a conference was organized addressing FOSS and open educational tools, targeting audiences such as teachers, headmasters, and ICT co-coordinators.

The Education Department in Flanders has created didactic sheets on the use of educational freeware and open content, based on the primary education curriculum topics. The didactic sheets have been published as a book, "ICT on the menu," and are searchable in a database through the portal. The scenarios are a helpful means to make the ICT integration in primary education more concrete. In 2005, a similar project was developed for secondary education. This time, the work was carried out by teachers from the secondary ENIS schools. The result is a publication, both on paper and online, called "Digital resources for secondary education." In 2006, a CD was published, with open learning tools and open source educational software that is currently under a validation process by the European Network of Innovative Schools (ENIS).

The Netherlands: Open Source and Open Standards in Education (OSS in het onderwijs)

Since 2003 in the Netherlands, the government has brought open standards and open source into the central focus of its attention. A variety of initiatives have been set up to work on cross-sectoral issues that touch upon open standards, as well as open source development. As for the education, there are initiatives, programs, and actions taken to foster the efforts in the field and to muster the common efforts.

The program "OSS in het onderwijs," translated as open source and open standards in education, is a joint initiative between Kennisnet, ICT op School, and a government-wide program called OSSOS, the Program for Open Standards and Open Source Software. Additionally, to involve a diversity of partners in the field of education, an association called EduStandaard has been set up. The association aims to manage the standards that are used in the Dutch educational field, comprising stakeholders such as publishers, schools and so forth.

Kennisnet promotes a program to improve the use of open standards for content. A central point for "OSS in het onderwijs" is a Webspace where the Dutch education community can discuss open source and open standards aiming at both the novices and experts. The main focus is on primary and secondary education, but also on the field of vocational training. The program is informative, aiming at offering alternative solutions for schools that have an independent budget to spend on educational technologies. The program targets mainly the IT coordinators, administrators, and teachers who are responsible for IT set-ups in schools, but also at teachers who use computers and ICTs in their lessons.

One powerful means to transfer good practices and ideas of the use of FOSS in education are the case studies that can be found at the Web site of "OSS in het onderwijs". These case studies are simple descriptive interviews with practitioners on topics such as how to use GIMP for manipulating images, and so forth.

"OSS in het onderwijs" has also prepared an info package, on a CD, that focuses on the use of open standards in all processes in school that can involve the use of information technologies from administrative tasks to using applications for learning purposes, gathering content about the student for portfolios, as well as other actions for creation, exchange, and alteration of the content. The idea was to identify all actions and propose alternatives where closed systems or standards are used. This aims at better overall interoperability within schools' information systems. The CD was released in the end of 2005. In the same spirit, a booklet on open source software was created in 2004 for schools. These information packages can be requested from the Web site, but they are also handed out at local ICT conferences.

The program "OSS in het onderwijs" can help schools to implement open source, not only in advisory terms, but they can make small amounts of money available to pay for a third-party programmer or consultant to, for example, find compatibility solutions between an existing system and the new one based on open source and standards. On the Web site, there is also a FOSS helpline for schools to help them to solve small-scale problems. In this regard, the program tries to match the need that schools have for support with existing supply in the market. On the Web site, one can find an overview of companies with experience of FOSS and education.

"OSS in het onderwijs" has been running for 3 years, 2005 being the final year with a big push, the continuation for the next year is still unsecured. A conference, with 1-day education track on the topics, was held in December 8 2005.

France: Distribution of FOSS

In France, the National Centre of Pedagogical Documentation (SCÉRÉN-CNDP) has led a

working group that evaluated some 30 educational open source software packages, with an emphasis on multiplatform usage. The software, and accompanying educational guidelines for its use in the classroom, was made available for schools, in the format of a CD, through a network of regional centers, at minimum charges, in 2004. The CD has had a good success, and its distribution continues.

On the school server level, advances have been made to introduce GNU/Linux for school servers. An initiative, SIIEE (service intranet-internet in educational establishments and schools), has deployed about 15, 000 Linux-based servers throughout the country.

