European Schoolnet's research into the use of learning environments confirms that a number of its members flavor the development of open source VLEs. Moreover, many expect the next generation of new learning platforms to facilitate the adoption of more learner-centered and collaborative pedagogical approaches. However, the same survey and subsequent observations suggest that these high expectations are not yet being met. Most teachers are still using VLEs as little more than a "digital distribution" space, somewhere to upload, store, and distribute content, and to issue assignments to students.

EUN, among the CALIBRATE project partners, will lead the development of a VLE that brings together two quite distinct and somewhat opposing methodologies for pedagogical affordance; the first comes from a background of social constructivist pedagogies and collaborative knowledge building, whereas the second has a background in SCORM and LCMSs. By drawing on both these approaches, a new open source toolbox will be built using the existing code from Future Learning Environment 3 (FLE3) based on Plone/Zope. The VLE will offer a richer feature set that will be developed with the help of practicing teachers.

CONCLUSION

Currently in the European educational policy and practices landscape, the existing open content and free and open source software initiatives are rather dispersed on a local, national, and European level, as well as being spread throughout all educational levels and systems. It is challenging to get a comprehensive overview on the state of the art being available, as well as capitalizing on the transfer of knowledge gained in one context. However, as this report clearly summarizes, European Schoolnet and its members are more and more focusing on the issues around open source and content development. It must be stated, though, that these activities still remain somewhat marginalized in discussions, country reports, and conferences; they rarely receive the limelight that they merit.

When it comes to actions taken by European Ministries of Education and other national educational authorities, it seems like they are keen to explore the advantages that open source software and content can offer to education. According to the interviews conducted for this chapter, it can be stated that 10 out of 25 EU member states have taken policy-level actions in e-learning to better exploit the use of FOSS in education. In this report, we looked at five different categories where attention is given: awareness raising of FOSS as an alternative solution for e-learning tools; feasibility studies regarding the use of FOSS to support education, both in teaching and administration; development of learning platforms based on FOSS; localization of GNU/Linux desktops to be used in schools; and finally, open content as an alternative means for digital content provision. It appears that the featured countries have taken actions in all these areas, some in all, whereas others in one or two. Moreover, some of the countries seem to have ventured into the area of FOSS just to find

out more about it, whereas the others have embedded FOSS into their policy-making strategies and initiatives in a more integrated way.

This chapter attempts to report on these developments, rather than going further to analyze them in details. Many interesting questions have been raised regarding these policy-level initiatives, more importantly, what are the synergies between grass-root actions in schools and the policy and decision-makers responsible for these initiatives, their continuation, their accountability, and so forth? Are these policy-initiatives a response to the demand in the field, or do they support the further uptake of FOSS in education?

It seems that it would be important to bring these somewhat disparate, but very pertinent national and regional initiatives into the European level to better help the transfer of good practices and to learn from one another. Furthermore, peer-learning possibilities on the policy level should be better exploited in this area, as have been done in other areas of ICT implementations.

Xplora carries out important work promoting science in education in European schools. The multiple ways to distribute software that is suitable for scientific studies allows schools a better access to the core of science: participate by practicing it.

Finally, the work EUN has carried out in publishing the Insight Special Reports has given a more prominent voice for FOSS in education, and been an important source of information for EUN's members and audiences on national levels.

The area of open content seems to be rather well accepted concept among EUN's partners. Thus, creating infrastructure and facilitating the content exchange of learning resources in schools is one of EUN's core areas where significant work is conducted to facilitate the coexistence of open and "closed" content. For example, the implementation of digital rights management framework is a step towards the coexistence of multiple stakeholders in the field of educational content. Also, some important work will be carried out in the context of EU-founded projects such as where the development and implementation of an open source collaborative "learning toolbox" for schools is being done.

ABSTRACT

The computer software education in vocational schools in Taiwan can hardly be deemed as effective. To increase students' learning motivation and develop practical skills, innovative learning designs such as problem-based learning(PBL) and self-regulated learning (SRL) are on trial in this specific context. We conducted a series of quasi-experiments to examine effects of these designs mediated by a web-based learning environment. Two classes of 106 freshmen in a semester course at Institute of Technology in Taiwan were chosen for this empirical study. Result sreveal that effects of web-enabled PBL, web-enabled SRL, and their combinations, on students' skills of application software have significant differences. The implications of this study are alsodiscussed.

INTRODUCTION

Professionals with a vocational degree represent a major portion of the work force in Taiwan. Vocational education is highly competitive in that it must attract enough student enrollments in the

face of a continually decreasing birthrate and a rapidly increasing number of schools. Students in these schools tend to have lower levels of academic achievement. They spend more time on part-time jobs and do not get involved in their schoolwork adequately. They also care less about their grades. Teaching in such a context, particularly teaching the curriculum of application software, is a great challenge to most educators.

No one doubts the guiding principles of practical applications in the vocational education in Taiwan (Tai, Chen, & Lai, 2003). However, most teaching and learning efforts in this area have been devoted to helping students pass written tests, and, thus, receiving awards or official certificates. Schools, facing the high pressure of market competition, often emphasize the proportion of students awarded such certificates before they graduate instead of quality education. This materialistic aim puts students' attention less on mastering application software and more on preparing for tests through memorization. Consequently, a student who has passed the examination may still be unable to apply what was learned in school, and worse, lack motivation to learn more in the future.

The courses in application software traditionally emphasize memorization by applying short, disjointed, lack-of-context examples. There is a wide gap between what is learned in school and what is required in the workplace (Wu, 2000). In this regard, the computer software education in vocational schools in Taiwan can hardly be deemed as effective. In order to increase students' learning motivation and develop practical skills, problem-based learning (PBL) is considered to be the most appropriate. PBL uses real-world, simulated, contextualized problems in practice to motivate, focus, and initiate content learning and skill development (Boud & Feletti, 1991; Bruer, 1993; Williams, 1993). We believe that PBL could help low-academic-achievement students to develop practical skills of application software through online courses.

Web-based instruction seems to be an ideal learning environment because students can access an almost-unlimited amount of information and apply it in multiple ways (Kauffman, 2004). However, implementing e-learning for low-academic-achievement students inevitably runs high risks. For instance, Internet addiction is quite common among low-academic-achievement students. When students enter the traditional classroom, they are used to logging on to MSN Web Messenger and checking their e-mail first. Many students like to chat with each other frequently via MSN Web Messenger, even though they are in the same classroom. They might browse shopping Web sites, even while a teacher is lecturing in the classroom. Thus, the teacher has to disconnect the network several times in his classroom to focus students' attention. It is even more difficult for students to concentrate on online learning because of this addiction to the Internet and a lack of on-the-spot teacher monitoring. To respond to this challenge, we propose an approach that can help students regulate their learning in a better way.

Success in online courses often depends on students' abilities to successfully direct their own learning efforts (Cennamo, Ross, & Rogers, 2002). It is very critical to develop students' self-regulation of learning before providing online courses to them. In web-based learning environments, physical absence of an instructor and increased responsibility of learners to effectively engage in learning tasks may present difficulties, particularly those with low self-regulatory skills (Dabbagh & Kitsantas, 2005). Student motivation may benefit from Web-based instruction with self-regulated learning (SRL) strategies. Students in the online environment, equipped with SRL competence, become more responsible for their learning and more intrinsically orientated (Chang, 2005). So self-regulation is important, particularly while learning in World-Wide-Web-supported environments (Winnips, 2000).

Although researchers have consistently shown that self-regulation helps high achievers reach their potential (Risemberg & Zimmerman, 1992),

it also makes a difference between failure and success for low achievers (Borkowski & Thorpe, 1994). However, there has been relatively little empirical research on students' SRL with such complex technology-based learning environments (Azevedo & Cromley, 2004). Therefore, this study applies SRL in this study to help vocational school students (particularly the low achievers) concentrate on their learning, leave time for learning after their part-time jobs, and furthermore, take responsibility for their learning.

There are few studies that have discussed effective online teaching methods for low academic achievers. In this area, the restructuring and translation of traditional computer software courses into e-learning has seldom been documented. Thus, this study redesigns a course in application software to integrate innovative teaching methods and learning technologies to help students learn and apply what they have learned. This study specifically explores potential effects of Web-based PBL and SRL on the development of low-academic-achievement students' skills in using packaged software.

AUTHENTIC ASSESSMENT

The traditional teaching approach regarded learners as passive recipients of information. Memorization of the content lectured by the teacher was the main goal of the instructional process. The assessment approach that accompanied this instructional approach was mainly operationalized by the so-called objective test, often standardized and with a true/false or a multiple-choice item format. Such assessments mostly do not seem to assess higher-order cognitive skills, such as problem solving, critical thinking, and reasoning (Segers, Dochy, & De Corte, 1999).

However, the objective tests are often given, even in computer software education. They could not evaluate students' practical skills, but also limit the potential application. Two innovative and practical teaching methods are applied in this study, so the traditional measurement is not appropriate to assess students' learning, particular in computer software education. More appropriate assessment methods for PBL would include reports, practical examinations, construction of concept maps, peer assessment, or oral presentations (Sonmez & Lee, 2003). In this regard, we measure students' skills of application software according to the correctness and completeness of their problem solving and artistry of their design instead of the memorization. The way we assess students' improvement in skills of application software is described in the "Measures" section.

PROBLEM-BASED LEARNING

Problem-based learning (PBL) is a teaching method that may engage students in authentic learning activities by using challenging problems in practice as a starting point, stimulus, and focus for learning (Barrows & Tamblyn, 1980; Boud, 1985; Barrows, 1985, 1986; Walton & Matthews, 1989; Boud & Feletti, 1991). PBL promotes student learning based on the need to solve problems. It not only emphasizes the learning in the subject area, but also provides opportunities for students to practice and apply knowledge and learned skills.

Davis and Harden (1999) indicate that PBL is one of the most effective teaching methods in recent 30 years. The probable reason is that the learning environment of PBL includes all kinds of factors currently known which can improve efficiency of learning, such as activity, cooperation, feedback, adaptability, and accountability. Albanese and Mitchell (1993) reveal that PBL helps students more in knowledge construction and reasoning skills compared with the traditional teaching approach. PBL may help students achieve learning goals, such as professional reasoning;

integration of scientific, academic, and professional knowledge; and lifelong learning skills (Dunlap, 2005).

Many Researchers examine PBL's positive impact on knowledge and skill acquisition and transfer, problem solving, attitudes and opinions about courses and programs, measures of performance, and self-directed learning (Norman & Schmidt, 1992; Albanese & Mitchell, 1993; Berkson, 1993; Vernon & Blake, 1993; Colliver, 2000; Davies, 2000). Furthermore, Polanco, Calderón, and Delgado (2004) point out that students in PBL groups attain significantly higher scores than students in a course from a control group composed of physics, mathematics and computer science.

In the domain of Information Science, Greening, Kay, Kingston, and Crawford (1996) consider that upper-level university students should have developed many key competencies. However, during teaching, they actually find many third-year students not having acquired necessary competencies from information science curriculum. PBL, as an alternative teaching method, demonstrates that it helps to improve students' key competencies. Yip (2001) points out that PBL can enhance competencies, both in professional and information systems education.

PBL is a flexible approach. It has demonstrated its working well with both small teams and large groups. However there might be disagreement whether PBL will be as effective, or even possible, for online learning. In this regard, Chanlin and Chan (2004) examine the effects of PBL in a Web-based approach. Results reveal that students in the PBL treatment group perform better than those from the control group. Therefore, it can be summarized that, in a Web-enabled learning environment, the effects of problem-based learning on students' skills of application software are positive, and higher than those without PBL.

SELF-REGULATED LEARNING

Zimmerman and Schunk (1989) define SRL in terms of self-generated thoughts, feelings, and actions, which are systematically oriented towards attainment of students' own goals. SRL is also defined as a learner's intentional efforts to manage and direct complex learning activities and is composed of three primary components, namely cognitive strategy use, meta-cognitive processing, and motivational beliefs (Kauffman, 2004).

Yang (1993) finds that students who are high self-regulatory skill users, as measured by a preexisting index, score significantly higher than their counterparts, low self-regulatory skill users, regardless of the level of control. Characteristics attributed to self-regulated persons coincide with those attributed to high-performance, high-capacity students, as opposed to those with low performance (or learning disabilities), who show a deficit in these variables (Roces & González Torres, 1998; Zimmerman, 1998; Reyero & Tourón, 2003).

Zimmerman and Martinez-Pons (1986) point out that students' frequency of self-regulated strategy use predicts a substantial amount of variance in their achievement test scores. Nota, Soresi, and Zimmerman (2004) indicate that the cognitive self-regulation strategy of organizing and transforming proves to be a significant predictor of the students' course grades in mathematics and technical subjects of high school, their subsequent average course grades, and examinations passed at the university.

As for the effects of SRL on computer software, Bielaczyc, Pirolli, and Brown (1995) incorporate self-explanation and self-regulation strategies in the attainment of the cognitive skill of computer programming. They find that their treatment group, which incorporates the self-regulation strategies of self-monitoring and clarifying comprehension

failures in conjunction with self-explanation strategies, outperforms a control group that did not have the benefit of instruction in these strategies. Their study implies that, in addition to knowledge acquisition strategies, students benefit from the incorporation of strategies which allow them to plan, monitor, and evaluate their understanding and strategy use (Bielaczyc, Pirolli, & Brown, 1995). In a similar vein, this study provides us an insight that SRL is appropriate to be applied in computer software education.

Researchers have consistently shown that self-regulation helps high achievers reach their potential (Risemberg & Zimmerman, 1992). It also makes a difference between failure and success for low achievers (Borkowski & Thorpe, 1994). Young (1996) identifies that low self-regulatory skill users are found to perform significantly lower in computer-based instruction that applied learner control of the sequencing. It is believed that SRL is effective to the low achievers, not only through face-to-face instruction, but also in computer-based or technology-based instruction. Learners who report more extensive use of SRL strategies show higher academic achievement than learners who use self-regulated learning strategies less often (Zimmerman & Martinez-Pons, 1986). In the same study, students' achievement could be predicted with 93% accuracy from reported use of SRL strategies.

Web-enabled learning environment is an interactive network system consisting of a variety of functions to support a virtual classroom to enhance the quality of teaching and learning activities (Poon, Low, & Yong, 2004). Students can access information at their convenience, are free to work at their own pace, and can revisit information that they find confusing and/or interesting (Lehman, Kauffman, White, Horn, & Bruning, 2001). Nevertheless, providing students with opportunities to integrate their knowledge through Web-enabled instruction may not be effective if they lack the skills needed to regulate their learning. Thus, strategies that prepare students for the rigors of learning at a distance and increase the probability of retention and success must be put into practice (Chang, 2005). Winnips (2000) suggests that self-regulation is particularly important when learning in World-Wide-Web-supported environments. In other words, it is even more critical for students to transform into self-regulated learners in Web-enabled learning. Previous studies have established that self-regulated skills can help foster learning from any instructional method (Weinstein, 1989; Zimmerman, 1990; Lindner & Harris, 1993; Ertmer, Newby, & MacDougall, 1996). To sum up, in the Web-enabled learning environment, effects of self-regulated learning on students' skills of application software are positive and performance higher than those without SRL.

PROBLEM-BASED LEARNING AND SELF-REGULATED LEARNING

In PBL, students work in collaborative groups to identify what they need to learn in order to solve problems. They engage in self-directed learning (SDL), apply knowledge they acquire to the problems, and reflect on what they have learned and the effectiveness of the strategies they have employed. That is, PBL is well-suited to help students become active learners as it situates learning in real-world problems and makes students responsible for their learning (Hmelo-Silver, 2004). PBL helps prepare students for lifelong learning by developing students' ability for self-directed learning and their meta-cognitive awareness (Dunlap, 2005).

PBL is a task-based approach that teachers can apply to support development of SRL. If PBL activities are designed carefully with teachers who provide appropriate modeling and scaffolding, they facilitate and necessitate SRL. PBL provides opportunities for self-directed learning by offering students choice, control of what to work on, how to work, and what products to generate. PBL

facilitates SRL because it places responsibility on the students to discover information, to coordinate actions and people, to monitor understanding, and to reach goals (Paris & Paris, 2001).

Hmelo-Silver (2004) points out that students' approaches to learn from problems are different qualitatively because of their degree of self-regulation. Ertmer et al. (1996) conducts a qualitative study of how veterinary students learned from problems. Low self-regulated learners have difficulty in adapting to the kind of learning required in problem-based instruction. They fluctuate according to their perception of the value of learning from problems. High self-regulated students value learning from problems and tend to focus on the problem analysis and reflection process. In contrast, low self-regulated students tend to focus on fact acquisition. Furthermore, the results of Ertmer et al. suggest that low self-regulated students may have difficulty in dealing with SRL demands of a PBL curriculum.

Combined training with self-regulatory and problem-solving strategies is effective for enhancing self-regulatory competences in solving mathematical problems (Perels, Gürtler, & Schmitz, 2005). However, there are very few studies that discuss the effects of PBL and SRL simultaneously, particularly through teaching Web sites. According to the literature reviewed , it is believed that the learning effect will be even stronger when teachers arouse students' interest, lead them to apply their skills and knowledge to solve problems, and encourage them to self-regulate their learning.

In this research, we hypothesize that students focusing on the aspects of problem-based learning variant with self-regulated learning would gain more development on the skills of application software than students studying the task without these co-existing treatments. We also hypothesize that learning effects of PBL and non-SRL group or non-PBL and SRL group are better than non-PBL and non-SRL group. That is, highest increase of development in skills of applying packaged software is expected in conditions wherein students are confronted with the situation of simulated problems and with self-regulated or self-directed learning style without teachers' pressure. Therefore, we propose the following: in a Web-enabled learning environment, the effects of PBL and SRL intervention on students' skills of application software are positive, and higher, than those without the combined intervention.

METHODS

Participants

Participants in this study are 106 fresh students taking a compulsory course of 'Packaged Software and Application' in an institute of technology in Taiwan. None of them major in the field of information or computer technology. However, in an institution for technological/vocational education, practical applications of technology are guiding principles (Tai, et al, 2003). Students are expected to spend more time and efforts in mastering a variety of technological skills, as compared to those in universities in Taiwan.

Course Setting

The course under study is a semester-long, two-credit-hour class, targeted at first-year college students from different majors. Students solve a series of authentic tasks by applying Microsoft Office (including Word, Excel, and PowerPoint).

Experimental Design and Procedure

In this study we explore whether students in the "Packaged Software and Application" course enhance their skills of application software via e-learning. Based on feedback from earlier research, we have re-designed the course and conducted a series of quasi-experiments to examine the effects of web-enabled PBL, SRL, and their combinations.

Figure 1. Expected effects of variation in instructional methods

	PBL	non-PBL
SRL	The most significant effect (C1 Group)	Medium effect (C3 Group)
non-SRL	Medium effect (C2 Group)	No difference (C4 Group)

The experimental design is a 2 (PBL vs. non-PBL) × 2 (SRL vs. non-SRL) factorial pretest-post-test design (see Figure 1). Students from four groups solve the same task but in different learning conditions. Participants are randomly assigned to one of the four experimental conditions in such a way that each condition contains 24 to 30 students. The PBL and SRL group (C1, n=30), PBL and non-SRL group (C2, n=25), non-PBL and SRL group (C3, n=24) are experimental groups, while non-PBL and non-SRL group (C4, n=27) is the control group. The sample size in this study is large enough to be tested in statistics.

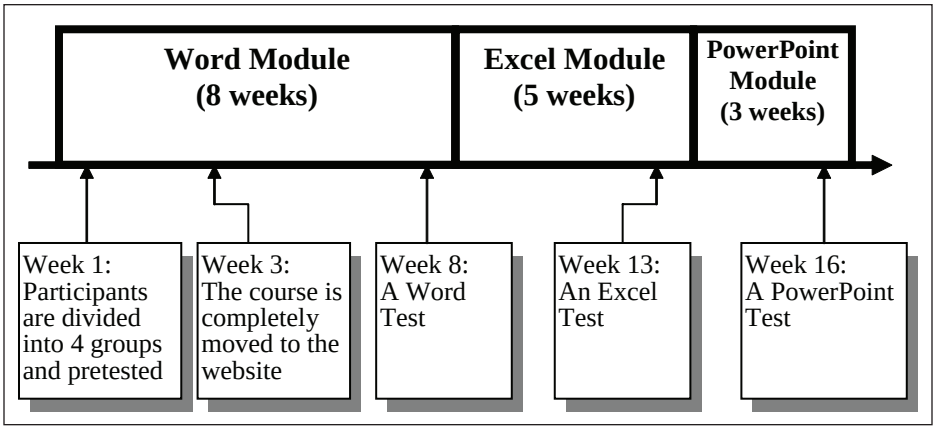
The course design in the present study consists of three subsequent modules: the Word module, the Excel module, and the PowerPoint module. A skill test is administered after the completion of each module. The first test is held during midterm examination (eighth week). The second test is held in the 13th week and the final one in the 16th week. A schedule of teaching of modules and skill tests is depicted in Figure 2.

In the beginning of a course, students are encouraged to adapt and learn via a course Web site. Teaching during this period is through a traditional classroom. A teacher records every session of the lecture first and then converts these lectures into a HTML file with flash, video, and voice. These HTML files are then loaded into the course Web site. Students can preview and review the course sessions on this course Web site. After three weeks, most of the coursework is moved onto the Web site. We help students to adapt to learning through the net and try lessen down a feeling of isolation. Within these three weeks, we adjust students' learning gradually and smoothly.

PBL Treatment

A teacher creates interesting, challenging, and authentic problem situations. In the first Word

Figure 2: Schedule of three modules and skill tests



module, students are required to apply for a job as Marketing Assistant in an online-game company. They are required to design and then build autobiographies and resumes by applying skills of application software that they have just learned. In the Excel module, students play roles as if they are employed by this same software company, and a marketing manager asks them to compare expenses resulting from different distribution channels. They have to survey and then complete a worksheet with some graphs to contrast differences between channels. Additionally, they must come up with a recommendation regarding the best combination of channels. In the last module of PowerPoint, they are promoted as Marketing Managers of higher rank. They are asked to develop a business proposal for a new online game. They have to present this proposal with visual aids to convince the managing director to enter in to a market. Therefore, a persuasive PowerPoint presentation is built at this stage.

A teacher demonstrates first how they could approach the situation and solve the problem with the help of a Web-based multimedia application. In addition to the teaching of skills of application software, similar situations and related applications are also discussed in the class. Latter, the teacher guides students in constructing their own models of problem-solving.

SRL Treatment

There is a SRL group in each class. Two SRL groups from the PBL class and non-PBL class are gathered in a classroom and a two-hour lecture is delivered discussing how to manage study time and regulate their learning. The lecture is given in an after-school course. Content of this SRL course is composed of following four processes addressed by Zimmerman, Bonner and Kovach (1996), that is,

- Self-evaluation and monitoring,
- Goal-setting and strategy planning,
- Strategy implementation and monitoring

Table 1. Teaching and learning activities in different experimental groups

Group	Teaching Activities	Learning Activities
C1	A teacher…	Students…
	• demonstrates how to solve authentic problems and discusses its potential applications.	• take on authentic tasks and learn by problem solving.
	• teaches SRL skills and urges students to study regularly.	• practice SRL and record learning behaviors every week.
C2	Teaching activities are the same as C1 but without SRL lectures.	Students experience authentic situations and solve the problems without extra requirements of SRL.
C3	A teacher…	Students…
	• converts his traditional way of teaching without any modification into an online format.	• receive traditional computer software course through internet.
	• teaches SRL skills and urges students to study regularly.	•practice SRL and record learning behaviors every week.
C4	Teaching activities are the same as C3 but without SRL lectures.	Students experience traditional style of teaching and do not deal with extra requirements of SRL, although teaching is conducted via Internet.

- Monitoring of the outcome of strategy.

Students are taught how to implement these four processes to become more regulated learners.

In addition to the two-hour lecture, students in SRL groups are required to prepare and read the textbook regularly before classes, and to review or practice the skills of application software they have learned after school. They are also required to record their learning behavior every week. Data is recorded on the course Web site instead of their notebooks in order to prevent falsification of records. A teacher cursorily examines students' records.

Treatments in four groups are illustrated and compared in Table 1.

Measures

To examine levels of change manipulated by variations in experimental conditions, we first measured students' skills of application software as a baseline before they entered the class. In the first week, students complete three Word documents as a pretest. We choose Microsoft Word for the pretest because almost every student in Taiwan learns Word before he learns any other software package.

The pretest grades show that computer skills of almost all are low. None of the participants are able to answer any of the pretest questions correctly. This confirms that all participants in the four groups had a little knowledge or a skill of software package. The difference in students' skills of application software at the beginning stage among the four groups was not statistically significant. Therefore, we assume that the students have equal or no computer skills before they take this course. In addition, none of them had any experience in taking a Web-based course. We then evenly and randomly divided the students into the four experimental groups.

Later, skill tests are administered at the end of each module. In this study, we applied two practical and authentic teaching methods. It is very important to measure students' practical skills in problem solving rather than the memorization. In this regard, the lecturer simulated practical problems for students to solve to evaluate their enhancement of skills of application software. For example, students are required to complete a worksheet with some graphs and tables to compare the market share with all competitors. They have to apply several functions to compute the numerals and sort them. Students' grades come from their correctness and completeness of problem solving, and the artistry of their designs. Students will get high grades if they completely solve the problems with exquisite designing.

Before testing, students are assigned random seats. All students are tested at the same time. Every test consists of five to seven questions. A teacher grades and records the results immediately after each test. A surrogate representing skills in application software is averaged from the scores of these three tests. Finally, the enhancement of skills in application software of a module is the result of one's grade minus pretest grade. We test differences in the enhancement of the skills of application software under different conditions.

Results

To examine levels of change manipulated by variants in experimental conditions, we first measured students' skills using application software as a baseline. The pretest confirmed that all participants from four groups had a little or no knowledge and skills in packaged software. The difference in students' skills of application software at the beginning stage among four groups was not statistically significant. In addition, none of them had any experience in taking a Web-based course. We then randomly divided the students into four experimental groups.

Independent sample t-test was used to compare improvement of grades between PBL and non-PBL teaching methods. As shown in Table 2, the improvement in students' grades for Word, Excel and PowerPoint modules in PBL class (67.09) was on an average higher than that in the non-PBL class (56.75). This is also true if one takes the test scores of each module into account separately. Therefore, effects of Web-based PBL on students' skills of application software are positive, and higher than those who do not receive PBL.

Results from Table 3 show that the average grade for Word, Excel and PowerPoint modules in SRL group (66.01) is higher than that in the non-SRL group (58.08). This is also true if one takes test scores of each module into account separately. Thus, the effects of web-based SRL on students' skills in using application software are positive, and higher than those without SRL intervention.

Finally, data from Table 4 shows that combination of PBL and SRL intervention a group results in the highest grades among four groups. The improvement of skills using application software in C1 is significantly higher than C3 and C4, and also higher than C2, though insignificant. Therefore, we conclude that the effects of Web-based PBL and SRL intervention on students' skills in using application software are positive, and higher than those who do not receive PBL or/and SRL.

For those teachers who wish to stick to traditional methods of teaching, directly transforming their teaching material into electronic form may not be a fruitful approach. Students

Table 2. Independent samples t-test: Improvement of grades

		N	Mean	S. D.	F	t-value	df	P
Word	PBL	55	64.29	11.063	2.604	3.147	104	.002**
	non-PBL	51	56.84	13.269

	non-SRL	52	49.50	28.021				
PowerPoint	SRL	54	72.54	12.462	.222	2.649	104	.009**
	non-SRL	52	66.52	10.831				
Average	SRL	54	66.01	11.305	.769	3.473	104	.001**
	non-SRL	52	58.08	12.195				

Table 4. One-way ANOVA (Analysis of Variance): Average of the improvement of grades.

Dependent Variable		(I) Group	(J) Group	Mean Difference (I-J)	Std. Error	Sig.
Average	Scheffe	1	2	5.862	2.910	.262
			3	8.436(*)	2.943	.047
			4	17.064(*)	2.851	.000
		2	1	-5.862	2.910	.262
			3	2.574	3.071	.872
			4	11.202(*)	2.983	.004
		3	1	-8.436(*)	2.943	.047
			2	-2.574	3.071	.872
			4	8.628(*)	3.015	.048
		4	1	-17.064(*)	2.851	.000
			2	-11.202(*)	2.983	.004
			3	-8.628(*)	3.015	.048

from the controlled group (C4) received lowest grades among four groups, and differences in grades among them are significant (see Table 4). It is suggested that teachers should redesign their courses and then adopt new instructional methods and technologies to fully exploit benefits of deploying Web-based learning environments.

DISCUSSION

This study provides valuable insights and sheds some lights on new, effective practices that can be used by schools (particularly vocational schools), scholars, and teachers planning to implement or presently engaged in implementing e-learning environments. The implications of this study consist of three-fold:

Firstly, the PBL teaching method was found to play a consistently positive role in enhancing students' skills of using application software (see Table 2). There are significant differences between PBL and non-PBL classes, either in case of individual module tests or in an average of the three module tests. It was demonstrated that PBL is good for computer software education in general and e-learning in particular. Teachers could redesign their courses by simulating meaningful and interesting business situations, and, thus, engaging students' imaginations and interest to solve challenging problems.

Secondly, evidence also supports that the second teaching method based on SRL also enhances students' skills of using application software (see Table 3). There are significant differences between SRL and non-SRL groups on three tests and in average. Interestingly, as we focused on the variation of P-value related to each module, it became clear that the effects of SRL increased over time. This suggests that the effects of SRL among low achievers can be significantly improved, even by a limited amount of intervention, such as two-hour lecture regarding SRL at the beginning of teaching program and later by students' monitoring their own learning.

Finally, this study found some support for the effectiveness of a combination of instructional

methods. As shown in Table 4, results show that the effects of a combination of PBL and SRL intervention on students' skills of application software are positive and higher than those who do not receive PBL or/and SRL, although the difference between C1 and C2 is not statistically significant.

This study contributes to e-learning practices in three different ways: (a) this study specifies how teachers can engage students in improving learning under authentic conditions. At the same time, teachers help students to regulate their learning by applying PBL and SRL instructional methods in a Web-based learning environment; (b) this study is one of the first attempts to explore learning effects of various combinations of PBL, SRL, and Web-based learning; and (c) this empirical study provides evidence that skills of low academic achievers, for using application software can be improved through e-learning.

Teachers face tremendous challenges in implementing e-learning among relatively low academic achievers. For example, Internet addiction is common, and it is not immediately clear how to focus students' attention and improve their learning in a Web-based environment without teachers' on-the-spot monitoring. This study proposes an effective approach in this kind of e-learning environment.

ABSTRACT

In the dynamic global economy that exists today the operation and structure of organisations have had to adapt to the reality of the information revolution which has taken place. This has been the case within the software industry where global software development (GSD) has become a popular strategy and software development has become a globally sourced commodity. Given the requirement for graduates to operate in this type of environment, we as educators considered how our teaching methods could be developed and enhanced to instil GSD competencies within our graduates. We provided students with the opportunity to take part in a learning experience that transcended geographical and institutional boundaries, giving them first-hand experience of working within globally distributed software teams. Two separate projects were undertaken.

One was with Siemens Corporate Research which was part of a larger project. The focus of this project was the shadowing of the development of an actual geographically distributed software product. The second project was carried out in collaboration with Ball State University, and the focus of this endeavour was virtual team software testing. Extensive qualitative research was undertaken on the data provided by the students. We identified three specific forms of learning which had taken place: (1) pedagogical, (2) pragmatic, and (3) the achievement of specific globally distributed competencies. Our findings would confirm that mimicking real-work settings creates the possibility of giving rise to the range of learning benefits that are associated with truly problem-based learning environments.

INTRODUCTION

This chapter explores the reality of the software industry today, which is becoming more virtual and globally distributed in its methods of operation. It discusses the educational implications of these strategies and how they impact graduates. It looks at what measures can be taken to prepare students to operate in this dynamic and virtual environment. It outlines two projects in which masters students participated in that transcended geographical and institutional boundaries. The projects and the students' experiences were researched and analysed. The results, which are presented here, demonstrate the benefits associated with utilising a hands-on, truly problem-based learning environment.

GLOBAL SOFTWARE DEVELOPMENT

GSD has given rise to the implementation of new types of development teams and project structures within organisations. In many software development organisations, teams are no longer local, but operate within a virtual team environment. As a result they are fundamentally different in their structure and modus operandi to those of a single site team. For educationalists, the emergence of new team and organisational structures require that graduates from software engineering courses be made familiar with these new methods of operation.

The number of organisations employing virtual,[1] team-based globally distributed software development strategies continues to increase (Powell, Piccoli, & Ives, 2004). GSD in essence allows distributed teams to split up the tasks of a project and distribute them as separate jobs (Grinter. Herbsleb, & Perry, 1999). This allows development decisions about each project task to be made with a degree of independence (Herbsleb & Grinter, 1999). However, managing this type of team is not a straightforward endeavour. Some of the difficulties encountered include the problems of understanding requirements and the testing of systems (Toaff, 2002). These difficulties are compounded by cultural and language differences, lack of communication, distance from the customer, different process maturity levels, testing tools, standards, technical ability, and experience. These issues are further augmented by the lack of "trust-building" communication techniques. Trust is important for software development teams to work together successfully, and it is harder to establish trust within virtual teams than it is with local teams (Robey, Khoo, & Powers, 2000), rising from the fact that face-to-face communication methods that can build trust are generally not present in a distributed team (Pyysiainen, 2003). Equally, established trust gained from co-located experiences can deteriorate over time in a distributed setting (Casey, 2007). To address these substantial issues, project management must change from the traditional to the virtual for a GSD strategy to be successfully implemented.

Making GSD Work

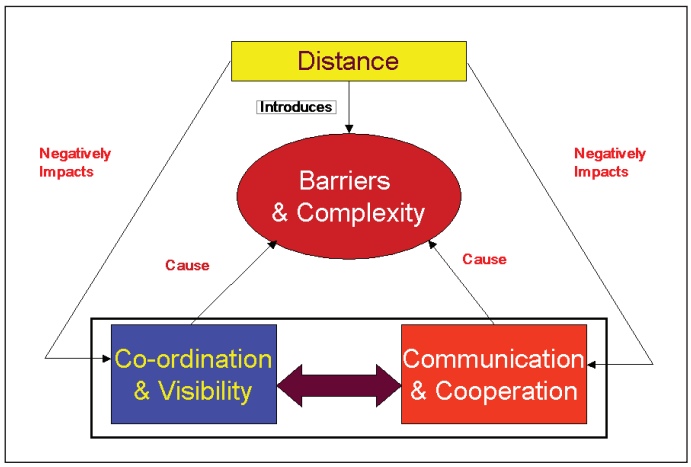
As the GSD team is dispersed across geographical locations, it operates differently to the co-located team. Regardless of the strategy implemented, distance is responsible for the introduction of barriers and complexity. These directly impact on the management and operation of the GSD team. However, other related factors also come into play. Coordination, visibility, communication, and co-operation are all negatively impacted by distance, and if their impact is not identified and correctly managed, they can produce further barriers and complexity within a project (see Figure 1).

Effective *coordination* is a key element in the success of a geographically distributed software development project. This includes undertaking realistic project planning and risk evaluation given the specific requirements of the GSD environment. Work must be partitioned between sites based on the technical needs of the project and on the capabilities and experience of the team members at different geographical locations. Furthermore, there is a requirement for the effective utilisation of technology across sites and between team members. Procedures should be put in place to facilitate and monitor the level of cooperation between team members in all locations. These should also allow for the identification and addressing of problems if and when they arise.

Visibility is another important factor in the successful operation of the global team. It is important for management to ensure that roles and responsibilities are clearly articulated. Each team member should be informed of work product requirements and due dates. This requires effective reporting schedules and a visible reporting strategy. There is a requirement for continuous visibility into the team's activities and operation at all locations. Team members should also be aware of the management structure within the team across all sites.

Communication issues should not be allowed to become a barrier to the successful operation of a distributed software development team. This necessitates the development and implementation of a common vocabulary for all aspects of the project. Effective communication tools, which are utilised and understood by all team members, should be provided. Communication between remote team members is normally electronic and asynchronous in nature with limited opportunities for synchronous contact, depending on the time zone difference between locations. The

Figure 1. Factors in virtual development (Source: Casey, 2007)



global team normally operates in a multicultural and multilingual environment, which may cross organisational boundaries (DeSanctis, Staudenmayer, & Wong, 1999).

Cooperation within global teams is essential to achieve a successful implementation of a GSD strategy. In distributed teams there are limited opportunities for one-to-one contact between remote colleagues. Project managers need to consider how team relationships can best be developed and fostered. The specific implications of cultural diversity on the project operation must be ascertained, monitored, and addressed. All team members should be given cultural training. The identification of a relevant subject matter expert (SME) is important, and team members should be informed who this is. Once identified the SME must be willing and able to provide the required support to local and remote colleagues.

EDUCATING THE GRADUATE

One of our tasks as software engineering educators is to produce graduates for the software market, and with the increase in GSD worldwide, it is incumbent on us as educators to provide these graduates with a background that allows them to work in the global environment.

To operate in the global environment students need to be aware of the factors involved in GSD. Through research carried out by the authors (Casey, 2007; Casey & Richardson, 2005), specific competencies that are needed have been identified. From the perspective of the graduate, these can be broadly divided into two categories: (1) competencies required by both the software developer and manager and (2) those required more significantly by the software development manager (see Table 1).

Competencies Required by the Software Developer and Software Manager

When working in the global environment, *communication and language* takes on greater importance than when working in a local team. English has become the international business language and is extensively used in GSD teams. However, many co-workers will not have English as their first language, therefore, misunderstandings can occur, as there may be different dialects of English and/or a number of regional accents in use (Kiel, 2003). A further consideration is the *use of communication tools* which must be done correctly and in such a way that it benefits and not hinders the project. Global teamwork is often

Table 1. Competencies required by the software graduate

Software Developer and Manager	Software Development Manager
Communication and language	Visibility and coordination
Use of communication tools	True cost of GSD
Culture	Technology transfer and knowledge management
Temporal issues	Roles, responsibilities, and competencies management
Cooperation	Partitioning of work
Software process	Management of fear and trust
Use of process tools	Motivation
Reporting schedule	“Teamness”
	Risk management

carried out through asynchronous communication tools like e-mail (Boland & Fitzgerald, 2004). This is not the environment in which graduates or locally experienced software developers are used to working—they need to learn and understand how to use language, communication, and communication tools efficiently and effectively in the global development team.

An advantage of having a variety of *cultures* involved in one team is diversity and bringing diversity together to work toward a common goal can increase the innovation within a project (Ebert & De Neve, 2001). However, those working within global software teams must learn to understand and appreciate cultural diversity. Cultural differences include values, language, approach to authority, concepts of space, regard for material goods, and time keeping (Carmel, 1999; McDonough, Kahn, & Barczak, 2001). Cultural differences, unless understood by all involved, can have a negative impact on the operation of the global team.

Those working on GSD teams should also have an appreciation of the *temporal issues* that may arise. A strategy which has been employed in establishing global teams has been to have team members in two or three time zones around the globe. For individuals working on such teams, this requires them to ensure that their working hours overlap somewhat with their remote colleagues (Casey & Richardson, 2004; McDonough, Kahn, & Barczak, 2001). Furthermore, responses to communications need to be made in a timely manner. Response delays can cause frustration and decreased motivation among team members. These difficulties can be exasperated if the person required is remotely situated (Herbsleb & Grinter, 1999).

As mentioned previously, cooperation is required for a global team to be successful. An advantage for GSD is that, given the diversity of global teams, the acquired mix of skill sets and life experiences within a team can result in improved coordination among GSD team members (Ebert & De Neve, 2001). However, geographical distance reduces the level of informal contact that can help build better working relationships, and consequently, support cooperation (Herbsleb, Mockus, Finholt, & Ginter, 2000). In the global environment, and without this level of informal contact, software developers need to develop cooperation between themselves and local and remote team members. They need to be able to modify their locally focused competencies to work successfully in the global environment.

With the increase in use, internationally, of software *processes* and the implementation of models such as the CMMI[2sm] and ISO15504 among others, software developers are becoming more au fait with the implementation of processes. However, processes in the global environment are typically different to those in the local co-site operation. They need to be set up with global information flow, global reporting, and the effective division of labour in mind. For example, if a wiki[3] is being used, project members need to continually keep it updated as they will not have the informal contact which, often in the local situation, allows team members to know what is happening on a project. *Process tools* can help local teams in managing processes such as configuration management, risk management, and testing. In the global environment, they can ensure that even though team members are not discussing issues on a face-to-face informal basis, processes can be efficiently controlled. Along with the technical use of such tools, team members need to understand the tools' effectiveness and requirements.

As mentioned previously, visibility of project activities is important. Culture has an effect on whether overruns in project tasks are reported. Furthermore, teams may be set up so that the project manager is based in one location only. To ensure visibility and to minimise difficulties arising through differences across global teams, it is important that *regular scheduled reports* are made to all team members. These reports should

be timely and accurate and submitted by all team members.

Competencies Required by the Software Manager

In addition to the competencies required by the software developer, the software manager working in the global environment must be able to ensure that the team for which he/she has responsibility can work effectively. This requires them to bring additional competencies and requirements to the team.

They are responsible for ensuring the *visibility* of, for example, tasks, team members, project structure, and reporting structures across the global team. They are likely to be co-located with some team members and may never meet face to face with all their global team. To coordinate the work of a global team in this environment may cause difficulties if they are not dealt with in an effective manner.

Companies are not always aware of the "true cost" of GSD, and indeed there is no "silver bullet" that can provide them with that information. However, it is something about which the software development manager should be aware. Negative influences within a global team are high risk and can cause decreases in productivity. For example, lack of communication can reduce the effectiveness of a project and can occur easily through the misuse of communication tools (Casey & Richardson, 2004).

Moving from a local co-site team structure to a global team environment requires *technology transfer* and *knowledge management*. The global software development manager has to understand how they can do this effectively. If new project members are being employed at an off-site location (normally global), how can these people be given the same transfer of technology and knowledge as would happen in a local environment where there are informal discussions and the availability of experts? This needs to be correctly managed with an effective training strategy put in place.

The global project manager must be able to decide upon the *roles and responsibilities* within the project team so that the team can work successfully together. In doing this, they must recognise the variety of competencies that individuals are bringing to the project, and they need to *manage these competencies* for the project's benefit. Considering the lack or limited opportunity for informal contact between teams, the impact this has in a geographically dispersed group is extremely important, and the failure to be cognisant of these factors can cause the team's effectiveness to be reduced (Casey, 2007).

Once the project team has been structured, the project manager must be able to *partition the work* in such a manner that the team's effectiveness is maximised. In some cases, the partitioning can be based around the software development life cycle, where the team members at each location undertake one element of the life cycle, for example, development or testing, while control is maintained at a central location. Another model, which is becoming increasingly popular, is to set up virtual teams, where team members work as one team even though they are located globally. This is not an easy task for the project manager to undertake (Nidiffer & Dolan, 2005).

Within countries, such as Ireland, who no longer are considered a low-cost economy, people who work on project teams can perceive the implementation of GSD as a step in the transfer of their jobs to low-cost economies in Eastern Europe and the Far East. This can, in turn, lead to an element of *fear and mistrust* among the project team members, which would not exist in a local team. The role of the software development manager is to understand these fears and address them where possible. The objective is to ensure that the team does not become de-motivated about the work they are expected to do. Maintaining a level of *motivation* is an important task that should not

be overlooked by the manager. This in turn will facilitate the development of "teamness" within the group, which has to be built across communities and geographical locations. It cannot be done in the informal manner in which local teams can gel together, through casual meetings on the corridor, or through more company-based structured activities, for example, starting a sports and social club (Linnane & Richardson, 2006).

The GSD manager has to consider all the risks involved in setting up and operating their global software development team. While *risk management* is an important element within a co-site software process and it is a level three process area of the Capability Maturity Model Integrated (CMMI[4sm]). The additional risks involved in managing a GSD team are significant and need to be specifically acknowledged and addressed.

Providing GSD Competencies to the Graduate

Given the requirements emerging from GSD, the graduate of the 21st century will not only be required to have competencies that are useful in the local development environment; they must also, for the success of GSD initiatives, demonstrate those other competencies that allow them to operate effectively in the global environment. As educators, we considered how our teaching methods could be developed and enhanced to instil these GSD competencies within the graduate. Our experience has shown that we must be prepared to introduce experiential learning to the student through extending education across international boundaries, cooperating globally between educational institutions and others, thus giving the graduate an educational experience which could not be provided in the local classroom. In the light of these principles the projects described in subsequent sections were undertaken.

When introducing an experiential dimension to student learning, the features of the learning environment can become different and ultimately more beneficial than they might otherwise be. By creating a learning experience that mimics the dynamics, pressures, and puzzles of "real-life" GSD environments, we present a learning context that has the potential of addressing some of the problems that may be associated with more conventional learning modes. In the light of these principles the projects described in the section, *Global Software Development in the Classroom,* were undertaken.

EDUCATIONAL OBJECTIVES ASSOCIATED WITH INTERVENTION

The GSD team structure and process created a problem-based learning environment for students, the benefits of which are well documented, for example, in Savin-Baden (2004) and Barrett (2005). In particular, the benefits of group work in which several students work together to solve a problem or to achieve a task have been evidenced in the educational literature. Joy (2005) has recently shown the particular way in which group working experiences can be beneficial in the context of a computer science curriculum by highlighting learning and experiential outcomes such as the application of knowledge, motivation, advanced cognitive competencies (or deep learning), and self-direction. The importance of ideological development is also relevant in the way that Reynolds (1994) has suggested. It is argued that working on real problems in a group setting can prepare students to become more collaboratively orientated and subsequently more willing to participate in collective effort.

By setting up virtual teams for software engineering students, we also argue that it is possible to inject several more specific learning benefits than the ones that have been briefly outlined. By learning from direct and relevant experience, students' own sense about the plausibility of their learning environment becomes stronger. Levitt and March (1988) and Luo and Peng (1999) are

among many who highlight the importance of real-world experience that is applied in the context of a genuinely and realistically problematic task. Being part of a virtual team in which other pedagogical support is also available can bestow a reflective dimension on learning that can allow students to learn more about themselves through reflection of the ways in which they engaged with the process.

Reflective practice in a "safe" environment is a process that can have both psychological and pedagogical benefits. It dismantles defensive reactions to problems and errors and allows participants to examine them in order to enhance understanding and cognitive command of their features. Indeed, defensiveness in many work environments often prohibits the capacity for learning in ways that are damaging to individuals, teams, and their organisations (Tjosvold, Yu, & Hui, 2004). Setting up early professional experiences in which teams can effectively reflect on and analyse their mistakes as well as their successes in a supported learning environment is one of the beneficial features that we hoped would prevail in this particular learning innovation.

We hypothesised that this type of innovation would create professional precedents that would make it more likely that participating students would engage professionally in more learning-oriented ways. This innovation went beyond just simulating an environment; it allowed students to become contributory members of GSD teams. This could have also created insights about how a sense of responsibility to deliver their part of the task is experienced, and how this sense of responsibility interacts with their learning. These are the kinds of integrated insights that might not otherwise have been possible using other modes of learning. We argue then that the sense of engagement and responsibility was automatically enhanced. These dynamics of learning are ones that have been highlighted as crucial to the creation of self-directed, responsible learners in higher education (e.g., Hwarng, 2001).

These real GSD experiences also have the potential to raise student awareness of the importance of related competencies that they might not otherwise have considered important. Such competencies include those related to communication and global interaction; language and intercultural awareness; and functioning effectively as part of a team (self awareness; creativity; formulation and implementation processes; problem solving; time management; and task completion).

By designing the learning experience described in this chapter, we hoped that we would be able to give rise to the learning benefits outlined previously. The following section captures the insights that participating students provided when asked to reflect on their experiences as part of the GSD team to which they had been assigned.

GLOBAL SOFTWARE DEVELOPMENT IN THE CLASSROOM

The University of Limerick (UL) delivers a Master of Science course in software engineering. Participants have previously completed a related undergraduate degree course. To date, one-third of the students are working in software development and are part-time. The remaining students are pursuing the degree in full-time mode—85% of these have no prior industrial experience, having commenced the degree directly after completing their undergraduate studies. When pursuing the MSc degree, students study a variety of modules which include software engineering quality, software engineering requirements, human computer interaction, software design, software development paradigms, software evolution, software engineering system design, and software engineering fundamentals. These modules account for 60% of course credits, and the remaining 40% of course credits are obtained through a final dissertation, encompassing a major study undertaken by the student.

As educationalists, and given the importance and growth of GSD within both multinational and small to medium-sized companies in Ireland, we strive to expose graduates from this course to GSD. We do this in some cases through lecturing on the topic. However, as we aim to maximise the pedagogic experience for students we have implemented two specific GSD projects for the course, where students were given the opportunity to participate in situated GSD projects. One of these projects, Ard na Croise,[5] is carried out in conjunction with Siemens Corporate Research, USA and has been running for 2 years. In each year, there has been one team of five people from the MSc class involved. Of these, nine had no prior industrial experience. The other project, Ainm an Eolaithe,[6] is a collaborative project with Ball State University, USA and has run during one course, with 12 full-time students participating in UL. Ten of these students had no prior industrial experience. Four of these students also participated in Ard na Croise.

In implementing these projects we aimed to equip students with the competencies required for software developers and managers as given in Table 1, while additionally expecting that at least some of the competencies required by software development managers in working with globally dispersed teams will be attained by the participants.

PROJECT DESCRIPTIONS

Ard na Croise with Siemens Corporate Research

Siemens Corporate Research, Inc. (SCR) has been conducting research aimed at developing a better understanding of the issues and impact of various practices with respect to GSD. By making this investment SCR hopes to establish itself as a GSD centre of excellence that can assist other Siemens operating companies to cope with the unique complexities of conducting GSD. SCR, in conjunction with Harvard Business School, University of Limerick, Carnegie Mellon University, Monmouth University, Technical University of Munich, the Indian Institute of Information Technology Bangalore, University of Toronto, Penn State University, and the Pontifícia Universidade Católica do Rio Grande do Sul (PUCRS) in Brazil have set up an experimental geographically distributed development project (GSP) using student teams to study associated issues. The project ran for 2 years, with different students involved in the teams each year within the participating institutions.

Organisation of the Global Studio Project

The project simulates a hub-and-spoke model. The hub is the central team at SCR in Princeton orchestrating the effort, and the spokes are the remote teams consisting entirely of participating students. The central team is responsible for project management, requirements, architecture, testing, and integration of the system. The remote teams are responsible for design, development, and unit tests for defined work packages that correspond to code modules or subsystems defined by the central team. Interactions between the central and remote teams are managed by the role of a *supplier manager*. There is a supplier manager for each remote team and the incumbent of this role is a member of the central team.

In the first year of the project the central team was staffed by four members of SCR's technical staff (part time) and two masters students (full time) working onsite at SCR. The team consisted of several roles: architect, requirements engineer, project manager, supplier manager, and build meister. The build meister handled the system testing, integration, configuration management, and delivery of artefacts from the teams.

For the second year of the project, the structure of the central team changed. It was staffed

with four interns working full time on the project along with one member of SCR's technical staff working part time in a supervisory capacity. Team roles were similar to the first phase but evolved to include an infrastructure manager, quality assurance manager, process manager, integrator, and wiki administrator. The role of a build meister was abolished as it encapsulated several key responsibilities that could be split and assigned to various central team members. Three graduates from the University of Limerick with an MSc in software engineering were central team members in the second year, one of whom became the central team contact for UL.

Remote development teams were set up at five universities across the globe in the first year. The teams consisted primarily of masters or graduate students in the field of software engineering. UL, Carnegie Mellon University, Technical University of Munich, and the Indian Institute of Information Technology each had one team while Monmouth University had three teams. In the second year of the project, an additional student team was established in PUCRS in Brazil. Each team member committed a specified number of hours each week on the project, taking the academic commitment within their own university into account. Each team had a direct contact on the central team.

Ard na Croise: UL's Involvement in the Global Studio Project

Participation by the MSc in software engineering students at UL in the Global Studio project has been implemented as part of the MSc dissertation process. Students are expected to research a topic relevant to their degree. Students who chose to participate in the GSP project were expected to become reflective practitioners within the project and use this analysis to compare with their chosen aspect of GSD in the "real world." For example, dissertations included a comparison of project management in the local versus the global, and how communication is carried out within global project teams.

In each year, five students volunteered to participate in the SCR GSP project. In the first year, none of the students had previous industrial experience and did not know each other prior to commencing the course a few weeks earlier. Each of the students assumed a role within the team—project leader, software architect, technical support, tester, and quality assurance. These roles were decided on by the team members themselves without any input from the supervisor. Internally, within the university, students were given the software and hardware that they required. This was located in a laboratory shared with students studying this course and other postgraduate courses. The UL team was assigned a supplier manager who was based in SCR. All contact for the first 2 months was via Internet or telephone. The supplier manager visited UL at that stage.

In the first year, as with all participating teams, the UL teams were engaged in the definition phase of the project. Initial tasks were assigned with the goal of bringing the teams up to speed with the building automation domain. Work breakdown was done considering several factors. The schedule, available weekly student hours, and the geographic proximity of the teams to the central team were all considered when defining the original work breakdown. During the first year, it was decided (as part of the research project) not to allow the UL team to communicate with any other team. Their communication was only with the central team. Work packages were defined and distributed to all of the teams. The initial work packages contained: requirements specification, high level architecture, market intent, specifications, high level project plan, and a description of the tasks to be completed by the team for the first engineering release.

In year 2, a new team was formed. One part-time student had significant experience, and he became the project leader of the team. Other roles

assumed by each of the team members were defined by the SCR central team. The UL team was also provided with a space that was private to the project team. The SCR central team contact for UL had been the project leader on the UL team the previous year. Prior to this, no member of the UL project team knew him, and none of them had met him. Furthermore, the restriction on the UL team communicating only with the central team was removed. A wiki, set up by the central team, was continually updated by students and central team members. Otherwise, the project structure was similar to that in year 1.

Ainm an Eolaithe with Ball State University

As with other aspects of GSD, distributed testing is becoming important to the global software development industry. Researchers from UL and Ball State University (BSU) have been involved in studying management and technical issues involved in the distribution of testing across countries within a multinational company who are based in Ireland, USA, and Malaysia (Casey & Richardson, 2005; Zage, Zage, & Wilburn, 2005). As part of this research project, we set up a collaborative teaching project involving MSc students from both UL and BSU. While we were interested in establishing "what works" and "what does not work" when implementing global testing, a further aim of this project was to provide knowledge and education on GSD to individual students in both locations.

The time frame for this joint project began with a week of instruction for the UL students. The projected testing time line of the project was to commence with black-box testing[7] (UL) in weeks 2 through 4. During the black-box testing time frame, it was expected that the white-box testers (BSU) would review the actual code, would review the unit testing environment, and prepare test scripts. At the end of the semester each BSU team was expected to submit the combined defect reports (UL and BSU), the white-box testing scripts, the white-box test cases accompanied by the testing resources, and a summary report. The black-box and white-box test cases were to be recorded in a collaborative testing tool (GATE), which was used by students from both locations. Within GATE, students had access to a wiki where they were free to enter discussions with each other and where they could add information about themselves.

Ainm an Eolaithe: UL's Involvement in the Testing Project

At UL, all full-time students studying software quality engineering (one module) as part of their MSc in software engineering course were randomly selected to participate in testing teams, which comprised two or three students based at UL. Many of these students did not know each other prior to the course, so in some cases they were working with people they had not met before they attended these classes. However, they had been in the MSc class together for 8 weeks before this project commenced. These teams were then paired, again, at random, with student teams from BSU, thus creating virtual teams.

Initially some difficulties arose with the provision of the product to be tested. UL students were given a week-by-week oral update of status and were also given regular updates through the class Web page. This impacted on the start of the initial projected time line for testing outlined perviously. The Irish students testing assignment started 3 weeks later than anticipated, which meant that their training was completed 3 weeks before they had an opportunity to start testing.

RESEARCH METHODOLOGY

Having instigated and managed both of these projects within the MSc class, both of which required extra collaboration and input from the

university lecturers, we were interested to establish the success or otherwise of both of these global projects. We collected and analysed data throughout the lifetimes of each of the projects described previously. The results presented in this chapter are based exclusively on the analysis of data obtained from UL participants.

Each member of the two UL Ard na Croise teams participated in a semistructured interview with one of the authors. These interviews focused on the expectations and experiences of each of the participants. When the interviews were conducted, five students had completed their dissertations, the remaining five had completed 3 months' involvement in the project.

During the Ainm an Eolaithe UL/BSU collaboration, UL students were required to maintain a log book describing their participation. As part of their continuous assessment submission, they were required, in teams of two or three, to write a reflective analysis on the experience of being involved in a GSD testing team.

While the educational objectives (outlined later on) were of interest to the researchers, a semistructured, grounded approach was adopted, so that students were facilitated in identifying learning-related issues in their own words and on their own terms. However, students were guided in the provision of responses and insights by a variety of prompts, which, for example, in the interviews that were conducted included questions like: Why did you participate in the project? What were your expectations? Were your expectations fulfilled? What did you learn? What was good? What was bad? What was done well? What was done badly? What should be changed? What should I keep? Would you participate again? These prompts had two functions. Firstly, they were designed to help students to make more sense of their experiences and to integrate those insights into their learning. Secondly, they allow us to capture and disseminate (via this commentary) issues that may be of use to teachers and academics planning similar interventions within their own contexts.

The interview notes, log books, and the reflective analysis was analysed by the researchers. A qualitative content analysis of these sources of data took place in order to identify overarching themes associated with the students' experiences of this learning intervention. A broad analysis of the frequency of different concepts was conducted based on an interrogation of the available data.

STUDENT INSIGHTS

The data gathered from students about their insights and experiences were rich and diverse, expressed mainly in their own words in response to various prompts and delivered as part of the reflective requirements of the programme of study on which they were enrolled. We categorised the feedback, reflections, and ideas that they provided, while also attempting to stay true to the student voices and the priorities that they reported. Throughout this process we maintained awareness of the emphases that we had established as educators. We observed certain insights, focusing on either pedagogical process or GSD requirements. Oftentimes, these observations were so intertwined, that they were essentially inseparable in the eyes of the students themselves. Therefore, this section organises these student insights into categories sequenced in order of the frequency and emphasis with which certain response categories appeared in the data. There is no explicit division between pedagogic and GSD issues.

Our analysis of the reflective, qualitative data reveals seven overarching categories of student insight into the learning experiences associated with the GSD project process. These categories can broadly be summarised under the following headings:

1. The importance and subtleties of communication and timing of contact.
2. Interpersonal awareness and team dynamics.

3. The movement from incompetence and uncertainty to confidence and command over ambiguous dynamics.
4. Issues associated with energy and emotion: stress, isolation, commitment, morale, satisfaction, and motivation.
5. Awareness of and concern with how students present themselves as individuals and teams, and how they represent their institution
6. Career development advantages.
7. Empowerment, responsibility, and decision making.

Each category is discussed in further detail. This discussion is supported by respondent statements (presented in italics).

Importance and Subtleties of Communication and Timing of Contact

A content analysis of student insights shows that the issue of communication was the most frequently invoked overarching "insight category." A variety of subcategories also emerged here which mainly focused on the inherent value, the subtleties, and the timing of communication. Participants frequently referred to the overall importance of having virtual team communication that was regular and positive, while also revealing perceptions that this was difficult to achieve. General comments about communication often revealed how important the participants considered (or came to consider) it to be:

Communication would be the big one.

Communication can be helped with emails. Phone calls, Wiki's, instant messenger etc but require effort and participation from distributed teams.

The pragmatic issue of timing of communication was seen generally as a problematic aspect of the experience, but also often recognised both as a realistic and inevitable challenge that needed to be managed. In addition, many of the insights that students provided suggested that "waiting" for responses from the team members in the remote location may have given rise to frustrations and anxieties that affected the group and its work.

We were told by SCR to sit tight and wait.

Timing can be a problem. If the [local] team finds an error at 8am then it won't be until the next day that team B will tackle the error, leading to delays.

One student made a link between early communication problems and a feeling of ambiguity and noted that addressing this would lend clarity and possibly more momentum to the work that they had been assigned:

There should be more phone conferences early in the req phase. This probably would help clear up ambiguity.

Another respondent recognised the importance of the proximity of certain types of expertise by saying:

The remotely located team may have different knowledge and experience than others and therefore communication is a key player to resolve this issue.

Subtleties of communication and the nuances, conflicts, and misinterpretations to which it can often be vulnerable, were also regularly invoked in this response category. Several respondents talked about the importance of face-to-face contact and seemed to suggest that tone and patience are more important when communicating with remote team members.

Learning point: Know what to say and what not to say.

Team in US was not as helpful as they could have been. They made us feel bad about it "Where is it?" I like meeting and talking to people.

With the teams so dispersed there was no face to face warming of the teams. This led to a slow start in stimulation of the participants.

The sense of interdependence between the locations was also invoked:

Coordination of effort also came into play after the black-box testing phase as the American teams used our completed tests to form a basis for white box testing. Our performance would obviously have an impact on that.

These comments echo with communication competencies that we identified in *Educating the Graduate* section as essential to facilitate the software developer and manager functioning effectively in the GSD environment. The student teams articulated insights about communication in a global classroom setting, a fact that should equip them to operate more effectively in subsequent GSD work environments.

Interpersonal Awareness and Team Dynamics

Commonly, students' reflective statements about their experiences as a part of the project, invoked the issue of interpersonal awareness and team dynamics. These statements were coded under this category when they specifically referred to issues about "getting to know" the remote team members or themselves more accurately. They were linked to issues of communication too, but the following statement types were deemed to be sufficiently different and more focused on team dynamics and interpersonal awareness issues to merit their own category:

We got on very well as a team. We did have problems. Some worked better with each other. Some were really pessimistic—could only see the downside of things. I tried as a team leader to see the upside—sometimes seeing the downside can stop a project too—it does stop the whole thing from happening, or stop the momentum but it gives a reality check.

I started to understand the importance of group work. I have more of an understanding of different personalities—what we had to deal with—laid back or not.

In particular, one of the respondents indicated a need to "get the measure" of people in the remote locations and refers directly to "making up" personalities. *[With this project] you never get a sense of what the other guys are like. We have made up a personality for [him] (S8).* This suggests the conscious "construction"of individual images along with their own mistrust in their theories about other people.

There also seem to emerge "theories" about team functioning. Several comments from respondents suggested that they had generated overall hypotheses about how teams should work, based directly on the experiences that they had with this task:

Teams should be more inquisitive.

When there are 5 people there are always problems of someone not there.

The development of a sense of "teamness" among all members of the virtual team was also highlighted more particularly as problematic through the following insights:

At no stage was a sense of teamness developed. In fact at times it felt very much a case of running test cases and hearing nothing back.

The aforementioned statements reflect a rich engagement with the development of insights about team characteristics, and an emerging sense of understanding gained about the strengths of different members of the team. Some of the statements provide evidence of a fine-grained development of knowledge about which team member's strengths relate to which aspect of the task. In addition, respondents demonsrated the feeling of getting to know different emotional orientations towards the processes in which they were immersed (for example, *some people could only see the downside of things*). It is difficult to see how such fine-grained knowledge of team dynamics could be achieved without the direct participation that they had experienced, and it is unlikely that the curriculum relating to their programme of study specifies this level of understanding and knowledge of the nuances and complexities of team functioning. The statement provided by respondent S8, reveals something even more complex—that is, a sense of caution and awareness about the assumptions made relating to personalities of people that had not yet been met in person. *We have made up a personality for [him]* is a statement that may reveal the need for team members to apply characteristics to people they have not yet met, accompanied by a recognition that the assumptions are only provisional and cannot be confirmed from a distance. In terms of interpersonal awareness and insight, such statements demonstrate strong and complex learning of some of the intangible aspects of GSD as a process and a task.

The Movement from Incompetence and Uncertainty to Confidence and Command Over Ambiguous Dynamics

There is plenty of evidence among the reflective statements provided in this study that a developing sense of competence and confidence started to emerge as part of the GSD experience. Statements that signalled a gradual unfolding of knowledge and engagement with the task included the following:

We did not know what they meant. As we went through the course more we got to know what they meant.

We learned from our mistakes and adapted.

It is often said that we learn more from our mistakes than our successes and in that case it has been fair to say that it has been a worthwhile experience.

It also seemed clear that part of the journey to competence included encountering an experience of ambiguity and confusion, as revealed by the following kinds of statement:

Hard to pin down how code was going to work in a new system.

A component was changed so all the work we did before Christmas was wasted.

Requirements were not good. We constantly had to read between the lines.

Insights about emerging confidence also appeared frequently in students' responses and reports, particularly in response to prompts that encouraged them to think specifically about what they had learned from the process. Familiarity, comfort, and confidence seem to have replaced the sense of the task having been "daunting" and of feeling out of their depth. The recognition of the importance of experience and the role that it has played in reinforcing and developing their learning seems to be clear:

Well now I've seen that (req doc) before so it won't be as daunting .

It all comes down to experience. If we could go back and do it again, we'd do it differently.

The fundamental purpose of education is to facilitate the journey towards competence. It is clear from the previous statements that students appeared to navigate a kind of pedagogical "journey" to competence. When looking back on this experience, their insights suggest that the negotiation of confusion and ambiguity was central, if not essential, to the learning processes in which they were involved. Again this suggests that there was something very crucial about the simulated GSD experience, and that in conventional learning environments the movement from ambiguity to clarity might not be as significant or as realistic as those experienced by this group of students. A link between these insights and the developing sense of "teamness" reflected in other comments suggests that the developing sense of competence might also occur in tandem with a developing sense of teamness. This may be evidence of the students' enhanced understanding of the sophisticated and complex dynamics of GSD.

Issues Associated with Energy and Emotion: Stress, Isolation, Commitment, Morale, Satisfaction, and Motivation

Another common statement category among students suggested that they were readily able to identify "emotionally relevant" aspects of the experience of working in a GSD team. The ability to signal the relevance of difficult feelings associated with stress and isolation as well as the more positive emotions associated with commitment, morale, and motivation demonstrate another dimension of self-awareness that may have developed and become enhanced over the course of the experience.

Student references to experienced stress and isolation included the following types of statement:

We felt isolated. We felt a bit alone as a small development team.

It was time consuming and stressful but at the same time I enjoyed it.

Some of the stress was linked to the time deadlines associated with the learning experience, while one respondent also highlighted that the emotional engagement with the task could be experienced as simultaneously positive and negative.

In addition, responding students also seemed to demonstrate an awareness of the commitment required in order to complete the task successfully and on time. Some of them demonstrated this awareness by highlighting that among their team members that commitment was not always present, while others took commitment as one of the learning outcomes of the process:

Make sure they understand the commitment they need to give to the project. People not coming in [on] time affects morale.

Are you going to be in at 9 a.m. during the 3 week break. It is worth it in the end if you can do it.

Others noted how the experience induced commitment by creating inherent motivators into their lives as students. Statements demonstrating this insight included the following:

This gave me something to get up and come into college for [even when my lecture schedule did not require it].

I have something to push me along.

The realisation of the effective dimension of working seems to have had an effect on students' recognition of how feelings can impact on projects. An explicit recognition of the added value of intangibles like commitment shows that students

are developing a more subtle comprehension of how team dynamics work and how emotions impact on those dynamics in sometimes fundamental ways.

Awareness of and Concern with How Students Present Themselves as Individuals and Teams, and How They Represent Their Institution

A very clear category of statements emerged from respondents that related specifically to the ways in which the local student team presented itself and appeared to the remote members of the GSD teams. A concern for how they came across to their corresponding team members in the other locations emerged as something that was important to students:

We didn't want to look like a bunch of muppets and you were our supervisor.

You don't want to be seen to be proven wrong. Very pleased when we were able to say the other team was wrong.

We didn't want to be seen as a failure.

These statements express that students were prevented from availing themselves of useful learning moments during the process. They were reluctant to clarify, question, and learn. This was not because of pressure from lecturers, project supervisors, or central team members but because of an internal pressure that they put on themselves and a concern regarding how they might be viewed by other stakeholders in the process.

It also seems clear that once they had met face to face with a representative of the remote team members, this reluctance and concern diminished significantly:

Once they met the guy from Siemens they were much happier.

This year's team haven't got that problem at all because the links are stronger.

Furthermore, the implementation of the wiki, which is used as a remote communication tool within the Ard na Croise project during year 2 has helped communication—*Wiki may be helping too—to break taboo about asking "stupid" questions.* The wiki contains questions from all students internationally—so UL students have visibility into queries from other international student teams. This was not the case in year 1 of the project, when UL students were isolated from communicating with other teams. This was a decision of the research project team.

The most striking aspect of this category of statements lies in its identification of a learning paradox within the student teams. On one hand, the concern for projecting themselves in a positive light led to them wanting to work hard and appear to be performing at high levels. This may have boosted their motivation and engagement with the task. On the other hand, the need to be seen in a positive light seemed, at least occasionally, to block good learning, as the students were reluctant to ask important questions at key stages in the process.

Career Development Advantages and Practical "Real-Life" Experience

Students tended also to invoke the pragmatic and instrumental benefits associated with having participated in the process. Many of them mentioned specifically how being able to say they had participated in the project would be helpful for their career opportunities, indicating particularly that it would give them "the edge" in an interview setting.

In addition the benefits of having been involved in an activity that reflected the real life pressures and structures of GSD was something that they invoked explicitly as being positive and beneficial:

While we did not hypothesise that this experience would be seen in such pragmatic ways by the participants, our research shows that the pragmatic benefits of participating in this kind of educational experience must not be underestimated. We as educators tend to look at the "whole curriculim" as contributing to the overall employability of our students. However, it seems in this instance that the specific GSD experience reported here was heavily weighted by students as having particularly useful career development effects. It is worth noting that out of five participants in one of the GSD projects, three were subsequently employed in GSD environments, a series of choices and opportunities that may not have arisen without their participation while studying.

Empowerment, Locus of Control, and Decision Making

Students also highlighted the struggles and issues that they encountered in the development of a more "internal locus of control" for the work that they were doing. They highlighted key questions and problems that seem to indicate that a gradual emerging of empowerment occurred over the course of the project. The worries associated with who was responsible for what were indicated in the following types of statements:

I'd feel a good bit responsible.

I didn't think we should go to Ita.

One student articulated an emerging conviction that the decision making relating to the task ultimately lay within their own team:

We had to learn to figure things out for ourselves.

Several noted the issue of responsibility and locus of control as something that needed to be defined and clarified:

Something like a contract would be good at the start.

It's important to assign responsibilities. If we don't, no-one will take it on for themselves.

Another intangible but important aspect of learning and work performance is relevant to this issue of locus of control. Understanding levels of responsibility and empowerment influences individual and group decision making in very significant ways. In grappling with the issue of locus of control and decision making in GSD contexts, students also seem to have gained a possibly deeper level of insight about their engagement with the tasks and processes.

The pragmatic effects of student participation can be seen explicitly when we analyse their career development advantages. However, there were other pragmatic effects observed in the study, for example, following their participation in the global projects, they recognise the importance of teamwork (*I learned a lot of things that are valuable like working with the group*), how they need to change their work practices (*It involved changing my mindset from haphazard to process*), and how to deal with responsibility (*Need to set ground rules and clarify responsibility*).

As illustrated in Table 1, graduates are expected to demonstrate competencies for use in the GSD environment. Through involvement in the projects discussed, students had exposure to all of the competencies required by the software developer. Through the discussion on interpersonal awareness and team dynamics, students developed communication and language and worked with other cultures. They also had exposure to communication tools and how these are used differently by different cultures (for example, *Differences in the Irish and American teams—Irish used email more, but US used discussion boards*). The reality of temporal issues became clear (*Communication may have been delayed as a result of the time difference*). The students were

also exposed to cooperation issues. Not only did they have to work together within local teams, they also had to cooperate with internationally dispersed teams. Furthermore, in the Global Studio Project, in particular, they were required to report to a "management" team in Siemens Corporate Research. As discussed earlier, this was not always an easy task and participation ensured that the students learned how to cooperate. In our interviews, statements from the students such as—*One would make breakthrough, others would put shoulders to the wheel*—illustrate this. In the global environment, as in other development environments, software developers should also be aware of processes and process tools. Participants in these projects were exposed to processes such as requirements and configuration management and were expected to continue development even with changing requirements. Global tools were implemented and used by the students. Students were expected to make regular reports to both their internal university supervisor and to the teams with whom they were working.

In addition to competencies required by the software developer, students were also exposed to some of those required by the software manager. In particular, they experienced roles, responsibilities, and competencies management. In one case, when the students stated: *We didn't want to look really bad. We all thought that if we kept ringing with questions, we did not want to seem incompetent;* they learned that to survive in the global environment, then they needed to do exactly the opposite and have their questions answered.

CONCLUSION AND OBSERVATIONS

Through the qualitative analysis of key reflective statements conducted for this chapter, it has been possible to extract several overarching themes that demonstrate participants' own perceptions of the learning concerns, experiences, benefits, and outcomes associated with being part of a virtual GSD team. We now bring these themes together in an effort to map the student experiences with pedagogical interventions and aims associated with this project.

Moore and Ryan (2006) remind educators that "*Important truths that seem obvious to experienced practitioners can often only be learned by students if they have been encountered in a 'deep' as opposed to a 'shallow' sense*." In the complex experience of joining an international, virtual GSD team, students gained insights, learned lessons, and acquired understanding that would otherwise have been very difficult, if not impossible to achieve. In an analysis of students' own words we have seen evidence of both cognitive and affective breakthroughs achieved directly as a result of their experience with a GSD environment and tasks. While students could be given vicarious insights (through lectures, tutorial sessions, and discussion forums) about the importance of knowing the subtleties of communication, team dynamics, and perceptions, we find it difficult to imagine how the range of work-based comprehension that they have reported could possibly be achieved outside of the experiential frame provided by this learning experience. In sketching out the framework of competencies that the literature highlights as central to the needs of GSD developers and managers, we are struck by the parallels found between this competence set and those identified by the students when discussing and explaining their learning outcomes.

For several decades now, there have been significant criticisms of conventional higher education environments. Biglow (1983) highlighted a direct link between university classroom norms and the problems faced by graduates on entering the workplace. Passivity, dysfunctional competition, and lack of a sense of responsibility are, he argues, all facilitated by inactive, disengaged educational environments. While conventional educational norms can be active, engaged, and

excellent, it is arguably much easier to create these conditions in more experiential settings like the ones described and evaluated in this chapter.

By observing the seven outcomes identified previously, it is possible to argue that there are three forms of learning impact experienced by students who participated in this project: (1) pedagogical, (2) pragmatic, and (2) achievement of specific GSD competencies. The pedagogical effects can be tracked most strongly through observed references to the journey from incompetence to competence. The pragmatic effects, while they may derive from this journey, are more closely evidenced by participants' own insights about the practical and optical value of participation. The specific GSD competency development is demonstrated through the students' own reported sense of achievement, but still requires confirmation through the normal curriculum assessment process. We do, however, argue that the sense of competence that the students report sets the scene for more positive and engaged learning, even in didactic contexts.

In summary, we champion the application of the learning experiences we have described in this chapter, while recognising that the implications of this for GSD learning are that educators need to work interinstitutionally and in tandem with industry where relevant. Mimicking real work settings creates the possibility of giving rise to the range of learning benefits that are associated with truly problem-based learning environments. Adding pedagogical support, opportunities for reflection, and the capacity to revise and develop ideas using experienced teachers as a sounding board creates an added-value environment that we believe should become a standard part of software engineering education curricula.

ACKNOWLEDGMENT

The research in this chapter has been funded by Science Foundation Ireland through the Principal Investigator, B4Step project (Grant no. SFI 02/IN.I/108) and Cluster project GSD for SMEs (Grant no 03/IN3/1408C) within the University of Limerick, Ireland; by the National Science Foundation (U.S.) within the Software Engineering Research Center, Ball State University, Muncie, Indiana, U.S. (Grant no: EEC-0423930); and by Siemens Corporate Research, Princeton, New Jersey, U.S.

Chapter 5.19
A Requirement Elicitation Methodology for Global Software Development Teams

INTRODUCTION

Failures during the elicitation process have been usually attributed to the difficulty of the development team in working on a cooperative basis (Togneri, Falbo, & de Menezes, 2002), but today there are other points that have to be considered. In order to save costs, modern software organizations tend to have their software development team geographically distributed, so distance between members becomes one of the most important issues added to the traditional problems of the requirement elicitation process (Brooks, 1987; Loucopoulos & Karakostas, 1995).

So far, literature has widely analysed real life Global Software Development (GSD) projects and pointed out the main problems that affect such environments, especially related to communication. As a complementary view, we have focused our research on analysing how cognitive characteristics can affect people interaction in GSD projects, especially during the requirement elicitation process, where communication becomes crucial.

In this article, we present the main characteristics of requirements elicitation in GSD projects and introduce a cognitive-based requirement elicitation methodology for such environments.

BACKGROUND

Advantages and challenges of GSD have been widely analyzed in literature. As part of the advantages, the most cited are:

- Taking advantage of time difference to extend productive hours (Herbsleb & Moitra, 2001);
- Minimizing development costs (Lloyd, Rosson, & Arthur, 2002);
- Locating developers closer to the customers (Damian & Moitra, 2006); and
- Taking advantage of diversity of stakeholders' knowledge and experiences (Ebert & De Neve, 2001).

On the other hand, the challenges that GSD must face are (Damian & Zowghi, 2002):

- the loss of communicative richness, affected by the lack of face-to-face interaction;
- the time difference between sites, that introduce delays in the project;
- cultural diversity, as a source of misunderstandings; and
- knowledge management, because of the need of maintaining information from many distributed sources.

Looking for solutions to improve communication in GSD, concepts from CSCW (Computer-Supported Cooperative Work) become important because this research area concerns the development of software for enabling communication between cooperating people (*groupware*), that can be simple systems (like e-mail or plain-text chat), more complex ones (like videoconferencing), or the combination of more than one of them. To be more specific, when talking about groupware we follow a convention: We refer to every simple communication technology (e-mail, chat, videoconference) as groupware tools, and to the systems that combine them as groupware packages (Gralla, 1996). Doing so, the most common groupware tools used during multisite developments are e-mails, newsgroups, mailing lists, forums, electronic notice boards, shared whiteboards, document sharing, chat, instant messaging, and videoconferencing (Damian & Zowghi, 2002; Gralla, 1996).

Another research area related to the distributed requirements elicitation process is Cognitive Informatics (CI), a transdisciplinary research area that encompasses informatics, computer science, software engineering, mathematics, cognition science, neurobiology, psychology and philosophy, and knowledge engineering (Chiew & Wang, 2003). In CI, there is a bidirectional relationship between cognitive sciences and informatics (Wang, 2002):

1) using computing techniques to investigate cognitive science problems like memory, learning, and thinking; and
2) using cognitive theories to investigate informatics, computing, and software engineering problems.

In our research, we have followed the second point of view, using concepts from cognitive psychology to improve the requirement elicitation process. Doing so, our research focused on learning styles models (LSMs), a cognitive psychology theory based on Jung's theory of psychological types published in 1921 (Miller & Yin, 2004), that classify people according to the ways they perceive and process information. These models have been discussed in the context of analyzing relationships between instructors and students, but we propose applying them to a virtual team that deals with a distributed requirement elicita-

tion process, considering an analogy between stakeholders and roles in LSM, because during the elicitation process everybody "learns" from others (Martin, Martinez, Martinez, Aranda, & Cechich, 2003), and stakeholders play the role of students or instructors alternatively, depending on the moment or the task they are carrying out.

After analyzing five LSM in Martin et al. (2003), we found out that every item in the other models was included in the model proposed by Felder-Silverman (Felder & Silverman, 1988), so that we may build a complete reference framework choosing this as a foundation. The Felder and Silverman (F-S) model classifies people into four categories, each of them further decomposed into two subcategories (*Sensing – Intuitive*; *Visual – Verbal; Active – Reflective; Sequential – Global*). To know their cognitive profile, people must fill in a multiple-choice test (available at http://www.engr.ncsu.edu/learningstyles/ ilsweb.html), that returns a rank for each category. Depending on the circumstances people may fit into one category or the other, being, for instance, "sometimes" active and "sometimes" reflective, so preference for each category is measured as *strong*, *moderate*, or *mild*.

Most of related works use learning and psychological style models with educational purposes, while few works use them to solve problems in software engineering. One work which uses cognitive styles as a mechanism for software inspection team construction is described in Miller and Yin (2004). They use the MBTI method, an instrument similar to the F-S model. Their intent is different from ours because they use the cognitive styles to set which people seem to be more suitable to work together, while we try to give the best solution (concerning technology) for an already chosen group of people.

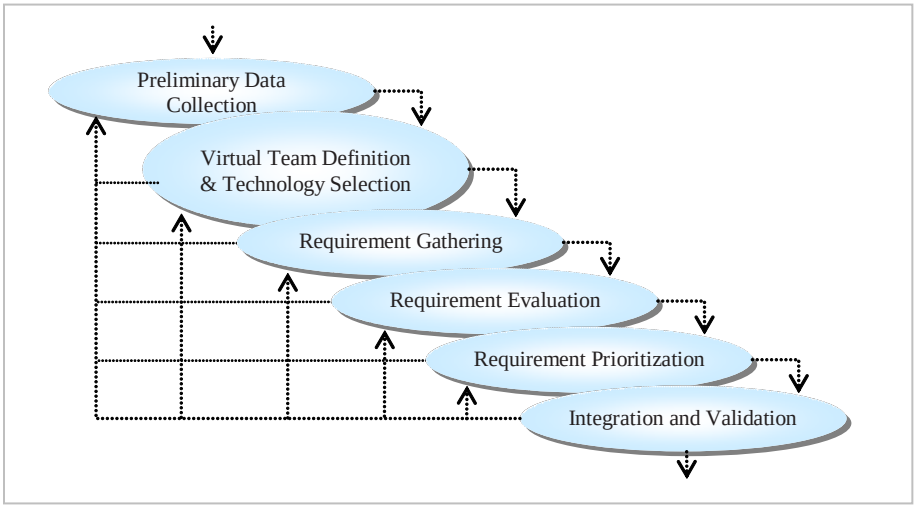
OUR METHODOLOGY: RE-GSD

In order to define the basis for a methodology for requirement elicitation in GSD projects, we have analyzed methodologies used in colocated development and proposed extending them from a cognitive point of view, using the F-S model as a basis for defining a model for technology selection.

We have called our methodology RE-GSD (Requirement Elicitation for Global Software Development projects) and, as a starting point for it, we have selected the models proposed by Christel and Kang (1992) and Hickey and Davis (2003). This selection is due to the fact that both models share a generic view of the selection of requirement elicitation techniques, which fits our intention of defining what to use according to stakeholders' personalities. Both models have been extended and adapted to a distributed environment, so that our methodology can be expressed as follows (see Figure 1):

1. Preliminary data collection: Further decomposed into two categories: (1) about the stakeholders, and (2) about the system and the domain.
2. Virtual team definition & Technology selection: Before starting the requirement gathering, it is important to determine who is going to participate in that stage, because not all the stakeholders in the project are required to participate in every iteration of the elicitation process. Then, the selection of appropriate technology should be carried out, that means, choosing the most appropriate set of requirement elicitation techniques and groupware tools for a given group of people, by taking into account their personal characteristics.

Figure 1. RE-GSD methodology



3. Requirement gathering: Once technology has been defined, it is time to apply the requirement elicitation techniques (which are combined with appropriate groupware tools) to obtain a new list of requirements, trying to answer "*what*" is to be built (Christel & Kang, 1992).
4. Requirement evaluation: In this stage, requirements lists must be analyzed in order to determine consistency between different statements.
5. Requirement prioritization: Once requirements are defined, it is important to give them an order of relative importance so as to know when they should be addressed in relation to other requirements (Christel & Kang, 1992). Specially designed tools for distributed requirement inspection (Lanubile, Mallardo, & Calefato, 2003), which allow synchronous and asynchronous discussion, voting, and so forth, can be used to address both this step and the previous one.
6. Requirement integration and validation: In this step, the new requirement list must be integrated to the requirements collected in the previous iterations, looking for inconsistencies also with the system's goals and organizational factors initially defined.

The following sections present the first two phases of our model that are related to our proposal of technology selection according to the stakeholders' cognitive styles.

PHASE 1: PRELIMINARY DATA COLLECTION

a) About the stakeholders
   1) Identify people whose participation is important for the requirement elicitation process, including people from different levels of the organization.
   2) Get personal information about stakeholders, using the form shown in Figure 2. Some important points for distributed environments are, for instance, distinguishing which is the given name and the family name, because different cultures use different order (for

Figure 2. Stakeholder's personal information form

Stakeholder's Personal Information Form						
Complete Name (as written in the ID card)						
Given Name		Family Name				
Nickname (optional)						
Birthday						
Gender						
Mother Language		Country of Origin				
		Country of Residence				
Academic degree		University / College		Years of study		
For each foreign language (mark with an X your level of knowledge)	<Language>	low	low-interm	interm	high- interm	high
	Writing					
	Reading					
	Speaking					
Felder and Silverman preferences		Active Reflexive	Sensitive Intuitive	Visual Verbal	Sequential Global	

instance, in China the family name goes first, while in most of occidental countries, the family name is the last one). Also, recording information about the country of origin and the country of residence is important to identify their mother language and possible differences in cultural background, as well as the foreign languages stakeholders know to choose a second language.

3) Get information about stakeholders' job, roles, responsibilities and schedules. And because they are distributed, obtaining information about each team member's location (time difference with other sites, work hours, lunch time, etc.) is relevant for other members to know how to contact each other. The form is shown in Figure 3.

b) Get information about the structure, culture, and internal politics of the organization (SWEBOK, 2004), to answer the following questions:

4) *About the groupware tools*: Which groupware tools are commonly used in the organization? Have stakeholders received training in the use of groupware tools? Which ones do they know better? Which ones have they not used before? Is there any policy that limits the use of groupware tools? Are stakeholders willing to learn how to use other groupware?

5) *About the requirements elicitation techniques*: Which requirement elicitation techniques are commonly used in the organization? Have stakeholders received training in the use of requirement elicitation techniques? Which ones do they know better? Which ones have they not used before? Are stakeholders willing to learn new techniques?

6) *About the organizational culture*: Do organizational policies allow stakeholders to communicate with others in the virtual team freely, or is there a person that must act as a mediator?

   7) Get information about the domain and the system in construction.
   8) Determine the system goals.
   9) Identify similar systems

PHASE 2: VIRTUAL TEAM DEFINITION AND TECHNOLOGY SELECTION

As we have mentioned before, we aim at defining strategies that analyze the personal characteristics of stakeholders with the objective of selecting the best groupware tools and requirement elicitation techniques for them. For that reason, selecting appropriate groupware tools is related to our goal of providing the stakeholders with the possibility of communicating with others in a manner closer to the way in which they perceive and process information. That means giving them the chance to feel comfortable with the way in which they interact (synchronously or asynchronously) and the kind of information they interchange (based on words, based on diagrams, etc.).

Even when the technology selection is done for a given virtual team before the elicitation process, obtaining the preference rules is a previous step.

Preference rules are obtained from a generic set of people that works on GSD projects, and then the resulting sets can be used in many different GSD projects as well as different virtual teams, at the same time that new information can be added to improve the source of knowledge of the fuzzy logic system.

Obtaining Preference Rules

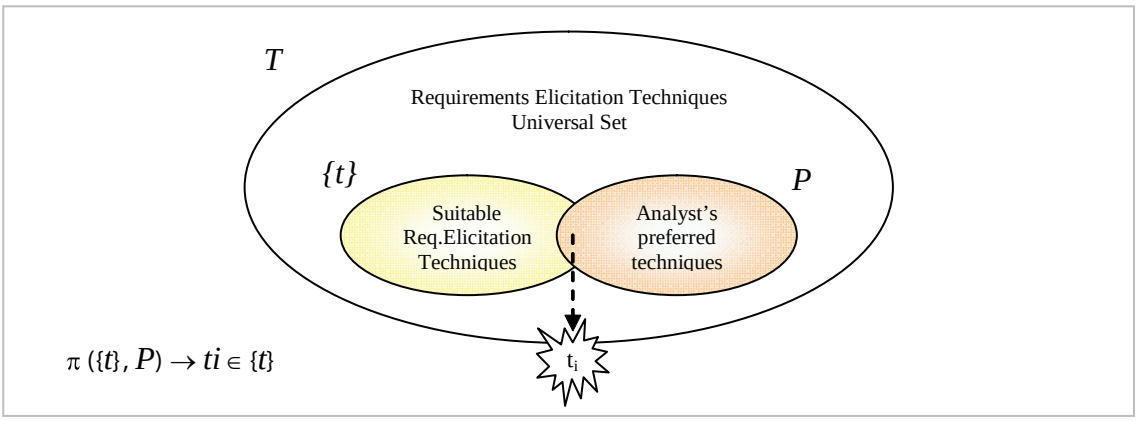
In order to support personal preferences toward groupware tools, in Aranda, Cechich, Vizcaíno, and Castro-Schez (2004) a model based on fuzzy logic and fuzzy sets to obtain rules from a set of representative examples has been proposed. The obtained rules represent patterns of behavior that indicate the preferences of stakeholders in their daily use of groupware tools and requirements elicitation techniques, according to their classification in the F-S model. To do so, we have collected examples of people preferences and applied a machine learning algorithm. The algorithm we chose (Castro, Castro-Schez, & Zurita, 1999) finds a finite set of fuzzy rules to reproduce the input-output system's behavior. Using this machine learning algorithm over a set of examples that represent the preferences of many stakeholders, we obtained a set of rules (Aranda, Vizcaíno, Cechich, Piattini, & Castro-Schez, 2006). The resulting set of preference rules can be applied to choose the best suite of groupware tools for a group of people by analyzing the results and combine them appropriately, as we will explain in the next section.