Furthermore, some regional French authorities have also embraced FOSS. For example, the Pays du Soissonnais has declared as its ambition to become an axle of excellence in open source, making it part of its regional policy, grouping a variety of local actors together to find ways to benefit from open source. The Region of Picardie participates in the initiative; already since 2004, each school receives earmarked money to be spent on open source software to buy services or to hire someone to do the work locally. Partially, the idea behind this initiative is to boost local economy (Picardie ranks high for unemployment), but the objective is also to use public money for the public good. Picardie, as a region, also has a high profile on free and open source software, and participates actively in the annual trophy competition for the best educational software.

Finland: Informing about Educational FOSS

In 2006, the National Board of Education in Finland launched an initiative to gather an information package for schools about the use of open source software and content for educational purposes. The aim is to distribute information on how open source software can be used to support educational purposes for creating educational content, as well as for school administrational matters, but also to clarify the basic terminology to be used in the area. The target audience is teachers, the ICT coordinators, and school heads. The information is gathered in collaboration with local experts in the field, as well as practitioners who have been using and adapting FOSS solutions in their schools and educational establishments.

Another type of interesting initiative can be reported from Finland, although it does not directly receive any educational attention. To make open source development rooted into a variety of sectors within society, including education, a sustainable plan for services and support should be in place. The Finnish Centre for Open Source Software (COSS) aims to help its building. COSS started at the beginning of 2004 with basic funding, granted by Finland's Ministry of the Interior, to help to build an ecosystem within business, research, and education. Currently, the Häme Centre of Expertise, as a partner of COSS, is responsible for developing open source based business in the field of e-learning. It could be contemplated that this type of idea and innovation feeding across sectors has a positive value for the uptake of open source software in educational establishments, as they will have local businesses to rely upon for the support, sale, and delivery of these e-learning services.

Ireland: Star Office for all Irish Schools

In late 2004, the National Centre for Technology in Education (NCTE), the Irish Government agency established to provide advice, support, and information on the use of ICT in education, concluded a licensing and distribution agreement with SUN Microsystems to provide all Irish schools with Star Office, an office suite based on open source OpenOffice.org. The offer was made to schools in a joint move by the NCTE and SUN Microsystems.

To help schools appreciate the opportunity and to explore the implications of taking up Star Office, or substituting the commonly used MS, schools were notified and local information sessions were organized for school representatives. These sessions were well attended and, following participation, the take up has been significant to date. Schools receive a free CD that allows unlimited copying for staff and students.

Prior to the large-scale offer of Star Office in 2004, the NCTE carried out a number of evaluations of Star Office in a number of schools in order to assess the appropriateness of this software for schools. The outcome of these trials proved very positive. Star Office was identified as being a relevant and very useful software tool, particularly for schools at primary level.

The UK: Evaluation on Open Source Software in Schools

In May 2005, the British Educational Communications and Technology Agency (Becta), released an evaluation on the use of open source software within a number of schools. In the UK, some previous government studies have suggested that the use of FOSS within the UK public sector can provide a viable and credible alternative to propriety software, and lead to significant cost savings.

The study, funded by the Department for Education and Skills, had three main aims: to examine how well the open source software approach works, compared with proprietary offerings, in supporting delivery of the school curriculum and administration; to compare the total cost of ownership (TCO) of using FOSS within school environments against that of non-open-source solutions; and to highlight examples of successful school-based open source implementations.

The report, "Open Source Software in Schools: A study of the spectrum of use and related ICT infrastructure costs," demonstrates that although the implementation of FOSS in schools needs careful planning and support, it can offer a cost-effective alternative to proprietary software. For the ways forward with FOSS, the report examines cost-effective models of support in OSS schools; best practice in licensing solutions; successful implementation to run the school's servers to provide school-wide facilities, operating systems, and administrative PCs, and FOSS applications on classroom and administrative PCs.

According to Becta's chief executive, Owen Lynch, Becta believes that software used in schools should be of a high quality and adhere to open standards, enabling compatibility and interoperability between products. Becta will now be undertaking more extensive research across a wider range of institutions to allow further analysis of these issues.