The Technology Selection Strategies

According to the analysis of real life projects, analysts are those who choose the techniques for requirement elicitation (Hickey & Davis, 2003). To model such a selection, Hickey and Davis' model considers a personal selector function π that returns a technique t_i, from a given a set of techniques $\{t\}$ and a set P that represents the personal preferences of the analyst. That means only the analyst's preferences are taken into account, as it is shown in Figure 4.

A first attempt to adapt the previous generic model to our cognitive point of view analyzes the preferences of all the stakeholders and chooses the technique that has more adherents (Aranda, Vizcaíno, Cechich, & Piattini, 2005). This extension of the π function, called π^*, is shown in Figure 5. In this formula PS_i represents a set of techniques that fit the *i-th* stakeholder's preferences (defined by the mechanisms based on fuzzy logic and fuzzy

Figure 4. Requirement technique selection according to analyst's preferences (π)



sets we have described previously), and $t_i \in \{t\}$ is the technique that appears in most of the PS_i. In this case, analysts are considered without any priority over the rest of the stakeholders.

A later improvement of π^* considers the relative importance of stakeholders' preferences by means of weighting them. Its purpose is that, if some stakeholders' preferences are stronger than the rest, the preferences that should be primarily considered are those of the first group of stakeholders. Also, the different weights might be used to prioritize preferences according to stakeholders' roles. The resulting function, called π^{**}, is shown in Figure 6. In this case, ws_i represents the weight (how strong the preferences are), and the resulting t_i is a technique that is appropriate for the current situation and is also appropriate for the stakeholder whose personal preferences are the strongest.

Figure 5. Requirement technique selection according to the most common preference (π^*)

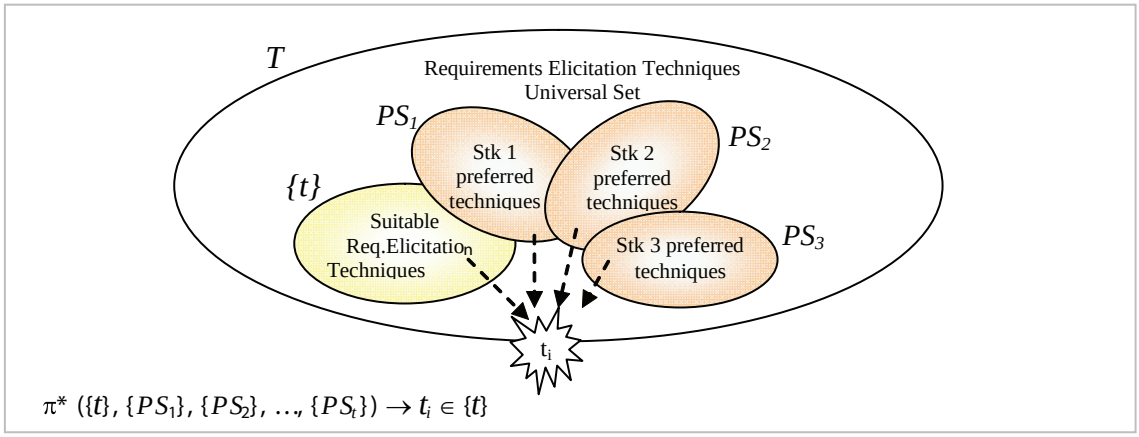


Figure 6. Requirement technique selection according to the strongest preferences in the group (π^{**})

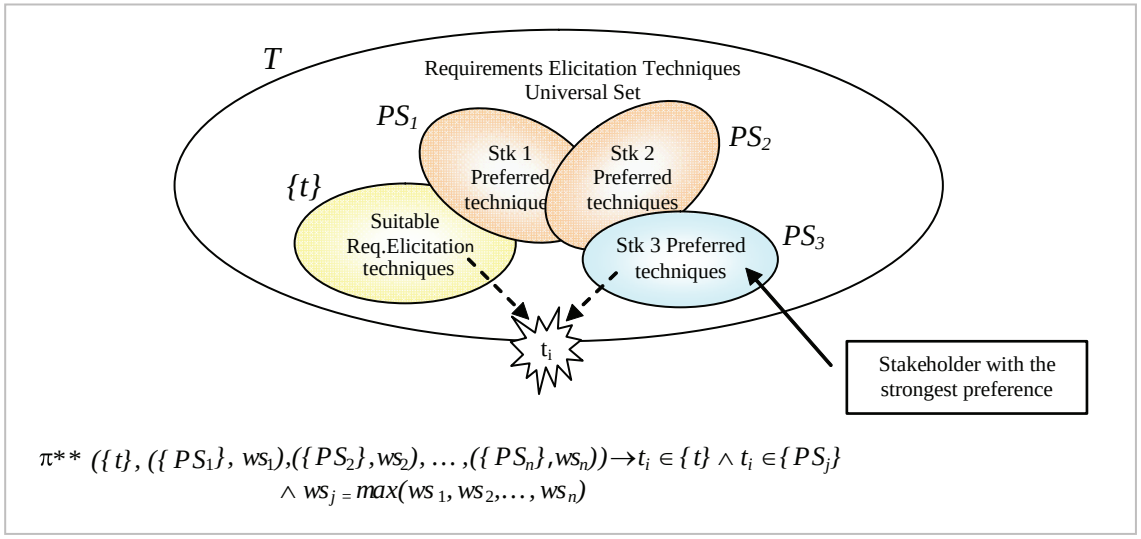

PHASE 3: REQUIREMENT GATHERING

At the moment of deciding how to conduct the requirement gathering, the first step is deciding which of the possible techniques is best, given a current state of knowledge and a particular situation. To do so, the Hickey and Davis model defines the selector function σ (shown in Figure 7).

In a scenario where stakeholders are distributed along many geographically distanced sites, the selector function σ must also consider other aspects. The most important are time difference and the level of knowledge of a common language.

Time difference is important because when timetable does not overlap, or overlaps for a very short period of time, synchronic communication is not possible, then the selection process should prioritize those techniques that work better on asynchronous basis. Similarly, when stakeholders do not share the same language, some of them would need more time to read, think quietly, look for some vocabulary in the dictionary, and so forth.

With those considerations in mind, we extended the selector function σ as it is shown in Figure 8, where T_i (time difference) indicates in which degree synchronous communication is pos-

Figure 7. Definition of the requirements elicitation techniques most suitable for a given situation in a collocated environment (σ)

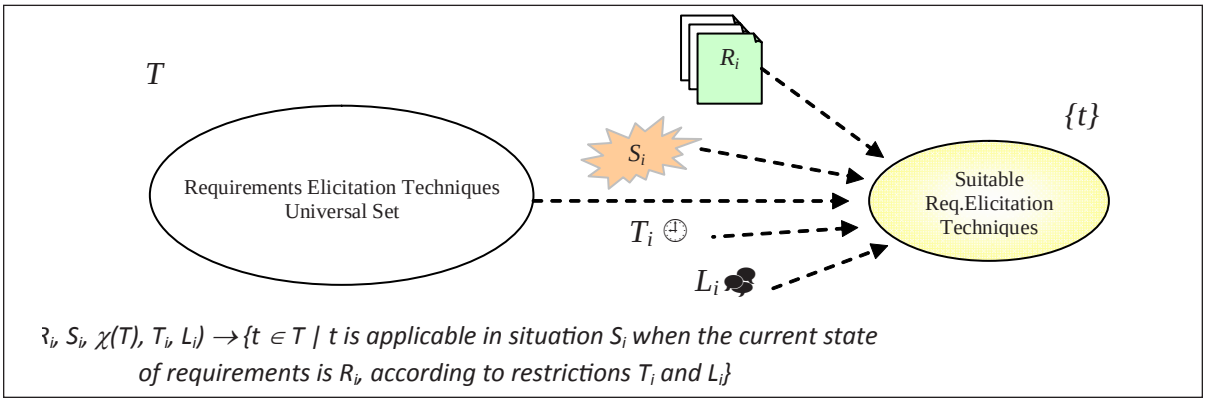

Figure 9. Requirement elicitation in GSD, as an iterative process of technique selection and application

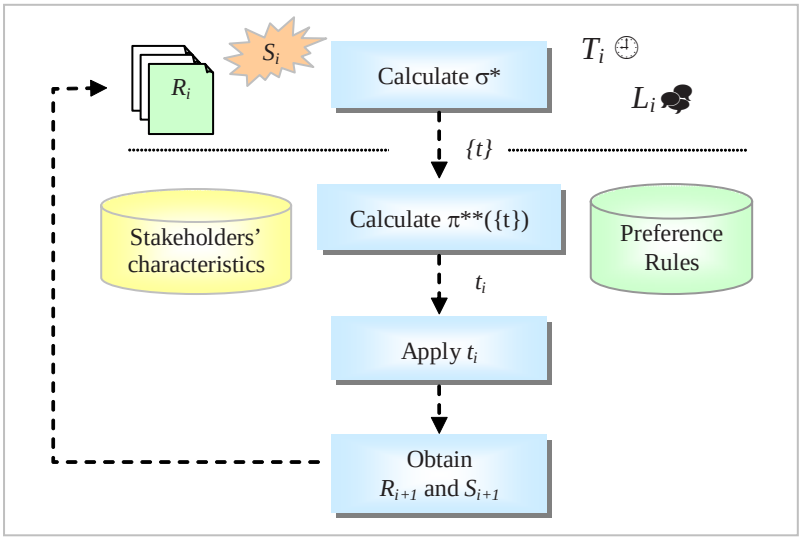

sible between the sites that need to interact; and L_i (degree of knowledge of a common language) indicates the level of fluency of communication.

Finally, a graphical representation of the requirement elicitation process in a distributed environment is shown in Figure 9.

FUTURE TRENDS

For many years, research on GSD has focused on improving technology as a supporting media for spreading global communication. Those technology topics are really necessary indeed, but not enough for a society challenged by cultural diversity and worldwide-located working teams. Currently, research efforts are looking at GSD as a human-intensive process, where new strategies to deal with socio-cultural differences and distance are bringing psychological and cognitive aspects into the arena. Human factors seem more complex than technological ones, so probably we will see many strategies in the future trying to find the most effective way people understand, choose, and communicate during GSD. Certainly, cognitive informatics will be one of them.

CONCLUSION

GSD projects are a common way of work these days. Looking for solutions to improve communication in virtual environments has led us to analyse human interaction and how to apply well-known techniques from the field of cognitive psychology (called learning style models) as a base for technology selection.

Based on a cognitive-based technology selection approach, we propose a methodology for requirement elicitation in GSD projects, which focuses on improving communication between distant stakeholders. Considering cognitive aspects of stakeholders is significant because the selection of requirement elicitation techniques according to personal characteristics of all the members of a virtual team (instead of just the

analyst) might affect positively the quality of the information gathered during the requirement elicitation process. In addition, as stakeholders might feel more comfortable expressing themselves when using a groupware tool closer to the way they perceive and reason about the world, communication in virtual teams is expected to be more fluid and personal satisfaction higher.

In this article, we show the first three phases of such a methodology, called RE-GSD, which are the most clearly different from traditional requirement elicitation methodologies. Current work is focused on defining experiments, in academic and industrial scenarios, to analyze its performance.

KEY TERMS

Cognitive Informatics: It is an interdisciplinary area that applies concepts from psychology and other cognitive sciences to improving processes in engineering disciplines, such as informatics, computing, and software engineering.

CSCW (Computer-supported Cooperative Work): It is a research area that focuses on how people work together and the design and development of software (groupware) that may help their work as a group.

Distributed Software Development: It is a way of developing software that allows the stakeholders to be distributed in geographically distanced sites.

Global Software Development: When the distribution of the members of a distributed software development team exceeds the frontiers of a country.

Groupware: Software that supports and improves group work. It can be a simple text-based technology like e-mail or more sophisticated like videoconferencing.

Learning Style Model: It is a cognitive psychology theory that classifies people according to a set of behavioural characteristics pertaining to the ways they perceive and process information. They can be used to improve the way people learn a given task.

Requirements Elicitation: It is the first stage in the process of understanding the problem the

software has to solve. It is crucially based on human communication between the development team and the customer. Other terms that are used as synonyms are "requirements capture," "requirements discovery" and "requirements acquisition."

Stakeholders: They are all the actors that have some interest on a system. They can be the people that pay for it, work on its development or people whose task will be affected by the system, among others.

Chapter 5.20
Project Quality of Off-Shore Virtual Teams Engaged in Software Requirements Analysis:
An Exploratory Comparative Study

ABSTRACT

The off-shore software development companies in countries such as India use a global delivery model in which initial requirement analysis phase of software projects get executed at client locations to leverage frequent and deep interaction between user and developer teams. Subsequent phases such as design, coding and testing are completed at off-shore locations. Emerging trends indicate an increasing interest in off-shoring even requirements analysis phase using computer mediated communication. We conducted an exploratory research study involving students from Management Development Institute (MDI), India and Marquette University (MU), U.S.A. to determine quality of such off-shored requirements analysis projects. Our findings suggest that project quality of teams engaged in pure off-shore mode is comparable to that of teams engaged in collocated mode. However, the effect of controls such as user project monitoring on the quality of off-shored projects needs to be studied further.

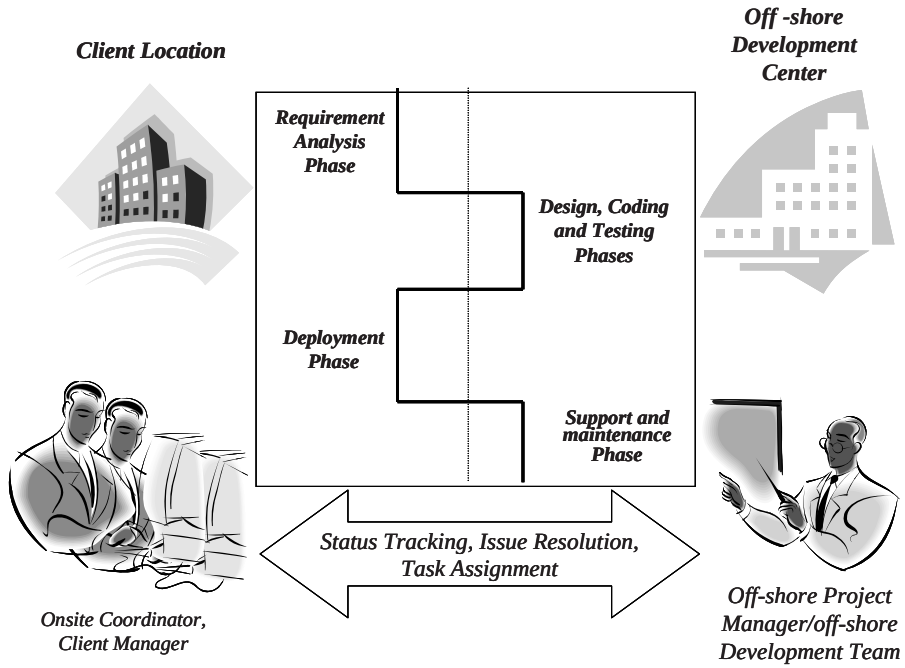
INTRODUCTION

The past two decades have witnessed significant globalization of the software development process with development rapidly moving away from the traditional collocated model, often called *on-site development,* to the off-shoring model. With the availability of increasingly skilled, flexible, and economical IT workforce in countries such as India, Malaysia, and China, it makes financial sense for United States and European client organizations to execute a significant portion of software projects in these countries. This growing trend towards off-shoring has, in turn, spurred growth in many Asian nations, creating improved economic and IT infrastructure and enhancing the viability of these countries as software service providers. For example, India has emerged as a dominant off-shore software development industry with revenue of about $16.7 billion, which is projected to reach $60 billion by the year 2010 (Carmel, 2006; National Association of Software and Service Companies, 2005).

The Indian off-shore software industry has matured over the years, and process capability has been steadily improving. Coordination and communication problems typically encountered in off-shore development (see Battin, Crocker, Kreidler, & Subramanian, 2001, for an extended discussion), are mitigated by the use of processes such as rational task assignments and liaisoning, and tools such as centralized bug reporting system and software configuration management platforms. A case in point is India's Infosys Technologies, which has significantly leveraged time zone differences with its clients by modifying its organizational culture, processes, and communication technologies (Carmel, 2006).

The typical off-shore development model, followed successfully for over a decade by many Indian software companies such as Infosys, Wipro, TCS, and Satyam, is illustrated in Figure 1.

Figure 1. The off-shore software development model



Requirements analysis refers to that stage of the system development life cycle wherein the information and information processing services needed to support select objectives and functions of the organization are (i) determined and (ii) coherently represented using well-defined artifacts such as entity-relationship diagrams, data-flow diagrams, use cases, and screen prototypes (Hoffer, George, & Valacich, 1999). As suggested in Figure 1, typically this phase is conducted at the client location, since this phase requires frequent and significant interaction between users and developers. Business and systems analysts are physically located at the client site to perform this activity. Global projects consultant teams from off-shore location travel to the user site to gather and analyze requirements in face-to-face meetings (Damian & Zowghi, 2002). The consultants then communicate the requirements to the development staff in the offshore site. Depending on the nature of the project, high-level design is conducted in both on-site and off-shore mode due to comparatively lower interaction needs with the client. Detailed design, coding, and testing are executed at the off-shore site. Off-shore vendors also deploy liaisons who coordinate activities between on-site users and the off-shore development team. These liaisons are critical for effective communication and coordination between users and developers (Battin et al., 2001).

Increasingly, both client and software providers are now considering the possibility of off-shoring the requirements analysis phase, traditionally done on client site, away from the client location. In such a scenario, analysts and developers located at the off-shore location would interact in a virtual mode with the clients situated at their premises to determine and structure the requirements. Such a shift could potentially improve the cost arbitrage of the projects for instance by cutting down travel costs incurred for sending analysts to the client site for face-to-face meetings. In an extreme case, the entire team of analysts and developers could be based in off-shore location such as India while the client could be in Europe or the United States. Requirements gathering would then be conducted between these virtual teams using existing computer-mediated communications such as chat, e-mail, and video conferencing. The questions of research interest then are:

1. Can requirements analysis conducted by collocated teams using face-to-face communication be comparable or better than those produced by virtual off-shore teams using computer-mediated communication?
2. What forms of control are necessary to facilitate high-quality outcomes from virtual requirements analysis undertakings?

Using theories of social presence, media richness (Burke & Chidambaram, 1999), as well as control theory (Kirsch, 2002), we develop and test hypotheses regarding these questions.

Traditionally, user involvement in IS projects has been an important contributor to project success (Hartwick & Barki, 1994; Foster & Franz ,1999; Lin & Shao, 2000; Sridhar, Nath, & Malik, in press). Lack of user proximity in a virtual setting can potentially limit the quality of requirements elicitation due to limitations of communications media. In order to mitigate these limitations and the absence of analysts and developers at customer premises, user involvement is expected to take the form of close project monitoring and control to ensure that requirements and project goals are met. Control theory provides the required theoretical foundations for analyzing the effect of different types of controls on teams (Crisp, 2003). In this study, we specifically consider user project monitoring as a behavioral control mechanism and examine its impact on project quality during requirements analysis phase of off-shored software projects. Further, we explore the intersection of media richness and control theories to find early answers to the research questions raised earlier.

This study is exploratory in nature. Without loss of generality, we restrict our attention to the requirements analysis phase as defined in the structured systems analysis and design (SSAD) methodology as defined by Hoffer et al. (1999). We define requirements analysis as subsuming the following two phases:

1. Requirements determination: The process by which the analysts determine the requirements of the system from the users through discussions and interviews and exchanging forms, reports, job descriptions and other necessary documents.
2. Requirements structuring: The process by which the analysts coherently represent the information gathered as part of requirements determination using process modeling and logic modeling tools as described in SSAD.

Our interactions with managers in client firms engaged in software development indicate that off-shoring of requirements analysis is still uncommon. Hence it is not practical to analyze this phenomenon of pure off-shoring of requirements in real-life setting. It is also difficult to do in-depth longitudinal or cross-sectional case studies. Given these arguments, an exploratory research study was conducted in an academic setting involving management students enrolled in a graduate-level information systems course at Management Development Institute (MDI), India, and management students enrolled in a graduate level IT Project Management course at Marquette University (MU), United States. MU students role-played as virtual users/project managers while MDI students were software developers for MU teams as well as user clients for collocated MDI teams. Prior to a full description of our undertaking, we first discuss existing literature on virtual teams in software projects. We then describe the theoretical foundations of this study and elaborate on our research design. Next, we discuss our measures and discuss study outcomes. The article concludes with implications for future research in this context.

VIRTUAL TEAMS IN SOFTWARE PROJECTS

In a pure off-shore mode, users at the client location and the developers at the off-shore location never meet face to face and hence operate as virtual teams, primarily linked through technology across national boundaries. It is in this context that we review previous research on such virtual teams, specifically those engaged in software development projects. Virtual teams are becoming the norm in most corporate environments such as consulting firms, technology products, and e-commerce (Lurey & Raisinghani, 2001) and are being increasingly examined in academic literature (see Powell, Piccoli, & Ives, 2005 for a comprehensive survey of virtual teams). Battin et al. (2001) described how Motorola deployed global virtual teams across six different countries for a Third Generation Cellular System product development. Software development in Alcatel was handled by a central group of several thousand engineers distributed throughout the world (Ebert & De Neve, 2001).

Few studies however, have, examined the use of virtual teams for requirements analysis. Edwards and Sridhar (2005) studied the effectiveness of virtual teams in a collaborative requirements analysis practice. In that study virtual teams at near and far locations participated in requirements analysis phase of the project. This typically is applicable in collaborative global product development exercises as described in Battin et al. (2003). In contrast, in this study we look at the requirements analysis phase of off-shored software projects in which the two protagonists are (i) users who specify the requirements, and (ii) developers who determine and document these requirements together constituting a col-

laborative virtual teams. Damian and Zowghi (2002) studied the interplay between culture and conflict and the impact of distance on the ability to reconcile different viewpoints with respect to "requirements negotiation" processes. They found that lack of a common understanding of requirements, together with reduced awareness of local context, trust level, and ability to share work artifacts significantly challenge effective collaboration among remote stakeholders in negotiating a set of requirements that satisfies geographically dispersed customers. Damian, Eberlein, Shaw, and Gaines (2000) examined the effect of the distribution of various stakeholders in the requirements engineering process. They found that highest group performance occurred when customers were separated from each other and collocated with the facilitator or system analyst. Our study further contributes to the literature on virtual teams engaged in off-shored software requirements analysis.

THEORETICAL FOUNDATIONS AND HYPOTHESES DEVELOPMENT

Social Presence and Media Richness Theories

Social presence is the extent to which one feels the presence of a person with whom one is interacting. Short, Williams, and Christie (1976) suggested that some media convey greater social presence than others. For instance, face-to-face interaction is considered to be high in social presence, primarily because of the capacity of the medium to transmit proximal, facial, and other nonverbal cues relative to other media. In contrast, computer-mediated communication such as e-mail exhibit inherently lower bandwidth than face-to-face interaction, thus permitting transmission of fewer visual and nonverbal cues and restricting socio-emotional communication (Rice & Love, 1987). In addition to differences in social presence, media richness theory proposes that, given their limited cue-carrying capacity, leaner media such as e-mail, will be less effective for groups performing ambiguous tasks which require a variety of cues to be exchanged. However, Burke and Chidambaram (1999) pointed out that despite some support for media characteristics-dependent theories, overall empirical evidence has been mixed.

Quality of Off-Shored Projects vs. Collocated Projects

Teams engaged in pure off-shored projects primarily rely on computer-mediated communications (synchronous such as chat, audio and video conferencing as well as asynchronous such as e-mail) for interaction. However, collocated teams have the luxury of rich face-to-face communication. Based on the social presence and media richness theories, we formulate the following hypothesis:

H1: *Collocated teams using face-to-face communication will produce higher quality project artifacts compared to virtual teams using computer-mediated communication during the requirements analysis phase of software projects.*

In a subsequent section, we define *quality of project artifacts* and how it is measured. To the best of our knowledge, quality of projects and performance of virtual teams engaged in the software requirements analysis has not been studied in the literature thus far. Although several researchers have compared performances of traditional collocated teams with that of virtual teams, the conclusions have been mixed. While one study reported greater effectiveness for virtual teams (Sharda, Barr, & McDonnell 1988), others such as McDonough, Kahn, and Barczak (2001) have found that virtual teams could not outperform traditional teams. Andres (2002) reported that teams working in face-to-face settings experienced greater productivity compared to those supported using videoconferencing. Generally,

computer-mediated teams exhibit lower frequency of communication than face-to-face teams, although they tend to exchange more task-oriented messages as a proportion of total communication (Burke & Chidambaram, 1999; Chidambaram, 1996). This enhanced communication leads to comparable or even higher performance of virtual teams as compared to collocated teams (Burke & Chidambaram, 1999). Consistent with these findings, Schmidt et al. (2001) reported that virtual teams are more effective in new product development decisions as compared to face-to-face teams. However, a majority of the early work has detected no difference between the two types of teams (Burke & Aytes, 1998). Other studies have found no significant differences between traditional and virtual teams when examining decision quality (Archer, 1990; Chidambaram & Bostrom, 1993) as well as the number of ideas generated by decision making teams (Archer, 1990; Lind, 1999; Sharda et al., 1988). Walther (2005) further suggested that complex human processes such as negotiation actually improve between physically distributed individuals who communicate using media low in richness. Studies comparing performance of virtual and collocated teams in software requirements analysis phase are even fewer. Damian et al. (2000) found that groups in face-to-face meetings performed no better than the electronically mediated groups in the requirements negotiation phase of the software development life cycle.

Control Theory

Control is defined as the set of mechanisms designed to motivate individuals to work in such a way that desired objectives are achieved (Kirsch, 1996). *Formal controls* rely on mechanisms that influence the controllee's behavior through performance evaluation and rewards (Choudhury & Sabherwal, 2003). Controllers utilize two modes of formal control: behavior and outcome (Kirsch, 2002). In behavior control, appropriate steps and procedures for task performance are defined by controllers, and then controllees' performance is evaluated according to their adherence to the prescribed procedures. In outcome control, controllers define appropriate targets and allow controllees to decide how to meet those output targets. Controllees' performance is evaluated on the extent to which targets were met, and not on the processes used to achieve the targets (Kirsch 2002).

Informal control mechanisms utilize social or people strategies to reduce goal differences between controller and controllee. Self-control, one mode of informal control, occurs when an individual sets up his or her own goals, self-monitors goal achievement, and rewards or sanctions him- or herself accordingly (Kirsch, 2002). *Clan control*, the other type of informal control, is implemented through mechanisms that minimize the differences between controller's and controllee's preferences by "promulgating common values, beliefs and philosophies within a clan, which is defined as a group of individuals who are dependent on one another and who share a set of common goals" (Choudhury & Sabherwal, 2003). Kirch et al (2002) extended the control theory to the role of client liaisons, exercising control of IS project leaders to ensure that IS projects meet their goals. The study examined the conditions under which client liaisons of IS development projects choose various modes of control. In a related work, Choudhury and Sabherwal (2003) examined the evolution of portfolio of controls over the duration of outsourced IS development projects. They conclude that in outsourced software projects outcome controls are exercised at the start of the project. Behavioral controls are added later in the project. Clan controls are used when the client and vendor had shared goals, and when frequent interactions lead to shared values. Both these studies analyzed the evolution and choice of controls in IS projects and not on the effect of these controls on project outcome. In this study we focus on the effect of formal modes of

control (both outcome and behavior) on the quality of project artifacts produced by virtual teams engaged in software requirements analysis. Project monitoring provides opportunities for both forms of formal control previously described through tracking, interpretation and transmission of status information (Crisp, 2003). In this study, we define *user control* to include not only monitoring the project plan (a form of behavioral control) but also the evaluation of the formal artifacts produced (a form of outcome control) during the requirements analysis process. Monitoring of costs is excluded as requirements analysis is often part of a large IS outsourcing project. Though cost monitoring is vital, it does not assume much significance when considered for only one phase of the project and hence is excluded. Based on the control theory and literature review of virtual teams, our second hypothesis is as follows:

H2: *Developer teams that are closely monitored by their users in a virtual team mode will produce higher quality of artifacts as compared to developer teams that are not closely monitored by their users.*

RESEARCH DESIGN

To test both the aforementioned hypotheses, we conducted two overlapping quasi experiments involving students at MU and MDI in controlled settings. Such experimental settings have been actively used in distributed software engineering laboratories and business schools to conduct virtual team exercises in their courses (Powell et al., 2005). A controlled experimental approach provides three benefits. Firstly, it makes available several teams that work in parallel, thereby generating rich data for drawing conclusions. Secondly, it permits researchers to experiment with newer approaches, which may not yet have been explored by the industry. Finally, it equips and trains software engineering students to understand and to handle the challenges of working in global software teams (Favela & Pena-Mora, 2001). A survey on virtual team research by Powell et al. (2005) cited 28 academic experiments and only 13 case study research papers. Our experimental setup is illustrated in Figure 2 and described in greater detail next.

Experiment 1—Testing H1: The Impact of Media Richness on Project Quality

For hypothesis 1 (H1), we compared the quality of projects produced by collocated teams with those that were produced by virtual teams. The collocated teams were students of the postgraduate program in management (equivalent to an MBA) who were attending a core course in management information systems (MIS) at MDI. One hundred and twenty-seven students were divided into two roughly equal sections, section *A* and section *B*. Students from section *A* were grouped into 10 teams of 5 or 6 students each. Each team played the role of users for the collocated project. Figure 2(a) shows one such team, referred to as MDI team A1. Students from section *B* were also grouped into 10 teams of 5 or 6 students each. Each of these teams formed developer teams for the collocated project. Figure 2(a) shows one such team, referred to as MDI team B1. Each MDI *A* team was then paired with one of the MDI *B* teams, as shown in Figure 2(a). Thus MDI team A1 served as users to MDI team B1, the developers in the collocated project. Similarly, MDI team A2 was the user for MDI team B2, and so on.

Setting for the Virtual Teams

MU students, enrolled in a graduate elective course in IT project management, assumed the role of virtual users. Twenty-eight students divided into 10 teams (each with a team size of 2-3 members), referred to as *MU Teams*. Figure 2(a) shows one of these MU teams, team 1. Each MU

(a) Experiment 1: Collocated vs. Virtual Teams

(b) Experiment 2: Virtual Teams Under Tight Project Monitoring vs. Loose Project Monitoring

team was paired with one of the MDI B teams. Thus MDI B teams became the off-shore development teams for the associated MU user teams. These teams consisting of users and developers worked in virtual team mode. In summary, each MDI team *B* was involved in the following two projects: (i) collocated project with MDI user team *A* and (ii) virtual off-shored project with MU user team.

In both projects, the MDI *B* teams were required to submit a project plan at the beginning of the project, detailing various activities and timelines. The final delivery date was predetermined by the instructors based on the course schedule. Project

monitoring was voluntary between MDI B and MDI A user teams, so as to minimize the impact of any other variables on the experiment. The MDI B development teams communicated with their corresponding user teams at MU through online means such as e-mail, instant messaging, and voice chats such as Skype and with their MDI A user teams through face-to-face meetings while having face-to-face interactions with their collocated MDI *A* teams. It must be noted that each developer teams (i.e., MDI *B* teams) had 5 or 6 members, thus controlling for the effects of team sizes on the quality of the project.

Experiment —Testing H2: The Impact of Project Monitoring on Project Quality

To test H2, we compared the quality of two sets of virtual teams, one in which the users imposed project monitoring (referred to as *tight* monitoring), and the other one in which user project monitoring was voluntary (referred to as *loose* monitoring). For this purpose, we used a portion of the data collected as part of experiment 1. Recall that in experiment 1 we already had a set of virtual teams, namely the teams formed by MU user team and the MDI *B* developer teams, operating in voluntary project monitoring mode. We then formed another set of virtual teams by pairing each MU user team with MDI *A* teams. However, in this experiment MDI *A* teams performed the role of developers for their corresponding MU user teams (compared to the role of users they played in experiment 1). MU user teams were required to tightly monitor their projects with MDI *A* teams. This is illustrated in Figure 2(b), where MU team 1 was the user for MDI team A1, under tight project monitoring, and was also the user for MDI team B1, under loose project monitoring (part of experiment 1). Similarly, the MU team 2 was the user for MDI team A2 and B2, and so on. Once again, each of the developer teams (i.e., MDI *A* and *B* teams) had 5 or 6 members, thus controlling for effects of team size on success of the project.

Tight and loose control was implemented as follows: In the case of virtual teams operating under imposed tight project monitoring (MU and MDI *A* teams), the developers were told to submit weekly project reports to their respective user teams. The user teams were required to review and ask for changes/actions as required, thus implementing behavioral control. In addition, MDI teams were required to conduct requirements analysis in iterative model, returning a set of intermediate artifacts which would also be reviewed and commented on by their users, thus implementing outcome control. This formed the control group in our experiment. In contrast, teams operating under voluntary user project monitoring did not have to submit regular project status reports nor any intermediate artifacts to their users. They received requirements specifications from their users, asked for clarifications where necessary, and submitted the final artifacts at the end of the project. Any communication between these teams and their users was strictly on a need-be basis. This formed the experimental group in our research design. MU teams were graded partly on the communication plans and weekly project status reports they developed for monitoring their MDI *A* teams. This ensured that MU team users spent more time and effort in monitoring their associated MDI *A* teams than MDI *B* teams. This design resulted in the two overlapping experiments 1 and 2 described previously. Table 1 illustrates the roles of MDI and MU teams in these experiments.

All student teams were formed in such a way that the technical background and average work experience of group members were almost the same across groups, thereby controlling team member heterogeneity. Table 2 provides ANOVA results comparing means of various parameters across teams. Results suggest no significant differences in the means of various parameters across teams confirming their homogeneity. Students

Table 1. Experimental set-up

	MU Teams	MDI *A* Teams	MDI *B* Teams	Treatment	Hypothesis Tested
Experiment 1	Users	Users	Developers	MU Users <-> MDI *B* Developers, Virtual Teams MDI *A* Users <-> MDI *B* Developers, Collocated Teams	H1
Experiment 2	Users	Developers	Developers	MU Users <-> MDI *A* Developers, Virtual and tightly controlled Teams MU Users <-> MDI *B* Developers, Virtual and loosely controlled Teams	H2

Table 2. ANOVA comparing means of variables across teams

Variable	*F*	Significance
Work Experience	0.601	0.795
Experience in Programming	1.356	0.213
Experience in Participating in Virtual Teams	0.803	0.614
Experience in Software Project Management	0.973	0.465
Experience in Systems Analysis and Design	0.543	0.841

had sufficient stake in the virtual team project as up to 30% of the course grade was assigned to the project.

Our research design adopts the quasi experiment approach where the participants are allotted to teams, based on certain criterion, as explained previously, and not randomly. Hence the limitations of quasi experimentation as explained in Campbell and Stanley (1966) applies to our research setting as well.

Tasks

Virtual Team Exercise

The virtual team interactions (in both experiments) were broken down into two phases: (1) *socialization*, which permitted the teams to develop relationships and negotiate communication terms and requirements; and (2) *project execution*, which allowed requirements gathering, clarifications, and exchange of analysis artifacts.

Phase 1: Socialization

It is an increasingly common practice in virtual teams to engage in formal socialization before embarking on virtual projects in order to understand each others' work styles and expectations, negotiate communications strategies and protocols, and build trust for sustained relationships (Jarvenpaa & Leidner, 1999). In our experiment, this was not feasible due to resource and other restrictions, not unlike those faced by organizations new to off-shoring as well as those involved in small, preliminary initiatives. Furthermore, our objective was to draw benchmark conclusions regarding effects of user project monitoring on teams engaged in a fully virtual team environment. Therefore we encouraged the MU and MDI teams to communicate and socialize with each other on-line before initiating actual work on the project. The virtual teams—MU, MDI *A*, and MDI *B*—socialized with each other using on-line media such as e-mail, Internet chat,

bulletin boards, and e-groups for a period of 2 weeks. Project details were withheld from all teams till conclusion of the socialization phase in order to ensure that communication was more personalized and oriented towards relationship and trust building (Sarkar & Sahay, 2002) rather than requirements exchange.

Phase 2: Project Execution

Subsequent to socialization, the projects were initiated, and team roles were detailed. Marquette University has a service learning office that obtains information systems projects from nonprofit organizations and small businesses in and around Milwaukee. Such real-life projects were given to MU users. Examples of these projects include a donation management system for a nonprofit organization, a volunteer management system, an alumni website, a tracking system for battered and abused women, and a book inventory management system.

The MDI teams elicited project requirements from MU teams through various on-line media, as described previously. SSAD methodology was used in the experiment. The gathered requirements were structured using process modeling tools such as context analysis diagram (CAD), data flow diagrams (DFDs) and process specifications. MDI teams also modeled the data and associated relationships using entity relationship diagrams (ERDs). MDI teams also created screen-based

prototypes as part of the requirements analysis exercise. These artifacts were submitted by the MDI teams to MU user teams as part of the deliverables.

In addition, the MDI A development teams that experienced tightly monitored projects submitted the following additional artifacts to the users:

a. A weekly status report of the project, explaining reasons for delays and plans for overcoming any slippages.
b. Any modifications to the project plan.
c. A draft (intermediate) version of all the above artifacts, midway through the project Based on their requirements, users provided feedback and corrections, which were incorporated by the developers into the final version.

Details of all these deliverables submitted by the different teams for this virtual team exercise are shown in Table 3. The table also shows several artifacts/reports that the MU teams had to submit to the course instructors.

Collocated Exercise

For the collocated team exercises, each MDI *A* team had at least one member who had prior work experience of 2 to 3 years. These individuals were asked to select an information system project they had encountered at work, to ensure realism and familiarity with system features. Each collocated team developed requirements analysis artifacts for these projects. The instructors had discussions with each group and scoped the projects such that the project complexity was almost the same as that of the virtual teams. The MDI *B* teams were asked to submit to MDI team *A* artifacts identical to those submitted to MU teams during the virtual team project (see Table 1). The entire project duration for both virtual and collocated projects was 8 weeks.

OUTCOME MEASURES

Quality of Projects

Quality of MU-MDI projects were determined through (i) expert evaluation of project artifacts produced by developer teams and (ii) user perceptions about the project deliverable quality. Quality of project artifacts was measured on several dimensions—namely, correctness of the artifacts (e.g., whether the data flow diagrams were drawn correctly, whether or not they satisfied user requirements), adherence of the artifacts to user requirements, and consistency of the artifacts with each other.

i. Completeness and Adherence of the Artifacts to User Requirements

Completeness and adherences were analyzed by an external expert who was not part of the MU-MDI teams. This expert had 2 to 3 years of experience in software projects and had taken courses in SSAD. The expert evaluated the completeness and adherence of each of the following artifacts:

1. Context analysis diagram
2. Data flow diagrams (DFDs)
3. Process specifications
4. Entity-relationship diagrams (ERDs)
5. Screen shots of the proposed system

The expert analyzed and scored the above artifacts for each project on a 7-point Likert-type scale. Though the expert had only 2 to 3 years of experience, by following a standard evaluation procedure such as the one outlined previously, this individual was able to arrive at an objective assessment of project quality. This evaluation was validated for consistency and accuracy by a second expert who had more than 20 years of SSAD industry experience, thus reducing possible

biases in the evaluation process. The average of these scores across all artifacts for each project was taken as a measure of completeness and adherence of project artifacts to user requirements. By making the team assignments to the projects blind to the expert, we minimized subjective bias of the expert during the assessment.

ii. Consistency of the Artifacts

The expert also analyzed the consistency of the screen prototypes submitted by development teams with the DFDs and ERDs submitted. Using a 7-point Likert-type scale, the expert analyzed and scored for each project the consistency across

1. Screen prototypes and DFDs
2. Screen prototypes and ERDs

Using the same evaluation and validation procedure described in (i), an average score measuring the consistency of the project artifacts was generated.

iii. User-perceived quality

User perceptions about the quality of artifacts submitted by the developer teams were also collected through a survey questionnaire as the third measure of team performance. A 7-point Likert-type scale was used to elicit response from the user team members. Items adapted from Edwards and Sridhar (2005) are detailed in Appendix I. Scores given by all the users to a particular development team were averaged and were treated as measure of user-perceived quality. Therefore, there was one rating/score per user teams. Based on measures of quality already mentioned, hypothesis H1, which was constructed in the previous section, can be refined and are presented in Table 4.

By specifying the two dimensions of completeness and adherence as well as consistency, any errors in the assessment of the quality of the projects was thought to be minimized.

Table 4. Detailed hypotheses based on different measures

Research Question	Hypotheses
Quality of Projects of Virtual Teams vs. Collocated Teams	**H1a:** Adherence and completeness of the requirements analysis artifacts produced by the collocated teams using face-to-face communication will be better than those produced by the virtual teams using computer-mediated communication. **H1b:** Consistency of the screen shots and requirements analysis artifacts produced by the collocated teams using face-to-face communication will be better than those produced by the virtual teams using computer-mediated communication. **H1c:** The users will perceive the quality of project artifacts produced by collocated teams using face-to-face communication to be better than those produced by the virtual teams using computer-mediated communication.
Impact of User Project Monitoring on of the Quality of Projects	**H2a:** Quality of project artifacts (as defined by the three measures of completeness & adherence, consistency, and user perception) produced by the developer teams that are closely monitored by their associated users in a virtual team mode will be better than those produce by the developer teams that were not closely monitored by their users.. **H2b:** Quality of project artifacts (as defined by the three measures of adherence & completeness, consistency, and user perception) produced by of the developers that perceived higher levels of project monitoring by their users will be better than those produced by the developer teams that perceived lower levels.

User Project Monitoring

We also measured perceived project-monitoring practices of all users and developers involved in both tight and loosely monitored projects. Responses were elicited on a 7-point Likert-type scale at the end of the project. Items are shown in Appendix I. In order to capture the responses for perceived quality and user project monitoring based on the roles they played (user/developer) and the team (collocated/ virtual) with which they did the projects, different versions of the survey was prepared and administered to students at MDI and at MU. The various versions included same items for each construct but were worded differently, depending on the roles the participants played. Based on the experimental measure of perceived project management practice, hypothesis H2 can be further articulated as in Table 4.

ANALYSIS, RESULTS, AND DISCUSSIONS

A principal component analysis was performed on the items constructed for the previously mentioned measures with Varimax rotation and Kaiser normalization; the results are given in Table 5. Reliability of all these measures of (i) completeness and adherence of artifacts, (ii) consistency of project artifacts, (iii) user-perceived quality, and (iv) perceived user project monitoring practices are given in Table 6. Cronbach's alpha values of 0.70 and higher indicate construct reliability.

Performance of Collocated vs. Virtual Teams

To test hypothesis **H1,** a one-way ANOVA test was performed on the three measures of project quality, as were previously described, between virtual and collocated teams that participated in Experiment 1. Note that in this case the project artifacts are produced by the same developer teams, and the project complexity of both the virtual and collocated projects were moderated by the instructors to be almost the same. However, due to constraints in conducting the experiment, the user teams could not be the same. User project monitoring was kept loose for both virtual and collocated projects. ANOVA results are represented in Table 7.

Results indicate that all the variations (H1a, H1b and H1c) of hypothesis H1 can be rejected. Although two of the mean quality measures of collocated teams are better than that of virtual teams, they are not significantly different. This is contrary to expectations that the quality of projects that are produced by collocated teams and that benefit from higher social presence, media-rich face-to-face communications is no better than that produced by virtual teams that use lean media. This potentially suggests that the requirements analysis phase of software projects may be successfully off-shored in full and conducted in virtual team mode without significantly affecting the quality of projects.

Effect of User Project Monitoring

To test H2a, we compared mean values of the quality measures between the tightly monitored control group and the loosely monitored experimental group. Results presented in Table 8 indicate that the completeness and adherence of project artifacts produced by the control group were significantly superior to those produced by the experimental group, suggesting that close project monitoring by users had a positive impact on this measure of project quality. However, neither the consistency of project artifacts nor the user-perceived quality differed significantly across the two sets of teams. As expected, participants in the control group perceived that their projects were indeed closely monitored, compared to those in the experimental group.

Table 5. Principal component analysis of various constructs indicating factor loadings of survey items

Item No	Adherence and Completeness of Project Artifacts	Consistency of Project Artifacts	User-Perceived Quality	Perceived User Project Monitoring
1	.792	.892	.882	0.663
2	.869	.885	.935	0.845
3	.699		.871	0.700

Perceived User Project Monitoring	**0.215 (0.021)**	0.042(0.643)	**0.281(0.002)**

Table 11. Summary of results of teams engaged in software requirements analysis

	Collocated Teams vs. Virtual Teams in Off-Shore Mode	User Project Monitoring of Off-Shored Projects in Virtual Team Mode	
		Control/ Experimental	Perceived
Completeness and Adherence of Project Artifacts	-	TPM > LPM	HUPM > LUPM
Consistency of Project Artifacts	-	-	-
User-Perceived Quality	-	-	HUPM > LUPM

Note. TPM = tight project monitoring; LPM = loose project monitoring;

HUPM = high user project monitoring; LUPM = low user project monitoring

Mean values of the perceived monitoring of the virtual team were then computed. We categorized those responses that were above the mean value as *high perceived user project monitoring* and those that were below as *low perceived project monitoring.* The performance measured on all the three dimensions were then compared across these two sets, using a one-way ANOVA test. The results as presented in Table 9 indicate that artifacts produced by developers who perceived higher levels of user project monitoring practices were better on the two dimensions of completeness and adequacy, as well as user-perceived quality, as compared to those who perceived low user monitoring.

A pair-wise correlation was carried out between perceived project monitoring and the three measures of project quality, which further confirmed these findings. (These correlations in presented in Table 10.)

It is important to understand the difference between imposed project monitoring as defined in the control and experimental groups and perceived project monitoring. Though ANOVA results in Table 8 indicate that the mean values of perceived project monitoring of the control group were significantly higher compared to that of the experimental group, the mean of the experimental group was significantly higher (4.35) in the Likert scale. We also observed that in the

experimental group, some of the MU teams, along with their corresponding MDI *B* teams, had voluntarily adopted closer project monitoring practices. These MDI *B* teams had been submitting their project plans and intermediate artifacts to their MU user teams, thus resulting in higher levels of perceived project monitoring. From an experimental perspective, there was a positive impact of both imposed project monitoring as well as perceived project monitoring on adherence of artifacts. At the same time, there was a positive impact of perceived project monitoring on user-perceived quality, possibly because of the close working relationship adopted by the users and developers. This could have occurred through informal behavioral control mechanisms such as clan control deployed by the MDI *B* teams and their corresponding MU user teams. However this issue warrants further analysis. Table 11 gives a summary of the results.

CONCLUSION

In this article we have described an exploratory study that examines two aspects of virtual teams in off-shored software development projects, specifically in the requirements analysis phase. First, we examine whether the quality of projects produced by virtual teams engaged in pure off-shore mode is at par with that of traditional, collocated teams. Secondly, within the ambit of virtual teams, we examine whether user monitoring of the projects has an impact on the quality of projects.

Contributions of the Study

Our study is one of the few to apply social presence, media richness and control theories to develop and test a research model of the antecedents of quality of software requirements analysis projects conducted in off-shore virtual team environment. As client and vendor organizations are increasingly considering off-shoring parts of requirements analysis phases, our early conclusions might enable organizations to design communications and governance structures that might facilitate virtual requirements analysis. Considering the rapid leaps in technological infrastructure globally, technology will become a moot point in this facilitation. From an academic perspective, the introduction of these two theories in an offshore context lays the foundations for extended empirical research.

We find that there is no significant difference in the quality of projects produced by virtual teams that used lean media and that by collocated teams that used rich face-to-face communications. This is similar to findings reported in Burke and Chidambaram (1999) where, despite the persistently lower social presence of leaner media, distributed groups performed better than face-to-face counterparts. Possibly, a more task-focused approach and limited social interaction may have enabled teams to generate higher quality outputs. This could be a potentially important result because it implies that off-shoring, which was so far restricted to the lower level phases of system development (such as low-level design, coding, and testing) could successfully be extended to the requirements analysis phase as well. A key benefit, of course, is that software firms could save significantly on costs by locating their business and systems analysts in off-shore locations and facilitating interactions with users through virtual channels. While this may currently be challenging, our study highlights the need for future research in improving these virtual interactions between users and off-shored development teams.

The effect of user project monitoring (control/experimental) on the quality of off-shored requirements analysis projects is ambiguous. Formal behavioral and outcome control implemented through the experimental set up had a positive effect on one measure of quality. It did not have any effect on the other two measures. Piccoli and Ives (2003) pointed out that behavior control mechanisms, which are typically used in

traditional teams, have a significantly negative impact on trust in virtual teams. It was reported that behavior control mechanisms increase vigilance and create instances in which individuals perceive team members failing to uphold their obligations. On the other hand, the perceived user project monitoring had significant positive effect on two dimensions of quality (one assessed and one perceived).

We also infer that, even when project management practices were not enforced, teams might have adopted these practices to improve their performance through clan control. This observation, though anecdotal based on class observations and our analysis of perceived user project monitoring, has important implications. It provides clues that, apart from forced formal controls, informal controls existed between the users and developers when they share common goals (Choudhury & Sabherwal, 2003).

Our findings have important implications for the industry as well. Companies engaged in off-shore software development have produced strong processes around their global delivery model. However, whether the same process and project monitoring discipline will lead to success of projects conducted in pure off-shore mode in virtual team setting during the early stages of system development work has not been explored. Our research indicates that teams engaged in virtual teamwork might develop their own informal control mechanisms and even bypass the forced control mechanisms necessitated by the standard operating procedures while doing their projects. The firms (viz. both the clients and software developers) engaged in off-shore work should develop a conducive climate for team members to develop these informal controls that seem to affect project quality. Apart from this, our study fills the gap in the literature in the area of analysis of quality of projects implemented by virtual teams engaged in off-shore system requirements analysis. Further research is needed to confirm our exploratory findings.

Limitations of the Study: Opportunities for Future Research

Use of Experiments

Literature in the area of virtual teams has mainly followed three research methodologies—case studies, industry surveys, and experiments. Experimental methods make possible the careful observation and precise manipulation of independent variables, allowing for greater certainty with respect to cause and effect, while holding constant other variables that would normally be associated with it in field settings (Damian et al., 2000). They also encourage the investigator to try out novel conditions and strategies in a safe and exploratory environment before implementing them in the real world (McGrath, 1984). The industry is yet to adopt off-shoring of the requirements analysis phase. This precludes the use of case study or industry survey for this research. Hence, we used experiments where we can explore this emerging phenomena.

In our experiment, MDI *A* teams played the roles of both users (in Experiment 1) and developers (in Experiment 2). The dual roles could have created conflicts that might have affected (positively or negatively) their project quality. The same is true with MDI *B* teams, who performed the roles of consultants for both MU teams as well as MDI *A* teams. MU teams also had to manage two projects: one with tight monitoring (with MDI *A* teams) and the other with loose monitoring (with MDI *B* teams). To remove the confounding effects of dual roles played by the teams, it is recommended that a true controlled factorial experiment be conducted to verify our findings.

Use of Students as Surrogates

There are criticisms for the use of students in academic experiments as surrogates. However, MBA students have been used as surrogate us-

ers in a range experiments conducted (see, e.g., Briggs, Balthazard, & Dennis, 1996; Hazari, 2005). Even in requirement negotiation phase, students with work experience were taken as users for developing a small system (Damian et al., 2000). Remus (1986) argued that graduate students could be used as surrogates for managers in experiments on business decision making. Students often represent a typical working professional and organizational member due to the variety of backgrounds and goals (Dipboye & Flanagan, 1979). Studies in industrial organization psychology and organization behavior have found that results obtained from students were similar to those from managers (see, e.g., Locke, 1986). Despite the fact that users and developers in our experiments had 2 to 4 years of work experience, limitations of using students as surrogates are still applicable in our study. As the industry evolves, we suggest the extension of these experiments to business settings.

Complexity of Projects

Requirements analysis is intensive, and hence it is not possible to completely replicate in student experiments. However, our objective was to study the research questions on comparable, relatively well-defined small projects in which complexity of requirements analysis is not high.

Though the experiments were carefully designed, the projects were limited in scope and size compared to large-scale industrial projects. Furthermore, no formal measures of complexity were used in the study so that we could compare the projects used in the experiments with real-world industrial projects. Further research is needed to assess the impact of these findings on large-scale industrial projects with complex requirements.

Future Research Directions

One way of dealing with the lack of realism in laboratory experiments is to use multiple methods (McGrath, 1984) so that strengths of some compensate weaknesses of others. To truly test the predictive ability of the research results, the studies must also involve a multiplicity of research methodologies in order to avoid biases due to the methods used (Jarvenpaa, Knoll, & Leidner, 1988). Simulated laboratory negotiations could be complemented by field studies or validations (whose strength is realism), if the lack of realism is an issue. In our research, internal validity of results was established through conducting experiments in a controlled environment. We expect to conduct external validity through industry survey.

Finally, while we have explored one variable of project control, quality of projects can be affected by other variables such as team motivation, trust, cohesion, coordination, and communication (Chidambaram, 1996; Jarvenpaa et al., 1998; Lurey & Raisinghani, 2001). Hence, a comprehensive model that defines all factors affecting the quality of off-shored software requirements analysis projects must be developed. Further research is required to determine how informal controls develop between the virtual team members. One cause may be the amount of initial online socialization, when the teams familiarize with each other before the start of the project, for the design of such experiments in the future. Since it may not always be feasible to make experimental and control groups adhere to experimental requirements in a classroom setting, a flexible approach is needed in experimental design.

Chapter 5.21
A Case Study on the Selection and Evaluation of Software for an Internet Organisation

Pieter van Staaden
Media24 Ltd., South Africa

ABSTRACT

The author conducted research to determine whether IT managers, IT auditors, users, management, etc. (all decision-makers) use a certain evaluation and selection process to acquire software to meet business objectives and the requirement of users. An argument was used that the more thorough the software evaluation and selection process, the more likely it would be that the organisation will chose software that meets these targets. The main objective of the research was therefore to determine whether Media24 uses evaluation methods and obtains the desired results. The results confirmed that Media24 uses suggested protocol as noted in the theory for software acquisition correctly during most stages.

INTRODUCTION

There is a wide variety of methods that can be used for selection of software in various fields of business (e.g., manufacturing, service providers, insurance, wholesale, retail, etc.). This software is used for a variety of purposes in businesses. However, selecting the software that meets organisational requirements and business objectives could prove to be a challenge considering the number of vendors and software available.

Choosing the right software for your company can be bewildering. There are thousands of titles to choose from, and programs and their functionality differ frequently. (Buyerzone.com, 2002)

A hurried, uneducated choice could lead to various problems in the company. Some of these are

failing to support an important business process, supporting a process inaccurately or inefficiently, unhappy customers, disgruntled employees, loss of sales, and poor financial performance.

Competition in the Western Cape requires good performance in all aspects of the electronic publication industry. Bad judgments or decisions in terms of software acquisition could cause a company some losses and complications in their daily operations. Choosing the right software is therefore important and can be achieved by using pre-determined evaluation and selection guidelines.

EVALUATION AND SELECTION OF A COMMERCIAL SOFTWARE SYSTEM

Decisions Made Prior to the Software Evaluation Process

As mentioned by Capterra's software selection methodology (2002), certain procedures should be completed before the actual evaluation is conducted. They suggest that the company should start off by interviewing some staff members, addressing corporate vision, analysing existing systems limitations and features, and looking at present policies and procedures. The company should also determine whether new software will help the business and if it will increase competitive advantage.

They argue that when the decision is made to purchase software, a project plan should be developed to evaluate and list the evaluation criteria that will be used during the process. A project team should also be selected to carry out the evaluation. This team must include representatives from all levels the organisation. If the proposed software incorporates financial aspects, the audit team should also be included.

Determine Requirements for the New Software Package

The purpose would be to create a comprehensive and prioritised list of requirements to help evaluate the software. Base Consulting Group (BCG) (2000) state that the requirements definition should consist of several processes (such as managerial requirements (budget/timing, reporting requirements), functional requirements (stated business needs, technical requirements), and IS standards (data flow diagrams, system interfaces, and hardware and network requirements with emphasis on capacity).

They also note that some companies do not develop detailed requirements and as a result may be dissatisfied with the final outcome. Romney and Steinbart (2000) support this statement and suggest that one or any combination of four strategies (listed below) should be used to determine requirements for the new software:

- Survey end-users to determine what their requirements for software is by using questionnaires, personal interviews, and focus group discussions.
- Analyse the existing system and eliminating requirements that have already been defined.
- Examine how the existing software is used, helping to determine the shortcomings of the system, and identifing any new requirements needed by users.
- Pilot demonstrations of applications/software systems could be utilised when there is a problem in identifying requirements.

Document the Requirements

The systems requirement document or software requirement specifications should be the starting point for measuring performance of the final

Table 1. Capterra's methodology (2002)

COLUMN NAME	DESCRIPTION
Functional department, business processes, and process.	This creates the requirements hierarchy and ensures that all processes are covered (e.g., would be creditors department, cheque printing, approving cheques for printing, etc.)
Requirement type	This identifies the requirement as functional, technical, vendor related, or contractual.
Requirement description	This details the requirement itself and should be as descriptive as possible.
Priority and ranking	*This could be used during the evaluation.*
Objective addressed	This could be used to match the requirement to a business objective.
Comments	This can be used for any additional comments or justifications.

system (Shelly, Cashman, & Rosenblatt, 1998). Users must understand the document to be able to improve the final version. The content of this requirements document will depend on the type of company and the complexity of the new system. BCG (2000) states that the requirements document is the cornerstone to evaluate the software and should be used to identify requirements. Capterra (2002) argues that there is a methodological approach available to help with requirement analysis. This is listed in Table 1.

Selecting Vendors

Michell and Fitzgerald (1997) argue that the range of services offered by IT vendors is large and growing rapidly. They also note that while searching for the "best" vendor, it should be borne in mind that the process of selection and evaluation of a vendor is important. Base Consulting Group (2000) suggests that the project team's first step should be to identify the vendors who offer software solutions that could be used. It could be a high-risk approach not to properly evaluate vendor companies. The sources used to compile the list of vendors should be recent and reliable. These sources include software user groups, databases, industry groups, research firms, consulting firms, trade shows, seminars and conferences, current users, personal recommendations and contacts, competitors, IT, and business magazines, as well as Web sites.

PRELIMINARY EVALUATIO OF VENDOR COMPANIES AND THEIR PRODUCT

Ward (2001) argues that selecting software from a vendor should be a simplified process. She suggests that vendors be invited to participate in a software demonstration because it reduces time

spent on evaluations. Companies could work toward solving the business problems earlier resulting in faster return on investment. Base Consulting Group (2000) states that inviting too many vendors to participate increases the costs and timelines of the project. Team members may also lose focus after seeing too many product demonstrations. In order to shorten the time of the process send the request for proposal (RFP) to a shortlist of 5 vendors, and do a preliminary evaluation of the vendors.

The evaluation team should look at things like:

- The standard functionality and key features of the product
- Technology requirements (hardware, additional software, database, operating system, network, development tools)
- Product considerations such as viability, stability, and cost
- Products targeting different, smaller, or much larger companies or industries should be eliminated
- Eliminate products that are in development or a recent release.
- Licensing and support costs are examined and products that are over/under priced should be eliminated (licensing escalation must be considered).
- Develop a request for proposal (RFP).

According to Levinson (2001), an RFP guides buyers through a process of tying business needs to technical requirements (e.g., as the particular platform on which the software needs to run on or the systems with which the solution must interface). It clarifies why they are undertaking a particular project. Schwalbe (2000) suggests that the RFP should include: statement of the purpose, background information on the company issuing the RFP, basic requirements for the products and/or services being proposed, HW and SW environment, description of the RFP process, statement of work (SOW), and other information added (as appendices). The SOW should describe the work required for the procurement of the software and help vendors determines if they can deliver required goods and services.

EVALUATION PREPARATIONS

Gather and Organise Resources

Lars and Matthew (2002) note that a reason for not detecting errors early is because the inadequacy of the test used by the team. The quality assurance of the evaluation project is jeopardised. To prevent this, the test team should ensure they have the resources to detect errors present. The adequacy of resources gathered should be determined at the same time potential vendors are identified. Resources could be added or updated to support the evaluation.

Determine the Evaluation Approach/ Technique

Restrictions on Evaluating Software

Dean and Vigder (2002) state that, while purchasing software, there are some unique constraints on the ability to conduct effective testing. In general, it should be assumed that there is no access to the source code. If the source code is available it could not be modifiable and it means that the executable part cannot be tested internally and this rules out white box testing. Documentation should consist of user manuals and advertising materials and is not directed at evaluating the software (e.g., it does not describe the behaviour of the software in response to abnormal input).

Evaluation Techniques and Methods

Romney et al. (2000) suggest benchmarking while processing times of software are measured. Software with the lowest time is normally judged the most efficient. Oberndorf, Brownsword, Morris, and Sledge (1997) engaged scenario-based testing methods to represent typical procedures for the software to be programmed and not the software undergoing tests. Test procedures are developed based on scenarios and each is evaluated against a set of criteria. In this case, the initial scenarios are established using preliminary operational definitions. The results of this will serve as confirmation that the software performed satisfactory against set parameters.

Romney et al. (2000) suggest a point scoring technique to evaluate the vendor. Each criterion is assigned a weight based on its relevancy. The vendor is assigned a score based on how their proposal measures up to each criterion. The vendor with the highest score is then judged the "best." They argue that "requirements" costing is an alternative where the total cost of the proposed software is calculated. This provides an equitable basis for comparison.

Another method suggested by Voas, Charron, and McGraw (1997) is the use of fault injection techniques. This is effective when buyers do not have access to the source code. The method consists of inserting erroneous values into the control stream and checking the results. This technique is an example of evaluating (for discovery) to determine unknown or unexpected reactions of the product under evaluation.

Beizer (1995) suggests *black box testing* to allow a tester to treat each module as a unit that can be defined by its inputs and outputs (the interfaces to the module) without considering the route by which an input is transformed into a particular output. Visibility into the internal workings of the code module is not necessary and source code not required. An example of black box testing is boundary value analysis where inputs are supplied to the software to be tested (these values represent valid, invalid and parameters). The outputs are measured and accepted if they fall within expected limitations. This type of testing is used during acceptance testing and is the basis of validation testing, confirming the software performed the required functions.

Other techniques (Hausen & Welzel, 1993) include analysing product documentation, presentations, using trial versions, scheduling demonstrations, or attending training of the software. They suggest that one or more of the previously mentioned techniques could be used to supplement the evaluation of software. The project team should use discretion when selecting evaluation techniques as a company's approach and resources may vary.

Evaluation Considerations

Hausen and Welzel (1993) mention that some of the following principles should be taken into consideration:

- Repeat testing of the same product using the same product specifications with the same testing techniques must deliver similar results (Repeatability).
- Repeat evaluation of the same product to the same product specifications by different parties must deliver similar results (Reproducibility).
- The evaluation is free from bias while achieving any particular result (Impartiality).
- The result is obtained with minimum subjective judgment (Objectivity).

Product Evaluation

Hausen and Welzel (1993) state that the evaluation process should consider software features (compared to the requirements document), product

information (acquired from the RFP, product demonstration, information gathered from investigating vendors, etc.), evaluation techniques, and process information (e.g., results obtained from the testing techniques).

Capterra's methodology (2002) states that all software should be evaluated to determine if it meets requirements (functional and technical). Any additional (functional/technical) requirements should be listed and re-calculated. Missing requirements should be listed and cost incurred to add these features should be calculated. Price and maintenance levels of the product have to be evaluated by totalling cost and maintenance levels. Firms must consider initial product costs (also long-term costs (such as training, implementation costs, maintenance, and upgrading costs). Project teams should keep in mind that software is expensive and by picking the wrong one could have costly repercussions.

Final Evaluation of Vendor Companies Providing Possible Software Solution

Pollard (1999) suggested the evaluation of the support and maintenance staff of the vendor. He notes that it is necessary to know the number of people in customer support. The response time can be measured by calling the customer support department. The availability and quality of the implementation support also ought to be evaluated. The new software could have bugs and other problems (e.g., not meeting the required deadline). The vendor must provide training because users want to use the system properly.

He suggests following up on customer references, reviewing case studies and finding out how many companies are using the software. The financial stability of a vendor is an aspect to consider. Pollard (1999) supports this by suggesting the examination of the financial history and the long-term financial stability of the vendor.

Selecting the Software System

The total score of the software should be recorded on a scoring sheet when a point scoring technique is used. All the software must be listed from the highest to the lowest. The software with the highest score would represent the best fit for the organisation. Although the software with the highest score might represent the best solution for the company, there may be reasons unrelated to the requirements that could prevent an organisation from selecting software. Inconsistencies should be identified (also extremes in scoring that may influence it—or a competency or deficiency within a single business function). Criteria such as a business partnership, potential future business, or other intangibles, must also be included.

Notify the Vendor

Once the steering committee has approved the vendor, then the vendor should be notified and a contract drawn up. The diagram (on the next page) was derived from the theory to illustrate steps used during the evaluation and selection process.

PROBLEM STATEMENT

Brown and Wallnau (1996) state that organizations should recognize the importance of technology "refreshment":

- To improve the quality of their products and services
- To be competitive with organizations providing similar products and services
- To remain attractive to investors

Any organization should invest in appropriate software to stay in business. Careful decision-

making on investment into software is therefore essential. Whether the release of an update, or the availability of new software, should force an organization to initiate an evaluation process that provides timely, balanced information on which decisions can be made.

The problem statement was thus stated as:

…the more thorough the evaluation of software, the greater the chances could be for the organization to select the software that will meet their business objective and the requirements of the users.

RESEARCH METHODOLOGY

Objective

The objective of the study is to determine whether Media24 uses the correct software evaluation and selection guidelines when purchasing software from a vendor as prescribed in the theory and whether these guidelines have obtained results. Based on the theory and the problem statement, the research questions were stated as follows:

- Is the software evaluation process of Media24 thorough enough to select software that fulfils their end-user requirements?
- Does the organisation pick software that meets the business objectives easily?

Limitations of the Study

The researchers had decided to exclude legal procedures and only focussed on the project from a technical viewpoint. Also they were not allowed to use the name of any software used by Media24 as it might discredit the vendor or Media24. The research scope also does not include the processes (e.g., contract negotiation) followed after a decision has been made.

Development of Questionnaire

The researchers compiled a questionnaire consisting of two sections (Section A and B). Section A contained seven sub-sections, covering aspects of evaluation and selection processes. Section B contains the user satisfaction survey. The questionnaire was handed to a Media24 IT manager who reviewed it. He also identified people responsible for evaluating and selecting software in Media24 to be respondents while he completed a questionnaire himself.

Section A was sent out to 15 decision-makers involved in acquiring software in Media24. The objective was to measure whether they used the evaluation techniques as prescribed in the theory. Section B was sent to 50 users of the software. The objective was to determine whether they were satisfied with present software. All questions where derived from the theory described earlier. A 5-point Lickert scale was used in most of the questions (it included questions that required respondents to pick more than one answer). The reason is to evaluate areas where answers from the respondent indicates an in depth approach to the evaluation process. At the end of each section, a section was dedicated to find out in more detail what respondents think.

Analysis of Data

The results of both sections were compared using cross tabulation. The data was captured and analyzed on an excel spreadsheet. Twelve "section A" respondents returned the questionnaires and 74% of the respondents who received section B returned the questionnaire.

Section A: Evaluation Process

Nearly all the respondents agree that the steering committee correctly directs the evaluation pro-

cess (11). This indicates that people realise that there is a structure in place that could oversee the evaluation of software and is in agreement with a similar comment by Capterra (2002).

All the respondents agree that there are sufficient resources available to ensure that the evaluation process runs smoothly. Nine of the respondents indicated that the project team has enough expertise to conduct an evaluation. Three indicated that they disagree with this. There might be a problem that falls outside the scope of this study and needs to be addressed by management. The organisation therefore needs to assemble a project team that is representative of the people working in the organisation (see also Dean & Vigder, 2002). Nine of the respondents indicated that Media24 used the interview method to determine requirements. The same respondents have also used the present system to ensure that they meet the correct requirements (see Figure 4). Six respondents have indicated that they use questionnaires to collect requirements. It seems that project teams in Media24 prefer to use three methods to determine software requirements.

All respondents have indicated that technical requirements are determined beforehand (systems interface). Ten of the respondents are happy that business objectives have been met while determining functional requirements. All agree that managerial requirements should be met when requirements are defined. Nine of the respondents noted that requirements are properly documented. Media24 needs to address this to ensure that people are in agreement otherwise it can become a problem.

Ten of the respondents agree that many sources should be investigated to identify correct software. The same number agrees that Media24 should ensure that software that meets requirements are evaluated. This is done to limit the number of products to be considered. On the other hand, 11 of the respondents agree that the support/maintenance staff provided by the vendor is evaluated on response time while the quality of support is rated high by 10 of the respondents. It seems to the authors that 'old fashioned' values are still important while looking at new IT investments. This is in agreement with the statement made by Capterra (2002) that end-users value help provided by the supplier.

The number of people working for the vendor is not regarded as important by the respondents;

Table 5. Request for proposal

	SA	A	NDA	D	SD
A Request for proposal is sent to Vendors.	10	1	1	0	0
The RFP includes…					
…the purpose of the RFP	1	9	2	0	0

...a statement of work (SOW) that includes the required work needed for the procurement of the new software solution.	1	9	2	0	0
AVERAGE	4	5	2.6	.4	0

as long as their service is not affected by it (quality is rated higher). Eight stated that cost plays a role while maintenance is evaluated. Most of the respondents noted that the vendor should be evaluated on financial stability and customer references. The number of clients and long-term strategy of the vendors were not used when looking how reputable the vendor is. This is something that Media24 and similar organisations need to investigate.

Table 5 displays the data collected on the RFP. Most of the respondents agree that this is complied with by Media24. Many (10) stated that the evaluation processes are properly documented while thought is given to objectivity (11) and impartiality (9). Most (10) of them agree that repeatability is lacking while reproducibility (7) is important and needs careful attention. Impartiality is an aspect that needs to be addressed as a third of the people noted that it is lacking. The averages for the request for proposal can be improved but because there are individual items that management of Media24 needs to pay attention to as stated. The common method used to evaluate the software is the point scoring technique (Figure 2). Trial versions of software have a better chance to be selected if it was analysed previously or used. The other method that Media24 uses to evaluate software is the expertise of their staff in a particular field.

Table 6 shows the evaluation process. The respondents were positive that the final score used to determine how well the software product meets the requirements is a good method. Nine respondents are in agreement that the documentation to do this evaluation is well laid out beforehand. Management needs to convince the three that does not agree to accept the documentation as presented. Objectivity is complied with but repeatability of the evaluation is not highly thought off (and the same for reproducibility). Nine of the respondents noted that the tests were

Table 6. Evaluation of the product

AVERAGE	3	5	2	1.8	.2

impartial. Again, it would be a task for management to convince the remaining three that this is the case before problems are experienced (also supported by Shelly et al., 1998).

Most of the people agree that the final decision to acquire software is based upon the evaluation results. Eleven of the respondents agree that they are happy with the results achieved by Media24. Agreeing meant that they use the methods as prescribed in theory but there are some methods that are not used presently (e.g., benchmarking and black box testing). These should be investigated and used to ensure that the methods presently being used is still considered the best (Beizer, 1995).

Table 7. Results obtained from decision makers

User Satisfaction and Overall Effectiveness of Evaluation Process Used

Nearly all the respondents (11) at Media24 are satisfied with the software that was purchased by Media24. Eight of the respondents have agreed that it falls within the parameters set by the organisation. The respondents that do not agree (4) may be users that were not part of the project team. They should be convinced that the software is of benefit to Media24. Eleven of the respondents agreed that the software meet their requirements. This is supported in their article by Michel and Fitzgerald (1997) who stated that normally most of the users who were part of the process are happy with the software.

This could mean that the individual user requirements agree with Media24's requirements. However, seven of the respondents agree that there is room for improvement This should be investigated in another study as this falls outside the scope

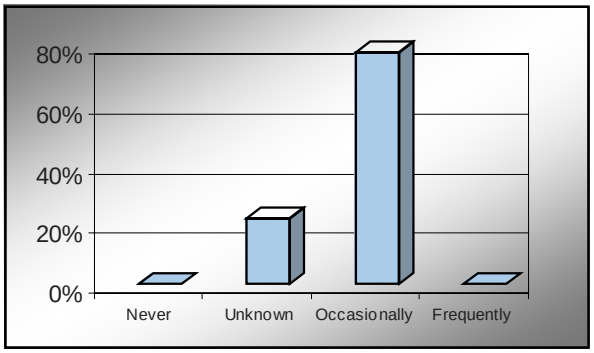
Figure 3. Number of complaints from users



of this study. This does not agree with previous statements made by the respondents. Maybe the present evaluation procedure should be extended to inquire about reasons why the respondents argue that there is room for improvement. This should be included as part of the evaluation.

The respondents (9) complain about the software occasionally to ensure that management pay attention. Seven of the users argue that there is room for improvement. This would require another survey to find out why users complain about the software and if there is room for improvement.

Section B: Assessment

The main objective of section B was to assess whether the users where satisfied with the software acquired by Media24. There are some complaints lodged by the respondents (e.g., the systems response time and redundant processes and procedures included in the current system and that the software does not integrate with other software). The figure on the next page illustrates the percentage respondents who agreed that they use the correct evaluation techniques. The results are summarized according to key areas.

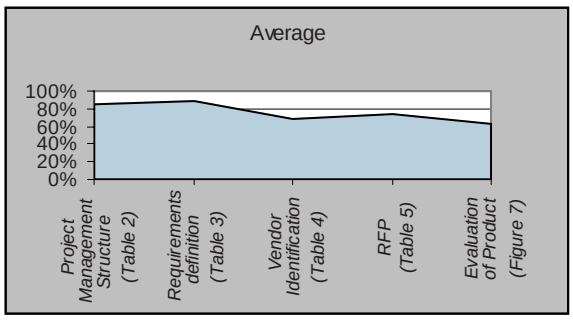
An area of concern should be the evaluation of the product for management (only 63% average with some areas that were identified that needs attention). Eighty-six percent of users agreed that they where satisfied with the software obtained. Sixty-five percent of users verified that the software systems meet the business objective and 84% noted that the software they are using meets their requirements (also supported by Voas et al., 1997).

DISCUSSION AND CONCLUSION

From the findings, the researchers conclude that Media24 has identified and used the better suited evaluation techniques as described in the theory. End-users were generally satisfied with the software and agreed that the software meet their requirements and business objectives. The above-mentioned statement answers the first research question. It is evident that software that help Media24 achieve its goal has a better chance of being selected (answer to the second research question).

The researchers note that there were some complaints mentioned by end-users. They feel that this "unhappiness" could be because not all employees were actively involved in determining the requirements or because the requirements were

Figure 4. Key area's average



not communicated to all users. A manager during an interview noted that the software he was using does not integrate with one of the sub-systems. This eventually leads to more work, as manual reconciliation has to be done between the sub-system and the software. This could be because the requirements or the software weren't described properly in the request for proposal. Most of the statements indicated that e-commerce organisations should be careful how they select software (Capterra, 2002; Hausen & Welzel, 1993; Lars & Methven, 2002). This was also supported by the research findings of this study.

FUTURE RESEARCH

Further research might be needed to refine or redesign the evaluation approach used by Media24. The reason is that the current software will be outdated soon and with the rise of new technology, the evaluation and selection process might have to be adjusted. There were also some issues that were not picked up before the installation of the product (e.g., integration with sub systems). This indicates why the evaluation and selection process might have to be revised. Other studies could help place emphasis on the use of specific evaluation models. In order to speed up the process and to gather more data more respondents will have to be included in the sample before the next survey is conducted.

Chapter 5.22
Planning and Managing the Human Factors for the Adoption and Diffusion of Object-Oriented Software Development Processes

Magdy K. Serour
University of Technology, Sydney, Australia

ABSTRACT

Although there are a large number of contemporary software development processes/methodologies available to assist and guide software professionals in developing software systems, there is no specific process that can assist organizations in planning and managing their transition to this new work environment. As a result, there are still a large number of information technology (IT) organizations that have not yet implemented any object-oriented (OO) process. For them, the transition to a new work environment and the adoption and utilization of a software process implies a number of problems, commonly including necessary human and organizational resistance to the ensuing cultural change. This chapter provides IT organizations and professionals with insights into the most important key success factors that may promote the entire process of organizational change. We investigate the effect of various human factors on the adoption and diffusion of an object-oriented software development process. Some of the human factors include motivation, leadership, resistance to culture change, and willingness and readiness to change. In addition, this chapter explores the significant role of these factors in controlling the entire process of implementing an OO process in practice, emphasizing the significance of planning and managing these "soft" factors to achieve clear advantages and gain enviable results.

INTRODUCTION

This chapter investigates and examines the effect of various human behavioral patterns during the organizational transition to an object-oriented (OO) work environment, and the adoption and diffusion of an OO software development process. Technology is only a tool; what makes the difference is the individual who makes use of the technology, and the culture that motivates people to realize and understand the advantages of adopting such technology (Zakaria & Yusof, 2001).

During any paradigm shift, human tendencies play a critical role that may invariably result in either success or failure. Examples of such human aspects may include cultural change coupled with people's resistance, motivation, education and training, communications, and leadership. Collectively, these factors can form either opposing or supporting forces that may influence and impact on the entire transition process. Therefore, human aspects must be seriously considered, well addressed, planned, and managed for a rewarding result.

Past studies (e.g., Gibson, 1999; Ioannidis & Gopalakrishnan, 1999; Nambisan & Wang, 1999; Auer & Dobler, 2000; Jurison, 2000; Burshy, 2001) of the process of organizational transition have related the transition process to how organizations adopted innovation, ideas, new technologies (e.g., Web services and e-business), or new "ways of doing things" (e.g., the adoption and deployment of an OO process).

What these processes missed in the past was the first (and the most critical) step towards the adoption of a new technology. They all missed the study of moving organizations from their current state or environment to their desired one where they can feel comfortable, familiar, and confident to adopt and diffuse an innovation or new technologies such as OO processes. Getting organizations ready to adopt and diffuse a new technology involves a number of serious managerial decisions that must be made to provide full management support, dedication, and commitment. Organizations must feel comfortable and familiar with the new way of "doing things" before any attempt is made to implement these new ways in practice to avoid or lessen people's natural resistance to change, and also increase their acceptance and readiness.

Hence, the main objective of investigating the impact of human issues is to gain a full understanding of individual behavior during the transition and also to examine different human factors that influence the response of individuals within organizations toward the adoption of an OO software development process.

ORGANIZATIONAL CHANGE AND HUMAN FACTORS

"The greatest difficulty in the world is not for people to accept new ideas, but to make them forget about old ideas." John Maynard Keynes

People Behavior During Organizational Change

During an organizational transition, different people play different roles, such as motivators, adopters, resistors, opposers, and neutral or observers (Bridges, 1995). How they respond to change during transition can, and in most cases does, dominate and determine the success or failure of the entire project. The inextricable reality is that people are different, and so act and react to changes differently; from time-to-time even the same person can behave in a different manner.

Bridges (1995) claims that changes are always accompanied by natural resistance, as changes often drive people out of their comfort zone. Consequently, people can develop a resistance to change and become the main obstacle to the whole organizational change.

Once an organization comes to realize what it needs to achieve and decides how it will accomplish its goals, the main challenge becomes the issue of effective and efficient management of human factors. It is quite surprising to know that 80% of project failures are traced back to mismanagement of human factors (Jacobson, Ericsson, & Jacobson, 1995).

Unfortunately, there are many organizations still struggling to deal with difficulties related to the effective management of human or sociological factors during technology adoption and diffusion. This type of problem is usually caused by management's lack of commitment to the human factors of IT. Szewczak and Khosrow-Pour (1996) relate this problem of mismanagement of human aspects to the fact that, in general, organizations traditionally invest a significant proportion of their resources to obtain the necessary hardware and software technologies, but with insignificant investment in the human aspect of technology. An experienced software development team that has been around for more than a decade, for example, is likely to have superior expertise in (and consequently be comfortable with) traditional software modeling techniques such as Flow Charts, Data Flow, and Entity Relationship Diagrams. Professionals of this type would not be openly receptive to changing their existing work culture and switching to modern OO techniques such as Object Model, Use Case, and interactions Diagrams. This kind of human culture change can form a major challenge during the transition that may increase people's resistance to change.

The Challenges of Human Factors

In general, human aspects are the most difficult challenge to be addressed during any organizational change (Zakaria & Yusof, 2001). The transition process to OO and the adoption of an OO process usually involves a large number of technical as well as non-technical issues. Various authors have referred to these non-technical issues as *soft factors* (Constantine, 1995) and *sociological factors* (DeMarco & Lister, 1987). We call these 'human' Key Success Factors in this discussion, since they deal with the 'human aspect' of change. These human factors necessarily require complete understanding and managing alongside the technological factors. Since OO contains elements relevant to all stages of the development lifecycle (not only coding), and includes models for requirements engineering, project management, team building, and so on, adopting OO process requires a combination of learning about technical issues as well as larger scale sociological issues.

People, procedures, and tools are the three critical aspects that must be well planned and managed during any organizational change (Serour, Henderson-Sellers, Hughes, Winder, & Chow, 2002). Certainly out of these three aspects, people are the most demanding aspect to be changed and managed. Eason (1983) argues that the human factors of technology are far more important than technical factors. The most challenging aspects of the transitioning to object-orientation remain in establishing a new software development environment and in introducing a new work culture to managers, software developers, and customers (Ushakov, 2000).

As a result, it is imprudent for management to expect every team member to agree with all the proposed changes. It may even be unwise to anticipate full commitment and belief in the new organization mission, especially at the early stage of transitioning. Organizations must face reality by realizing that change is often difficult in the best of circumstances and seldom goes exactly to plan. Management must be mindful that only a minority of individuals will wholeheartedly welcome any proposed changes to the way they have done things for so long.

The challenge to software professionals is to change and adapt to a new environment. A pos-

sible scenario may ensue where developers need to adopt new ways of 'thinking' about software, followed by OO modeling/designing, developing, quality assuring, and testing the software. Adopting a new approach of developing software may include technical factors (e.g., CASE tools, Programming languages, and databases) that require a reasonable degree of human culture change in order to utilize them to their maximum potential. Individuals, especially those working on software projects, work under the influence of various personal, motivational, and social factors. These factors, more often than not, remain in the background. Due to their elusive and intangible nature, these human factors are often difficult to discern, analyze, and improve on when change is about to be implemented.

As a result, moving working professionals to new ways of perceiving and undertaking various tasks is very difficult (Fingar, 1996). However, many studies such as Szewczak and Khosrow-Pour (1996) suggest many organizations are still struggling to deal with problems related to the human aspects of technology. Furthermore, they correlated this problem to management's lack of commitment to the human side of IT.

It is vital, then, that organizations pay careful attention in addressing all human or soft factors, and be open and ready to confront and solve any conflicts that may influence the entire transition. Organizations need to appreciate individual behavior when examining the transition and the adoption of new OO process; they need to investigate and explore the different factors that influence the response of individuals within the organization towards the new technology. To accomplish a successful transition, an organization needs to advance people's motivation and enthusiasm, maintain management commitment, and provide efficient and persuasive mentors whose leadership may be seen as the source of expert guidance (Jacobson et al., 1995).

The art of managing cultural interfaces has become an everyday business challenge at every organizational level (O'Hara-Devereaux & Johansen, 1994). The main question here, and management's major challenge, is how an organization makes the transition a driving force for all people involved in being adopters and supporters of the change, instead of opposers or neutral players. Constantine (1996), during the OOPSLA'96 panel discussion pertaining to human factors, contended that it is quite easy to communicate with machines and solve problems, but with people it is difficult. The main reason is because people are very difficult to "generalize."

Human Factors and Risk Issues

Organizations must be aware of the consequences and the possible risks involved in mismanaging the human factors during the introduction of a new work culture such as OO process. The improper planning and managing of human factors can easily lead to undesirable consequences, such as building resistance to change, and adding more confusion, uncertainty, and fear that can considerably diminish the chance of success. Schein (1999) interestingly states that there was no such failure for technology adoption; instead it was a failure to understand the organizational and the individuals' culture.

As a result, organizations that are aiming to adopt an OO process need to address not only the technological factors of the adoption, but also the human factors. As an example, organizations must provide adequate education and training to their people in order to understand and grasp the fundamentals and underpinning concepts of object-orientation and development processes, as it is a critical factor to avoid those risky consequences. Bridges (1995) argues that the most prevailing cause for the unsuccessful implantation of organizational changes can be attributed

to a lack of planning in managing the impact of change on individuals. He also emphasizes that many organizations that are not properly geared to handle this facet of change can run the major risk of jeopardizing their own existence.

Therefore, management may be very well advised to create a plan to manage and mitigate these potential risk factors by answering the following questions:

- How are people likely to respond to the change?
- What is required to convince people that the change is worth the effort?
- What actions are necessary to earn people's support and commitment to the change?

In addition, management needs to identify the ultimate and most effective means in achieving the following objectives:

- Selling the change to all people involved, including customers.
- Motivating people to make the transition.
- Reducing people's resistance to change.
- Eliminating people's fear and uncertainty.
- Minimizing the change's disruption to people.
- Mitigating the increasing tensions between people during the change.
- Encouraging people to be enthusiastic for the change, as opposed to being apathetic and an obstacle.

By answering the above questions and achieving the related objectives, organizations will be able to use persuasive approaches to human change, ensuring that everyone is comfortable and willing to accept, and make use of, the new OO process with all its associated changes.

THE HUMAN FACTORS

Human Culture and Necessary Culture Change

"In a time of rapid change, standing still is the most dangerous course of action." Brian Tracy

The Oxford English Dictionary (9th edition) broadly defines human culture as the arts and other manifestations of human intellectual achievement regarded collectively as the improvement by mental or physical training. In particular, Palvia, Palvia, and Roche (1996) define the culture of IT professionals as the set of values and practices shared by these members of an organization involved in information technology activities, including managers, developers, and customers/end users.

Personal culture is usually characterized and distinguished by the individual's values, such as behavior, attitude, experience, and beliefs. There are people who work well under pressure, whereas others work well only when properly supervised and directed, and then there are the 'cowboys' (Constantine, 1993) who prefer to work on their own. Cooper (1994) asserts that an IT person's culture may resist the introduction of a new process which realigns status, power, and working habits, especially when they violate some of the group's shared values. Current personal culture can be incompatible with certain new processes to the degree that risky consequences may be incurred, including resistance to change, a negative attitude and behavior, implementation failure, or the achievement of totally unsatisfactory results. Human culture change—that is, the physiological change that people undergo to alter the way they carry out their work on a daily basis—is one of the hardest and most longstanding parts of the adoption of an OO software development process (Fayad & Laitinen, 1998).

Natural Resistance to Change

Coupled with the introduction of a new work culture, people tend to naturally build resistance to any challenge of changing their culture and/or learning new things. The unfamiliarity with the new changes can lead to a discomfort that naturally increases people's resistance. In general, change is often seen as a personal threat by those involved in transition (Huse, 1975).

Resistance to change can also come from management, project leaders, and customers/end users for similar reasons, including fear of change and uncertainty of their capability of carrying out these changes (Fayad & Laitinen, 1998). Furthermore, adopting an OO process also requires people to advance their skills and knowledge, and/or gain new ones, as well as learning new tools and techniques. All these changes can lead to a threat that, if people are not capable of changing their culture, they will be out of the workforce, and be replaced by others who possess the required OO knowledge and skills and are capable of utilizing the new process. Resistance may also happen during the course of adoption when people are faced with serious impediments. For example, people may reach a stage when they feel that they cannot use their old ways (ad hoc) and at the same time they are not comfortable with the new ways (OO process). They then try to escape or oppose the changes. This leads to an increased level of resistance.

During organizational change, managing people's resistance becomes a critical issue that must be seriously considered so as to accomplish satisfactory results. For that reason, organizations must be able to effectively manage people's resistance to leading and directing the change process. To do so, management must first understand what resistance really means. What do people really resist? Do they resist the new environment, new technology, or the changes they have to undertake? And finally, why do people really resist? Do they resist for psychological reasons, technological issues, personal concerns, or a combination of all?

What Resistance Really Means?

Naturally, people want to improve and find better ways of doing things. A part of making improvements is causing changes, and changes are always faced with different types of resistance. People's resistance can be a result of different human reactions that sometimes form obstacles, impediments, hindrances, and difficulties to change. One of the risky issues regarding people's resistance is that, sometimes, managers see resistance as a sign of laziness, stupidity, or just unwillingness and opposition to change (Fayad & Laitinen, 1998).

In actual fact, resistance can be a sign of people's disinterest or they could be busy with more pressing issues. Resistance could also be a signal of conflict of interest or contradictory point of views. Moreover, resistance could be a silent request for assistance, more information, or an assertion of different priorities. Resistance can be viewed as an opportunity to gather information and learn better about current and desired state (Bamberger, 2002).

What People Really Resist?

Naturally, people do not like to lose. They do not like their own things to be taken away from them, and that is exactly what people resist. People associate change with the loss of their existing comforts. People do not resist the change itself, so much as they resist the uncertainties, fear, and discomforts associated with it. People, especially those who are confident and comfortable with their existing culture, resist the idea of changing their ways of doing things, and facing the risk of becoming unfamiliar and uncomfortable with the new ways. In addition, every change involves a degree of risk, and people are naturally reluctant to take risks and face the unknown.

Why People Really Resist?

To manage the resistance to change, it is important first to understand the various reasons behind it. Resistance could happen at an early stage of the introduction of the new change and/or at a later stage, during the change process. People resist change when they are unaware of the need to change and, accordingly, are uncertain of the final result. On the other hand, Bamberger (2002) notes that change often meets with resistance because it is seen as a personal threat that leads to fear of failure and rejection. Fayad and Laitinen (1998) relate resistance to the lack of a clear view of the current state and objective goals. They further note that resistance to change often exists as a result of structural conflicts within the organization. Lack of management's commitment and inconsistent actions with the new change can also elicit resistance.

Bridges (1995) declares that when changes take place, people get angry, sad, frightened, depressed, and confused. These emotional states can be mistaken for bad morale, but they rarely are. Rather they are more likely to be a sign of grieving, the natural sequence of emotions people go through when they lose something that matters to them. People resist the loss of competence that they once had and which was associated with their old familiar tasks. Transition is tiring; during the change, people build resistance when they feel unfamiliar and uncomfortable with the new ways. Resistance happens when people feel that they cannot use their existing old ways, and at the same time they are not comfortable and familiar with the new ways. From a different perspective, people build resistance when they feel that the new ways they have to follow can negatively affect their productivity. For example, an inappropriate new process or technique can discourage people to change, as it can lead to a drop in people's productivity.

Accordingly, with the introduction of a new OO process, people's resistance to transition and culture change could be a result of one or more of the following human behavior factors:

- They see the transition with its necessary changes as a threat to their jobs.
- They do not have inadequate knowledge and experience related to the new OO process.
- They are afraid of learning new ways of carrying out their jobs.
- They doubt the benefits of adopting a new OO process.
- They are afraid of failure or that they will not be able to understand the new process.
- It is exhausting to learn new things, and some think they are too old to learn a new process.
- Some prefer to do what they know best, even when they acknowledge there may possibly be a better way *(The devil you know!).*
- They are overloaded with their current projects with no time to learn new things.
- They are not in favor of the new process with its associated modeling language and/or CASE tools.

Even during the transition process, and when changes take place, people can develop more resistance and be less motivated for different reasons including:

- Anxiety rises and motivation falls.
- They are afraid of failing.
- They are unsure of the new way.
- They are afraid that they may be blamed if something goes wrong.
- They try to avoid learning new things.
- They become self-protective.
- They respond slowly and want to go back to the "old way."
- They doubt the benefits of the new way.
- They feel panic and confused.

Unsurprisingly, even customers may develop some resistance and be reluctant to accept the

changes as a result of the risk factors involved in introducing a new process that would affect their products. Therefore, customers must be involved in the change process owing to their effective role in supporting the organization's adoption of a new OO process. The customer role needs to be changed from being just a customer requesting and running a software application to that of being an effective and supportive partner in the whole process of producing their products.

Defeating People's Resistance to Change

As discussed above, many managers see resistance as a sign of laziness, stupidity, or just plain perversity on the part of employees (Fayad & Laitinen, 1998). Lawrence (1969) suggests that resistance to change should not be treated as a problem, but rather as an expected symptom and an opportunity, or a request, for learning and better knowing the unknown. Also, Senge (1990) stated that resistance to change generally has a real basis that must be understood in order for it to be dealt with. In order to manage people's resistance to change, organizations need to understand better the very human reactions they face when they are asked to do something differently or change their work habits. Management must plan and practice some strategies to manage and deal with people's resistance.

To do so, management must begin to understand what "resistance" really is? What are the major reasons for people to build resistance to change? Then they must establish a suitable work environment for people to undergo the required changes. Management cannot change people, they have to change themselves and they only change when they have the appropriate and supportive environment (Boyett & Boyett, 2000). Bridges (1995) reported that most managers and leaders put only 10% of their energy into selling the problem, but 90% into selling the solution to the problem. Management must put more energy into "selling" the problem that is the reason for the change, because people are not interested in looking for a solution to a problem they do not know they have. Management must realize that culture change is very tiring. People will feel tired, overwhelmed, down, and depressed. Management must look at those symptoms as a natural human reaction, and work hard to rebuild its people self-confidence and give them the feeling of competence in mastering the new way. Management must realize their people's capabilities and give them what they can do best without any fear of failure. Anxiety is natural, and the best way to defeat it is to educate and train people on their new environment. Adequate education and training regarding the newly adopted process can easily eliminate the fear of the unknown, the uncertainties about the final result, and thus lead to elimination of people's resistance.

Defeating Resistance with Participation

One of the most effective ingredients to defeat people's resistance to change is by encouraging them at an early stage to participate in planning for the change; Huse (1975) confirms this fact by assuring that people—during transition—see change as a threat unless they have participated in its planning. Lawrence (1969) has demonstrated through one of his case studies, where an identical change was introduced to several factory groups, that the first group, who was not offered any explanation, resisted all management's efforts, whereas the second group, who was involved in the change planning, carried out its transition with minimal resistance, and an initial small productivity drop was rapidly recovered.

Involvement of people in planning their change allows them to understand why they need to go through it and what they should expect. Humphrey (1995) affirms that people's resistance can be gradually changed to acceptance, once people are convinced of the necessity of the changes, and also they can see the value of undergoing

the change. So, management must show and convince people that the change they need to go through is not a threat, but rather an opportunity for improvement.

Defeating Resistance with Small Wins

Humphrey (1995) asserts that people's resistance to change is proportional to its magnitude. Therefore, resistance can be reduced by planning a number of small changes instead of a hefty change. Transitioning an IT organization to OO environment and adopting an OO process involves outsized changes. Psychological, organizational, and technological changes that can be planned in an incremental manner are "*small wins.*" By introducing the new changes in small increments, each increment will be easy to sell and implement. People will feel confident and positive every time they successfully achieve one increment, and become even more enthusiastic and motivated to implement the next increment. This technique can lead to a smooth transition by enhancing people's willingness to participate and reducing their total resistance. For example, the process of adopting a new OO method could well be started by addressing the Requirements Engineering (RE) activity as a major focus to engender everyone's involvement. An initial RE approach, using a well-defined technique such as the use case technique, can be introduced and utilized without the burden of all other activities and techniques. Once people feel confident in carrying out the RE activity, another major activity such as user interface design can be introduced in the same manner and so on for all other activities.

Education and Training (Knowledge and Skills)

Younessi and Marut (2002) define education as an opportunity to learn and ideally master a number of theories—principles that enable the recipient to assess, analyze, and act appropriately to a broad range of relevant situations. The impact of education is usually more abstract and wide in scope. They also defined training as the provision of an opportunity to learn and ideally practice some skills in a controlled environment to carry out a particular task(s). The impact of training is usually more focused, direct, and narrow in scope. In other words, education provides people with the answer to "*know what*," whereas training provides them with the answer to "*know how.*" People can gain knowledge and skills either through education and training courses provided by their organization and/or through real-life work experience.

In general, people need education and training in their discipline to enable and empower them to assess and perform their duties in a professional and satisfactory manner. In the context of the adoption of a new OO process, technical people need to learn about the new process and associated technology to feel comfortable when using it (Zakaria & Yusof, 2001). The individual's knowledge and experience related to the new process play an effective role in making the decision for the adoption. People with adequate and appropriate knowledge and experience of their new OO process can be more self-motivated and enthusiastic to make a transition than others. On the other hand, during an organizational change, lack of knowledge and/or experience could elicit people's resistance to change and increase their feeling of incompetency and frustration.

Necessity of Education and Training for Transition

Younessi and Marut (2002) have emphasized the vital role of education and training during the adoption of a new OO process by suggesting that education and training is an obligatory component for the successful introduction of software processes into an organization. Furthermore, they considered education and training as a Critical Success Factor for adopting these processes. Perkins and Rao (1990) stated that

the more knowledge and experience people have, the more they are able to contribute to decisions regarding the adoption of OO processes. They also emphasized the impact of training related to the new technology that increases their ability to adopt, diffuse, and master processes, techniques, and tools. Conner (1992) demonstrates the imperative role of education and training in adoption by saying that people change only when they have the capacity to do so.

People's experience towards OO processes should have a positive impact on the adoption (process) of such technology. In the context of adopting a new OO process, Sultan and Chan (2000) stated that the greater the knowledge and skills of individuals, the more likely they are to adopt it.

Management must recognize the critical nature of proper education and training, since experience has shown that between 25 and 40% of the total cost of an extensive project will be spent on education and training (Mize, 1987). More experience enables people to contribute more towards the transition and the adoption of new OO processes. People's appropriate knowledge, experience, and education may have a positive impact on their transition. The greater the work experience of individuals with the organization, the more likely they are to transition and adopt the new process. Highly skilled staff can manage themselves more easily, particularly during a paradigm shift. Therefore, an individual's satisfactory level of knowledge and education towards the new technology and processes forms another imperative management challenge.

Motivation

"Motivation is the release of power within a person to accomplish some desired results. It is a major key for achievement and success." Dr. Len Restall

Motivation has a remarkable power and is a major influence on people's behavior towards any achievement (Humphrey, 1997). In order to investigate the importance of motivation during the organizational adoption of OO processes, we need to understand what motivation is, its role during the adoption, and what motivates people.

What is Motivation?

Bolton (2002) defines motivation as a sociological concept used to describe individual factors that produce and maintain certain sorts of human behavior towards a goal. Hence, motivation, as a goal-directed behavior, is a driving force that stimulates people to achieve a set of planned goals.

Motivation is often driven from a desire or an inspiration to accomplish a defined objective, combined with the ability to work towards that objective. In other words, Motivation is the ability of taking good ideas or serious changes, and coupling them with appropriate knowledge and skills to achieve desired objectives.

Consequently, people who are aiming to achieve a specific goal must be both motivated and have the power and ability to work towards that goal. People who are motivated towards an accomplishment must be also capable and empowered to do so (carry out the work).

In the context of this chapter, motivating people during the adoption of a new OO software process could mean those factors which cause individuals within the organization to do more than they otherwise would. For example, to transit a development team to a totally new OO environment and/or adopting a new process, people need to work more than usual to change their existing work culture and adopt a new way. Then, motivation becomes a measure of an individual's level of readiness and willingness to participate effectively towards a successful transition.

Role of Motivation During Adoption

Pfeffer (1982) states that when people understand and accept a goal, and believe they can meet it, they will generally work very hard to do so. Additionally and from a different perspective, Maslow (1970), when he described his "*Hierarchy of Needs,*" stated that people are capable of achieving their goals if they believe that they can achieve them.

Motivation provides people with the understanding of the reasons for the change that increases their acceptability, which in turn improves their ability to accomplish a successful mission. Moreover, motivated people more often than not are capable of defining and achieving their own goals.

During an organizational change, people need to have compelling and persuasive reason(s) why they have to go through changes. Once they are convinced and believe in their mission, they will feel more competent to carry out their necessary changes successfully. This becomes a positive motivation that makes people desire to accomplish their goals that result in their very best performance (Humphrey, 1997).

On the other hand, lack of motivation during adoption can lead to negative consequences that may contribute to undesirable results. Those consequences may include fear, confusion, frustration, and uncertainty. Humphrey (1997) confirms the vital role of motivation by saying, "Without motivated and capable employees, no technical organization can prosper."

As a result, management must improve and maintain people's motivation to help them to be more effective and efficient in moving to their desired work environment with the adoption and utilization of a formal OO process. Motivation addresses the degree to which people want to, and are willing to, complete the work necessary to change their existing work culture. Furthermore, during transitioning to a new work environment, management must maintain people's motivation if they try to give up easily, or too soon, so as to encourage them to keep trying as long as they believe in their goals.

What Motivates People?

Bolton (2002) suggests that a good first step towards understanding what motivates people is to know what people want from their jobs. The answer could be gaining financial advantages, acquiring more skills and knowledge, or working with the latest technologies. In reality, it is very difficult to predict and judge on people's desire because it depends on the individual's values and beliefs.

What motivates people to change their work culture and adopt a new process differs, all depending on their needs and perception of the new process. Hence, not all people can be motivated by the same things and to the same degree. Therefore, management—especially during transition—needs to understand why their people do their work, and consequently elicit what motivates them and how to maintain that motivation through the entire process. Understanding people's aspiration can help management not only motivate people, but also support their motivation by maintaining and increasing the reasons for motivation.

Motivation is often seen as the driving force that moves people to perform some actions. Then, in the context of the adoption and diffusion of an OO process, people need a comfortable, familiar, valuable, and convincing driving force or "*motivation factor*" to move them to perform more effectively than they usually do.

People feel comfortable when they confidently know how to do their jobs. Enhancing people's skills and knowledge to the required level for transition makes them feel comfortable with the new process. Formal and professional education and training pertaining to OO processes are considered to be effective and efficient techniques

to achieve people's self-confidence. In order to motivate people, training must include clarification of language and jargon or commands used to avoid further frustration and anxiety, as new technologies usually have a mystifying and alienating potential. The more comfortable people feel with the new technology (here OO process), the more willing they are to experiment with it (Zakaria & Yusof, 2001).

Motivation factors must also add extra values for people such as financial reward, or learning a new language, process, or tool. For example, someone likely to retire in a year is unlikely to learn a new way of doing things. On the other hand, an enthusiastic newcomer to the project is likely to put in the extra effort needed to pick up new methods of thinking and modeling.

People who are in the move (e.g., changing profession, changing company, or reaching retirement) will not be interested in changing their culture, and they become difficult to motivate to change their current culture because they will not gain any benefits. To motivate people to change their culture, they need assurance of benefiting from the change.

The driving force must also be convincing, it must be relevant to what people usually do, and it must be in a way that people can believe and make use of. Most people must be convinced of the need to change before they will willingly comply (Humphrey, 1995).

Leadership

"Leadership is the ability to provide those functions required for successful group action." Weldon Moffitt

Leadership is well thought-out by many researchers and authors as a fundamental activity of project management, and they simply describe it as motivation plus organization (Stogdill, 1974; Thite, 2001; Phillips, 2002; Castle, Luong, & Harris, 2002).

In general, leadership plays a significant role in how people effectively perform their jobs. Rogers (1995) defines leadership as the degree to which an individual is able to guide, direct, and influence other individuals' attitudes informally in a desired way. Stogdill (1974) describes leadership as a process of influencing group activities toward goal setting and goal achievement.

Leadership is a practice that needs special skills and talent to motivate people to get things done in a favorable and constructive way. Bridges (1995) affirms that leading a team of professionals efficiently is an invaluable resource to any leader who is eager and willing to understand how to inspire team members. Also, it is a vital ability to augment teams' cooperation and individuals' commitment and productive participation. Above all, an effective leadership is a Critical Success Factor on how team members become adaptable to changing circumstances (Thite, 2000).

Leadership is basically situational. Fiedler (1967) suggests that there is no one style of leadership that suits every project situation. Rather, it should be contingent upon the nature of the organization, the team, and the project situation. Leadership style should be flexible and agile enough to be adapted to suit the project at hand in the most appropriate manner. Phillips (2002) claims that the "appropriate" leadership style is the style with the highest probability of success. Additionally, a good leader should effectively mix and cooperate with team members.

Leadership Style for Adoption

"A leader is best when people barely know that he/she exists." Whitter Bynner

During an organizational change situation, leadership style must be adapted to promote and support the organizational change. Social factors such as the style of leadership can influence the individual's ability to transit to a new work climate. Thite (2000) emphasizes the importance of

the appropriate leadership style during a change situation by considering it as a Critical Success Factor.

Changing people's work culture and introducing them to a new way of doing their job is usually accompanied by increasing anxiety, ambiguity, and insecurity. During such time, a supportive leadership style can effectively contend with and overcome these problems.

Due to the fact that an effective leadership style should depend on the follower and the project situation, leaders must use the most appropriate style of leadership that best suits the project situation that yields the best chance of success (Phillips, 2002). Furthermore, Phillips states that managers must be able not only to determine the most appropriate leadership style, but also to apply that style correctly.

Stodgill (1974) supports that argument by saying, "The most effective leaders exhibit a degree of versatility and flexibility that enables them to adapt their behavior to the changing and contradictory demands made on them." Moreover, Hersey, Blanchard, and Johnson (1996) proclaim that successful and effective leaders are able to adapt their leadership style to best fit the requirements of the situation. Therefore, leaders within an organization about to introduce a major change to their work environment—such as the adoption of a new OO process—must have adequate resources (mainly time), a strong interest in the mission, and a greater exposure to the new process they are about to adopt. Sultan and Chan (2000) firmly assert that the greater the opinion leadership among group members, the greater the chance of a successful transition and adoption.

Leadership always means responsibility. Consequently, an effective leadership style for a transitioning organization must be driven from top management with full support and commitment, and it must be also coupled with a rational degree of authority. Co, Patuwo, and Hu (1998) support that by saying: "Ideally, the team leadership should come from top management: one who is a 'doer', and who commands respect throughout the entire company."

During the organizational transition to a new work environment, leadership should foster strong alignment with the organization's vision. Team members that depend primarily on strong alignment with their organization's vision are at their best with well-understood practices applied to well-understood problems. Furthermore, successful leaders must be able to create a new work environment in which team members feel comfortable and familiar, and also enjoy what they are doing.

Lockwood (1991) and Constantine (1994) affirm that the working culture shapes the style in which software development is carried out. Different styles of organization during different situations require somewhat different forms of leadership style and management, and each will tend to have somewhat different software practices.

Leaders who are leading their teams through a serious change—such as adopting a new OO process—must be able to:

- Define a clear vision and mission.
- Provide convincing and compelling reasons for the change.
- Focus on and be concerned with the *why to* aspect of the transition, rather than the *how to*.
- Manage and motivate team members.
- Maintain an authority level to make appropriate decisions in the face of uncertainty.
- Provide full support and commitment to their followers.
- Provide adequate and appropriate resources including time, education, and training.
- Establish clear communication channels with team members.
- Monitor and review tasks allocated to team members.
- Recognize and appreciate achievements, and reward people for doing good work.

Perception of OO Processes

While IT organizations perceive new OO processes as an essential means to advance their existing software development culture and effectively compete in the marketplace, individuals could have a different perception. Since people are different, their needs and expectations are also different. The more positively people perceive their new process with regard to its characteristics—advantages, observability, compatibility, complexity, and trialability—the more likely it is that the process will be adopted and utilized.

Management of Expectations

From past projects, it has been proven that people with life experience are able to deal with conflicts of interest that may arise due to their ability to make any decision regarding the transition (Hill, Smith, & Mann, 1987). To emphasize the vital role of education on conflict resolution, Barclay (1991) stated that any organization's members who have adequate education and significant real-life experience are well prepared to deal with interdepartmental conflict. It has to be made very clear from the beginning, to both managers and developers, that following a new OO process is not a magic wand or a silver bullet to make the entire organization's dreams come true, but rather is simply today's best approach option for software development. Nonetheless, it is also important that managers appreciate not only the benefits of adopting a new process, but also become aware of all the pitfalls and consequences of changing people's existing work culture.

Different stakeholders such as managers, developers, and customers may look at, assess, and evaluate OO processes, as a new technology to be adopted and utilized, from a different perspective. Senior managers are always looking for the dollar value return for their spending and investments. They evaluate the technology based on how much it will reduce the cost of software production with improved quality. Project managers and team leaders may assess the new OO processes from a different perspective. They emphasize project management aspects, gaining more control and meeting customer's expectations with on-time delivery based on building the software system from the pre-tested and proven software components. Software developers may value the proposed process for adoption as the new fad and trend to developing software. They view the transition process as a good opportunity to acquire new skills, and learn new tools and techniques. Unquestionably, this will insert desirable additions in their resume, add value to their worth in the market, and make them in more demand.

From the above discussion, unrealistic expectation from adopting a new OO process and also any conflict of people's interest can have a negative impact on the entire transition process. People will be reluctant to work effectively together as a team if they do not share the same interest and/or have different expectations.

In order to overcome the barrier of the conflict of interest, management and champion teams must include a specific plan to resolve that conflict between people, and reach mutual perceptions, consensus, and understanding.

Proper education, mentoring, and open discussions are examples of good techniques that can be used to achieve good understanding and realistic expectations of the new process. Stakeholders must come to some sort of consensus as to what they can expect from adopting a new process and also should be fully aware of the new technology pitfalls as much as its benefits. Stakeholders' consensus and shared understanding, as well as realistic expectations of the new process, can lead to a good working environment that can positively impact on the process of transition and thus the quality of the software produced.

Sharing the Vision with the Organization

People perform better if they feel that they share the value of the change with their firm. Managers need to provide the right organizational climate to ensure that their employees can see that, by working towards the organizational goals, they are also achieving some of their own goals. These goals could be financial rewards, or personal rewards such as the respect of their colleagues, or job satisfaction, or a combination of any number of things that the employee considers to be important.

During organizational change, such as the adoption and diffusion of an OO process, to gain people's acceptance, management should get people involved during the initial stage, listen to what they have to say, respect their view, and involve them in discussions and debates regarding the change. Follow up with them on any further progress. Give them the feeling that they are the owners and supporters of the change. Give them the impression that we are only interested in the change if it will help them and make their job more efficient and more enjoyable. Never blame the people for any faults or mistakes, but rather blame the product, the techniques, and/or the tools being used. Organizations need to try everything they can during the adoption of a new process to gain their people's willingness and support such as:

- Choose a flexible software development process/methodology to be tailored to best suit the organization's environment.
- Obtain senior and middle management support and commitments.
- Set an appropriate change management plan.
- Establish a transition support team to sell the changes to everyone and to deal with all transition issues.
- Plan for adequate resources.
- Plan for rewarding people behind the transition.
- Carry out the changes gradually and avoid overloading people.
- Plan for the appropriate type of education and training to enhance people's skills that minimize their fear and confusion.
- Introduce new ways in formal and informal ways as required.
- Never blame people for any failure; instead blame the process (*no* criticism).
- Listen to people and encourage their individual contribution.
- Reinforce the new way of following the new adopted process.
- Start with small jobs with high chance of success so they to gain self-confidence.
- Celebrate success with people.

Organizations should set a well-defined set of guiding beliefs that the mission of the transition and adopting a new OO process is worthy and must be shared with people. Individuals must be in harmony and agreement with an organization's value and goals. When individuals share the same values and beliefs as the organization, they form a psychological union as a group. They become more congruent to the organization. Thus, the efforts of adopting a new process are determined and rigorous. The sharing of ideas and commitments through cooperation and harmony within an organization often leads to an effective change and positive participation. Needless to say, whenever individual goals are in alignment, or close to alignment, with the organizational goals, then any initiative undertaken by the organization to adopt and diffuse a new technology—in our case, OO process—will be easily accepted and utilized by individuals. When people share the vision and beliefs with their organization, they feel that they share the ownerships of their new process and the accountability of the whole transition procedure.

This feeling can motivate the individuals and assist management to defeat resistance to change should it arise. A strong organizational culture is usually measured by the way in which the key values are intensely held and widely shared. It has a greater influence upon employees than weak culture.

Communication Channels

When Zakaria and Yusof (2001) analyzed the implementation of technological change from a user-centered approach, they asserted that communication is a critical element in ensuring the success of a new technological change such as the adoption of OO processes.

Communications are defined as a process by which individuals exchange information through a common system of behavior. The process of communication between individuals has an influence on organizational transition, because it has a strong impact in conjunction with the leadership. A strong and effective communication network has a strong positive impact on adoption of a new technology. Proper and open communication channels can, from one side, help management to express their commitment and support to their people. From the other side, these channels can give people opportunities to discuss and exchange their concerns regarding their transition in order to adopt the new process. This can strongly increase people's cooperation, which enhances their ability to carry out the required changes effectively. From a project management point of view, open communications keep management in continuous contact with their people, and they can closely observe the transition progress to quickly resolve any problems that may occur. Communication can take different forms such as meetings. During an organizational transition to a new work environment and adopting a new process, meetings—driven by management—are seen as ways of undoubting management's commitment and support to change.

CONCLUSION

It can be clearly noticed that by considering and managing the human factors in great detail, the chances of successful adoption and diffusion of a software development process are enhanced significantly. Based on our research projects and several empirical studies, we conclude the following:

- Human factors play a vital role during the organizational transition to adopt and diffuse an OO process, as they can form either a promoting or resisting force.
- Understanding of the new desired OO process work environment can assist management in putting together a plan to manage the necessary cultural change.
- During an organizational change, managing people's resistance becomes a critical issue that must be seriously considered so as to accomplish satisfactory results.
- Organizations must be able to effectively manage people's resistance to leading and directing the change process.
- Involving individuals in planning and making decisions can positively eliminate their resistance to change and enhance their ability to carry out a successful transition.
- The individual's knowledge and experience related to the new process play an effective role in making the decision for the transition.
- More knowledge and experience enable people to contribute more towards the transition and the adoption of new technologies, including OO processes.
- The greater the work experience of individuals with the organization, the more likely they are to transition and adopt the new process.
- Gaining adequate knowledge and proper training on OO processes and associated

tools can significantly contribute to enhancing people's ability to positively involve themselves in the transition process.

- The more knowledge and experience the organization's individuals have regarding OO processes, the more likely they are to change and adopt the new work culture and thus enhance the chances of a successful transition to a totally new OO software development environment.
- When people understand and accept a goal and believe they can meet it, they will generally work very hard to do so.
- Motivation provides people with the understanding of the reasons for the change that increases their acceptability, which in turn improves their ability to accomplish a successful transition.
- Maintaining and enhancing people's motivation during transition can be a driving force for people to wholeheartedly and positively participate.
- Successful and effective leaders are able to adapt their leadership style to best fit the requirements of the situation.
- The greater the opinion leadership among group members, the greater the chance of a successful transition and adoption.
- The more positively people perceive the new process with regard to its characteristics—advantages, observability, compatibility, complexity, and trialability—the more likely that the process will be adopted and effectively used.
- Management of expectations of the new process and conflict resolution can lead to a good working environment that can positively impact the change process.
- When individuals share the same values and beliefs with the organization, they are more likely to effectively participate towards the change.
- When people share the vision and beliefs with their organization, they feel that they share the ownerships and the accountability of the whole change practice and thus their new OO process.
- The sharing of ideas and commitments through cooperation and harmony within an organization often leads to an effective change and positive participation.
- The more individuals find values in the organizational change, the more likely they are to contribute to the transition success.
- The more congruent and rewarding the individuals perceive the organization's values, the more positive is the influence on the transition and the adoption.

Chapter 5.23
Developing Software in a Bicultural Context:
The Role of a SoDIS®[1] Inspection

Don Gotterbarn
East Tennessee State University, USA

Tony Clear
Auckland University of Technology, New Zealand

Wayne Gray
The University of Auckland, New Zealand

Bryan Houliston
Auckland University of Technology, New Zealand

ABSTRACT

This article introduces the SoDIS process to identify ethical and social risks from software development in the context of designing software for the New Zealand Maori culture. In reviewing the SoDIS analysis for this project, the tensions between two cultures are explored with emphasis on the (in)compatibility between a Maori worldview and the values embedded in the SoDIS process. The article concludes with some reflections upon the key principles informing the professional development of software and ways in which cultural values are embedded in supposedly neutral technologies, and reviews the lessons learned about avoiding colonization while working on a bicultural project.

INTRODUCTION

Rogerson and Gotterbarn (1998) developed an early warning system that can be used by software developers to identify and address potential ethical, professional, and social risks in software development. The method, a software development impact statement (SoDIS) inspection (Gotterbarn, Clear, & Kwan, 2004), uses

ethical relations to connect broad-based project stakeholders to the project tasks and deliverables. The SoDIS methodology based upon standard Western ethical values has been proven effective in a variety of environments. It has been applied to the development of a data warehousing project in Boston, the development of software for the analysis of psychometric test data for youth, Web sites in New Zealand, and electronic voting in the UK. In each of these cases, the SoDIS inspection process identified significant risks in the development process and in the final product (Gotterbarn & Rogerson, 2005). This identification of the risks gave management the opportunity to develop successful risk mitigation strategies.

This article introduces the Software Development Impact Statement process and discusses its application to a bicultural project. In reviewing the SoDIS analysis for this project, the tensions between the two cultures are explored with emphasis on the compatibility between a Maori worldview and the values embedded in the SoDIS process. The article concludes with some reflections upon the key principles informing the professional development of software and reviews the lessons learned about working on a bicultural project.

The article recounts the application of the SoDIS process to an ethically sensitive project involving software development for a Maori Tribal Authority. Maori are the indigenous people of New Zealand, a bicultural society in which the other culture could broadly be termed *Western* (comprising subsequent New Zealand settlers from a predominantly European immigrant community). Clear and Gotterbarn used this opportunity to address action research questions such as the following:

1. Would the ethical connectives between task and stakeholder that had been derived from software codes of ethics and codes of practice be adequate to identify ethical risks in a manner that was sensitive to the indigenous culture in this bicultural context?
2. Would the use of the SoDIS process colonize the software system for Maori stakeholders with Western cultural values?

BACKGROUND AND TERMS RELATED TO THE PROJECT

Historical Context

The history of New Zealand, as with most former colonies, reflects a complex series of struggles between the colonizing settlers and the indigenous peoples. A unique feature of New Zealand history is the signing of the Treaty of Waitangi in 1840 between the British Crown and a large number of the indigenous Maori tribes. This controversial treaty, in which the Maori people engaged as equal parties in a partnership whereby they ceded a degree of sovereignty to the crown in exchange for certain rights, since has been regarded as "the legitimate source of constitutional government in New Zealand" (Walker, 1990, p. 98). The English and Maori language versions of the treaty differ in substantial ways and are each open to quite different interpretations. Subsequent debate has revolved around these differing interpretations of the treaty, and consequent actions have been taken by the Crown and its agents. Walker (1990, p. 98) observes that "acquisition, control and, ultimately, expropriation of land were the key factors in the consolidation of sovereignty" by the Crown. This was in spite of the treaty's guarantees to the Maori signatories of "full exclusive and undisturbed possession of their Lands and Estates, Forests, Fisheries, and other properties which they may collectively or individually possess, so long as it is their wish and desire to retain the same in their possession" (Walker, 1990, p.

92). He argues that the "outcome of colonization by the end of the century was impoverishment of the Maori, marginalisation of leaders and chiefly authority and a structural relationship of Pakeha [European] dominance and Maori subjection" (Walker, 1990, p. 10).

Relatively recently, a process of reconciliation has been engaged in by the Crown, one element of which has involved the devolution of responsibilities from the former Government Department of Maori Affairs to Maori tribal authorities known as Runanga. The intention was to move from a paternalistic governmental model of service provision to Maori toward a self-determined model managed by the Maoris themselves. An earlier key step in the reconciliation process had been the establishment in 1975 of a specialized tribunal (the Waitangi Tribunal) to hear and to adjudicate upon Crown breaches of the treaty brought by Maori claimants. A number of settlements have resulted from this process, in which significant financial compensations have been made to claimant tribes.

One of the most significant nationwide settlements resulting from the Maori Fisheries Act 1989 and the subsequent Deed of Settlement 1992 has resulted in the establishment of the Maori Fisheries Commission, a Crown body with more than NZD$700 million worth of fisheries assets to be redistributed to several claimant tribes. This redistribution will be effected by the establishment of a "new trust, Te Ohu Kai Moana … with iwi (the Maori tribes) as beneficiaries" (Maori Fisheries Bill, 2003, p. 1). The trust will undertake a process of allocation of groups of shares to tribal authorities, who then will apportion them accordingly to bona fide members of that tribe. "For individual Maori to become shareholders in this asset they must be registered with their iwi" (Tuhono, 2004). Thus, in order to demonstrate membership of a tribe, a process of tribal registration similar to voter registration will be required.

Project Context

In mid-2002, a number of students at Auckland University of Technology (AUT) began work on a project to extend the existing IT systems of a Maori tribal authority, Te Runanga a Iwi o Ngapuhi (TRAION), the statutory body representing the Ngapuhi tribe, or *iwi* (Clear et al., 2004). Proposed changes in a broadly conceived project included the following:

- Online registration of tribal members
- Linking members to several groupings of significance to Maori
  - Extended family (*whanau*)
  - Subtribe (*hapu*)
  - *Marae* (a meeting-house complex used for several cultural purposes and serving the Maori community centered in that location)
- Creating a database of genealogical (*whakapapa*) information
- Creating a database of interests in communally owned tribal land

The TRAION project, then, was entering into sensitive areas. For Maori, "Identity and worth were found in family and tribal connectedness [and] …identity was linked to both ancestry and place" (King, 2003, p. 77). As a consequence, Maori people have known sensitivities about research related to *whakapapa* (genealogical and land-based information), which is considered a *taonga* (treasured possession) particular to the groupings (*whanau*, *hapu*, and *iwi*) who have interests in this information.

To better articulate the risks and to investigate the issues inherent in computerizing such sensitive information, a Software Development Impact Statement (SoDIS) analysis was undertaken.

THE SODIS PROCESS

There is significant evidence that many software projects fail because, during development, they do not adequately identify and address significant qualitative risks, including social, professional, and ethical risks. Rogerson and Gotterbarn (1998) developed a process, Software Development Impact Statements (SoDIS), to address this problem. The SoDIS process was prototyped in software (SDRF, 2005). These unidentified risks and associated software failures can range from trivial annoyances to cumbersome and dangerous situations. Developers frequently are surprised by the impacts of the software they develop and their own failure to pay attention to a wide range of risks. Sometimes, the missed risks can have tragic consequences.

A major cause of failed software projects is the narrow focus of risk analysis on only the concerns of the developer and the customer. Risk analysis sometimes is extended also to include those with a financial stake in the software. But this limited scope of analysis excludes those who do not have a financial stake in the development of the software. Because they have no financial stake in the development of the software, the needs of the pacemaker recipient, or the vehicle passenger whose life is affected by the successful application of anti-lock braking software, often are overlooked. The SoDIS methodology is designed to include in the risk analysis those people who are impacted by the development of the software. Broadening the base of stakeholders requires a broadening of the types of risks considered.

The decision support technique, Software Development Impact Statements, is a modification of an environmental impact statement. Software impact statements, like environmental impact statements, are used to identify potential negative impacts of the planned software and to specify actions to mediate those impacts. SoDIS is intended to reflect both the software development process and the more general ethical obligations to various stakeholders. In particular, it was designed to access the possibility of ethical, professional, and social risks — risks that occur where the software interacts with people or modifies their social environments.

The SoDIS process is an ethical decision support process insofar as it focuses on the developer's responsibility to consider the diversity of stakeholders and the special nature of the project tasks. The SoDIS analysis precedes the software development. A SoDIS analysis identifies concerns about the potential impact of particular planned tasks on individual stakeholders. It highlights changes in some planned tasks and additional possible tasks that are needed to prevent any anticipated problems. The analysis is done first during the planning stage for software development.

On a very high level, the SoDIS process can be characterized as examining the way every task or function of a proposed system impacts a stakeholder. Unacceptable potential impacts are identified, and the developer has the opportunity to address the risk before the product is developed. The process generates a series of questions of the form, "Might task *n* have a specified ethical impact on the particular stakeholder?" For example, a retirement payment system may require all data on a single screen. "Failing to take into consideration the needs of" is an ethical impact issue. Thus, a SoDIS question might be, "Might putting all data on a single screen fail to take into consideration the needs of the senior citizen (visually impaired) stakeholder?"

The SoDIS process can be reduced to four stages: (1) the identification of the immediate and extended stakeholders in a project; (2) the analysis of the tasks in a project; (3) for every task for each stakeholder, the identification of potential ethical issues raised by the completion of that task; and (4) the recording of the details and solutions of those ethical issues and a decision whether the current task needs to be modified or a new task created in order to address the identified concern.

The process of developing a SoDIS encourages the developer to think of people, groups, or organizations related to the project (stakeholders in the project) and how they are related to each of the individual tasks that collectively constitute the project. This encouragement is done by generating a series of questions for the analyst.

The generation of these questions requires the list of tasks, the potential issues connecting (ethical relata and impact issues) task and stakeholder, and the list of stakeholders. The task list can be at a variety of levels of abstraction and is provided by the requirements, function lists, or a project task list.

The SoDIS process identifies overlooked risks through the inclusion in the analysis of a broader range of stakeholders. Stakeholders include individuals or groups who may be directly or indirectly affected by the project and thus have a stake in the development activities.

Stakeholder Identification Techniques

The stakeholders can be identified in several ways. A preliminary identification of software project stakeholders is accomplished by examining the system plan and goals to see who is affected and how they may be affected. When determining stakeholders, an analyst should ask whose behavior, daily routine, or work process will be affected by the development and delivery of this project; whose circumstances, job, livelihood, or community will be affected by the development and delivery of this project; and whose experiences will be affected by the development and delivery of this product. All those pointed to by these questions are stakeholders in the project.

The identification of stakeholders also must strike a balance between a large list of stakeholders who are ethically remote from the project and a list

Figure 1. SoDIS® process (Gotterbarn & Rogerson, 2005)

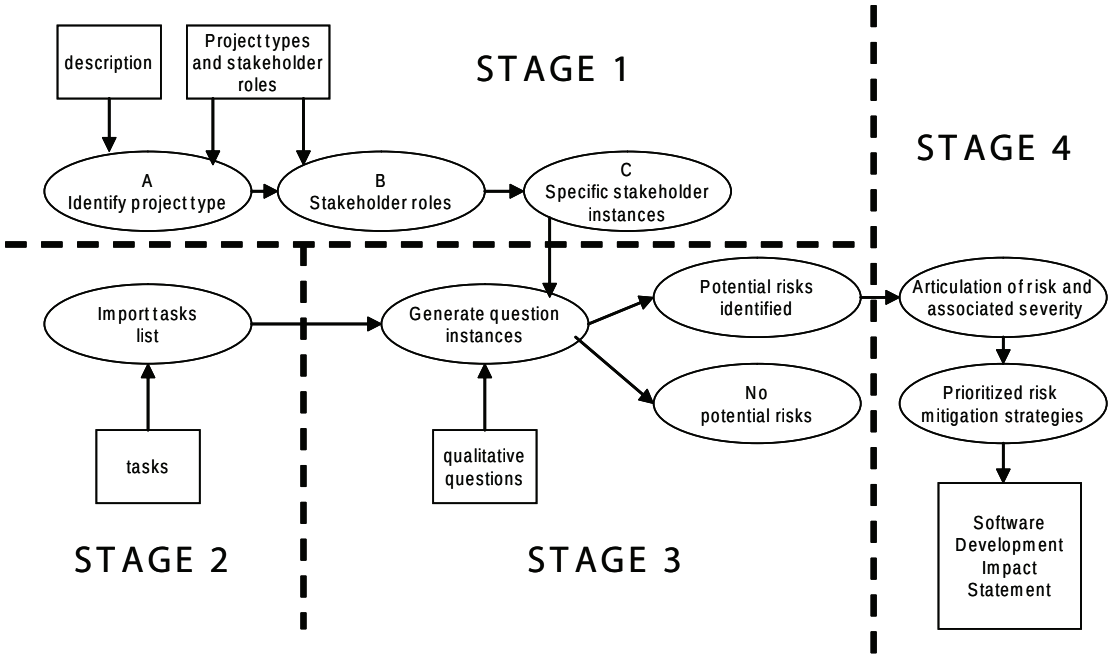

Table 1. Gert's moral rules

Don't kill	Don't cause pain	Don't disable	Don't deceive
Don't deprive of freedom	Don't cheat	Don't deprive of pleasure	Keep your promises
Do your duty	Obey the law		

of stakeholders that only includes a small portion of the ethically relevant stakeholders. Rogerson and Gotterbarn (1998) proposed a method to help achieve a balance between an underestimation and overestimation of the relevant stakeholders based on Gert's (1988) moral rules. Gert gives the 10 basic moral rules shown in Table 1. These rules carry with them a corresponding set of rights, such as the rights to liberty, physical security, personal liberty, free speech, and property.

One approach to stakeholder identification is to use Gert's (1988) rules as stakeholder search criteria, search for stakeholders who would be caused pain by a particular project task, search for stakeholders who would be disabled by a particular project task, and so forth. A preliminary identification of software project stakeholders is accomplished by listing each of these rules and rights and examining the system plan and goals to see who is affected and how they may be affected. For example, according to the rule "don't cause pain," we should ask if the system changes the level of pain felt by anyone.

Stakeholders are also those to whom the developer owes an obligation. The imperatives of the Software Engineering Code of Ethics and Professional Practice and similar codes of ethics and practice define the rights of the developer and other stakeholders. These imperatives can be used to guide the stakeholder search. The process of identifying stakeholders also identifies their rights and the developers' obligations to the stakeholders.

Ethical Relata

These codes also can be used to identify the impact issues connecting tasks and stakeholders. Many of the computing codes have similar imperatives, which embody the software profession's views of responsibility. The SoDIS process uses abstracted imperatives from many codes and organizes them under general moral principles. These imperatives have been organized as a set of 32 impact issues, which form questions when relating tasks and stakeholder. There may be some special circumstances that are not covered by these 32 questions, so the SoDIS analyst can add impact issues. Only codes of western professional computing societies were abstracted (e.g., the British Computer Society, the Association of Computing Machinery, etc.). There is in each of the codes a clear statement that protects individual rights of ownership. The ethical umbrella under which the SoDIS was developed seems to reflect a Western, largely individualistic worldview (see Hofstede [1980] and discussion in the section "The Ethical Problem") of software development and ethical rights and responsibilities.

We now can modify our initial research questions as follows:

1. Would the ethical connectives between task and stakeholder that had been derived from software codes of ethics and codes of practice be adequate to identify ethical risks in a manner that was sensitive to the indigenous culture in this bicultural context? This can be put as the following more general question:
   1*. Does the application of a Western worldview of software development constrain (impact, affect, colonize) the system it develops with more general ethical values (which would include indigenous values or the general value sets implicit in the Western worldview)?
2. Would the use of the SoDIS process colonize the Maori software system with Western cultural values? This is now divided into the following two questions:
   2*. Does the SoDIS process really embody Western values, or does it embody a view that is conditioned by software development rather than a social-ethical culture?
   2**. Does the SoDIS process necessarily force such constraints on a different culture?

Question 2** is different from the question, "Can the process be used in such a way to colonize values into another culture?" A simple example of software colonization is the loss of accountability in vote counting caused by the development of vote counting machines that do not produce paper audit trails for votes cast.

THE PROPOSED PROJECT AS TARGET FOR THE SODIS PROCESS

The Ngapuhi *iwi*, 103,000 according to the 2001 census, have their interests represented and managed by Te Runanga a Iwi o Ngapuhi, the project client. Because the majority of these members live outside the tribal boundaries in the Northland, identifying and maintaining contact with members is a costly and difficult exercise.

The software project, TRAION, was to replace the current paper-based membership system with only 2,000 recorded members. The *iwi* is very large and dispersed, but a complete roster is needed for representative decision making in *iwi* matters, such as the long-term management and reporting of tribal resources and the facilitation of Treaty of Waitangi settlements. Communicating with the diverse membership is facilitated by a Runanga-developed Web site (http://www.ngapuhi. iwi.nz). A major function of the Web site is the distribution of *iwi* membership application forms. "Nevertheless, providing a fully dynamic, robustly architected website had been beyond the resources of the Runanga at the time of commissioning the project" (Clear et al., 2004, p. 8).

The Tribal Membership System

One of the immediate needs of the Runanga was the establishment of an up-to-date membership system verifying that people, indeed, are members of the *iwi*. This list was required for *iwi* management and the potential disbursement of settlement funds, a task made more difficult by the international dispersal of members of the *iwi*.

Implications for the Project: Technical and Social Issues

To meet the membership recording needs of the Runanga, it was decided that the system would be Web-based. The project as originally conceived (i.e., developing a full genealogical/land-based system) could not be completed in the time allocated for a student project. "Developing a land information system revolves around not merely providing the right technology, but the difficulty

of the information gathering process and the accuracy and currency of the results garnered from the process" (Clear et al., 2004, p. 10).

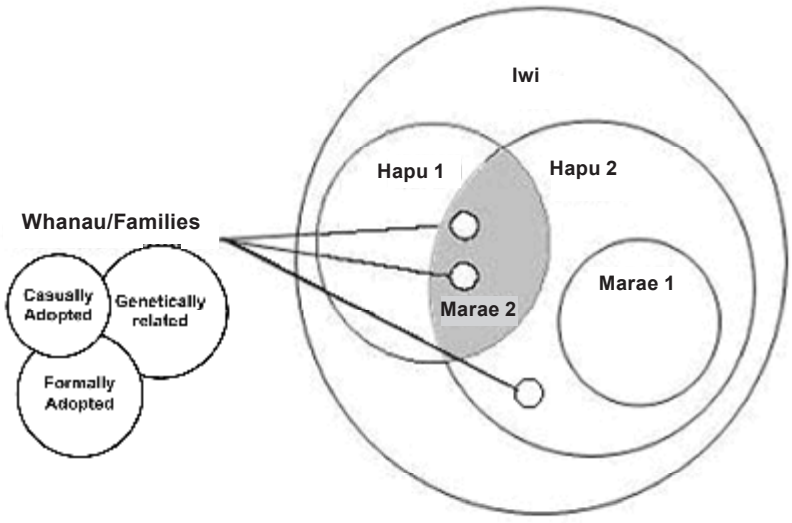
Determining land ownership is very complex for Maori. As in other societies, land is inherited through family linkages, but there is not a complete paper trail of all of these linkages. The most accurate information can be found by investigating the family relationships and background of land ownership candidates. Another problem is that the Maori culture is community-based, so there are often hundreds of owners for one block of Maori land, with each owning a proportion. The records for these dispersed owners are often inaccurate.

The three factors of land, genealogy, and tribal membership are interconnected and provided the original scope of the investigation. A decision was made to focus on the membership system requirements, with the database designed to allow for future implementation of genealogical and land information system requirements.

Membership Information Structure Difficulties

Given the lack of genealogical documentation, tribal debate informs matters of *whakapapa*, and every piece of information is important in genealogical research, regardless of the correctness of the information at the time of examination. Even dubious data must be preserved to allow for later reinvestigation. Not only must inconsistent stories be maintained, but the system also must track the time-based nature of genealogical data. Instead of a simple hierarchical structure, the Maori also have an overlapping network structure in different groups (i.e., family, *hapu*, tribe, etc.). The levels of family relationship (shown in Figure 2) include parent-child, *whanau* (extended families), *marae* clusters within *hapu* (local meeting complexes within the territories of a subtribe), and *hapu* clusters within a larger tribe (*iwi*). The Whanau is not a simple genetically related group but frequently includes members who have been

Figure 2. Iwi relationship structures (adapted from Clear et al., 2004)



adopted formally from other Whanau; it also includes those who have been adopted casually by a Whanau. Thus, someone who is adopted casually into a particular family will be a member of that family's *marae* of their *hapu* in their *iwi*, but that same person is related genetically to a different family that could belong to a completely different *iwi*.

THE SODIS APPLIED TO THIS PROJECT

Smith (1997) identified several Maori concerns about putting cultural information on the Internet, including concerns relating to threats to cultural values, loss of control of information, intellectual and cultural property ownership issues, accuracy and authority of information, the commercialization of information, and access issues. Based on consultation with the Maori about computerization of Land Court records, the Department of Courts (1999, p. 3) noted that Maori had objected to the database being made available over the Internet and believed "that management of the records (paper and electronic), the information therein, and access, has to be consistent with the following principles: the *mana* (authority) of the records/information comes from *iwi*, [and] *whakapapa* is intrinsically *tapu* (sacred)."

The Maori say that cultural information (here, *whakapapa*) has an intrinsic value, while in the West, information is viewed primarily in an instrumental sense; the value of the information is a function of its usefulness. In addition to the cultural concerns, there are significant technical issues with the TRAION project. The potential of the final outcome of this project to support not only the production of a tribal membership register but also the recording of *whakapapa* and consequential land ownership rights gave rise to natural concerns about the design of the system, use of data provided in the course of the project, the responsibilities for management of the resulting information, and access to this sensitive data.

The Ethical Problem

Given that *whakapapa* is sacred, would the analysis of the project tasks manage to identify the development of this database as a potential instance of cultural colonization of the Maori by another culture?

Our investigation requires at least a distinction between the two cultures. Culture is a complex phenomenon and generalizations are all too easy to make. Nonetheless, differences do exist, and some categorization such as the dimensions proposed by Hofstede (1980) can be helpful. In one such example, at a country level, New Zealand has been categorized, along with countries such as Canada, Great Britain, and the United States, as possessing an individualistic culture (Jarvenpaa & Leidner, 1998), whereas Maori would be classified more appropriately as possessing a collectivist culture. The group is a dominant structure in the Maori world, just as the individual is dominant in the Western perspective of the previous country grouping. Avison and Myers (1995, p. 52), arguing that culture is essentially an emergent phenomenon, have refuted simplistic definitions, noting, "The assumption that cultures are separate, distinct entities which identify and distinguish one group from another … is too simplistic." As with all generalizations, there are obvious exceptions with each culture, but the individualism — collectivism dimensions — seem to be based upon strong conceptual foundations. Given this obvious difference in perspective, forcing the values from one culture onto another would be an example of ethical/social colonization.

Therefore, when engaging with Maori as with many other indigenous cultures, we need to acknowledge that the Western perspective is different from the Maori. To develop software that accommodates this difference in perspective

requires that we work in a partnership model and that we have tools and techniques that can surface issues based on these different perceptions. The SoDIS process is one such analytical technique. The SoDIS was designed with a fiduciary model of professionalism in mind (Bayles, 1981). A fiduciary model of professionalism imposes high standards of development, but the resulting software is developed in partnership with those affected by the developed product. But we are wrestling with the extent to which its underpinning logic is essentially Western and fails also to address the different value systems of indigenous peoples who come from a strong tribal or clan-based community culture. The tools used require a focus on what that community values.

THE RESULTS OF THE FIRST APPLICATION

The SoDIS process is part of an inspection process. The first step in the SoDIS inspection process (Gotterbarn, Clear, & Kwan, 2004) is the identification of potential high-level risks — clusters of concern. The awareness of these high-level issues is used as a filter for the SoDIS analysis. In application of the SoDIS process through a SoDIS inspection of the TRAION project, the following four distinct clusters of concern were identified:

- Client-developer communications
- Sensitive data
- User experience
- Academic considerations

Within these clusters, the specific concerns later identified during the detailed SoDIS analysis related to several further subcategories.

Client-developer communication concerns that were identified related to a conflict of interest between the local proxy client, who was a member of the *iwi* and also of the academic staff at the developers site, and the remote client at the Runanga itself, who would operate the final systems once delivered. Questions arose about the ability of the proxy client to adequately represent the requirements to the developers and mechanisms for securely transferring sensitive project related documentation between the development and client sites.

Sensitive data concerns related to reasons for collecting data (consistency with privacy legislation and mechanisms for obtaining consent for provision of data for genealogical research purposes [http://www.caldeson.com/RIMOS/nzguide. html]) and access to data (determining authorization protocols, managing privacy considerations, keeping data over time, managing multiple copies of the database, etc.). Cultural sensitivity and avoiding exploitation through commercialization were concerns, especially over display of cultural artefacts over the Web or use of *whakapapa* information for commercial purposes.

The user experience concerns related to unusual circumstances (e.g., where contested values over tribal groupings were held and where members could be refused enrollment under their chosen groupings, or when dealing with cases of adoption and the desire to represent both natural and adoptive lineages); refusing membership and the resulting impact on tribal members, whether that refusal was by design or through administrative, security, or data integrity occasioned errors; access and performance issues for rural members with slow dial-up connections; visual and language impairments (e.g., the impact of Maori language text without translation for young members who are more frequently non-Maori speakers and for the elderly who have poorer eyesight and for whom the choice of a suitable font will be an important consideration).

Academic considerations were concerns related to developer inexperience with taking a system through all the activities of a full devel-

opment life cycle to production use, and time constraints potentially leading to shortcuts and quality compromises.

This SoDIS-generated list of Clusters of Concern and subcategories did not impose Western social values. The list appears as a relatively culturally neutral collection that has identified issues that would be of concern to any professional developer and likewise to their clients and other stakeholders in the system. As we shall see, there are, however, some issues here that are of specific concern to Maori due to their cultural priorities and values. We return to the research question 1* — Is the SoDIS with its Western cultural base capable of including indigenous values?

SOME SEEMINGLY CULTURAL DIFFERENCES RELATED TO THE DATABASE AND THREATS TO CULTURAL VALUES

In this clash of values between Maori and Western perspectives, however, we have identified some critical issues. Broadly speaking, we can say that Western culture is inherently individualistic (whether through natural persons or notion of the firm as a natural person) and tends to assert property rights through ownership; it also tends to view resources through a utilitarian ethic as opportunities for personal gain through some form of exploitation. Maori culture, by contrast, is group-based, emphasizing the collective good and views resources not simply as opportunities for exploitation but from an innate sense of oneness with the natural world, as entities deserving respect in their own right. The notion of collective responsibility for the guardianship of these natural resources is an accompanying strong cultural imperative.

Solomon (2000, p. 4) phrases the distinction as follows:

Acknowledging the spiritual dimension of their universe and respecting the mauri or central life force of every living thing was fundamentally important to the Maori world view. In other words, the reciprocity of obligations was balanced against the right to use and exploit. This can be contrasted with the notion of intellectual property rights which focuses on the economic right to exploit for profit and financial gain. The needs of the individual, and corporate legal personalities such as multinationals, are preferred to the collective good.

Under this capitalist model, resources are viewed entirely as a means of exploitation for economic gain. There is little or no reciprocity or respect for the integrity of the resources as living and breathing entities with their own mauri or life force.

A New Stakeholder

This raised an interesting question. We hold a model of data as information to be used for our purposes, which underpins the informational perspective of *whakapapa*. Does our model violate the Maori ethic relating to *whakapapa* as a sacred entity warranting respect and for whose respectful guardianship we have a collective responsibility? Thus, the notion of a data collection itself (here, the *whakapapa* is the collection considered) having an inherent integrity in its own right leads us to reconsider the notion of stakeholder. Not only the impacted individuals and groups but even the very information may be a stakeholder, if we adopt a Maori perspective (Floridi, 1998). Thus, including *whakapapa* in our stakeholder list and conducting subsequent analysis to determine whether the integrity of the whole collection is at risk by actions in the course of the project may assist in bridging the gulf between the two cultures. In this way, we may apply a tool based on Western value systems in a manner nonetheless

consistent with the worldview of a very different culture. The key is being able to adopt the Maori perspective when doing the analysis.

The inspection itself had identified as a concern issues to do with data integrity, in general, but had not done so through a perspective that animated in this way the data itself as a collective stakeholder. Thus, the Maori perspective appears capable of being represented through the SoDIS inspection process, but only if the analysts themselves adopt a similar and compatible (in this case, animist) mindset. This is a subtle but significant shift in thinking. Research question 1* is answered affirmatively. The SoDIS process is capable of identifying more general value issues.

2** is not resolved.

ANOTHER SENSE OF COLONIZATION AND THE SODIS WESTERN PRINCIPLES

Myers and Young (1997) have noted how an information system may act as a steering mechanism enlisted to serve the agenda of a power elite, and, in this way, the system itself may act as a colonizing device. While the term *information system* has been used by Myers and Young (1997), it equally might be substituted by a systematic process, a set of processes, or a software tool used in support of a process. One reason for the concern about cultural ethical colonization is the fact that the ethical relata in the SoDIS process were derived from a Western cultural-ethical perspective embodied in codes of professional ethics. A necessary condition in order for the process to avoid colonization is its application from a Maori perspective. But is that a sufficient condition, or does the SoDIS process' seeming foundation in a Western ethic mean that the use of the process in other cultures necessarily colonizes social and ethical values in this way?

Our initial questions were (1) Would the ethical connectives between task and stakeholder that had been derived from software codes of ethics and codes of practice be adequate to identify ethical risks in a manner that was sensitive to the indigenous culture in this bicultural context? and (2) Would the use of the SoDIS process colonize the Maori software application with Western cultural values?

Did the SoDIS Have These Threats — 1* Was it Adequate to the Task? and 2** Did it Necessarily Act to Colonize the Maori Culture?

a. SoDIS and Western Culture or Professionalism. The SoDIS process embodies standards of professionalism, which, at a certain level, are universal but may be sociologically defined as merely a set of norms. However, there does appear to be a common ethic inherent in the international community of practice (Wenger, 1998) constituted by professional software developers. Is this ethic to do their job well, sensitively, and in a manner that does not cause harm, a universal ethic of the profession?

b. The derivation of the connecting issues between tasks and stakeholders in the SoDIS analysis was driven by ethical imperatives common to software codes of conduct and codes ethics. A significant number of ethical imperatives were gathered from the various codes and were assigned as instances to one or another of Gert's (1988) moral rules. Some of the imperatives derived from professional codes did not fit clearly under any particular Gertian moral rule. These imperatives were related specifically to a moral approach to a project and did not have a stakeholder other than the project itself. These included issues like "require the developer to work on projects with infeasible goals." This process identified 32 common issues distributed among five distinct principles depicted in Table 2.

Table 2. Alignment of SoDIS principles with those of Gert

SoDIS Principles	**Gert's Original 10 Principles**
Project issues (no stakeholder focus)	none
Cause harm	Don't kill, Don't cause pain
Unreasonably restrict	Don't disable, Don't deprive of freedom
Involve deception	Don't deceive, Don't cheat
Conflict with your responsibility toward	Don't deprive of pleasure, Keep your promises, Do your duty, Obey the law

As some imperatives seemed to belong equally under two different Gertian rules, it was decided to collapse the rules under more general moral principles, so "Don't kill" and "Don't cause pain" were subsumed under the principle "Cause harm." The negative form of the principles was used so that when a question was answered with a *yes*, it would indicate an ethics violation. For example, affirming that "a particular task will cause harm to a stakeholder" indicates the need for remedial ethical action.

The resulting generic SoDIS principles and the relation to Gert's rules are in Table 2.

Some of the rights and obligations identified when following this method of categorization may be in conflict, and it will become necessary to prioritize how these rights are addressed and which of them can, within the bounds of the five previous principles, be addressed. This prioritization, of course, involves value decisions and a setting of priorities among values identified. As Rikys (1980, p. 26) has noted, these value-determined priority choices may create an opportunity for cultural exclusion, since "if planners are not exposed to or in possession of some values, these values will fail to be reflected in the planning policies and priorities which result from planning." One of the general ways to help prioritize the ethical obligations within a project is to determine what actions are necessary in order to satisfy the perceived obligation and to evaluate those actions in terms of whether they are morally required, morally wrong, or merely morally permissible. This approach to evaluating potential actions is a variation on Green's (1994) decision tree for assessing obligations.

Colonization of Social and Ethical Values

One of the research questions in general and in particular for a multicultural process is related to the derivation of the ethical issues relating the task and the stakeholder. This potential problem may be more likely because change of the moral rules used in the SoDIS may have an impact on the way stakeholders will be identified. It may seem that this change might be a cause of ethical colonization.

Justification of the Process as Non-Colonizing

There are three items that weigh against the charge that the SoDIS engages in ethical colonization. The first is that the underlying premise of the SoDIS is an analysis of an expanded set of stakeholders. The second is that the set of

principles and questions is expandable by the user and, thus, does not mandate the ethics of the analyst. Third, the ethical questions are answered from the analyst perspective and subject to the analyst's interpretation. In this regard, it may be the analyst who is guilty of ethical colonization rather than the SoDIS process. This risk normally is mitigated by conducting the analysis process jointly with stakeholders from the client organization or community. This ensures that participants are well-versed in the cultural context and subject domain.

No Ethical Colonization

First, the process expands rather than narrows who the stakeholders are so that it broadens the issues and is not colonizing. If the stakeholder expansion were consistent with the Western business ethics model that the primary stakeholders in any project are only those who have a financial interest (Mitchell et al., 1997), then enlarging the stakeholder base indeed would be colonizing. As we have seen, however, stakeholders are identified by the following three questions that address affected parties in their cultural circumstance:

- Whose behavior, daily routine, or work process will be affected by the development and delivery of this project?
- Whose circumstances, job, livelihood, or community will be affected by the development and delivery of this project?
- Whose experiences will be affected by the development and delivery of this product?

By stakeholder, we mean individuals or groups who may be affected directly or indirectly by the project and, thus, have a stake in the development activities. Those stakeholders who are affected negatively are particularly important regarding ethical sensitivity, because they are often the ones overlooked.

Negative effects include both overt harm and the denial or reduction of goods. So, obviously, the development of a medical software package that delivered erroneous dosages of medicine that killed patients would have a negative effect. But SoDIS analysts also would include software that limited people's freedom of expression as having a negative effect. Limitations on positive ethical values and rights are negative effects. It can also be argued that the failure to promote positive ethical values is also a negative effect. This is the model that was used in part for the project questions about tasks.

Therefore, we extend the traditional software project stakeholder list from customers and corporations or shareholders to include all those who will be affected by the software and by its production. This includes users of the software, families of the users, social institutions that may be altered radically by the introduction of the software, the natural environment, social communities, software professionals, employees of the development organization, and the development organization itself. If the analysis is done from a Maori perspective, those affected further include *whakapapa* and related social groupings.

Space precludes a fuller discussion here, but this inclusive motivation could be considered to be broadly consistent with the Habermasian (1984) desire to avoid distorted forms of communication, whereby dominant groups use systems as mechanisms to effect a "colonization of the lifeworld" (Myers & Young, 1997, p. 226) of other groups.

Second, the SoDIS is tailorable in two ways: (1) new questions can be asked and existing ones can be ignored and (2) the meaning of terms is conditioned by one's worldview. A basic assumption of the SoDIS process is that the original ethical relata are a starting point for the analysis. The SoDIS analyst should add appropriate ethical relata to the analysis. The ethical relata are about software development impacts.

Third, the questions are answered from the perspective and understanding of the analyst. The analysts answer questions from the perspective of the stakeholder. The effect of taking the stakeholder perspective can be seen by looking at some specific ethical issues and the guidance contained in the SoDIS process. For example, the principle, "Does task *cause harm* to the stakeholder?" includes the alteration of information (interpreted from a Maori perspective to include *whakapapa*) as a potential harm. This approach also facilitates the addition of context-relevant stakeholders. So, in the case of the Ngapuhi, the information is a stakeholder who is exposed to significant risks.

Under the principle *cause harm* are the ethical relata that follow.

Does the task in question:

- Allow unauthorized access or alteration of the data of the stakeholder?
- Violate the privacy and confidentiality of the stakeholder?
- Discriminate against the stakeholder?
- Fail to take into consideration the needs of the stakeholder?
- Involve the design or approval of software that may lower the quality of life of the stakeholder?
- Cause loss of information, loss of property, property damage, or environmental impacts that affect the stakeholder?

It is clear from the earlier discussion that these principles are broad enough when interpreted from a Maori cultural perspective to encompass most of their specific concerns with this project.

Even if the SoDIS process were to attempt to colonize, we have seen Maori resistance to possible colonization in their resistance to the computerization of land court records and other information (see the earlier section "The SoDIS Applied to this Project").

MAORI-SPECIFIC ETHICAL RELATA FROM THE SODIS INSPECTION

Of the issues identified in the SoDIS inspection (see the earlier section "The Results of the First Application"), several had specific significance from a Maori cultural perspective. While some of the concerns raised could be viewed as fairly relevant to any software development context, the Maori dimension often introduced further culture-specific elements.

In the first cluster of *client developer communication*, the key Maori ethical questions related to who could legitimately represent the *iwi* as the project client. Walker (1990) has noted historical situations in which the authority of the chiefs had been subverted and the authority structures of Maori society undermined by the colonizer. Thus, when engaging in research and development with Maori (Bishop, 1996), the processes of initiation and the need to work through due tribal and group decision making and authority structures are critical.

In the second cluster of *sensitive data*, several Maori ethical questions arose. Privacy concerns and mechanisms for obtaining consent for provision of data for genealogical research purposes raised complex questions of who could legitimately view what data. The collective ownership of *whakapapa* at different levels meant that group and individual access rights had to be negotiated. Individual data were personal, but *whanau* data were the property of the family group to decide, and *hapu* and *iwi* had their own interests and group decision-making processes in order to determine these rights. For instance, what rights would system administrators, data entry clerks, and Runanga management have to access or restrict access to this data? These policies and authorization protocols would need to be developed and agreed upon through accepted tribal decision-making processes. Similarly, protocols concerning display of cultural artifacts over the

Web or use of *whakapapa* information for commercial purposes (e.g., to defray expenses of the site or to support storage and research costs) would need to be agreed upon at the tribal level in order to offset concerns over commercialization and inappropriate use of treasured information and sacred objects. Data integrity and the need to preserve the very authenticity of *whakapapa* as a stakeholder in its own right has been noted as a key Maori concern.

In the third cluster, *user experience*, several more Maori ethical questions arose. Again, questions over authority in disputed circumstances would need to be settled (i.e., who could determine official groupings and their standing?). For instance, a particular Northern grouping, Ngati Hine, claims *iwi* status but has been deemed by Te Ohu Kai Moana as a *hapu*. How do such determinations hold standing, who decides official lists of *hapu* and *iwi*, and how are dissenting voices to be registered? Likewise, under what criteria are membership applications to be refused registration and what is the impact for those refused? What authority will systems administrators and Runanga clerks possess, and what controls will be in place to ensure the integrity of data entered and stored? How is the integrity of *whakapapa* to be maintained in each of these circumstances?

Questions related to access and performance arose, with concerns over slow Internet access speeds for rural users. For indigenous peoples who often live in rural areas, access issues present known problems. Burn and Loch (2001) have observed how the digital divide particularly impacts the rural poor and rural and central city minorities. In a relatively recent report (T.P.K., 2001, p. 7), it was found that "65 percent of Maori respondents reported they had never used the internet, and about 8 percent reported they used the internet on a daily basis…only 34% of Maori households possessed a computer."

Visual and language impairments were further concerns, with untranslated Maori language text a potential barrier for younger Maori, who would frequently be less fluent, and font selection an issue for older Maori.

Another *whakapapa*-related concern arose for those who were adopted (whether formally or informally) and how their data would be represented; for instance, would both natural and adoptive lineages be stored? Who would need to give consent for such a practice?

Thus, it can be seen that the SoDIS process has been able to identify concerns of particular relevance to Maori in this bicultural project. The input from Maori project participants to the SoDIS inspection seems to have resulted in an outcome whereby the Maori perspective has been incorporated successfully. This incorporation of the Maori perspective has been realized by working through the questions of the process derived from the general ethical principles identified in Table 2. While relatively generic, the questions have forced consideration of many issues critical to the stakeholders in this project. The detailed operation of the principles can be seen in the appendix to this article, which provides the full wording for each of the SoDIS principles considered relevant to Maori.

POTENTIAL LIMITATIONS OF THE SODIS IN THE BICULTURAL CONTEXT

Joint Governance Models

In her report to the New Zealand government on the issues related to online authentication and e-government, Kamira (2004) proposes joint governance models to operate in such large technology projects with potential negative impacts for Maori. The joint governance model is intended to enable power sharing between Maori and governmental agencies and to ensure that cultural differences are taken into account (i.e., the key importance

of face-to-face relationships in Maori culture stands to be lost in a computerized authentication process wherein access to government services could become more alien and inaccessible to Maori users of services).

Key notions underpinning a governance-*kaitiaki* (guardianship) model to operate at program and project levels are drawn from the Treaty of Waitangi, the founding partnership document between the two peoples, which include:

- Active participation and participation in decision making;
- Active protection of Maori interests, rights and taonga; and
- An ongoing right to development that is not locked into an 1840 "time closet." (Kamira, 2004, p. 35)

Thus, a general model of oversight is proposed in order to operate at a program level when an information-technology-based program of change is to be implemented in a bicultural context. While we believe that this is a sound approach to an engagement model recognizing difference and seeking partnership, we also believe that this is a difficult model for the dominant partner to adopt and to adhere to consistently.

While the SoDIS process specifically does not operate at this governance level, it can act in support of such structures by offering a mechanism for its operationalization within a project. In some cases, where a joint governance model has not been agreed upon, the SoDIS process even may compensate for its absence. For instance, the SoDIS process can act in concert with several of the following key factors indicated by Kamira (2004) for establishment of governance-*kaitiaki*:

- Align with the treaty (by ensuring joint participation in the analysis process);
- Encompass different cultural considerations;
- Protect the sensitivity of information;
- Ensure that ultimate accountability be to the intended beneficiaries of the project; and
- Cultivate trust and strong working relationships.

Professionalism and Culture

Multicultural discussions often take a "silo" approach to the description of diverse cultures, emphasizing what makes them different at the expense of complete accuracy. We have looked at the question of colonization with this approach in mind and have assumed that cultures are like a series of silos, each isolated and distinct from other cultures. Despite this presumption of difference, two such cultures, Maori and Western, seemed to interact in the application of the SoDIS inspection process to the development of a Maori software application.

The SoDIS principles are designed for the engagement of professionals in the development of software across all cultures. The SoDIS is applied within the silo in order to help the system developers to attend to the social and ethical risks within that silo. The SoDIS could be used as a tool in a paternalistic model of professionalism, where the analyst uses it to impose his or her cultural values on another; but the SoDIS was designed with a fiduciary model of professionalism in mind (Bayles, 1981). A fiduciary model of professionalism imposes high standards of development, but the resulting software is developed in partnership with the culture in which it works. Fiduciary means trust, which must be won by both partners in the endeavor.

The SoDIS provides a model for software inspection, and the values (i.e., acknowledging that *whakapapa* is a stakeholder) are derived from the perspective of the analyst(s) working with project stakeholders in the inspection team. In the Maori context, where models of group decision making based upon oral modes of consensus discussion

(*hui*) are common, it could be argued that the SoDIS process needs to incorporate opportunities for such group conversations, which is certainly an area for adapting the SoDIS process and worth exploring further.

CONCLUSION

Although the SoDIS inspection identified some risks unique to Maori and some more general risks, it did not identify all of the risks. SoDIS, in fact, is limited in that it is not designed to identify risks arising from the interaction of multiple tasks. The application of the SoDIS process, however, has provided several interesting lessons. The application of the SoDIS process did not colonize the TRAION software project, so we can say the following:

1. The use of a Western-based development process need not colonize an indigenous software project, even using several concepts of colonize. The positive result is the following:
2. The process was able to identify some Maori unique issues. The features that facilitated this positive result are as follows:
    - 2a. The underlying premise of the SoDIS is an analysis based on an expanded set of stakeholders.
    - 2b. The set of principles and questions is expandable by the user and, thus, does not mandate the ethics of the analyst.
    - 2c. The ethical questions are answered from the analyst's perspective and subject to the analyst's interpretation.

We believe that these lessons, gained in a bicultural context-developing software with NZ Maori, will be applicable to other indigenous peoples, especially those who have a history of colonization, such as Australian aboriginals, Native Americans, Peruvian Indians, the Inuit peoples, and so forth. In developing software for people with such differing worldviews, the careful use of software development impact statement (SoDIS) inspections may ameliorate the worst forms of re-colonization by Western values through software and may enable the development of software in respectful partnerships, applying techniques that enable deep cultural differences to surface and to be addressed specifically rather than being accorded mere lip service.

APPENDIX. TEXT OF SODIS PRINCIPLE GUIDANCE WITH PARTICULAR RELEVANCE TO MAORI

Principles with Particular Maori Relevance

CAUSE HARM TO

As a software project is undertaken, a central principle requires that the project and its product cause no harm, either direct or indirect. *Harm* means injury or negative consequences, such as undesirable loss of information, loss of property, property damage, or unwanted environmental impacts. This principle prohibits use of computing technology in ways that result in harm to users, the general public, employees, or employers. Harmful actions include intentional destruction or modification of files and programs leading to serious loss of resources or unnecessary expenditure of human resources, such as the time and effort required to purge systems of computer viruses. As the Association of Computing Machinery (ACM) puts it, "Well-intended actions, including those that accomplish assigned duties, may lead to harm unexpectedly. In such an event the responsible person or persons are obligated to undo or mitigate the negative consequences as much as possible. One way to avoid unintentional harm is to carefully consider potential impacts on all those affected by decisions made during design and implementation" (ACM).

CAUSE Loss of Information, Loss of Property, Property Damage, or Environmental Impacts

Software can harm property and the environment directly and indirectly. Examples might include software that regulates chemicals or machine control software and financial systems. The task should be evaluated in light of the current stakeholder's interests.

INVOLVE the Design or Approval of Software that Will Not Lower the Quality of Life

Software first should not harm and, if possible, should improve the quality of life. Each task should be evaluated to determine the effect it will have on the quality of life of each relevant stakeholder. Examples of diminished quality of life could include applications that cause repetitive strain injuries, the inability of customers to return unwanted or damaged merchandise, or software-controlled machinery that is excessively noisy.

FAIL to Take into Consideration the Needs of

Software tasks, projects, and products often are completed without considering the needs of certain stakeholders. The omission of these considerations can lead to mediocre software, disgruntled stakeholders, and, in the worst case, unacceptable products.

DISCRIMINATE Against

Codified, systematic discrimination can damage entire demographic groups and, in the worst cases, result in class-action litigation. Health insurance or life insurance eligibility software, for example, inadvertently can discriminate against persons from certain economic backgrounds. Single-language automated teller machines can prevent groups from getting access to their accounts. Each task should be evaluated to determine whether its outcome might discriminate against the current stakeholder.

VIOLATE the Privacy and Confidentiality of

Could the current task compromise the privacy or confidentiality of the current stakeholder? If so, what steps must be taken to ensure that the stakeholder's needs will be considered and resolved?

ALLOW Unauthorized Access or Alteration to the Data

Could the current task compromise the information security of the current stakeholder? If so, what steps must be taken to ensure that the stakeholder's needs will be considered and resolved?

This work was previously published in the International Journal of Technology and Human Interaction, edited by B. Stahl, Volume 2, Issue 2, pp. 1-23, copyright 2006 by IGI Publishing (an imprint of IGI Global).

Chapter 5.24
Issues, Limitations, and Opportunities in Cross-Cultural Research on Collaborative Software in Information Systems

Dongsong Zhang
University of Maryland, Baltimore County, USA

Paul Benjamin Lowry
Brigham Young University, USA

ABSTRACT

Globalization has led to the increasing use of organizational teams comprising individuals with diverse cultural backgrounds. Existing research suggests that collaborative software may benefit multicultural teams. However, most prior studies are limited by their focus on U.S. and Western cultures. We explore this issue by comprehensively examining the literature on cultural effects on collaborative software use. This article makes several contributions by providing common nomenclatures and theoretical perspectives that are essential to promoting scientific progress in this area. It focuses mainly on empirical collaborative software studies in which culture is a key conceptual construct. We discuss underlying cultural theories, research methodologies, and findings of major collaborative software studies on the impact of culture. This article provides insights into various issues surrounding this line of research and highlights future research opportunities.

INTRODUCTION

Globalization has affected business by increasing the competitiveness of the marketplace, restructuring organizational boundaries, and creating

new challenges for managers who deal with multinational companies or international alliances. Businesses often use multicultural collaborative groups working in distributed environments to cope with uncertainty, change, ambiguous problem definitions, and rapidly changing information (e.g., Vick, 1998). Hence, a critical need exists for managers "to develop a new repertoire of skills and abilities to manage and/or work with people whose cultures and value systems can be significantly different from those at home" (Tung, 1995, p. 485).

Improving group processes and outcomes has been one of the most highly investigated research issues of the past two decades. The advance of information technologies makes it possible for distributed teams to be supported through collaborative technologies such as group support systems (GSS) and computer-mediated communication (CMC), which are collectively known as collaborative software (CSW). CSW refers to computer systems that combine communication and decision-support technologies to facilitate the formulation and execution of various group activities.

Culture is central to how people experience their world, make sense of concepts, express themselves, and make decisions. Information technology is not "culturally neutral and may come to symbolize a host of different values driven by underlying assumptions and their meaning, use, and consequences" (Leidner & Kayworth, 2006, p. 359). First, beliefs and values shared by the members of a group affect group behavior in a variety of ways that can either accelerate or retard the implementation of technological changes (Veiga, Floyd, & Dechant, 2001). For example, many management and organization practices developed in Western countries are viewed with suspicion and often fail when introduced into other cultures (Kim, Park, & Suzuki, 1990). Likewise, when group tasks involve cross-cultural teams, cultural conflicts can arise. Since CSW design is typically based on Western cultural values, adopting CSW successfully in another culture may require both technical and social modifications (Watson, Ho, & Raman, 1994).

Second, the manner in which CSW may change group behavior is likely dependent on culture (Tan, Watson, Wei, Raman, & Kerola, 1993). Samarah, Paul, Mykytyn, and Seetharaman (2003) find that cultural diversity has a significant, positive moderating effect on group agreement and perceived decision quality when using CSW. To better understand how CSW can be successfully applied to a variety of cultures, researchers need to systematically compare the effects of CSW across different cultures (Tan, Watson, & Wei, 1995). Yet, only a small number of existing studies have empirically and theoretically examined cultural effects.

To advance this knowledge, we review and critique existing empirical research that specifically addresses cultural effects on CSW-supported group decision making. This article is different from recent literature reviews that focus on relationships between information technology and culture in general (Gallivan & Srite, 2005; Leidner & Kayworth, 2006). We attempt to focus primarily on empirical studies of multicultural, CSW-supported group work, which is critical for testing and validating propositions and hypotheses, and for developing theories about cultural influence in collaborative groups. We hope that our attempts at assimilation and analysis of existing studies will stimulate further research along this line.

The scarcity of literature in this area makes meta-analysis infeasible. For each specific research question/issue, there are usually only two to three studies. Most prior studies had very small sample size (effect sizes are typically small). Thus, our review and discussion are offered from a descriptive and critical perspective that aims to provide a roadmap for researchers. In addition, we focus only on empirical studies that include: (1) participants from different cultures, (2) the use

of certain CSW in face-to-face and/or distributed settings, and (3) culture as a key conceptual construct. Our coverage includes papers published before 2005 in journals and conference proceedings in information systems (IS) and management fields (see Table 1). During the search, we used a variety of searching terms such as cross-culture groups, culture and group collaboration, virtual teams, and virtual community.

In the remainder of the article, we will discuss underlying cultural theories, research methodologies, and findings of the studies we reviewed. We will then provide insights into the limitations of existing studies and highlight some directions for future research.

CULTURE AND COLLABORATIVE SOFTWARE

In general, CSW has been proven useful in alleviating problems associated with intercultural communication primarily by reducing many behaviors that might offend members of other cultures (Gray & Olfman, 1989; Aiken, Martin, Shirani, & Singleton, 1994). However, theories relating to group and organizational behavior and other disciplines are dependent on the culture being studied. Because each culture has unique beliefs, values, and norms, considerable differences may exist in how technologies are used and diffused across cultures (De Vreede, Jones, & Mgaya, 1999).

Since the majority of CSW studies on group performance have been conducted in the United States and other countries with Western cultures, culture is largely neglected or assumed to be irrelevant (Fjermestad & Hiltz, 1999). In an earlier review of 230 CSW studies (Fjermestad & Hiltz, 1999), only nine were found that included culture as either an independent variable or a moderator. Few studies both advance theories involving culture and employ empirical data to test assumptions and hypotheses. Consequently, the benefits of CSW identified mostly from research on Western cultures may not be manifest in different cultures under the same circumstances. For example, Kim et al. (1990) report that some incentives used to motivate North American workers can be counterproductive in collectivistic cultures.

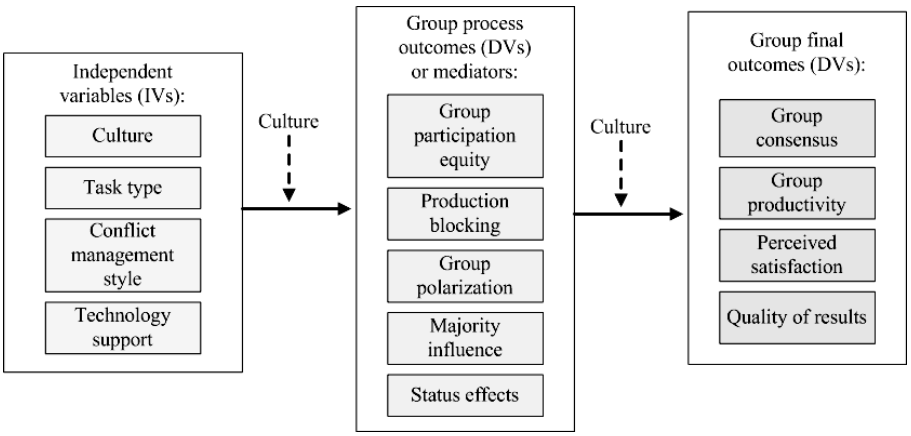
This article discusses CSW studies on cultural influence from several perspectives (see Figure 1). Those studies primarily examine the following independent variables: culture, task type, conflict management style, and technology support. We examine the effects of cultural differences on group processes (including group participation equity, production blocking, group polarization, status effects, and majority influence) and outcomes (including group consensus, perceived satisfaction, group productivity, and quality of results). Culture can also be used as a moderator while studying group process and final group outcome (Samarah et al., 2003). We will discuss the reviewed studies in terms of independent variables (IVs), dependent variables (DVs), and major findings and limitations.

Independent Variables

Culture

Individuals are socially conditioned by their culture (Zakour, 2004). Cultural differences in different nations, religions, ethnic groups, and societies are stable over time and often have existed for centuries. Kluckhohn (1962) states that culture "consists of patterns, explicit and implicit, of and for behavior acquired and transmitted by symbols, constituting the distinctive achievement of human groups, including their embodiments in artifacts" (p. 73). Hofstede (1991) defines culture as the "collective programming of the mind which distinguishes the members of one group or category of people from another" (p. 5). Groeschl

Figure 1. An overview of independent and dependent variables used in CSW studies



and Doherty (2000) assert that "culture consists of several elements of which some are implicit and others are explicit. Most often these elements are explained by terms such as behavior, values, norms, and basic assumptions" (p. 14). Based on previous culture literature, we define culture as a system of implicit and explicit beliefs, values, norms, preferences, and behaviors that are stable over time, are held in common by a group of people, and that distinguish one group from others.

The majority of cultural theories we studied focus on group value orientations such as value dimensions of national culture or the competing values framework at the organizational level

Table 2. Hofstede's cultural dimension model (Hofstede, 1991, p. 28)

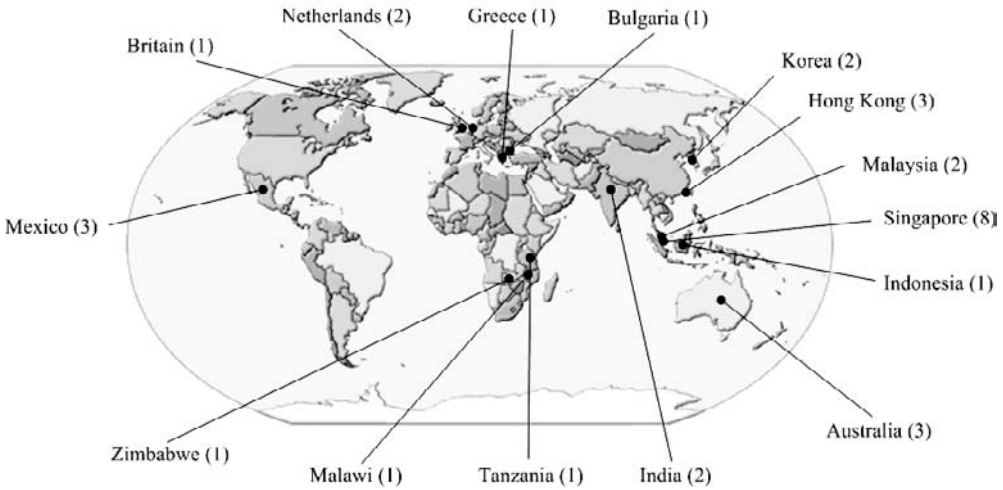
Cultural Dimension	Definition	Examples
Power Distance	***Power distance*** is the extent to which the less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally.	**Low:** U.S. and Canada **High:** Japan and Singapore
Individualism and Collectivism	***Individualism*** describes cultures in which the ties between individuals are loose. ***Collectivism*** describes cultures in which people are integrated into strong, cohesive groups that protect individuals in exchange for unquestioning loyalty.	**Individualistic:** U.S., Australia, and Great Britain **Collectivistic:** Singapore, Hong Kong, and Mexico
Masculinity-Femininity	***Masculinity*** pertains to cultures in which social gender roles are clearly distinct. ***Femininity*** describes cultures in which social gender roles overlap.	**Masculinity:** Japan, Austria, and Italy **Femininity:** Sweden, Norway, and The Netherlands
Uncertainty Avoidance (UAI)	***Uncertainty avoidance*** is the extent to which the members of a culture feel threatened by uncertain or unknown situations.	**Low:** Singapore, Jamaica, and Denmark **High:** Greece, Portugal, and Japan
Confucian Dynamism	***Confucian dynamism*** denotes the time orientation of a culture, defined as a continuum with long-term and short-term orientations as its two poles.	**Long-term:** China and Japan **Short-term:** U.S. and Canada

(Leidner & Kayworth, 2006). Although many culture theories have been developed (Triandis, 1972; Hofstede, 1984; Hall & Hall, 1990), most CSW studies that focus on the impacts of culture rely on Hofstede's (1991) model of national culture, which was developed based on a large body of survey data about the values held by people in more than 50 countries. The participants in Hofstede's study were employees in local subsidiaries of IBM. His model defines five generalizable cultural dimensions based on value orientations that are considered important and are shared across cultures: power distance, individualism and collectivism, masculinity-femininity, uncertainty avoidance (UAI), and Confucian dynamism. Table 2 summarizes these cultural dimensions.

There have been several debates about and criticisms of Hofstede's cultural model. For example, the model is criticized on the grounds that it is rather crude and simplistic, that a survey may not be a suitable way of measuring cultural differences, and that a study of the subsidiaries of one company may not provide information about entire national cultures (Walsham, 2002). Despite these claims, Hofstede's model has been widely validated by theoretical and empirical evidence (Usunier, 1998). Myers and Tan (2002) examined 36 studies on culture in the IS literature. Among them, 24 used Hofstede's dimensions. Although Hofstede's model has various limitations, the general cultural constructs or dimensions appear to be useful for explaining potential differences in culture regarding the use of technology (Vogel, Davison, & Shroff, 2001a). In our literature review, almost every empirical study adopted some of the cultural dimensions of Hofstede's model.

All of the studies we reviewed involved at least one culture other than U.S. culture, as summarized in Appendix A. Figure 2 graphically depicts the non-U.S. countries examined in those studies. As shown, the majority of existing cultural research on CSW involves Asian and European countries, the U.S., and Australia. Only one study involves Africa (De Vreede et al., 1999), and none focuses on Central or South America. The lack of research on Africa, South America, and Central America may be attributable to the relatively rare adoption and use of CSW in those regions due to economic, political, and technological barriers.

Figure 2. Countries examined by existing studies



So far, IS researchers have not developed models or theories for the cultural effects on CSW-supported group work. Some of the empirical studies we surveyed failed entirely to base their hypotheses on any previous cultural model (e.g., Aiken, Hwang, Magalhaes, & Jeanette, 1993; Daily, Whatley, Ash, & Steiner, 1996; Daily & Steiner, 1998).

Although Hofstede's model is the dominant cultural model used in existing IS studies, the individualism-collectivism and power-distance dimensions of his model have received more attention in IS literature than have other dimensions (Leidner & Kayworth, 2006). These two dimensions delineate stark differences between cultures and can be cleanly operationalized for observations between cultures in a controlled setting. Watson et al. (1994) assert that individualistic groups are more likely to embrace the social structures of CSW because those structures conform with their individualistic culture; collectivistic groups are less likely to adopt CSW because the social structures of CSW conflict with their collectivistic nature. Triandis (1989) suggests that researchers develop hypotheses concerning the relationship between culture and social behavior based on the individualism-collectivism dimension. Conversely, the cultural dimensions of masculinity-femininity, UAI, and Confucian dynamism in Hofstede's cultural model have been rarely adopted in cross-cultural CSW research for various reasons. UAI, for example, can only explain Western cultures because a cultural bias toward "truth" is not as respected in Eastern cultures (Hofstede, 1991). Although various cultures examined in a study may differ in several cultural dimensions, the dependent variable(s) may be less influenced by one dimension than another. For example, in a study that examines the effect of majority influence in culturally heterogeneous and/or homogeneous groups, if student subjects with equivalent status are used, then the variance in the individualism-collectivism dimension would have a much larger impact on majority influence than would the difference in power distance. Power distance should, of course, be considered only when there is a hierarchical or non-egalitarian structure among participants. Therefore, while doing cross-culture research, researchers should identify which cultural dimensions would most likely play a role in the treatment of the IT artifact.

Technology Support

Cultural studies on CSW often use technology support as an IV, concentrating on how group processes and outcomes differ with and without CSW support (Ho, Raman, & Watson, 1989; Watson et al., 1994; Daily et al., 1996; El-Shinnawy & Vinze, 1997; Mejias, Vogel, & Shepherd, 1997b; Daily & Steiner, 1998; Tan, Wei, Watson, Clapper, & McLean, 1998a; Quaddus & Tung, 2002; Tung & Quaddus, 2002; Reinig & Mejias, 2003). Those studies have mainly compared three work modes: (1) traditional face-to-face groups without CSW support; (2) face-to-face (FtF), synchronous groups supported by CSW; and (3) distributed, anonymous groups supported by CSW. To our best knowledge, very few CSW studies have examined culture in distributed, asynchronous, and CSW-supported groups, distributed and identified groups, or distributed, culturally heterogeneous groups, mainly because of the great technical and logistic challenges in carrying out empirical studies in those environments.

Different communication media provide different levels of information cues (Daft & Lengel, 1986), social pressure, and immediacy of feedback (i.e., synchronous vs. asynchronous communication). For example, in traditional face-to-face communication, communication partners see and hear each other and have to respond to others immediately, while in a distributed setting, communication partners will have fewer cues but more time for preparing and rehearsing their responses. In addition, direct confrontation between group members which often occurs in

the face-to-face environment is reduced via the use of CSW. Given previous research on the topic, we argue that the cultural influence on group process may vary according to different amounts of social presence afforded by various types of communication media.

Social presence is "the degree to which a medium facilitates awareness of the other person and interpersonal relationships during the interaction" (Fulk, Schmitz, & Steinfield, 1990). According to social presence theory (Short, Williams, & Christie, 1976; Miranda & Saunders, 2003), face-to-face communication typically offers the highest level of social presence, while CSW-supported communication is typically low in social presence. In a study conducted by Zhang, Lowry, Zhou, and Fu (2007), the impact of culture on majority influence was manifested differently in three various communication settings. Because different communication work modes affect the degree to which culture impacts communication, work modes should be examined separately in culture studies.