Lithuania: Research Study and Recommendations for Actions in Open Source in Education

The Ministry of Education and Science of the Republic of Lithuania commissioned a study in 2004 to further investigate the possibilities of open source software in education in Lithuania. The global fight against the use of illegal software and piracy, and the openness of the source code to guarantee more transparency and ease of localization, were mentioned in the goals of the study as important to go forward with.

The conclusions of the study outlined the following; open source software has an indirect positive impact on the economy of education through the emergence of a competitor to commercial software, forcing a reduction in the price of commercial software and translations into the languages of small nations spoken by few people.

The study furthermore proposed some actions both at the state level and ministerial level. The state level proposal included, among others, the following: it is necessary to ensure the adaptation and localization of general purpose open source

software at the state level; it is necessary to take care of the cultural and linguistic quality of open source software; the promotion and support for open source software could help solve the problem of the legality of software.

At the ministerial level of the Ministry of Education and Science, the proposed actions included analyses of localization of educational Linux distributions and open source virtual learning environments to determine which one would be appropriate to be localized and used in Lithuanian schools. As to introducing FOSS in education, the following was proposed: higher schools' training educators should introduce their students to both commercial software and equivalent open source software necessary for teaching and learning; at school, students should be introduced to general purpose software of both types: commercial software necessary for teaching and learning, as well as to equivalent open source software. Furthermore, to assure the quality of localization, an interesting proposal was made: a course on localization of software for some students specializing in information technologies and philology.

EUROPEAN SCHOOLNET'S PROJECTS DEALING WITH OPEN CONTENT AND OPEN SOURCE

This section presents the Xplora project, which promotes science education in European schools, and briefly presents the work that EUN carries out in the area of learning resource exchange (LRE), where digital learning resources and/or their metadata are exchanged between educational repositories.

Xplora, Distributing Science for Education in its True Way: Openly

Xplora, the European Science Education Gateway, is operated by European Schoolnet. Xplora portal is supported by the PENCIL project, a project funded by the European Commission's Directorate General for Research as part of Science and Society.

Xplora offers science teachers tools, information, and resources to help them to conduct engaging science lessons that make students attracted to science. Commonly, with 30+ students in classes, science teaching is somewhat blocked by poorly equipped school laboratories. Among the resources that Xplora offers are the usual Web-based tools like online games, downloadable materials, and guides to software that is usable in science lessons.

Xplora portal also offers new tools that have not been used in the classroom before. Among these tools are the Web experiments or remote controlled experiments (RCL), in which real experiments are shared via the Internet. Such experiments do not only solve the problem of the true way of science teaching by experiments, but it also opens new pedagogical concepts for science classes. These Web experiments deliver results that students have to process in order to get a lab report.

Using Software: A Key Skill in Scientific Research

Participating in science education today means extensively using software. For instance, for the Web experiments where, in many cases, students get the result of an experiment as an image, the image analysis is a fundamental task. The main tasks for students in science education are (1) create a lab report with mathematical expressions, chemical formulas, Feynman diagrams, images, tables, and graphs; (2) analyze images, for example, measure length, angles, area, and intensity; (3) calculate results, for example, numerical processing, creating graphs, regression, and curve fitting; (4) create animations; (5) run simulations; (6) create and play with mathemati-

cal models, and (7) use CAS software to verify results of calculations.

While office suites text-processing software is useful and broadly applicable to be used in schools, it is, in many cases, not sufficient for specific science tools. One of the examples is simple text editing. For science lab reports, a text writer must be able to handle mathematical equations, chemical formulas, and Feynman diagrams, just to mention the most exotic pitfalls.

Many of the open source software packages have origins in scientific environments. Thus, there are many applications that can be used for science teaching in classroom, with some prior training. Xplora recommends the use of the following software packages, displayed in Table 2, for science teaching. On the portal, one can find articles and short descriptions for their usage.