Several studies use the anonymity feature of CSW as an IV to examine its effect in different cultures (Atkinson & Pervan, 1998; Mejias et al., 1997b). Anonymity works better in an individualistic culture than in a collectivistic culture, because individualistic cultures encourage free exchange of ideas, egalitarian decisions, and creativity (El-Shinnawy & Vinze, 1997; Tung & Quaddus, 2002). Collectivists are accustomed to conforming and restricting their ideas by following the group majority or the group leader's preferences—even when using CSW. Thus, the use of the anonymity feature may induce more conservative decision making and reduce participation equity in a collectivistic culture.

Task Type

Groups primarily exist to complete collaborative tasks, and the choice of group tasks in collaboration research is critical because it may account for 50% of total group performance (Poole, Seibold, & McPhee, 1985).

Most CSW studies use McGrath's task circumplex (1984). This topology proposes four general types of processes: generating alternatives, choosing alternatives, negotiating, and

Table 3. McGrath's task circumplex

Task Category	Task Type	Task Description	Used in Previous Studies
Generate	Type 1: Planning tasks	Generating action-oriented plans (e.g., problem-solving tasks)	None
	Type 2: Creativity tasks	Generating ideas (e.g., brainstorming tasks and idea generation)	(Aiken et al., 1993; Aiken, Kim, Hwang, & Lu, 1995; Atkinson & Pervan, 1998; Daily & Steiner, 1998; Daily et al., 1996; De Vreede et al., 1999; Mejias, Shepherd, Vogel, & Lazaneo, 1997a; Mejias, Vogel, & Shepherd, 1997b; Quaddus & Tung, 2002; Tung & Quaddus, 2002)

continued on following page

Table 3. continued

Task Category	Task Type	Task Description	Used in Previous Studies
Choose	Type 3: Intellective tasks	Solving problems with a correct answer; such tasks have a demonstrable right answer, and the group task is to invent/ select/compute that correct answer	(Tan et al., 1998a; Vogel et al., 2001a, 2001b)
	Type 4: Decision-making tasks or preference tasks	Dealing with tasks for which the preferred or agreed upon answer is the correct one; tasks for which a demonstrably correct answer does not exist and for which the group's task is to select, by some consensus, a preferred alternative (e.g., tasks used in choice shift, and polarization studies; mock juries)	(De Vreede et al., 1999; El-Shinnawy & Vinze, 1997; Griffith, 1998; Ho, Raman, & Watson, 1989; Morales, Moriera, & Vogel, 1995; Quaddus & Tung, 2002; Reinig & Mejias, 2003; Souren, Priya, Imad, & Mykytyn, 2004; Tan et al., 1998a; Tan, Wei, Watson, & Walczuch, 1998b; Tung & Quaddus, 2002; Watson et al., 1994)
Negotiate	Type 5: Cognitive-conflict tasks	Resolving conflicts of viewpoint; tasks where members of the group do not just have different preferences but have systematically different preference structures (e.g., some jury tasks)	None
	Type 6: Mixed-motive tasks (resolving conflicts of interest)	Resolving conflicts of motive-interest (e.g., negotiation and bargaining tasks, mixed-motive dilemma tasks)	None
Execute	Type 7: Contests/battles/ competitive tasks	Resolving conflicts of power; competing for victory (e.g., wars, winner-take-all conflicts, competitive sports)	None
	Type 8: Performances/ psycho-motor tasks	Executing performance tasks; psychomotor tasks performed against objective or absolute standards of excellence (e.g., many physical tasks)	None

executing, which are further divided into eight types of tasks (see Table 3).

As shown in Table 3, creativity and preference tasks are the most popular ones selected, followed by intellectual tasks. The other five task types have never been used in previous research. Among the reviewed studies, four used task type as an IV (Tan et al., 1998a, 1998b; Quaddus & Tung,

2002; Tung & Quaddus, 2002). The preliminary findings suggest that group members with diverse cultures behave differently while performing different tasks.

It is interesting to note that although tasks in *negotiate* and *execute* categories are common in real life, they have never been used in previous studies. We speculate that because most participants in those studies were university students, they lacked sufficient knowledge and experience with such tasks. As a result, those types of tasks may be inappropriate for university students, but should be used in field studies.

Conflict Management Style

Conflict refers to situations in which group members believe their needs cannot be mutually satisfied, reconciled, or integrated. Conflict among group members can emerge for various reasons, including a group's cultural composition (Reinig & Mejias, 2003). Different ways of handling internal group conflict are termed "conflict management styles" (Souren et al., 2004). They include avoidance, accommodation, competition, collaboration, and compromise (Rahim, 1983).

Conflict management styles often vary by culture. Hofstede's dimensions of power distance, individualism-collectivism, and UAI can help explain how conflict is managed differently in different cultures. First, in low-power-distance cultures, people believe in the legitimate use of power and equal rights; when making group decisions, members' views are more likely to be judged according to their merits rather than by the status of their contributors. In high-power-distance cultures, low-status individuals are usually dependent on and respectful of high-status individuals; they are more likely to accept the views of higher-status members. Therefore, we propose that in cultures with higher power distance (e.g., Singapore, Japan, and China), conflicts between low-status and high-status members in a group are less likely to occur, and even if they do occur, they will be more easily resolved than those between members of low-power-distance cultures.

Second, members of individualistic cultures are expected to look after themselves and their immediate families; speaking one's mind is a virtue; self-actualization and individual achievements are valued. Thus, individualists tend to resolve conflict via open and direct communication. In collectivistic groups, relationships prevail over tasks. Such groups tend to employ indirect means for conflict resolution since the maintenance of harmony and the ability to forge consensus are highly regarded. As a result, collectivists are more inclined to reach consensus and resolve conflicts by following majority views than are individualists (Tan et al., 1998a; Zhang et al., 2007).

Third, low-UAI cultures are characterized by people who are comfortable in ambiguous situations, and tolerant of dissent and deviance (Hofstede, 2001; Tan et al., 1995). In high-UAI cultures, people fear ambiguous situations; groups are more likely to suppress deviant ideas and behavior and to resist innovation. As a result, conflicts are more easily resolved in high-UAI groups.

Some studies have shown how culture affects conflict management styles. Samarah et al. (2003) investigated whether the cultural heterogeneity of a group influences the styles of conflict management adopted by group members. Their study used a fuzzy task (Campbell, 1988) to examine the behavior of U.S. homogeneous, Indian homogeneous, and U.S.-Indian culturally heterogeneous groups. Results showed that group heterogeneity, as well as the interaction between collaborative conflict management style and cultural diversity, had positive moderating effects on perceived decision quality and the degree of group management. Another study (Souren et al., 2004) used conflict management style as an IV to examine its effect on group performance using homogeneous and heterogeneous groups consisting of U.S. and Indian members. The study found that the culturally heterogeneous groups had a lower level of collaborative conflict man-

agement style than did homogeneous groups. In addition, the collaborative conflict management style positively influenced user satisfaction with the decision-making process, perceived decision quality, and perceived participation.

Dependent Variables

We discuss DVs in two categories: (1) group *process* variables that assess group process gains or losses, and (2) group *outcome* variables that evaluate the final results of group interaction.

Process: Group Participation Equity

Group participation equity is defined as equal and effective group participation (Steiner, 1972). Barriers to group participation equity often result from cultural and social norms (Steiner, 1972; Hofstede, 1984; Robichaux & Cooper, 1998). Because CSW encourages participation through anonymity and simultaneity, participation equality is often greater in groups supported by CSW than those without support (Reinig & Mejias, 2003).

Mejias et al. (1997b) compared group productivity levels and perceived participation equity in U.S. (individualistic) and Mexican (collectivistic) groups. U.S. groups generated more comments per participant and more unique ideas per group than their Mexican counterparts, even when participants were not anonymous; U.S. groups reported no differences in perceived participation equity between CSW and face-to-face groups, whereas Mexican CSW groups reported higher perceived participation equity than Mexican face-to-face, non-software-supported groups did; Mexican CSW groups also perceived higher levels of participation equity than their U.S. counterparts did. One possible explanation for these results is that CSW might encourage equal participation by reducing the dominance of some members, particularly in collectivistic groups.

Researchers also compare the perceived levels of equal participation between U.S. (individualistic) groups and Asian (collectivistic) groups. In Ho et al. (1989), the use of CSW led to more equal member influence in both U.S. groups and Singaporean groups. The anonymity feature of a group decision support system allowed dominant members in Singaporean groups to openly express negative opinions about other group members' contributions, a behavior that would otherwise be culturally unacceptable. Reinig and Mejias (2003) reported that participants from both the United States and Hong Kong supported by CSW perceived less dominance than did traditional face-to-face participants. Hong Kong participants reported less dominance in both face-to-face and CSW treatments than U.S. participants reported.

These findings conform to the view that the use of CSW, by alleviating status effect and avoiding direct confrontation, should encourage equal participation and reduce individual dominance. In the American culture, openness and directness in communication are often considered a virtue. In contrast, people from Singapore or Hong Kong (who are of high power distance and low individualism) tend to be modest and nonconfrontational with others through direct, open communication. On the one hand, the use of CSW can encourage participation particularly from those low-status group members from cultures with high power distance and low individualism. On the other hand, high-status members in such cultures may be unhappy because they feel they lose the power and influence over other group members because of CSW, which poses challenges to their authority and changes traditional social norms. As a result, those high-status members may be uncomfortable with or even resist the adoption and use of CSW in support of group tasks.

Process: Production Blocking

Production blocking refers to productivity loss in brainstorming groups when group members must take turns to express their ideas. This interferes

with idea generation in two possible ways. First, it disrupts the generation of ideas when delays are relatively long. Second, it reduces the flexibility of idea generation when delays are unpredictable. Because CSW enables parallel input from group members, it can significantly reduce production blocking that is common in face-to-face groups without CSW support.

Three studies have explicitly used production blocking as a DV, either examining whether the use of CSW reduces production blocking or comparing levels of production blocking between Asian and U.S. groups (Aiken et al., 1993, 1995; Reinig & Mejias, 2003). They all found that CSW reduced production blocking in both U.S. and Asian groups. Non-Western participants supported by CSW often experience significantly more production blocking than Western users of CSW did (Chung & Adams, 1997; Reinig & Mejias, 2003). This is likely because collectivism influences CSW users to contribute in a slower, more reserved manner. For example, in the study conducted by Reinig and Mejias (2003), the U.S. and Hong Kong participants were asked to assume the role of members of a "Community Resource Allocation Task Force" and rank nine projects that would be most deserving of money donated by local corporations. The perceived production blocking was measured by three survey questions. GSS participants from both the U.S. and Hong Kong reported less production blocking than those in non-GSS groups reported, indicating that the features of anonymity and parallel communication were successful in reducing process losses. In addition, Hong Kong participants reported more production blocking across both face-to-face and GSS treatments than did U.S. participants, which might be attributable to their cultural difference as collectivists—Hong Kong participants had a higher tendency to be modest and listen to others first, causing delays in expressing their ideas and increasing production blocking.

Process: Group Polarization

Group polarization is the tendency of individuals in a group to engage in more extreme decisions than their original individual inclinations (Moscovici & Zavalloni, 1969). CSW may alter group polarization because it allows people to participate in group discussion with reduced social presence in comparison to face-to-face verbal communication. To date, only one study has examined the impact of technology and culture on group polarization (El-Shinnawy & Vinze, 1997). That study used persuasive arguments theory (PAT) (Pruitt, 1971) to study group behavior in a CMC setting and in a face-to-face, non-CMC setting that included two cultures—the U.S. and Singaporean. The power-distance and individualism-collectivism dimensions of Hofstede's model were used as the theoretical basis. It was found that Singaporean groups polarized in a riskier direction, whereas U.S. groups polarized in a more cautious direction.

Process: Status Effects

Status effects occur when high-status members negatively dominate or marginalize the contributions of low-status members (Berger, Fisek, Norman, & Zelditch, 1977). Cultures that emphasize the status or power differences among members can increase evaluation apprehension and conformance pressure. Cultural norms dictate that critical remarks should be avoided in order to steer clear of conflict (Robichaux & Cooper, 1998). In high-power-distance cultures, status differences among individuals are prominent; individuals with higher status are powerful and exude excessive influence during group communication; people strive to maintain harmony; and relationship concerns tend to prevail over task concerns (Earley, 1994). Therefore, status influence is likely to be strong in high-power-distance cultures. In low-power-distance cultures,

status differences among individuals are less significant and people believe in equal rights, and high-status individuals do not exercise excessive influence during group communication. Hence, status influence is likely weak.

Only one cultural study on CSW has examined status effects (Tan et al., 1998b). That study indicated that the power-distance and individualism-collectivism dimensions of Hofstede's model were relevant to status effects. It examined status influence, sustained influence, and perceived influence. *Status influence* is the extent to which low-status individuals defer to the opinions of high-status individuals during group communication. *Sustained influence* is the amount of status influence remaining after group communication when high-status individuals are no longer present. *Perceived influence* is the amount of status influence that low-status individuals perceive during group communication. The study used Singaporean and U.S. groups and two different tasks (intellective vs. preference tasks). Results showed that the task type and communication medium (face-to-face verbal communication vs. CMC) had significant main effect on both status influence and perceived influence, whereas national culture had nearly significant main effect. National culture, task type, and communication medium had significant effects on sustained influence. Status influence and sustained influence were higher in preference task groups than in intellectual task groups. CMC was able to reduce status effects in both U.S. and Singaporean CSW groups.

Process: Majority Influence

Majority influence is the attempt by a majority of members in a group to impose their common position upon group dissenters during a decision-making process (Levine & Russo, 1987). Individualism-collectivism in Hofstede's model is a pertinent factor to be considered in cultural research on CSW and majority influence. In individualistic cultures, when people disagree with a majority position, they are likely to contradict it. In collectivistic cultures, people are integrated into strongly cohesive groups and base their self-understanding on the reactions of others. When CSW replaces verbal and visual communication, group majorities may exercise less normative influence on minorities (Ridgeway, Berger, & Smith, 1985). Several empirical studies conducted in North America have examined the effects of CSW on majority influence (e.g., Zigurs, Poole, & DeSanctis, 1988; Connolly, Jessup, & Valacich, 1990; Jessup, Connolly, & Galegher, 1990; Clapper, McLean, & Watson, 1991; Gallupe, Bastianutti, & Cooper, 1991). Some argue that minority members are more likely to oppose a majority viewpoint when they use CSW, especially when working anonymously (Dennis, Hilmer, & Taylor, 1998). One possible explanation, according to the Media Richness Theory (MRT) (Daft & Lengel, 1986), is that CSW is a lean medium that results in lower levels of social presence and conformance pressure than experienced in traditional face-to-face communication.

One study investigated majority influence in U.S. groups vs. Singaporean groups using two different tasks in three different communication settings (Tan et al., 1998a). The results showed that the impact of CMC on majority influence was contingent upon national culture. In the U.S. groups, participants challenged the majority position in the CMC settings more often than they did in the face-to-face, unsupported setting. In Singaporean groups, participants using CMC were less willing to challenge the majority position, and majority influence remained unchanged when CMC replaced verbal and visual communication—indicating that CMC may not be able to reduce conformance intention of collectivistic members. The results also showed that the impact of CMC on majority influence was not moderated by the type of group task.

Outcome: Consensus

Consensus refers to the achievement of group solidarity in decision making. Collectivistic cultures are more oriented toward consensus and less tolerant of conflict and discord (Triandis et al., 1994) than individualistic cultures are, which embrace open conflicts.

Research results vary as to the relationship between CSW use and different levels of group consensus in various cultures. In Reinig and Mejias (2003), Hong Kong CSW groups had significantly higher levels of initial consensus than their U.S. counterparts; however, U.S. CSW groups achieved greater change in consensus than Hong Kong groups did. Watson et al. (1994) also reported that Singaporean groups supported by CSW had significantly higher pre-meeting consensus than their U.S. counterparts, but they reported no difference in levels of post-meeting consensus. Mejias et al. (1997b) found that Mexican CSW groups generated higher levels of consensus than U.S. groups did, although no difference existed between Mexican and U.S. CSW groups in the change of consensus levels. Overall, results indicate that collectivistic groups may favor a more defined approach to convergence and agreement in comparison to U.S. groups. Individualists may be more adept at accommodating divergent viewpoints than collectivists are.

Outcome: Group Productivity

CSW can increase group productivity in terms of time spent (Dennis, 1994), idea production (Gallupe, DeSanctis, & Dickson, 1988), and document length (Lowry & Nunamaker, 2003). A few cultural studies on CSW have investigated group productivity in terms of idea generation and reported mixed results. In Atkinson and Pervan (1998), participants from high-power-distance cultures who used the anonymity feature of CSW derived a higher level of productivity than those from low-power-distance cultures (i.e., Malaysia > Indonesia > Singapore > Australia). Conversely, Mejias et al. (1997b) compared group productivity levels between U.S. and Mexican groups and found that culture had a significant impact on group productivity. U.S. groups and Mexican groups supported by CSW (both anonymous and identified) generated more comments per participant than did face-to-face groups without CSW. Regardless of CSW, U.S. groups generated more comments on average per individual than Mexican groups did; U.S. groups also produced more unique ideas per group than Mexican groups did in face-to-face settings without CSW and in identified settings supported by CSW. Another study (Quaddus & Tung, 2002) supported these results, with Australian groups (low power distance) having higher productivity than Singaporean groups (high power distance).

Daily et al. (1996, 1998) compared the productivity of culturally homogeneous and culturally heterogeneous groups. Among groups using CSW, culturally heterogeneous groups produced a significantly higher number of unique ideas than culturally homogeneous groups did. A possible explanation for this finding is that CSW may aid in conflict management and diffuse intergroup conflict in culturally diverse groups, thus increasing productivity. According to Triandis, Hall, and Ewen (1965), when a culturally heterogeneous group employs a process to reduce stress and communication problems, it becomes more creative than a homogeneous group.

Outcome: Quality of Group Outcome

CSW can increase the quality of group outcome by providing group members with equal opportunities to contribute instantaneously and anonymously (George, Easton, Nunamaker, & Northcraft, 1990). Three cultural studies investigated the effects of CSW on the decision quality but reported contrasting findings. Daily et al. (1996) found no significant differences in the quality of solutions produced by culturally

homogenous and culturally heterogeneous groups supported by CSW; Samarah et al. (2003) and Souren et al. (2004), however, reported that the interaction of collaborative conflict management style and cultural diversity of groups supported by CSW had a significant effect on perceived decision quality.

Outcome: Satisfaction

User satisfaction reflects perceived individual goal attainment, as well as perceived future gains (Briggs, De Vreede, & Reinig, 2003). Results of traditional CSW studies on user-perceived satisfaction are mixed, with some showing higher satisfaction (George et al., 1990) and others lower (Gallupe et al., 1988). Because cultures may differ in the nature of individual goals, results of user satisfaction in previous studies are also mixed. Some studies find that Western users of CSW have higher levels of satisfaction than non-Western users (Reinig & Mejias, 2003). Yet more studies report that CSW evokes feelings of comfort and satisfaction among participants from non-Western cultures (Morales et al., 1995; Mejias et al., 1997b; De Vreede et al., 1999). For example, Mejias et al. (1997b) reported that Mexican groups supported by CSW perceived higher levels of satisfaction than their U.S. counterparts did. This difference might be caused by the interactive effect between the culture factor and experimental treatment factors.

The findings discussed above suggest that some national cultures may be susceptible to different types of group dysfunctions than others and that CSW may be used to neutralize those negative influences.

Culture as a Moderator

Although the majority of previous studies considered culture as an independent variable, culture may also be a moderator of other factors (Tan et al., 1998a; Samarah et al., 2003). For example, the effect of communication media may be moderated by culture (Tan et al., 1998a). Thus, if we assume that collectivistic cultures value relationship building and openness, and that distributed communication tends to decrease satisfaction in general groups, then it is possible that the degree of collectivism would moderate satisfaction in distributed groups. Other moderation relationships are possible and remain largely unexplored.

DISCUSSION: LIMITATIONS, EXTENSIONS, AND NEW OPPORTUNITIES

In the previous section, we reviewed the existing literature and analyzed various issues regarding cultural differences and their impact in group settings supported by CSW. This section seeks to highlight major limitations of current research and provides some insights into future research opportunities and methods.

Existing research has barely begun to address fundamental research questions. More empirical research needs to be conducted to fully examine whether and how the effective use of CSW is contingent upon cultural norms. Since culture is a prominent factor in general IT adoption (Hasan & Ditsa, 1999), it also likely affects the adoption and use of CSW. Research suggests that groups are more likely to adopt a technology if their own values match or fit the values embedded within the technology or those associated with its development (Leidner & Kayworth, 2006). One might thus assume that the use of CSW would be more suitable in a collectivistic culture than in an individualistic culture, but this is not necessarily true (Davison, 1996). In collectivistic cultures, the use of CSW that incorporates anonymous communication may have dysfunctional effects (Watson et al., 1994). Further, in collectivistic cultures in which public dissent is discouraged and early consensus is encouraged, members have a social obligation to conform to rules that place

national or group interests higher than individual interests. Although the structure and anonymity of CSW can facilitate expression of conflict in North American groups, they may not help collectivistic groups because CSW forces group members to be direct and open. This feature is undesirable in collectivistic cultures in which people prefer to express disagreement indirectly in order to preserve group harmony. Therefore, the degree of fit between a group's social values/norms and the values embedded in the CSW is an important construct for studying the relationship between cultural values and the adoption of CSW.

To guide future empirical research, we highlight seven major limitations identified in existing research and discuss potential future research opportunities.

Failing to Pass the "Absurdity Test"

Related literature clearly shows that culture matters but does not fully and consistently explain and predict *why* culture matters. Some authors simply note the observed differences among subjects from different countries and label them as "cultural differences," without linking those differences to specific cultural beliefs or values and/or without having any cultural theory as a theoretical foundation (Gallivan & Srite, 2005). Failing to answer "why" may be the greatest limitation of existing research and the greatest opportunity for future research.

The strongest theoretical argument against existing research is that it appears to fail the "absurdity test" for developing a theory. In positivist and postpositivist inquiry, the aim of the empirical researchers is to study effects rather than causes of effects. To develop theories, researchers should check for logical absurdity by examining whether an increase or decrease in a cause logically results in some kind of corresponding increase or decrease in the phenomenon of interest (i.e., effect) (Briggs & Dean, 2005). This simple test checks whether IVs are expressed in a manner that logically gives the possibility to the rise of DVs. For example, "more culture" does not logically lead to "more satisfaction" because culture is a construct too abstract to give logical rise to satisfaction. Conversely, a "higher degree of collectivism" could logically lead to more satisfaction. Hence, researchers can benefit from being clearer in defining the phenomenon of interest they are studying. To do so, researchers should develop generalizable theories and research models to explain and predict the chosen phenomenon and define constructs that operationalize logically to pass the absurdity test.

In order to understand the "why" behind relationships between variables, researchers in the field of computer-supported multicultural collaboration need to more concretely define the phenomenon of interest. There are two major theoretical weaknesses in some existing research. First, rather than focusing on one or two major phenomena of interest, several studies examine a cocktail of outcomes. The problem with the cocktail approach to theoretical outcomes is that it tends to place theoretical explanations and predictions on shaky theoretical grounds by making empirical studies look more like "fishing expeditions" for statistical significance. The cocktail approach leads to at least one violation of the absurdity test as researchers essentially propose something like: "More CSW use in cross-cultural groups leads to more productivity, more outcome satisfaction, more process satisfaction, more efficiency, and more quality of decision." Although this approach allows researchers to operationalize and hypothesize specific measures, it is theoretically flawed because each phenomenon of interest should have a theoretically sound explanation and prediction as to what causes it. Deep theoretical investigations into common phenomena such as productivity, satisfaction, and quality demonstrate that entirely different mechanisms typically exist for explaining and predicting their existence.

Thus, mixing disparate effects often creates theoretical hodgepodge. We need to develop good theories that can succinctly explain and predict the phenomenon of interest affected by culture in collaboration environments.

Second, although CSW is an appropriate operationalization of a particular technology to be used as an IV, a specific technology should not be used as a construct in a theoretical proposition. Accordingly, researchers need to break down specific theoretical constructs of CSW that give rise to the improvement of a group's results; otherwise, the developed theories will be technology dependent and not generalizable. For example, social presence is an underlying construct that has been proposed as a theoretical explanation for superior or inferior technological outcomes. Social presence is constant and potentially generalizable in effects, regardless of specific technologies that will come and go. Given appropriate theoretical explanations and predictions, a study could pass the absurdity test by following a proposition pattern such as: "A higher level of social presence leads to higher satisfaction with group outcome." An IV can then be operationalized for specific CSW, such as various versions of GSS or CMC products. Defining the phenomenon of interest and using a generalizable framework will help build the body of knowledge that supports the "why" behind culture, collaboration, and technology support.

Our theoretical criticisms highlight many promising opportunities in this line of research. First, researchers need to clearly demonstrate that certain constructs, which are known to instantiate differently across cultures, can give rise to differences in certain outcomes that may be important. For example, people are motivated by status attainment in most cultures, but the means of attaining and symbolizing status may differ by culture. Hence, researchers should develop clear taxonomies, conduct studies on particular constructs that are known to manifest themselves differently across cultures, and explain why. For instance, we intuitively know that software developers who are Hispanic Baptists living in Texas are culturally different from those in India who are Hindu. Those differences can create strong team management challenges for a global software engineering firm. Yet it is atheoretical and not generalizable to create a pseudo-theoretical proposition such as: "Baptists behave in a certain way, whereas Hindus behave in another way."

Singular Focus on National Culture

The logic that "Americans will behave in a certain way while citizens of another country X will behave in another way" is the dominant paradigm in prior research. Straub, Loch, Evaristo, Karahanna, and Srite (2002) and Myers and Tan (2002) highlight and criticize the focus of previous research that leans on nationalistic definitions of culture. They assert that with globalization, culture aligns itself less with the definition of a nation-state because many countries are melting pots of various cultures. In addition, culture may not be static. It becomes increasingly difficult for any cultural group to remain isolated and uninfluenced by other cultures. Over time, societies may experience attitude changes towards gender, environment, race, family life, and religion, although these changes would rarely happen as fast as technological changes. Thus, defining a culture by nation may be too simplistic. These critics also argue that in empirical research that involves culture, researchers should identify individualistic or collectivistic individuals rather than preassigning participants to categories based solely on the country in which they live.

Cultures are generally stable in the short term, but cultural change may occur because of immigration, the influence of global media, and other social and technological innovations (Gallivan & Srite, 2005). We agree that researchers may adopt a more dynamic view of culture—one that sees

culture as contested, temporal, and emergent. For example, most prior studies simply followed the findings reported in Hofstede's study to justify their cultural categorizations, without further examination of the cultural differences among participants in the experiments. Watson et al. (1994) and Tan et al. (1998) assumed, based on Hofstede's original study, that the subjects recruited in Singapore were collectivists. We suggest that when a researcher uses national culture as an IV manipulation, it is important to validate the cultural characteristics of recruited participants to ensure that expected cultural differences exist. There should be a manipulation check of participants' cultural characteristics.

Another challenge in IS-culture research is the assumption that all individuals from a specific national culture will behave consistently based on the group's cultural values. This does not take into account the possibility of individual differences that may lead to different behavioral outcomes (Leidner & Kayworth, 2006). This indicates that researchers may need to consider individual differences (e.g., disposition) as a factor when studying the impacts of culture on group processes and outcomes.

Limited Sampling

Because of difficulty in recruiting participants with different cultural backgrounds, many studies have problems of small sample size. It is common in previous studies to have less than six groups in each experimental condition (e.g., Aiken et al., 1993, 1995; Daily et al., 1996; Walther, 1997; Atkinson & Pervan, 1998; Daily & Steiner, 1998; Quaddus & Tung, 2002; Souren et al., 2004). Such small sample size, though understandable given the challenging nature of conducting this type of research, may significantly weaken the validity and generalizability of findings. Small sample size is also the likely cause of some of the mixed findings.

Lack of Research on Group Heterogeneity

With globalization, more tasks are being accomplished by distributed teams consisting of members from varied cultural backgrounds, making it imperative to examine such groups. Thus, one area in need of expanded research is culture's influence on distributed, culturally diverse teams. More research needs to be conducted to examine how diverse team member values complement or contradict each other (Leidner & Kayworth, 2006). Specifically, it would be useful to investigate how group processes and outcomes can be improved in both culturally homogeneous and heterogeneous groups supported by CSW within a broader context of diversity management. Debate exists over whether cultural diversity improves or suppresses group performance (Anderson & Hiltz, 2001). Very few empirical studies have examined how to improve the dynamics associated with a culturally diverse workforce. In such groups, cultural diversity may cause difficulties in reaching an agreement; as a result, group harmony and cohesion might suffer, resulting in psychological pressures such as discomfort and weak feelings of belonging to the group (Samarah et al., 2003). These considerations become more complicated when considering diversity management in a broader sphere that includes nationality, expatriatism, race, ethnicity, gender, and religion.

Several research issues related to culturally heterogeneous groups are worth investigating in future research. One is the potential difference in the level of status effect and majority influence (two of the most common phenomena in group work) on group members from different cultures, which can be reflected by their behavior during a group task. For example, according to the power-distance dimension of Hofstede's model, it can be assumed that in a culture with high power distance, low-status group members may easily follow the opinions of high-status members, even

though they disagree. However, in a culture with low power distance, when there is a disagreement between low- and high-status group members, low-status members are less likely to accept the views of higher-status members if they disagree with them. Will this truly happen? Furthermore, would group members from different cultures behave differently under status effect and majority influence in face-to-face and distributed communication environments? Will the use of CSW reduce (or increase) such influences? Will the individualistic members dominate in a group task? How can managers encourage equal participation in culturally heterogeneous groups? These are all practical and interesting questions to be answered.

Language barriers could significantly prevent team members who speak different native languages from communicating with each other effectively. The inferior capability for communication due to language problems could lead to misunderstandings and less participation. Therefore, selecting appropriate participants for cross-cultural studies that examine culturally heterogeneous groups is crucial. Researchers must ensure that all team members in a culturally heterogeneous group can communicate via a common language (e.g., English) well enough. Some studies, for example, have used foreign students who are currently studying in the U.S. and can communicate in English well enough to form culturally heterogeneous groups with U.S. students (Setlock, Fussell, & Neuwirth, 2004). However, researchers should be cautious and perform manipulation checks on participants' cultural dimensions to make sure that the cultural norms of participants from foreign countries have not dramatically changed.

Too Much Focus on Face-to-Face Groups

Although work mode is one of the major IVs in previous research, participants in most studies worked only in face-to-face mode. Future studies should extend to other work modes such as distributed and asynchronous working environments. According to social presence theory, a communication medium (e.g., FtF communication) that provides more social cues will generate a higher level of social presence, thus leading to stronger social pressure and normative influence on individual group members. Such social pressure may have more impact on group members from cultures characterized by high power distance and low individualism than on those from a culture characterized by low power distance and high individualism (Zhang et al., 2007). By contrast, distributed communication supported by CSW offers fewer social cues. As a result, the corresponding social pressure and normative influence on group members are reduced, leading to potentially different behavior of group members when compared to the FtF work mode. We argue that findings in the FtF environment may not be applicable to a distributed environment. So far, only a few studies examined the effects of culture in distributed groups (Montoya-Weiss, Massey, & Song, 2001; Vogel et al., 2001a, 2001b; Walther, 1997). However, the findings about distributed work in general may provide some theoretical and empirical foundation for theory development and experimental design for research that explores the relationship between culture and distributed work.

FtF and distributed communication may be confounded by task type. Media Richness Theory (Daft & Lengel, 1986) suggests that managers can improve performance by matching media characteristics to the needs of organizational information-processing tasks, which are categorized based on uncertainty and equivocation. When ambiguity and uncertainty in tasks are high (or low), high-richness (or low-richness) media should be used. Thus, an important element of studying culture is examining various work modes with different levels of media richness and the confounding effect of task type. Watson et al.

(1994) suggest that FtF, anonymous meetings are suitable for individualists, while asynchronous and distributed meetings may be more suitable for collectivists. All hypotheses of existing research focus on synchronous communication, which may put time and emotional pressure on participants. It would thus be useful to conduct studies using distributed, asynchronous groups and to examine whether collectivistic group members behave differently when there is less social and time pressure, in contrast to their behavior in FtF, synchronous communication. In such a group, the social and time pressure is probably minimal among all communication media. That being said, studying distributed, asynchronous groups will pose many challenges to the design and execution of the research.

Singular Focus on Small Groups

Almost all studies we reviewed used only small groups (i.e., consisting of three to five members), yet it is well recognized that group size affects group outcomes and the degree of conflict within a group's structure (Steiner, 1972; Valacich, Wheeler, Mennecke, & Wachter, 1995). Small groups are more likely to resolve opinion differences, whereas in larger groups consensus is more difficult to achieve (Hare, 1981). In traditional FtF groups without CSW support, increasing group size can significantly increase process losses (Bouchard & Hare, 1970; Steiner, 1972). CSW has been shown to be effective in support of larger groups (e.g., Gallupe et al., 1992; Dennis, 1994; Valacich et al., 1995). Future research needs to examine cultural effects in groups of different group sizes and to determine whether the group size has a moderating or mediating effect on cultural influence.

Lack of Realism

All of the reviewed previous studies except Morales et al. (1995), De Vreede et al. (1999), and Calhoun, Teng, and Cheon (2002) used students working on hypothetical tasks as opposed to organizational members engaging in real-world tasks. There are a few potential problems in employing lab experiments using student subjects. First, students may not be representative of their culture. Second, some culture values examined, such as power distance, are unlikely to be reflected by participants with equal status. Although the relative homogeneity of student participants prevents a source of uncontrolled variance, their motivation to maximize the quality of group tasks is sometimes questionable. Also, an interaction might exist between types of participants and the effectiveness of technology (Fjermestad & Hiltz, 1999). Likewise, most research is conducted on groups that have no working history. Existing relationships between group members established prior to carrying out group tasks set conditions for a group's interaction (McGrath, 1984; Watson et al., 1994). Future studies should examine the performance of established groups vs. ad hoc groups.

To increase realism, researchers should consider using nonstudent participants performing realistic work tasks. The duration of group tasks may be more varied. Hong, Morris, Chiu, and Benet-Martinez (2000) note that under conditions of heavy time pressure, participants in experimental studies tend to behave in a manner consistent with trait-based cultural norms. Future studies may take a longitudinal focus, with enhanced sensitivity to group characteristics and intergroup dynamics. Since any single group session may not correctly detect long-term effects of CSW, a multilevel perspective in looking at differences between cultures should be adopted. Besides, most prior studies concentrated mainly on one task, limiting the generalizability of research findings. It would be useful to examine the processes and outcomes of cross-cultural groups that deal with different types of tasks.

Finally, we want to point out that compared to general research on CSW, conducting empirical

studies on cultural influence on group processes and outcomes is typically much more challenging and resource consuming, especially when studies involve culturally heterogeneous groups in a distributed setting. One challenge is that researchers may have to deal not only with differences in language (e.g., translating and back-translating related documents used in the experiment) and time zones, but also more complicated logistic issues and experimental design. In addition, the group task(s) and CSW selected for a study have to be equally and unambiguously understood by participants from different cultures. For example, the mock jury task that is commonly used in empirical group studies in the U.S. is not appropriate for participants from China and some other countries where jury systems do not exist.

CONCLUSION

With increasing globalization, CSW is recognized as an important family of technologies supporting collaborative work. This article makes several contributions by providing a common taxonomy of CSW research that examines the impact of culture on group collaboration. Our review and analysis lead to four general conclusions. First, interest in research on cross-cultural collaboration appears to be increasing. However, compared to hundreds of papers published in the field of CSW research, only a limited number of studies have examined the impact of culture. The body of relevant literature is too small to be able to draw any significant and general conclusions. As Ford, Connelly, and Meister (2003) point out, the research has been conducted in a manner that resists building a cumulative tradition. Findings obtained within specific contexts are difficult to generalize. Second, existing studies have investigated only limited types of group outcomes under limited contexts. The effects of cultural differences on many important constructs have yet to be investigated. Third, prior research shows that culture affects group processes and outcomes; however, the findings are still inconsistent. Part of this inconsistency may arise from the research using CSW with different features and design goals, different group tasks, and varying statistical power. Fourth, as an emerging area of research, this line of research lacks comprehensive and empirically validated theories. Researchers should realize that no single solution is universally applicable to all organizational, cultural, or social problems. Many factors can affect the performance of groups supported by CSW. It is imperative that practitioners introducing collaborative technologies into groups with disparate cultures understand cultural differences and their impact. Developing a deeper theoretical understanding of differences in cross-cultural groups will go a long way toward assisting global organizations to manage their groups more effectively. More advanced and validated theories need to be built, and better-designed empirical research needs to be conducted.

APPENDIX A. EXISTING STUDIES ON CULTURE AND COLLABORATIVE SOFTWARE

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Aiken et al. (1993)	Preliminary study comparing North American and Malaysian groups using GSS; had Malaysian groups switch between English and Malay	Laboratory experiment	Creativity task	(IV) language; (DV) production blocking, evaluation apprehension, satisfaction	9 Malaysians speaking Malay; 9 Malaysians speaking English; 16 North Americans speaking English	Not specified	No differences were found between all-North American groups and all-Malaysian groups using GSS in terms of production blocking (all low), evaluation apprehension (all low), and satisfaction (all high).
***Aiken et al. (1995)	Compares the perceived effectiveness and satisfaction of users who use English and Korean versions of the same GSS	Laboratory experiment	Creativity tasks	(IV) language (Korean vs. English); (DV) production blocking, evaluation apprehension, process satisfaction	12 Korean students at University of Mississippi (1 group)	Confucian philosophy in Korean society	No significant differences were found between English and Korean versions of systems in terms of ratings of evaluation apprehension, production blocking, and process satisfaction; GSS reduced negative effects of verbal meetings conducted in Korea.

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Anderson & Hiltz (2001)	Compares groups from the same cultural background with groups from varied cultural backgrounds when they use two different communication media systems	Laboratory experiment	A value-based cognitive conflict (negotiation) task	(IV) communication mode (manual F2F and asynchronous distributed) and group composition (culturally homogeneous and heterogeneous); (DV) adaptation factors and outcome factors	A total of 46 groups: 20 homogeneous (U.S.) manual F2F groups and distributed groups; 26 heterogeneous groups consisting of members from non-U.S. countries	Hofstede's cultural dimensions	Face-to-face culturally heterogeneous (mixed) groups had the highest level of post-meeting consensus, while asynchronous culturally homogeneous (U.S.) groups had the lowest level; no significant differences were found based on cultural composition of the groups.
Atkinson & Pervan (1998)	Exploratory study compares productivity of groups from four national cultures using GroupSystems	Exploratory laboratory experiment (4*2 repeated measure design)	Creativity task (idea generation)	(IV) anonymity and culture; (DV) group productivity	Australia (3 groups), Singapore (1 group), Malaysia (1 group), Indonesia (1 group); most groups included 10 participants	Hofstede's model	Exploratory, low sample study indicates higher power-distance cultures may derive greater productivity from anonymity; all groups from different cultures perceive anonymity as an advantage.

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Calhoun et al. (2002)	Exploratory survey study that examines the use of IT for organizational decision making in Korea and U.S.	Survey	Respondents were asked to consider the use of CMC to send and receive info in decision making	(IV) intensity of IT use for decision making; (DV) 17 decision attributes	65 Korean participants; 77 U.S. participants; all were employees	Hofstede's model	Exploratory results show that decision makers in Korea and the U.S. had different perceptions of the IT use that impacted their decision-making activities.
Daily et al. (1996) Daily & Steiner (1998)	Examines the influence of a GSS on contribution and commitment levels in culturally homogeneous and CC (cross-cultural) decision-making groups Two papers report on the same study's data.	Laboratory experiment (with 2*2 factorial design)	Three creativity tasks	(IV) GSS support (w/ and w/o GSS), cultural diversity; (DV) perceived contribution, number of unique ideas generated, solution quality, commitment, personal influence	Hispanic, Anglo, and others; 12 groups: 6 heterogeneous and 6 homogeneous groups (4 to 5 members per group)	Not specified	Culturally diverse groups outperformed culturally homogeneous groups on the number of ideas generated, but no significant effect on the solution quality. None of the effects of perceived contribution, commitment, or personal influence were found to be significant.

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
De Vreede et al. (1999)	Explores the effective use and acceptance of GSS in a CC context	Field study	Multiple tasks, including preference task and creativity task	(IV) culture; (DV) the use of GSS for decision making	3 countries: Tanzania, Malawi, and Zimbabwe; group sizes varied from 5 to 120 in each project	Hofstede's model and Technology Acceptance Model (TAM)	GSS could lead to significant differences in technology acceptance, use, and diffusion, as well as user satisfaction.
El-Shinnawy & Vinze (1997)	Examines the impact of GSS and culture on the process and outcomes of group decision making (polarization)	Laboratory experiment (2*2 repeated factorial design)	Preference task (the Pentium problem)	(IV) medium (face-to-face vs. CMC) and culture; (DV) polarization, persuasive arguments, novelty, validity	U.S. (24 groups) vs. Singapore (24 groups); 6 members per group	Hofstede's model; Persuasive Arguments Theory (PAT)	Culture and communication medium had significant effects on polarization; neither medium nor culture had main effects on persuasive arguments; the GSS medium had a higher impact on groups in the U.S. than on groups in Singapore.
Griffith (1998)	A cognitive model of CC implementation is tested using GroupSystems and Bulgarian and U.S. students	Laboratory experiment	Preference task (lunar survival problem)	(IV) culture; (DV) innovation, critique, satisfaction	U.S. (16 students) vs. Bulgaria (15 students); data analysis on individual level	Hofstede's model (power distance)	Showed that Bulgarian students may be more likely to challenge authority than their U.S. counterparts. Power distance mediates some effects between culture and satisfaction with GSS.

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Ho, Raman, & Watson (1989)	A GSS study (using SAMM) in Singapore that explores the cultural differences between U.S. and Singapore	Laboratory experiment	Preference task (allocation of funds to 6 projects)	(IV) level of support (3 levels); (DV) post-meeting consensus, influence equality	Singapore: 48 5-person groups' results were compared with the findings in a similar U.S. study (Watson, 1987)	Hofstede'sindividualism-collectivism dimension	Singaporean groups were indirect in the communication and seldom expressed disagreement in an open manner; the anonymity feature led to lower influence equality in Singapore.
Mejias et al. (1997a)	Examines the effect of culture on productivity, consensus level, and participation equity during the use of GSS	Field study with 2*2 within-subjects design	Creativity task	(IV) GSS support, anonymity, national culture; (DV) number of ideas and unique ideas, participation equity, consensus level, satisfaction with decision	U.S. (22 groups) vs. Mexico (20 groups); all were divided into 3 treatments	Hofstede's model (first 4 dimensions)	Significant differences were found in the number of ideas generated, consensus levels, and relative levels of user satisfaction across cultures.
Morales et al. (1995)	Explores the application of GroupSystems in regional development in Mexico and compares with findings from the U.S.	Field study	Preference task (regional development)	Not specified	293 Mexican participants from actual organizations	Hofstede's model	Participants agreed that communication within the group was more effective with the use of the GSS; there was disagreement as to whether FtF communication would be more effective than the use of GSS.

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Niederman (1997)	Exploratory and atheoretical study compares Mexican and U.S. group facilitators using key elements of meeting success and selection of GSS tools	Interview and tape recordings	Not specified	Not specified	U.S. vs. Mexico: 7 Mexican group facilitators, 37 U.S. facilitators	Hofstede's model	Results found no compelling differences between what Mexican and U.S. facilitators consider important measures of meeting success, expected benefits and concerns, tool selection, and so forth.
Quaddus & Tung (2002)	Compares two cultures in the context of group conflict generation and management via a non-networked GSS	Laboratory experiment (2*2 factorial design)	Preference and creativity tasks: (1) resource allocation, (2) strategic planning	(IV) technical support and task; (DV) amount and type of conflict, conflict resolution strategies, productivity	5 groups for both Australia and Singapore (3 or 4 members per group)	Hofstede's model	Higher levels of conflict were generated in Australia than in Singapore; Australians tended to use fewer avoidance strategies and report more productivity than the Singaporeans.
Reinig & Mejias (2003)	Examines the influence of GSS and national culture on group processes, meeting satisfaction, and group outcomes	Laboratory experiment (2*2 factorial design)	Preference task	(IV) GSS support and national culture; (DV) levels of consensus, production blocking, dominance, satisfaction, participation equality	U.S.: 22 groups (11 GSS and 11 FtF groups, with 7 to 8 members per group); Hong Kong: 18 groups (9 GSS and 9 FtF groups, with 7 to 8 members per group)	Hofstede's model and Social Information Processing (SIP) theory	No substantial differences found between cultures: GSS users reported less production blocking and dominance, and lower levels of consensus and satisfaction than did FTF participants across both the U.S. and Hong Kong samples.

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Samarah et al. (2003)	Examines the moderating effect of cultural diversity on the relationship between the conflict management style and group performance	Laboratory experiment	Fuzzy task	(IV) conflict management style; moderator: culture diversity; (DV) degree of agreement, perceived decision quality, participation; moderator: culture	U.S. vs. India: 4 U.S. homogeneous groups; 9 Indian homogeneous groups; 9 heterogeneous groups; 3 to 4 members per group	Hofstede's model	Showed that cultural diversity has a positive moderating effect on the degree of group agreement and perceived decision quality.
Souren et al. (2004)	Investigates the impact of heterogeneity and collaborative conflict management style on the performance of synchronous virtual teams using a Web-based GSS	Laboratory experiment (4*2 factorial design)	Preference task (selecting one option to recommend to a university about adopting a computer-use fee)	(IV) group heterogeneity vs. heterogeneity and conflict management style; (DV) satisfaction, perceived decision quality, perception of participation, group agreement	U.S. vs. India: 15 4-person groups and one 3-person group; U.S. homogeneous groups	Mentions Hofstede's model but not to generate hypothesis or interpret results	Collaborative conflict management style positively impacted satisfaction with the decision-making process, perceived decision quality, and perceived participation of virtual teams; weak evidence links a group's heterogeneity to its collaborative conflict management style.

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Tan et al. (1998a)	Investigates whether CMC can reduce normative influence from majorities in three decision-making settings	Laboratory experiment (3*2*2 factorial design)	(1) An intellectual task; (2) a preference task (mock jury)	(IV) national culture, task type, and communication medium; (DV) the number of rounds taken by the group to reach consensus	U.S. (8 groups in each treatment) vs. Singapore (11 or 12 groups in each treatment); 4-person groups; 6 treatments	Hofstede's model (individualism-collectivism)	Subjects in the unsupported setting took fewer rounds to reach consensus than those in FtF CMC and dispersed CMC; for both tasks, majority influence did not vary with communication medium.
Tan et al. (1998b)	Examines whether CMC can reduce status effects during group communication in two national cultures	Laboratory experiment (2*2*2 factorial design)	(1) An intellectual task; (2) a preference task	(IV) national culture, task type, and communication medium; (DV) status influence, sustained influence, perceived influence	U.S. (45 groups) vs. Singapore (48 groups); five-person groups; four treatments, with 10 to 12 groups per treatment	Hofstede's model (individualism-collectivism and power distance)	Task type and communication medium had significant main effects on status influence; status influence was not significantly stronger in Singapore groups than in U.S. groups; status influence was higher in preference task groups than in intellective task groups, etc.
Tung & Quaddus (2002)	Conducts a comparable study on the use of GSS in two different countries to explain the impact of culture on differences in results	Laboratory experiment (2*2 factorial-repeated measure)	Preference task and creativity task: (1) resource allocation; (2) strategic planning	(IV) task and technical support; (DV) outcome in terms of the "productivity" of the conflicts	Australian: 6 groups (3 to 5 members per group); Singapore: 20 groups (3 or 4 members per group)	Hofstede's model	Revealed differences in the significance of technical support and tasks with productivity in the Singaporean and Australian studies (higher avoidance behaviors in Singaporean groups and higher levels of interpersonal conflict in Australian groups).

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Vogel et al. (2001a)	Explores how GroupSystems can facilitate virtual teams in an educational environment	Field study	7 joint projects (identify the impact of software defects and CSFs) (intellectual task)	Not specified	The Netherlands, Greece, and Hong Kong; no between-group comparison; each project consists of one group only, with at least 48 students from 2 different regions	Hofstede's model and Sociocultural Learning Theory	Encountered some communication problems; richer interaction led to higher performance; attraction to work with different cultures varied greatly among students; cultural differences emerged in team feelings.
Vogel et al. (2001b)	Reports the cultural difference reflected in group member behavior in a CC course project	Field study	A 7-week joint project on a specific IT-related subject, resulting in a joint report (intellectual task)	Not specified	32 Hong Kong students and 39 Dutch students;10 CC groups, with 6 to 10 members per group	Hofstede's model and Sociocultural Learning Theory	A cultural effect existed, reflected by different behaviors of members from different cultures (e.g., Hong Kong students tended to resolve issues by discussing them with their local teammates, while Dutch students were more inclined to address teammates from both cultural backgrounds).

Authors	Research Focus	Research Methodology	Task(s) Used	Independent (IV) and Dependent (DV) Variables	Cultures Involved and Group Size	Underlying Theory or Model	Major Findings
Walther (1997)	Examines the interplay of culture with long-term and short-term groups in FtF and distributed CMC conditions	Laboratory experiment (2*2 factorial design)	Writing a paper summarizing, critiquing, and commenting on 5 articles	(IV) team duration (long term vs. short term), identity (social vs. individual); (DV) social attractiveness, task attractiveness, physical attractiveness	54 students, in groups of 5 to 6, drawn from U.S. and Britain	Recent interaction theories	Distributed groups were just as effective when examining social attractiveness, task attractiveness, and physical attractiveness.
Watson et al. (1994)	Evaluates the cultural effect on change in consensus and influence equality in three different communication settings	Laboratory experiment (3*2 factorial design)	Preference task: allocation of money to 6 projects	(IV) type of decision support (CS, manual, baseline), national culture; (DV) change in consensus, influence equality	U.S. vs. Singapore: U.S.: 3 to 4 members per group, group sizes for 3 decision support treatments were 27, 26, and 29; Singapore: 5-person groups; group sizes for 3 decision-support treatments were 14, 16, and 15	Hofstede's model and Adaptive Structuration Theory (AST)	Singaporean groups had higher pre-meeting consensus than U.S. groups; all groups in both cultures had the same level of post-meeting consensus; change in consensus was greater in U.S. than in Singaporean groups.

Chapter 5.25
Online Behavior Modeling:
An Effective and Affordable Software Training Method

Charlie Chen

Terry Ryan
Claremont Graduate University, USA

Lorne Olfman
Claremont Graduate University, USA

ABSTRACT

Organizations need effective and affordable software training. In face-to-face settings, behavior modeling (BM) is an effective, but expensive, training method. Can BM be employed effectively, and more affordably, for software training in the online environment? An experiment was conducted to compare the effectiveness of online BM with that of face-to-face (F2F) BM for software training. Results indicate that online BM and F2F BM provide essentially the same outcomes in terms of knowledge near transfer, immediate knowledge far transfer, delayed knowledge far transfer, perceived ease of use, perceived usefulness and satisfaction. Observed differences were not significant, nor were their patterns consistent, despite sufficient power in the experimental design to detect meaningful differences. These results suggest that organizations should consider online BM as a primary method of software training.

INTRODUCTION

Investment in software training can improve productivity, boost employee morale (Bell, 2004) and reduce employee turnover rate (Heller, 2003). End users who have not received proper software training often feel insecure about their jobs, and this insecurity can contribute to turnover costs and productivity losses (Aytes & Connolly, 2004). The departure of a newly hired IT employee within 180 days of hiring can cost a company as much

as $100,000 (Brown, 2000). The departure of employees who leave their companies due to a lack of proper training can have a variety of negative consequences (McEvoy & Cascio, 1987).

In contrast, properly trained end users often feel confident and secure, with positive implications for productivity. Increases in individual performance can add up to substantial improvements for businesses. The American Society for Training and Development (ASTD) conducted a study of 575 United States (U.S.)-based, publicly traded firms between 1996 and 1998 to examine the relationship between organizational training investments and total shareholder return. This study found an 86% higher return on such investments for the top half of firms (in terms of training investment) than for the bottom half of firms (Bassi, Ludwig, McMurrer, & Van Buren, 2000).

Software training requires a significant financial outlay. The most effective software training at present involves F2F behavior modeling, but such training is expensive to deliver. One possible way to reduce delivery costs is by offering similar software training, but through less expensive online delivery.

Allen and Seaman (2003) forecast that online learning would grow at a rate approaching 20% per year. The world corporate online learning market has been predicted to grow to nearly $24 billion by 2006 from $6.6 billion in 2002, an annual increase of 35.6% (International Data Corporation, 2002). The continuous growth of the online training market has prompted discussion about the effectiveness of Web-based virtual learning environments (Piccoli, Ahmad, & Ives, 2001).

While it is commonly agreed that online software training is less expensive and more flexible, it may also be less effective. Online software training continues to be of great interest to organizations, but significant challenges remain in implementing online solutions. These challenges include: (1) the cost of acquiring online learning systems, (2) the time for developing online learning materials, and (3) the need to be convinced of online learning's effectiveness compared to other training models (Bloom, 2004).

Three general training methods have been compared experimentally in F2F settings: instruction based, exploration based and behavior modeling. Instruction-based training occurs when trainers tell trainees about software, but do not model the use of it. Exploration-based training teaches trainees through practice by trainees on relevant examples, also without trainer modeling of software use. BM training teaches trainees via demonstrations, in which trainers model the use of software for trainees. Evidence exists that BM is the most effective method for F2F software training (Compeau & Higgins, 1995; Simon, Grover, Teng, & Whitcomb, 1996).

This research compares experimentally the relative effectiveness of F2F BM and online behavior modeling. Since prior research has indicated that the BM method dominates the instruction-based and exploration-based methods in F2F settings, this study does not include the latter two methods. Online asynchronous methods of software training, because they allow more favorable ratios of trainers to trainees and do not require training participants to meet, have the potential to achieve significant cost savings over F2F approaches. On the other hand, given that live trainers are not present in online asynchronous software training, there can be no direct interaction between trainers and trainees. This difference in direct interaction could mean that F2F training might be more effective than online training. Knowledge about the relative effectiveness of these methods will be valuable to people who must make decisions about how to provide software training.

THEORETICAL BACKGROUND

Software Training Method

As mentioned, three methods are common in F2F software training: exploration-based, instruction-based and BM (Simon et al., 1996). In exploration-based training, the assumption is made that learning is "a matter of rearranging or transforming evidence in such a way that one is enabled to go beyond the evidence so reassembled to additional new insights" (Burner, 1966, p. 22). Exploration-based training involves an inductive process through which individuals learn general concepts by trying to solve specific tasks (Taba, 1963). In instruction-based training, "the entire content of what is to be learned is presented to the learner in the final form" (Ausubel, 1963, p. 16). Instruction-based training is deductive and programmed, with low trainee control and a focus on software features (Davis & Davis, 1990). The BM method is in some ways a hybrid of exploration- and instruction-based training, and is centered on having trainees treat the behavior of their trainer as a model for their own (Simon et al., 1996).

When assessing the applicability of training methods for online asynchronous software training, researchers must bear in mind that some key elements of F2F software training may be lost in a movement to the online asynchronous setting. The opportunities for direct interactions between trainers and trainees are necessarily fewer, if they exist at all, in online asynchronous software training. Thus, the beneficial effects of trainer-trainee interactions typical of F2F software training may be missing. Videotapes, transcriptions, simulations or virtual reality are unlikely to serve as complete substitutes for live interactions between trainer and trainee. Along these lines, the features that distinguish BM training from exploration- and instruction-based training may perhaps be less evident in the online asynchronous software training situation.

Online asynchronous software training does not provide close monitoring of trainees by the trainer, as is common in F2F software training. This lack of monitoring can be expected to lead to increased levels of distraction among trainees. Trainees in online asynchronous software training might be inclined to attend to matters other than their training, such as surfing the Web, to a much greater extent than they would in F2F software training. Furthermore, online asynchronous software training may deliver content less tailored to trainees' interests than content provided in F2F software training. As a result, trainees may experience a higher degree of boredom in online asynchronous settings than in F2F settings, leading to poorer performance and more negative reactions to training experiences.

Online Training Modes

There are two temporal modes of online training: synchronous and asynchronous. Either mode can be used for software training. Text messaging, audio conferencing and video conferencing are examples of online applications that can be used for training purposes in a synchronous mode. Web pages, files to be downloaded, e-mail, newsgroups and discussion forums are examples of applications that can support training asynchronously.

Horton (2000) suggests that synchronous training and asynchronous training be designed differently. Synchronous training demands the control of schedule, time, people, class size, video and audio equipment, and place. These factors limit the possibilities for reaching trainees in a cost-effective manner. This study focuses on online asynchronous software training in part to avoid the influence of these factors, and in part to concentrate on the methods most likely to keep costs low. This choice reflects the reality that most online training delivered across continents is provided in the asynchronous mode and that use of the online asynchronous mode is destined to grow.

Behavior Modeling in Face-to-Face and Online Asynchronous Software Training

Social cognitive theory (Bandura, 1986) serves as a theoretical basis for behavior modeling. According to this theory, "most human behavior is learned by observation through modeling" (p. 47). Observational learning allows one to form rules to guide future behavior by watching what others do and noting what consequences such behavior has for them. Further, observational learning can make use of symbolic models, allowing people to consider words and images in coming to appreciate what happens to others when they behave in particular ways, thereby extending what can be learned beyond the immediate environment. Learning by modeling involves four kinds of processes: (1) attention, (2) retention, (3) production, and (4) motivation (Bandura, 1986). These

Table 1. F2F BM vs. online behavior modeling: strengths and weaknesses

	BM Approaches	
	F2F behavior modeling	Online behavior modeling
Strengths	• Regardless of learning styles, trainees are motivated to use the training approach. • The approach is less influenced by learning style and is the most effective. • The teaching quality is contingent on both the quality of entire course materials packaged in final form and supplementary materials (e.g., handouts). • Trainer's teaching abilities and trainees' participation are major determinants for training outcomes. • Real-time two-way feedback. • Both trainers and trainees have equal power to control the learning pace.	• Regardless of learning styles, trainees may be motivated to use the training approach. • The approach may be less influenced by learning style and should be an effective training approach. • Teaching quality may be contingent on both the quality of entire course materials packaged in final form and supplementary materials on the Internet. • Trainer's teaching abilities and trainees' participation may be major determinants for the training outcomes. • Web-based peer-to-peer interaction may improve commitment and participation. • Both trainers and trainees may have equal power to control the learning pace.
Weaknesses	• Needs longer time to exercise the training approach. • Constrained by the length of time, a trade-off between instruction and exploration learning is needed. • A trainer's experience will influence the decision quality of the trade-off, thereby affecting trainees' motivation and their learning outcomes.	• Trainees may have trouble modeling the behavior of the trainer without direct interaction. • Demonstrative lecturing may need to rely on videotaped or scripted course materials. • Asynchronous, one-way communication may lower motivation, thereby degrading learning outcomes. • Real-time reiterative learning process to confirm understanding may be lost.

processes are influenced both by characteristics of the events observed and characteristics of the observer.

Learning by modeling or observing people's behaviors may be more effective than learning by trial and error, because the former approach can avoid unnecessary mistakes and harm. Modeling a trainer's behavior empowers trainees to (1) learn new behavior from the trainer, (2) self-evaluate their behavior against the trainer's, and (3) reinforce their current adequate behaviors. The BM approach is different from learning by adaptation. The former approach teaches via demonstration, while the latter approach influences the behaviors of learners by reward and punishment (Skinner, 1938).

An early application of BM training was in the area of interpersonal communication and management skills (Decker & Nathan, 1985). In the realm of training for software and computer usage, BM training has been shown consistently to be more effective than instruction- or exploration-based training (Compeau & Higgins, 1995; Gist, Schwoerer & Rosen, 1989; Simon, Grover, Teng & Whitcomb, 1996). Yi and Davis (2001) found that the effects of BM could be enhanced by the provision of training features to support retention enhancement and practice.

BM is readily employed in F2F training, but may be difficult to apply in online settings, which may be less suited to demonstrations of behavior. Limitations of the media typically used in online synchronous instruction in terms of their richness constitute one possible constraint. Another is a reduced level of reinforcement possible in online settings, compared with F2F instruction. For example, in a live training class, the trainer is able to demonstrate a software process and immediately ask the trainees to repeat the activity under the trainer's close supervision. However, in an online asynchronous situation, in which there is no live trainer, demonstrations lose the benefit of immediate feedback. In an online synchronous situation, bandwidth constraints and compromised reciprocity may undermine the effectiveness of demonstrations. In online environments, effectiveness can be further compromised with the absence of learning by doing, another key element of F2F BM training (McGehee & Tullar, 1978). Table 1 summarized the strengths and weaknesses of F2F BM and online behavior modeling.

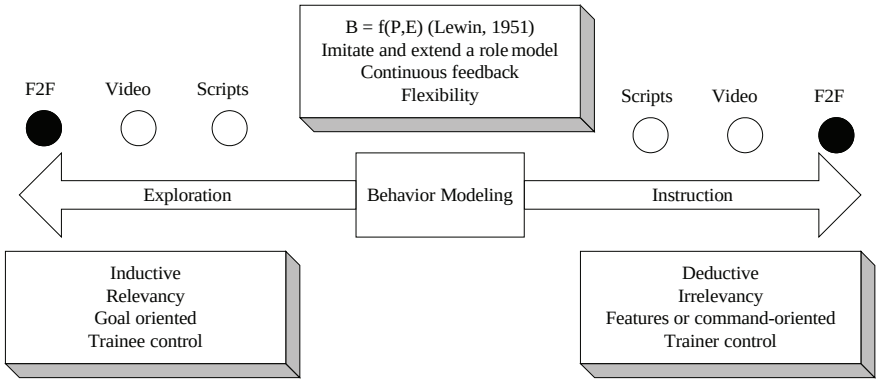
Trying to use BM for online software training would involve the issues mentioned above. Therefore, there is a strong possibility that the BM approach cannot be fully replicated in the online asynchronous setting and, therefore, will not be as effective in the online environment as in the traditional environment. On the other hand, if online BM were to prove as effective as F2F behavior modeling, organizations would prefer it, because it would cost less and promise higher returns on investment. The increasing use of online asynchronous software training by businesses and schools raises questions: What training methods should be used under what circumstances in the online asynchronous environment?

RESEARCH MODEL AND HYPOTHESES

This study tested the relative efficacy of BM training, in two different environments: experimentally and in a field setting. Experimentation can allow testing of causal relationships among variables. A field setting can provide greater confidence in the meaning of experimental tasks than in a laboratory setting. A field experiment methodology has the merits of being able to test theory and answer practical questions (Kerlinger & Lee, 2000).

The independent variable for the experiment was *training method*, set at two levels of behavior modeling – F2F and online. Training materials were designed to operationalize each level by integrating key elements of BM training, as illustrated in Figure 1.

Figure 1. Key elements of behavior modeling training



The online BM treatment was designed to be video-demonstration oriented. Trainees watched a recording of the trainer using the software to perform tasks. All communication between the trainer and trainees was one-way. Following the video, trainees completed tasks to demonstrate their level of mastery of the training materials. Online reference sources were available to them as they completed the tasks. Control over what occurred was shared between the system and trainees. Online behavior modeling, as conceived here, shares features with both exploration and instruction approaches, including both inductive and deductive aspects.

The F2F BM treatment was designed to be direct-demonstration oriented. Trainees watched the trainer performing tasks in person. Two-way communication between the trainer and trainees was possible. Following the demonstration, trainees performed a task assigned by the trainer. No online reference sources were available. Control over what occurred was shared between the trainer and trainees. The F2F condition included a trainer (other than one of the researchers, to reduce chances of awareness of the hypotheses being tested). The trainer followed the same script as the one designed for the online condition.

The length of time allotted to training was the same for both conditions. Both conditions included the same pre- and post-training tests. All training sessions were conducted in the same computer classroom.

Dependent Variables

Regardless of teaching environment, most training is intended to instill a competency of some kind. Software competency depends on the kind of knowledge acquired in training. Learning effectiveness can be evaluated through trainees' reactions and knowledge transfer (Kirpatrick, 1967). Knowledge levels can be categorized as near transfer or far transfer (Simon et al., 1996). Near transfer of knowledge is necessary for understanding of basic software commands and procedures. Far transfer of knowledge allows the solving of problems different from those worked out in training. The measurement of near-transfer knowledge involves direct assessment of what was learned about the specific objects (such as software

features and commands) covered in training. The measurement of far-transfer knowledge has to do with evaluating the extent to which what was learned is available to trainees in their solution of problems similar to those included in training. For far-transfer knowledge, it is interesting to assess learning both immediately after training and after some delay, because software competency is intended to be a long-term effect of training.

In this study, software competency was measured in terms of near-transfer knowledge, far-transfer knowledge (assessed immediately) and far-transfer knowledge (assessed with delay). The measure of *near transfer (NT)* consisted of 10 multiple-choice questions concerning details of the software covered in training. *Immediate far transfer (IFT)* was measured with a problem to be solved with the software during the experimental session. *Delayed far transfer (DFT)* was measured with a problem administered later in the academic term as part of the final exam.

In addition to how well it instills software competency, software training should also be judged by the reactions that trainees have to it. It is common to use satisfaction as a surrogate for the effectiveness of information systems (Ives, Olson, & Baroudi, 1983) and it has been adopted as an indicator of success in software training (Simon et al., 1996). Perceived usefulness and perceived ease of use have been shown to predict attitudes and behaviors with information systems (Davis, Bagozzi, & Warshaw, 1989).

In this study, the reactions of trainees were captured through three measurement scales: *satisfaction (SAT), perceived usefulness (PU)* and *perceived ease of use (PEOU)*. SAT, PU and PEOU were measured with scales administered during the experimental session, as described below.

Hypotheses

As discussed above, the online BM approach replaces the live instructor with the scripted demonstration, and some key elements of the F2F BM approach may be lost. Characteristics of the online asynchronous environment—particularly limitations on trainer-trainee interactions—suggest that BM training done in a F2F manner should be superior to BM training done in the online mode. BM training in the F2F mode may be more effective at improving the learning outcome for a trainee than the BM approach in the online asynchronous mode. Proving that the F2F BM is more or less effective than online BM could justify the validity of replicating the same pattern in the online asynchronous environment. Hence, it is only hypothesized that the F2F BM approach is more effective than the online BM to improve learning outcomes for trainees of all learning styles. The hypotheses listed below correspond to this expectation with respect to NT, IFT, DFT, SAT, PU and PEOU.

- H1: NT scores will be greater with F2F BM than with online BM.
- H2: IFT scores will be greater with F2F BM than with online BM.
- H3: DFT scores will be greater with F2F BM than with online BM.
- H4: SAT scores will be greater with F2F BM than with online BM.
- H5: PU scores will be greater with F2F BM than with online BM.
- H6: PEOU scores will be greater with F2F BM than with online BM.

Trainees and Setting

The setting for the experiment was an introductory computer course requiring trainees to learn spreadsheet software (Excel 2000). Trainees in this course were freshmen, majoring in management information systems or accounting. Participation in the study was voluntary. The faculty for the course agreed to run the experiment near the end of the academic term. As a result of this timing,

none of the trainees in the experiment were complete novices with respect to computers; all had some literacy and experience.

It was not desirable in this study for experimental trainees to have prior knowledge of spreadsheets. Therefore, as part of the experimental procedure, a pre-test of 10 multiple-choice questions about Excel 2000 was given to each trainee; trainees who scored higher than 50% were excluded.

Training Procedure

The trainer conducted the traditional F2F BM by following the same procedures as delineated in the online BM training package (Figure 2). The first stage of the package provides examples of how to manage a database using Excel 2000. The second stage lists online asynchronous training tools that can be used to assist the trainee. These tools are: (1) examples that are relevant to trainees'

Figure 2. F2F BM and online BM procedures

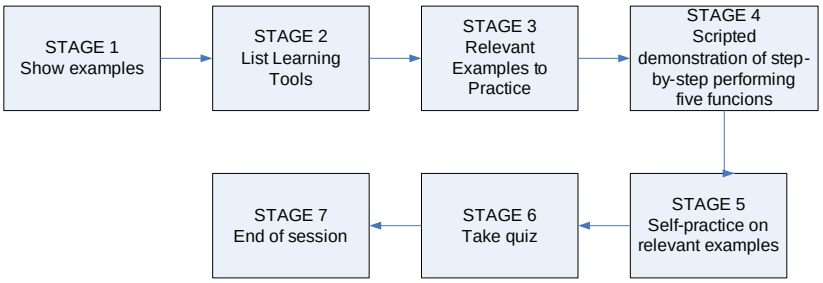


Figure 3. Scripted demonstration of step-by-step, performing five functions: The fourth step of online BM method (enabled by Excel's macro functions)

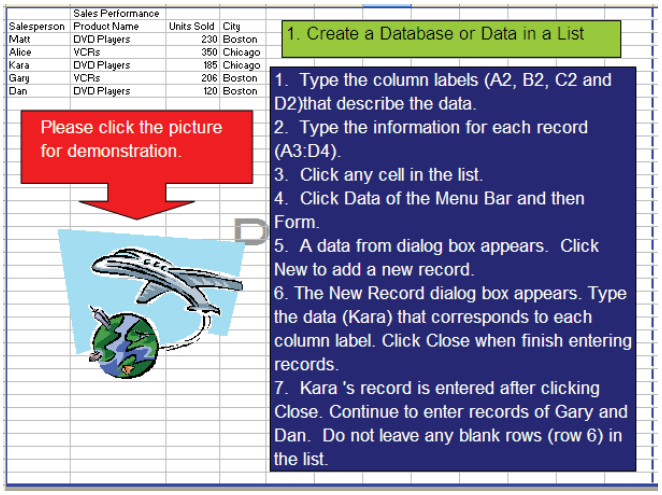

backgrounds, (2) a self-practice worksheet for each function of database management, and (3) online reference sources. The third stage allows trainees to choose relevant examples to use for practice throughout the training session.

Two examples were prepared for each major. Trainees were encouraged to practice with examples relevant to their majors. The training covered five database management features of Excel. These features allow one to (1) create a database without using a data form, (2) create a database with a data form, (3) sort data in a data list, (4) filter data in a data list, and (5) add subtotals to a data list. Step-by-step instructions were adopted to illustrate each function.

Additionally, trainees could choose to watch or not to watch a demonstration for all database functions. On the same page as the demonstration, a self-practice worksheet was presented. Practice results could also be carried over to the next practice. Trainees of the online BM group took the same quizzes as the F2F group and then concluded the study. Figures 3 and 4 are two screenshots of course materials used for the online BM approach. The demonstration of a live instructor was substituted for fixed-time (12 seconds) transition of page presentations. Each scripted demonstration focused on one particular function of the database management topic. At each learning point of a particular function, trainees were encouraged to experiment by practicing the related exercises.

RESULTS

A total of 114 trainees completed the study by submitting valid questionnaires. This amounted to approximately 46% of the trainees who had been registered for the course. Although a higher rate of participation in the experiment was expected, the achieved rate may have been due to the experiment being a voluntary activity at the end of an academic term. Of the trainees who did participate, 31 had too much prior spreadsheet knowledge to qualify as trainees for the experiment, leaving 83 trainees whose data were analyzed.

Table 2 shows the number of trainees for each experimental treatment. Note that the counts of trainees in each condition, although not exactly the same, are similar enough not to cause analytic difficulties. The sample size, although not

Figure 4. The first step of scripted demonstration for the first subject: Sort data in a list

Total	*114*	*31*	*83*

as large as might be desired, also is not a source of analytic problems.

Multivariate analysis of covariance (MANCOVA) has advantages over analysis of variance (ANOVA) in removing some systematic errors and uncontrolled individual differences. Although the researchers planned to adopt MANCOVA, a cursory investigation showed no interaction effect between two dependent variables—user satisfaction and learning performance. This indicates that learning performance and satisfaction effects are separated; interaction among them is not the issue in this study. The possibility of inflating type I error due to the analyses of multiple univariate ANOVAs is minimum. Furthermore, due to the small sample size of some cells and the unequal cell sizes, complying with the assumptions of two-way ANOVA can improve the reliability of data analysis. Each dependent variable was treated and analyzed independently with ANOVA as a result. Data analysis using a histogram graph shows that each dependent variable complies with univariate

Table 3. Descriptive statistics by treatments

Dependent Variable	*Mean/Standard Deviation*	*Online BM*	*F2F BM*
NT	*mean*	*45.33*	*49.38*

Table 4. Results for training methods

Variable	*Hypothesis*	*Result in Correct Direction?*	*Significant p-value?*
NT	*Face-to-face > online*	*T*	*n.s.*
IFT	*Face-to-face > online*	*F*	*n.s.*
DFT	*Face-to-face > online*	*T*	*n.s.*
SAT	*Face-to-face > online*	*T*	*n.s.*
PU	*Face-to-face > online*	*T*	*n.s.*
PEOU	*Face-to-face > online*	*F*	*n.s.*

normality assumptions. Additionally, Levene's test at $\alpha = 0.10$ shows that the null hypothesis, *the error variance of the dependent variable is equal across groups,* is not violated. The tests indicate that the data is normally distributed. An ANOVA was conducted for each dependent variable. ANOVA is robust for situations having a limited number of data points (Moore & McCabe, 1989). Table 3 provides descriptive statistics for dependent variables by experimental treatment. Table 4 summarizes ANOVA results for training methods in terms of learning outcomes. Direction and significance of differences between treatments are indicated.

From a hypothesis-testing standpoint, four out of six hypotheses, all concerning the superiority of F2F BM over online BM (H1, H3, H4, and H5), were in the direction hypothesized. Despite this, these hypotheses were not supported in a statistical sense.

DISCUSSION

Although none of the hypothesized relationships are fully supported, the results obtained are interesting. The most intriguing result is that—contrary to expectations—there are no statistical reasons for preferring F2F BM to online BM for software training of this kind. The pattern of results indicates that while F2F BM results in better outcomes than online BM for four of the six dependent variables, it never does so at a statistically significant level. One interpretation of this is that online BM training is no worse than F2F BM training across all dependent variables. (Trainees in the online BM condition actually score higher than F2F BM trainees in IFT.) The pattern of results for F2F BM suggests that trainers might choose online BM—which ought to be a less costly alternative to F2F BM—without making any significant sacrifice in either learning or trainee reaction outcomes. The complex picture of the implications of these four treatments must be more clearly illustrated.

Two methods can illustrate this complexity. The first is the "insufficient difference" finding between online BM and F2F BM. The second is the beginning of a strategy for online asynchronous software training. As a first result, the conclusion of "insufficient difference" between online BM and F2F BM depends on being able to say there is not enough difference between their effects to justify the difference in their costs. A practical difference between F2F BM and online BM—one that matters in cost/benefit terms—must have some minimum size. Specifying a practical difference involves knowing the costs of F2F BM

and online BM, as well as how effect size maps to benefits.

Ability to detect effect sizes is nothing more than statistical power (Cohen, 1977). In information systems research, "studies are unlikely to display large effects and that, typically, small- to medium-effect sizes should be anticipated" (Baroudi & Orlikowski, 1989, p. 90). Because this study exercised due care with experimental procedure and made use of reliable instruments, there is justification in addressing statistically insignificant results. Before executing the experiment, efforts were made to maximize the difference between F2F BM and online BM conditions; a Delphi study was conducted regarding the design of course materials to reflect the different training approaches. Despite this careful control over operationalization, there was not enough difference between F2F BM and online BM effects to justify the difference in their costs.

Due to the undeveloped nature of research in this area, it may be inappropriate to establish an index for effect size based on prior research on software-training strategy in the traditional environment (Mazen et al., 1987). To explain the phenomenon carefully, we employ Cohen's (1977) approach to estimate proxy effect-size levels based on the standardized difference d of two populations taking different training approaches (see Table 5).

Table 5. Effect size estimation

Dependent Variables	Standardized Difference between F2F BM and online BM	* Estimated Effect Size
Knowledge NT (KNT)	25.47%	0.20
Knowledge FT (KFT)	-46.45%	0.50
OS	58.82%	0.50
PEOU	-21.05%	0.20
PU	57.97%	0.50

** Calculated based on Cohen's (1977) Effect Size Conventions*

The estimated effect size is 0.5 for all dependent variables except KNT and PEOU. Since PEOU is related to the design of the e-learning system rather than the treatment of training approach, smaller effect size across different groups is understandable. However, the study cannot detect differences of effect size for KNT. This indicates that it makes no difference whether F2F BM or online BM is employed to improve KNT. Online trainers can choose either F2F BM or online BM to improve end-users' KNT if either approach has relatively similar costs.

Contrary to the expectation of hypotheses, a larger effect size was detected for KFT in the short term and long term. This practical difference indicates that the benefits of online BM outweigh F2F BM for KFT in the short and long term. Larger effect size was also detected for the measures of end-user satisfaction: OS and PU. This practical difference supports that F2F BM is a better approach than online BM to improve end-user satisfaction. The difference between knowledge absorption capability and end-user satisfaction poses many interesting questions.

As a second result, this study can offer concrete suggestions about the beginning of a strategy for online asynchronous software training. One result of interest is that F2F BM might be better than online behavior modeling. Of the six hypotheses concerning relationships between these two methods, four are in the expected direction, none significantly so.

These findings indicate that use of online BM may be the best software-training strategy for the online asynchronous setting. To confidently offer such suggestions, the study needs to discuss the design decisions that trainers face in the online asynchronous environment. The study provides support for using online BM over exploration- and

instruction-based training, given that the prior contribution makes the point of favoring online BM over F2F BM. Since our suggestions are a start on an online asynchronous software training strategy, we will present the outline of the strategy that includes "to-do" and "not-to-do" lists. This online asynchronous software training strategy will allow trainers and vendors to capitalize on these opportunities and avoid costly mistakes.

The largest implication for practice is that online BM may provide a cost-effective substitute for F2F BM without significant reductions in training outcomes. Compared to F2F BM, online BM allows trainees to have more control over their learning. Cognitive learning theory indicates that the learning process can be improved via active learning (Shuell, 1986) and problem-solving learning (Alavi, 1994). In the virtual learning environment (VLE), trainees have higher control of learning and can choose to use exploration- or instruction-based training approaches depending on tasks and individual needs. For instance, trainees with more experience and knowledge related to a particular trainee may resort to meaningful learning and use relevant examples to practice. Trainees with little knowledge about another trainee may resort to rote learning and use generic examples to practice. The VLE allows trainees to switch freely between meaningful and rote learning, to their advantages.

Since trainees have control flexibility, online BM can be viewed as more effective than the F2F BM in helping trainees perform well on near-transfer and far-transfer tasks. In the VLE, the individualized and contextual learning provides anchoring for trainees to transform their mental models. While more must be learned about this relationship, it is encouraging to see evidence that there may be a desirable leverage from online asynchronous software training.

Another thing trainers need to bear in mind when designing an online asynchronous software training strategy is that the effectiveness of online asynchronous software training methods does not necessarily go hand-in-hand with overall satisfaction, perceived ease of use and perceived usefulness. In particular, it may still be the case that learning effectiveness is neutral to learning style. Improving satisfaction by customizing learning approaches may be the right decision to make, but performance might not be the deciding factor.

Online BM and F2F BM allow trainees to have some control of the learning process and information acquisition regarding its content, accuracy, format, ease of use and timeliness (Doll, Xia, & Torkzadeh, 1994), which leads to somewhat higher satisfaction levels. In itself, higher levels of satisfaction may be justification for online BM and F2F BM use, but much remains to be learned about the effects of these methods for training performance.

Assimilation Theory suggests that being receptive to new procedural knowledge on how to operate a new target system is the prerequisite to meaningful learning (Mayer, 1981) or far-knowledge transfer. With the time constraints, a more focused learning approach can be useful at assimilating new knowledge. Hence, the online BM approach is a logical solution for meaningful learning, because the approach allows trainees to not only acquire new knowledge, but also gives them flexibility to search their long-term memory for "appropriate anchoring ideas or concepts" (p. 64) and to use the ideas to interact with new knowledge (Davis & Bostrom, 1993).

LIMITATIONS

While it seems unlikely, given the care taken in the design of the study, there is always the possibility that the independent variable, training method, could inadequately represent its intended construct. With any complex treatment, such as the establishment of a training method here, there is a chance that operationalization can be less than what is needed for effects to occur. Additional re-

search is required to refine and perfect the training method treatments as much as possible. There is no simple manipulation check for verifying the efficacy of this kind of treatment, but continued investigation should reveal the extent to which the manipulation is a successful one.

Future research can attempt to improve the reliability of the findings by controlling the experimental environment more tightly (e.g., equal cell size, larger cell size and longer training sessions) or by improving the strategy's generalizability through the examination other variables (e.g., trainees vs. professional workers, number of training duration sessions, type of training media, self efficacy, experiences of using the online learning system and software types).

IMPLICATIONS FOR RESEARCH

The findings here raise additional questions for research. Some that might be addressed in the immediate future include:

- To replicate the experimental equivalence of F2F BM and online BM methods of software training with different software and trainees. With this, to demonstrate a practical (i.e., cost-based) advantage of online BM over F2F BM for software training in practical settings.
- To study the impact of training duration on performance and trainee reactions. Trainees should be exposed to the same training methods for different durations.
- To improve the reliability of the study by manipulating some useful blocking variables. A series of comparative studies can be conducted to assess the impact of individualism as a cultural characteristic, computer self-efficacy, task complexity, professional backgrounds, and the ratio of the training duration to the quantity of information to be processed, among others.
- To investigate the impacts of social presence and information richness (SPIR) (Fulk, 1993) features of online asynchronous software training media on training outcomes. Future studies might vary the SPIR features of training media (e.g., F2F vs. online asynchronous scripted or Web cam modes).
- To conduct longitudinal studies of the influence of learning style on learning performance and trainee reaction.
- To continue to study the relationship between learning style, training methods and training outcomes. Learning style is somewhat associated with the cultural backgrounds of online trainees. Trainees with varying cultural backgrounds may prefer to adopt training media with different SPIR features. Cultural differences, such as relative degree of individualism, may affect preference for SPIR characteristics. Some combination of training methods, learning style and SPIR attributes may jointly determine learning outcomes.

Implications for Practice

The largest implication for practice is that online BM may provide a cost-effective substitute for F2F BM without significant reductions in training outcomes. While more must be learned about this relationship, it is encouraging to see evidence that there may be a desirable leverage from online asynchronous software training. Also, when designing an online asynchronous software training strategy, trainers need to bear in mind that both F2F BM and online BM are equally effective to improve learning outcomes (including satisfaction), and performance might not be the decision factor if these two approaches need to be chosen from. Other decision factors, such as trainer's preference, equipment availability, budget and scheduling, could be more important than the efficacy issue. Online BM and F2F BM allow trainees to have some control of

the learning process, leading to somewhat higher satisfaction levels. This advantage in itself may be justification for their use, but much remains to be learned about the effects of these methods for training performance.

CONCLUSION

The success of an online asynchronous software training strategy depends on its effectiveness in improving learning outcomes. This study builds on a well-accepted framework for training research (Bostrom, Olfman & Sein, 1990; Simon, Grover, Teng & Whitcomb, 1996), examines the relative effectiveness of four training methods and begins to derive a strategy for online asynchronous software training. Testing the following hypotheses provides an empirical basis for the development of an online asynchronous software training strategy: (1) F2F BM is more effective than online BM for learning performance and trainee reactions, and (2) online BM is more cost effective than F2F BM.

While these hypotheses are not fully supported statistically, and while many of the observed results are difficult to interpret, the study discovers important potential implications for practitioners and researchers. The formulated online asynchronous software training strategy suggests that trainers customize their training methods based on desired learning outcomes.

What is learned from this study can be summarized as follows: When conducting software training, it may be as effective to use an online BM method as it is to use a more costly F2F BM method. Although somewhat better results are sometimes evident for F2F BM, observed differences are not significant, nor are their patterns consistent.

The study has accomplished its major goal—it provides evidence as to the relative effectiveness of various methods, particularly those of an online asynchronous nature, for software training. Within its limits, this research takes a first step in developing a strategy for online asynchronous software training.

ABSTRACT

To improve the performance of software projects, a number of practices are encouraged that serve to control certain risks in the development process, including a lack of essential skills and knowledge related to the application domain and system development process. A potential mediating variable between the lack of skill risk and project performance is the ability of an organization to acquire the essential domain knowledge and technology skills through learning, specifically organizational technology learning. However, the same lack of knowledge that hinders good project performance may also inhibit learning. This study examines the relationship between information system personnel skills and domain knowledge, organizational technology learning, and software project performance with a sample of professional software developers. Indications are that the relationship between information systems (IS) personnel skills and project performance is

partially mediated by organizational technology learning.

INTRODUCTION

The importance of technical and business skills and knowledge for information systems personnel has been advocated in the IS literature for decades (Cheney & Lyons, 1980; Jiang, Klein, Van Slyke, & Cheney, 2003). In spite of the recognized importance, empirical investigations that examined the relationship between IS personnel skills and project performance, as measured comprehensively by attainment of goals and budgets, have been lacking in the IS research literature. To address this lack, Byrd and Turner (2001) conducted a study using the perceptions of chief information officers (CIOs) to evaluate IS personnel skills and the success of information systems in building competitive posture. To one's surprise, their study did not find a significant positive relationship between IS personnel skills and eventual success of the developed system. Why should an empirical study contradict experience? They suspect that the relationships in an organization where IS personnel skills are applied have too many complexities to be modeled accurately. Could there be a mediating variable between IS personnel skills and IS project performance that further explains how to overcome this essential lack?

Researchers have observed that activities during information system development and implementation offer an opportunity for organizational technology learning, or the ability and practice of bringing new skills and knowledge into the organization related to IS development and the application of IS tools to business domains (Ko, Kirsch, & King, 2005; Stein & Vandenbosch, 1996). For a successful IS implementation, skills must be brought to bear from the application domain and technical domains, which can best happen when the organization encourages the learning of newer skills and knowledge, and has practices to incorporate these newly acquired assets into current and future projects. In short, organizational technology learning is a critical factor for predicting final IS project performance, and a base of knowledge and skills in the IS project team are a necessary condition for organizational technology learning to occur. This suggests that organizational technology learning is a mediator between IS skills and knowledge and the performance of the IS project. Unfortunately, no empirical study has attempted to validate this reasoning.

The focus of this study is, therefore, to examine the relationship from IS staff development skills and domain knowledge to project performance with organizational technology learning as a mediator. A positive result of this study will provide additional insights on IS skill research and provide an alternative explanation to the unsolved IS skills puzzle of Byrd and Turner (2001). From a survey sample of 212 Institute of Electrical and Electronics Engineers Computer Society members, the results indicate that the lack of system development skills and knowledge in the application domain have a direct negative impact on organizational technology learning and project performance. Furthermore, organizational technology learning has a significant positive impact on final project performance, showing that the impact of IS personnel skill levels on project performance is partially mediated by organizational technology learning.

BACKGROUND AND RESEARCH MODEL

Broad categories of critical IS personnel skills are identified, including (1) technical specialties/ technology management skills and (2) business domain knowledge and skills (Jiang et al., 2003). Unfortunately, given decades of emphasis, these IS skills were still not linked to IS project performance (Byrd & Turner, 2001). This may be

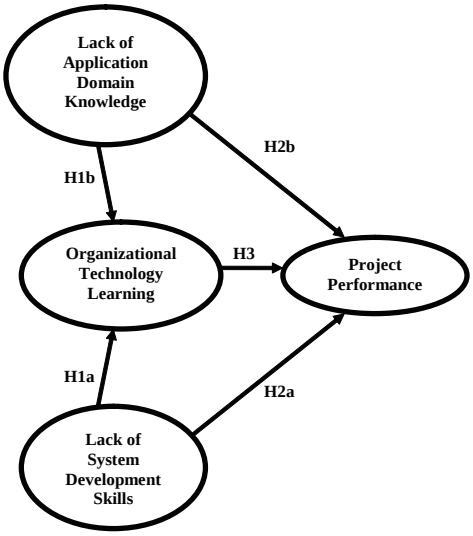
due to the lack of an intervening variable similar to an established relationship between IS staff competency and firm performance where learning is a mediator (Tippins & Sohi, 2003). This study investigates the possibility of a variation on learning as a mediating variable in the project context between IS personnel knowledge and skills and IS project success.

This research considers learning from the perspective of general technology skills acquired by the firm in the project context (Cooprider & Henderson, 1990). Organizational technology learning is an organization's furthered understanding of its operational business procedures and information system technology capabilities (Lee & Choi, 2003). The IS application development process itself can be viewed as an intensive activity of skill learning and knowledge acquisition (Rus & Lindvall, 2002). Such learning results in associations, cognitive systems, and memories that are developed and shared by members of an organization. These learned skills can then be used to enhance the performance of a software project and, thus, the organization. From concept generation to implementation, integration of skills and knowledge to achieve a desired product can be viewed as the central theme of the software development process. IS projects require such an in-depth set of skills and knowledge of application domains (Badaracco, 1991).

Various project stakeholders (e.g., IS developers and end-users) bring different repositories of expertise, skills, knowledge, and perspectives to the project teams. This potential pool of skills held collectively by project stakeholders represents *embedded* knowledge (Schramer, 2000). The delivered system represents *embodied* (i.e., learned) knowledge – referring to how the technical knowledge and knowledge of application domain is formalized and incorporated in the design, functionality, policies, and features of a system. Okhuysen & Eisenhardt (2002) indicated that the successful integration and learning of embedded knowledge into embodied knowledge is the key to successful product and service developments. The information system development process is a process of converting embedded knowledge into embodied knowledge (Robillard, 1999). Proposed organizational practices to achieve this conversion can be found in various literature on knowledge management, organizational learning, and employee education (Chiva & Alegre, 2005; Kayes, Kayes & Kolb, 2005). In particular, practices have been proposed to enhance knowledge management via information systems, promote learning during development, and educating through training (Majchrzak, Beath, Lim, & Chin, 2005; Olfman, Bostrom, & Sein, 2003; Sher & Lee, 2004). As a result, a relatively stable and accessible body of embedded knowledge that exists within the project team may become a necessary condition for an occurrence of organizational technology learning and improved project performance.

The notion of organizational entities, like project teams as vehicles for integrating fragmented knowledge, is the core of knowledge-based theory (Grant, 1996). Some knowledge is codified in documents or embodied in procedures and policies, and much is held tacitly in the minds of individuals. The development of new products and services require combining both tacit and explicit knowledge held by many individuals (Kogut & Zander, 1992). Many of the "run-away" IS projects can be related to either embedded customer or technical knowledge that are difficult to be embodied in a system: vague requirements, new technologies/methods, new development methodologies, new ideas, and changing user needs. To be successful, technical knowledge and knowledge about user functions and needs must be learned by the organization and embodied in the system design and implementation. Based upon the above discussion, we propose the following research model (see Figure 1). We propose that the lack of system development technical knowledge and the lack of application domain knowledge will negatively impact organizational technology learning, and, in turn, negatively impact final project outcomes.

Figure 1. Research model of risk impact on learning and performance



The detailed hypotheses examined in this study are discussed in the following section.

HYPOTHESES

For learning to occur, it is accepted that certain conditions must be in place in the organization. One seeming catch-22 is that existing knowledge must be in place for learning to occur (Cohen & Levinthal, 1990). In this instance, learning is not merely the sum of the basic knowledge and skills of the individuals, but the structure in place to retain and transfer knowledge throughout the organization (Schulz, 2001). This by itself indicates that individual knowledge is not sufficient to guarantee that organizational technology learning will take place. Knowledge and skills must be the collective of a project team that can be directed to accomplish the goals of a software development project (Schulz, 2001).

Absorptive capacity is a theory-based explanation of this phenomena (Cohen & Levinthal, 1990). The basic premise of absorptive capacity is that the IS project team must have prior related knowledge and skills to assimilate and utilize the new knowledge. Research in other fields supports this premise. Memory development research suggests that an accumulation of prior knowledge improves the ability to store new knowledge and the ability to recall and use knowledge as skills (Bower & Hilgard, 1981). Furthermore, lack of knowledge in the appropriate context limits the ability to make new knowledge intelligible (Lindsay & Norman, 1977). New knowledge must be exploitable as skills and depends upon the transfer of knowledge within the organization (Sarin & McDermott, 2003). Essentially, a lack of knowledge blocks organizational access to further knowledge and the ability to utilize the skills derived from the knowledge. A previous knowledge base is important to the rapid dissemination and

assimilation of the knowledge required to exploit technology and adopt new technology into productive domain applications (Ko et al., 2005). In addition, diversity of knowledge is important for further learning in order to place new knowledge in a corporate context (Fichman & Kemerer, 1997). Based upon absorptive capacity theory and existing studies demonstrating the importance of previous knowledge, we expect:

- **H1a:** There is a negative relationship between the lack of system development skills and organizational technology learning.
- **H1b:** There is a negative relationship between the lack of application domain knowledge and organizational technology learning.

Risk-based software engineering describes why software project uncertainties have an adverse impact on performance (Boehm, 1991). According to this theory, project uncertainties can be viewed as risk drivers that increase the performance risk of the project. The purpose of software engineering is to manage the particular sources of project risks and lead to a successful project development. If this holds, then project performance depends upon the reduction or control of the various risks in place, including those associated with knowledge deficiencies on the part of the IS development staff. Research based upon the analysis of risk in project environments supports this notion (Jiang & Klein, 2000). Researchers and practitioners have indicated that the lack of knowledge on the part of the IS staff is a significant project risk that could negatively impact a project's outcome (Schmidt, Lyytinen, Keil, & Cule, 2001). In the IS skill literature, Jiang et al. (2003) found that the lack of skills was correlated with project failures. Based upon the risk management theory and above discussion, we expect that:

- **H2a:** There is a negative relationship between the lack of system development skills of IS staff and project performance.
- **H2b:** There is negative relationship between the lack of application domain knowledge of IS staff and project performance.

Various learning models incorporate the concept of feedback (Argyris, 1999). Single-loop learning is defined as matching expected consequences to those incurred from action and correcting the actions when a match is not present. Double-loop learning occurs when the mismatch causes a reflection on the underlying rules and principles of the system. This mechanism is similar to the feedback and control mechanisms of cybernetic (control) theory (Henderson & Lee, 1992). In projects, when expectations are not met, this creates feedback that is then used in a learning process to prevent the errors in the future. Thus, when organizational technology learning occurs, subsequent errors in the software development projects are reduced through either corrective action or reformulation of the principles of practice.

Performance improvement by learning is a general assumption in learning research (Lee & Choi, 2003; Sarin & McDermott, 2003). A study on shared knowledge has found positive relationships to group performance (Nelson & Cooprider, 1996). Project teams pursuing project goals are usually defined to be groups along the lines of those whose performance can be improved by shared knowledge (Klein, 1991). Organizations benefit from knowledge management practices implanted during system development and completed system projects (Fedor, Ghosh, Caldwell, Maurer, & Singhal, 2003; Sher & Lee, 2004). This process of sharing knowledge is considered one form of learning (Schulz, 2001). Thus, based on limited empirical results and the adaptive learning model, we expect support for:

- **H3:** There is a positive relationship between organizational technology learning and project performance.

RESEARCH METHODS

Sample

Questionnaires were mailed to 1,000 randomly selected IEEE Computer Society members. The letter salutation was directed to software engineers. This sample is likely familiar with software development activities and, thus, appropriate for study. Instructions in the letter told the targets to consider their responses in light of their most recently completed software development project. From the initial mailing and a follow-up, 221 responses were received. Nine questionnaires were eliminated due to missing data, leaving a final sample of 212 used in the data analysis. Demographic features of the sample population are in Table 1.

Non-response bias occurs when the opinions and perceptions of the survey respondents do not accurately represent the overall sample to which the survey was sent. One test for non-response bias is to compare the demographics of early versus late respondents to the survey (Armstrong & Overton, 1977). T-tests on the means of key demographics (work experience, gender, recent project duration, and team sizes) to examine whether significant differences existed between early and late respondents in the first mailing, and from those received in the first mailing to those in the follow-up mailing, found no significant differences.

Since all independent and dependent variables were collected from the same subject at the same time, common method bias was assessed using Harman's one-factor test (Podsakoff & Organ, 1986). Two models, a single factor model and a four-factor model, were created and tested in EQS. The model fit indices of the single factor model (GFI=0.514, CFI=0.564, Chi-Square = 1343.264, df =152, RMR=0.231, and RMSEA=0.193) were worse than the model fit indices of the four factors model (GFI = 0.849, CFI = 0.928, Chi-Square = 343.6, df =146, RMR=0.068, RMSEA=0.08) indicating that common method bias will not be a potential problem in the following analysis.

Constructs

Project performance is a comprehensive view that includes meeting project goals, budget, schedule, user requirement, and operational efficiency considerations. This is also reflected in the information systems literature in terms of meeting system budget, meeting delivery schedule, fulfilling user requirements, the amount of work produced, the quality of work produced, and an ability to meet project goals (Jones & Harrison, 1996). The items used in this study were adopted from a previous study (Henderson & Lee, 1992). The questionnaire asked respondents' satisfaction with the project team performance when developing information systems. The specific items are listed in Table 2. Each item was scored using a five-point scale ranging from criterion not met at all (1) to criterion fully met (5). All items were presented such that the greater the score, the greater the satisfaction of the particular item.

Organizational technology learning describes the technology knowledge being acquired by the firm (Cooprider & Henderson, 1990). This instrument was applied in previous studies involving organizational technology learning (Cooprider & Henderson, 1990). Three items were used to measure this construct and are shown in Table 2. Respondents were asked to indicate the extent of the items typically incurred when developing IS applications in their organization. Each item was scored using a five-point scale ranging from never occurring (1) to always occurring (5). All items were presented such that the greater the score, the greater the extent of the particular item occurring during the system development.

Table 1. Demographic information

1. Gender	
Male	189
Female	23
2. Position:	
IS Manager	55
Project Leader	71
IS Professional	75
Others	8
3. The industry type of your company:	
Service	110
Manufacturing	78
Education	12
Others	6
4. Average IS project duration in your organization:	
1 years and under	85
1 – 2 years	75
2 – 3 years	23
3 – 5 years	11
6 or more years	13
5. Average size of IS project teams in your organization:	
7 and under	113
8 – 15	69
16 – 25	13
26 and over	13

Lack of application domain knowledge relates to the IS staff's knowledge of the new application areas. *Lack of system development skills* is the IS staff's overall lack of expertise of the development methods used during system development. These two risks are all based on items proposed in earlier studies (Barki, Rivard, & Talbot, 1993; Jiang, Klein, & Means, 2000). The items associated with each of these risks are in Table 2. All items were presented such that the greater the score, the greater the extent of the particular item present during the system development projects.

Analytical Procedures

The analysis followed a two-step procedure. In the first step, confirmatory factor analysis (CFA) was applied to develop a measurement model describing the nature of the relationship between a number of latent factors and the mani-

Table 2. Measurement model—confirmatory factor analysis

Construct Indicators	***Loadings***	***T-value***
Project Performance (α=.90)		
Ability to meet project goals	.79	12.64*
Expected amount of work completed	.76	11.98*
High quality of work completed	.82	13.43*
Adherence to schedule	.75	11.87*
Adherence to budget	.71	10.30*
Efficient task operations	.76	12.09*
Organizational Technology Learning (α=.80)		
Knowledge is acquired by your organization about use of key technologies	.86	13.31*
Knowledge is acquired by your organization about use of development techniques	.83	12.69*
Knowledge is acquired by your organization about supporting users' business	.57	7.95*
Lack of System Development Skills (α=.87)		
Lack of expertise in the development methodology used in projects	.84	13.86*
Lack of expertise in the development support tools used in projects (e.g., DFD, flowcharts, ER model, CASE tools)	.90	15.41*
Lack of expertise in the project management tools used in projects (e.g., PERT charts, Gantt diagrams, walk-throughs, project management software)	.79	12.68*
Lack of expertise in the implementation tools used in projects (e.g., programming languages, data base inquiry languages, screen generators)	.62	9.03*
Lack of Application Domain Knowledge (α=.86)		
The members of the development team are unfamiliar with the application types	.68	10.25*
Insufficient knowledge of organizational operations	.89	14.97*
Lack of knowledge of the functioning of user departments	.95	14.04*
Lack of expertise in the specific application areas of new systems	.71	10.71*

fest indictor variable that measures those latent variables. In step two, the measurement model serves to test the theoretical model of interest. The indicators used to present the latent variables in the theoretical model tested are identical to those presented in the measurement model. This analysis step may be described as a path analysis with latent variables. The path model consists of the unobservable constructs and the theoretical relationships among them (the paths). It evaluates the explanatory power of the model and the significance of paths in the structural model, which represent hypotheses to be tested. The estimated path coefficients indicate the strength and the sign of the theoretical relationships.

Three important assumptions associated with path analysis are: 1) normal distribution of the variables examined; 2) absence of multicollinearity among the variables; and 3) a limit on the maximum number of variables in the model. To test for normality, Mardia's multivariate kurtosis and normalized multivariate kurtosis tests were conducted. No violation was found. Multicollinearity is present when one or more variables exhibit very strong correlations with one another. The correlations between variables (see Table 3) were all less than .80, thus no significant violation of multicollinearity was present (Anderson & Gerbing, 1988).

When conducting a CFA, if the model provides a reasonably good approximation to reality, it should provide a good fit to the data. The CFA for the measurement model resulted in a root mean square residual of .07 (<= .10 is recommended), a chi-square/degree of freedom ratio of 2.41 (<= 3 is recommended), a comparative fit index of .90 (>= .90 recommended), and a non-normed fit index of .89 (>= .90 recommended) using the SAS CALIS procedure. The recommended values are based on research traditions and established authors in the field of structural equation modeling (Bentler, 1990). The measurement model was adequate for the data set.

Convergent validity is demonstrated when different instruments are used to measure the same construct, and scores from these different instruments are strongly correlated. Convergent validity can be assessed through t-tests on the factor loadings, such that the loadings are greater than twice their standard error (Anderson & Gerbing, 1988). The t-tests for the loadings of each variable are in Table 2. The results show that the constructs demonstrate a high convergent validity since all t-values are significant at the .05 levels. In addition, the reliability of each construct is examined by the Cronbach alpha value, all of which exceeded the recommend level of .70 (Nunnally, 1978).

A threat to external validity occurs if the sample shows systematic biases in terms of demographics. An ANOVA was conducted by using project performance as the dependent variable against each demographic category (as independent variables). Results did not indicate any significant relationship to project performance. Similar results were found for the remaining variables in the model. The external validity of the findings is also threatened if the sample is systematically biased – for example, if the responses were generally from projects that are more successful. Table 3 shows the descriptive statistics for the construct. The responses had a good distribution for project performance since the mean and median were similar, skewness was less than two, and kurtosis was less than five (Ghiselli, Campbell, & Zedeck, 1981). Similar results held for the remaining variables. Lastly, external validity is improved if the measures are similar to those found in other studies. In our case, the project performance measure matches within 2% to two other studies (Henderson & Lee, 1992; Jones & Harrison, 1996).

Discriminant validity is demonstrated when different instruments are used to measure different constructs and the correlations between the measures of those different constructs are relatively weak. Discriminant validity is assessed

Table 3. Descriptive analysis and correlations of measures

	Organizational Technology Learning	*Lack of Development Skills*	*Lack of Application Knowledge*	*Project Performance*
Mean	3.64	2.64	2.47	3.52
Std. Dev.	.83	.93	.8	.75
Median	3.67	2.75	2.50	3.67
Skewness	-.34	.09	.07	-.51
Kurtosis	-.26	-.56	-.50	.22
Correlations				
Lack of Development Skills	-.36 (.0001)			
Lack of Application Knowledge	-.37 (.0001)	.64 (.0001		
Project Performance	.54 (.0001)	-.46 (.0001)	-.36 (.0001)	

by using the confidence interval test (Anderson & Gerbing, 1988). A confidence interval test involves calculating a confidence interval of plus or minus two standard errors around the correlation between factors and determining whether this interval includes 1.0 (or -1.0). If the interval (for each pair of constructs) does not include 1.0, discriminant validity is demonstrated. No violations were found.

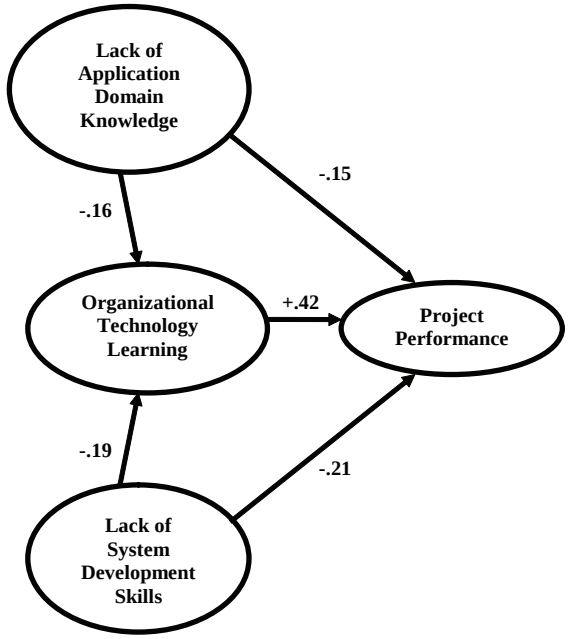
RESULTS

The theorized model in Figure 1 fit the data reasonably well, with a root mean square residual of .08, a chi-square/degree of freedom fit of 2.47, a comparative fit index of .88, and a non-normed fit index of .86. Hypotheses H1a, H1b, H2a, H2b, and H3, were all supported at the .05 significance level. The high R-square value (.49) indicated that the independent variables included in this model were all critical to the project performance. The strengths of these relationships, path coefficients, are on Figure 2.

DISCUSSION

The importance of system development skills and business domain knowledge for IS personnel has been advocated in the IS literature for decades. However, empirical examinations that investigated the relationship between these skills and system success provided conflicting results

Figure 2. Research model path coefficients



(Byrd & Turner, 2001). To provide an alternative explanation of the IS skill puzzle in the literature, this study proposed that organizational technology learning is a mediator between the lack of system development technical skills and application domain knowledge and project performance. Results indicate that risk of lack of skills and knowledge adversely impacts IS software development projects and interferes with the organizational technology learning required to help overcome the risks. Furthermore, organizational technology learning was found to promote project performance.

For researchers, this study complements existing literature in several respects. First, learning does not take place unless a set of knowledge and skills is in place to use as a foundation (Cohen & Levinthal, 1990). This result has specific consequences to the limited framework of the study but also puts forth the idea that risks thought to be associated with project performance may impact other organizational processes and remedies. Second, lack of knowledge and skills is shown to be a large risk to the performance of projects. This study confirms the IS skill literature that a lack of skills does have a *negative* impact on project performance. Third, the *positive* relationship between IS skills and project performance may be explained by the mediator -- organizational technology learning. This extends the mediation results found in the organizational setting to the project environment (Tippins & Sohi, 2003). It provides an alternative explanation for a lack of positive relationships between IS skills and project performance in previous studies. Some natural actions to promote learning of the technology may be needed for the newer developments (Schulz,

2001). Additionally, a direct link between organizational technology learning and the performance of IS projects is established. This goes beyond the literature that considers success limited to the completion of learning, the dissemination of new ideas, or the adoption of new methodologies.

For practitioners, the results encourage management to seek ways to overcome risks associated with knowledge deficiencies. The IS personnel literature contains studies of composing teams that have a variety of knowledge and skills (Jiang, Klein & Balloun, 1998). This goes along with a need for a diversity of knowledge and skills. The knowledge management literature supports this knowledge diversity through examples of loyalty in personnel and cross-fertilization of specialties (Nonaka & Takeuchi, 1995). A set of knowledge must be present in order to acquire more knowledge and must be present in the individuals in order for the organization to acquire and utilize the knowledge as applied skills (Cohen & Levinthal, 1990). Hiring practices must be set to ensure the requisite variety and background in the organization as a whole and in the individual expected to grow the knowledge and skills of the organization.

Organizational policies or practice may also contribute to the ability to overcome lack of knowledge and skills. Training is still an effective tool in the preparation of employees; however, the organization must appropriately target the training. Employees, or groups of employees, with limited background may not gain as much as employees with a stronger background. Employees with a broad technical, business, and liberal arts background have a larger learning set to grow from than do employees with strictly a technical background. Appropriate structures that promote growth of knowledge should serve to leverage existing knowledge (Nonaka & Takeuchi, 1995). Knowledge systems within an organization serve to distribute the knowledge more widely (Davenport & Prusak, 2000). Each of these techniques must be carefully weighed to determine their value in overcoming deficiencies.

The study is limited by its scope and sample. The scope is narrowly defined to include only certain components and only learning that occurs about technology application. However, though this study took a unique posture in its scope, it does confirm existing learning theory. A bigger limitation is on the risks considered. Other risk factors are well known to play a critical role in project performance (Barki et al., 1993). What must be remembered is that risks are not isolated and are often interrelated. The control of one risk factor may lead to an associated increase in another. This study does not account for all of the possible interactions inherent in risk interrelationships.

Chapter 5.27
Patterns for Organizational Modeling

Manuel Kolp
Université Catholique de Louvain, Belgium

Stéphane Faulkner
University of Namur, Belgium

ABSTRACT

Organizational modeling is concerned with analyzing and understanding the organizational context within which a software system will eventually function. This paper proposes organizational patterns motivated by organizational theories intended to facilitate the construction of organizational models. These patterns are defined from real world organizational settings, modeled in i* and formalized using the Formal Tropos language. Additionally, the paper evaluates the proposed patterns using desirable qualities such as coordinability and predictability. The research is conducted in the context of Tropos, a comprehensive software system development methodology.

INTRODUCTION

Analyzing the organizational and intentional context within which a software system will eventually operate has been recognized as an important element of the organizational modeling process also called early requirements engineering (see e.g., Anton, 1996; Dardenne, van Lamsweerde, & Fickas, 1993; Yu, 1995). Such models are founded on primitive concepts such as those of actor and goal. This paper focuses on the definition of a set of organizational patterns that can be used as building blocks for constructing such models. Our proposal is based on concepts adopted from organization theory and strategic alliances literature. Throughout the paper, we use i* (Yu, 1995) as the modeling framework in terms of which the proposed patterns are presented and accounted for. The research reported in this paper is being conducted within the context of the Tropos project

(Giorgini, Kolp, Mylopoulos, & Pistore, 2004; Giorgini, Kolp, Mylopoulos, & Castro, 2005), whose aim is to construct and validate a software development methodology for agent-based software systems. The methodology adopts ideas from multi-agent system technologies, mostly to define the implementation phase of our methodology. It also adopts ideas from Requirements Engineering, where actors and goals have been used heavily for early requirements analysis. The project is founded on the premise that actors and goals are used as fundamental concepts for modeling and analysis during all phases of software development, not just early requirements, or implementation. More details about Tropos can be found in Giorgini, et al., 2005. The present work continues the research in progress about social abstractions for the Tropos methodology. In Kolp, Giorgini and Mylopoulos (2002a), we have detailed a social ontology for Tropos to consider information systems as social structures all along the development life cycle. In Giorgini, Kolp, and Mylopoulos (2002); Kolp, Giorgini, and Mylopoulos (2002b); and Kolp, Giorgini, and Mylopoulos (2006), we have described how to use this Tropos social ontology to design multi-agent systems architectures, notably for e-business applications (Kolp, Do, & Faulkner, 2004). As a matter of fact, multi-agent systems can be considered structured societies of coordinated autonomous agents. In the present paper, which is a extended and revised version of Kolp, Giorgini, and Mylopoulos (2003), we emphasize the use of organizational patterns based on organization theory and strategic alliances for early requirements analysis, with the concern of modeling the organizational setting for a system-to-be in terms of abstractions that could better match its operational environment (e.g., an enterprise, a corporate alliance, etc.).

The paper is organized as follows: The second section describes organizational and strategic alliance theories, focusing on the internal and external structure of an organization. The third section details two organizational patterns—the structure-in-5 and the joint venture—based on real world examples of organizations. These patterns are modeled in terms of social and intentional concepts using the i* framework and the Formal Tropos specification language. The fourth section identifies a set of desirable non-functional requirements for evaluating these patterns and presents a framework to select a pattern with respect to these identified requirements. The fifth section overviews the *Tropos* methodology. Finally, The sixth section summarizes the contributions of the paper and provides an overview of related work.

STRUCTURING ORGANIZATIONS

Organizational structures are primarily studied by *organization theory* (e.g., Mintzberg, 1992; Scott, 1998; Yoshino & Rangan, 1995), that describes the structure and design of an organization and *strategic alliances* (e.g., Dussauge & Garrette, 1999; Gomes-Casseres, 1996; Morabito, Sack, & Bhate, 1999; Segil, 1996), that model the strategic collaborations of independent organizational stakeholders who have agreed to pursue a set of agreed upon business goals.

Both disciplines aim to identify and study organizational patterns that describe a system at a macroscopic level in terms of a manageable number of subsystems, components, and modules interrelated through dependencies.

In this article, we are interested in identifying, formalizing and applying organizational modeling patterns that have been already well-understood and precisely defined in organizational theories. Our purpose is neither to categorize them exhaustively nor to study them on a managerial point of view. The following sections will thus only insist on patterns that have been found, due to their nature, interesting candidates, also considering the fact that they have been studied in great detail in the organizational literature and presented as fully-formed patterns.

Organization Theory

"An organization is a consciously coordinated social entity, with a relatively identifiable boundary, that functions on a relatively continuous basis to achieve a common goal or a set of goals" (Morabito et al., 1999). Organization theory is the discipline that studies both structure and design in such social entities. Structure deals with the descriptive aspects, while design refers to the prescriptive aspects of a social entity. Organization theory describes how practical organizations are actually structured, offers suggestions on how new ones can be constructed, and suggests how old ones can change to improve effectiveness. To this end, since Adam Smith, schools of organization theory have proposed models and patterns to try to find and formalize recurring organizational structures and behaviors.

In the following, we briefly present organizational patterns identified in Organization Theory. The structure-in-5 will be studied in detail in the next section.

The Structure-in-5

An organization can be considered an aggregate of five substructures, as proposed by Minztberg (1992). At the base level sits the *Operational Core,* which carries out the basic tasks and procedures directly linked to the production of products and services (acquisition of inputs, transformation of inputs into outputs, and distribution of outputs). At the top lies the *Strategic Apex* which makes executive decisions ensuring that the organization fulfils its mission in an effective way and defines the overall strategy of the organization in its environment. The *Middle Line* establishes a hierarchy of authority between the Strategic Apex and the Operational Core. It consists of managers responsible for supervising and coordinating the activities of the Operational Core. The *Technostructure* and the *Support* are separated from the main line of authority and influence the operating core only indirectly. The Technostructure serves the organization by making the work of others more effective, typically by standardizing work processes, outputs, and skills. It is also in charge of applying analytical procedures to adapt the organization to its operational environment. The Support provides specialized services at various levels of the hierarchy, outside the basic operating workflow (e.g., legal counsel, R&D, payroll, and cafeteria). We describe and model examples of structures-in-5 in the next section.

The Pyramid Pattern

A well-known hierarchical authority structure. Actors at lower levels depend on those at higher levels. The crucial mechanism is the direct supervision from the Apex. Managers and supervisors at intermediate levels only route strategic decisions and authority from the Apex to the operating (low) level. They can coordinate behaviors or take decisions on their own, but only at a local level.

The Chain of Values

The chain of values merges, backward or forward, several actors engaged in achieving or realizing related goals or tasks at different stages of a supply or production process. Participants who act as intermediaries, add value at each step of the chain. For instance, for the domain of goods distribution, providers are expected to supply quality products, wholesalers are responsible for ensuring their massive exposure, while retailers take care of the direct delivery to the consumers.

The Matrix

The matix proposes a multiple command structure: vertical and horizontal channels of information and authority operate simultaneously. The principle of unity of command is set aside, and competing bases of authority are allowed to jointly govern the workflow. The vertical lines are typi-

cally those of functional departments that operate as "home bases" for all participants, the horizontal lines represent project groups or geographical arenas where managers combine and coordinate the services of the functional specialists around particular projects or areas.

The Bidding Pattern

The bidding pattern involves competitive mechanisms, and actors behave as if they were taking part in an auction. An auctioneer actor runs the show, advertises the auction issued by the auction issuer, receives bids from bidder actors and ensures communication and feedback with the auction issuer who is responsible for issuing the bidding.

Strategic Alliances

A strategic alliance links specific facets of two or more organizations. At its core, this structure is a trading partnership that enhances the effectiveness of the competitive strategies of the participant organizations by providing for the mutually beneficial trade of technologies, skills, or products based upon them. An alliance can take a variety of forms, ranging from arm's-length contracts to joint ventures, multinational corporations to university spin-offs, and franchises to equity arrangements. Varied interpretations of the term exist, but a strategic alliance can be defined as possessing simultaneously the following three necessary and sufficient characteristics:

- The two or more organizations that unite to pursue a set of agreed upon goals remain independent, subsequent to the formation of the alliance.
- The partner organizations share the benefits of the alliances and control over the performance of assigned tasks.
- The partner organizations contribute on a continuing basis in one or more key strategic areas, e.g., technology, products, and so forth.

In the following, we briefly present organizational patterns identified in strategic alliances. The joint venture will be studied in detail in the third section.

Joint Venture Pattern

The joint venture pattern involves agreement between two or more intra-industry partners to obtain the benefits of larger scale, partial investment, and lower maintenance costs. A specific joint management actor coordinates tasks and manages the sharing of resources between partner actors. Each partner can manage and control itself on a local dimension and interact directly with other partners to exchange resources, such as data and knowledge. However, the strategic operation and coordination of such an organization, and its actors on a global dimension, are only ensured by the joint management actor in which the original actors possess equity participations. We describe and model examples of joint ventures in the third section.

Arm's-Length Pattern

The arm's-length pattern implies agreements between independent and competitive, but partner, actors. Partners keep their autonomy and independence but act and put their resources and knowledge together to accomplish precise common goals. No authority is lost or delegated from one collaborator to another.

Hierarchical Contracting Pattern

The hierarchical contracting pattern identifies coordinating mechanisms that combine arm's-length

agreement features with aspects of pyramidal authority. Coordination mechanisms developed for arm's-length (independent) characteristics involve a variety of negotiators, mediators, and observers at different levels handling conditional clauses to monitor and manage possible contingencies, negotiate and resolve conflicts, and finally deliberate and take decisions. Hierarchical relationships, from the executive apex to the arm's-length contractors, restrict autonomy and underlie a cooperative venture between the parties.

Co-Optation Pattern

The co-optation pattern involves the incorporation of representatives of external systems into the decision-making or advisory structure and behavior of an initiating organization. By co-opting representatives of external systems, organizations are, in effect, trading confidentiality and authority for resource, knowledge assets, and support. The initiating system has to come to terms with the contractors for what is being done on its behalf; each co-optated actor has to reconcile and adjust its own views with the policy of the system it has to communicate.

MODELING ORGANIZATIONAL PATTERNS

We will define an organizational pattern as a metaclass of organizational structures offering a set of design parameters to coordinate the assignment of organizational objectives and processes, thereby affecting how the organization itself functions. Design parameters include, among others, goal and task assignments, standardization, supervision and control dependencies, and strategy definitions.

This section describes two of the organizational patterns presented in the second section: the structure-in-5 and the joint-venture.

Structure-in-5

To detail and specify the structure-in-5 as an organizational pattern, this section presents two case studies: LDV Bates (Bates, 2006) and GMT (GMT, 2006). They will serve to propose a model and a semi-formal specification of the structure-in-5.

LDV Bates

Agate Ltd. is an advertising agency located in Belgium that employs about fifty staff, as detailed in Table 1.

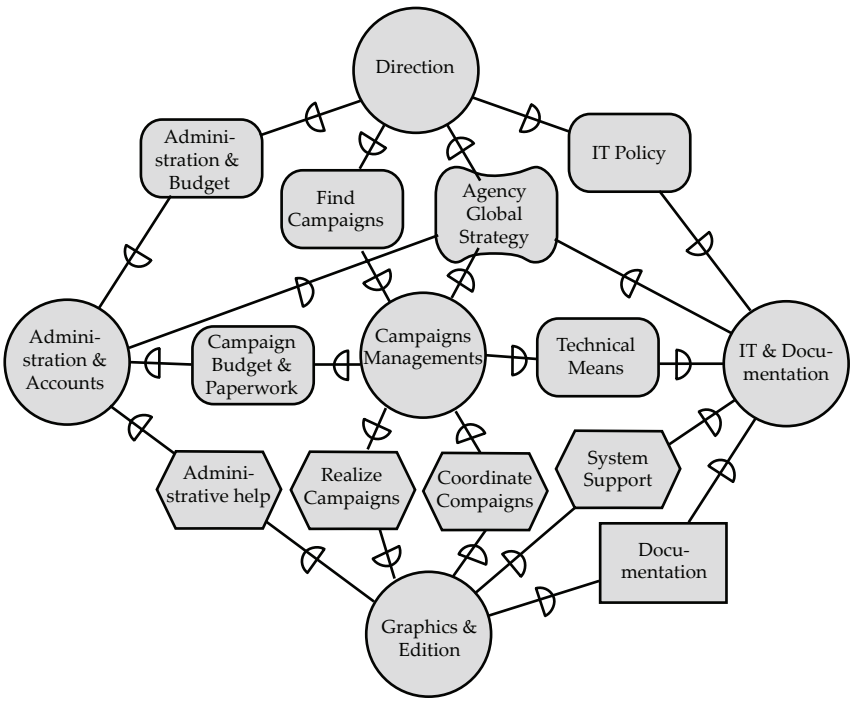
The *Direction*—four directors responsible for the main aspects of LDV Bates's *Global Strategy* (advertising campaigns, creative activities, administration, and finances)—forms the *Strategic Apex*. The *Middle Line*, composed of the *Campaigns Management* staff, is in charge of finding and coordinating advertising campaigns (marketing, sales, edition, graphics, budget, etc.). It is supported in these tasks by the *Administration and Accounts* and *IT and Documentation* departments. *Administration and Accounts* constitutes the *Technostructure* handling administrative tasks and policy, paperwork, purchases, and budgets. The Support groups the IT and Documentation departments. It defines the *IT policy* of Agate, provides *technical means* required for the management of campaigns, and ensures services for *system support* as well as information retrieval (*documentation* resources). The *Operational Core* includes the *Graphics and Edition* staff in charge of the creative and artistic aspects of realizing *campaigns* (texts, photographs, drawings, layout, design, and logos).

Figure 1 models LDV Bates in structure-in-5 using the i* strategic dependency model. i* is a framework for organizational modeling (Yu, 1995), which offers goal-and-actor-based notions, such as *actor, agent, role, position, goal, softgoal, task, resource and belief, as well as* different kinds

Table 1. Organization of LDV Bates

Direction	***Edition***	
1 Campaigns Director	2 Editors	***IT***
1 Creative Director	4 Copy writers	1 IT manager
1 Administrative Director		1 Network administrator
1 Finance Director	***Documentation***	1 System administrator
	1 Media librarian	1 Analyst
Campaigns Management	1 Resource librarian	1 Computer technician
2 Campaign managers	1 Knowledge worker	
3 Campaign marketers		
1 Editor in Chief	***Administration***	***Accounts***
1 Creative Manager	3 Direction assistants	1 Accountant manager
	4 Manager Secretaries	1 Credit controller
Graphics	2 Receptionists	2 Accounts clerks
6 Graphic designers	2 Clerks/typists	2 Purchasing assistants
2 Photographers	1 Filing clerk	

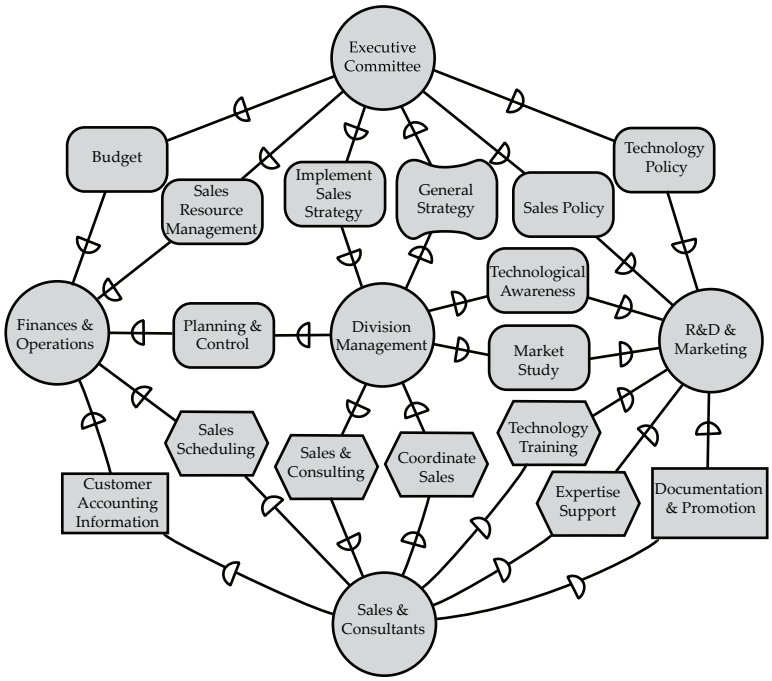
Figure 1. LDV Bates as a Structure-in-5



of social dependency between actors. Its strategic dependency model describes the network of social *dependencies* among actors. It is a graph, wherein each node represents an actor, and each link between two actors indicates that one actor depends on the other for some goal to be attained. A dependency describes an "agreement" (called *dependum*) between two actors: the *depender* and the *dependee*. The depender is the depending actor, and the dependee, the actor who is depended upon. The type of the dependency describes the nature of the agreement. *Goal* dependencies represent delegation of responsibility for fulfilling a goal; *softgoal* dependencies are similar to goal dependencies, but their fulfillment cannot be defined precisely (for instance, the appreciation is subjective or fulfillment is obtained only to a given extent); *task* dependencies are used in situations where the dependee is required to perform a given activity; and resource dependencies require the dependee to provide a resource to the depender. As shown in Figure 1, actors are represented as circles; dependums–goals, softgoals, tasks, and resources–are represented as ovals, clouds, hexagons, and rectangles, respectively, and dependencies have the form *depender* → *dependum* → *dependee*.

GMT is a company specialized in telecom services in Belgium. Its lines of products and services range from phones & fax, conferencing, line solutions, internet & e-business, mobile solutions, and voice & data management. As shown in Figure 2, the structure of the commercial organization follows the structure-in-5. An *Executive Committee* constitutes the *Strategic Apex*. It is responsible for defining the *general strategy* of the organization. Five chief managers (*finances*, *operations*, *divisions management*, *marketing*,

Figure 2. GMT's sales organization as a structure-in-5



and *R&D*) apply the specific aspects of the *general strategy* in the area of their competence: *Finances & Operations* is in charge of *Budget* and Sales *Planning* & *Control, Divisions Management* is responsible for *Implementing Sales Strategy*, and *Marketing* and *R&D* define *Sales Policy* and *Technological Policy.*

The *Divisions Management* groups managers that coordinate all managerial aspects of product and service sales. It relies on *Finance & Operations* for handling *Planning* and *Control* of products and services, it depends on *Marketing* for accurate *Market Studies,* and on R&D for *Technological Awareness.*

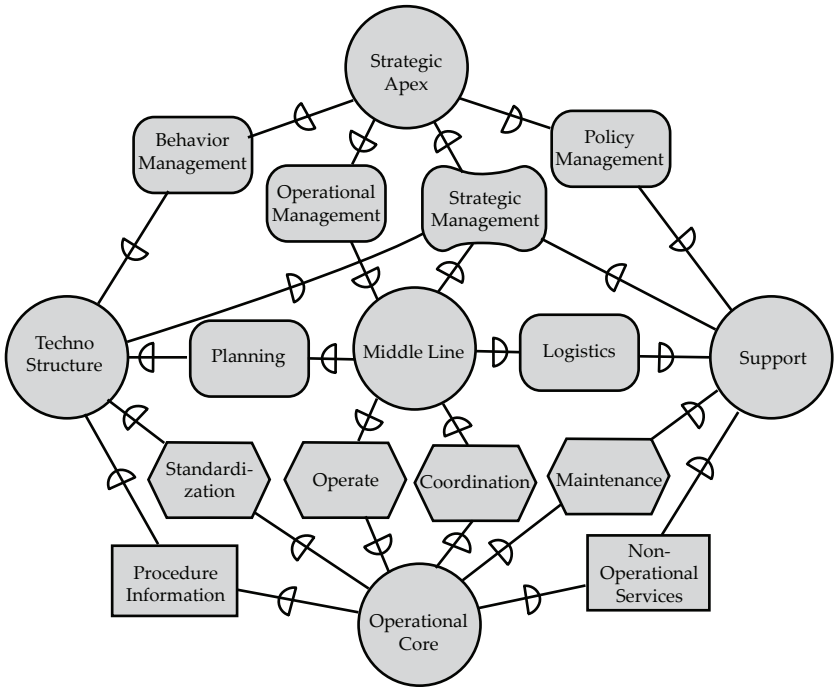
The *Finances & Operations* departments constitute the *technostructure* in charge of management *control* (financial and quality audit) and sales *planning,* including *scheduling* and *resource management.*

Support involves the staff of *Marketing* and *R&D.* Both departments jointly define and support the *Sales* Policy. The Marketing department coordinates *Market Studies* (customer positioning and segmentation, pricing, sales incentive, etc.) and provides the *Operational Core* with *Documentation* and *Promotion* services. The *R&D* staff is responsible for defining the technological policy, such as *technological awareness* services. It also assists *Sales people* and *Consultants* with *Expertise Support* and *Technology* Training.

Finally, the *Operational Core* groups *the Sales people* and *Line consultants* under the supervision and coordination of *Divisions Managers.* They are in charge of selling products and services to actual and potential customers.

Figure 3 abstracts the structures explored in the case studies of Figures 1 and 2 as a structure-in-5 pattern composed of five actors. The case

Figure 3. The structure-in-5 pattern



studies also suggested a number of constraints to supplement the basic pattern:

- Dependencies between the *Strategic Apex* as depender and the *Technostructure*, *Middle Line*, and *Support* as dependees must be of type goal
- A softgoal dependency models the strategic dependence of the *Technostructure*, *Middle Line*, and *Support* on the *Strategic Apex*
- Relationships between the *Middle Line* and *Technostructure* and *Support* must be of goal dependencies
- *Operational Core* relies on the *Technostructure* and *Support* through task and resource dependencies
- Only task dependencies are permitted between the *Middle Line* (as depender or dependee) and the *Operational Core* (as dependee or depender)

To specify the formal properties of the pattern, we use *Formal Tropos* (Fuxman, Liu, Mylopoulos, Roveri, & Traverso, 2004), which extends the primitives of *i** with a formal language comparable to that of KAOS (Dardenne, et al., 1993). Constraints on *i** specifications are thus formalized in a first-order linear-time temporal logic. *Formal Tropos* provides three basic types of metaclasses: *actor, dependency, and entity* (Giorgini, Kolp, & Mylopoulos, 2002). The attributes of a *Formal Tropos* class denote relationships among different objects being modeled.

Metaclasses

Actor : = **Actor** name[attributes] [creation-properties] [invar-properties][actor-goal]
With subclasses:
Agent(with attributes occupies: Position, play: Role)
Position(with attributes cover: Role)
Role
Dependency : =**Dependency** name type mode **Depender** name **Dependee** name [attributes] [creation-properties] [invar-properties] [fulfill-properties]
Entity:=**Entity** name [attribute] [creation-properties][invar-properties]
Actor-Goal := (**Goal**|**Softgoal**) name mode **FulFillment**(actor-fulfill-property)

Classes: Classes are instances of Metaclasses.

In Formal Tropos, constraints on the lifetime of the (meta)class instances are given in a first-order linear-time temporal logic (see Fuxman et al., 2004 for more details). Special predicates can appear in the temporal logic formulas: predicate *JustCreated*(*x*) holds in a state if element *x* exists in this state but not in the previous one; predicate *Fulfilled*(*x*) holds if *x* has been fulfilled; and predicate *JustFulfilled*(*x*) holds if *Fulfilled*(*x*) holds in this state, but not in the previous one.

In the following, we only present some specifications for the *Strategic Management* and *Operational Management* dependencies.

Actor StrategicApex
Actor MiddleLine
Actor Support
Actor Technostructure
Actor OperationalCore

Dependency StrategicManagement
Type SoftGoal
Depender te: Technostructure, ml: MiddleLine, su: Support
Dependee sa: StrategicApex
Invariant
$\forall dep : Dependency\ (JustCreated(dep) \rightarrow Consistent(self, dep))$
$\forall ag : Actor - Goal\ (JustCreated(ag) \rightarrow Consistent(self, ag))$

Fulfillment

$\forall dep : Dependency\ (dep.type = goal \wedge dep.depender = sa \wedge (dep.dependee = te\ dep.dependee = ml\ dep.dependee = su)) \wedge Fulfilled(self) \rightarrow \blacklozenge Fulfilled(dep)$

[*Invariant properties specify, respectively, that the strategic management softgoal must be consistent with any other dependency of the organization and with any other goal of the actors in the organization. The predicate Consistent depends on the particular organization we are considering and it is specified in terms of goals' properties to be satisfied. The fulfillment of the dependency necessarily implies that the goal dependencies between the Middle Line, the Technostructure, and the Support as dependees, and the Strategic Apex as depender have been achieved some time in the past]*

Dependency OperationalManagement **Type** Goal
Mode achieve
Depender sa: StrategicApex
Dependee ml: MiddleLine
Invariant

$Consistent(self, StrategicM\ anagement)$
$\exists\ c : Coordination\ (c.type = task \wedge c.dependee = ml \wedge c.depender = OperationalCore \wedge ImplementedBy(self, c))$

Fulfillment

$\forall ts : Technostructure, dep : Dependency\ (dep.type = goal \wedge dep.depender = ml \wedge dep.dependee = ts) \wedge Fulfilled(self)) \rightarrow \blacklozenge Fulfilled(dep)$

[The fulfillment of the Operational management goal implies that all goal dependencies between the Middle Line as depender and the Technostructure as dependee have been achieved some time in the past. Invariant properties specifies that the Operational Management goal has to be consistent with Strategic Management softgoal and that there exists a coordination task (a task dependency between MiddleLine and Operational Core) that implements (ImplementedBy) the OperationalManagaemnt goal.]

In addition, the following structural (global) properties must be satisfied for the Structure-in-5 pattern:

- $\forall inst1, inst2 : StrategicApex \rightarrow inst1 = inst2$

[There is a single instance of the Strategic Apex (the same constraint also holds for the Middle Line, the Technostructure, the Support, and the Operational Core)]

- $\forall sa : StrategicApex, te : Technostructure, ml : MiddleLine, su : Support, dep : Dependency\ (dep.dependee = sa \wedge (dep.depender = te \vee dep.depender = ml \vee dep.depender = su) \rightarrow dep.type = softgoal)$

[Only softgoal dependencies are permitted between the Strategic Apex as dependee and the Technostructure, the Middle Line, and the Support as dependers]

- $\forall sa : StrategicApex, te : T echnostructure, ml : M iddleLine, su : Support, dep : Dependency : (dep.depender = sa \wedge (dep.dependee = te \vee dep.dependee = ml \vee dep.dependee = su) \rightarrow dep.type = goal)$

[Only goal dependencies are permitted between the Technostructure, the Middle Line, and the Support as dependee, and the Stategic Apex as depender]

- $\forall su : Support, ml : M iddleLine, dep : Dependency$
  $((dep.dependee = su \wedge dep.depender = ml) \rightarrow dep.type = goal)$

  [Only task dependencies are permitted between the Middle Agency and the Operational Core]

- $\forall te : T echnostructure, oc : OperationalCore, dep : Dependency$
  $((dep.dependee = te \wedge dep.depender = oc) \rightarrow$
  $(dep.type = task \vee dep.type = resource))$

[Only resource or task dependencies are permitted between the Technostructure and the Operational Core (the same constraint also holds for the Support)]

- $\forall a : Actor, ml : M iddleLine,$
  $(\exists dep : Dependency(dep.depender = a \wedge dep.dependee =$
  $ml) \vee (dep.dependee = a \wedge dep.depender = ml) \rightarrow$
  $((\exists sa : StrategicApex(a = sa)) \vee (\exists su : Support(a = su) \vee$
  $(\exists te : T echnostructure(a = te)) \vee (\exists op : OperationalCore$
  $(a = op))$

[No dependency is permitted between an external actor and the Middle Agency (the same constraint also holds for the Operational Core)]

This specification can be used to establish that a certain *i** model does constitute an instance of the structure-in-5 pattern. For example, the *i** model of Figure 1 can be shown to be such an instance, in which the actors are instances of the structure-in-5 actor classes (e.g., *Direction* and *IT&Documentation* are instances of the *Strategic Apex* and the *Support*, respectively), dependencies are instances of structure-in-5 dependencies classes (e.g., *Agency Global Strategy* is an instance of the *Strategic Management*), and all above global properties are enforced (e.g., since there are only two task dependencies between *Campaigns Management* and *Graphics&Edition*, the fourth property holds).

Joint Venture

We describe here two alliances—Airbus (Dussauge & Garrette, 1999) and a more detailed one, Carsid (Wautelet, Kolp, & Achbany, 2006)—that will serve to model the joint venture structure as an organizational pattern and propose a semi-formal specification.

Airbus. The Airbus Industrie joint venture coordinates collaborative activities between European aeronautic manufacturers to build and market airbus aircraft. The joint venture involves four partners: British Aerospace (UK), Aerospatiale (France), DASA (Daimler-Benz Aerospace, Germany), and CASA (Construcciones Aeronauticas SA, Spain). Research, development, and production tasks have been distributed among the partners, avoiding any duplication. Aerospatiale is mainly responsible for developing and manufacturing the cockpit of the aircraft and for system integration. DASA develops and manufactures the fuselage, British Aerospace the wings, and CASA the tail unit. Final assembly is carried out in Toulouse (France) by Aerospatiale. Unlike production, commercial and decisional activities have not been split among partners. All strategy, marketing, sales, and after-sales operations are entrusted to the Airbus Industrie joint venture, which is the only interface with external stakeholders, such as customers. To buy an Airbus, or to maintain their fleet, customer airlines could not approach one or another of the partner firms directly, but have to deal with Airbus Industrie. Airbus Industrie, which is a real manufacturing company, defines the alliance's product policy and

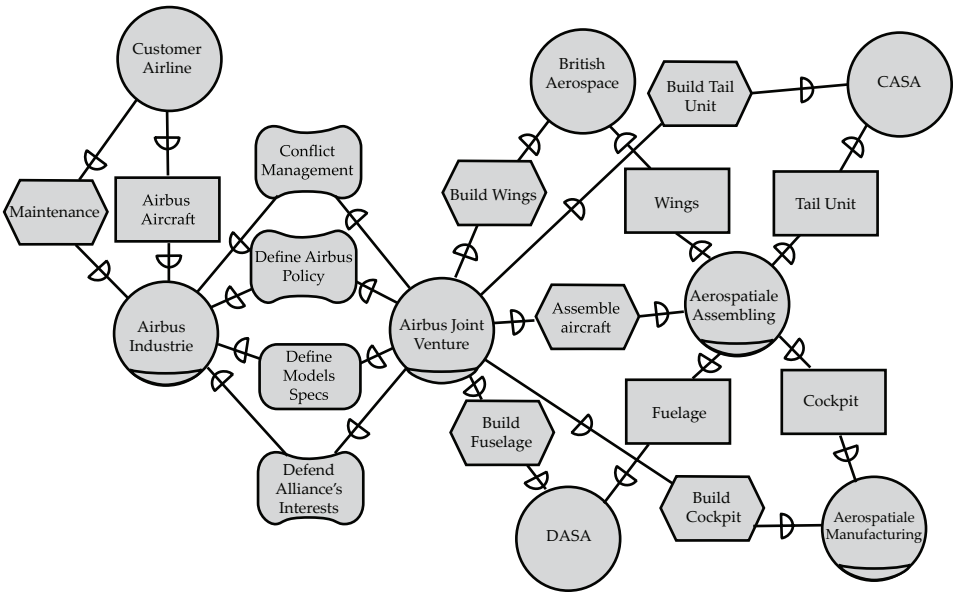
elaborates the specifications of each new model of aircraft to be launched. Airbus defends the point of view and interests of the alliance as a whole, even against the partner companies themselves when the individual goals of the latter enter into conflict with the collective goals of the alliance.

Figure 4 models the organization of the Airbus Industrie joint venture using the *i** strategic dependency model. Airbus assumes two roles: Airbus Industrie and Airbus Joint Venture.

Airbus Industrie deals with demands from customers, *Customer* depends on it to receive airbus aircrafts or maintenance services. The *Airbus Joint Venture* role ensures the interface for the four partners (*CASA*, *Aerospatiale*, *British Aerospace*, and *DASA*) with *Airbus Industrie* defining Airbus strategic policy, managing conflicts between the four Airbus partners, defending the interests of the whole alliance, and defining new aircraft specifications. *Airbus Joint Venture* coordinates the four partners, ensuring that each of them assumes a specific task in the building of Airbus aircrafts: wings building for *British Aerospace*, tail unit building for *CASA*, cockpit building and aircraft assembling for *Aerospace*, and fuselage building for *DASA*. Since Aerospatiale assumes two different tasks, it is modeled as two roles: *Aerospatiale Manufacturing* and *Aerospatiale Assembling*. *Aerospatiale Assembling* depends on each of the four partners receiving the different parts of the planes.

Carsid (Carolo-Sidérurgie) is a joint venture that has recently arisen from the global concentration movement in the steel industry. The alliance, physically located in the steel basin of Charleroi in Belgium, has been formed by the steel companies Duferco (Italy), Usinor (France)—that also partially owns Cockerill-Sambre (Belgium) through the Arcelor group—and Sogepa (Belgium), a public investment company representing the Walloon Region Government. Usinor has also brought its subsidiary Carlam into the alliance.

Figure 4. The Airbus Industrie joint venture

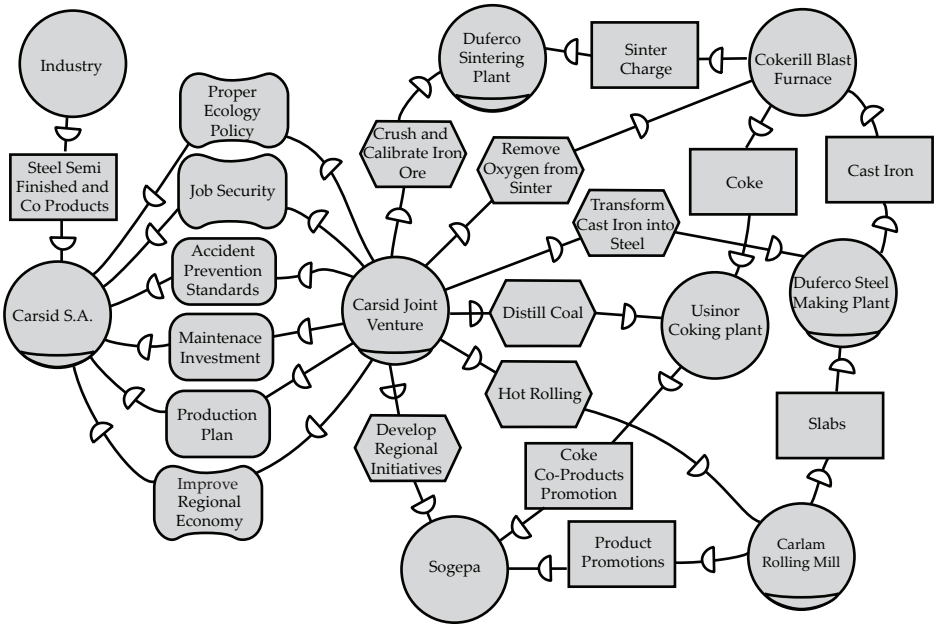


Roughly speaking, the aim of a steel manufacturing company like CARSID is to extract iron from the ore and to turn it into semi-finished steel products. Several steps compose the transformation process, each step is generally assumed by a specific metallurgic plant:

- **Sintering plant:** Sintering is the preparation of the iron ore for the blast furnace. The minerals are crushed and calibrated to form a sinter charge.
- **Coking plant:** Coal is distilled (i.e., heated in an air-impoverished environment in order to prevent combustion) to produce coke.
- **Blast furnace:** Coke is used as a combustion agent and as a reducing agent to remove the oxygen from the sinter charge. The coke and sinter charge are loaded together into the blast furnace to produce cast iron.
- **Steel making plant:** Different steps (desulphuration, oxidation, steel adjustment, cooling, etc.) are necessary to turn cast iron into steel slabs and billets. First, elements other than iron are removed to create molten steel. Then, supplementary elements (e.g., titanium, niobium, and vanadium) are added to make a more robust alloy. Finally, the result—finished steel—is solidified to produce slabs and billets.
- **Rolling mill:** The manufacture of semi-finished products involves a process known as hot rolling. Hot-rolled products are of two categories: flat (plates, coiled sheets, sheeting, strips, etc.) produced from steel slabs and long (wire, bars, rails, beams, girders, etc.) produced from steel billets.

Figure 5 models the organization of the Carsid joint venture in *i**. Carsid assumes two roles: Carsid S.A. ("Société Anonyme"–the English equivalent is "Ltd") and Carsid Joint Venture.

Figure 5. The Carsid joint venture

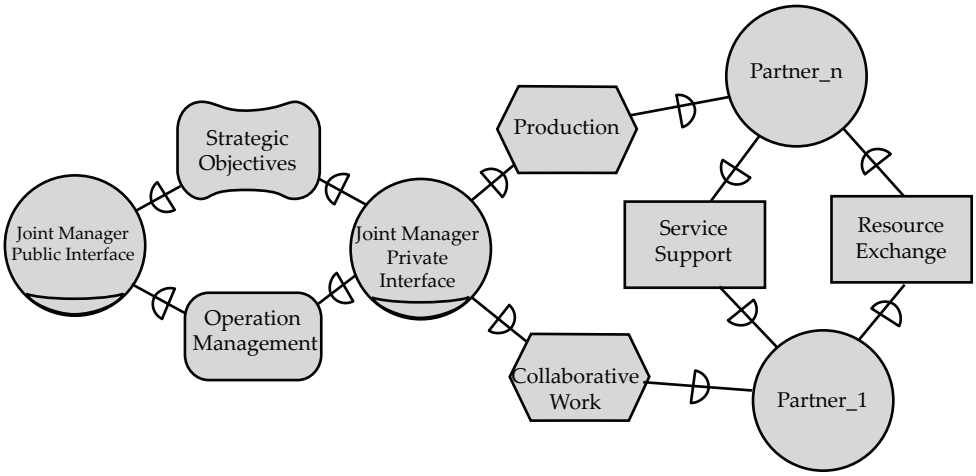


Carsid S. A. is the legal and contractual interface of the joint venture. It handles the sales of *steel semi-finished products* (bars, plates, rails, sheets, etc., but also slabs and billets) and *co-products* (coke that does not meet blast furnace requirements, rich gases from the different plants, godroon, naphtalin, etc.) to external *industries* such as vehicle manufacturers (e.g., automobiles, trains, and boats), foundries, gas companies, and building companies. It is also in charge of the *proper environment policy*, a strategic aspect for steelworks that are polluting plants. Most important, Carsid has been set up with the help of the Walloon Region to guarantee *job security* for about 2000 workers in the basin of Charleroi. Indeed, the steel industry in general and the Walloon metallurgical basins in particular are sectors in difficulty with high unemployment rates. As a corollary, the joint venture is committed to *improve regional economy* and maintain work in the region. Carsid has then been contractually obliged to plan *maintenance investment* (e.g., blast furnace refection, renovation of coke oven batteries, etc.) and develop *production plans* involving regional subcontractors and suppliers. Since steelmaking is a hard and dangerous work sector, Carsid, like any other steelworks, is legally committed to respect, develop, and promote *accident prevention standards.*

The *Carsid joint venture* itself coordinates the steel manufacturing process. The sintering phase to *prepare iron ore* is the responsibility of *Duferco Sintering Plant* while *Usinor Coking Plant, distills coal* to turn it onto *coke*. The *sinter charge* and *coke* are used by the Cokerill Blast Furnace to produce *cast iron* by *removing oxygen from sinter.* The *Duferco Steel Making Plant transforms cast iron into steel* to produce slabs and billets for the *Carlam Rolling Mill* in charge of the *hot rolling* tasks. Carlam (Carolo-Laminoir). *Sogepa*, the public partner, has the responsibility to *develop regional initiatives* to promote Carsid activities, particularly in the Walloon Region and in Belgium.

Figure 6 abstracts the joint venture structures explored in the case studies of Figures 4 and 5. The case studies suggest a number of constraints to supplement the basic pattern:

Figure 6. The joint venture pattern



- Partners depend on each other for providing and receiving resources
- Operation coordination is ensured by the joint manager actor, which depends on partners for the accomplishment of these assigned tasks
- The joint manager actor must assume two roles: A private interface role to coordinate partners of the alliance and a public interface role to take strategic decisions, define policy for the private interface, and represent the interests of the whole partnership with respect to external stakeholders

Part of the Joint Venture pattern specification is in the following:

Role JointManagerPrivateInterface Goal CoordinatePatterns
Role JointManagerPublicInterface
Goal TakeStrategicDecision
SoftGoal RepresentPartnershipInterests
Actor Partner

and the following structural (global) properties must be satisfied:

- ∀jmpri1, jmpri2 : J ointManagerPrivateInterface
  (jmpri1 = jmpri2)

  [Only one instance of the joint manager]

- *∀p1, p2 : P artner, dep : Dependency*
  (((dep.depender = p1 ∧ dep.dependee = p2)
  ∨ (dep.depender =
  p2 ∧ dep.dependee = p1)) → (dep.type = resource))

  [Only resource dependencies between partners]

- *∀jmpri : JointManagerPrivateInterface, p : Partner, dep : Dependency((dep.dependee = p ∧ dep.depender = jmpri)*
  →dep.type = task)

  [Only task dependencies between partners and the joint manager, with the joint manager as depender]

- *∀jmpri : JointM anagerPrivateInterf ace, jmpui : JointM anagerPublicInterf ace, dep : Dependency ((dep.depender = jmpri ∧ dep.dependee = jmpui)*
  → (dep.type = goal ∨ dep.type = softgoal))

[Only goal or softgoal dependencies between the joint manager roles]

- *∀dep : Dependency, p1 : Partner ((dep.depender = p1 ∨ dep.dependee = p1) →*
  ((∃p2 : P artner(p1≠ p2 ∧ (dep.depender = p2 ∨ dep.dependee = p2))
  ∨ (∃jmpi : J ointM anagerP rivateInterf ace ((dep.depender = jmpi ∨dep.dependee = jmpi))))

  [Partners only have relationships with other partners or the joint manager private interface]
- *∀dep : Dependency, jmpi : J ointM anagerP rivateInterf ace ((dep.depender = jpmi ∨dep.dependee = jpmi) →*
  ((∃p : P artner((dep.depender = p ∨ dep.dependee = p))) ∨
  (∃jmpui : J ointM anagerP ublicInterf ace ((dep.depender = jmpui ∨dep.dependee = jmpui))))

  [The joint manager private interface only has relationships with the joint manager public interface or partners]

EVALUATION

Patterns can be compared and evaluated with quality attributes (Shaw & Garlan, 1996), also called non-functional requirements (Chung, Nixon, Yu, & Mylopoulos, 2000). For instance, the requirements seem particularly relevant for organizational structures (Do, Faulkner, & Kolp, 2003; Kolp, et al., 2006):

- **Predictability** (Woods & Barbacci, 1999): Actors can have a high degree of autonomy (Wooldridge & Jennings, 1995) in the way that they undertake action and communication in their domains. It can be then difficult to predict individual characteristics as part of determining the behavior of the system at large. Generally, predictability is in contrast with the actors' capabilities to be adaptive and responsive: Actors must be predictable enough to anticipate and plan actions while being responsive and adaptive to unexpected situations.
- **Security:** Actors are often able to identify their own data and knowledge sources and they may undertake additional actions based on these sources (Woods & Barbacci, 1999). Strategies for verifying authenticity for these data sources by individual actors are an important concern in the evaluation of overall system quality since, in addition to possibly misleading information acquired by actors, there is the danger of hostile external entities spoofing the system to acquire information accorded to trusted domain actors.
- **Adaptability:** Actors may be required to adapt to modifications in their environment. These may include changes to the component's communication protocol or possibly the dynamic introduction of a new kind of component previously unknown or the manipulations of existing actors.

Generally, adaptability depends on the capabilities of the single actors to learn and predict the changes of the environments in which they act (Weiss, 1997), and also their capability to make a diagnosis (Horling, Lesser, Vincent, Bazzan, & Xuan, 1999), that is, being able to detect and determine the causes of a fault based on its symptoms. However, successful organization environments tend to balance the degree of reactivity and predictability of the single actors with their capabilities to be adaptive.

- **Coordinability:** Actors are not particularly useful unless they are able to coordinate with other agents. Coordination is generally (Jennings, 1996) used to distribute expertise, resources, or information among the actors (actors may have different capabilities, specialized knowledge, different sources of information, resources, responsibilities, limitations, charges for services, etc.), solve interdependencies between actors' actions (interdependence occurs when goals undertaken by individual actors are related), meet global constraints (when the solution being developed by a group of actors must satisfy certain conditions if is to be deemed successful), and to make the system efficient (even when individuals can function independently, thereby obviating the need for coordination, information discovered by one actor can be of sufficient use to another actor that both actors can solve the problem twice as fast).

Coordination can be realized in two ways:

1. **Cooperativity:** Actors must be able to coordinate with other entities to achieve a common purpose or simply align their local goals. Cooperation can either be communicative in that the actors communicate (the intentional sending and receiving of signals) with each

other in order to cooperate or it can be non-communicative (Doran, Franklin, Jennings, & Norman, 1997). In the latter case, actors coordinate their cooperative activity by each observing and reacting to the behavior of the other. In deliberative organizations, actors jointly plan their actions so as to cooperate with each other.

2. **Competitivity:** Deliberative negotiating organization (Doran et al., 1997) are like deliberative ones, except that they have an added dose of competition. The success of one actor implies the failure of others.

- **Availability:** Actors that offer services to other actors must implicitly or explicitly guard against the interruption of offered services.
- **Fallibility-tolerance:** A failure of one actor does not necessarily imply a failure of the whole organization. The organization then needs to check the completeness and the accuracy of information and knowledge transactions and workflows. To prevent failure, different actors can have similar or replicated capabilities and refer to more than one actor for a specific behavior.
- **Modularity:** (Shehory, 1998) increases efficiency of service execution, reduces interaction overhead, and usually enables high flexibility. On the other hand, it implies constraints on inter-organization communication.
- **Aggregability:** Some actors are parts of other actors. They surrender to the control of the composite entity. This control results in efficient workflow execution and low interaction overhead. However, it prevents the organization to benefit from flexibility.

As an illustration, we evaluate the patterns with respect to coordinativity, predictability, fallibility-tolerance, and adaptability. The evaluation can be done in a similar way for the other non-functional requirements. Due to the lack of space, we refer the author to the bibliography for the other attributes.

The structure-in-5 improves coordinativity among actors by differentiating the data hierarchy (the support actor) from the control hierarchy—supported by the operational core, technostructure, middle agency, and strategic apex. The existence of three different levels of abstraction (1) Operational Core; (2) Technostructure, Middle Line, and Support; (3) Strategic Apex addresses the need for managing predictability. Besides, higher levels are more abstract than lower levels: Lower levels only involve resources and task dependencies while higher ones propose intentional (goal and soft-goal) relationships. Checks and control mechanisms can be integrated at different levels of abstraction assuming redundancy from different perspectives and considerably increase fallibility-tolerance. Since the structure-in-5 separates data and control hierarchies, integrity of these two hierarchies can also be verified independently. The structure-in-5 separates independently the typical components of an organization, isolating them from each other and allowing them dynamic adaptability. But since it is restricted to no more than five major components, more refinement has to take place inside the components themselves.

The joint venture supports coordinativity in the sense that each partner actor interacts via the joint manager for strategic decisions. Partners indicate their interest, and the joint manager either returns the strategic information immediately or mediates the request to some other partners. However, since partners are usually heterogeneous, it could be a drawback to define a common interaction background. The central position and role of the joint manager is as a means for resolving conflicts and preventing unpredictability. Through its joint manager, the joint-venture proposes a central communication controller. It is less clear

how the joint venture pattern addresses fallibility-tolerance, notably reliability. However, exceptions, supervision, and monitoring can improve its overall score with respect to these qualities. Manipulation of partners can be done easily to adapt the structure by registering new ones to the joint manager. However, since partners can also exchange resources directly with each other, existing dependencies should be updated as well. The joint manager cannot be removed due to its central position. Table 2 summarizes the strengths and weaknesses of the reviewed patterns.

To cope with non-functional requirements and select the pattern for the organizational setting, we go through a means-ends analysis using the non functional requirements (NFRs) framework (Chung et al., 2000). We refine the identified requirements to sub-requirements that are more precise and evaluates alternative organizational patterns against them, as shown in Figure 7. The analysis is intended to make explicit the space of alternatives for fulfilling the top-level requirements. The patterns are represented as operationalized requirements (saying, roughly, "model the organizational setting of the system with the *pyramid*, *structure-in-5*, *joint venture*, *arm's-length* ... pattern").

The evaluation results in contribution relationships from the patterns to the non-functional requirements, labeled "+", "++", "–", "– –". Design rationale is represented by claims drawn as dashed clouds. They make it possible for domain characteristics (such as priorities) to be considered and properly reflected into the decision making process, e.g., to provide reasons for selecting or rejecting possible solutions (+, –). Exclamation marks (! and !!) are used to mark priority requirements while a check-mark "√" indicates an accepted requirements and a cross " X " labels a denied requirement.

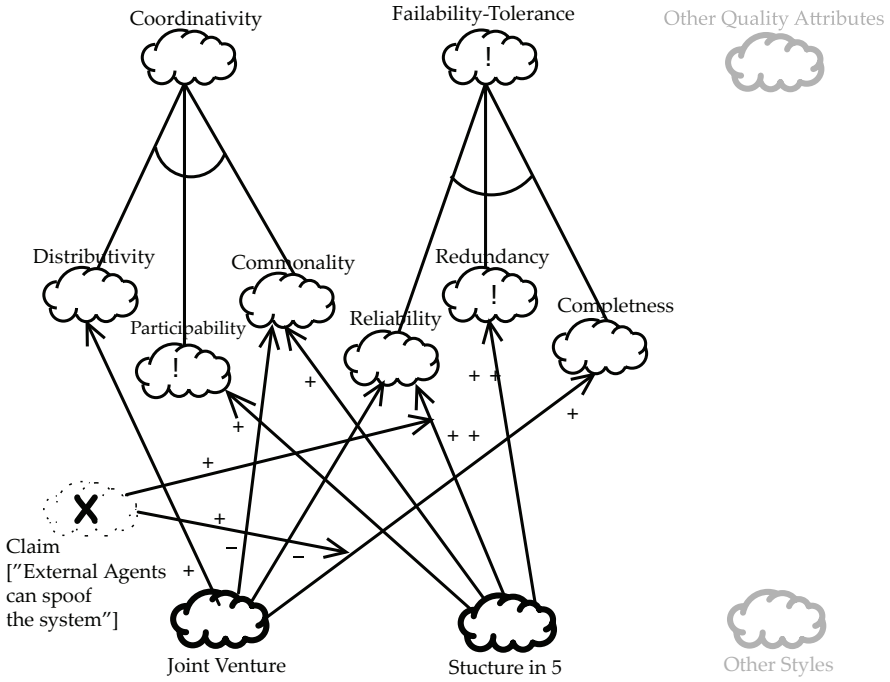
Relationships types (AND, OR, ++, +, –, and – –) between NFRs are formalized to offer a tractable proof procedure. AND/OR relationships correspond to the classical AND/OR decomposition relationships: if requirement R0 is AND-decomposed (respectively, OR-decomposed) into *R*1,*R*2,...,*Rn*, then all (at least one) of the requirements must be satisfied for the requirement R0 to be satisfied. So, for instance, in Figure 7 Coordinativity is AND decomposed into Distributivity, Participability, and Commonality. Relationships "+" and "–" model respectively a situation where a requirement contributes positively or negatively towards the satisfaction of another one. For instance, in Figure 7 Joint Venture contributes positively to the satisfaction of Distributivity and negatively to the Reliability. In addition, relationships "++" and "– –" model a situation where the satisfaction of a requirement implies the satisfaction or denial of another goal. In Figure 7 the satisfaction of structure-in-5 implies the satisfaction of requirements Reliability and Redundancy.

The analysis for selecting an organizational setting that meets the requirements of the system to build is based on propagation algorithms presented in Giorgini, Mylopoulos, Nicchiarelli, and Sebastiani (2002). Basically, the idea is to assign a set of initial labels for some requirements of the graph, about their satisfiability and deniability, and see how this assignment leads to the labels propagation for other requirements. In particular, we adopt from Giorgini, Mylopoulos, Nicchiarelli

Table 2. Strengths and weaknesses of some patterns

	Structure-in-5	Joint-Venture
Coordinativity	++	+
Predictability	+	+
Fallibility-Tolerance	++	+
Adaptability	+	+

Figure 7. Partial evaluation for organizational patterns



and Sebastiani (2002) both qualitative and a numerical axiomatization for goal (requirements) modeling primitives and label propagation algorithms that are shown to be sound and complete with respect to their respective axiomatization. The following is a brief description of the qualitative algorithm.

To each requirement *R*, we associate two variables. *Sat*(*R*), *Den*(*R*), ranging in {*F, P, N}* (full, partial, none) such that $F > P > N$, represents the current evidence of satisfiability and deniability of the requirement *R*. For example, $Sat(R_i) >= P$ states there is at least partial evidence that A_i is satisfiable. Starting from assigning an initial set of input values for $Sat(R_i)$, $Den(R_i)$ to (a subset of) the requirements in the graph, we propagate the values through the propagation rules of Table 3. Propagation rules for AND (respectively OR) relationships are min-value function for satisfiability (max-value function) and max-value function (min-value function) for deniability. A dual table is given for deniability propagation.

The schema of the algorithm is described in Figure 8. *Initial*, *Current*, and *Old* are arrays of pairs $Sat(R_i)$, $Den(R_i)$, one for each R_i of the graph, representing respectively the initial, current, and previous labeling status of the graph.

The array *Current* is first initialized to the initial values *Initial* given in input by the user. At each step, for every requirement R_i, $Sat(R_i)$, $Den(R_i)$ is updated by propagating the values of the previous step. This is done until a fixpoint is reached, that is, no updating mode is possible (*Current == Old*). The updating of $Sat(R_i)$,

Table 3. Propagation rules for satisfiability in the qualitative framework. A dual table is given for deniability propagation.

	+ $G2 \rightarrow G1$	- $G2 \rightarrow G1$	++ $G2 \rightarrow G1$	-- $G2 \rightarrow G1$
Sat(*G*1) *Den*(*G*1)	*min{ Sat*(*G*2), *P }* *N*	*min{ Sat*(*G*2), *P }*	*Sat*(*G*2) N	*N* *Sat*(*G*2)

Figure 8. Schema of the label propagation algorithm

```
1 Current=Initial;
2 do
3 Old=Current;
4 for each R_i do
5 Current[i] = Update label(i, Old);
6 until not (Current==Old);
7 return Current;
8 for each Rel_i s.t. target(Rel_i ) == Ri
do
9 satij = Apply Rules Sat(i, Rel_i , Old);
10 denij = Apply Rules Den(R_i, Rel_i ,
Old);
11 return max(max_i (sati_i ), Old[i].
sat),
12          max(max_i (deni_i ), Old[i].
den);
```

Den(R_i)works as follows. For each relation Rel_i incoming in G_i, the satisfiability and deniability values $sati_i$ and $deni_i$ derived from the old values of the source requirements are computed by applying the rules of Table 3. Then, it returns the maximum value between those computed and the old values.

A REQUIREMENTS-DRIVEN METHODOLOGY

This research is conducted in the context of the *early requirements* phase of *Tropos* (Giorgini et al., 2004; Giorgini et al., 2005), a software development methodology for building multi-agent systems founded on the concepts of actor and goal.

The *Tropos* methodology adopts ideas from multi-agent systems technologies, mostly to define the detailed design and implementation phase, and ideas from requirements engineering and organizational modeling, where agents/actors and goals have been used heavily for early requirements analysis (Dardenne et al., 1993; Yu, 1995). In particular, the *Tropos* project adopts Eric Yu's *i** model which offers actors (agents, roles, or positions), goals, and actor dependencies as primitive concepts for analyzing an application during organizational modeling. The key assumption which distinguishes *Tropos* from other methodologies is that actors and goals are used as fundamental concepts for analysis and design during *all phases of software development*, not just requirements analysis. That means that, in the light of this paper, *Tropos* describes the organizational environment within which a system will eventually operate, as well as the system itself in terms of the same concepts and patterns. *Tropos* spans four phases of software development:

- Organizational modeling, concerned with the understanding of a problem by studying an organizational setting; the output is an organizational model which includes relevant actors, their goals and dependencies.
- Requirements analysis, in which the system-to-be is described within its operational environment, along with relevant functions and qualities.
- Architectural design, in which the system's global architecture is defined in terms of subsystems, interconnected through data, control, and dependencies.
- Detailed design, in which behavior of each architectural component is defined in further detail.

CONCLUSION

Modelers need to rely on patterns, styles, and idioms to build their models, whatever the purpose. We argue that, as with other phases of software development, organizational modeling can be facilitated by the adoption of organizational patterns. This paper focuses on two such patterns and studies them in detail through examples, a formalization using Formal Tropos and an evaluation with respect to desirable requirements. There have been many proposals for software patterns (e.g., Kolp, Do, & Faulkner, 2005) since the original work on design patterns (Gamma, Helm, Johnson, & Vlissides, 1995). Some of this work focuses on requirements patterns. For example, Konrad and Cheng (2002) propose a set of requirements patterns for embedded software systems. These patterns are represented in UML and cover both structural and behavioral aspects of a requirements specification. Along similar lines, Fowler (1997) proposes some general patterns in UML. In both cases, the focus is on requirements analysis, and the modeling language used is UML. On a different path, Gross and Yu (2002) propose a systematic approach for evaluating design patterns with respect to non-functional requirements (e.g., security, performance, and reliability). Our approach differs from this work primarily in the fact that our proposal is founded on ideas from organization theory and strategic alliances literature. We have already described organizational patterns, but to be used for designing multi-agent system architectures (Kolp et al., 2006) and e-business systems (Kolp et al., 2004). Considering real world organizations as a metaphor, systems involving many software actors, such as multi-agent systems, could benefit from the same organizational models. In the present paper we have focused on patterns for modeling organizational settings rather than software systems, and emphasized the need for organizational abstractions to better match the operational environment of the system-to-be during organizational modeling.

Chapter 5.28
A Multi–Methodological Approach to Study Systems Development in a Software Organization

Paivi Ovaska
South Karelia University of Applied Sciences, Finland

ABSTRACT

Large-scale systems development is a complex activity involving number of dependencies that people working together face. Only a few studies concentrate on the coordination of development activities in their organizational context. This research study tries to fill at least part of this gap by studying how systems development process is coordinated in practice. The study uses a multimethodological approach to interpret coordination of systems development process in a contemporary software organization in Finland. The methodology is based on the empirical case-study approach in which the actions, conceptions, and artefacts of practitioners are analyzed using within-case and cross-case principles. In all the three phases of the study, namely multi-\site coordination, requirement understanding, and working with systems development methods, both the qualitative and quantitative methods were used to an understanding of coordination in systems development. The main contribution of this study is to demonstrate that contemporary systems development is much more complex and more driven by opportunity than is currently acknowledged by researchers. The most challenging part of the research process was the combination of qualitative and quantitative methods, because of the lack of multimethodological work done in IS discipline.

INTRODUCTION

Large-scale systems development is a complex activity involving number of dependencies that people working together face. Furthermore, in

distributed and multiparty information systems projects, there is even a larger number of stakeholders involved, and a great number of dependencies. These dependencies create a need for coordination that requires continuous effort by developers. Broadly defined, coordination is management of interdependencies between activities (Malone & Crowston, 1994). This definition assumes that if there are no interdependencies, there is nothing to coordinate. The activities can be activities or objects; everything that has dependencies requires coordination (Malone & Crowston, 1994). Coordination is an inherent aspect of work in any organization and takes place in the form of meetings, scheduling, milestones, planning, and processes.

To systematize coordination, many methods and process models have been proposed over the years. These models mainly focus on the sequence of steps used by developers to develop information systems. The status of methods as a whole has been described as a "method jungle," as "an unorganized collection of methods more or less similar to each other" (Jayaratna, 1994). Though these methods and process models have helped companies to gain certification and attain global standards, they do not take into account interpersonal interactions and various other social aspects of development organizations. The development of new methods has tended to be more technology driven, often being influenced by the introduction of improved techniques and software tools (Nandhakumar & Avison, 1999).

Only a few studies concentrate on the process of systems development and coordination of development activities in their organizational context. Kraut and Streeter (1995) found that coordination becomes much more difficult as project size and complexity increases. Apparently, complexity increases when the project is located in multiples sites. Communication is a salient part of coordination, and it has been observed (e.g., Allen, 1977) that distance affects the frequency of communication. Communication delays and breakdowns taking place in software development projects are discussed in several studies (Curtis, Krasner, & Iscoe, 1988; Kraut & Streeter, 1995; Herbsleb et al., 2000).

Systematic surveys of the existing literature in both Information Systems (Wynekoop & Russo, 1997) and Software Engineering (Glass, Vessey, & Ramesh, 2002) fields revealed that most of the research papers in these fields consist of normative research in which concept development is not based on empirical grounding or theoretical analysis, but merely upon the author's opinions. Because of that, many researchers (e.g., Curtis et al., 1988; Orlikowski, 1993) call for more empirical studies in order to understand how information systems are developed in today's organizations and how development work is coordinated in various types of organizations before development of new methods.

This research study tries to fill at least part of this gap by further clarifying how systems development process is coordinated in practice. This objective is reached by conducting a series of empirical studies of two systems development projects in a contemporary organization that competes in the information technology business. We study the early systems development, which we consider to be most important phases in development process: requirement elicitation and architecture design. In this study, the actions, conceptions, and artefacts of practitioners are interpreted and analyzed using multimethodological approach. By multimethodological approach is meant research approach that uses different research methods structured as a set of guidelines or activities to assist in generating valid and reliable research results (Mingers, 2001). The objective for this research is twofold: (1) to understand how practitioners coordinate the systems development process and (2) to make a contribution to the theory and practice of systems development.

The rest of this chapter is structured as follows. First we describe the other research using multiple research methods and then the research

framework is created and the research process used is explained. After that, the research findings are summarized. The discussion of using this methodology by comparing it to framework proposed by Mingers (2001) as well the general experiences in using the methodology is given in the sixth section. Finally, we summarize the used methodology and research findings and give direction for future research.

RELATED RESEARCH

Combining different research methods has been the subject of much debated after 1990s. Mingers (2001) advocated multimethodological research on the grounds that both the target of the research and the research process were complex and multidimensional, requiring range of different approaches.

There have been numerous reviews of the information system research literature, each with different purpose, but few of them specifically considered combining methodologies. Mingers (2003) reviewed systematically the six IS top journal published in the time period from the year 1993 to 2000 and studied the extent of multimethodological research. The results of this study clearly show a lack of multimethodological research published within IS. In the following table is shown the proportion of multimethodological research papers in these journals.

Mingers also looked at the particular combinations of methods used. He found that the vast majority (70%) involve only observation, survey, case study, and interview. In these studies, the mixture of hard (quantitative) and soft (qualitative) methods were rare.

Example of studies in IS discipline using multimethodological approaches are Markus (1994), Ngwenyama and Lee (1997), Trauth and Jessup (2000), and Ormerod (1995), but the literature around the theme is quite scarce.

In relation to IS field, in the area of Management Science, a research of Munro and Mingers (2002) showed that the use of multimethodological

Table 1. Proportion of multimethodological papers (1993, 2000) adapted from Mingers (2003)

Year	ISR (%)	ISJ (%)	MISQ (%)	EJIS (%)	AMIT (%)	JIT (%)	Average (%)

methods were very common among practitioners within organizational interventions and was driven by the demands of complex real-world problem situations. According to this study, practitioners used two, three or even more methods together in this area.

DEVELOPING THE METHODOLOGY

Studied Organization

The research study was carried out in a software development department of an international ICT company. The software development department was an internal partner for the company's business units. The development of applications and services was assigned to an in-house software development unit (Internal Development Unit, later referred as IDU) or outsourced companies. The use of IDU for development of new services was mandated by the company's top management. IDU had approximately 150 employees that had formerly focused on R&D work in the company. During the past few years, it had tried to improve its software skills and processes in order to make its development more effective and also to prove its capability to other business units. All the business units of the company did not agree with IDU's processes and did not trust in its software development capability. Their attitudes towards IDU competencies in software development were quite suspicious, mainly because of IDU's history as an R&D department. Quite often business units preferred outsourcing instead of developing in-house.

The projects, called here the "DS project" and the "EC project" respectively developed mobile services to both the global and domestic telecommunication markets. A major goal of both projects was the renewal of old platform architecture to allow the services to be better and easier modifiable, maintainable, and scalable.

The DS project developed a directory service platform for international markets. The project was partitioned into two subprojects to facilitate easier management. Partitioning was carried out on the basis of the architecture and technology: one subsystem had a highly distributed, component-based architecture (Server) and the other was a centralized subsystem (Client), which handled authentication, authorization and user interfaces. The functionality of the services required subsystems to communicate only through an extensible and configurable interface.

The goal of the EC project was to develop an Electronic Commerce mobile service platform. The system was intended to enable organizers or their sponsors to promote their products in all kinds of events, such as ice hockey and football games. The system was composed of two subsystems: the platform in which the services are run (Platform subsystem) and the toolbox (Tool subsystem). The Tool subsystem allowed adding, configuring and simulating of services to run in a Windows PC and with a service platform in an UNIX environment.

The actual systems development projects took place in IDU during the year 2001 and they were planned and organized according to a traditional waterfall model with distinct requirement elicitation, analysis, software design, implementation, and testing phases.

Shaping the Research Problem

The basic notion of systems development, namely systems development as a process that involves real people in real environments (e.g., Lyytinen, 1987), formed the ground for constructing our research methodology. To truly understand systems development, it is imperative to study people-systems development practitioners as they solve real development problems in real environments. Therefore, as

Rosen (1991) puts it, "to understand social process one must get inside the world of those generating it." This kind of goals favoured interpretive approach that enables researcher to understand human thought and action in social and organizational contexts (Walsham, 1995).

Systems development in organizational environment arouses different kinds of dependencies. The structure of the software system itself creates dependencies between software elements, while the structure of the development process creates dependencies between software developers. Each of these both shapes and reflects the development process; therefore, the other objective of selecting the research methodology to this study was to focus on different aspects of systems development (both technical and social dependencies) and therefore to get richer understanding of the dependencies.

Yet another goal was also to be more convinced of information accuracy also discussed in Yin (1994). Quantitative evidence can indicate relationships which may not be salient to the researcher. It also can keep researchers from being carried away by vivid, but false impressions in qualitative data, and it can bolster findings when it corroborates those findings from qualitative evidence (Eisenhardt, 1989).

Above objectives favoured selecting the interpretive approach (Walsham, 1995) and integrating different methods according to multimethodological approach (Eisenhardt, 1989; Mingers, 2003). Used methods are described in another section along with description of research process. In the following, the basic principles of the shaping the research methodology are explained in more detail.

Phases Adopted in Research

The research included three phases: studies on how architecture affects a multi site development project, studies on how requirements were shaped and interpreted during the systems development and how this process is to be estimated, and a study on how practitioners work with systems development methods. It is briefly explained how these three phases shaped the research problem:

Phase One: Multisite Coordination

The objective of this phase was to clarify the systems development problems related to software architecture and investigate how practitioners cope with these problems in systems development. This phase consisted of two parts: a qualitative study about social complexities and a quantitative analysis of technical complexities. During the phase, the problems found in the qualitative study evolved more to coordination and communication problems for which architecture provided a tool. In the quantitative study, the understanding of the architecture as a size predictor in the project cost estimation got its basic shape. The results from this phase of study are given in another section.

Phase Two: Requirement Understanding Process

In the beginning of phase two, we tried to find coordination problems or problems related to software architecture, but observed that the problems were more related to requirement understanding and organizational conflicts. This observation shaped the research problem towards the interpretation of the requirement understanding process and how this could be measured to get better estimates of the project timetable along with the architecture measures from phase one. The results from this phase are given in another section. At the end of this phase, the observations so far suggested that methods in the organization played an important role in the case study projects. This led us to shape the study towards the interpretation of the role of methods and their use in the studied organization.

Phase Three: Working with Systems Development Methods

In this phase, the comparisons of the results of phase one and phase two according to their similarities and differences (cross-case analysis). During this analysis, it appeared that the coordination and the requirements understanding in the projects were the result of using and adapting methods based on the practitioner's background, experience and the development situation at hand. The results from this phase are given in another section.

RESEARCH PROCESS

In this section, the research process is explained. Figure 1 explains the flow of research phases and tasks. After that the process is explained in a more detailed level.

Preparing for the Study

The beginning of our research study included an initial definition of the research question, a selection of cases and crafting instruments and protocols.

Each of the phases of the study had the research questions of its own. Table 2 summarizes the research questions of each three phases.

The selection of cases relied on the theoretical sampling principle (Glaser & Strauss, 1967), in which cases are chosen as extreme situations and polar types in which the process of interest is "transparently observable." The sampling strategy of the current study was designed to be built around projects displaying problems in systems

Figure 1. Research process

development, big problems that caused delays to the project's timetable. Within these projects in the studied organization, we chose projects of polar types: one project had problems inside the project, the other problems with the customer; one was smaller and the other one bigger; they both produced service platforms for different business areas. The analysis revealed that the projects had even more different features, such as the orientation, attitudes, and experience of the participants, and the communication between participants that extended the emergent theory (Eisenhardt, 1989). To facilitate iteration and comparison, which is an inevitable feature of the grounded theory method (Locke, 2003), these two projects were analyzed one by one.

Data Collection

During the study, most of the data was collected from project extensive documentation (see Table 3) based on the dynamic process of data collection (Glaser & Strauss, 1967), where samples were extended and focused according to the emerging needs of the theoretical sampling. In both case projects, the project documentation data was complemented with interviews among project participants (customer, project managers, designers, etc.).

The interviews were all tape-recorded and completely transcribed. The length of the interviews varied from half an hour (focused interviews) to 2 hours (group interview). Several hundreds of pages of project documentation, the transcribed interviews, and 170,000 lines of program source codes were analysed during the studies.

The data for the quantitative statistical analysis in both phases one and two was collected from the architecture and component design specifications, source code, project management database, and bills from subcontractors. Some metrics (or property values) of the software system were calculated based on these documents. In the phase this metric was related to software architecture and in the phase two to requirements evolution. In the project management database, the data included the time spent on each task (development effort) by the project participants. In the cases where foreign consultants were involved in the development work, the development effort data was taken from the subcontractors' bills.