Xplora-Knoppix, Making Science Accessible for Schools

To ease some of the organizational problems that schools face in terms of software availability, installation, and access in general, the Xplora team developed a live bootable DVD called Xplora-Knoppix. It is a based on the Linux Debian distribution, and completely contained on a self-booting DVD. As this Knoppix version is especially mastered for Xplora, the team has added software applications needed for science education (Table 2), as well as a number of educational materials from the Xplora repository. The Xplora-Knoppix has multilingual support. This concept ensures easy access to scientific tools for education. Being open source software, it can be given away freely and copied as many time as needed.

Xplora produced 600 DVDs to be given freely to schools. Moreover, the ISO image of the DVD is freely downloadable from the Internet and can be used to produce the copies needed for the students. This DVD is occasionally updated. Additionally, Xplora has partnered with a company that sells the Xplora-Knoppix DVD for the production plus shipping cost.

EUN Content Services in Pipeline

Since 2000, European Schoolnet has lead EU-funded projects to give better access to digital educational resources for teachers and learners across Europe. The CELEBRATE project (2002-2004) provided the first large-scale demonstration and evaluation of learning object (LO) interoperability and the use of LOs in schools at a European level.

In 2004, a survey of 13 Ministries of Education participating in European Schoolnet also indicated that they wished to take forward the vision of learning resource exchange (LRE) based on the architecture demonstrated in the project. Furthermore, many communicated that LOs are increasingly seen as an important, and in some cases, a key component in the content development strategies of Ministries of Education. Also, the majority expressed interest in open source content development strategies where "learning object economy" was created for open source and commercial content to coexist.

EUN continues its work towards an enhanced architecture for learning resources in Europe. EUN will continue to lead the development of the LRE based on a brokerage system architecture (of which the code for the brokerage system is licensed under the LGPL) involving a variety of stakeholders, from content providers, both public and commercial, to end users in European schools.

A set of more tailored services will be offered to the members of LRE, such as federated searches, learning resource exchanges, and digital rights management. It is envisaged to support multiple digital rights expression languages, and permit content providers to select the level of digital rights management that best fits their needs in terms of intellectual property protection. This requires a proper digital rights management (DRM). The

Name of software	URL	Description	Application
OpenOffice.org	http://www.openoffice.org	The Open Source office software for scientific text processing, database applications, graphics creation.	Lab reports. Calculation of results Creation of simple charts
LyX	http://www.lyx.org	Scientific text processor software, making use of LaTeX properties. Full support of mathematical expressions and all Postscript output from scientific programs.	Lab reports with even the equations, and output of all X11.
Xfig	http://xfig.org	Vector drawing program with a large and extendable parts library.	Preparation of schematic drawings (experimental setups) for lab reports.
Grace	http://plasma-gate.weizmann.ac.il/Grace/	Data analysis program	Plots diagrams of every complexity. Good software for creating regression and line fit.
GIMP	http://www.gimp.org	Graphics program to analyze images	Image analysis (length, angle)
ImageJ	http://rsb.info.nih.gov/ij/	Image analysis program	Analysis of intensity distribution in an image.
Xdrawchem	http://xdrawchem.sourceforge.net/	Program to draw chemical structures	Report on chemistry lab exercises.
OpenRasmol	http://www.openrasmol.org/	Program to visualize 3d molecules	Chemistry classroom use and creating images for reports.
Feynman	http://rpmfind.net/linux/RPM/suse/9.0/i386/suse/i586/feynman-1.00-581.i586.html	A program to create Feynman graphs	Particle physics teaching.
Ghemical	http://www.uku.fi/~thassine/ghemical/	A molecular modeling software package	Chemistry teaching in high schools
Gcompris	http://www.ofset.org/gcompris	A software package for the kids	For elementary schools. Many different applications around elementary schools teaching
KDE Edu	http://edu.kde.org/	The KDE Education project	Many educational software packages mainly focusing on lower-level education.

objective is to design and implement a DRM framework that takes into account requirements from all stakeholders; thus, supporting available DRM standards like ODRL and Creative Commons.

European Schoolnet supports the use of Creative Commons licenses within its services, and has already implemented an integrated interface for its users to choose an option of Creative Commons license for the resources that they submit to various EUN projects.

Open Source Learning Toolbox to Support Collaborative Learning