Seed Categories

Specification of a priori constructs (Eisenhardt, 1989) or also called seed categories (Miles & Huberman, 1984) can help research. In phase one, a notion of the common object from Malone

and Crowston's coordination theory (Malone & Crowston, 1990, 1994) was used to interpret the coordination in the project. In phase two, the concept of a technology frame of reference (Orlikowski & Gash, 1994) was used to interpret the requirement understanding in the project.

Data Analysis

In these studies, we used the principle of within-case and cross-case analysis to interpret the findings in different phases of this thesis (Eisenhardt, 1989). In the within-case analysis "the overall idea is to become intimately familiar with each case as a standalone entity" allowing unique patterns to emerge before trying to generalize patterns across cases (Eisenhardt, 1989). In the first two phases of the research, the qualitative data analysis was based on the grounded theory (Glaser & Strauss, 1967; Strauss & Corbin, 1990). In those phases, quantitative data analysis with a simple linear regression method (Lawson, 1995) was carried out. The principal researcher conducted the qualitative analysis alone in all the phases, but, in phases one and two, two other researchers did the quantitative data analysis and provided complementary insights (Eisenhardt, 1989) into the qualitative analysis in our discussions. As outsiders of the qualitative data collection, they were able to look at the data more with greater objectivity (Nandhakumar & Jones, 1997), which facilitated a more reliable data analysis as a whole.

In the first and second phase of the study, the qualitative data analysis started quite early, right after the data on the project meeting minutes was collected. In the first phase, data collection continued with design specifications simultaneously with the analysis of the data on the project meeting minutes. In phase two, the collection of requirement specification data started while the analysis of the data on the project meeting minutes was still being performed. The quantitative data collection started as soon as some initial findings of the qualitative data analysis were made. Such overlap of data collection and analysis is strongly recommended by Eisenhardt (1989) and Strauss and Corbin (1990). To help manage the quite extensive amount of information and the analysis process, the Atlas.ti (Scientific Software, 2001) tool was used. It helped in the analysis process, for example in the retrieval of categories, memo making and recording of semantic relationships.

The quantitative data analysis was hypotheses testing in nature and naturally used a priori constructs. Both hypotheses were based on the initial findings of the corresponding qualitative studies. To the statistical data analysis, we used the Matlab Optimization Toolbox (MathWorks Inc., 2003).

In the following we describe the data analysis process in the three phases of the study.

Phase One

Data analysis started with open coding according to Miles and Huberman (1984). In open coding, a researcher tries to find relevant categories based on research questions. Open coding started with the finding of problems and deviations related to coordination and software architecture (relevant categories in this study) in the project progress, using mainly project meeting minutes and the group interview as a data source. We further used architecture and design specifications to help pinpoint the problems. We observed in total 329 deviations and problems related to software architecture and coordination.

Data analysis continued with the axial coding, in which categories found in open coding were refined, developed further, and related. In this phase, we used a notion of common object as a seed category based on Malone and Crowston's coordination theory (Malone & Crowston, 1990, 1994) to help in the interpretation of coordination problems in the project. We identified two types of common objects from the study, namely component and development activity. The following example (Figure 2) shows a translated excerpt of a transcript after axial coding. This example shows how common objects were interpreted from the project material.

In the selective coding phase, where the "core category," or central category that ties all other categories in the theory together, was identified and related to other categories (Glaser & Strauss, 1967). The identification of common objects helped in finding the interdependencies between activities that caused coordination problems in the project. We identified three interdependencies between components and three interdependencies between development activities. These interdependencies are explained in another section.

After finding the interdependencies, we tried to find an answer to the research question of how the problems in coordination differed in multisite and same same-site environments (cross-case analysis). To find these differences, we compared the two subprojects and analyzed the differences in the coordination processes between them.

In the quantitative analysis, we used metaphorical analysis (Frost & Morgan, 1983; Lakoff & Johson, 1980; Schultze & Orlikowski, 2001) to help understand the architecture of the system. According to our metaphor of architecture drawing, we identified three categories that described the architecture of our case study system best. Within these categories, we attempted to select the properties, which were simple and could be

Figure 2. Translated excerpt of a transcript after axial coding in the phase one

”On the Server side, we gained experience from new technologies, like XML, XSL and CORBA”	Technical orientation of the Server Common object: development activity
”We had a lot of problems with Client and Server synchronization. The Client was first and the Server was behind, it should be wice versa ”	Interface and interdependence problems Common object: component

calculated based on project design specifications. We chose the simple linear prediction model to analyze the correlation between architecture properties and systems development effort. From these 7 property values for six components, a total of 42 property values were calculated. From these property values, we calculated coefficient values using Matlab Optimization toolbox. In the end of this quantitative process, we calculated the model errors to determine the quality of our cost effort estimation model and analyzed the results based on coefficient values.

Phase Two

Phase two started with the identification of problems and deviations in the project progress. During the development, these were issues that were brought to the project meetings for discussion and decision-making. The steering and project group meeting minutes were the main sources for problem and change identification. We observed in total 150 problems and deviations related to project progress. Most of the concerns brought to the steering group were related to the

other subsystem and its requirements. Also the system development styles and strategies caused concerns.

To better understand the requirements of the system, we investigated in more detail the requirements specification document. We were able to extract only four initial requirements that were related to the other subsystem. Our analysis continued as we used three conceptual models of both subsystems developed in the qualitative study.

Through these models, we were able to grasp how the subsystems evolved through different phases of systems development. The content of these conceptual models suggested to us that the other subsystem's requirements changed considerably during the process. This led us into investigating further why this subsystem's requirements changed so much, while the other subsystem's requirements remained stable.

To answer this question, we made focused interviews among the project participants to identify the reasons for these changes. Project participants were asked to reflect on the project's history by showing the analysis and implementation models of the system and to describe their understanding of what happened in the project between the requirement analysis and implementation phases. Four of the interviewed project participants were from the development side and three from the business side. Business side representatives were also asked about the competences and processes of development side during the time the project was running and how these competences and processes had evolved after that. The interviews were audio taped and fully transcribed to preserve all the details.

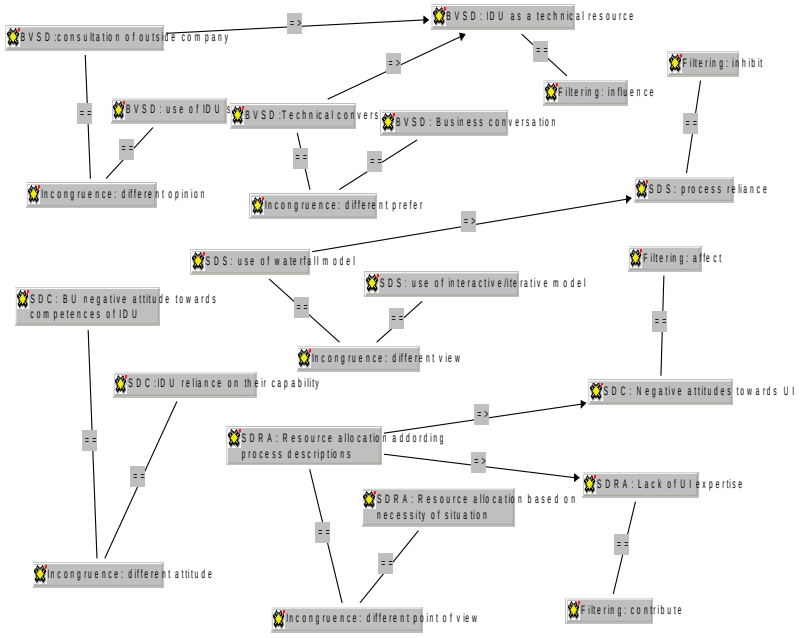
Based on the interviews, we observed that requirements did not change that much during the project, but the understanding of them changed. The open coding proceeded in parallel, treating each interview as confirmation or further development of results from earlier findings. During this process, the categories developed gradually. First, we identified quite concrete concerns of system development. In further analysis, we found more subtle contextual attitudes and expectations about how systems development should be performed. These attitudes and expectations were so strongly visible in the data that we could interpret them as technology frames (Orlikowski & Gash, 1994). In further analysis, we used technology frames as a priori construct or lenses to the data. This further analysis consisted of group analysis, cross-group analysis and re-examination of the categories. This iterative examination of the data yielded five categories of technology frames, which were used as a basis for the next phase, axial coding.

During the axial coding, we identified four processes of stereotypical "tensions" between these attitudes and expectations, which affected how project participants emphasized these frames of understanding in different phases of the project. These tensions and explained in another section.

In the selective coding phase, the causal relationships between categories were recorded with Atlas.ti's (Scientific Software, 2001) semantic network capability. Figure 3 shows an example of such a network diagram. In Figure 3, the boxes represent categories, the arrows the interpreted causalities between them, and the lines simple associations between the categories. The abbreviations business value of system development (BVSD), system development strategy (SPS), system development capability (SDC), and system development resource allocation (SDRA) correspond to the categories of frames of understanding.

Based on project material, interviews, and analysis, we formulated the project narrative to trace how the participants' attitudes and expectation influenced the systems development process. In the end of the research process, the project narrative was sent by e-mail to the project manager to get her opinion on the correspondence of the narrative with the reality. She adjusted some details, which did not affect the main findings.

Figure 3. An example of semantic network diagram using Atlas.ti (Scientific Software, 2001)



In the quantitative analysis, we formulated the metric describing the identified requirement evolution in the project. The metric was quite simple: it calculated the concepts found during the analysis and implementation models of the system. These analysis and implementation models were formed based on the project specifications. In the statistical analysis, we used the same simple prediction model as in phase one of the study. The other metrics needed were chosen based on simplicity and wide usage. Using this prediction model, we calculated the correlation between metrics chosen and the development effort. In the end of the process, we formulated the model errors to determinine the reliability of our prediction model and analyzed the results.

Phase Three

In phase three, we used cross-case analysis to interpret the final results in this thesis (Eisenhardt, 1989). We searched for cross-cased patterns to compare the multi-site and same-site development by listing their similarities and differences (Eisenhardt, 1989). We selected pairs of cases and listed similarities and differences between each pair. In this phase, the number of cases was actually three because one of the case projects consisted of two subprojects. The cross-category table produced in this process is shown in Table 4.

Table 4. Cross-category table between projects in the studies

Category	*Case Project 1* *subproject A*	*Case Project 1* *subproject B*	*Case Project 2*
Adaptation to method	yes	no	yes
Problems	minor technical inside project	inside project, coordination and architecture understanding	conflicts with client, requirement understanding
Timetable estimation	no major problems	problems	problems
Orientation and attitudes	Architect's technical orientation	Architect's business orientation	Designer's positive attitude towards UI and windows
Experience	Experienced project group	Unexperienced project group	Unexperienced project group
Communication	good	bad	in the beginning bad, later good
Understanding the system	fairly good	not very good	in the beginning no, learning to understand
Understanding the development situation	yes	no	in the beginning no later yes
Method purpose	communication and coordination	method use failed	communication and learning
The most meaning metric (relative to development effort)	Coupling (NIC)	-	Requirements Creep

Shaping the Hypothesis

From the within-case analysis, the cross-case analysis and overall impressions, tentative tenses and concepts and their relationships begin to emerge, which is called hypothesis shaping (Eisenhardt, 1989). The idea is that researchers constantly compare emergent theory and "raw" data—iterating towards a theory with closely fit data (Eisenhardt, 1989).

In the hypothesis shaping, we used the semantic network diagram capability of Atlas.ti software (Scientific Software, 2001). This semantic network is shown in Figure 2. This network shows the relationships between the core categories used to interpret the role of methods.

Finishing and Reporting the Studies

Eisenhardt (1989) distinguishes the phase "enfolding literature." By this phase, Eisenhardt means the comparison of the findings with similar and conflicting literature. The aim of this phase is to raise confidence, creative thinking, and the validity, generalizability, and conceptual level of the findings. Yin (Yin, 1994) refers to this as "analytic generalization" to distinguish it from the more typical statistical generalization that generalizes from a sample to a population. In phase one, the main comparisons were done with Malone and Crowston's (Malone & Crowston, 1990, 1994) coordination theory and cost estimation literature. The comparisons of phase two were made with traditional requirement engineering approaches and existing sociotechnical approaches to requirement elicitation, especially the concept of a technological frame. All these provided conflicting and similar concepts and patterns, which all provided an alternative and more creative view to our findings. In phase three, the findings were compared to a few empirical studies of the role of methods in systems development.

SUMMARY OF FINDINGS

Phase One: Multisite Coordination (Ovaska & Bern, 2004; Ovaska, Rossi, & Marttiin, 2004)

In phase one, we discovered six different coordination processes to explain most of the coordination problems related to software architecture in the case studies. These six processes can be summarised as follows:

1. *Interfaces*: Managing interfaces between system components
2. *Integration*: Managing the assembly of system components, enabling their integration into a full, working system architecture
3. *Interdependence*: Managing the interdependencies between system components
4. *Communication*: Managing the communication processes between development participants
5. *Responsibility*: Managing the allocation of responsibilities for key decisions related to the software architecture and subsystem designs
6. *Perspectives*: Managing the different perspectives development participants brought to the project and managing negotiations related to these perspectives

This phase suggest that technical dependencies among software components (interfaces, integration, and interdependence) create social dependencies (communication, responsibility, perspectives) among the software developers implementing those components. It also supports the Malone and Crowston's coordination theory by highlighting the importance of the coordination of interdependencies between activities instead of purely coordinating activities in systems development.

Phase Two: Requirement Understanding (Ovaska, 2004; Ovaska, Rossi, & Smolander, 2005)

In phase two of the research process four categories of technology frames were identified that could explain attitudes and expectations that affected people's understanding of requirements and which were directly related to the ISD process. These categories can be summarised as follows:

1. *Business value of systems development*: attitudes and expectations about the re-

lationship between business and system development.
2. *Systems development strategy*: attitudes and expectations about the system development lifecycle model and associated ISD processes.
3. *Systems development capability*: the assumptions, attitudes and expectations surrounding the various competencies of project participants in different areas of system development
4. *Systems development resource allocation*: the assumptions, attitudes and expectations as regards scheduling, budgeting, and prioritisation of systems development activities

Within these four frames it was possible to identify stereotypical "tensions" which emerged as the projects unfolded. These tensions and the processes associated with them had important effects on how the project participants emphasized various technology frames during the different phases of the project:

1. *Incongruence*: this tension emerged when understanding, attitudes, or expectations differed among the stakeholders, causing conflicts and misunderstanding
2. *Filtering*: this tension surfaced when a stakeholder of the development process left something out of scope because of his/her particular perspective, attitude, series of expectations, or experience of ISD
3. *Negotiation*: this refers to tensions associated with the various negotiations between project participants and took place in order to resolve incongruities
4. *Shifting*: this emerged when the understanding of a frame changed (called a "frame shift"). After a frame shift, the parties involved achieved an understanding of a frame that was more aligned and suitable for the current situation than before the shift.

In this phase, we observed that preconceptions, attitudes, and expectations about systems development among project participants filtered the understanding of software requirements, negotiating between project participants resolved the issues caused by filtering and shifts in these attitudes and expectations facilitated changes in the understanding of requirements. In spite of this observed filtering, shifting, and negotiation, the developed system exceeded the customer's needs and expectations even though it was delivered late. The results of this phase suggest that the current conceptions regarding requirement elicitation do not correspond with the needs of practice. The traditional requirement engineering research concentrates on detecting and representing requirements and ensuring that they are complete and consistent. It sees requirements mainly in a system context assuming that they already exist somewhere ready to be picked in the requirement elicitation phase. Our study has consequences beyond such a view. It suggests that requirement elicitation is in practice an ad-hoc and iterative process involving political, cognitive and social aspects that affect the interpretation of requirements during the whole project lifetime.

Phase Three: Working with Methods (Ovaska, 2005)

During the cross-case analysis in phase three of the research process, we discovered the five categories which summarised various ways in which methods were used in the target projects:

1. *Methods used as tools*: rather than following predefined phases and tasks practitioners used ISD methods as if they were a set of tools which could be variously deployed or discarded as the need arose
2. *Methods used to coordinate*: practitioners primarily used methods to coordinate systems development

3. *Methods used a communication language*: methods were used to provide common communication language between various project participants, and the methods thus helped to set the agenda for many discussions
4. *Methods as a means to aid understanding of the system and its requirements*: methods were used to help develop an understanding of the system in terms of requirements and expectations of users and align these with various technical and nontechnical issues which arose
5. *Understanding the development context*: methods were used by participants to make sense of the development situation as it shifted over time

This phase suggests that working with methods is complex social interaction and a mutual understanding process between project participants. The methods were used in our case study as a tool for communication and learning and as a resource in project planning among system development participants, not as a list of phases to be followed in detail. Method use requires communication between project participants to adopt the method to the development situation. Without communication, methods use failed. When participants gained common understanding

of the appropriate development strategy and method, the method use became a learning process. In this learning process, system development participants changed their understanding of the system, according to changing development situations. Without the common understanding of the system between project participants, the estimation of project timetable and resources did not succeed. Based on the observations of our study, we argue that methods are used more as support and guide the development than strict phases to be followed in detail.

DISCUSSION

In this section the multimethodological approach used in this study is discussed related to the multimethodological guidelines set out by Mingers (2001). The guidelines suggest that in designing research one should consider the following domains:

- *The context of the research*—in particular the relationships between the research situation and task, the methods and theories available, and the researchers' own competencies and commitments
- *The dimensions of the research situation*—in particular, the material, social, and personal aspects

In the following, these domains are explained in more detail along with the comparison our multimethodological approach to it. Finally, we summarize the general experiences of using the methodology and its limitations.

The Context of the Research

The multimethodology used in this study lies on the most close to dominant type of design in which one method is the main approach with contributions from the others. The qualitative methods were our main method in all phases contributed from qualitative statistical analysis. The reasons for such a design were formed from the nature of systems development as a social process.

The professional and scientific background of principal researcher provides some explanations for understanding the selection of the research method and also the role of the researcher in the interpretive research process. Because of her educational background in engineering, she also wanted to get some "hard evidence" of the projects, maybe to become more assured of the reliability of the research. She wanted to carry out some statistical, quantitative calculations that would

support the qualitative work. During the learning process in the research work, the quantitative calculations faded into the background and shifted more towards an interpretive approach.

Although the principal researcher did not work on the chosen projects, she acquired "deep familiarity" (Nandhakumar & Jones, 1997) with the research context and its actors during the 5 years working in that company. During the observation period, she was fully involved in the activities of the company. During the analysis period, she was not involved in the activities, but had full access to all project documents gaining access to information that would not otherwise have been divulged. The used data in the study was mainly documents gathered during the projects. Without her personal experience in the company, it would have been difficult to interpret the local meanings, dominant perceptions, tacit knowledge, and nonverbal communication (Nandhakumar & Jones, 1997) from the documentation. Without the deep familiarity with the research context and its actors, it would not be possible to gain additional insight in the actors' interpretations, their motivation, and perspectives (Nandhakumar, Jones, 1997) in the focused interviews carried out during the study. Her role as a researcher was somewhere between an outside observer and involved researcher (Walsham, 1995); it can be called an "involved observer" participating in the work of the company before the analysis period.

The Dimensions of the Research Situation

According to Mingers (2001), each research situation is the combination of three worlds: the material world, the social world, and the personal world. Each domain has different modes of existence and different epistemological possibilities as followed:

- *The material world* is outside and independent of human beings characterized as objective in the sense that it is independent of the observer although our observations and descriptions of it are not. Our relationship to this world is one of *observation.*
- *The personal world* is the world of our own individual interpretations, experiences, thoughts, and beliefs. We do not observe it, but *experience* it.
- *The social world* is the world that we share with others in a particular social system and *participate* in it.

In comparing our research situation and methodology to this framework, all these worlds were present to the following extent. The study covered material aspects, such as architecture as a predictor of system size or requirement creep as a measure of requirement evolution. The interpretive analysis of documentation and interviews explored the meaning of coordination and requirements understanding for particular individuals; and group interviews and their interpretations revealed the social aspects of coordination and requirements understanding.

General Experiences

In general, we experienced the methodology highly iterative learning process, in this process the research themes and questions changed during its phases.

The most challenging part of the research was the combination of quantitative and qualitative methods, mainly because of the lack of the empirical frameworks to guide the work; therefore the frameworks would be helpful in designing and developing this kind of research.

Limitations of the Methodology

A critical issue for researchers concerns the generalizability of the results of their work, and Yin (1994) notes that this issue is often rose with respect to case studies. Different arguments for

the generalizability of case study research have been given (Dutton & Dukerich, 1991; Eisenhardt, 1989; Walsham, 1995; Yin, 1994). It is argued that in case study research, the identified concepts and categories are compared to theoretical concepts and patterns, unlike in statistical generalization from a sample to a population. Still, due to the nature of this study in which the understanding of method use was interpreted on the basis of separate phenomena found in one organization, the generalization of the use of methods may be limited. Therefore, the understanding gained in these studies provides a basis for understanding similar phenomena in the same settings rather than enabling the understanding of phenomena in other contexts.

SUMMARY AND FUTURE WORK

This chapter has described the multimethodological approach to study coordination of systems development process. We used the principle of within-case and cross-case analysis to interpret the findings in different phases of the study. In all these three phases, we used both qualitative and quantitative methods to get richer and more reliable understanding from coordination phenomena.

The three phases of the study have provided a rich picture of different aspects of systems development in the software organization. In the first phase of the study, we examined the role of architecture in coordination and cost estimation in a multisite software development from quantitative and qualitative viewpoints. The second phase involved two studies, one qualitative and the other quantitative, on the evolving requirement understanding process and the measurement of this process. The third phase was a study based on the first two studies on the role of methods and how practitioners work with them using principle of cross-case analysis. The research process of these phases was explained.

We experienced the methodology highly iterative and adaptive learning process, in which the research themes and questions evolved during its phases. The study covered material aspects, such as architecture as a predictor of system size as well as personal and social aspects. Highly interpretive analysis of documentation and interviews covered aspects of particular individuals whereas the group interviews and their interpretation revealed the social aspects of coordination of systems development work.

The main contribution of this study is to demonstrate that contemporary systems development is very complex and more driven by opportunity than is currently acknowledged by researchers. We need more knowledge of the current and emerging business and organizational contexts in which and for which these systems are developed. This study suggests that further rich, multimethodological research is urgently needed in order to build a picture of how communities of practice make sense of systems development. Only in this way we can begin to find ways to understand and address the problems in systems development.

The most challenging part of the research process was the combination of qualitative and quantitative methods because of the lack of multimethodological work done so far; therefore the frameworks would be helpful in designing and developing multimethodological approaches.

In the future, our multimethodological framework needs deeper work towards a theory-building approach, especially related to analysis process in the phase three. Also, the replication of our study in other contexts and redefinition of the framework based on experiences is necessary.

Chapter 5.29
Integrating Usability, Semiotic, and Software Engineering into a Method for Evaluating User Interfaces

Kenia Sousa
University of Fortaleza, Brazil

Albert Schilling
University of Fortaleza, Brazil

Elizabeth Furtado
University of Fortaleza, Brazil

ABSTRACT

We present artifacts and techniques used for user interface (UI) design and evaluation, performed by professionals from the human-computer interaction (HCI) area of study, covering usability engineering and semiotic engineering, which can assist software engineering (SE) to perform usability tests starting earlier in the process. Tests of various interaction alternatives, produced from these artifacts, are useful to verify if these alternatives are in accordance with users' preferences and constraints, and usability patterns, and can enhance the probability of achieving a more usable and reliable product.

INTRODUCTION

In a software development process (SDP), it is crucial for developers, customers, and users to interact in order to specify, generate, and evaluate the software. From software specification to its delivery, various kinds of tests must be performed, involving aspects such as: functionality, portability, performance, and usability. This work focuses on the context of usability, communicability, and functionality tests (e.g., appropriateness of a chosen interface design alternative to user preferences, consistency to a visual pattern, efficient execution of interactive tasks on interface objects, etc.).

Through our researches on tests in HCI and SE, and through our experiments on their integration in a SDP, we verified that HCI concepts facilitate the UI evaluation work performed by the test team of an interactive system under development. More specifically, by means of UI generation based on HCI models (e.g., task model), it is possible to evaluate the UI earlier (e.g., its functionality), independent of having the entire noninteractive specification ready. Prototypes, for instance, can represent UI design alternatives that may be tested early by HCI experts to verify if they are in accordance with user preferences, usability patterns, and so on.

This work presents a SDP to design and evaluate UIs, based on the integration of concepts, models, and activities of usability, semiotic, and software engineering.

This chapter is structured as follows: The "User-Interface Evaluation" section shows the contribution of each engineering area to UI evaluation; "The Process" section describes the UI design process; "The Evaluation Strategy" section describes the UI evaluation process, showing which concepts are used to perform tests and when they are performed; the "Case Study" section describes the case study in which we designed and evaluated UIs for the Brazilian System for the Digital Television (SBTVD); and, finally, the "Findings and Future Works" section describes findings and future works, and the "Conclusion" section concludes this work.

USER-INTERFACE EVALUATION

In this section, we present concepts and evaluation techniques from usability engineering, software engineering, and semiotic engineering.

Usability Engineering

Usability engineering is a set of activities that ideally take place throughout the lifecycle of the product, with significant activity at the early stages even before the UI has been designed. The need to have multiple usability engineering stages supplementing each other was recognized early in the field, though not always followed in development projects (Gould & Lewis, 1985).

In usability engineering, techniques and methods are defined aiming to assure a high usability level of the interactive UIs. Among them, we emphasize the application of ergonomic criteria in the UI design. Verification of these criteria in designed UIs is called heuristic evaluation, performed by usability experts without user participation. Evaluators examine the IS searching for problems that violate general principles of good UI design, diagnosing problems, obstacles or barriers that users will probably encounter during their interaction. In addition, methods to capture usability requirements attend to user preferences, restrictions, and use-context. A usability requirement can be derived from an interaction restriction; such as if part of the system needs to be implemented for palm-top devices.

The evaluation approaches from usability engineering suggests a structured sequence of evaluations based on "usability inspections methods" and on "usability tests".

Some inspection methods are: (1) heuristic evaluation, verification of usability heuristics (Nielsen, 1993); (2) review of guidelines, verification if the UI is according to a list of usability guidelines (Baranauskas & Rocha, 2003); (3) consistency inspection, verification of the consistency among the UIs related to terminology, color, layout, input and output format, and so on; and (4) cognitive walkthrough, simulation of the user "walking" through the UI to execute typical tasks.

Some usability test methods are: (1) thinking out loud, we request the user to verbalize everything he or she thinks while using the system, and we expect that their thoughts demonstrate how the user interprets each UI item (Lewis, 1982); and

(2) performance measures, quantification of some evaluated items to make future comparisons.

Software Engineering

Software engineering is composed of technologies and practices that are used in the development of software products, enhancing software productivity and quality, by providing a more systematic and controlled SDP (Sommerville, 2001).

In software engineering, there are various types of tests to be performed in each test stage, such as: usability tests to ensure that access and navigation through functionalities are appropriate for users; UI tests, to ensure a good functionality of the UI components and verify conformity to corporate patterns; and functionality tests, which are responsible for verifying if the generated software achieves all the proposed functionalities according to the customer's requests. Test cases (Myers, 2004) are normally generated and comprise procedures to be followed in test activities in order to deal with all possible situations when using the software, including basic flows, as well as error treatment and invalid data verification.

According to Pressman (1995), the main goal of test cases is to derive a set of tests that will probably reveal errors in the software. To achieve this goal, software engineering basically proposes two test categories: white-box and black-box tests.

For Pressman (1995), the white=box test must verify the internal part of the product, tests can be performed to guarantee that the components are integrated, and the internal operation achieves the performance level as specified in the requirements.

Functional tests, or black box tests, represent a test approach in which tests are derived from specifications of the system. In this kind of test, the evaluator is concerned with the functionality, not with the software implementation (Sommerville, 2001).

In these two test categories, software engineering defines four main types of tests: unit tests that are generally white-box tests; acceptance and regression tests that are usually black-box tests, and integration tests that blend this two categories.

Semiotic Engineering

Semiotic engineering is an HCI theory that emphasizes aspects related to the metacommunication designer user(s) via user-system communication, which passes through the UIs of interactive applications. The system is considered to be the "deputy" or a representative of the system designer (Souza, Barbosa, & Silva, 2001). The content of messages is the application usability model. Its expression is formed by the set of all interaction messages sent through the UI during the interaction process. The user plays a double role: interacting with the system and interpreting messages sent by the designer.

Semiotic engineering is essentially involved in test procedures with final users (empiric evaluation), aiming at system communicability analysis — based on qualitative evaluation, in which there are four phases: test preparation; labeling; interpretation, and formatting — and elaboration of the semiotic profile of the application to be evaluated. The techniques used in theses phases are: system-user observations, questionnaires, (somative-evaluation) inspections, interviews, filming,and so on.

Semiotic engineering is essentially present in tests with final users (e.g., empiric evaluation), aiming at analyzing the system communicability. A UI has a good level of communicability when it is able to successfully transmit the designer message to the user, allowing him or her to understand the system goal, the advantages of using it, how it works, and the basic UI interaction principles.

Evaluation

After studying about evaluation techniques, artifacts and approaches from software, usability, and

semiotic engineering we are able to conclude that an evaluation process can be seen under various perspectives.

Concerning software engineering, we noticed the importance of software quality concerning functionality, performance, portability, and other nonfunctional requirements. Its artifacts and techniques include the evaluation of these aspects in an objective manner.

Usability engineering focuses in providing more ease of use, ease of learning, and efficiency to interactive systems.

Semiotic engineering includes procedures that allow the evaluation of the quality of the interactivity of systems by observing the communication through messages of the user to the system.

Based on these perspectives, we believe that an approach for UI evaluation of interactive systems that integrates these approaches is able to guarantee a system with quality concerning functionality, usability, and interactivity, derived from software, usability, and semiotic engineering, respectively.

Next, we will describe a lightweight development process for interactive systems, called UPi (Sousa & Furtado, 2004), which integrates HCI and SE activities, artifacts, and professionals.

THE PROCESS

UPi can serve as a guide, providing useful steps and artifacts that can be tailored and customized when organizations intend to develop usable interactive systems. One of the best advantages of UPi is the idea to focus on activities, artifacts and guidelines that add value to the UI generation. With this approach, it can be integrated with any other process and inherit activities that are vital to the entire process, but that are better defined and solidified in other processes. For instance, project management, configuration and change management, implementation, and deployment activities are very well detailed in the RUP (Kruchten, Ahlqvist, & Bylund, 2001). Besides the RUP, UPi can also be applied in conjunction with ISO 13407 (ISO 13407, 1999), which already has other activities defined and validated, such as project planning, testing, and so on.

UPi is composed of activities that aim at designing UIs. These activities are based on RUP activities, but they follow different guidelines that take into consideration usability aspects.

In this work, we are integrating UPi with UPi-Test (to be presented in the next section) in order to guide professionals that are developing interactive systems to evaluate them throughout the entire development process.

Phase I: Inception

The main goal in this phase is to elicit requirements from users in order to develop an interactive system that best suits their needs through the execution of some activities (presented as follows). These requirements are documented through certain artifacts: use-case models, task models, usability requirements, and paper sketches.

Use-case models represent a well-established manner to define the system functionality, while *task models* can be used to detail use cases by breaking them down into tasks. *Usability requirements* represent users' preferences or constraints that can be part of a usable interactive system. *Paper sketches* focus on the interaction, UI components, and on the overall system structure, keeping the style guide secondary, without being too abstract.

The purpose of the *Elicit Stakeholder Needs* activity is to understand users, their personal characteristics, and information on the environment where they are located that have a direct influence on the system definition, and to collect special nonfunctional requirements that the system must fulfill, such as performance, cost, and device requests.

The purpose of the *Find Actors and Use Cases* and *Structure the Use-case Model* activities is

to define the actors (users or other systems) that will interact with the system and the functionality of the system that directly attend to users' needs and support the execution of their work productively.

The purpose of the *Detail a Use Case* activity is to describe the use case's tasks using the task model, to describe any usability requirements related to the use case, to define the system navigation based on the task model hierarchical structure, and to create paper sketches.

The purpose of the *Review Requirements* activity is to verify, with usability experts, if the paper sketches are in accordance to the task model and validate, with users, if the requirements are in conformance with their needs by showing them the elaborated paper sketches.

Phase II: Elaboration

The main goal in this phase is to transform the requirements in a representation that can be understood by UI designers and programmers. These representations are provided by the following artifacts: system architecture, UI Definition Plan, and drawing prototypes.

System Architecture is composed of smaller components that represent the main functionality of the entire system. The *UI Definition Plan* is a new artifact that aims to define which visual objects should be part of the UI. *Drawing prototypes* produce an accurate image of the system and they are useful to demonstrate patterns and style guides.

The purpose of the *Define and Refine the Architecture* activity is to (re)design the classes that represent the data that are handled by users while performing certain tasks.

The purpose of the *Define UI Plan* activity is to define which visual objects and which usability patterns can be part of the UI according to the nonfunctional requirements defined in the *Elicit Stakeholder Needs* activity.

The purpose of the UI Prototyping activity is to design a UI prototype in drawings following the description specified in the task models, in the UI definition plan and in the system architecture.

The purpose of the *Evaluate Prototype* activity is to verify if the UI prototypes are in accordance to usability principles and to validate with users if the UI prototypes are in conformance with their needs.

Phase III: Construction

The main goal of this phase is to implement and verify the accuracy of the components implemented and of the UI designed.

The purpose of the *Implement Components* activity is to develop the classes previously designed and implement the UI prototyped.

The purpose of the *Evaluate the Version of the System* activity is to verify if the functionality of the interactive system is in accordance with users' requirements.

Phase IV: Transition

The main goal of this phase is to deliver to the customer a system with high level of quality and usability.

The purpose of the *Deploy the System* activity is to make the system available for the customer.

The purpose of the *Evaluate the System* activity is to validate with users (by using the system in the deployment site) if the system conforms with their view of the system.

All of these phases are supported by processes concerning configuration and change management and project management, such as the RUP. This support is provided for the *Manage Change Requests* activity, which aims at evaluating the impact of change requests, deciding if they are to be included in the current iteration, and, if they are accepted, manage the changes in the appropriate artifacts.

Concerning the evaluation activities performed in each phase, they will be more thoroughly explained in the next section.

THE EVALUATION STRATEGY

The unified process for evaluating interactive systems "UPi-Test" (Schilling et al., 2005) has the same phases as the RUP (inception, elaboration, construction, and transition) (Kruchten, Ahlqvist, & Bylund, 2001). This process is based on the Unified Process for Interactive Systems, called UPi (Sousa & Furtado, 2004) and follows the approach to design UI prototypes dependent on the device (Coyette, Faulkner, Kolp, Limbourg, & Vanderdonckt, 2004).

Each phase is directly related to a specific area. This way, usability engineering supports the verification and validation in the inception and elaboration phases, software engineering supports verification in the construction phase, and semiotic engineering supports validation in the transition phase.

Figure 1 illustrates these four phases in the UPi-Test, each one with its flow of activities, artifacts, and techniques.

UPi-Test includes the verification and validation of usability and functionality of interactive systems UIs. Nonfunctional requirements are not in the scope of this work, such as aspects related to database (e.g., connection, integrity, etc.), security, and architecture. These aspects can be supported in future versions of this process.

Phase I: Inception

The inception phase is important in guaranteeing that the following phases achieve results to attend to users' and customers' usability goals. This phase has the constant participation of users in order to understand their requests, which are verified and validated according to usability engineering to allow the development of these requests. The description of the activities and artifacts in this phase is presented as follows.

Talk with Users and/or Customers

This activity consists of the first contact with users or customers, in which system analysts understand their profiles, objectives, and the scenario where they are included. In this activity, it is necessary to use a technique to elicit requirements.

We propose an initial informal talk in order to better understand users' environment. Then, we suggest the performance of interviews, with the use of a questionnaire that aids in the identification of users and/or customers and their intended goals, preferences, and possible constraints.

Obtain Users' and Customers' Preferences and Constraints

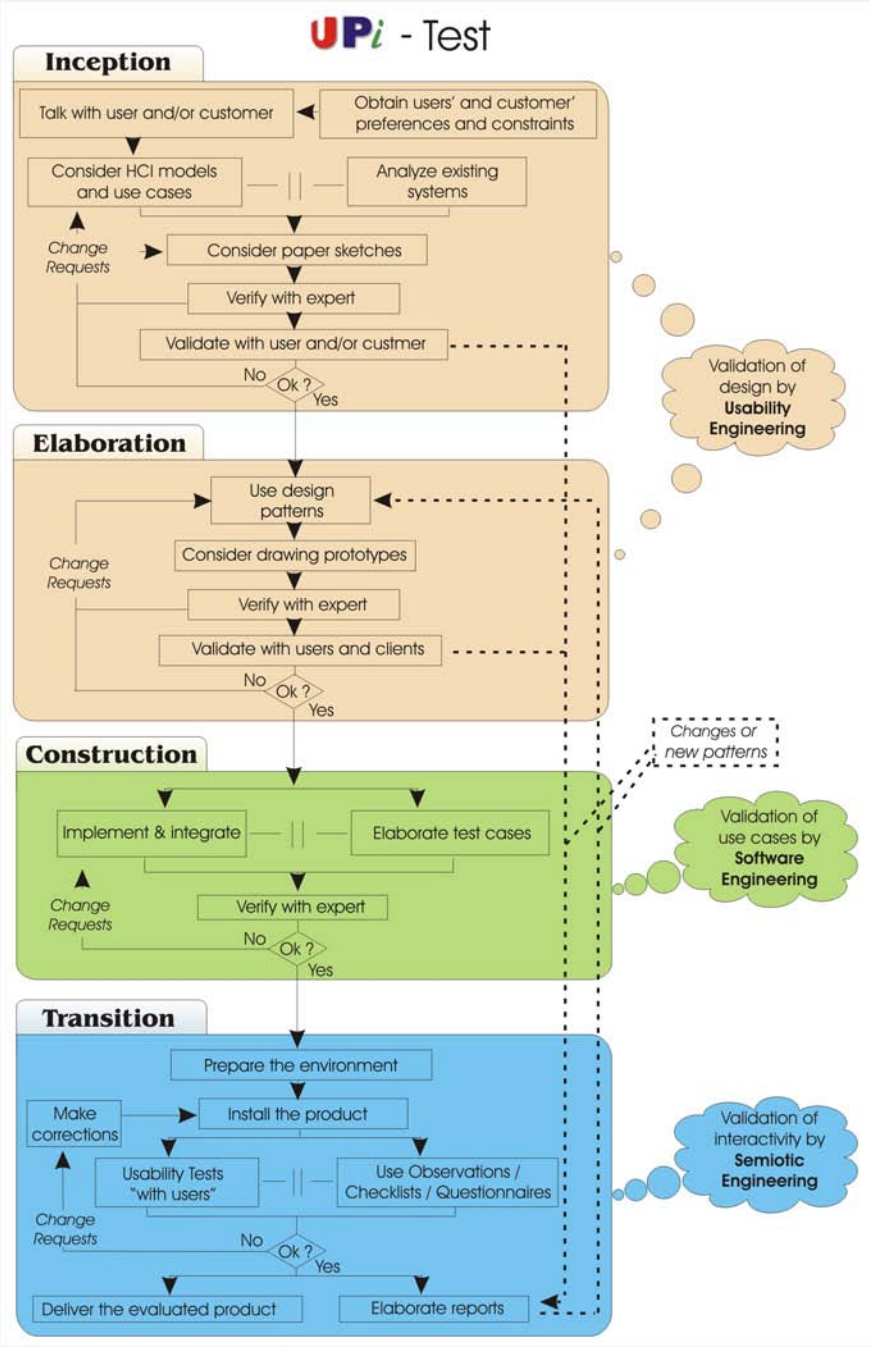
In this activity, system analysts aim at eliciting users' and customers' preferences and constraints in order to design UIs that attend their needs and also to help usability experts during evaluation and to help UI designers during prototyping. Some examples of preferences are: design colors, font styles, navigation schemes. Some examples of constraints are: technology constraints, such as platform, device, and so on.

Consider HCI Models and Use Cases

Use cases represent an artifact from software engineering that identifies the functionality of interactive systems; users' interactions, expressed through users' tasks; and the system's responses to perform these interactions (system's tasks).

Task models detail a use case or a group of related use cases by specifying users' tasks and system's tasks. It is useful to support UI designers in the elaboration of prototypes because it is easy to identify the necessary views and objects in the prototype from the task model hierarchical structure.

Figure 1. Evaluation process of UIs



Analyze Existing Systems

In this moment, it is important to analyze existing systems. This involves a comparative study of similar systems. These systems can be used as a reference in order for system analysts to propose new functionality or to choose design patterns, which are all useful for the design of UI prototypes.

Consider Paper Sketches

After talking with users and customers, the UI designer designs paper sketches. This prototype is verified and validated, as presented in the next activity.

Verify with Expert

This activity consists of the verification of paper sketches by the usability expert. The expert is concerned with verifying if users' goals, in terms of functionality, were included in the prototype, as well as if usability principles were used.

We propose that experts use the heuristic evaluation approach (Nielsen, 1993) as an inspection method. The usability heuristics will guide the usability expert in the process of verifying UIs' quality of use. We also suggest the use of the task model to verify if all the specified functionality was designed in the prototype.

When the expert notices that a functional requirement or any usability principle is missing, change requests can be made, which leads to changes in the models and new proposals of prototypes.

Validate with Users and Customers

After the verification with the expert, we propose a validation with users and customers so they can approve the generated artifacts. If the prototypes do not attend users' needs, change requests can be made, which leads to changes in the models (if new functionality is requested) and new proposals of prototypes (if changes in the navigation are requested). This process is repeated until the generated prototype attends users' preferences and needs.

This activity early in the process provides flexibility for users and customers to evaluate the evolution of the system, therefore, designers and users feel more confident with the UI design.

After the conclusion of the inception phase, the resulting artifacts are verified and validated as paper sketches.

Phase II: Elaboration

The elaboration phase is concerned with designing and evaluating drawing prototypes. In this phase, we use verification and validation techniques, such as heuristic evaluation and validations with users. After this phase, the resulting artifacts are drawing prototypes validated according to usability requirements and patterns. The description of the activities and artifacts in this phase is presented as follows.

Use Design Patterns

In order to guarantee the quality of the product and efficiency of the project, we suggest the use of design patterns for graphical UIs. These patterns will guarantee that we elaborate and develop UIs following already verified and validated parameters, which can be incremented by the reports generated in the end of the transition phase.

Consider Drawing Prototypes

UI designers are responsible for designing drawing prototypes based on paper sketches previously validated, and on usability patterns. These prototypes are verified and validated by the following two activities.

Verify with Expert

This activity consists of verifying the usability of drawing prototypes by experts. We propose that experts use the heuristic evaluation approach (Nielsen, 1993) as an inspection method to verify whether or not certain usability principles are present in the prototype.

When the expert notices that any usability principle is missing, change requests can be made, which leads to new proposals of prototypes. At this moment, it is not necessary to make changes in the models because this approach evaluates the quality of use, not functionality aspects, which were evaluated in the previous phase.

Validate with Users and Customers

After verification with the expert, a validation is proposed to users and customers so they can approve the generated prototypes. At this moment, users and customers evaluate the used usability patterns and the style guide. This process is repeated until the generated prototype attends users' preferences and constraints. If the prototypes do not attend users' needs, change requests can be made, which leads to new proposals of prototypes.

After the conclusion of the elaboration phase, the resulting artifacts are verified and validated drawing prototypes, which support development, tests, and deployment activities.

Phase III: Construction

In this phase, the UI is developed and the application is integrated with it. Considering software engineering, we propose functionality tests of an executable prototype (i.e., a product with some functionality) or the final product (i.e., a product with all the functionality), using functional test cases.

The activities and artifacts in this phase are presented as follows.

Implement and Integrate

These activities consist of developing the UI and integrating it with the application. The integrated product, either a prototype or the final system, can be useful for evaluating the navigation, interactivity, and functionality aspects.

Elaborate Test Cases

Test cases can be elaborated starting in the inception phase, using paper sketches, they can then be updated in the elaboration phase, using drawing prototypes, and finished in this activity. This artifact focuses on the system functionality, not on nonfunctional aspects.

The technique used to define test cases includes the following topics: association to a use case, specification of the item to be tested, preconditions to execute before testing, identification of valid and invalid inputs, and the expected outputs. The actual outputs are compared with the expected outputs described in the test cases and this comparison is used as validation of the use case.

Verify with Expert

This activity consists of the verification of the functionality of the product by usability experts and developers. Examples of aspects that are verified are: consistency of the outputs, navigation, existence of error messages, results after clicking on objects, as well as other aspects identified in the test cases.

After this verification, developers and experts can generate change requests to correct the errors; which leads to the repetition of the implementation and integration activities.

After the conclusion of the construction phase, the resulting artifact is the integrated product, which is tested with consideration to usability aspects in the transition phase.

Phase IV: Transition

This phase comprehends, in general terms, the preparation of the test environment, which can be a test laboratory or the environment where the system is used. With consideration to semiotic engineering, we use some validation techniques and artifacts. The description of the activities and artifacts in this phase is presented as follows.

Prepare the Environment

To prepare the environment, we suggest the installation of the system, software for capturing the system's use, and equipment, such as video cameras and necessary hardware devices. We also suggest the creation of questionnaires and checklists.

The test laboratory must be similar to the real user environment — with consideration to physical structure, climate, sound aspects, and equipment — in order to allow users to live the same conditions of the real environment. There should be a room where the test takes place and another one for observation.

Install the Product

In this activity, the product is installed, either a partial version or the final version of the system, in order to allow users to use the system in their real environment. This installation allows the tests to be performed.

Usability Tests "with Users"

This evaluation is performed with users. In it, evaluation techniques, proposed by semiotic engineering, are used, such as: recording, observation, questionnaires, and so on.

Before starting the tests, the usability expert talks with the user in order to: clarify that the system is under evaluation, not him/her; present the scenario used for the test; and make the user feel comfortable; which are aspects that influence the final results.

Observers that are in the observation room should fill out the questionnaires and checklists.

This activity can be divided in two moments, the first one, when the user interacts with the system to perform a task of his/her own interest; the second one, when the expert requires the user to perform a specific task.

In this activity, navigability, interactivity, and acceptability will be evaluated.

Use Observations/Checklist/ Questionnaires

Observations, questionnaires, and checklists are artifacts and techniques proposed by the semiotic engineering in order to verify the user-system interactivity and communicability. Experts and observers will use these artifacts during the tests, which result in the definition of the quality of the interactive system. These results can lead to change requests for developers to correct the detected mistakes.

Users' comments and the actual execution of the tests will be recorded to help in the analysis of the results of the questionnaires and of users' observations.

Make Corrections

In this activity, developers make corrections proposed by experts after the tests. After the changes are made, users validate the product.

Deliver the Evaluated Product

As a result of the process, we have the results of evaluations, which are useful for future versions; and we also have a verified and evaluated product according to a set of techniques proposed by usability, software, and semiotic engineering.

If the product is a final version of the system, it is ready to be delivered for use. If it is a partial version (e.g., executable prototype), the professionals need to perform the activities in the construction phase, then in the transition phase, until the product reaches its final version.

Elaborate Reports

The results obtained will be used as a basis for the elaboration of evaluation reports, which propose adaptations in the used patterns and in the creation of new patterns that can be used in future iterations.

CASE STUDY

In this chapter, we describe the case study of this research work, which is concerned with the evaluation of UIs for the SBTVD project, focusing on the applications: electronic portal, insertion of texts, and help.

Introduction

The digital TV represents digital and social inclusion for a great part of the Brazilian population, especially for people less privileged, who do not have access to computers, and therefore, cannot access the Internet.

The SBTVD must be adapted to the socioeconomic conditions of the country, as well as allow the use of conventional TV sets already in large use in the country in order to decrease risks and costs for the society.

The digital TV creates various possibilities of interaction between the TV and the user, such as: exchange of text or voice messages, virtual chats, searches for a favorite show, access to information about the government, and so on. These possibilities are different from the characteristics of the conventional TV, in which the user plays a passive role.

In the following section, we describe the performance of the activities proposed by UPi and UPi-Test. It is important to point out that the SBTVD is still under development. That is the reason why we cannot demonstrate all the activities of the process.

Phase I: Inception

Talk with Users and/or Customers

This activity was difficult to perform in this project because there is an almost unlimited number of users and/or customers. Fortunately, there were specific and clear specifications, established by the Brazilian government. Such specifications were used as requests from users and customers.

To define the scope of the application under our responsibility (access portal), we had meetings with representatives of the government and with other institutions that are participating in the project. These meetings were supported with brainstorming and the resulting decisions were analyzed and were shared with all the institutions through e-mails and discussion lists.

After these meetings, we decided that the portal will consist of a main application that allows the access to all other applications in the SBTVD, which can be: electronic mail, electronic commerce, EPG, help, electronic government, and so on.

Obtain Users' and Customers' Preferences and Constraints

The SBTVD project is concerned with various users' profiles, including the ones who are and those who are not used to technology, but not including the ones with any kind of disabilities.

In order to identify their possible preferences and constraints, we studied existing systems; we had many meetings and workshops. The opinions of all the participants in the project were taken into consideration because we can also be considered to be potential users.

Our main goal in the usability workshops was to choose the best usability pattern for each requirement based on the evaluation of positive and negative aspects of each proposed usability pattern, as specified in the UPi activity define UI plan.

These proposed usability patterns were selected from a list, such as the one available in Welie (2005), which are organized in the following format: problem to be solved, solution, context in which it can be used, and graphical illustration.

For the participants to evaluate the usability patterns, we provided a set of guidelines. After they read the guidelines, each group evaluated the positive and negative aspects of each usability pattern suggested for the requirement. Then, the participants discussed and reached the final decision as to what was the best usability pattern for the requirement under discussion.

The personalization group considered the guidelines as they evaluated the positive and negative implications of each usability pattern, aiming at achieving Nielsen's usability goals. For demonstration purposes, we focus on presenting the personalization of colors.

As a result of the evaluation, the personalization group decided to use color templates because of the greater impact of positive implications over the negative ones. The result of this work was the generation of a document associating usability patterns with their positive and negative implications. For instance, the selected pattern with more positive implications was "Provide predefined color templates to change font/background colors" instead of the pattern "Offer a list of colors from where the font/background colors can be chosen" because of the following positive implications: efficiency of use, compatibility of the system with the real world, and clarity of information. The second option had more negative implications than the first one, such as difficulty in use by beginners and the constant need to resize the space reserved to the presentation of information.

We defined that the applications in the SBTVD need to have a high level of usability. There was a list of technology constraints, especially the ones related to memory and processing capacity. Besides that, graphical representations need to be simple because conventional TV sets do not support images as computer monitors do, and the TV luminosity is very different from the one in monitors; consequently, colors and texts appear differently.

Consider HCI Models and Use Cases

In this activity, analysts and usability experts elaborated use case and task models, and then changed them, when change requests were made after the evaluation of users in the end of the Inception phase. The requests resulted in changes in the models because they were changes in the functionality, such as: do not consider access to multiple applications simultaneously (technical constraint) and include personalized help. These changes reflected in the models and will be considered in the prototypes.

Analyze Existing Systems

In this activity, we researched on the Internet in order to find digital TV systems already in use. It was very difficult to find them because there are few systems available for access in the Internet.

This analysis was used to identify some UI design patterns for the digital TV, such as: upper and bottom options bar, menu on the left, navigation icons, interaction buttons, and so on.

Consider Paper Sketches

After the analysis of existing systems, UI designers elaborated paper sketches (Figure 2). However, they needed to be redesigned after the evaluation of users in the end of the inception phase, which resulted in change requests.

Figure 2. Paper sketch: Personalization

Some change requests resulted in the following changes in the prototypes: transfer the bar from the top to the bottom of the screen, include the "TV" button in the bar when accessing an application or in the portal; include the "Portal" button in the bar when accessing an application, take off activated icons (because of technical restrictions), and give a preview of the requested options of personalization. However, other requests resulted in changes in the models as well as in the prototypes, such as the ones mentioned in the activity "Consider HCI models and use cases."

Verify with Expert

In this activity, we performed heuristic evaluations with three experts who considered the usability of the paper sketches. They observed aspects, such as: navigation between views and if usability principles were applied. Besides that, the experts verified if all users' goals, in terms of functionality (in the task models), were included in the prototypes.

Validate with Users and Customers

In meetings with the institutions participants of the project and with representatives of the Government users evaluated the elaborated prototypes.

Various change requests, as well as users' preferences were identified. These requests resulted in updates in the models and in redesign of the paper sketches.

As examples of preferences, we point out the following: Include the "TV" and "Portal" in the remote control; the bottom options bar should overpass the application; and make available a set of options for inserting text, such as the one used in computer keyboards, the one used in mobile phones, and in alphabetical order.

Phase II: Elaboration

Use Design Patterns

In this activity, the UI design patterns, identified while analyzing existing systems, were evaluated and the UI designers started to design drawing prototypes using the design patterns.

Consider Drawing Prototypes

The UI designers used image editors, such as Photoshopâ and Corel Drawâ, in order to design the drawing prototypes (Figure 3), which followed the selected patterns, the updated task models, and paper sketches. In this prototype, the small view on the right shows the preview of the required personalization about the color of the screen before applying it.

Verify with Expert

The drawing prototypes were evaluated by experts (Figure 4), who observed various aspects, such as: layout, colors and fonts, UI design patterns, and usability principles applied.

Validate with Users and Customers

This activity is yet to be fully performed in this project, currently; we have finished the document that specifies the SBTVD graphical UI, which is going to be evaluated by representatives of the Brazilian Government.

Figure 3. Drawing prototype: Personalization

Figure 4. Verification with expert

Figure 5. Validation with users

We scheduled a workshop with the other institutions participants of the project to evaluate the drawing prototypes (Figure 5). They requested us to elaborate other alternatives of UIs (including association of options in the UI with options on the remote control), increase the size of the options and fonts in the upper bar, and change the way to differentiate the selected option.

Phase III: Construction

Implement and Integrate

The implementation of the portal has not started yet. However, the developers have been studying and implementing simple applications for the digital TV, such as three possibilities of insertion of text (the one used in computer keyboards ('qwert'), the one used in mobile phones, and in alphabetical order).

Table 1. Test case: Personalization

Test Case	Personalization
Test Items	Changes in font and background color Changes in font size
Pre-conditions	The user must be accessing the portal
Inputs	The user must select a type of personalization: Font color The user selects green
Expected Result	The portal must present the personalized content with a green background color

Elaborate Test Cases

The elaboration of functional test cases has started since the inception phase, when use cases and paper sketches were elaborated. Functional requirements were selected and the associated test cases were elaborated: structure applications, access applications, access help and personalization (Table 1).

Verify with Expert

In this activity, the programmers and the experts verify the applications using the test cases for guidance. Some of these evaluations were done in the small applications developed for insertion of text.

Phase IV: Transition

The usability experts and the developers have prepared the test environment. For that, they have: prepared the physical structure (e.g., TV, video camera, couch, computer to simulate the set-top box, etc.) and installed the necessary software (i.e., software to capture the user interaction with the TV, Linux Operating System, Java Virtual Machine, and applications to be tested).

A group of three usability experts were responsible for performing the following activities before the tests started: First, they defined a questionnaire to apply with users in order to understand their characteristics and familiarity to the DTV technology. Second, they selected appropriate metrics (e.g., number of errors, number of access to the help, etc). Third, they created a checklist based on Nielsen's usability goals and on the metrics from the previous step. Fourth, they prepared the environment with a DTV, a couch, and a center table in order to make users feel at home. Fifth, they selected ten users with different profiles between the ages of 18 and 26.

When the users arrived, each one at a time was taken to the DTV room, where a usability expert explained the goals of the test; applied the questionnaire; and defined a specific goal to be achieved while interacting with the DTV. While the user interacted with the application, usability experts filled out the checklist in the visualization room, where we monitored the environment and the user with a camera and captured the interaction with the DTV using specific software.

FINDINGS AND FUTURE WORKS

After the tests, we evaluated the checklists and generated reports with solutions to the problems encountered during the tests. These reports contain comments about the icons, the navigation, and the help module of the portal application.

- No user realized the possibility of navigation through the numbers associated to each icon, which represents an interactive application (see Figure 6).
- When they were told about this, they used it and said it was very practical.
- For them, the icons were not a natural representation, but they did not want to give any opinion about possible solutions.
- Some users did not notice the application that was selected. They said it was better to have a big square around the icon instead of the current selection.
- When the users were confused and wanted some help, they did not look for it in the portal (the blue option in the bottom bar that activates the help module). Some users activated the menu button of the remote control and others waited for the evaluator to tell them what was necessary to do to obtain the help.
- As the bottom bar is used as a design pattern to put the navigation options, and as each option is different depending on the situation (the application being executed), the users got very confused. We realized they looked

Figure 6. The portal application

at this bar only once, and then they did not look at it any more. After memorizing the options, they wanted to use them all the time, but the color was different, so they made many navigation errors.

From the execution of these tests, we were able to quantify the results: 85% of the users found the system easy to use, easy to read, and easy to navigate, but on the other hand, 50% had difficulties in identifying that an option was selected and in getting out of an unexpected situation.

Our next step is to make the necessary changes that are related to improving the layout, color contrast, and icon selection. In addition, the next tests will be done with the elderly in order to investigate people who are not used to interaction devices.

CONCLUSION

In this chapter, we present a new method, which focuses on integrating different techniques of usability, semiotic and software engineering. The aims are to design usable UIs following a model-based UI design process and to facilitate the test process by using the evaluated HCI models. In this manner, we hope to contribute to the development of interactive systems that are easy for users to learn and use, and to help testers in performing their usability tests in an efficient manner.

As main contributions, we focus on evaluating the usability of UIs with the constant participation of users and customers. Besides that, the integration of various approaches results in positive outcomes for the prototypes, as well as for multidisciplinary team members, who are better integrated and can have their knowledge

enhanced, since they are continuously exchanging information and experiences.

Chapter 5.30
The Work of Art in the Age of Mechanical Production

Thomas B. Cavanaugh
Embry-Riddle Aeronautical University, USA

ABSTRACT

When Walter Benjamin wrote his famous essay *The Work of Art in the Age of Mechanical Reproduction*, he shone a light on the cultural changes inherent in technology's ability to infinitely reproduce and distribute art. One of the important consequences of this development was the democratization of art's availability, allowing the general population to experience artwork that they would otherwise be unable to access. Now technology has advanced to a point where not only is art's reproduction available to anyone who wants it, its very production is now accessible to almost everyone, even if the prospective artist is utterly devoid of training, expertise, or even talent. With software-based artistic assistance and low-threshold electronic distribution mechanisms, we have achieved the promise of Benjamin's blurred distinction between artist and audience. As a result, the process by which art is produced has now been democratized, resulting in legitimate questions regarding quality, taste, and the legitimacy of authorship in a human-technological artistic collaboration.

INTRODUCTION

When Walter Benjamin wrote his famous essay *The Work of Art in the Age of Mechanical Reproduction*, he shone a light on the cultural changes inherent in technology's ability to infinitely reproduce and distribute art. One of the important consequences of this development is the democratization of art's availability, allowing the general population to experience artwork that they would otherwise be unable to access—artwork that previously was only available to a privileged elite.

Now technology has advanced to a point where not only is art's reproduction available to anyone who wants it, the very production of art is now accessible to almost everyone, even if the prospective artist is utterly devoid of training, expertise, or even talent. This development is symptomatic of a wider self-service mindset that pervades western society, what I have dubbed the "kiosk culture." The term "kiosk culture" connotes the general acceptance and even encourage-

ment of self-service for the postmodern citizen. From touchtone telephone answering systems to Web-based electronic commerce to scanning our own groceries at the neighborhood supermarket, self-service is as much an expectation for the postmodern consumer as it is a business necessity for the provider. The kiosk culture represents nothing less than a cultural transition to a naturalized "do it yourself" attitude.

In the production of art, the do-it-yourself aesthetic of the kiosk culture has been actualized by the introduction of performance support technology into all manner of expression. Just as with consumer-oriented tasks, artistic performance support technology compensates for any skill-based shortcomings, allowing a novice to achieve the same level of performativity as an expert. As such, the very process by which art is produced has been democratized. But when these support technologies are applied to the creation of art, the cultural implications are quite different from those in the business milieu. It raises essential questions such as *What is good art*? *Is art developed with the assistance of performance support technology as valuable as that produced without it? Who really is the artist—the human or the machine?*

Art, of course, does not exist independently from a complicated infrastructure of production, distribution, and consumption, tied together by social relationships that maintain it. As described by Bourdieu (1993) and others, the consumption of art involves social, economic, and class implications. Recognizing this larger context, it's important to note that the subject of this essay focuses only on the production of art—specifically the production of art as enabled by the use of assistive performance support technology.

Software such as Dramatica and Scriptware assists the aspiring screenwriter to prepare a screenplay. In many cases, this support goes far beyond surface assistance such as formatting and spelling to include brainstorming services, story ideas, and other cognitive help normally considered the sole domain of the artist. Marketing literature for Dramatica® Pro touts the collaborative aspect of the software's artistic support, calling it "the 'Ultimate Creative Writing Partner.'" Another software product from the same company, Writer's DreamKit™, is promoted specifically as a tool for beginning screenwriters and even promises to co-write your script. "(A)s your mentor, the Writer's DreamKit will do something no other writing program can do—it predicts parts of your story based upon creative decisions you make!" (Write Brothers, 2004, p. 5-6)

With technological tools like these and low-threshold distribution mechanisms such as self-publishing, podcasting, and blogs, we have achieved the promise of Benjamin's blurred distinction between artist and audience. Benjamin (1968) predicted that the distinction between author and public is about to lose its basic character:

The difference becomes merely functional; it may vary from case to case. At any moment the reader is ready to turn into a writer. As expert, which he had to become willy-nilly in an extremely specialized work process, even if only in some minor respect, the reader gains access to authorship… Literary license is now founded on polytechnic rather than specialized training and thus becomes common property. (p. 232)

Just as we no longer need to be a trained cashier in order to use the complex point-of-sale (POS) technology of the retail industry, likewise we no longer need to possess any expertise in how to write a screenplay to accomplish the writing task. The embedded performance support technology compensates for our lack of competence. The "readerly" has literally become "writerly," where "the reader [is] no longer a consumer but a producer of the text" (Barthes, 1970, p. 4).

NOVICES AND EXPERTS

But what about other artistic endeavors, especially those that require the direct use of complex technology? The most obvious example might arguably be photography. Referring specifically to digitization, Willis claims that the "means of production of ... visual imagery is undergoing a mutation as significant as the invention of photography" itself (1990, p. 197). Unlike painting, for instance, where the artistic technology (e.g., the brush) doesn't easily permit compensatory performance support, photographic equipment utilizes a variety of compensatory performance support technologies, such as red-eye reducing flash bulbs, auto-focus, backlight adjustments, and digital enhancement tools. Even before the introduction of this technological assistance, photography had already secured a place as an equalizer between the amateur and professional.

From the middle of the nineteenth century, "with its low cost and availability, photography democratized the visual image…For the first time, it was possible for the ordinary person to record his or her life with certainty and to create personal archives for future generations" (Mirzoeff, 1999, p. 65). Although the technological elite of the time tried to categorize photography as a pursuit solely for society's upper classes, the low cost of materials and relative usability of the technology trumped any attempts to restrict its growth. "With the invention of the collodion-glass negative process in 1852, prints became affordable to all…working people. They availed themselves of this resource en masse to the despair of elite critics who disparaged the results as 'fried fish pasted onto metal plaques'" (Mirzoeff, 1999, p. 72). But the genie was already long out of the bottle. "Despite the attempts by [*photographic pioneers Louis Jacques Mande*] Daguerre and Fox Talbot to claim elite status for their devices, photography was quickly claimed as the people's medium" (Mirzoeff, 1999, p. 71). With the addition of compensatory performance support technology to photographic equipment, this even more true today.

One might argue that any literate and reasonably coordinated person can string two words together or point a camera and press a button and, as such, literary authorship or photographic competence are easier for an amateur to achieve than an artistic pursuit more dependent upon manual dexterity. For instance, what about music? At one time in our past, playing music was a common amateur activity and musical training was a requisite component of the bourgeois education. But with the advent of mechanized music in the late nineteenth century, such as that offered by the gramophone, homemade music rapidly declined. This phenomenon manifested in what Thompson (2002) calls "a wide chasm" between professionals and amateurs. An early attempt at musical performance support to reduce that chasm was the simplified sheet music produced by publishers for home use:

> *As amateurs gradually abandoned their own music making and listened increasingly to professional musicians, a wide chasm opened between the two groups… Sheet music publishers did their best to bridge the gap, by offering 'Brilliant but not Difficult' versions of the most popular showpieces, but the effect of the discrepancy was gradually but effectively to silence many amateur performers of music. By the end of the century, countless parlor pianos had been replaced by automatic 'reproducing' pianos or other mechanical devices that recreated the performances of great concert pianists. …The result of these trends was a new dissatisfaction with amateur music and, perhaps more significantly, a heightened engagement by amateurs with the experience of listening to professionals.* (pp. 49-50)

Thompson quotes an 1894 article from the *Atlantic* magazine which describes the term

"amateur" pejoratively, equating amateur efforts with "bad work" (p. 49-50).

Benjamin's colleague Adorno would likely agree with the *Atlantic*'s assessment, excoriating any attempts to produce "Brilliant but not Difficult" sheet music of popular tunes for the untrained masses. He refers to such products designed to bridge the gap between amateur and professional as a:

sort of musical children's language…it differs from the real thing in that its vocabulary exists exclusively of fragments and distortions of the artistic language of music. In the piano score of hit songs, there are strange diagrams. They relate to guitar, ukulele and banjo, as well as the accordion—infantile instruments in comparison with the piano—and are intended for players who cannot read the notes. They depict graphically the fingering for the chords of the plucking instruments. The rationally comprehensible notes are replaced by visual directives, to some extent by musical traffic signals. These signs, of course, confine themselves to the three tonic major chords and exclude any meaningful harmonic progression. The regulated music traffic is worthy of them. (1982, pp. 290-291)

Adorno would agree that playing a musical instrument is difficult (clearly privileging the piano) and rightfully so, or it might have no more value than any other common activity, as unique as walking across the room. Mastering a difficult activity such as playing a musical instrument is what makes the artist admired. Even that great contemporary prophet of technological usability, Donald Norman, accepts the usability challenges of musical instruments, stating that they "take years of dedicated practice to be used properly, and even then, errors and poor performance are common among nonprofessionals. The relative unusability of musical instruments is accepted, in part because we know of no other alternative, in part because the results are so worthwhile" (2004, p. 77-78).

But is this really the case? With today's technology, do instruments really *need* to be so difficult in order to retain their value? Just as you might be able to envision the design of an airplane with embedded transparent performance support that enables an untrained novice to pilot it successfully, why can't you picture a musical instrument equipped with similar performance support? What if a piano's keys could be internally illuminated in time to a musical score, allowing a novice to perform within an acceptable margin of error even if he or she had never sat on a piano bench before? What if a saxophone's interface (its keys) could be equipped with both visual support (such as lights or shades of color) and haptic feedback (such as localized vibrations or mild electrical sensations)? What if other, more sophisticated and transparent performance support technology were embedded within musical instruments? Instruments are, after all, technology. By definition, performance support technology is technology that helps humans use other technology. When a novice user is unable to accomplish the artistic/musical performance, he/she activates the support (directly or indirectly) and the resulting performance is one far more polished than the novice could otherwise achieve. A popular example is the video game Guitar Hero, which allows a novice musician to play music on a simulated guitar with embedded support and performance feedback.

If, as Thompson suggests, the widening gap between musical novices and professionals is a symptom of modernity—something surely celebrated by a high modernist such as Adorno—then, perhaps the obliteration of that gap by transparent performance support technology is indicative of a postmodern evolution. In this context, the only relevant criterion is the musical performance. How that performance is achieved is irrelevant. This is no different than the goal of performance support in an industrial environment. When viewed via this extreme postmodern perspective, terms such as "novice" and "expert" become meaningless.

There are no novices or experts. There is only *in-situ* "performance."

Taylor (2001) addresses this transition directly, connecting it to the "modern" chasm between amateurs and professionals, but recognizing what may be a postmodern shift. "Before the advent of recording technology and radio, people made their own music most of the time, but what is radically different today is that it is now possible to create entire worlds of sound all by yourself with your computer" (p. 139). The days are now gone when you need formal musical training in order to produce music. The *performance now resides in the situation.* "Digital technology…makes home music making possible as never before. One can create complex, polyphonic music at home with a computer and other digital equipment without having had years of piano lessons" (Taylor, 2001, p. 13). We have reached a musical point where Benjamin's reader (listener) has become writer (composer). And this is not limited solely to music. "The relatively low cost of new media…and the internet allows many more people to be both producers and consumers of visual and other media" (Mirzoeff, 1999, p. 256-257). The postmodern atomization of both artistic production and distribution have contributed to this new producer/consumer phenomenon, where at any given time, any given individual can be found on either side (or both) of the creation-consumption continuum.

THE QUESTION OF TASTE

Although performance may be the most important metric for success in both business and art, unlike many businesses, the art world cares very much about the human being responsible for the performance. With transparent performance support, the difference between the artist and the technological helper is hazy at best. Lanham (1993) describes the challenge in attributing artistic responsibility and assessing talent:

> *Programs available widely and cheaply…allow novices to compose pleasant sounding music by enlisting the computer as co-composer. Far from…thinking that the computer diminishes human originality and skill, the authors of such programs often regard the physical skills needed for performance, and the theoretical knowledge needed for notation, as elitist prejudices…What "musical talent" is thought to be may itself change…In Laurie Spiegel's Music Mouse, you move the Macintosh mouse around on its pad and the linear motions are translated by the computer into musical sounds. Time and space, drawing and music, are made one by digitization. And if the music sounds good, as often it does, what does "good" mean here? "Who" has created the goodness?* (p. 12)

Does it matter "who" is responsible, as long as the result—the performance—is the desired outcome? What, after all, is "taste?" As Lanham said, what is "good?" Is there any objective definition of good taste that can be applied across society? As noted by Freedman (2003), "even the term art has traditionally signified a judgment of quality" (p. 53).

This notion of quantifying aesthetic taste was an issue addressed by pioneering acoustical physicist Wallice Sabine as early as 1902. Sabine first became known for the development of a scientific acoustical formula that allowed him to predict how sound would behave in any interior environment, based upon a set of variables. After the initially favorable reviews of the musical acoustics of the newly constructed Boston Symphony Hall, on which Sabine consulted, dissenting critical voices began to complain about those very same acoustics. So Sabine convened a committee of faculty members from the New England Conservatory of Music and conducted a series of acoustical tests to determine the optimal amount of acoustical reverberation (Thompson, 2002, p. 55-56).

What Sabine attempted to do, in true scientific fashion, was determine an algorithm for taste.

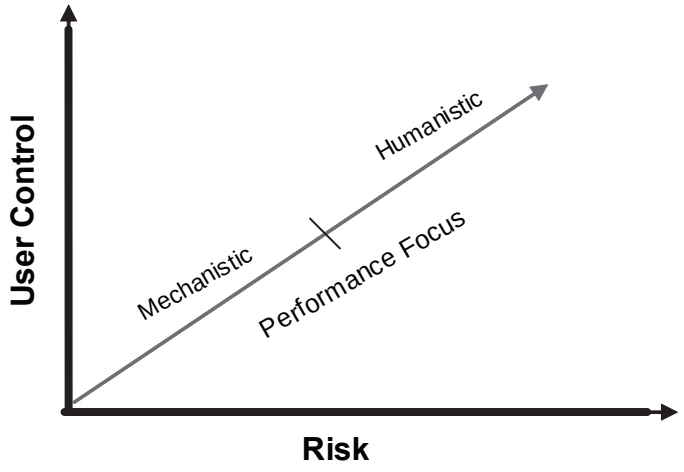
Whether he or his acoustical successors achieved this goal is debatable. Throughout the history of sound, the amount of ideal reverberation continued to be adjusted based upon the individual preferences of the audience and the fashion of the time. Sabine, of course, was trying to objectify the *external* quality of the sound. He wanted to answer the question: *what is good sound*? He did not address the *internal* quality of sound, specifically its content—*what sounds good?* This, naturally, begs the question: can an algorithm be developed that describes exactly what constitutes a "good" song? Can we derive a formula for taste?

In essence, that's exactly what screenwriting software, entry-level musical composition software, and photographic auto-focus attempt to do. In order for a novice to possibly write a screenplay or compose a song, the system must make some transparent "intuitive" performance support decisions about how that artistic expression will be created. Those decisions—the variety of choices offered, the amount of user control—constitute a *de facto* taste algorithm. By changing the values of the few variables in the formula we are permitted to adjust, we create an original piece of art within prescribed limitations.

The result, however, seems to be (to echo Barthes in *Image-Music-Text*) a general "flattening" of the qualitative differences between pieces (1977, p. 189). For example, with musical composition software, on the bottom end, the system prevents you from producing something so horrible as to be universally unrecognizable as music. However, by so doing, it also prevents you from really excelling at the top end. The very performance support decisions that enable a novice to compose a song actually preclude someone with real talent and experience from composing something truly wonderful. The system is only capable of producing music in a general "fair" range.

It seems that an equation could be derived that states that the user's ability to leverage his/her own talent and experience is directly proportional to the amount of control that a piece of software affords that user (Figure 1). That amount of

Figure 1. Control vs. risk with artistic performance support technology



control, however, is also proportional to the risk that a novice has of failure. The lower the risk of failure, the lower the ability to excel.

Greater User Control =	Greater Risk of Failure Increased Ability to Excel
Lesser User Control =	Lesser Risk of Failure Decreased Ability to Excel

This equation can very likely be applied to any example of artistic performance support technology, including the earlier examples of screenwriting software.

As the amount of user control lessens, the greater the level of mechanical influence. Conversely, as the amount of user control increases, so do the humanistic/organic characteristics. Control is an important issue relative to performance support across all areas of society—whether in business, the arts, medicine—since it is intrinsically linked to risk and success (financial, artistic, physiological). Norman (1988) addresses this issue directly when he writes:

All tasks have several layers of control. The lowest level is the details of the operation, the nimble finger work of sewing or playing the piano, the nimble mental work of arithmetic. Higher levels of control affect the overall task, the direction in which the work is going. Here we determine, supervise, and control the overall structure and goals. Automation can work at any level. Sometimes we really want to maintain control at the lower level. For some of us, it is the nimble execution of the finger or mind that matters. Some of us want to play music with skill. Or we like the feel of tools against wood. Or we enjoy wielding a paintbrush. In cases like these, we would not want automation to interfere. At other times we want to concentrate on higher level things. Perhaps our goal is to listen to music, and we find the radio more effective for us than the piano; perhaps our artistic skill can't get us as far as can a computer program. (p. 197)

The risk of creative failure is mitigated, of course, through the use of artistic formulas. An artistic formula, like a mathematical formula or algorithm, is simply a structure in which variables can be adjusted to produce a predicted result. However, unlike mathematics, where a formula is generally perceived as a useful tool, artistic formulas have traditionally been denigrated as clichés and the work of hacks. "The more stuffed the poem with 'formulas,' the more it passes for successful," wrote Barthes (1979, p. 112). Unfortunately, in the world of arts education, where the professional artists of tomorrow are being trained, "the value of originality is imparted at the same time as the value of following rules" (Freedman, 2003, p. 8). This mixed message—originality vs. following rules—is fundamental to the challenge faced when trying to balance issues of control. As formula-based performance support technology embeds itself more intrinsically into the tools of artistic production, questions will arise regarding the value of artistic education. If the performance is resident in the instrument (or camera, or word processor), then why do we need master artists or teachers? This is a dangerous question, of course, and one that will likely be rejected by those within the established artistic community.

Adorno doesn't spare the rod when addressing the formulaic structure of popular music. He laments the "standardization" of this music and foreshadows the very "flattening" evidenced by entry-level musical compositional software:

The harmonic cornerstones of each hit—the beginning and end of each part—must beat out the standard scheme. This scheme emphasizes the most primitive harmonic facts no matter what has harmonically intervened. Complications have no consequences. This inexorable device guarantees that regardless of what aberrations occur, the hit will lead back to the same familiar experience, and nothing fundamentally novel will be introduced. (1941, p. 17)

Of course, what constitutes a formula may only be in the eye of the beholder. Just because Adorno or the musical elite might denigrate the music of a currently popular but critically panned artist such as Ashlee Simpson doesn't mean that her music has no value. She brings pleasure and enjoyment to her fans, who would likely roll their eyes if Adorno suddenly appeared and told them they were being duped by the great manipulative apparatus of corporate music. The critical lambasting of Ashlee Simpson and her music is consistent with Mirzoeff's observation of mass culture (specifically visual culture) that "the generalized antipathy of intellectuals to popular visual representations may be displaced hostility to those who participate in and enjoy mass culture" (11). But are the critics even relevant? The Beatles and Elvis were panned at first, too. Besides, is there anything wrong with someone listening to what they like and actually enjoying it? Does everyone have to enjoy the same music?

This is likely the primary reason why achieving a "taste" algorithm is so difficult. If you prefer Ashlee Simpson and I prefer Beethoven, then how could our tastes possibly agree in order to be captured in any type of meaningful equation? The answer may lie in those very differences. What if you could choose the type of music you liked best and then the embedded performance support technology helped you create music in that style? Inventor Ray Kurzweil has written at length about this issue and his "Poet's Assistant" software is an excellent example of this concept:

The Poet's Assistant provides a simple word processor ("poem processor") in which you write your poem or song lyrics. Besides providing standard text editing features, the Poet's Assistant monitors your "poem-in-progress," and provides a wide range of helpful suggestions as you type…Each suggestion is based on a "poet personality" that you select…The standard version…includes 50 poet personalities…For example, the Poet's Assistant can provide rhymes (words that rhyme with one of your words) or half-rhymes that were used by Robert Frost; alliterations used by Yeats; a set of "next words" used by Shelley; and entire lines (or stanzas) of poetry that are based on (but which were not actually written by) Emily Dickinson (or based on a combination of contemporary poets). From these lines and/or stanzas, you can find ideas for words and turns of phrase. (2005a)

Kurzweil also offers the next step in mechanistic art, what he terms a completely "cybernetic poet" in which a human being isn't even necessary. Called the Ray Kurzweil Cybernetic Poet (RKCP), the system auto-generates poems using an algorithm based upon pre-selected poet styles. This "unique recursive poetry generation algorithm" is rooted in an analysis of the selected poet's technique (2005b). When tested, it was difficult for a combined general audience of juvenile and adult readers to determine which poems were written by the actual poet and which were written by the computer (Kurzweil, 1992).

However, Kurzweil's cybernetic poet strays a bit far from the domain of performance support technology, which, by definition, requires a human to be supported. The cybernetic poet is more indicative of automation (a term invoked by Norman in the earlier quote regarding issues of control). But I include it here to illustrate recent attempts to develop taste algorithms. Are they successful? To many, especially those who couldn't tell the cybernetic poetry from that of Eliot or Frost, the answer is certainly "yes"; although, to others, the jury is still decidedly out.

When Kurzweil discusses "language modeling techniques" and a "recursive poetry generation algorithm," we can't help but speculate on a post-human stylistic recursion. Will we reach a point where the very poetry generated by the computer is being used as a stylistic model for future cybernetic poetry, in a sort of technological Ouroboros, a great mechanical serpent continually swallowing its own tail, reducing humanity to an uninvolved bystander? As Kahn (1999) says,

"The relationship of techniques to technologies is…complicated since it is clear that technologies can derive from techniques…and techniques can derive from technologies" (p. 15). Musicians today, especially those working in sampled sounds, are creating music that can only be produced by very specific technology. The technology is molding the technique, which, in turn, continues to influence the technology of music production.

Yet, if performance support technology employs formulas to assist in the creation of art, even if those formulas are based on T.S. Eliot or J.S. Bach, perhaps all we're left with is a computerized Minou Drouet (to reference Barthes), where the formulaic banality of the work is masked by the novelty of who (or what) produced it. It's possible that, as Adorno stated, "the golden age of taste has dawned at the very moment in which taste no longer exists" (1982, 280-281). Adorno, of course, implored us to resist what he called "the cult of the machine…For the machine is an end in itself only under given social conditions—where men are appendages of the machines on which they work. The adaptation to machine music necessarily implies a renunciation of one's own human feelings and at the same time a fetishism of the machine such that its instrumental character becomes obscured thereby" (1941 p. 17-48). To many, the simple fact that a particular piece of music was created by a computer is what makes it interesting, regardless of any artistic merit. Such listeners have fetishized the machine to the detriment of the art.

"A TRIUMPH OF AMATEURISM"

However, some artists today do resist the overmechanization of the creation process. This goes back to the essential issue of control. The more experienced and/or talented the artist, the less he/she wants to abdicate control of the creative process to a machine. Talent is a rare commodity and those who have it are unlikely to dull its edge with assistive technology. Trained artists with legitimate talent may naturally resist the unrestricted democratization of artistic production. Perhaps extending the kiosk culture into the arts eventually leads to an overall cheapening of the value of artistic talent. How many of the scripts generated by the screenwriting software would be movies you would want to see? How much of the computer-mediated music is worth listening to? Will we lose something intrinsically—exclusively—human by layering in compensatory artistic performance support technology?

The answer to this question may very well be different for each person depending upon your own perception of personal artistic talent. Hayes (1991) feels that such human-computer collaborations could result in "a triumph of amateurism. Computer-based tools may compensate for the amateur's lack of skill, but they cannot make up for a failure of taste or judgment" (p. 15). Do we end up with, as the critics of early amateur photography protested, "fried fish pasted onto metal plaques" (Mirzoeff, 1999, p. 72)? Barthes astutely observed that the difficulty in mastering Beethoven is related more to the artistry of the music—the code—than in any technical skill required to perform it (1977, p. 152).

Benjamin himself remarks on the rarity of talent in a long note at the end of *The Work of Art in the Age of Mechanical Reproduction*. He quotes at length from Huxley (1949), who declares that "artistic talent is a very rare phenomenon," in both the visual and auditory arts. With the increase in the sheer volume of artistic material produced, the result is that:

the gramophone and the radio have created an audience of hearers who consume an amount of hearing-matter that has increased out of all proportion to the increase of population and the consequent natural increase of talented musicians. It follows from all this that in all the arts the output of trash is both absolutely and relatively greater than it was in the past; and that it must remain

greater for just so long as the world continues to consume the present inordinate quantities of reading-matter, seeing-matter, and hearing-matter. (pp. 217-251)

The production of art of dubious merit is only exacerbated by the rise of performance support technology. A quick internet search will reveal literally millions of homemade songs, podcasts, and other creative expressions available for the general public.

Nevertheless, for the novice or untalented, the machine offers access to previously unavailable artistic expression. Perhaps self-service art is the ultimate extreme in egalitarianism, opening the closed, rarified world of art to anyone who wants to join in. Any layman who wants to write or paint or compose or play an instrument can do so successfully. If that results in more people enjoying the creation of and participation in art, is that so bad?

Where technology once created distance between amateurs and professionals (Thompson's "wide chasm"), technology is now pulling both sides back together into a homogenous group where at any given moment someone can be either creator or audience (or both). "With digital technology, there is some hope that people—at least those who can afford computers—will begin to make music for themselves again using their computers and cheap, easily available software" (Taylor, 2001, p. 5). Taylor quotes from a publication aimed at amateur composers of electronica music: "'Forget about talent,' says 'How to Become a Techno God,' a guide to making your own techno music; 'talent just gets in the way'" (p. 164).

Whether in music or the visual arts, this attitude is reflective of "a young generation that seems increasingly resistant to the seductions of production values and actively engaged in a 'do-it-yourself' aesthetic…the production of visual imagery is by now so diversified that it collectively signifys [sic] a shift away from the passive consumer trying to invest consumption with meanings towards a consumer-producer" (Mirzoeff, 1999, p. 257). Recall, too, Lanham's remark that the programmers of composition software regard the physical skills of musicianship as "elitist prejudices." Who needs talent when it's already programmed into the software?

Although he would probably cringe at artistic performance support technology, even Adorno might smirk at some of its cultural consequences. As more and more art is produced by people who were previously unable to do so, traditional distribution channels are being torn asunder. There is simply too much content now. As a result, the seams of the traditional pipelines are popping open under the pressure of volume and artistic expression is finding new, unorthodox ways to reach the public.

USA Today recently observed that "new sounds and new bands are emerging from Web cabals, a blow to radio and labels used to setting the agenda… That's causing a democratic shift, as more phenomena filter up and fans elect their own stars rather than accept the dictates of radio or MTV" (Gunderson, 2005). The vast corporate musical apparatus is losing the power to dictate what kinds of popular music the mass consumer should listen to. Media can now be "distributed both locally and globally by activist groups, charities and other small-scale organizations" (Mirzoeff, 1999, p. 257). This sentiment is resonating across the media spectrum with the emergence of outlets such as the Current television network, which is founded on the principle that its programming will be produced largely, if not entirely, by amateurs. Such direct distribution channels, with podcasting being the most acute example, are undermining the role of Bourdieu's mediators (1984), which until now have been serving as "cultural intermediaries," controlling the presentation of commoditized artistic goods and services.

As a catalyst for this shift, enabling amateurs to produce art and other media, performance support technology helps to answer some of Adorno's

Marxist critiques of the music industry while at the same time validating Benjamin's vision of artistic democracy. If, as Freedman (2003) has written, "all art is political" (p. 52), then the politics of artistic performance support and postmodern technological distribution channels are certainly "democratic." The kiosk culture is "of the people, by the people, and for the people."

Perhaps the role of artistic performance support technology isn't to fundamentally change the process of creating art. It seems unlikely that it will turn talentless hacks into artist poseurs. By and large, especially over time, audiences can tell the difference. Audiences grow increasingly sophisticated and, despite Adorno's assertions, Mirzoeff (1999) appears to be on the right track when he declares that "it is no longer possible to suggest that the mass audience will gullibly consume any product that is offered to it containing a simple formula of entertainment" (p. 255). The example of *American Idol* notwithstanding (although the show's eventual winners do generally seem to have legitimate vocal ability and much of the show's appeal lies in its spectacle of poor talent), this is why copycat films and trend-chasing television programs rarely succeed. The true promise of artistic performance support technology lies elsewhere.

If a musical composition software program were used to introduce a child to the concept of reading music, combined with the positive reinforcement of a technologically-enabled early compositional success, it could quite easily serve as a catalyzing inspiration for a lifelong love of music. And if, as a result, such a child happened to discover a previously unrealized natural musical talent and blossomed from that early nurturing into tomorrow's Ludwig van Beethoven or George Gershwin or Brian Wilson, that wouldn't be such a bad thing. With artistic performance support technology, anyone can now go from reader to writer, listener to performer. Benjamin's vision is realized, where the cultural democracy of artistic production grows increasingly more democratic every day.

Section VI
Managerial Impact

This section presents contemporary coverage of the managerial implications of software applications. Particular contributions address agile practices in project management, virtual software teams, and computer-aided management of software development. The managerial research provided in this section allows executives, practitioners, and researchers to gain a better sense of how software applications can inform their practices and behavior.

Chapter 6.1
Open Source Software and the Corporate World

Sigrid Kelsey
Louisiana State University, USA

ABSTRACT

This chapter discusses various ways that open source software (OSS) methods of software development interact with the corporate world. The success achieved by many OSS products has produced a range of effects on the corporate world, and likewise, the corporate world influences the success of OSS. Many times, OSS products provide a quality product with strong support, providing competition to the corporate model of proprietary software. OSS has presented the corporate world with opportunities and ideas, prompting some companies to implement components from the OSS business model. Others have formed companies to support and distribute OSS products. The corporate world, in turn, affects OSS, from funding labs where OSS is developed to engaging in intellectual property disputes with OSS entities. The consumer of software is sometimes baffled by the differences in the two, often lacking understanding about the two models and how they interact. This chapter clarifies common misconceptions about the relationship between OSS and the corporate world and explains facets of the business models of software design to better inform potential consumers.

INTRODUCTION

Open source software (OSS) is impacting the corporate world in numerous ways, from providing software and competing with its proprietary software companies to changing the direction of the software industry. While some corporate giants are embracing the OSS business model, launching OSS projects of their own, and supporting existing OSS projects, others are vigorously competing with the OSS movement and its products. Still others are capitalizing on successful OSS products by packaging, distributing, and providing support for them. Sharma et al. (2002) assert that the success of OSS is turning the software industry from a manufacturing to a service industry in which customers are paying more for support and service than for the product itself. In addition, the OSS model of production

has gained recognition as an "important organizational innovation" (Lerner & Tirole, 2002, p. 1). Without a doubt, the OSS movement has had a substantial influence on the software industry and the corporate world.

BACKGROUND

Both the OSS and proprietary models of software productions have existed since the early days of software development. Unix, for example, was developed at Bell Laboratories in the late 1960s and early 1970s and distributed freely to universities during the 1970s. Unlike the altruistic motivations of many OSS products, the reason for Bell Laboratories' free distribution was to keep the "consent decree" that resulted from a 1956 antitrust litigation that prevented AT&T from marketing computing products (Vahalia, 1996). In fact, AT&T's 1979 announcement that it would commercialize UNIX prompted the University of California Berkeley to develop its own version, BSD UNIX (Lerner & Tirole, 2002). AT&T's move to make the cooperatively developed UNIX into a proprietary product came four years before Stallman's decision to develop GNU and General Public License.

By 1980, a business model for software had emerged, restricting the copying and redistribution of software by copyright. Bill Gates had already established himself as a supporter of this proprietary model, stating in his February 3, 1976, "An Open Letter to Hobbyists":

As the majority of hobbyists must be aware, most of you steal your software. Hardware must be paid for, but software is something to share. Who cares if the people who worked on it get paid? … Is this fair? … One thing you do do is prevent good software from being written. Who can afford to do professional work for nothing? (Gates, 1979)

Gates' letter indicates the differences in philosophy between proprietary and free software proponents that have existed since the early days of software development.

In 1984, computer scientist Richard Stallman, frustrated that all available operating systems were proprietary, quit his job at MIT to develop the GNU (pronounced guh-noo, a recursive acronym for GNU's Not Unix) system. His goal, in addition to developing a new operating system, was to change the way software was created and shared, giving users freedom to modify or add to programs, redistribute the programs with their changes, cooperate with each other, and form communities. Stallman also developed the concept of "copyleft" and the GNU General Public License (GPL) in 1989, publishing all of his work under that license. Copyleft gives software a copyright and users permission to change the software, add to it, and redistribute it, as long as it remains under the GPL terms. By preventing the software from entering the public domain, the GPL prevents users from turning free software into a proprietary derivative. Thus, the beginnings of the OSS movement were a reaction to the proprietary corporate model. In 1990, University of Helsinki student Linus Torvalds wrote the Linux kernel, releasing it under GPL, and filling the gap for a piece of Stallman's system still under development. Soon after, the Apache Web server was developed, providing an OSS application for Linux. This combination of software offered a new option to Internet service providers and e-commerce companies, which, until then, had only proprietary options.

Stallmans's Free Software Foundation Web page, reminding readers that free software means "free" as in "free speech," not as in "free beer" (Free Software Foundation, 2005), echoes a concept brought forth perhaps more eloquently by Thomas Jefferson and widely-quoted by OSS advocates that "ideas should freely spread from

one to another over the globe, for the moral and mutual instruction of man, and improvement of his condition ... ." With the growth of the OSS movement, some of the values of the OSS culture have diversified, but freedom and sharing remain integral to its success and completely dissimilar to the proprietary model of development and distribution.

The corporate and OSS models and philosophies continued to influence one another and develop throughout the 1990s. The "open source" label came out of a 1998 meeting, and shortly thereafter, the Open Source Initiative was created. Also in 1998, the Digital Millennium Copyright Act (DMCA), criminalizing the production of software for the purpose of evading copyright, and the Sonny Bono Copyright Term Extension Act, extending U.S. copyright terms by 10 years, both passed. Despite the divergent directions the two movements were taking, the difference between free software and proprietary software has never been reducible to a battle between anti-corporate OSS proponents and the profiteering corporate world, as many people perceive. Corporate companies with a stake in the software industry have, in fact, navigated various approaches to succeed in an industry in which the motivations for developing software go beyond the commercial value of the product or ownership of intellectual property. While the two models of software production and distribution are competitive in many ways, it was also in the 1990s that it became common for commercial companies to interact with the OSS community (Lerner & Tirole, 2002).

During 1998, Torvalds appeared on the cover of *Forbes*, Netscape announced a decision to make the next version of its Web browser an OSS product, and IBM adopted the Apache Web server as the core of its Websphere line of products (O'Reilly, 1999). Like IBM, some corporate giants have chosen to use and support OSS voluntarily. Others have found it necessary to contribute in order to market products to Linux users; still others have fought intellectual property battles with OSS constituents. The relationship between the OSS and corporate cultures is complex, but it is clear that the OSS culture is making an impression on the corporate world, and vice versa.

As the OSS community has grown to include professionals, students, hobbyists, corporate giants, universities, and others, the freedom of ideas and sharing knowledge remains the crux of the OSS ideology. To integrate into the OSS culture, therefore, the corporate world must be willing to share its developments. This chapter summarizes some ways in which the OSS movement has motivated change in the software industry and corporate world, citing some specific examples of corporations reacting to OSS software and strategies in different ways, which serves to illustrate the larger picture.

MAIN FOCUS OF THE CHAPTER

Corporate Culture and Motivations of OSS Developers

A misconception often associated with OSS developers is that they are volunteer programmers, willing to "dedicate their time, skills, and knowledge to the OSS systems with no monetary benefits" (Ye & Kishida, 2003, p. 1). In fact, there are many money-making opportunities for open source developers, from providing software support to programming for companies or institutions using the software. While it is true that many OSS developers are paid to make the developments, Eric Raymond is quick to point out that while OSS developers may be paid for their contributions to the software, their salaries rarely depend on the sales value of their software (Raymond, 2001). OSS contributors may work for support companies, universities, and other organizations with motivations not attached to selling the software. This is a key difference between the OSS and proprietary software business models. Stallman's

1985 GNU Manifesto not only outlines his reasons for creating GNU but also offers some suggestions for how programmers can make money in an OSS environment.

While too often OSS advocacy is reduced to an anti-Microsoft position, the challenge that the OSS community has posed to the software giant does provide an illustration of the extent of the movement's success. For example, throughout the Microsoft Corporation antitrust case, Linux was a named threat to Windows domination, with Microsoft CEO Steve Ballmer referring to open source as a "cancer" (Microsoft Exec, 2006). In the midst of the antitrust trial, Eric Raymond became the recipient of two leaked internal Microsoft memos, posting them on a Web site and naming them the "Halloween Documents." The documents, acknowledged by Microsoft to be authentic but according to Raymond dismissed as an engineering study not defining company policy, discuss the success of Linux, acknowledging the achievements of the OSS movement and outlining strategies to "beat" Linux (Raymond, n.d.). Microsoft is not the only corporation combating the success of Linux and other OSS products.

The SCO Group is a software company currently involved in a number of disputes regarding intellectual property, including lawsuits with IBM, Red Hat, and Novell. SCO filed a complaint against IBM in March 2003 claming that IBM has misappropriated SCO's proprietary knowledge by contributing to the GNU/Linux systems with code SCO claims to own, alleging damages of at least $1 billion. The result of the ongoing litigation will set a precedent for future cases.

In 2005, Columbia University law professor Eben Moglin formed the Software Freedom Law Center to help protect OSS development from similar litigation. The center provides pro bono legal services to FOSS projects and developers; its mission to help provide FOSS developers with "an environment in which liability and other legal issues do not impede their important public service work. The Software Freedom Law Center (SFLC) provides legal representation and other law-related services to protect and advance FOSS." His foundation is one of several helping to defray legal costs for litigation against FOSS developments. The Open Source Development Labs (OSDL) Linux Legal Defense Fund has raised more than $10 million to provide legal support for Linus Torvalds and others subject to SCO litigation (Goth, 2005, p. 3).

While Microsoft and SCO are resisting the OSS model of business, others in the corporate world have come to see the benefit of working with OSS producers and products. Silicon Valley's NetApp, for example, became involved in Linux because its Linux-using customers were experiencing difficulty moving files between their computers and NetApp filers. Although it was a Linux problem, customers complained to NetApp, and with a vested interest in fixing it, NetApp cofounder and chief of engineering talked to Linus Torvalds. Mistrustful of companies like NetApp, Torvalds declined NetApp's offer to fix the problem, naming instead his choice programmer for the job, Trond Myklebust. NetApp, along with Linux developers worldwide, could submit suggestions to Myklebust in hopes that he would accept them. Therefore, if NetApp was to market its product to Linux users, it was obliged to join the OSS culture (Lyons, 2004). The NetApp circumstances demonstrate that any company wishing to make its product compatible on a Linux platform has a stake in the OSS world. Yet while the OSS culture is able to influence the actions of the corporate world, so the corporate world is able to do likewise.

In 1999, NetApp began funding the University of Michigan's Center for Information Technology Integration (CITI), home to a lot of Linux NFS development. By 2002, NetApp was paying Myklebust a stipend and providing him office space in the lab and a company-paid apartment in Ann Arbor. Peter Honeyman, scientific director of the lab where Myklebust works who receives $192,000 a year from NetApp, notes, "What's in it for [NetApp] is sales; it can sell into the Linux

market. This is not about philanthropy. There is plenty of mutual benefit going on here" (quoted in Lyons, 2004). Torvalds, who was mistrustful of NetApps' offer to help, works at a Beaverton, Oregon, lab funded in part by Hewlett-Packard (Lyons, 2004). In response to the apparent conflict between picking up a salary from a revenue-hungry corporation and developing OSS, Torvalds compares himself to an athlete with a corporate sponsor (Lyons, 2004).

The OSS culture, therefore, is not separate from the proprietary model of development; rather, the two models interact with and influence each other in many ways. Indeed, the OSS, corporate, and academic worlds have a complex relationship, each able to control, to some extent, the others' directions.

A 2004 *Forbes* article notes that many top technical firms hire Linux programmers in hopes of manipulating the direction of Linux development (Lyons, 2004). Hewlett Packard Vice President Martin Fink acknowledges that the closer he can get to Torvalds, the more influence he can have on Linux, saying "I try to keep it under two hops. ... The way to get stuff done in the Linux community is to hire the right people." In 2003, Hewlett Packard generated $2.5 billion in Linux-related revenue; IBM $2 billion; and Red Hat, which distributes a version of Linux, $125 million in revenues. Linux runs in datacenters of places like Charles Schwab & Co. and Sabre Holdings (Lyons, 2004). These corporations have recognized the benefits of the OSS culture, and many of them have become sponsors of its research.

IBM has been a powerful corporate advocate of OSS development for years. In 2005, IBM promised free use of 500 of its U.S. patents to open source developers, stating, "The open source community has been at the forefront of innovation and we are taking this action to encourage additional innovation of open platforms" (IBM, 2005). IBM's Bob Sutor, vice president of standards, says that this move was made in hopes of starting a "patent commons" for companies to contribute intellectual property for open source developers to use freely without fear of litigation (Goth, 2005, p.4) from companies like SCO. OSS supporters generally believe that software patents hinder advancements in software research; in Europe, efforts are underway to prevent laws that would allow the patenting of software (Carver, 2005).

With IBM and other such corporations designing their products with OSS platforms in mind, and contributing to the furthering of OSS research, it is plain that the two cultures have learned to work together.

Reliable Code, Reliable Support

The success of OSS projects like Linux, Apache, and Perl evince the success of the bazaar model on the code itself. The traditional paradigm of collaborative development follows Brooks' Law, which ascertains that only a select circle of experts should be allowed to collaborate, with little or no feedback, to improve a product before it is finished. Brooks' Law states, "Conceptual integrity in turn dictates that the design must proceed from one mind, or a very small number of agreeing resonant minds" (Neus & Scherf, 2005, p. 216). Eric Raymond dubs the bazaar approach Linus' Law in which software is released early and often, evolving as users around the world use it and contribute to it. Making the code freely available and open to review by one's peers makes the quality better (Bergquist & Ljungberg, 2001). Open source has proved itself to be a formidable model for creating quality software, and as OSS projects become even more widely adopted, the culture and communities grow larger.

Customers often question the availability or longevity of support available for OSS. Without a revenue-generating company supporting it, it is difficult for OSS newcomers to imagine that any support will exist. But the success of OSS projects like Linux, GIMP, and Apache provide examples of the bazaar model's success. In fact, with proprietary software, the support is propri-

etary as well, where anyone who is able to provide support for OSS is free to do so. O'Reilly Media, Inc., a strong supporter and early advocate of OSS, points out on its Web site that its success came in part because it was not "afraid to say in print that a vendor's technology didn't work as advertised" (O'Reilly, n.d.). Besides publishing numerous support books, O'Reilly provides online services and hosts OSS summits and conferences. O'Reilly is not the only company providing support for OSS. The OSS culture of sharing and helping gives assurance that with any successful OSS product, adequate support is available.

FUTURE TRENDS

A July 2005 article reports that 70% of Web servers on the Internet use Apache compared to roughly 25% using Microsoft's Internet Information Server (Bradbury, 2005). Already, European governments have adopted OSS for their computing needs, and California has started a U.S. trend toward the same, making a 2004 recommendation for the use of OSS in its performance reviews. Products like OpenOffice, named by Developer.com as a 2006 Open Source Product of the year, offer products that are able to compete with Microsoft's Office Suite. The state of Massachusetts is currently deciding whether to go forward with a decision made by the former CIO to use OpenOffice, with Harvard Law School Professor John Palfrey predicting, "If Massachusetts gets this right, others will follow" (McMillan, 2005).

OpenOffice is already common in Israel, in part because OpenOffice works well with the Hebrew language and because Microsoft software is expensive. China, where software theft has discouraged proprietary companies from marketing, has embraced OSS, creating the China Standard Software Company (CSSC) and the China Open Source Software Promotion Alliance (Bradbury, 2005). The growing trend to adopt OSS has spread worldwide. With such support, the OSS culture and movement will continue to grow. Market researcher IDC predicts that by 2008, Linux server sales could approach $10 billion.

The GPL has yet to be ruled enforceable in a U.S. court of law; until now, it has only been enforced in private negotiation or settlement agreements (Carver, 2005). In Germany, however, a Munich district court has ruled it valid and enforceable (Carver, 2005). The result of ongoing litigation between SCO and IBM will set a precedent for how the GPL is interpreted in the United States.

Lerner and Tirole acknowledge that the future of the open source development process is difficult to predict with existing economic models and that further research is needed from an economic perspective.

CONCLUSION

The predominating shared norms, values, attitudes, and behavior that characterize OSS culture are deeply rooted in valuing freedom and sharing. As OSS has grown to offer software options for large entities like governments, companies, and universities, reasons for joining the OSS movement diversify. While the movement has grown and the culture has shifted, the basic values have remained in tact. Its success has impacted other cultures and traditions worldwide, from academic publishing and research to government to the corporate world. Clearly, the initial ideas and philosophies set forth by Jefferson and echoed by Stallman are affecting the culture of research worldwide, with the OSS movement proof that a culture of sharing is beneficial to everyone involved.

KEY TERMS

Free Software (FS): Software that users have the freedom to alter, use, and redistribute, usually under the terms of the General Public License. Closely related to Open Source Software, the two terms are sometimes used interchangeably. "Free" is not associated with cost but with the freedom associated with it. However, free software is often cost-free as well.

General Public License (GPL): A license created by Richard Stallman that protects free software from being turned into proprietary software.

Open Source Software (OSS): Software that allows the user to see and alter the source code; closely related to free software.

Proprietary Software (PS): Software that does not allow the user to see or alter the source code.

Chapter 6.2
Combining Tailoring and Evolutionary Software Development for Rapidly Changing Business Systems

Jeanette Eriksson
Blekinge Institute of Technology, Sweden

Yvonne Dittrich
IT-University of Copenhagen, Denmark

ABSTRACT

This article reports on a case study performed in cooperation with a telecommunication provider. The telecom business changes rapidly as new services are continuously introduced. The rapidly changing business environment demands that the company has supportive flexible software. The company's continuous evolution of the IT-infrastructure makes it necessary to tailor the interaction between different applications. The objective of the case study was to explore what is required to allow end-users to tailor the interaction between flexible applications in an evolving IT-infrastructure. The case study followed a design research paradigm where a prototype was created and evaluated from a use perspective. The overall result shows that allowing end-users to tailor the interaction between flexible applications in an evolving IT infrastructure relies on, among other things, an organization that allows cooperation between users and developers that supports both evolution and tailoring.

INTRODUCTION

End-user development (EUD) is one way to provide a flexibility that allows companies to compete in rapidly changing business environments. Telecommunication provision is one such example of a rapidly changing business area. Telecommunication providers compete by, among other things, providing their customers with new

types of services, and as the business changes, the business systems supporting it must also change. One way of conducting EUD is end-user tailoring. End-user tailoring is an activity allowing end-users to modify the software while it is already in use, as opposed to modifying it during the development process (Henderson & Kyng, 1991). End-user tailoring ranges from setting the values of parameters to adding code to the software. Since evolution of software is inevitable (Lehman, 1980) and since tailoring is recognized as a way of reducing the efforts when keeping the system up to date through further development (Mørch, 2002), tailoring could be an alternative to increase the sustainability of software in a rapidly changing business environment.

Tailoring research so far has focused on flexible stand-alone systems. In earlier projects, we too focused on the design of flexible and end-user tailorable applications (Lindeberg, Eriksson, & Dittrich, 2002). However, interaction with other systems turned out to be a bottleneck, since business systems in telecommunication are part of an IT-infrastructure consisting of heterogeneous data sources. Other research also indicates that software and IT-infrastructures pose new challenges for software engineering (Bleek, 2004). Normally, the data exchange between different systems is the realm of the software developers, but in this article we use the evaluation of a prototype to answer the question: What is necessary to allow *end-users* to tailor the interaction between flexible applications in an evolving IT-infrastructure? Our results support the claim that end-users can even tailor the interaction between business applications. The analysis of a user evaluation of a case-based prototype results in a number of issues to be addressed regarding the technical design, the know-how demanded of the users, and the organizational setting, particularly the cooperation between users and developers. These issues both confirm and extend existing research on end-user development and tailoring.

We start by briefly describing the relevant work practices and business systems of our industrial partner. We then present how our research relates to others' work. In the following section, we describe our research approach in detail and the design of the prototype is presented to provide a basis for the evaluations and discussions. Thereafter, we present the outcome of the evaluation, which points out three different categories of issues that are important when providing end-users with the possibility to manage interactions between applications in an evolving IT-infrastructure. The discussion relates these results to the state of the art.

HISTORY AND BACKGROUND

The research reported here is part of a long-term cooperation between the university and a major Swedish telecommunication provider, exploring the applicability of end-user tailoring in industrial contexts (Dittrich & Lindeberg, 2002). The subject of the prototype is part of the telecommunication provider's back office support infrastructure for administering a set of contracts and computing payments according to these contracts. To compute payments, the system must be supplied with data from other parts of the IT-infrastructure. When creating new contract types based on different data, flexibility is constrained by the hard-coded interface to other systems. As a work-around, ASCII files can be created providing the necessary data sets – or events – to compute the payments. The data for these extra payments is handled and computed manually. To compute the data for an extra payment, members of the administrative department first run one or more SQL queries against the data warehouse. The result is stored in ASCII files. Next, the user copies the data from the ASCII files and pastes it into a prepared spreadsheet. When the user has thus accumulated the data, the user works through the spreadsheet in order to remove irregularities. The contents of the sheet are eventually converted again to an ASCII

file that is imported into the payment management system. The manual procedure to compute the data for the extra payments has worked well until recently, although it is time consuming. The competitiveness of the telecom business is however continually forcing the company to come up with new services; more and more types of extra payments will be needed. This situation necessitates a tool to define and handle the new data sets or events. To make such event tool as flexible as possible, it must allow the collection and assembly of data from different kinds of systems. Experience suggests that it is impossible to anticipate the structure of future extra payments or which details will be needed. As a result, the tool must be able to communicate with any system in the IT-infrastructure. It is also essential that the tool allow for expansion of the tailoring capabilities, meaning that new data sources can be added. The addition of a new source should be as seamless as possible. Since different system owners and developers are responsible for these systems, it is their responsibility to make new data sources available. Such changes are part of the maintenance of the other systems, and here the limits of end-user tailoring are reached.

RELATED WORK

The research on end-user tailoring addresses mainly the design of tailorable applications, tailoring as a work practice, and cooperation between users and tailors. Examples of research on the design of tailorable systems are (Eriksson, Warren, & Lindeberg, 2003; Lindeberg et al., 2002; Mørch, 1997; Stiemerling, 2000; Stiemerling & Cremers, 1998). Of these, only two address tailoring in the context of distributed systems. In Eriksson et al. (2003) a prototype that dynamically connects different physical devices (video cameras, monitors, tag readers, etc.) is presented. The tool can be regarded as tailoring the interaction between different intelligent devices. Stiemerling (2000) and his colleague (Stiemerling & Cremers, 1998) show how to build a search tool by using customized Java Beans. The users customize search and visualization criteria. The tailorable search tool is used within a distributed environment provided by a groupware system. Neither of the distributed tailoring approaches is evaluated by users to explore beyond technical issues of how end-users can manage interaction between applications.

Several researchers have studied how tailoring activities are carried out in work practice, for example (Gantt & Nardi, 1992; Trigg & Bødker, 1994). In a study involving tailoring spreadsheets, Nardi and Miller (1991) identify collaboration between three kinds of users of CAD (Computer Aided Design) systems (1) users who do not program (2) users who acquired the skill to program small macros, and (3) local developers: users having a more or less formalized responsibility for supporting other users and maintaining the macro selection of a group or department.

Carter and Henderson (1999) invented the expression *tailoring culture* to express the need for organizational support for tailoring. Kahler (2001) also points out that, in order to make tailoring successful, an organizational culture must evolve that supports the development and sharing of tailoring knowledge. Kahler also emphasizes three often coexisting levels of tailoring culture, identified and addressed by different researchers:. First there is a level with equal users; people help each other to tailor the software (Gantt & Nardi, 1992) or there is a network of whom to ask when encountering trouble when tailoring the software (Trigg & Bødker, 1994). Second, there is a level with different competencies (Gantt & Nardi, 1992). The third level is a level of organizational embedment of tailoring efforts and official recognition of tailoring activities (MacLean, Carter, Lövstrand, & Morgan , 1990). We will return to this classification in the discussion of our results, as our findings propose the consideration of a fourth level of tailoring culture when implementing and deploying tailoring possibilities in an IT-infrastructure environment.

THE CASE STUDY

Research Approach

Our research approach can be described as a single case study (Yin, 2003) following a design research paradigm (Nunamaker, Chen, & Purdin, 1991). The question "What is necessary to allow end-users to tailor the interaction between flexible applications in an evolving IT-infrastructure?", addresses the design and deployment of a previously inexistent functionality. In design research, the design and development of a (prototypical) information system can be used both to answer technical questions and as a probe to explore requirements posed by the deployment of the technical possibilities. Hevner, March, Park, and Ram (2004) especially emphasize the need for combining design research and behavioral science. The technical design of the prototype is discussed in (Eriksson, 2004).

The practical work was conducted during a period of slightly more than one and a half years. Prior research indicates that the collection of data to process the so-called extra payments was a bottleneck both for the users' work as well as for deploying the flexibility implemented in the existing systems. During the initial field studies focusing on the work practice of the business department, we visited our industrial partner once or twice a week to observe and interview both users and developers. These field studies informed the development of the overall research question and also the design of the prototype.

In the beginning of the design phase, workshops were arranged involving researchers, users and developers. When designing the prototype, one of the researchers was stationed at the company two or three days a week to ensure that the prototype conformed to existing company systems. Field notes were taken, and meetings and interviews were audio taped, during all phases of the case study.

The prototype was evaluated by all three employees involved in the collection of data and computation of the extra payments and by one developer involved in the maintenance of the payment system. These evaluations were video taped. The analysis in the section of this article entitled "Outcome of Evaluation" is mainly based on the latter tapes, but uses the other field material as a background. For secrecy reasons, videotaping is not allowed on the telecommunication provider's premises. We therefore installed the system on a stand-alone computer outside the actual work place. To allow the users to evaluate the prototype realistically, we reconstructed part of the IT-infrastructure in a local environment and populated it with business data, developing our prototype into a case-based prototype (Blomberg, Suchman, & Trigg, 1996). The users were given two tasks. One task was to construct the collection and assembly of data for an extra payment that they implemented regularly (in the manual fashion described above) as part of their normal work. For the second task they had to construct a totally new but realistic payment. The users were asked to *talk-aloud* while performing the task. This method is common when evaluating software in a use context (Ericsson & Simon, 1993; Robson, 2002). The researcher performing the evaluation observed and asked exploratory and open-ended questions to provoke reactions that differed from our expectations. The developer who worked with maintenance of the regular system evaluated the prototype in a workshop, and discussed advantages and drawbacks concerning use, tailoring, and expansion of the tailoring capabilities.

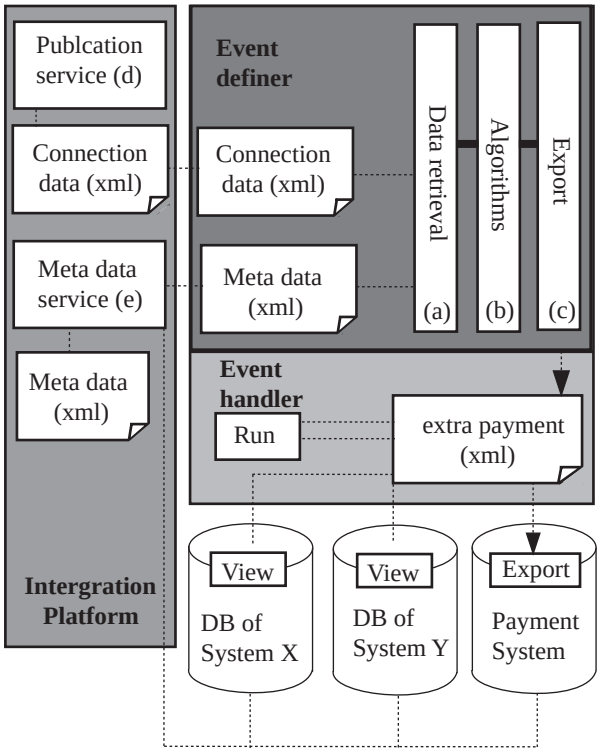
We analyzed the data in a manner that was inspired by grounded theory. A coding scheme was developed with its starting point in the transcripts of the evaluation sessions. The researchers coded the interviews independently from one other and then compared their results. The resulting categories were finally merged into three core categories, that is, design issues, user knowledge, and organizational and cooperative issues. The categorization can be found in the evaluation section.

The Prototype

The prototype is divided into two parts, the Event Definer and the Event Handler (Figure 1). By using the Event Definer, the end-user can tailor communication and data interchange between systems, that is, the end-user defines the event types for the computation of the above-described extra payments. It allows the user to: define the assembly of data from different sources (Figure 1a), set up rules for aggregation and algorithms that will be performed on the data when aggregating the data (Figure 1b) and define how to map data sets to the format required by the receiving application. (Figure 1c). The Event Definer needs to be used only when defining new types of extra payments. The Event Handler handles the execution of extra payments or events and is to be used once a month to run the different extra payments.

Various solutions exist that provide the functionality needed to manage the connections between applications. These are found in tools for system integration that connect systems, in network management for monitoring the IT-infrastructure, in component management (if you choose to regard the different systems as components) and in report generation for assembling data. These tools are designed exclusively for system experts, not for end-users. A possible exception is report generation, which sometimes supports end-users but often needs support from developers to adapt it to fit new data sources. We found that none of these approaches was suitable for fulfilling the requirements for a tool for interapplication communication that can be adapted by users. Neither were the approaches suitable for the purpose of exploring what is necessary to allow end-users to tailor the interaction between flexible applications in an evolving IT-infrastructure. For our prototype we used an existing platform that supports integration between the telecommunication provider's back office applications. The

Figure 1. The connection between the prototype and the surrounding systems



integration platform makes it possible to publish events that other applications can subscribe to. We had a somewhat different intention when using the platform. We wanted to collect the information when needed, and we used the platform to provide the prototype with information about how to get in touch with desired resources and what data were accessible at these resources. We created a service (Figure 1d) on the integration platform that allowed the developers of the different systems to publish information about available data and showed how to connect to the respective database. To do so, the developers must set up a database *view* containing data that could be accessible to other systems (such as the prototype). The service produced an XML file containing connection data for all published data sources. When the Event Definer starts, the XML file is fetched from the integration platform. Yet another service (Figure 1e) provided the prototype with metadata from the data sources, for example, which fields (attributes) could be accessed in a specific database, and the types of the fields.

Tailoring

The graphical tailoring interface of the Event Definer was constructed to consist of seven different steps. These steps are intended to guide the user through the process, but could also be used in an arbitrary order as the end-user chooses.

Step 1: Naming the extra payment.
Step 2: Choosing which databases to connect to.
Step 3: Choosing which fields to use from the selected databases.
Step 4: Setting up criteria for what data to collect from the different databases, that is, by drag and drop, the end-user chooses which field should be used and the end-user can also specify how the different views should be linked together, for example, fieldX in SystemX must be equal to fieldY in SystemY.
Step 5: Showing the specified criteria from Step 4 as SQL queries, that is, here the user can edit the SQL queries to set up more complicated (and unusual) conditions for data retrieval than can be accommodated by the graphical interface.
Step 6: Setting up algorithms for what to do with the collected data. (partially implemented.)
Step 7: Mapping the input table structure to the output table structure, that is, the end-user can map the assembled and computed data to a receiving system by dragging the fields from the assembled data table and dropping them in a table representing the receiving database.

All these choices, criteria, algorithms, mapping and so forth, were finally brought together and arranged into an XML file (extra payment in Figure 1).

Use

The XML files produced by the Event Definer are then used whenever the end-user decides to execute the extra payment. The Event Handler contacts the chosen systems one by one and collects the data specified in the XML file. When the data is collected and assembled in a single table it is displayed to the user to allow for checking and correcting the result where necessary. By clicking on a button, it is possible for the end-user to export the result to the system handling the payment data, in accordance with the mapping specification (Step 7).

Expansion of Tailoring Capabilities

There will inevitably be situations where end-users wish to define extra payments based on data that is currently unavailable. If the data and metadata are unavailable, the end-users are unable to perform new tasks. They have neither the

authority nor the ability to alter or add views in surrounding systems. In this case the surrounding systems, as well as the tailorable system, have to evolve to meet the additional requirements from the end-users. The developer responsible for the respective system must then (a) alter the system by creating a new view or changing an existing view, so that it contains the required data, and (b) make the changes available through the integration platform. To support the latter, the publication of a new source was supported by a web interface where the developer (also system owner) could fill in the necessary data.

Outcome of Evaluation

The evaluation presented here focuses on issues beyond the technical design and the appearance of the graphical interface of this specific application. It addresses overall design issues for this kind of application, the end-user knowledge necessary to handle such complex tailoring tasks, and organizational issues to deploy such systems in a sustainable way. We have also evaluated the prototype against functional requirements, but the results are not reported here. Individual opinions held by only one or two of the subjects are disregarded in the following presentation.

Design Issues

In terms of technical support we focused on the different interfaces provided by the prototype: the tailoring interface, the deployment interface and the development interface.

The Tailoring Interface

Functionality for Controlling and Testing

All users appreciated the freedom to alternate between the seven steps. They found that the steps provided not only guidance and an overview but also the freedom to alter something performed in previous steps, without losing the overall view. To be able to overview all choices and trace them backwards was one way of providing control. But there was also a need for error control and limitation. The users, especially the beginners, wanted some kind of guidance in order to feel secure.

It became very obvious that the design must enable the end-user to test and control the correctness of the specification of extra payments. Control facilities must be provided to ensure security for the users in their work. Although control and test functionality was important for all users, the attitude towards test and control varied between the users. The better the knowledge of the task, the surrounding systems and possible errors, the less important explicit test and control seemed to be. Following statements exemplifies different attitudes towards control and test functionality: *When you make an extra payment for the first time you would probably like to make a test run to see that it really works correctly.* (user comment, evaluation session, February 24, 2004)

and

there isn't the same protection as in SystemZ … but to make a more flexible solution, then you can't expect it to be strictly user friendly (user comment, evaluation session, February 24, 2004).

Clear Division Between Definition, Execution and the Tailoring Process

When tailoring, the user rises from one level of abstraction to another, higher level. From thinking only in terms of the execution of an extra payment the user had to think in more general terms of what characterizes this extra payment, what kind of data were fetched, what variables there were, and so forth. The users had to think in terms of levels which is not an easy step to take. We found that a clear separation between execution and the tailoring process helped the users to make this step successfully.

The users also started to discuss the division of labor enabled by a system resembling the prototype. For example, one of the users said:

I think it is very good because then someone is very familiar with how to make a new extra payment and then all employees in the group can run the extra payment. (user comment, evaluation session, February 24, 2004)

Unanticipated Use Revealed to the Tailor

Systems that continuously evolve through tailoring aim to support unanticipated use. The possibilities for unexpected use are inevitably limited by the technical design. To support unanticipated ways of tailoring, the system has to provide additional information of what is possible to do and what the limitations are. In the prototype this was achieved by providing information for the user that is not directly applicable to the type of extra payments that exist today. As one of the users expressed it when seeing the opportunity for one of the export systems to also act as input source:

this is interesting! It opens up new opportunities. It might be like one extra payment uses another payment as a base (user comment, evaluation session, February 24, 2004).

Complexity

We found that the users preferred more information, rather than a less complex tailoring interface, resulting in more tailoring possibilities. Their opinion was that, as tailoring is not routine work, performed several times a day, it is allowed to take extra time. Then it is better to have a more complex interface providing more opportunities to tailor the system.

The Deployment Interface

Simplicity

One thing that was revealed and worth mentioning is that it seems that the deployment interface should be even simpler than an ordinary user interface. The users expressed the opinion that the tailoring interface and the tailoring process may be rather wide-ranging if that allows for a simpler deployment interface.

The Development Interface

One Point of Interaction

The development interface in the prototype was a graphical Web interface where the developer could fill in the data that was to be published about the respective source system. During the evaluation of the development interface, the software engineer emphasized the importance of having one point where changes to the data sources are published. The developer should not be forced to make changes in several places in the application in order to extend the tailoring capabilities.

End-User Knowledge Required for Tailoring

Even previous to the evaluation session we had experienced the high expertise of the users not only regarding their tasks but also regarding the data available in the different databases that are part of the IT-infrastructure. The users acquired the knowledge in order to perform the assembly manually. The communication between different systems is normally hidden from the user in a data communication layer for the separate systems. Our prototype is designed to make exactly this communication tailorable. Its deployment depends on the respective expertise of the users.

Task Knowledge

Business knowledge about contracts and payments provides the base on which the users decided what data to collect. Extensive business knowledge was a prominent feature of the results of the evaluation. The users' reflections on which data to collect always concerned different aspects of the business tasks.

System Knowledge

To map requirements regarding the task at hand and the available data, demands expertise regarding the available data in the different systems. And the users knew where to find the data needed for defining a specific extra payment. The prototype just helped with the exact location of the data, for example it guided the user to which fields to use, by listing the fields with examples of the data they contained. However, the user had to understand the sometimes quite cryptic names and know where to look for specific data.

Error Knowledge

All users were extremely aware of which errors could occur,that is, errors concerning the use of the prototype, the IT-infrastructure and the task. Task-specific errors are particularly important for the end-user to overview since they may cause serious consequences for the company if the errors are not prevented. On several occasions during the user tests the users expressed concern about making errors. They made statements like:

when you work as we do you must know a little about database management, you have to understand how the tables are constructed and how to find the information. And also in some way understand the consequences of or the value of the payment. In other words how you can formulate conditions and what that leads to. (user comment, evaluation session, February 24, 2004)

Organizational and Cooperative Issues

The system for which the prototype was a test would depend on data published by many different surrounding programs. Each one of these systems is itself the subject of both tailoring and evolution. Both the users, and the software engineer who evaluated the prototype, addressed the necessary interaction with other system owners and the assignment of responsibilities regarding the publication and updating of the connection information and the kinds of data available.

Publication and Update Responsibilities

During the workshops it became apparent that there is already friction in the coordination between the payment system and the changes in the surrounding systems. When one system in the IT-infrastructure is changed, the changes are orally communicated to the owners of other systems that may or may not be affected by the change. For the prototype to function as designed, it was important that the systems that the prototype was expected to communicate with were visible and accessible. The design of the prototype solved this problem by requiring every change relevant to the prototype to be reflected in the published information. In other words, it was designed so that the respective system owners were responsible for keeping their system visible and showing its current status. As the prototype was dependent on accurate just-in-time information, the evaluation revealed a need for coordination concerning publication and updates of surrounding systems and tailoring activities in the prototype.

Collaboration Between Developer and End-Users

The fieldwork revealed, and the evaluation confirmed, that it is impossible to know what future contracts will look like. Therefore there will

always come a time when the end-user wants to retrieve data that is not published in any available view. In this case the system that can provide the data has to be identified and the respective system owner or developer has to be persuaded to implement a new view of the system or update existing ones, and publish the relevant information.

Another issue related to communication and cooperation between users and developers concerned the decision of how much information to make available for the users to do a good job of tailoring. The users wanted to see as much information as possible, provided it was within reasonable limits. In order to have better control over the execution of the system and to decouple maintenance that would not necessarily impact the communication with the payment system, the developers would rather prefer to restrict the user's options. These two perspectives have to be negotiated.

In this company, cooperation between business units and the IT unit works very well. The users evaluating the system were quite aware of the limit of their own competences and knew when to consult the responsible developers. All users frequently referred to developers when they experienced that something was beyond them. None of them considered the necessary coordination and cooperation to be a serious problem.

Summary of Outcome of Evaluation

The evaluation revealed many issues to consider when making a system that continuously evolves through tailoring work in a rapidly changing business environment. The issues could be divided into three categories regarding design issues, user knowledge, and organizational and cooperative issues. Below, the issues are summarized and listed under the respective category.

DESIGN ISSUES

1. Functionality for controlling and testing changes has to be integrated into the tailoring interface and there must be sufficient technical support for the end-user to estimate and check the correctness of the computation.
2. A tailorable system has to define a mental model that makes a clear division between definition, execution and tailoring. This mental model must be adopted in the tailoring interface and be shared by users, tailors and developers.
3. The tailoring interface also has to reveal potential for unanticipated use to the tailor. This means, that the information flow must, to a certain extent, exceed what is currently necessary.
4. The tailoring interface can be more complex, provided the tailoring process makes the deployment easier. The tailoring interface is not used as often as the deployment interface and additionally the tailoring itself often involves careful thought.
5. The deployment interface should be simpler than ordinary user interfaces.
6. The developer expanding the tailoring capability should only interact with one clearly defined point in the tailorable system, that is, changes are made at one point in the system.

End-User Knowledge

7. End-users must have sufficient knowledge of how the systems are structured and what the systems can contribute.
8. End-users must have solid knowledge of the nature of the task and what data is required to perform it.
9. End-users must have knowledge of which errors can occur and what the consequences of these may be.

Organizational and Cooperative Issues

10. System owners or developers must be responsible for making their systems publicly

available within the company. System owners or developers must also be responsible for updating the systems according to external requirements.

11. The necessity to extend the possibilities for end-users to manage the interaction in an evolving IT-infrastructure requires effective collaboration between the developer and end-users.

DISCUSSION

Our results are applicable in other areas that are similar to telecommunications, and that depend on an IT-infrastructure for a major part of their business and where the development of new products requires changes in this IT-infrastructure. On one hand, our results confirm existing research: Users ask for additional functionality to guide the tailoring and test the outcome (Burnett, Rothernel, & Cook, 2003). We found that users wished to incorporate control of the tailoring process in the form of an outline, preferably in a step-by-step fashion. They also asked for visualization and test facilities in order to check the impact of the separate steps on the end results. The evaluation of the interface allowing software engineers to expand the tailoring possibilities confirms and expands previous research results addressing the developer responsible for the evolution of tailorable systems as an additional stakeholder whose requirements also have to be considered (Eriksson et al., 2003; Lindeberg et al., 2002).

On the other hand, the results indicate that tailoring in an IT-infrastructure of networked applications provides additional challenges for the design of the software, the competence of the users and tailors, and the cooperation between users and developers. Changes—independently of whether they are implemented by tailoring or by evolving the software—can depend on and affect changes in other applications of the IT-infrastructure and the interaction between applications. This requires coordination between tailoring and development, and cooperation between the persons responsible for tailoring and developing the different applications. And this, in turn, requires a different set of competences from users and developers. The use of an application such as the prototype discussed here, for example, required knowledge of the surrounding systems and their data structures. Developers as well as users have to understand not only the system they are responsible for but also the dependencies between different systems and tasks. Several researchers have discussed collaboration between users and tailors, but not between users, tailors, and professional developers. For example Nardi and Miller's approach (1991) differs from ours in that they see local developers and programmers as being skilled users, while we take the concepts a step further and state that there is also a need for collaboration between users and professional developers who can perform programming tasks to extend the tailorable software beyond the script level.

What we claim is that in order to make tailoring really successful,it must be made possible for the tailorable system to evolve beyond the initial intention when building the tailorable system. Kahler's three levels (2001) of tailoring culture— cooperation between tailoring end-users, cooperation between tailors and users, and the organizational recognition and coordination of tailoring efforts—have to be extended with a fourth level, of organizational support for coordinating tailoring and development activities *involving the cooperation not only between users and tailors but also between tailors and software developers.*

CONCLUSION

Allowing end-users to tailor the interaction between flexible applications in an evolving IT-infrastructure requires that the tailoring activities are supported by the design of the system, for

example by providing a clear division between execution and tailoring, by revealing potential for unanticipated use, and by supporting single interfaces for changes to the software. It is also essential that the competence of the end-users is sufficient in terms of knowledge of how the systems are structured and what the systems can contribute. End-users must also have substantial knowledge of the task and which errors can occur and what the consequences of these may be. To allow end-users to tailor the interaction between applications in an evolving IT-infrastructure, the organization has to allow for cooperation between users and developers.

The main conclusion of the research described here is that it is possible to provide end-users with the possibility to tailor not only the applications, but if necessary also the interaction between different applications that are part of an IT-infrastructure. The evaluation clearly showed the dependencies between tailoring and the further development of the tailoring capabilities. The evaluation also made it apparent how the different actors were aware of their colleagues' skills and of what each individual could contribute. To ensure a sustainable tailorable system when deploying a system intended to evolve continuously through tailoring, it is necessary to take into account resources concerning various skills and collaboration between users and developers. Without smooth collaboration between the parties an extended fourth level of tailoring culture will not be provided for, and therefore the system will soon become partially obsolete and the competitive advantages provided by the system will decrease dramatically. The results challenge the clear division between software use and evolution on one side and software development on the other side, when developing and maintaining an IT-infrastructure. Collaboration between the end-user and the developer must work satisfactorily in order to achieve tailorable, sustainable software. In other words, in a rapidly changing business environment with continuously changing requirements, such as the one presented in this paper, the tailoring activities have to be coordinated with the software evolution activities.

ACKNOWLEDGMENT

This work was partly funded by The Knowledge Foundation in Sweden under a research grant for the project "Blekinge - Engineering Software Qualities (BESQ)" (http://www.bth.se/besq).

Chapter 6.3
Differentiated Process Support for Large Software Projects

Alf Inge Wang
Norwegian University of Science and Technology, Norway

Carl-Fredrik Sørensen
Norwegian University of Science and Technology, Norway

ABSTRACT

This chapter presents a framework for differentiated process support in large software projects. Process support can be differentiated in different levels based on the size of the development organization and the need for coordination across different levels of the organization. We have defined four main perspectives: individual, group, team, and project level, where the framework consider essential issues when planning and executing the software development processes in organizations with different levels of management. Further, a guideline is provided that suggests what is required of process support in the various organizational levels.

INTRODUCTION

Development of large and complex software systems involves large organisations. In such working environments, it is essential to plan and coordinate the process, feed the involved developers with necessary documents, tools and files, track the process and effort, and learn from and improve the process.

Software process modeling is aimed at understanding, guiding, coordinating, automating, and improving the software process to thus improve the software quality and reduce the effort of developing software products (Wang, 2001). Many ***process models*** and ***process-centred support environments*** (PSEs) have been created with the assumption that the same process support should be provided at every level in an organization (Conradi, Fuggetta, & Jaccheri, 1998; Derniame, Baba, & Wastell, 1998; Finkelstein, 2000; Fuggetta, 2000; Nitto & Fuggetta, 1998).

If we consider development of large software systems, the organisations in such projects usually involve several levels of management. Depending on the level of an organisation a person is working in, the perspective and goal of the work will vary.

For a programmer, the main concern would be to have access to all necessary files, documents, and tools to carry out efficient programming. Personnel working at higher levels in the organisation would typically have other concerns like coordinating people, scheduling of the process, quality assurance, planning of activities and so forth. Thus, it is essential that the process support in such organisations reflects the levels being supported. It is also important that the way the processes are modeled is tailored for the organisational level and the characteristics of this level.

This chapter presents a differentiated process support framework that describes the elements required to model the software process, the required external resources (like tools and documents), and the required process support provided by a process-centred environment. Our framework describes the required process support from four perspectives: At the individual level, at the group level, at the team level, and at the project level. Thus, the objectives of this chapter is to give insights into essential issues to be considered when planning and executing a software development process for large software projects consisting of several levels of management. The chapter also provides a guideline for what is required of process support for the various levels of an organisation. This guideline can be used as input when evaluating tools to be used to support the development and management processes of large software projects.

BACKGROUND

This section gives an introduction to the background and the important terms used in our framework, and describes related work.

Software Process and Software Process Modeling

At a NATO Conference in Garmisch-Partenkirchen in 1968, the term ***software engineering*** was first introduced (Naur & Randell, 1969). The conference discussed what was called the "software crisis" introduced by third generation computer hardware. The work within the software engineering domain has been concerned with methods, techniques, tools, programming languages, and more to face the problems in software projects like delayed products, cost overruns, and bad reliability and performance in software products. Despite the many efforts to try to solve the software crisis, we are still struggling with the same problems as they did in the sixties. Brooks (1986) argues that there is no "silver bullet" that can solve all problems in software engineering. The only way to limit the negative effects identified as the software crisis is to use best practices in the many areas of software engineering. There are no best practices that solve all problems, but in combination many issues can be eliminated. One best practice is to improve the software process itself involving all the activities necessary in developing a software product. This chapter is intended as a guideline for improving the software process at different levels in a software development organisation.

Before we take a closer look at the software process support for different levels of an organisation, it is necessary to agree on the central terminology used in this chapter. As mentioned before, the term *software engineering* covers most aspects involved when developing large software systems. According to Sommerville (1995):

Software engineering is concerned with software systems which are built by teams rather than individual programmers, uses engineering principles in the development of these systems, and is made up of both technical and non-technical aspects.

As Sommerville states, software development involves more than the technical aspects like dealing with the source code of the system. Important nontechnical aspects of developing software involve scheduling, budgeting, resource

management, and so forth. In addition, the term *software process* (Lehman & Belady, 1985) is used to denote all activities performed within a software organisation.

In this perspective, *software process modeling* describes the activities of understanding and describing a given software process (Wang, 2001). Several elements have been proposed that need to be identified to describe a software process, but the most common model involves the elements *products* (a set of artefacts related to the software product), *resources* (assets, like tools or human resources needed to carry out the process), *activities* (steps of the process) and *directions* (policies, rules, and procedures that govern the activities) (Derniame et al., 1998). To be able to provide process support, the software process must be modeled. Software process modeling is, according to Høydalsvik (1997), defined as "*The activities performed, and language and tools applied, in order to create models of software development processes within a software development organisation.*"

Another term related to software process is ***workflow***. Workflow is by the Workflow Management Coalition (1999) defined as "*The automation of a business process, in whole or part, during which documents, information or tasks are passed from one participant to another for action, according to a set of procedural rules.*"

The main difference between software process and workflow is that workflow focuses on business processes. However, this does not rule out the possibility to use workflow tools to support the software process.

When talking about software processes, we also often mention the term ***software lifecycle*** (Royce, 1987) that describes the life of a product from the initial stage to the final production and maintenance. A software lifecycle consists of several phases that a software product usually must go through: requirement specification, system design, implementation, testing and operation, and maintenance. During these phases, the required process support will vary. For the two first phases, the main focus is on analysis and documentation. For the three last phases, the main focus is on the source code and computer system. For all these phases, various tools exist to make the software development easier.

In addition, there are other parts of the software process that are phase independent, for example, software configuration management, software cost estimation, software quality management, software process improvement, and software process technology (Wang, 2001).

The lifecycle of a software product can be organised in various ways. The classical approach is the *Waterfall model* (Royce, 1987) that describes the lifecycle as a predefined sequence of phases, where each phase has a set of defined activities. Each phase has an input and output, and the output from one phase is the input to the next. The Waterfall process is in principle linear and a succeeding phase should not start until the previous phase has been finished.

The *evolutionary development model* is another way of viewing the software development process. This approach interleaves the phases; specification, implementation and validation, and is based on rapid prototyping. A prototype is developed early in the project in cooperation with the customer and is refined until the customer is satisfied. An example of an evolutionary development model is the *Spiral Model* (Boehm, 1988) that can incorporate different development processes through separate iterations.

Agile software development models like *eXtreme Programming* (Beck, 1999) focus on being lightweight and flexible. Such model embraces short development iterations to be able to cope with upcoming changes in requirements, minimum project documentation apart from comments in source code, user involvement during development, and other best-practices. Agile methodologies fit very well for high-risk projects with unstable requirements.

A software process model gives an overview of all the required activities and how they relate to each other, documents, tools, actors, methods, techniques, standards and so forth. This chapter is not limited to process support of a specific lifecycle model, but focuses rather on the required process support independent of how the software process is modeled and carried out in detail. Thus, this chapter describes guidelines that are important to incorporate when planning and supporting a software process. This may make it easier to improve the software process, thus improving the software product.

Related Work

The framework described in this chapter divides the software process into four distinct levels. The Personal Software Process (PSP) (Humphrey, 1997) defines the software process at the individual level in a software development process. The intention of PSP was to help software engineers to do their daily work well by applying practices that work well based on experiences from the software engineering field. Further, PSP describes detailed methods for making estimates and plans, shows how software engineers can track their performance, and describes how defined processes can guide their work. The process model in PSP is described only at a high-level. The model consists of the activities Planning, Design, Code, Compile, Test, and Post-Mortem. The PSP fits very well with the individual process level described in this chapter. However, note that PSP does not say anything explicitly about coordination of developers and project management on a higher organisational level.

The Software Process Engineering Metamodel (SPEM) defines software process models and their components using UML notation (OMG, 2002). In SPEM, a software development process is usually described by a *Process role* performing an *Activity* on a *Work product*. In addition, SPEM provides modeling elements to express phases, iterations, lifecycles, steps and so forth. This means that SPEM can visualise different organisational levels of a software process. Thus, SPEM can be used in combination with our framework to describe the software processes at different levels. However, SPEM was not made with software process enactment in mind. This means that to provide process support for a process specified using SPEM, the model has to be translated to an enactable process model language (PML).

UML4SPM is executable software PML based on UML 2.0 (Bendraou, Gervais, & Blanc, 2006). In UML4SPM PML, a software process can be represented at different hierarchical levels by using the main building blocks Process, Activity, and Action. The organisational structure can also be modeled in a hierarchical manner using the model building blocks Team and Agents. Although UML4SPM support modeling of a software process at different levels, it uses the same PML to represent all levels of an organisation. As the PML represents processes as activity-networks, collaborative activities beyond coordination are hard to represent in such PMLs (Wang, 2002).

Serendipity-II is a process management environment that supports distributed process modeling and enactment (Grundy, Apperley, Hosking, & Mugridge, 1998). The PML allows hierarchical modeling of software processes represented as process stages and subprocesses. Moreover, Serendipity-II is based on a decentralized distributed architecture that enables users to collaboratively edit process models synchronously and asynchronously. This approach enables support for autonomous suborganisations that can tailor their specific part of the process to their needs, which is essential to support different levels of a software organisation.

Kivisto (1999) describes the roles of developers as a part of a software process model for development of client-server process. Kivisto proposes a process model in three dimensions: Organisational, Technological, and Process. The organisational dimension focuses on what roles

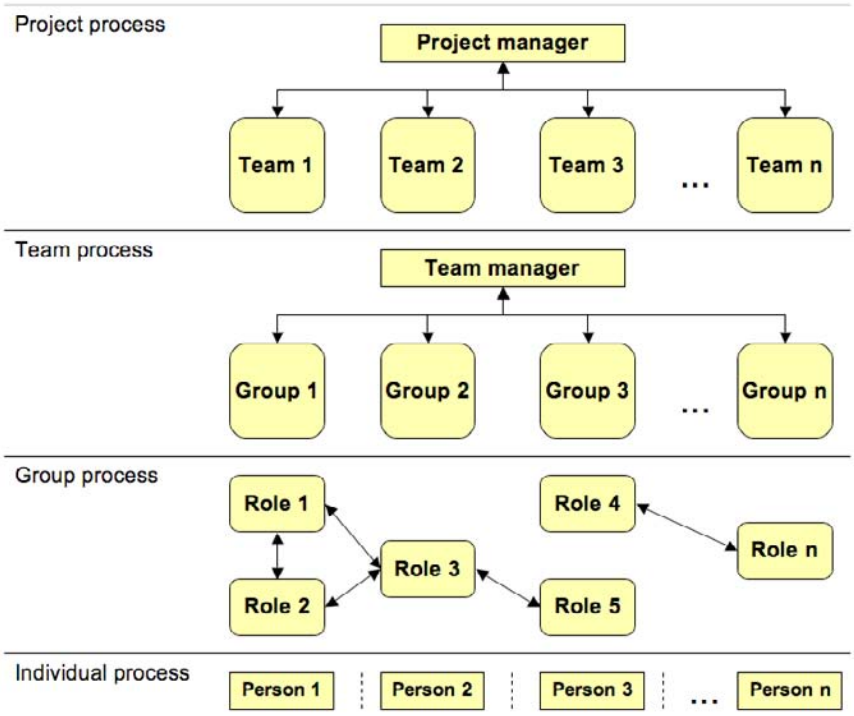
are involved in the development process and how these roles are organised. The technological dimension focuses on issues related to client-server software architecture and technology choices for such a system. The process dimension gives an overview of how the development process can be organised in phases and tasks, and the assignment of roles to specific tasks.

A taxonomy for characterising metaprocess categories with the main focus on process changes is presented in Nguyen and Conradi (1994). The taxonomy reflects the following questions to be asked concerning the metaprocess: *What* aspects of the software process are allowed to be changed, due to what reasons (*Why), How* can the changes be implemented/installed and be propagated (*When)* by which roles *(Whom)*? The *Why* aspect identifies four sources for process changes: the external world, an organisation, a project environment, and individuals. The framework described in this chapter can be mapped to the individual (individual level), project environment (group and team level), and organisation (project level). Changes in the process support will affect the processes at all levels in our framework, while modifications of the production process (the way the software is developed) would typically be mapped to the team level and below. Modifications of the metaprocess (changes and evolvement of the process model) would typically be mapped into the project level. The taxonomy described in Nguyen and Conradi (1994) is useful for analysing process changes at all four levels in our framework.

PROCESS SUPPORT IN DIFFERENT LEVELS IN A SOFTWARE DEVELOPMENT ORGANISATION

This section describes issues that must be considered when planning the process support for large software projects being organised in groups and teams (typically 20 or more people). In such software development organisations, the process

Figure 1. Overview of process support in different levels



support required is very dependent on where you are in the hierarchy in the organisation. For example, the software process support needs for an individual developer is totally different from the needs of a project manager.

Our framework as detailed below, describes the software process support from four perspectives based on the organisational level, as shown in Figure 1. The *first level* in the framework focuses on the *individual process* reflecting the personal software process in the daily work. The *second level* describes group processes where two or more individual collaborate and interact. The *third level* is concerned with management of groups within a team. Finally, the *fourth level* is concerned with project management where several teams are involved. Typically for smaller projects, the team and group levels will merge.

Table 1 shows the four levels of process support required in a big software organisation. For each level, the model describes:

- **Process elements:** The required process elements needed to model the process,
- **Process relations:** The required relationships between process elements,
- **Required external resources:** The resources used by the process-centred support environment (PSE), and
- **Required process support:** The process support required at a specific organisational level.

The framework specifies interfaces that describe the input and output between levels. The uppermost interface specifies the relationships to the company and customer(s). Some activities are carried out at all levels of an organisation, for example, quality assurance and configuration management.

The rest of this section will describe each level of the framework in more detail.

Individual Process

The lowest process level in an organisation is the *individual* process level focusing on the individual tasks of a software developer. An example of a role related to this level is a programmer with typical tasks like reading documents, writing code, writing documentation, debugging code, compiling code, building code, and so forth.

Table 1. Process support in an organisation

Org. level	Process elements	Process relations	Required external resources	Required process support
	Interface: Product, Experiences and knowledge, Resources, Project management rules and practice			
Project process	Teams, Team processes, Milestones	Team coordination, Assigned team(s)	Project management tools and Artefacts, Experience-/ knowledgebase, Estimation models and tools, Resource tools	Project planning, Project management, Experience exchange, Project estimation, Resource management
	Interface: Input and output artefacts, Team and resources assigned, Team process state			
Team process	Groups, Group processes	Group coordination, Assigned group(s)	Team management tools and Artefacts	Team management
	Interface: Input and output artefacts, Group assigned, Group process state			
Group process	Roles, Process fragments, Cooperative activities	Cooperation and coordination rules, Assigned role(s)	Cooperative tools, Configuration management and Artefacts	Coordination, Negotiation, Collaboration
	Interface: Input and output artefacts, Role assigned, Process fragment state			
Individual process	Activities	Assigned activities	Tools and Artefacts	Process guidance, automation, calendar

Generally, the process of an individual actor typically consists of a set of activities related to the roles that the actor plays (an actor can play more than one role). It is very important that the process support is adaptable and configurable, making it possible for the actor to fit the work to personal preferences. The required process support is very dependent on the experience level of the individual actor. An inexperienced person would typically need process guidance to show the tasks to do next, what procedures to follow, what tools to use, where to find documentation and so forth. However, for an experienced person that knows all the basics, extensive process guidance would be a hindrance to work effectively. For the latter, it would be more useful to provide automation of repetitive tasks. Independently of the experience level of the actors, the process support should provide quick and easy access to the required tools and artefacts. The activities of the individual process should be integrated with personal digital calendars to enable activity states and deadlines to be accessible on personal computers, personal data assistants (PDAs), and mobile phones. This means that the execution environment for the process support also must be capable of communicating and utilising mobile devices and networks.

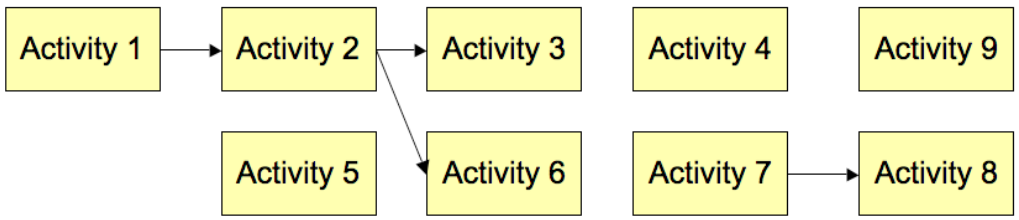
The framework presented in Table 1 identified activity as the main building block for individual process models. Another approach could be to use roles with responsibilities as the main building block. However, the most common approach is that individuals represent the daily work as a set of activities. Also, the most used process tools for individual processes also focus on activities, like calendar software. In addition, activities or tasks are the most common output of many project-planning tools, where individuals are assigned a set of activities. This means that using activities as process model elements makes it easier to integrate with higher-level management processes and tools. In addition, because people are used to the representation of work as a set of activities and tools that represent the work as activities, it is also easier for the individuals to tailor their own processes (reschedule activities, etc.). In some cases, it can be useful to let an actor model her or his own processes. In Wang (2002), an experiment indicates that it is easier to use activity-based than role-based modeling for individual processes. This is especially true for inexperienced process modelers.

The process relation with respect to individual processes is the assign relation. A team or project manager typically assigns activities to an individual actor. In some cases, some activities must be carried out in a specific sequence, putting constraints on how the work should be carried out and how the individual process can be modified. A representation of an individual process is illustrated in Figure 2.

The process model in Figure 2 shows a collection of activities. Some of the activities have pre-order relations (the activities 1, 2, 3, 6, 7, and 8). The remaining activities have no constraints and can be carried out regardless of the state of the process.

In this chapter, we define a collection of related activities (e.g., activities related to the same

Figure 2. An individual process model



phase in the process and the same project) to be a *process fragment* (PF). The name process fragment indicates that this collection of activities is part of a larger process at a higher level of the organisation. The process of assigning activities to an individual actor in the organisation is carried out by delegating one or more process fragments to the actor. The state of the process fragment is determined by looking at the state of the activities. A process fragment is completed when all actvities in the fragment are completed.

The goal of the individual process is to produce various artefacts like requirement and design documents, source files, build files, test files and so forth. To provide a sufficient software process support at this level of the organisation, it is essential that the PSE can be integrated with production tools such as office applications, integrated development environments (IDEs), and other similar tools. The process support environment should make it easy to access all necessary tools and files, and handle configuration management.

When the individual actor initialises her/his process, the process models could either be fully specified by, for example, a team or project manager or be provided as a process template where all necessary activities are defined. For the latter, the actor must detail her/his own process to meet her/his needs and preferences. During the process enactment, the individual actor might also add, change, or delete activities depending on how the process proceeds (e.g., change of project plan, changed priorities, or changed process goals). Some PSEs might provide support for changing the process automatically or semi-automatically. It is important that the PSE is flexible enough to managing instantiation of template process fragments as well as allowing changes of the process during process enactment (Grundy et al., 1998).

Group Process

The next level in the framework is the *group* process level focusing at the cooperative aspects of the software process. Traditionally, software process modeling and enactment of software processes have been focusing on ”forcing” and guiding people to work according to a specified model, where interaction between people has been coordinated through a strictly defined control/data flow. Such approaches are usually based on modeling processes as activity-networks consisting of subprocesses, activities, tasks, or operations. Cooperative aspects of the software development process have often been either eliminated or ignored because it has been hard to model cooperative activities in existing systems, or there has not been an interest for doing so. The software development processes are also human-centred processes. Cugola and Ghezzi (1998) state that ”Human-centred processes are characterised by two crucial aspects that were largely ignored by most software process research: They must support cooperation among people, and they must be highly flexible.”

The cooperative process involves coordination of activities carried out by several actors or roles, cooperative activities where two or more persons must participate to complete the activity, and coordination and negotiation of artefacts and resources.

At this level, ***configuration management*** (CM) is very important because two or more actors often will share the same resources (including files). The sharing of resources might cause conflicts where two or more actors would like to update the same data at the same time. Thus, the CM environment must be integrated with the PSE to provide support for initiating negotiation processes in case of conflicts regarding resources (e.g., files), and support for synchronising output artefacts from the process (Wang, 2000; Wang, Larsen, Conradi, & Munch, 1998).

The group process defines the synchronisation points for individual processes involving several actors. These synchronisation points represent parts of the software process where files or other resources need to be exchanged and synchronised

(mainly coordination of artefact and process). In addition, the group process involves cooperative activities where two or more actors are involved. An example of such activities can be distributed brainstorming, electronic voting, collaborative authoring, and conflict management. Cooperative activities have very different characteristics compared to individual activities. While the main emphasis of the individual activities is on the activities themselves, cooperative activities are all about interaction and coordination between roles. This means that the process support for cooperative activities must provide an infrastructure to enable efficient interaction of the involved roles and to enable flexible exchange of artefacts. Note that most people working in a large software project will be involved in both individual and group processes.

The cooperative processes can be represented in many ways. However, to represent cooperative processes as a set of related activities, as described in a previous section, does not make sense because the focus is on interaction between roles. We propose two alternative approaches to represent cooperative processes at the group level.

Cooperative Software Agents

Cooperative software agents can be used to represent actors involved in cooperative activities. The cooperative agents will act on behalf of the involved actors to provide the required infrastructure for collaboration (coordination, negotiation, etc.). In Wang, Conradi, and Liu (2000), a cooperative agent framework developed to provide process support is presented. In this framework, all actors have their own workspace where they can interact and configure their agents. Agents interact on behalf of various actors in agent meeting places that represent neutral workspaces where services and artefacts can be exchanged. The collaborative aspects are supported through coordination agents, negotiation agents, and mediation agents. When software agents are used, the agent environment usually provides a set of ready-to-use agents that provide support for various collaborative tasks and that can be configured for specific user needs. If the required functionality is not supported by the predefined agents, new agents can be implemented using a high-level API. A similar approach to support group processes using software agents is described in Glaser and Derniame (1998). This approach uses agents to look for competence profiles that match the tasks to be carried out.

Role-Based Process Environments

Role-based process environments can also be used very efficiently to model and provide support for cooperative activities, for example, like the workflow system ProcessWeb (Yeomans, 1996). In ProcessWeb, all involved in the process are modeled as *roles*, and *interactions* are used to provide communication channels between roles. A role is defined by its *actions* (methods) and its *resources* (attributes). Preconditions called *"when guards"* are used to select action for enactment, and they are expressed as **if** statements. Interactions are unidirectional, asynchronously typed communication channels provided through a takeport and a giveport. A *takeport* receives data or control flow from another role, and a *giveport* sends data or control flow to another role. Similar approaches can be found in Fadlia, Said, and Nora (2005). Most role-based process modeling approaches are object-oriented and the modeling process will be similar to programming in an object-oriented programming language. This gives a very flexible and expressive PML, but it requires a certain level of expertise to handle.

A comparison of how well cooperative activities can be modeled and supported in software agents, activity networks, and role-based process environments is described in Wang (2002). The results show that activity networks are not well suited, but software agents and role-based process environments are able to represent cooperative activities very well.

In the previous section, the term process fragment was used to denote a collection of activities that represents the process for an individual actor. To model group processes, it is necessary to model the relationships between the process fragments of the individual actors as well as cooperative activities and the roles involved. *Cooperative rules* (Wang et al., 2000) can be used to define the relationships between process fragments and cooperative activities. The cooperative rules specify conditions for cooperative activities that should be initiated depending on the condition of the individual process fragments. The cooperative rules also specify how the individual processes should proceed depending on the outcome of a cooperative activity. Thus, the cooperative rules specify a loose coupling between the individual process fragments and the cooperative activities enabling federation of different PSEs for individual and group processes.

Figure 3 illustrates a group process model consisting of roles, process fragments, a cooperative activity, and cooperative rules (C1-C6). The model describes how cooperative rules describe the relationships between process fragments (individual processes) for each role and the cooperative activity. The cooperative rules are modeled as result-reaction pairs that specify the *reaction* that should be taken based on the *result* (outcome) of a cooperative activity or a process fragment. Typical reactions can be to execute, regroup, halt, change, or add a process fragment. In addition, a reaction can initiate or change cooperative activities (e.g., initiate a specified agent) or change the cooperative rules (reflective).

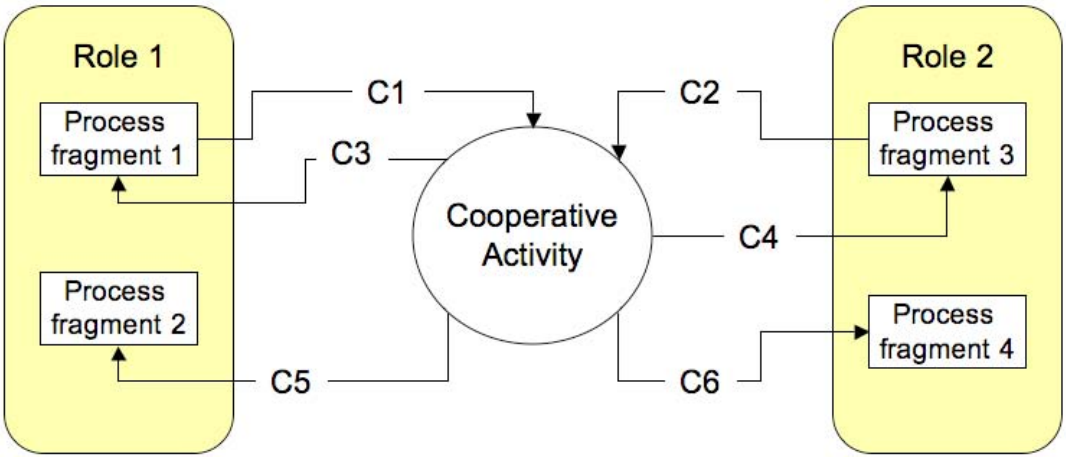
The cooperative rules in the process model in Figure 3 specifies that *Process fragment 1* and *3* must be completed before the cooperative activity will be executed (C1 and C2). Depending on the outcome of the cooperative activity, either *Process fragment 1* and *3* will be re-enacted (C3 and C4), or *Process fragment 2* and *4* will be initiated (C5 and C6).

In addition to provide support for cooperative activities in a PSE, it is also important for the PSE to provide access to other collaborative tools like chat-applications, collaborative editors, Wikis, discussion forums and so forth. The output of group processes is artefacts produced by the group and the individuals.

Team Process

The *team* process level is related to middle management and specific roles in a software project like a team manager. The team manager manages

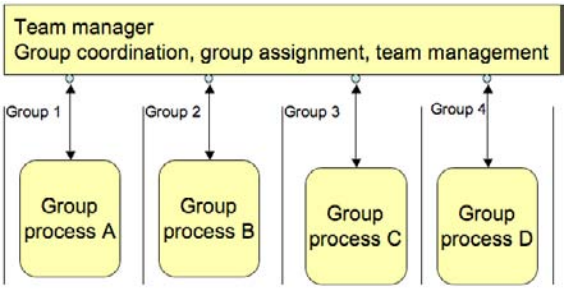
Figure 3. Group process model



the development of one or more main parts of a software system within the competence of the team (e.g., security, business logic, etc.). Typical tasks at this level can be planning of group processes, assignment of group process to groups, tracking progress of the team, monitoring resource usage, and low-level quality assurance. The process support required at this level is monitoring of the ongoing processes, computation of resource usage, prediction and estimation of progress and resource usage, and creation and editing of process models. It is also essential that the team process model can integrate the group and individual process models and provide a process environment that will exchange artefacts and state changes between the individual and group processes. The main difference between the coordination and cooperation at the group and team levels is the granularity. At the group level, the cooperation between group members is tight and frequent. At the team level, the groups are independent but the coordination is still important to, for example, manage available resources and exchange project artefacts (document, source code, programs, tools, etc.). It is the team manager who is responsible for the coordination of groups. Thus, it is important that the process support provides the infrastructure and tool to support and ease this job.

Figure 4 illustrates a process model at the team level that consists of team process coordination and assigning group processes in addition to other team management activities. The group processes are coordinated through defined interfaces provided by the PSE (illustrated by the small circles). Another alternative could be to allow direct coordination between groups. This approach might cause problems because two levels of coordination must then take place at the group level: coordination of individuals and coordination of groups. Another advantage by coordination groups through a team manager is that it is easier to make correct decisions about changes of the process, as this level gives a better overview of the process and the state of the different parts of the process.

Figure 4. Team process model



The output from the team process level is the artefacts from all groups as well as the state of the team process.

Project Process

The *project* process level represents the software development process at the highest abstraction level, usually managed by a project manager. For this role, the required process support involves tools and procedures to create a project plan (project process model) for the whole project, establish and change teams and groups, assign personnel to teams and groups, estimate project resource usage, track progress of the whole project, monitor resource usage, perform company quality assurance procedures, assess and improve the development process, and so forth.

At this level it is not unusual to have external subcontractors to carry out parts of the project that require special expertise or expertise that is not present in the company. From a process support point of view, it is also likely that external subcontractors use their own process models and support environment. Thus, it is essential for the process-centred support environment to enable federation of various process model languages and tools to enable monitoring and process enactment of the whole project.

Another essential activity at the project level is to package artefacts, process models, and knowledge and experiences from completed projects that can be used as input when planning,

estimating, modeling, and managing new projects. One method for harvesting experiences from completed projects is to use postmortem analysis methods (Birk, Dingsoyr, & Stalhane, 2002) like Affinity Diagram (KJ diagrams) (Scupin, 1997) and Root Cause Analysis (Straker, 1995). Affinity diagrams provide a method for carrying out a structured brainstorming focusing on successes and problems in the project. The root cause analysis investigates one particular issue found in the brainstorming process (positive or negative) to discover the causes and subcauses of the success or problem. In addition, reusable code and documents need to be identified and described with meta-information to enable search on historical information. A knowledgebase or experience-base is the most common tool to store and manage project experiences and reusable artefacts (Dingsøyr & Røyrvik, 2003).

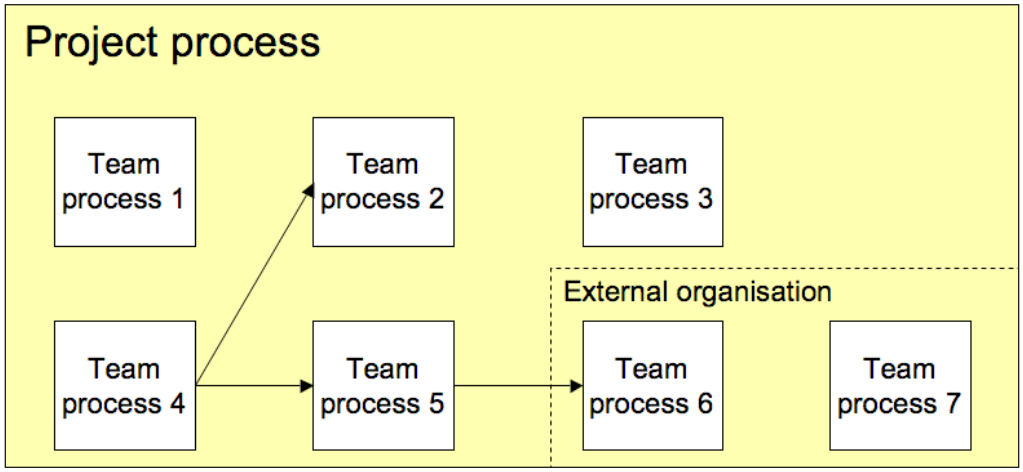
Figure 5 illustrates a process model at the project level. A project process consists of several team processes. Some of these team processes must be carried out in a specific order (e.g., Team process 4, 2, 5, and 6). The pre-order constraints are most often caused by one team process that requires a finished product from another team process before it can start. Note also that parts of the process might be carried out by external organisations. This might implicate that this part of the process model will be expressed in a different process modeling language compared to the in-company models. Also, this part of the process model might need integration with another PSE.

The output of the project process is the final software product along with experiences and knowledge acquired during the project. The completion of a project will also release resources that can be used in new projects. The input to the project process should also be experiences and knowledge from previous projects. Further, a new project is allocated resources like people, tools, equipment, and money. Other important inputs to the project process are company policies and project management rules and practices that must be followed. These constraints will influence the way the process is organised and how the software process will be modeled.

Organisational Issues

This section has so far only briefly mentioned the organisational issues that have to be taken into consideration when planning multilevel process support. This section will briefly look at organisational issues that must be taken into account.

Figure 5. Project process model



At all levels of an organisation, people involved play different roles related to the activities they are involved in. What roles people play varies from project to project. The role also depends on the domain of the project, the company culture, and the culture of the nationalities of the people employed in the company. Kivisto (1999) describes the roles involved in the development of client-server applications to be: application developer, business object developer, database developer, end-user, team leader, project manager, quality assurancer, tester, and expert. Further, these roles are mapped into a hierarchy where the project manager is responsible for managing team leaders, and team leaders are responsible for managing the rest of the roles. This organisational decomposition fits well with the two top levels and the bottom level of our framework. For a specific project, the roles involved must be described and people that fit these roles must be found. An employee profile database can be used for this purpose to find the correct person for a specified role.

McGrath (1998) has proposed a software process modeling framework that incorporates the behavioural issues of software development. The framework has three levels: the universe of discourse (level 1), the conceptual model (level 2) and the external models (level 3). The framework includes behaviour aspects such as attitudes, opinions, beliefs, knowledge, organisational power, politics, culture, and structure. These important issues are not covered in the approach presented in this chapter.

CREATION OF A MULTILEVEL PROCESS MODEL

We propose two main approaches to create a multilevel process model for a software project: top-down and bottom-up. These two approaches are presented in this section.

Top-Down Approach

In the top-down approach, a project manager will typically first create a high level process model based on experiences from previous projects found in the knowledgebase, and the present information (constraints and resources) about the new project. This process model should at least identify the processes at the team process level. Further, the model might contain representations of group and individual processes at a coarse level. It is important that the individual and group processes are not constrained in such a way that they cannot be tailored by the process participants carrying out the processes. If the group and individual processes are modeled by a project manager (at the project level), then the process model should be described by a process template rather than an instantiated process model. If the project manager has not modeled any group or individual processes, the team manager must identify and model individual and group processes. It is also essential that the individual activities are not modeled in such a way that they cannot be altered or tailored by the process participants at the individual process level. The team manager should include sufficient content to the individual process level like activity description, necessary documents and tools, and a proposed sequence of the activities. In some cases the sequence of activities must be frozen because of coordination and synchronisation between developers. The top-down approach is suitable when the top management has a good idea of how the software is being developed in the company or the company management wants to enforce a specific way of developing software motivated by software improvement initiatives (e.g. CMM). For the latter, it is important that the project manager has a good dialogue with the people working in the teams to avoid sabotage of the process. If a process is enforced on the individual actors, they need to be motivated and know why they have to

do their work in a particular way (e.g., because of quality or economical reasons).

Bottom-Up Approach

The button-up approach aims to harvest the process models by starting at the individual processes and moving upwards in the hierarchy of the software organisation. This means that the team process models will be created based on the underlying group and individual process models, and that the project process model will be created based on the underlying team process models. If no processes or process models are described or defined in the company, the bottom-up approach can be applied to create a process model that represents how the organisation is currently working. This process model can be used as a starting point to improve the process by identifying parts of the process that are cumbersome or uses unnecessary resources. However, it is likely that the process needs to be simplified to be able to model it and provide process support for it.

What Approach to Choose?

There is no clear answer if a software organisation should use the top-down or the bottom-up approach. The choice depends on the strategic goals of the organisation and on the working routines used. If the current work processes are causing several problems, a top-down approach inspired by established software development practices could be used to establish a new and more efficient way of working. If the current work processes are efficient and the employees are pleased with the way they work, a bottom-up approach should be chosen. Many organisations are in between these two extremes. If this is the case, a combination of top-down and bottom-up can be used. To succeed in combining the two approaches, it is necessary for the different levels of the organisation to interact often and synchronise the process models to make sure they fit. This chapter can be used as a checklist of what should be considered at each level of the organisation. In addition, the chapter identifies the interfaces between the organisational levels, making it possible to provide one process model for the whole project consisting of autonomous parts.

CONCLUSION

This chapter has presented a framework that describes process support in four levels in a large software development organisation.

The *first level* is the individual level where the main focus is on the activities of individual developers and the process support they require. At this level it is important that the process support can be integrated with calendar applications running on personal computers, personal data assistants, or mobile phones. In addition, it is essential that the process support provides easy access to the required files and tools.

The *second level* is the group level where actors involved in the development process need to collaborate, and coordinate and negotiate shared resources. The process model at this level focuses on cooperative activities, cooperative rules, and the process fragments of the individual participants. The cooperative activities can be modeled and supported using software cooperative agents or role models. Because files are likely to be shared at this level, configuration management is essential. The configuration management system should be integrated to the process-centred support environment to provide process support for negotiation for shared resources.

The *third level* is the team level where the team manager coordinates the various groups in the team. The main focus at this level is team management that involves assigning work to groups, and provides the necessary infrastructure and support for intergroup coordination.

The *forth level* is the project level where the project manager initiates, manages, and finalises

projects. At the end of a project, it is important that experiences, knowledge and reusable artefacts are packaged in a knowledgebase for later usage. In the initialisation phase of a new project, the knowledgebase plays a vital role when making resource estimates, modeling the process, assigning resources, and finding the reusable software components. It is also important at this level to make a heterogeneous PSE able to interact with PSEs in external organisations, as some team processes might be carried out by external resources. Finally, support for monitoring the process consisting of several teams that also might be external to the company is essential.

The main contribution of this chapter is a description of the process model elements required in a process model at each level of a software development organisation, and a description and discussion about the required process support at these levels.

FUTURE RESEARCH DIRECTIONS

Professional industrial software development organisations are always looking for ways to improve their development and project processes. One way of improving the software process is to provide the appropriate support for the process at different levels of the organisation. Most research within software process modeling assumes software development made by one company with a stable organisation and where the requirements are stable. This is not always the case.

The success of large open source projects have made open source development practices interesting to also apply within larger software organisations that perform global software development.

The ITEA COSI project (Codevelopment using inner & Open source in Software Intensive products, http://itea-cosi.org/) has observed a shift in software development, to more cooperation, new coalitions, and more collaboration with open source communities. These forms of network-enabled collaborations create new challenges for software developers (Lacotte, 2004). These new forms of development make the normal development processes less scalable and flexible because more and more of the software is harvested through reuse of internal components, through COTS, or through open source projects. In addition, a lot of the actual development efforts are outsourced, making it harder to ensure quality, productivity, and control of the software project(s).

The percentage of code actually produced locally in an organisation is decreasing, while the complexity and size of the products are still increasing. Large software companies like IBM and Sun Microsystems have made parts of their product portfolio as open source, creating precedence for how to make and publish software.

Participants in open source projects are increasingly employed by industrial companies. Many of these participants are very flexible with respect to how software is developed, and will often adapt the development practices used in the open source project.

When considering software process support for open source processes, the most important issues that must be considered are collaboration and coordination between many distributed developers and flexible and open PSEs that can be integrated with a large set of tools.

Agile methods (Abrahamsson, Warsta, Siponen, & Ronkainen, 2003) have gained much attention in recent years by moving the attention from documents and specifications to customer participation and incremental and iterative development of the products. Smaller projects are more likely to adopt agile methods, while large projects still will employ project management practices that are more heavyweight. To use agile methods in larger organisation, the main problem is to manage multiple cooperating teams that facilitate various overlapping, informal cross-team communication. Kahkonen (2004) describes an approach for introducing agile methods in large

organisations. This approach was tested by Nokia with success, where the informal cross-team communication problem was solved by using communities of practices theory.

Our proposed framework is embracing these new trends by differentiating the process model and support for different levels of organisation.

Chapter 6.4
Computer-Aided Management of Software Development in Small Companies

Lukáš Pichl
University of Aizu, Japan

Takuya Yamano
International Christian University, Japan

ABSTRACT

This chapter focuses on the principles of management in software development projects and optimization tools for managerial decision making, especially in the environment of small IT companies. The management of software projects is specific by high requirements on qualified labor force, large importance of the human capital, low level of fixed costs, and highly fluctuating product demand. This yields a dynamic combinatorial problem for the management involving considerable risk factors. The key aspects addressed here are structuring of the project team, cost estimation, and error avoidance in the implementation phase of the project. Special emphasis is put on human resource and fault-tolerant management of the project cycle. Discrete faults and continuous stochastic inputs are used to test and evaluate project variants. We have developed an online simulation tool for this purpose that facilitates findings of optimal resource structures and creation of optimal network from task relations. General principles of software project management are presented along with the analysis of the software project simulation tool in a brief case study.

INTRODUCTION

The history of modern project management in general dates back to the 5th decade of the last century in connection with large military projects. About 1 or 2 decades ago, a close attention started to be paid to risk assessment and coordination of mammoth software projects (MS Windows development, etc.). Although it is fully recognized that the way of management of software projects

often matters more than financial resources (and a frequent success of small software companies sold at astronomic profits to giant SW development companies demonstrates this point), relatively little is known what are the crucial factors for success. A project can be defined as a temporary endeavor undertaken to create a unique product or service (i.e., in the present case, software) or another product by using software at a large scale. It is noteworthy that a complexity limit was empirically discovered in the software development, which is as low as about 10 software engineers working on one project. Therefore, an appropriate management is crucial since most of the software projects exceed this number.

Software development and its successful management is a key issue for a number of small IT companies and, with increasing importance, also for their clients. The project management (PM) common fundamentals are integration, scope, time, cost, quality, human resource, communications, risk, procurement, delivery and service to customers. Software project management (SPM) is, in addition, characterized by unique success factors derived from the unique components of IT projects. There are specific requirements on the applicability of standards, fault-tolerance, risk management, project scheduling, code development and testing techniques. Further important issues are selection and use of third-party software and also the intellectual property rights.

It has been noted in recent surveys that most software projects suffer from inadequate management techniques that ignore the unique characteristics of this field (cf. Northwest Center for Emerging Technologies, 1999; US Government Accounting Office, 1979, 2000). The most cited reasons are poor strategic management and underestimation of human factors in particular. It is known that about one half of software projects was delayed in completion and one third was over budgeted in 1997-1999, similar to the first study conducted in 1979 on this problem by the US Government Accounting Office. This remarkably persistent problem has been gaining increasing attention in scientific literatures for about a decade (cf. Abdel-Hamid & Madnick 1991; Humprey & Kellner, 1989). Since then, books and practice guides (e.g. Bennatan, 1995; Jalote, 2002) have appeared with different levels of rigor, but the number of detailed investigations in scientific journals has been rather limited (cf. Drappa & Ludewig, 1999; Rodrigues & Bowers, 1996). There is also a nuance to be noted: Traditional PM aims to solve certain types of *problems*, while SPM is rather a *process* than a solution of a problem, and therefore it requires a different approach.

Major authorities among the professional organizations in the field of SPM are Project Management Institute (PMI), Software Engineering Institute (SEI) and IEEE Software Engineering Group. These recognize the following important factors for a successful project:

- Leadership,
- Communication,
- Negotiating,
- Problem-solving methodology,
- Information sharing and training, and
- Relevant technical expertise.

Coordination and cooperation are the key factors; this is within the responsibility of the administrative hierarchy that typically includes a coordinator, assistant project manager, program manager, and a software development coordinator. Each project typically involves a team, targets certain customers and relies on contractors, and must be backed by sponsors, executives, and functional managers.

The first principle of project management is that there exists no universal principle at all. Attention has to be paid to project size, project type, culture of the project team and other factors. Software projects, in addition, require a special emphasis on the communication of *technical* experts in order to guarantee code portability

and program compatibility. Thus, one may raise a question whether a rigorous methodology for SPM is, in fact, possible. In this chapter, we (a) give an overview of managerial approaches in the field, and (b) address the gap in the standard SPM theory and practice, which is the lack of portable and customizable computer simulations for accurate estimation of project costs. In the early (but crucial) project phase when decisions are made so as to whether start a particular software project or not, such estimations are typically very crude. Such strategic decision making then inevitably leaves a space for cost increases, software delivery delays and even project failures.

Software companies are complex environments in which managers are faced with the decision-making problem involving uncertainty. Because of the complexity in the interactions among project tasks, resources, and people, estimates using average values of the project factors are very crude, and the errors are typically in the orders of 25%-100 % or even more. It is well known in the queuing theory that average output of a system with stochastic inputs can be substantially different from system output based only on average inputs. Many software projects at present disregard this point, or attempt to address it by using the best, mean, and the worst scenario, which still ignores the queuing structure of the project components (two blocks in a queue, each with the mean scenario, can produce a result even beyond the average worst-case scenario, for instance when a peak congestion in the queue results in a hardware damage or suspension of software service). Therefore even the overall worst-case estimates may be too optimistic and vice versa.

A deterministic algorithm can hardly be applied to estimate project costs, but the cost of false decision is typically enormous. Simulation techniques form a bridge to overcome this problem and to find the probabilistic optimum. In this work, we deal with a decision-making problem in the context of the software project management using three levels of detail, namely, (a) a decision whether to accept or refuse a new contract for a specific software project (complete computer simulation screening), (b) how to organize the project team (human aspect), and (c) what measures to take in order to optimize the cost of an accepted project with a given project team (resource optimization). Because of the importance of human factor in project management, we have decided to develop and provide a customizable, object-oriented, and free software project simulation environment that facilitates duration and cost estimates and supports decision making. Such a tool is consider more applicable than a fully deterministic optimization program with an implicit hard-encoded "general" project topology, however complex its parameterization might be.

The chapter is organized as follows. In Section 2, we review the managerial recommendations for project management, focusing on the specific features of software projects. Then we proceed to computer simulation of software projects in Section 3, discussing general design issues along with their particular implementation in the presently developed object-oriented simulation tool. Section 4 gives the simulation results for a selected case study along with discussion of their broader implications. Concluding remarks close this chapter in Section 5. We also recognize that the SPM area is, in fact, very appropriate for agent-based simulations, although it has been largely neglected in AI applications thus far.

MANAGEMENT OF SOFTWARE PROJECT

A successful project strategy is a balanced blend of development fundamentals, risk management, schedule-control, and mistake-avoidance techniques, adjusted to a certain trade-off in product quality, project cost and delivery schedule. One of important specific features in software projects is the huge range in productivity and ability of human

resources. Therefore selection, organization, and motivation of the team are the key factors of SPM success or failure. In this chapter, we elaborate especially on these factors. Considering what has been outlined above, it is unlikely if not impossible to find a generally applicable SPM strategy. Instead, we focus on the development of a software simulation tool that helps to select project teams, estimate the project risks in a variety of possible scenarios, and to identify possible failures before these really occur. Here we develop a SW project simulation tool that is customizable for a particular product, human resource structure and development environment. The source code is open and the tool is free to download (Online simulation application, 2005). Let us note that there exist commercial PM tools too, e.g. MS Project 2000. Their inbuilt computer simulation features are often limited. Since no two projects are really the same, the proprietary source code of the commercial products which does not allow any modification means also a serious limitation to their applicability.

Principal functions of a general project management can be listed as (Northwest Center for Emerging Technologies, 1999):

- Define scope of project
- Identify stakeholders, decision-makers, and escalation procedures
- Develop detailed task list (work breakdown structures)
- Estimate time requirements
- Develop initial project management flow chart
- Identify required resources and budget
- Evaluate project requirements
- Identify and evaluate risks
- Prepare contingency plan
- Identify interdependencies
- Identify and track critical milestones
- Start the project and track its progress
- Participate in project phase review
- Secure resources as needed
- Manage the change control process
- Report project status
- Finalization or quitting of project

In order to plan or monitor a certain project, the basic useful tools are project flow charts and network queuing diagrams for interdependent operations (visualization of tasks and their relations). Any project design should start from the final product. Therefore it is important to asses the product characteristics, size, requirements and methods of management. Project planning then means determination of available resources, selection of life-cycle model, and the design of a development strategy. Once the project starts, it needs to be tracked for costs, schedule and human efforts. When discrepancies between the plan and real state arise, a portfolio of appropriate measures should be available to handle such case. Each project can be classified into certain phases (i.e., milestones in the project tracking and project management). In case of SPM, these are:

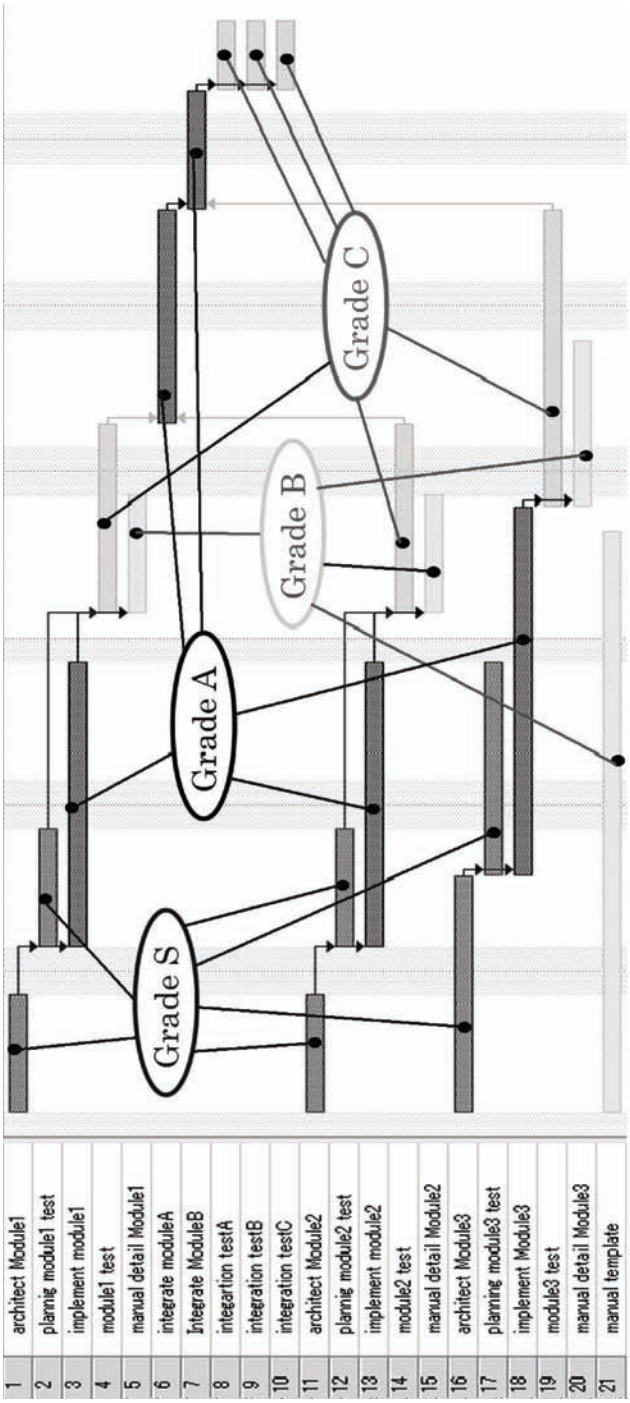
1. Software concept;
2. Resource requirements;
3. Architecture development;
4. Detailed design;
5. Implementation, programming, and debugging;
6. System integration, testing, and quality assurance; and
7. Product deployment, distribution, and maintenance.

Interestingly, major mistakes in failed software project (identified ex post) appear to be very alike. It is therefore crucial to identify their emergence based on certain fingerprint patterns and eliminate them as early as possible. To that aim, one can used the so-called McConnell's Anti-Patterns, related to failures in human resource, process, product, and the technology. For instance, these are the customer-developer friction (the programmer "knows better" what the customer "should" need), "politics over substance" (e.g., prestige competi-

tion on international level in science policy and R&D), wishful thinking (withholding cooperation quietly by sticking to formal procedures), or the lack of money ("priority shift" in the middle of the project) rank among the most serious issues.

Process related mistakes include unrealistic schedules (following "optimistic variants"), contractor failure (resources in computer engineering are often stochastic), insufficient planning for phases under time pressure (e.g., complications

Figure 1. Work breakdown structure (WBS) for a sample project



arising in debugging of "nasty codes"—applies to the author of the code, the more to someone else). Product-related mistakes typically include lack of customers (e.g., "products for researchers in bioinformatics or nanoscience" or certain "software products for the elderly"). Technology related mistakes often include unrealistic extrapolations of available resources ("counting on the Morse law", or admiration to new platforms "preference over a CPU maker without caring for compiler availability").

The important issues to check are: What will be the total cost? How long will it last? How many developers does it need? What resources are required? What can go wrong? And finally, the most important question for financial managers is the rentability, measured in the net present value (NPV), return on investment (ROI) or payback period. Since the required rentability can be viewed as an associated fixed cost, we do not need to consider it explicitly in what follows.

Before proceeding to the design and simulation issues in the next section, we would like to note that there exist various movements attempting to change the landscape of software development completely. One of these is eXtreme Programming (XP), a lightweight methodology for small teams, a highly iterative approach in which programmers closely interact with application users about the SW test releases in development (originally for small release applications based on certain HW or software architecture spikes). In a cycle of test scenario, user stories (bug reports, feedback from on-site customers) and incremental release version planning, the code development can be enormously accelerated. The reverse side of this methodology is high requirements on coders skills and enthusiasm for the project. In this respect, there is also an important problem of measuring the programmer's output and determining appropriate rewards. One measure frequently applied is the number of lines of code (LOC) together with the number of program function points. This is certainly an informative criterion but a care should be taken when to use LOC as a motivation and remuneration basis. LOC may work well in case of standard large-size projects but is certainly inappropriate in case of XP and other lightweight SW development methods.

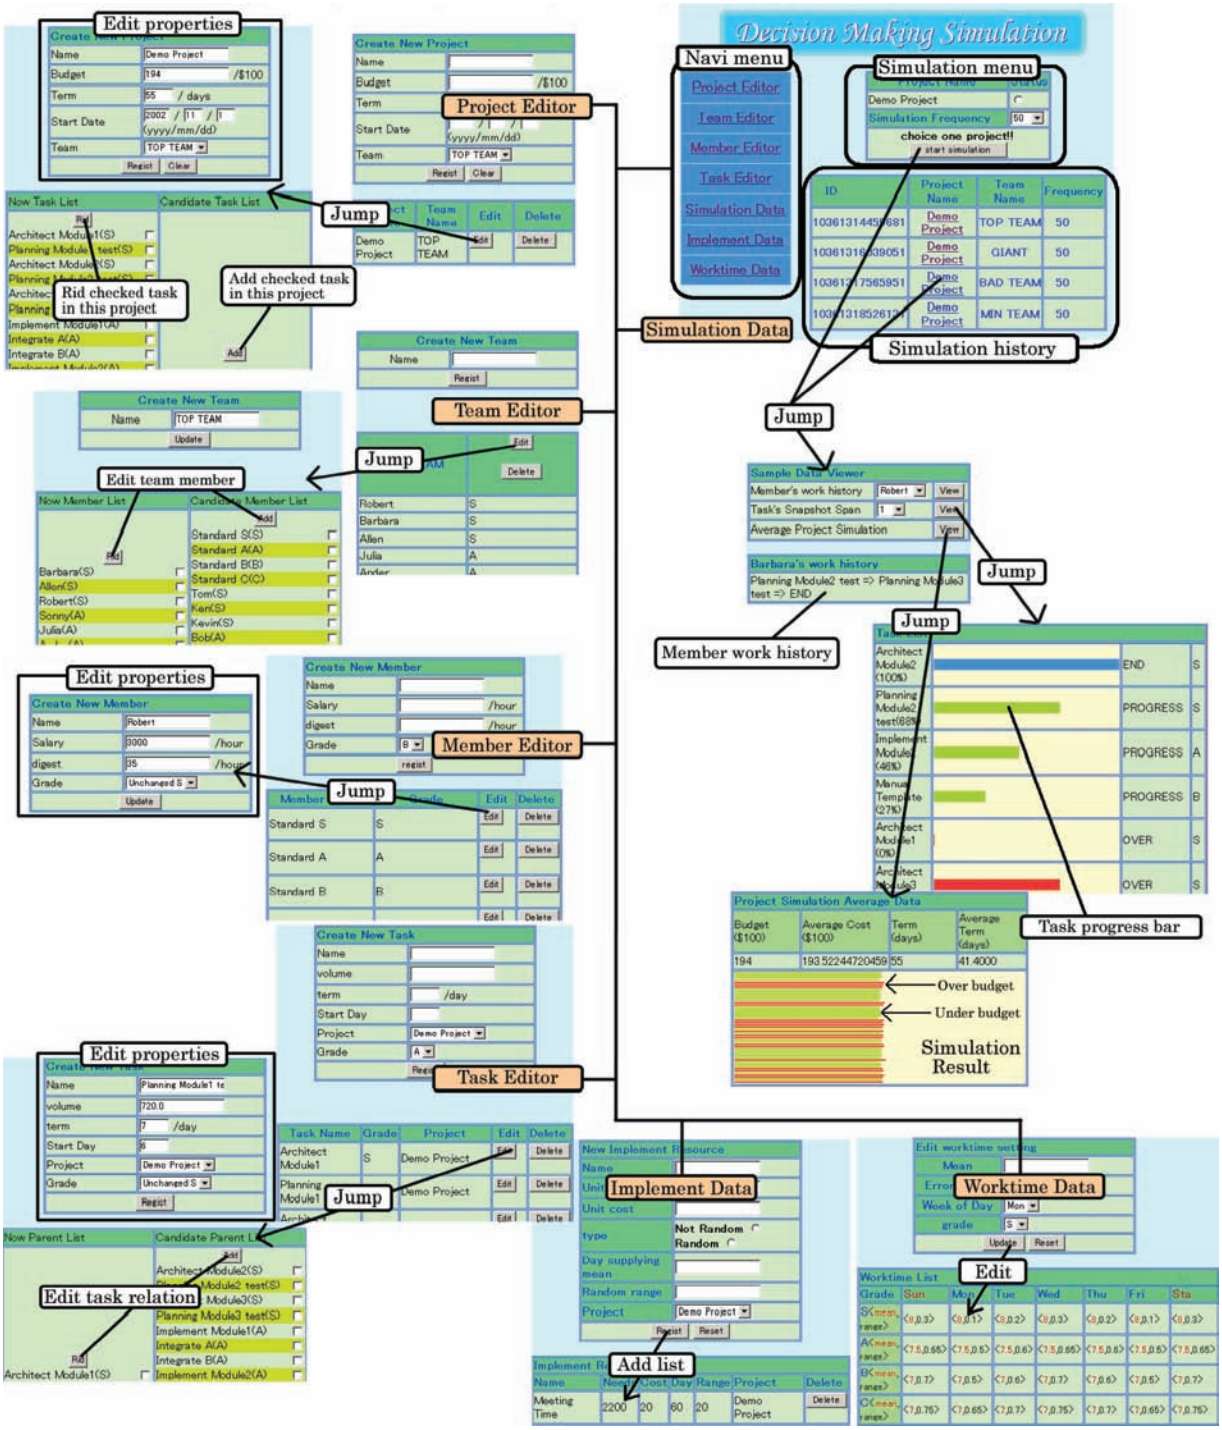
In the next section, we develop a general purpose simulation tool for software projects, focusing on the project structure, planning and stochastic resources (including stochastic failures).

COMPUTER SIMULATION OF SOFTWARE PROJECT

In order to facilitate the software development process in a specific way, we have developed a java-based online application with Graphical User Interface (GUI), which allows the user to define tasks, properties, resources, and team members including various attributes. The structure closely follows the principles of SPM. Java was selected because it is an object-oriented programming language with an easily implementable and well-established Web interface. Structure of project activities is outlined in Figure 1. The screen shots of the simulation environment are shown in Figure 2, starting from the front page entitled "Decision Making Simulation" in the right upper corner of the figure.

In the application program, there are four types of data: project data, task data, human resource data, and team data. These are all subject to optimization. The stochastic environment is simulated in two modes: (a) binary process that occurs with a given probability per unit of time (typically a false outcome of a certain task, for example, we set higher probability for coding mistakes on Monday mornings and Friday nights), and (b) probability distribution of some input data with a predefined range of values (data bandwidth available in external network, supercomputer CPU time available for rent, etc.). Both the discrete probabilities and continuous probability densities can be derived

Figure 2. Application interface includes project, team, member, task, resource and worker editors, and displays all data



from histograms of real systems and input into the model by specifically tailored non-uniform random number generators. In particular, this procedure is as follows:

- Divide the range of the stochastic factor, $<x_1, x_2>$, into representative bins $\{b_i\}$.
- Create a statistical record of the stochastic factor over a suitable period of time.
- Generate probability for each bin $p_i = N_i/N$, where N_i is the number of observations falling in bin b_i and is the total.
- Tailor a custom random number generator by using the following algorithm:
  - Repeat
  - Generate a uniform random number $r = x1 + (x_2 - x_1)\times$rnd()
  - Generate a uniform check number $c = p_m \times$ rnd() ($p_m = \max_i \{p_i\}$).
  - Determine bin i_o (r) for the number r
  - If return r (and exit).
  - Until forever

Here stands for a uniform float random number generator with values between 0 and 1 (a standard function in the libraries of most programming languages). Our simulation environment (cf. Figure 2) allows to set the relationship of tasks and structure human resources in a flexible manner. The task's determinants are time, grade, deadline and the queueing structure (standard and priority queues). Human resource (worker) determinants are skill, grade, and wage. Workers pick up tasks from the queue based on custom project team structure. Human resource is divided into four grades. Any group can take a task, if the group grade permits. Last is the project resource determinants, such as CPU time required or office supply items. Registered resources are acquired and consumed by units of days and increase the project cost. Cost of each resource is in principle time dependent, therefore various cost pricing schemes (FIFO, LIFO, opportunity costs) can be included in a straightforward manner.

Data Structures in the Simulation

The particular data structures in any SPM tool should derive from project resources and project organization. In order to design the simulation environment as general as possible, we do not hard-encode the project structure. Instead, several online editor forms allow to add project components as needed and register their mutual relations (Project, Team, Member and Task Editors in Figure 2; also Resource Editor, not shown).

The present java application stores all simulation data in a database (implemented with the MySQL relational database management system). The main database components are Member, Task, Project and Resource. Member is determined by name, identification number, wage or salary, and performance measures (A, B, C and S). Task is determined by identification, queuing schedule, progress indicator, deadline, and difficulty grade. Projects are distinguished by name, identification number, budget limit, team available, task composition and the deadline. Resources are determined by identification, number of units required by each project, unit cost, average daily supply, distribution width, and identifications of calling projects. Functional relations of the data during the course of simulation are shown in Figures 1 and 2. The simulation program is executed in discrete units by taking series of snapshots of the current progress (project, task, worker), incrementing the project immediate cost step by step. For the sake of simplicity, we implemented two particular types of random parameters: worker's fault probability p_i and a continuous randomized resource x (e.g. daily cash flow from

$$\rho(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{\frac{-(x-\mu)^2}{2\sigma^2}}.$$

Generalization to a general histogram is straightforward as discussed above.

Application Data

In order to test the simulation environment, we have adopted sample model data. The respective Work Breakdown Structure (WBS) is shown in Figure 1. WBS is a useful tool to estimate project duration and workload of project participants. It is a 1D hierarchical list of project work's activities which shows inclusive and sequential relations. The 21 items listed in Figure 1 are the project activities. The labels "A", "B", "C" and "S" in the Figure show the lowest grade of the labor force qualified to deal with them. More detailed WBS in managerial applications may also distinguish the managerial level (project, task) from the technical level (subtask, work packages with definable end results, effort level). Instead of a chart, decimal catalogue-like form is sometimes used.

Next, we have created a sample case study project consisting of three modules. Each module has an architecture phase, implementation phase, integration phase and testing phase. The number of project modules and resource sharing among them is completely flexible. This is an extremely important point for the decision making support, since the entire company can be simulated in such framework by combining various modules (or projects) in one large scale simulation. Therefore

Table 1. Prototypical teams

TOP TEAM: high output, low cost					id	name	salary	out pt.	No
5	Robert	3000	35	S	1	S	2000	20	S
6	Barbara	2780	27	S	2	A	1500	20	A

9	Allen	2500	25	S	26	Sander	750	23	C
12	Julia	1650	23	A	28	Anne	650	20	C
13	Bob	1500	20	A	29	Richard	600	18	C
14	Eva	1500	18	A	MINI TEAM: size is small				
15	Larry	1450	17	A	8	Ken	2200	20	S
19	Diana	1300	23	B	9	Allen	2500	25	S
20	Mike	1100	22	B	11	Sonny	1800	23	A
21	David	1000	20	B	12	Julia	1650	23	A
23	Ernie	1200	23	B	19	Diana	1300	23	B
26	Sander	750	23	C	23	Ernie	1200	23	B
27	Nita	700	24	C	24	Melissa	900	26	C
28	Anne	650	20	C	25	Nancy	800	25	C

the general design above and our java application tool in particular should not be misunderstood as a mere "single project simulation" unrelated to other activities in the SW company.

In particular, we implemented four sample teams: "TOP TEAM", "GIANT", "BAD TEAM" and "MINI TEAM" (see Table 1). These teams consist both of common and extra members. The project optimized here uses a stochastic resource—external supercomputer time—of 2,200 minutes in total (normal distribution with 1 hour mean and 20 minute dispersion). The flow of task relations among workers of 4 grades (S>A>B>C) in time is shown in Figure 1. Simulation is executed for each team, and the results are evaluated in the application program. Because of the general project structure that can be flexibly created using the online "Editor" forms for each project component, a universal optimization routine cannot be efficiently used, except for a full screening (gradually building teams by adding members still available; gradually including resources from the pool of resources available). Although this brute-force (full screening) approach feature was implemented in our program for the sake of completeness and suffices in case of small companies, it is not recommended in large simulations for obvious efficiency reasons. Let us note that the application performs two types of computations: (a) multiple simulation runs and the best-case, average, and worst-case analysis for each managerial decision (i.e., for each fixed project structure), and (b) brute-force full screening for the best project structure (small-sized projects). Because the SPM in practise is a multivariant decision making process, it is also preferable that the management modifies project structures as desired and then evaluates each variant separately, learning the most important trends and worst-case scenarios from the simulation results.

Interface and Technology

Let us briefly summarize the software project management tool developed in this work. In the simulation environment, users change and input all data with the Graphical User Interface based and Java Server Page. Logic programming is also implemented in Java. Mysql database is used to store simulation data. The interface described by Figure 2 allows the user to choose from a variety of functions in the left navigation menu of the window "Decision Making Simulation," to set the simulation properties and to check simulation progress and history. There are five editors for members, projects, teams, tasks and resources. The editor page can create and delete relations among the data. There are three main parts in Figure 2. The first one is the team member's working history. The second is a progress snapshot of all project tasks, each having one status assigned from "READY", "PROGRESS", "OVER", "END", and "NO STATUS." At last, the simulation result graph shows the total cost and indicates whether the simulation run is over the project budget or not (long and short lines indicated by arrows in the window "Simulation Result"). Work time data sheets enable editing of worker's grade and performance. The parameters are the mean and the stochastic error range. The resource editor page adds the resource data and their possible stochastic distributions for any project. Resources can be fixed or random; these are especially important to decide the need of the project and its final cost.

After multiple simulation runs, project variants are compared in order to find the optimum. This environment is used to design the best team possible for a given project (or a set of projects). The optimization is conditioned, (i.e. the Top Team in Table 1 is chosen if the project manager

needs the most economical team, and the Giant team in Table 1 is chosen only when maximum speed is the criterion). Whenever a task over the deadline is found, its margin is checked, the length is edited and all other related tasks are adjusted. Thus the optimal decision making is possible with using the simulation data. Input data can be changed flexibly, including task relationships, team members, project teams, project budgets, workers ability or random input streams, and then reused for the simulation.

CONCLUDING REMARKS

In spite of various established project management models and quality management systems, such as ISO-9001, Capability Maturity Model, or Constructive Cost Model (COCOMO), SPM simulation has not received sufficient attention in academia. Also software projects in businesses often suffer from inadequate management. The complexity of software projects with various stochastic features involved implies that an object-oriented computer simulation is a very appropriate approach. In addition, because of the autonomous human factor in program coding and complexity in motivation of software developers, agent-based simulations are expected to contribute to this field in the future.

This chapter summarized principal features of software project management along with presenting a newly developed SPM simulation tool. The tool is a general purpose object-oriented simulation environment with emphasis on fault-tolerance in the development process. Randomized inputs, randomized faults, variable team structures, branching queues and idle time analysis are included (Online simulation application, 2005). The online Java program adopts flexible data structures for the teams and stores all simulation data in a dynamic database. The contribution of this work consists in developing simulation technology for the new area of SPM.

Chapter 6.5
A Survey of Competency Management Software Information Systems in the Framework of Human Resources Management

Alfonso Urquiza
Francisco de Vitoria University, Spain

ABSTRACT

One of the greatest surprises of the Internet economy is that far from replacing people, the use of advanced technology is confirming that talent is the most valuable asset in today's organizations. In this context, competency management (CM) software automation practices become the most valuable business approach to define, measure, and manage talent needs, the human capital of the organization.This chapter's position is that CM process automation in competitive, knowledge-intensive e-business oriented organizations requires that information technology (IT) address software strategy in a comprehensive human resources management (HRM) framework. Core competency management-related applications are deployed in current corporate e-business transformation processes in association with the use of innovative employee—facing relations management technology and reengineering most HR transactional domain type of applications in place.The chapter shows the CM software evolution from a previous fragmented market situation to a much more integrated scenario in which best-of-breed single-function oriented products preferences are now swiftly moving to the enterprise resource planning (ERP) type of architecture.

INTRODUCTION

As the Internet age transforms the way people work and live, organizations keep continuously embracing the new opportunities and challenges

generated by this relatively recent and significant change, introducing a new knowledge revolution (Nordstrom & Ridderstrale, 2000).

Today's economy is creating a new breed of "intelligent" organizations, where a very high percentage of the total workforce is comprised of knowledge workers. In this context, the ability to effectively manage human capital investments becomes essential to ensure business success. Organizations gain real advantages by applying Internet technology to the measurement and management of their talent needs, the human capital of the organization.

The long transition from traditional *"personnel administration"* activities to most recent *"human resources (HR) management,"* has meant an evolution from a purely functional to a process-oriented approach in which all those activities associated with the management of employment and work relations are included (Boxall & Purcel, 2003).

Traditionally, organizations of any size or activity used to focus primary attention on automating payroll & basic administrative functions. Other administrative-required functions (like recruiting, training, etc.) were largely assumed and performed in a non-automated way, thus creating large staff departmental units in these areas, non-associated with the organization's primary business.

IT solutions at the time were not designed to manage *knowledge assets*; they were focused on managing *physical assets.* Individual employees and managers used to call upon HR to satisfy different kinds of requests. Individual employees typically required tracking and processing personal information, such as compensation, benefits, or other related data. Managers required HR to provide information on recruitment or training services**.**

In recent HR management, the new e-business context has transformed and automated most HR operations, thus generating additional efficiency: process flows are handled like "automated transactions" and self-service functions appear, simplifying individual employee/manager relations within the organisation, automating administrative tasks and enhancing task-driven routines formerly performed by HR departments.

In the new "*human capital*" (HC) paradigm, it is not just about modeling and automating "tactical" HR functions. Two new dimensions are introduced. The first to consider is that a new role appears for HR: that of *strategic asset (talent) management.* The second is that HR becomes just another component in the organisation, like financial management, supply chain management, customer relations management, or IT, all of them driven to produce a product or service that generates value to the customer (Laudon, 2004).

It is in this new, comprehensive management context where competency management fully develops itself, becoming the integrating "glue" element in HC management systems (Sagi-Vela, 2004), thus reshaping today's and future HR management implementation strategies.

In the context of this work, competence is understood as the set of knowledge, skills, and attitudes required in people to perform a specific task in an efficient way (Sagi-Vela, 2004). CM is a comprehensive HR process that starts by defining the required organizational competencies, assigns them to employees, observes them through behaviour, asses them according to an organization's defined values, and permanently improves them (Levy-Leboyer, 1997). Unlike in traditional transaction-oriented HR practices, a CM strategy should pursue the following goals:

- Support business objectives, providing information to *acquire*, *maintain*, *influence*, *develop*, and *retain* the *right employees.*
- *Align* people, processes, and technology around *shared values.*
- *Measure* the strategic value of human capital investments.
- *Anticipate* human capital changes.
- *Learn* from industry-best practices, leveraging benchmark data.

In today's knowledge-intensive organizations, competency management is not viewed just like a new function associated with a single job topic (learning, employee career development, etc.), nor is it an additional responsibility, to be added to the traditional list of activities that the organization expects to be accomplished by the HR department.

Experience shows that effective CM strategies succeed most when all HR processes in operation—not just a portion of them, like career development, performance management, or learning, for example—are reviewed and aligned to the talent management vision, accomplishing a real e-business transformation in organization's processes. This remains true even in situations where CM strategies are focused to a limited extent in overall taskforce, applied only to strategic level of employees within the organization (i.e., managers), which happens very often, particularly in large-size organizations.

The main objective pursued in this chapter reflects this business reality: There is not just a simple, unique solution that automates CM process in an organization. CM is not an IT vendor product; it is a full *comprehensive strategy* that transforms the HR management function from a mere, although mature, administrative level to a strategic business alignment role.

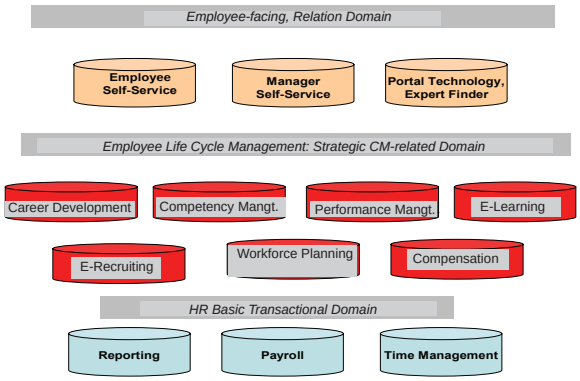
This chapter's proposed detailed position is that, when it comes to implementing a CM strategy in a competitive, knowledge-intensive e-business-oriented organization, IT components in the three areas showed in Figure 1 should be addressed (to the extent placed upon defined CM deployment requirements) or sometimes re-engineered as a 'combined' operation:

The *transactional domain* type of applications are not obviously related to CM functionality, but some processes in this area require small re-engineering enhancements to work in a CM driven e-business environment. Functions included in the *employee life cycle domain* are driven to enhance employee value, core in CM deployment. *Employee-facing* relations management technology deployment usually exceeds the scope of HR, but the use of such tools significantly improves CM-related process efficiency: use of paper and forms-oriented types of activities are replaced by Web-based self service processes, generating significant return on investment (ROI) in large organizations and employee satisfaction in online experience.

In order to fully understand this chapter's business-oriented perspective, the rest of this chapter is structured as follows:

The next section shows the background in which this work is based, followed by an analysis of IT industry response to the CM evolutionary organizational requirements. Then, a characterization of most relevant HR processes is presented, depicting inter-process relations, and supporting

Figure 1. HC key components in CM deployment strategies



and clarifying the proposed comprehensive approach to CM implementations. Finally, today's commercial CM-related technology scenario is presented, followed by future trends and final conclusions uncovered in this survey.

BACKGROUND

Competency management is considered by some authors (Sagi-Vela, 2004) as a complementary methodology to other related HR management practices, such as emotional intelligence or, more often, knowledge management. Knowledge management (KM) is a very close concept to CM, and technical literature (Alle, 1997) tends to generate some confusion when analysing KM and CM management systems.

In the scope of this work, KM management systems are those directed to capture, analyze, apply, and re-use organizations' know-how, with the objective of performing higher-quality business processes at a lower cost and generating a competitive advantage. CM systems' focus is on employee life cycle, covering competency requirement analysis (Lindgren & Stenmark, 2002) and other related HR management topics, such as personnel selection and compensation (Sagi-Vela, 2004).

Contributions on KM designs and product evaluations are widespread in scientific literature (Benson & Standing, 2001; Friss, Azpiazu, & Silva, 2004; Kamara, Anumbad, & Carrillo, 2002; Rollet, 2003), but technical literature on CM is still scarce and dedicated to specific areas, such as organizations adjustment to CM (Lindgren, 2005) or competency development (Hardless, 2005).

In addition to above, the software capability maturity model initiatives (CMM I, 2002) have been complemented by the Software Engineering Institute with the people capability maturity model (People CMM) (Curtis, Hefley, & Miller, 2001) as the foundation for a model of best practices in managing an organization's workforce. And competency management is obviously present in various significant People-CMM process areas:

In this context, a CM software information systems survey in the framework of a comprehensive HR management process scenario might be of great value in further CM software research, for example, investigating compliance relationships between the five People CMM evolutionary maturity levels with CM market products research and development.

COMPETENCY MANAGEMENT AND THE SOFTWARE INDUSTRY

Today's SW products and services marketplace in the HR domain has been shaped in the last 25 years by the business evolution described above.

It is no surprise to anyone that until the e-business transformation with the arrival of the

Figure 2. The Process Areas in People CMM

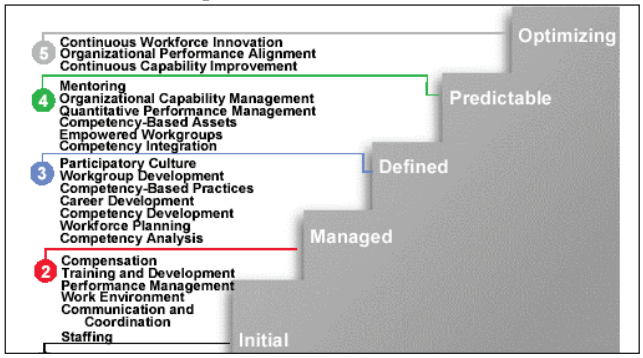


Figure 3. IT portfolio management methodology

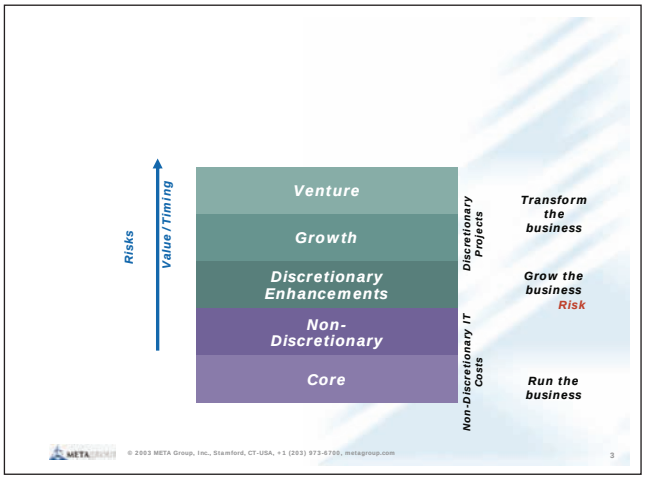


Internet age during the late ’90s, HR businesses have created a sort of IT industry *fragmented* market. There exist hundreds (if not thousands) of different HR administration and management solutions (payroll, learning, PM, CM, etc.) in organizations around the globe. Some are global market-oriented, other vertical cross-industry oriented; most are local and country-driven solutions, aimed to satisfy specific single-market demands.

In addition to the above situation, the amount of in-house developments and custom-made implementation solutions in this field far exceeds expected figures compared to other types of support applications, such as financials, business analytics, and so forth.

But the above scenario is now changing very fast today, and the e-business evolution is driving industry from the previous IT-fragmented scenario to an extremely *concentrated* one. The vast majority of today’s large organizations (those in which CM has the largest deployment potential) are automating HR (or planning to do so) within the scope of one out of three global, integrated ERP products: SAP, PeopleSoft or Oracle.

To better understand this evolution that is reshaping the market in which CM software progress takes place and is making many best of breed stand-alone HCMS solutions disappear, let’s apply a modern, innovative approach that is useful to map organizations’ business requirements with information technology decisions. The Meta Group Technology Analysts call it portfolio management:

Independently of the economic environment, a key challenge for IT professionals has been to assess and permanently communicate the value of IT investments to the business units.

Today’s advanced organizations don’t just require a functional justification and a “business case” study to make a technology decision. The *portfolio management approach* introduces financial issues to any IT investment, as for example:

Level of risk versus expected benefits/value: Just like a pure financial investment. In IT, project deployment time, magnitude of investment, and so forth are taken into account.

Current fair value, at any time.

Expected life cycle: when will investment pay off?

Perceived relationships: defining the IT domain, its platform, and architecture.

IT assets and projects are categorized as shown in Figure 3.

The run-grow-transform classification defines the primary goal for any IT project:

"*Run the Business*" investments are focused to keep business operational (i.e., maintenance contracts, utilities, etc.). *Core* spending is for business-critical activities, like customer service, sales ordering, and so forth. *Non-discretionary* relates to organic growth in core IT assets (servers, DBMS, etc.). Business *risk* is low and expected *reward* usually medium to high.

"*Grow the business*" IT expenditure is applied to expand organization's scope, in product or services. Learning activities to develop new skills fall in this category.

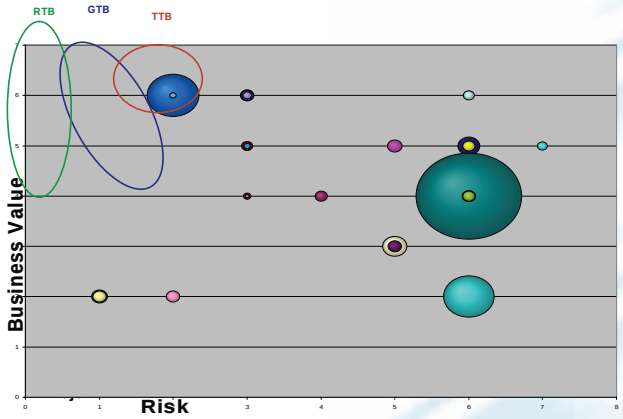
"*Transform the business*" initiatives are related to opening new markets or issues having a major impact on the current business model. Business *risks* and expected *rewards*, in the last two categories, are both moderate to high. Organizations sometimes afford the high risk (of unplanned events) and expect also high reward in *venture* initiatives, where speed is usually the way to proceed (i.e., be the first to deliver a product).

The IT industry in most recent e-business process transformations (that obviously applies to HR) drives SW product development & projects investment decisions, analysing three dimensions: investment business impact, cost and performance expectations, and risk and opportunity appraisal.

There are many SW tools in the market to analyse and manage IT portfolios: ProSight (www.prosight.com/solutions/software/), Primavera (www.primavera.com/about/trillion.asp), Niku (www.niku.com/), and so forth. The example in Figure 3 depicts a view of the different SW implementations in place in an organization, associating the value and the risk dimension.

Now, if we apply portfolio management's approach to HC management and CM, and clearly understand IT's decision-making process, current technology scenario, and, also, expected trends for the future, it will be much better understood. For this purpose, we will analyse IT-phased evolution, within the proposed HC framework in which CM strategy develops in today's advanced

Figure 4. IT portfolio classification example



organizations: the employee transactional, life cycle management, and relations management domains.

Let's first focus on the employee transactional domain. Traditionally, payroll and basic employee administration services have been considered the primary, core HR organization's service. Mistakes in this area do have a clear "dissatisfying" effect, thus damaging HR internal image. And particularly in medium- to large-size organizations, some specific processing difficulties led to prompt IT automation: earning and deductions complexity derived from different, concurrent labour agreements to apply in single organizations, continuous updates in country regulatory requirements, gross-to-net permanent calculations, and finally, banking reconcilement and automated interfaces requirements.

Payroll, therefore, rapidly became the first core "*run the business*" type of investment in HR management, parallel to other basic back-office applications like accounting. *Business risks* were *low* (processes are quite stable) and *benefits* were *medium*.

Other transaction-oriented processes followed automation in a segregated manner, just when business required the need due to growth, changes in HR policy, merging events, and so forth. Some of these processes were compensation and benefits or time management, typically non-discretionary enhancements, *low business risks*, and *high benefits*.

Initial market products' scope was local, coexisting with many made-to-measure solutions in place. Outsourcing of services models began to develop, particularly in the low- to medium-size type of organizations.

Employee life cycle management is the primary core domain for HC competency management strategy deployment in any organization. Competencies are created to manage organizations' required *talent* across the employee life cycle:

Attract talent (e-recruiting) ➔ *Assign* talent (workforce planning) ➔ *Influence* talent (performance/compensation management) ➔ *Developing* talent (e-learning) and ➔ *Retaining* talent (career & potential development).

Although integrated solutions are the most relevant implementation solutions in today's IT industry (see section *"HC market applications: The CM contribution"*), stand-alone products are also growing. We will shortly analyse performance management and CM and E-Learning, these two being the most relevant convergent solutions in the CM market today.

a. Performance and competency management

Early non-integrated deployed performance management (PM) systems were perceived by employees as non-useful, time-wasting applications. It is not until the e-business transformation process generated during the last five years that organizations perceived real business impacts in developing values and competencies, enhancing employees' business alignment. Medium- to large-size organizations started to create and track measurable skills and competencies through the deployment of advanced e-business-oriented PM solutions. About 40% of large organizations have already defined competencies for some type of jobs, and 10% have a well-defined enterprise-wide set of competencies. And the IT market today still has large expectations: 60% are still non-automated, paper-based solutions, about 25% in-house developments, and 10% product based (PeopleSoft, SAP, Workscape, etc.).

CM solutions are mostly "*grow the business*" and, to a lesser extent, "*transform the business*" *venture*-type applications. Business *risks* and *reward* are, typically, *moderate to high*.

b. E-learning

Early (1980s to mid 1990s) learning management systems (LMS) were just tools driven to automate instructor-led training activities. E-learning

today is somehow different. Cisco chairman John Chambers said in August 2003 that "*the two great equalizers in life are the Internet and education.*" More than 70 million people received education over the Internet that year.

LMS' most relevant change in the Internet age is that employees now become themselves *responsible for their own learning requirements.* Training is delivered in a personalized way, thus facilitating individual *competency development* as required and planned by the organization.

IT's e-learning products have a singularity compared to the rest of HC applications related to competency management implementations: The LMS market is dominated by stand-alone solutions. Platforms like Saba (www.saba.com/),Centra (http://www.centra.com/education/resources/index.asp), IBM's Lotus ("www-306.ibm.com/software/info/ ecatalog/es_ES/products/N105931Y77809P74.html"), and 70-plus more represent today 95% of the total market, and just 5% (although growing) are tied to ERP-integrated packages (i.e., SAP, PeopleSoft).

E-learning solutions fit into the "*grow the business*" category. Business risks are moderate and reward is, typically, moderate to high.

IT products in the employee relations management domain don't address or directly process CM-related information. They are viewed as communication-integrated tools, driven to "automate" most (if not all) HC processes, as in other parallel e-business environments. Typical applications in this domain are employee self service (ESS), manager self service (MSS), workflow, and expert finders. Let's shortly describe them.

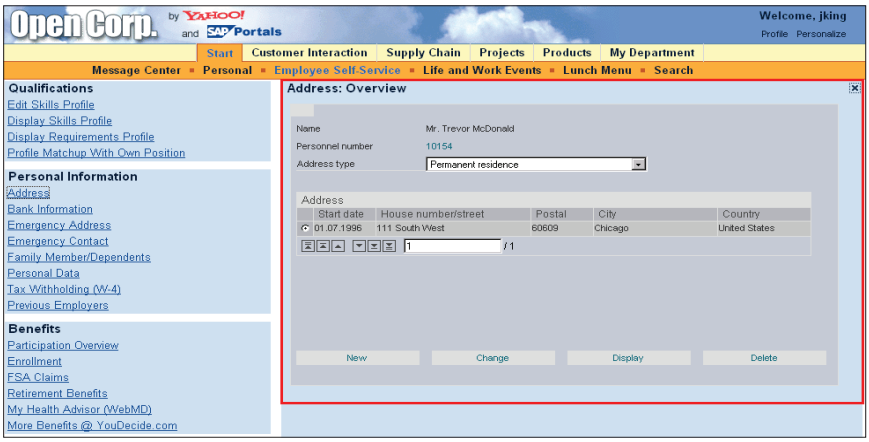
ESS are portal-driven solutions created to ensure comprehensive and controlled employee access to internal or external information and applications. Employee satisfaction and dramatic reduction in transaction cycle time over HC services are proven benefits in using this tool, typically integrated within HR ERP application.

ESS Portal solutions are in the "*grow the business*" category. Business *risks* are moderate and *reward* is, typically, *moderate.*

MSS technology and purpose is of the same nature as ESS. The only difference is in the nature of the type of applications that are relevant to this type of employee's role within the organization. Managers require a single access point to information, otherwise disseminated throughout the organization. They manage people, budgets and

Figure 5. Generic structure of ESS portal implementation

Figure 6. Example of a real ESS



groups assigned responsibilities in an effective, proactive way.

Again, MSS solutions are in the "*grow the business*" category. Business *risks* are moderate and *reward* is, typically, *moderate.*

Workflow represents a highly critical enabling technology to automate HR processes, thus critical too for comprehensive CM deployment policies: workflow replaces paper notifications with *messages notification*, *routing*, and *approval.*

Workflow servers solutions are mostly *discretionary enhancements* within the "*grow the business*" category, creating new levels of process efficiency and effectiveness (or process agility). Business *risks* and *reward* are, typically, *moderate*.

Expert finders are Web-based tools typically found in integrated ERP HC solutions used to provide the means to find and locate employees having specific knowledge or competency profile ("*who is who*"-type of approach) and, finally, ensure contact with the expert for the required period of time. Usually works tie to the workflow server functionality.

Expert finders solutions are considered discretionary enhancements within the "*grow the business*" category. Business risks and reward are typically moderate.

HUMAN RESOURCES MANAGEMENT PROCESSES

The foremost trend in information systems restructuring in recent years is process-based working. This approach enhances knowledge development and sharing, forcing IT professionals and business decision makers to collaborate and share information concerning IT and business trends. Successful corporate e-business transformation initiatives necessarily incorporate process improvement and transformation. Process understanding provides the bridge between corporate strategy and IT implementation.

CM software technology is no exception to this reality. As indicated in the introduction, CM market analysis requires a comprehensive approach within the HC domain. This brings about an excellent opportunity to critique and model value delivery mechanisms, thus clarifying business relationships.

In today's advanced organisations, *a process* is defined as a "set of activities directed to obtain a service or a product that creates value to the client." Although human capital management fits into the corporate management support domain functions (same as financials, planning, etc.), the same definition applies. Competency management

is the cornerstone in this proposed client-oriented process approach: People drive results.

The following is a generic level 1 definition of all relevant industry-accepted HC management processes representing the framework in which CM software is deployed. Best-process practices indicators are proposed, as well as information concerning the most significant internal and external application inter-relationships.

This framework will facilitate the understanding of the competency management business "ecosystem." Some HR management processes are very much tied to CM strategy deployment, and others are not. This comprehensive view will have significant value to further evaluate and assess the various software system architectures and market products available against the People CMM model.

Persons Administration and Payroll

Payroll processing represents the primary HR automated function in most organizations. It ensures that the workforce gets accurately paid on time. Critical activities are usually linked to specific country regulatory requirements, the amount and structure of labour-related accounting models to consider, and other specific reconcilement tasks.

Best practices key process indicators in this area are the following:

- Employee's administration and information flow is integrated within HR or global corporate ERP.
- Administrative tasks are performed using ESS methods, implementing portal/intranet-driven solutions and workflow technologies.

The Process Reference Model for Payroll & Administration is shown in Table 1.

The internal and external process relationship is shown in Figure 7.

The external-related applications are financials, ESS, travel management, and CRM (to directly manage incentives typically associated to sales or commercial goals).

Time and Attendance Management

In the context of knowledge persons management, TM (time control of employee time) is not a high-priority process and often deployed to a very limited extend. See Table 2.

Figure 8 shows internal and external process relationships.

The only significant interface to consider here is with any clock-in system (when required). Notifications are often made via ESS or simple workflow dialogs with authorising persons.

Best practices key process indicators in this area are the following:

- Presence control management integrated within HR or global corporate ERP.
- Decentralization of absence and time off registry.
- Absence/permit and vacation request approvals flow is fully automated.

ORGANIZATIONAL DEVELOPMENT AND CHARTING

Structure management is often a centralized process that creates, organizes, and manage organizational directory information. See Table 3.

Figure 9 shows the internal and external process relationships.

Best practices key process indicators:

- Structure definition and job description information processed within HR or global corporate ERP.
- Decentralization of organizational changes across corporation.

Table 1. Process reference model for payroll & administration

Activity	Name	Description
PA_01	Employee data maintenance	Workforce data and changes in employee status, relevant to payroll, are introduced in HR system. Sometimes, employee time reporting is the front end of payroll overall process.
PA_02	Payroll process	Taking into account monthly changes, backdate payment rules, corporate and country regulatory requirements, gross and net earnings, and deductions are calculated.
PA_03	Checking of calculated results	Post-payroll process report writing is made to check possible errors prior to HR results formal approval, prior to post-information further processing.
PA_04	Individual payroll forms generation	Payroll forms are generated and made available to employees in printed or electronic format for individual ESS access.
PA_05	Legal Social Security report generation	Adequate automated monthly files (FAN type or other) are generated, together with established payment forms (TC1s)
PA_06	Tax reports generation	According to company type and local regulations, adequate report (i.e. 110, 111, 190) is periodically generated. Earning and retention information is prepared for personal direct consultation (vía ESS).
PA_07	Social benefits information delivery	System interfaces with agreed social benefit provision companies
PA_08	Prepare bank transfer files	Files generated for bank use with net earning to be transferred to employee's account.
PA_09	Accounting File generation	As agreed with the financial department for accounting processing (general ledger, etc.)

- Change organization approval process is managed using workflow mechanisms via ESS/Intranet.

WORKFORCE PLANNING AND ANALYTICS

HR requires automated processes to evaluate generic and specific income change proposals, benefits, or any other HR cost-related issue that may be considered. Simulation and analytical tools are essential to assume control of present and future HR budget responsibilities. See Table 4.

Figure 10 shows the internal and external process relationships.

Best practices key process indicators:

- Organization HR budget calculated through HR or global corporate ERP.
- Full integration with payroll and payroll simulation and analysis.
- Full integration with the organization module (to simulate organisational changes).
- Automated budgetary analysis and measurements, identifying unusual patterns in data through technologies such as data mining and understanding correlations between measurements.

Figure 7. Internal and external process relationships

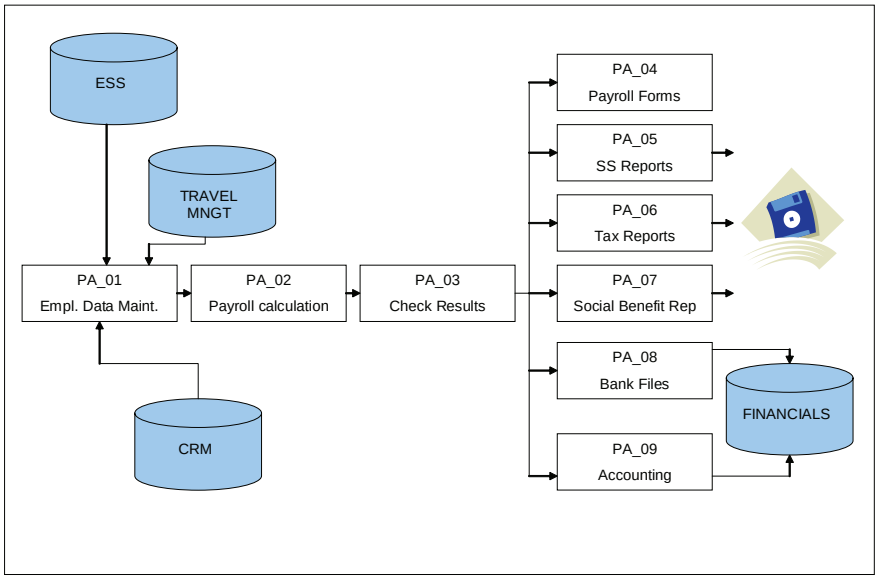


Table 2. Process reference model for time and attendance management

Activity	Name	Description
TM_01	Time schedule definition	Relevant labour calendar information is prepared: work hours, flexible schedules, and so forth. Relevant only if clock in control is in place.
TM_02	Time off request	Applicable to vacation periods or special permits.
TM_03	Time off authorisation	Authorise or reject employee request and inform HR department.
TM_04	Collect clock-in data	Exit and entry information is registered by external clock-in device, located in work premises.
TM_05	Identify deviations	Based upon calendar and work hours information, a contrast task is performed with clock-in data in order to identify eventual deviations.
TM_06	Deviations justifications	The employee justifies detected work absence, then approved or rejected by superior.
TM_07	Registry of time incidences	Time off accruals, vacation, sick leave type of information for HR information and management.
TM_08	Inform payroll	Only the payroll-relevant information is transferred for adequate processing.
TM_09	Statistics	Periodically, HR obtains statistic information to be delivered to employees via ESS.

COMPETENCY MANAGEMENT

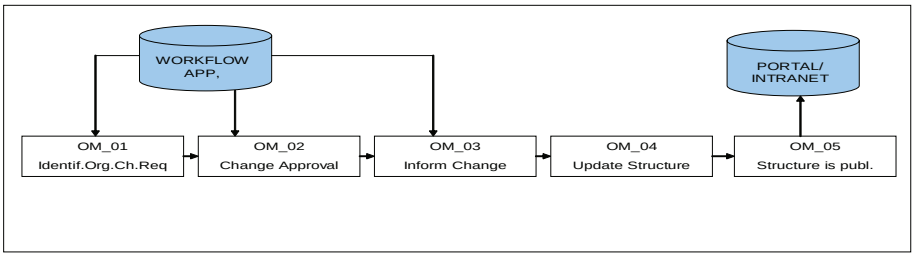
CM processes flow across organizational divisions and units as the most challenging practice in workforce management activities.

Managing knowledge assets like managerial behaviours, problem-solving skills, and so forth is somehow different than managing physical assets. The ultimate CM process goal is to provide the means to ensure *continuous development* of

Table 3. Process reference model for organizational development and charting

Activity	Name	Description
OM_01	Identify organisation change request	Every year each department performs a business strategic and functional review identifying recommended changes as business develops. Structure updates proposals are then submitted for approval.
OM_02	Change request approval	Change proposal is aggregated at organisation department level, then approved by board of directors.
OM_03	Inform on change to HR	Once new structure has been approved (includes new assignments, positions, etc.) HR assumes control to update organisation-dependent information.
OM_04	Update structure	Updating structure often requires changes in HR master data and cost centres allocation.
OM_05	New structure is made public	Internally (via B2E mechanisms) and externally if required. Quality assurance manuals also updated.

Figure 9. Internal and external process relationships



employees and organizations' competencies. It implies **observing** them through behaviour, **assessing** them according to organizations' defined values, and permanently **improving** them.

Competencies are usually linked to career planning, so employees permanently have a view of the potential career paths they are offered by the organization.

CM strategies are as good or effective as the information available. Even though CM is about managing intangibles, without the right information measuring or predicting how employees or the organization will be affected is just hit or miss. See Table 5.

Figure 10 shows the internal and external process relationships.

Best practices key process indicators:

- Corporate competency catalogue defined within HR or global corporate ERP.
- Integration with all relevant applications, supporting HR processes.
- Automated gap analysis process, matching employee profile with profile required.
- Competency profile information through B2E communication-based links.

EMPLOYEE RECRUITMENT

Even though procedures vary from one region and organization to another, the process is driven to ensure the best tracking of applicants (internal or external to organization), based upon skills and competencies to match into the required job profiles. See Table 6.

Figure 6 shows internal and external process relationships.

Figure 10. Internal and external process relationships

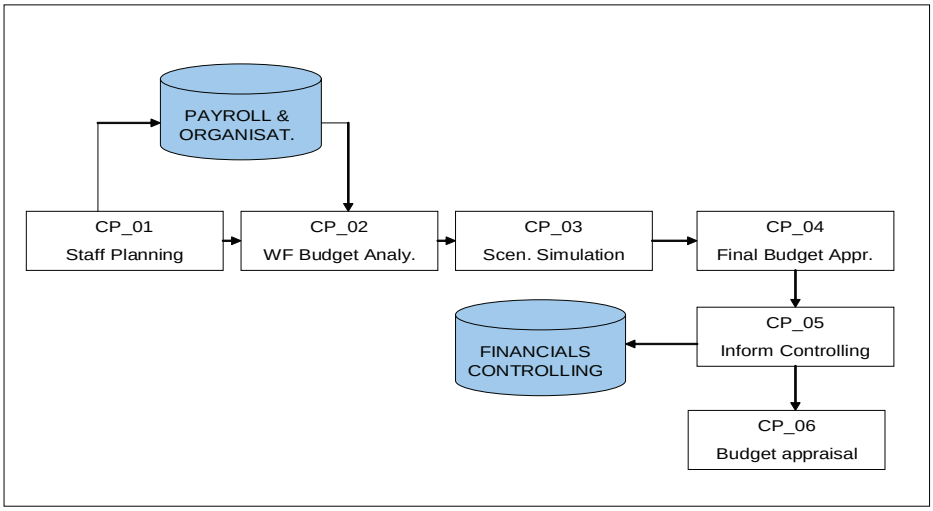


Table 4. Process reference model for workforce planning analytics

Activity	Name	Description
CP_01	Staff planning	Departments and business unit staff requirements and status requirements are processed. Aggregated information is then validated and budgeted.
CP_02	Actual cost evaluation	Current payroll cost is used to estimate cost for next period. Planned staff increase cost is estimated based upon current figures.
CP_03	Workforce budget analysis	Payroll cost models are simulated based upon previous calculations. Cost and budget effects due to organizational changes, new statutory requirements, or updated payroll and benefits configurations are simulated.
CP_04	Final configuration approval	Final proposal is approved and submitted to management committee.
CP_05	Accounting control is updated	New approved budget is incorporated in accounting.
CP_06	Budget appraisal	Permanent budget appraisal.

Best practices key process indicators:

- Recruitment process supported by HR or global corporate ERP.
- Full integration with administration application.
- Automated CV information data registry (through B2E).
- Automated mail service.

TRAINING

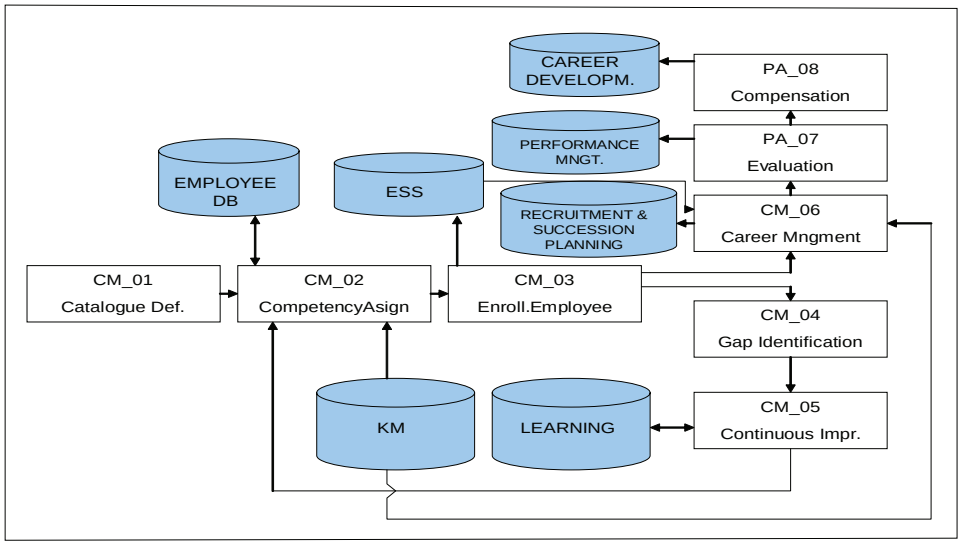
This process helps managers to evaluate and plan organization's training requirements and events. Information is processed on prerequisites, objectives, content, schedules, and locations, as well as appraisal course's results and additional management required data. See Table 7.

Figure 7 shows internal and external process relationships.

Table 5. Process reference model for CM

Activity	Name	Description
CM_01	Catalogue definition	Core and other required competencies, plus proficiency level required for each job profile within the organisation, are established and catalogued as a corporate dictionary.
CM_02	Competency assignment	Once competencies are assumed by management, an assessment process defines procedures and level-assignment rules. Competencies are then matched to employees. This is often a time- and cost-consuming non-automated set of activities.
CM_03	Employee enrollment	Individual employees may leverage competency and potential career paths within organization.
CM_04	Competency gap identification	Gap between competency level definition and employee status is identified. This information is the basis for employee continuous improvement process, usually linked to CM.
CM_05	Employee-continuous improvement activities	Individual person's development is supported in learning (e-learning) programs, providing the means to develop required competencies.
CM_06	Career management	Supported on KM information and individual development, "profiles" matching job vacancies are identified within organizational scope. Succession planning information is analysed.
CM_07	Performance evaluation	Continuous matching employee-assigned business objectives with actual performance based upon the CM model. Evaluation information is created, then managed by HR evaluation process.
CM_08	Compensation	Individual salary and benefits compensation is triggered by evaluation, thus closing the periodically updated employee development cycle.

Figure 11. Internal and external process relationships



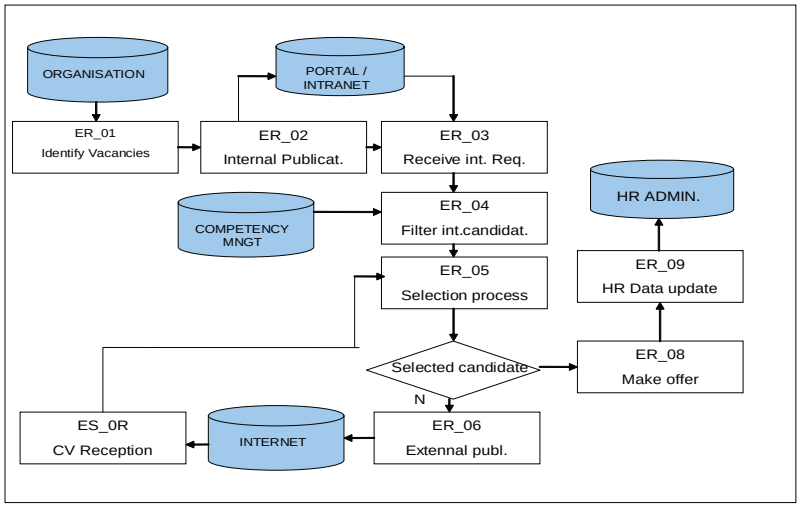
Best practice's key process indicators:

- Training management supported by HR or global corporate ERP.
- E-learning integration within ERP.
- Integration with other related ERP processes.
- Automated mail service activities required to manage training courses.

Table 6. Process reference model for employee recruitment

Activity	Name	Description
ER_01	Vacancies identification	Next-period strategic HR planning is taken as input information to identify vacancies to be assigned.
ER_02	Organization internal publication	Required position and expected candidate profile are made public within organization.
ER_03	Internal candidates reception	CV is usually updated by employee prior to candidature submission.
ER_04	Internal candidates filtering	HR analyses candidatures and filters position profile compatibility against candidate profile.
ER_05	Selection tests	HR and required technical and managerial personnel are involved during the selection process. Tests are designed in accordance to position. Technical knowledge and person's profile suitability tests are executed.
ER_06	External recruitment	Applies when no internal candidate gets position assignment. Scheduling.
ER_07	Prequalification and CV's reception	The selection application inputs candidates' information for further assessment and tracking.
ER_08	Recruitment proposal	Selected candidate receives notification and formal offer to accept position.
ER_09	HR administration incorporates selected candidate information	Once formal offer is accepted, starting work date is fixed. Organization-required administrative information is entered and legal employment agreement is created.

Figure 12. Internal and external process relationships



EMPLOYEE'S CAREER DEVELOPMENT

This process creates a roadmap for success, determining future development activities. With CM, focus is made on high-potential employees and leadership-oriented careers.

Figure 8 shows internal and external process relationships.

Best practices key process indicators:

- Employee's development plans defined in HR or global corporate ERP.
- Individual development initiatives managed from ERP results registry .
- HR ERP integration with other relevant processes.
- Employee's potential and preferences registered in ERP.

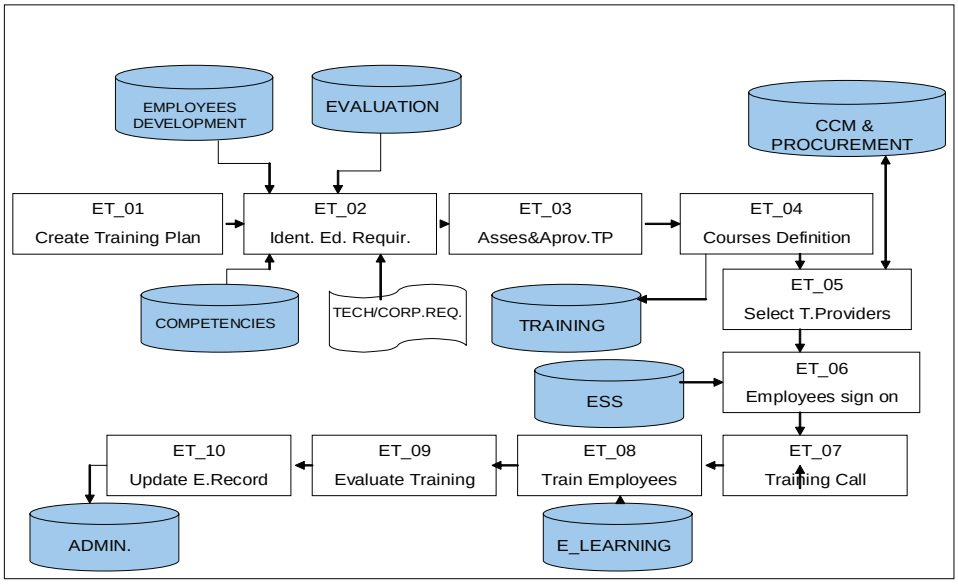
PERFORMANCE MANAGEMENT

Associated to any CM strategy, organizations require employees' daily execution to be aligned to corporate strategy, committed to achieve measurable business results. HR focus is on skills

Table 7. Process reference model for training

Activity	Name	Description
ET_01	Create training plan	A training plan is established every business year. It includes all educational methodologies applied within the organization and is finally approved by executive committee.
ET_02	Identify education requirements	Following inputs are considered: Business units plans. Cross-organization corporate initiatives. Training topics generated by management, derived from evaluation results. HR corporate-defined improvement needs.
ET_03	Training plan assessment and approval	Executive committee approves plan and budget.
ET_04	Courses & training units definition	According to budget, priority, and expected employee usage.
ET_05	Select training and education providers	Internal and external providers, content and methodology evaluation against organization requirements, and cost and budget negotiations through established business-to-business commerce chain management procurement process.
ET_06	Assign employees to training units	Assignment is based upon profiles. E-learning initiatives are usually managed by organization based upon employee's self-initiative.
ET_07	Training call	Arrangements are made according to employees' job schedules, presence, or distant learning method used, instructors' and logistics availability.
ET_08	Perform training	In accordance with plan. HR receives assistance and evaluation report.
ET_09	Training evaluation	Following aspects are evaluated: Quality: content, instructor (by attendance). Student's attitude, knowledge acquisition (by tutor/teacher). Employee contribution to business (after training).
ET_10	Update employee competency record	By HR and management, after complete evaluation.

Figure 13. Internal and external process relationships



tracking, targeting leadership and high-potential employees. It includes skills and competency personal assessment, and, sometimes, 360-degree type of evaluations and feedback.

Best practices key process indicators:

- Evaluation definition and results registry defined in HR or global corporate ERP.
- Individual self-evaluation made via ESS and workflow-based approval process.
- Integration with other relevant ERP modules.

COMPENSATION AND INCENTIVE MANAGEMENT

Compensation is critical to fix adequate wage structures within the organization. Incentive management is required to manage employees' variable retribution and benefits. Complexity varies according to extent and type of benefits (pension plans, private medical services, insurances, etc.). Usually third-party required information tracking and reports are used. Best practices key process indicators:

- ERP-based variable retribution, calculated for employee evaluation.
- ERP-based market salary survey.

Market Applications: The CM Contribution

HCMS is considered today a mature market for the IT industry. Although the administrative, transaction-based type of applications have very limited growth potential (only outsourcing, hosted services in small and medium size business), the strategic talent management-type of applications, driven primarily by *competency management* business interest, is on the rise.

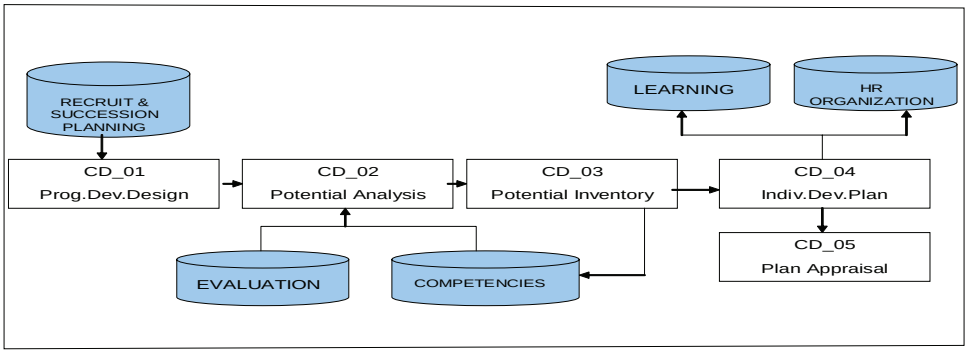
Similarly to other enterprise-wide applications, where process integration becomes essential, the vast majority of medium to large organizations are now automating HC process in one out of three products: SAP, PeopleSoft, or Oracle, and two companies, because Oracle finally acquired PeopleSoft during 2005. Around 40% of the worldwide HCM market is concentrated in these two companies.

This merger and acquisition wave is not an isolated exception (Adonix acquired Meta4, Cy-

Table 8. Process reference model for employee's career development

Activity	Name	Description
CD_01	Career development plan design	Based upon employee's potential and strategic HR CM development objectives (includes target employees segment, criteria to identify potential, application period, etc.). Succession planning information is filtered.
CD_02	Employee potential analysis	Following actions are taken: Identify employees matching profile employee appraisal.
CD_03	Employee's potential inventory	Update HR master employee data with employee's information to ensure that opportunities are considered: job vacancy opportunities, special task assignments, and so forth.
CD_04	Generate personalized development plans	Individual career plans for competency development. Usually based upon employee performance evaluation, training opportunities, special task assignments, etc.
CD_05	Development's plan appraisal	Periodic checks to confirm suitability and compliance to organization's business objectives.

Figure 14. Internal and external process relationships:



borg merged with HR Services, Infinium with SSA, etc.). Microsoft (the world's leading IT corporation but still not an important player in HCMS) and SAP announced merging conversations last year.

Best-of-breed products' previous business preferences are now swiftly moving to the ERP (trough acquisitions). Market fragmentation in HC management is therefore ending, and many small, single-function-oriented products are being incorporated in ERP suites or just disappearing. Maybe the LMS market is the exception to the rule, with an approximately 15% growth expectation in a $450M world market (2005).

It is quite difficult to quantify which percentage of the global HCMS market corresponds just to CM processes. Most organizations enter ERP-based solutions (acquiring licences), automating just part of the functionality. Usually, deployment corresponds to most critical business functionality, with limited CM process automation. Companies invest in ERP suite licences and deploy functionality over the years with the confidence that the ERP vendor will ensure a long process integration.

Worldwide HRMS and payroll administration revenues in 2004 reached around 3.900 M de € with an estimated growth rate for 2005 of 7%. About 30% of the revenue corresponds to payroll and 70% to HR management processes. This survey assumes that, although not all product licences are devoted to comprehensive compe-

Table 9. Process reference model for employee's performance management

Activity	Name	Description
EV_01	Competencies and business objectives definition	Frequently mix of global, business unit, and personal objectives plus competencies and shared values.
EV_02	Self-evaluation	According to person's perceived achievement.
EV_03	Formal evaluation	Performed by management, and employee agrees.
EV_04	Formal approval	HR validates and ensures organization's coherence.
EV_05	Results analysis	Information is obtained to shape next period's educational requirements and assigns variable benefits.

Figure 15. Internal and external process relationships

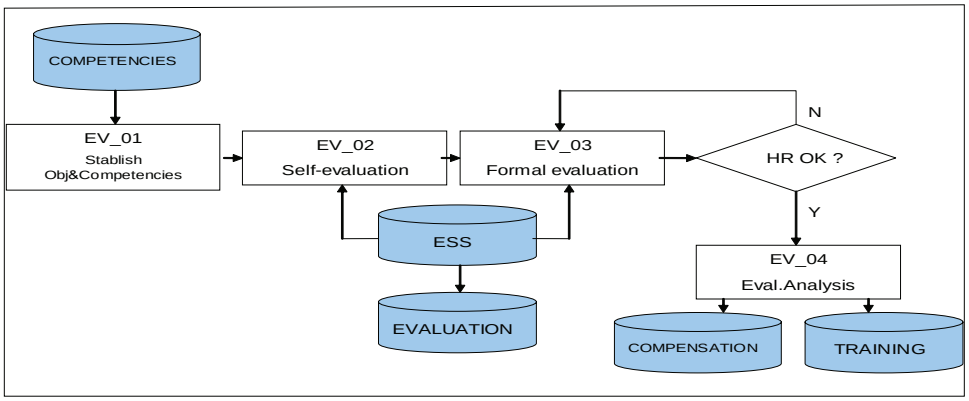


Table 10. Process reference model for employee's compensation and incentive management

Activity	Name	Description
CO_01	Compensation plan	Plan is established according to strategic retribution policy, considering internal and market reference information.
CO_02	Evaluation results analysis	Competency development and business objectives and accomplishments are evaluated.
CO_03	Compensation schema elaboration and review	Based upon results and time schedule to be applied to individuals. HR approves and submit schema for approval.
CO_04	Management approval	Management board approves final plan.

Figure 16. Internal and external process relationships

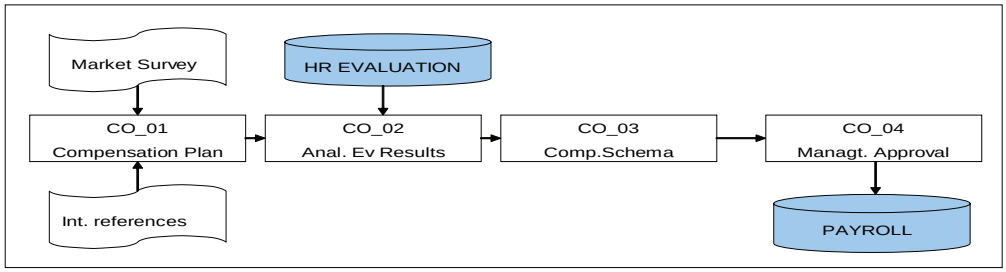

Figure 17. Best practice cost distribution for competency management

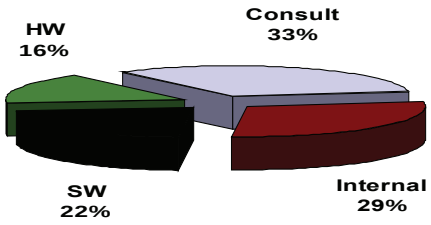
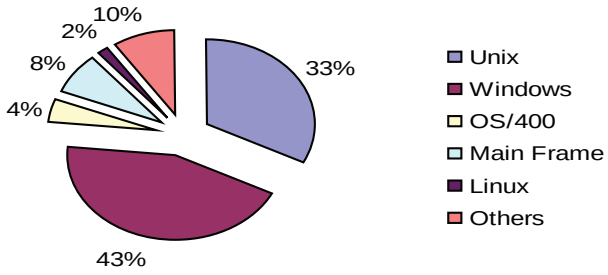


Concept	*%*	*Ratio*
Consultancy & Engineering	33%	1,50
Product Licences	22%	1,00
Hardware	16%	0,73

Figure 18. OS Environments in CM Implementations (2005)



tency management deployment strategies, about 40% ($1,300 M) is the market size for HC direct CM-related process.

The estimated figures reported in this study refer only to product licence fees and maintenance costs. Consultancy and implementation engineering costs are not included. In order to obtain overall comprehensive IT-related cost distribution statistics, the following experience-based statistics method may be applied:

Figure 17 shows current OS environment usage for CM-related solutions. Trends indicate a significant increase of Windows 32 and 64b. and reductions in AS400, others, and mainframe environments.

Figure 18 shows that, for each Euro spent in the software product licence, 1.5 Euros are spent on consultancy and engineering services and 0.73 Euros in hardware.

Technical Architecture Reference Characteristics

The next point in this survey shows a generic evaluation model used to asses IT and HR business specialists in selecting the most adequate technology to deploy a competency management strategy in any medium- to large-size organization. As we will see later on, the product's technical architecture is an important issue in this process.

This section depicts the technical architecture to be considered as a reference in CM strategy deployments.

Which are the relevant aspects define a good (or poor) technical architecture?

- Quickly and flexibly.
- Facilitating the introduction of new performance and scalability mechanisms.
- In a true multi-tiered approach, using comprehensive standards-based interfaces:

The client side is basically a user terminal (Web browser, PDA, etc.). Technologies: HTML, JavaScript, WML, Servlets, JSP, and so forth.

The Server side consist on the Server elements, as a Web or WAP Server, that send information to the User Terminal.

The business logic is the core application intelligence that makes the CM logic possible (application server with Java support, EJBs, servlets, etc.).

Data Logic is responsible for data storage and transactional services (DBMS, etc.).

Enhancing SW reusability and development skills specialisation, using component-based software.

Competency Management Market Products

Product solutions vendors that automate CM processes fall in one of these four categories:

- Large integrated ERP suites: These vendors dominate the high-end HCMS market; also competitive in SME Markets. Organizations select these solutions usually to automate more than one corporate business processes (in the areas of financials, CRM, HC management, e-procurement, etc.). Even recognising that these vendors do not always deliver the best solution for any given particular function, their value proposition is founded on *process integration* and *proven, reliable comprehensive process automation*. Most market CM strategy deployment demand comes from large-size organizations to an extent that in the coming years, CM may be considered the most relevant *business driver* that will facilitate HCM market growth.
- SME integrated ERP suites: Similar functional scope to previous high-end ERPs with simpler parametrization options, much faster to deploy, *tailored to SME-type organizations.*
- Standalone HCMS: Large- and SME-driven solutions from vendors exclusively dedicated to payroll & HCMS, not providing support for other corporate business processes (as

Figure 19. Deliver Comprehensive E-Business functionality, across and between Multiple cChannels

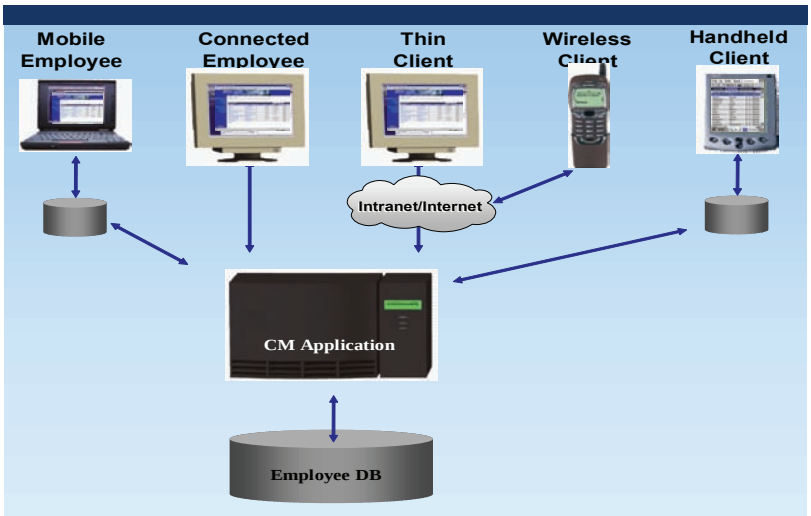


Figure 20. CM Development Architecture

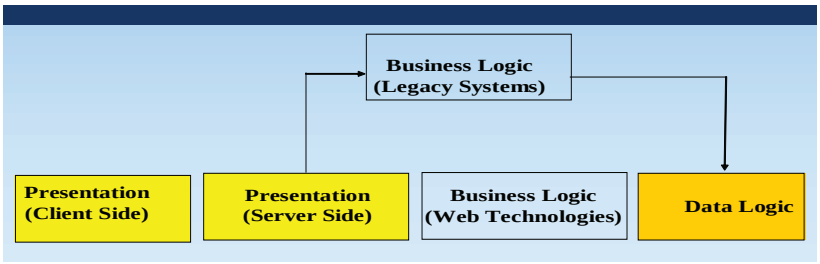

supply chain management, CRM, financials, etc).

- Standalone CM solutions: They automate CM processes, sometimes in combination with performance management and eventually providing support for some other related CM process, in a non-comprehensive, integrated way.

The following part of this chapter shows for each CM product-type category previously indicated, IT- and business-relevant vendor information, evaluating their product offering according to the next proposed evaluation method. Some additional markets are based on four evaluation criteria, as indicated hereafter:

CONCLUSIONS AND OUTLOOK

Following are the most relevant market conclusions and outlook uncovered in this survey:

- HCM and CM application market scope is strong, clearly on the rise. Organizations have to adapt fast to changing, unstable business conditions in a way that CM paper and spreadsheet manual-based processes will have to evolve to a much more flexible, automated employee management-type practice.
- Market preference for ERP-integrated CM solutions instead of best-of-breed standalone products will continue in the future. ERP integration ensures that HR and business managers can efficiently align, measure, and automate individual employee competencies and organizational goals and objectives.
- In this context, IT managers estimate that the integration value provided by global ERP suites far exceeds the benefit of using best-of-breed solutions for each HC business function. The e-business technological transformation and the processes model depicted in this survey clearly show the inter processes and software dependencies required in CM deployment strategies.
- And again, the fact that the trend has been widely adopted creates additional confidence in large vendors' ability to deliver HC-proven process automation. This loop affects CM implementations, where process automation is critical. In some particular CM tasks (like competency assessment), process efficiency, when adopting a stand-alone option, increases fairly moderately compared to the asset they replace. This situation also increases pressure in IT managers to adopt the comprehensive, integrated ERP suite way.
- Large, multinational companies require comprehensive multi-region, often centralized, HC deployment solutions. Global processes and local country localizations makes the three large ERP solutions analysed in this survey the strongest CM option in the future for this type of organization, thus

Table 11.

Evaluation Criteria	Key Factors	Description
COMPANY	Financial stability strategy and vision Partners and alliances Research and development Professional services	Vendors with high potential to survive in the IT market and strong product maintenance and support are highly rated.
MARKET PRESENCE	Product current and previous versions References CM functionality references	Evaluate product stability, installed base and market credentials in previous implementations.
FUNCTIONALITY	Competencies definition Competencies diagnosis Competencies development Competencies monitoring Rest of CM-, HC-related processes	Matching of vendor product standard functionality vs. organizational requirements in current needs and expected required support in the future.
PRODUCT TECHNOLOGY	Technical architecture E-business support Flexibility Integration facilities with required organizations Applications Security compliance	Although e-business engineering practices are widely used, product architecture, scalability, and configuration remain an important differentiator.

displacing fragmented solutions.

- Small and mid-size organizations (less than 4,000 employees) and large, single-country type installations have many more options. According to required functionality, together with associated licence and engineering costs, they may select in the high-end or mid-market type of products, thus accessing a wider menu of options.
- Hosting and outsourcing HRMS services keep growing at a fast pace, particularly in small- to medium-size market companies. This trend represents an intelligent business option for small best-of-breed vendors, having experienced competency assessment experts and staff (apart from being acquired or just disappearing). Some product vendors, apart from the traditional, large-size HRMS service providers (i.e., ADP), are successfully, adopting this delivery model(i.e., Ultimate Software, Ceridian, etc.).

Table 12. Large Integrated ERP Suites Software Products

SAP AG

Evaluation Criteria	Considerations
COMPANY	SAP AG (Waldorf, Germany) is the world's third-largest independent SW company, devoted to enterprise management, and is the world's leading ERP vendor. More than 28,000 clients, 1,500 partners, and 34,000 employees with local support in more than 50 countries. World's leading vendor in combined administration and HC management, with a 650 M € year revenue (2004), second in HC management (560 M €), close behind PeopleSoft, although No. 1 in Europe.
MARKET PRESENCE	SAP started in the 1970s with the first market product to automate financial applications (R/1). Evolution from the first R/1 installations to the present's comprehensive corporate processes (financials, HCMS, CRM, SCM, e-procurement, business warehouse, portals, etc.), applications under R/3, in which HC and CM solutions are integrated, is a history of sound evolution, incorporating worldwide process excellence and real customer migration support in an all-new product version (currently, once a year).
FUNCTIONALITY	All CM-related processes identified in this survey are included in the integrated, SAP R/3 Solution. Its international focus has ensured extensive local regulatory worldwide support for administrative functions (i.e., payroll). Some processes remain rigid to implement (compensation, benefits) compared with best-of-breed solutions, but overall CM associated functionality rating is very good.
PRODUCT TECHNOLOGY	SAP NetWeaver's architectural design comes from a rigid client-server Model, supported on a vendor's proprietary environment (ABAP). Product evolution in the last three years offers a reasonable Java support and interoperability with .NET and IBM WebSphere (J2EE). Development, deployment and execution environments run on its own SAP Web Application Server (WAS), providing combined ABAP, J2EE, and Web services support.

Table 12. Continued

PeopleSoft

Evaluation Criteria	Considerations
COMPANY	Acquired by Oracle in 2005, world's second-largest independent SW company (See Oracle, next company).
MARKET PRESENCE	PeopleSoft's roots within the enterprise management business are in HR, then extended to financials, SCM, CRM, and e-commerce applications. Leader in the US, far behind in European sales due to SAP's dominance and lateness in incorporating country-required regulations in HHRR administrative and payroll processes in some countries.
FUNCTIONALITY	PeopleSoft Enterprise suite **represents the most advanced, integrated process automation solution for HC management on the market**. Last product versions have introduced enhancements in CM management and workforce analytics, integrating financial, transactional HR, and external market data to provide strategic performance management. Workforce rewards manages compensation and retention policies. PeopleSoft's own Balance Scorecard is effectively used to manage HR effectiveness under workforce scorecard module.
PRODUCT TECHNOLOGY	PeopleSoft architecture is a very flexible combination of database, application, Web, and file Server, fully e-business compliant. The PeopleTools Application Server runs the business logic and facilitates access to most client types, using the Internet architecture and allowing interfaces to visual basic-visual C-based user programs.

Table 12. Continued

Oracle

Evaluation Criteria	Considerations
COMPANY	Oracle is the world's second-largest independent SW company. The combined Oracle + PeopleSoft + JDEdwards (previously acquired by PeopleSoft) has made Oracle the world's second-largest business application vendor (behind SAP) with an estimated annual revenue (fiscal year 2004) in this business of 450 M €, and first vendor in HC and competency management-related solutions, largely because of PeopleSoft enterprise market share. Extensive global partner support and country-assigned services in most locations.
MARKET PRESENCE	Oracle's HCMS has 3,000-plus installations in more than 80 countries.
FUNCTIONALITY	Full HCMS process support as part of e-business suite, integrated suite; includes all required functionality to deploy CM-related strategies. Its *Daily Business Intelligence* supports excellent HC analytical service. Performance, compensation, and e-learning management are excellent and efficient CM-related modules.
PRODUCT TECHNOLOGY	Oracle has now three independent suites to manage: its original ERP, PeopleSoft Enterprise, and JD Edwards' Enterprise One/World. The biggest challenge for Oracle is to ensure a product strategy that combines strengths from all different products, delivering customers a reliable and affordable evolutionary roadmap from its current products' diversity. During the next two to three years, it is expected that Fusion Oracle's applications will incorporate many of the current features from PeopleSoft Enterprise.

Table 12. Continued

Lawson Software

Evaluation Criteria	Considerations
COMPANY	Started operations in the U.S. in 1975 in the corporate analytics and management applications market to become a global ERP solution provider, with particular focus on financials, HR, and procurement. Its business growth strategy has been based on best-of-breed product acquisitions (Account4, ijob, Armature, etc.) and most recently (June 2005), Intentia (Swedish leading SW company, small-size organizations ERP vendor), to create a 3,500-employee company, with 4,000 customers distributed in 40 countries. Large U.S. technology partners list but lacks international, long-term local support and consulting partners outside U.S. Lawson software sales in HC- and CM-related business reached 44 M € in 2005 with financial growth difficulties in last three years.
MARKET PRESENCE	Until recently, business was focused in the United States, Canada, and the U.K. markets. Once merging with Intentia concludes sometime next year, more European technical support may be expected. Product stability and roadmap evolution needs to be ensured in following years.
FUNCTIONALITY	Offers HR suite as part of Lawson. Insight series application includes some CM-type functionality within its personnel administration module but lacks a comprehensive CM functionality (poor performance management, no e-learning part). Strong workforce analytics that compare internal metrics with external sources (provided by Saratoga) in areas such as compensation, staffing, and organizational effectiveness.
PRODUCT TECHNOLOGY	E-business compliant, Web-based architecture, with interesting software extension tools to facilitate integration with other applications (business component integrator).

Table 13. SME-Integrated Suites

Northgate Information Solutions

Evaluation Criteria	Considerations
COMPANY	U.K.-based software applications and outsourcing services vendor. Created in 1969, has become leading U.K. HR and payroll supplier in the U.K. trough, small and leading state-of-the-art companies (Prolog, PWA, CaraPeople, Rebus HR Group). Apart from HR, includes SME-driven, ERP-type solutions for financials and CRM. Currently employs 3,300 people, having 5,000-plus SME clients, 58 M € revenue in HC management, mainly in the U.K.; presence in the U.S., Australia, and New Zealand.
MARKET PRESENCE	In the U.K., long history of success in SME organizations, offering comprehensive product licence sales, engineering, and outsourcing services.
FUNCTIONALITY	It offers wide functionality in HR, starting with basic processes and product-based automation. Usually requires extensive specific software development, particularly in areas as workforce management. Includes recruitment, training, benefits, and ESS-type access. Most CM implementation requires product made to measure changes integration with external applications.
PRODUCT TECHNOLOGY	Open, scalable, Web-based, non-integrated, standard ERP-type of architecture.

Table 13. Continued

Microsoft Business Solutions

Evaluation Criteria	Considerations
COMPANY	Microsoft is the world's largest SW company, providing products and services to individuals and organizations around the globe. Its business solutions division (Microsoft Dynamics) is an international provider of integrated solutions for most SME functional areas. Microsoft entered the ERP market through acquisition of small leading market vendors (Great Plains, Solomon Applications, Navision, etc.). The most significant ones in HRMS are Navision and Axapta, the latest one incorporating an advanced competency management solution for SME.
MARKET PRESENCE	Microsoft's market share in HCMS is low (30 M €, representing just a mere 1.3 % of the world's market) in relation to company profile and business market size, mainly because of current SME-driven strategy, until now. In this segment, implementations history is consistent with good customer references, although each product within the family (Axapta, Navision, Great Plains) follows individual development road maps.
FUNCTIONALITY	Microsoft Axapta is easy to implement and operate with integrated HCMS (plus financials, CRM, project management, etc.) in SME-type organizations. Excellent CM functionality, driven to detect training requirements among individual employees, as well as career plans and organizations' re-structuring functions.
PRODUCT TECHNOLOGY	Open, scalable Web-based architecture .NET and Java, e-business-compliant solutions.

Table 14. Standalone HRMS Products

Kronos

Evaluation Criteria	Considerations
COMPANY	Kronos incorporated began operations in 1977 as a hardware time-clock vendor and has successfully evolved into an HR payroll and management company, reaching $519 M in sales in fiscal year 2005. **It's the world's third-largest vendor in HC management** (first non-global ERP provider), just behind SAP and Oracle, with total 2004 sales of 210M €. About 2,900 employees, offering comprehensive licences sales, consulting, implementation and learning services around the company's HR products. Included in Forbes' "200 Best Small Companies."
MARKET PRESENCE	An excellent record of customer retention through service satisfaction, combined with visionary product evolution from a hardware to the most dynamic software HC management business, sometimes by acquisitions (i.e., AdOpt, excellent workforce planning module). Business focus is driven primarily to the U.S., and some customers are in Canada and U.K.
FUNCTIONALITY	Kronos offers a comprehensive HR administration and management solution for SME and some large-size organizations, including most relevant CM-related processes. Probably the most successful WF management solution in the U.S. market. Its workforce central suite includes core CM functionality. Focus in aligning skills and competencies to corporate objectives, tracking skills, and certifications, and competency enhancements trough training initiatives.
PRODUCT TECHNOLOGY	Open, scalable Web-based architecture. Deploy Java applets to facilitate dynamic user interfaces, as well as HTML access.

Table 14. Continued

Meta4

Evaluation Criteria	Considerations
COMPANY	Spanish-based company, founded in 1991, acquired by Adonix in November 2004, strengthening previous company's financial situation and clearing future market development. In November 2005, the Sage Group Plc announced the acquisition of Adonix under an operation that explicitly excludes the business of Meta4 (leaving control of French entrepreneur Emile Hamou).
MARKET PRESENCE	Large and medium-size extensive customer list (1000-plus) in 20 countries. Leading HC, CM market product in Spain with a strong competitive position in other European markets (France, Portugal, U.K.) and South America, with implementations in large as well as mid-size organizations. In October 2005, Meta4 reopened operations in the U.S., supporting its new operations for the Americas in Miami, through partnership with independent HR consultant Vision 3. Extensive technology, consultancy, and service, outsourcing providers in operational Markets.
FUNCTIONALITY	Meta4 PeopleNet/MindSet suite has an excellent administrative process functionality, except in benefits administration, and a powerful competency management strategy and set of tools, particularly competency assessment and performance management. Full CM-related processes automation, including employee/manager self-service and comprehensive integrated knowledge management environment.
PRODUCT TECHNOLOGY	State-of-the-art e-business technology design and implementation. 3-Tears components-based architecture: Supports pure HTML, Java (applets), and Windows (Active X) Clients, application server and DB Server.

Table 14. Continued

Ultimate Software

Evaluation Criteria	Considerations
COMPANY	Ultimate Software is a successful payroll and HCMS dedicated company, expanding its business from a mere licence sales vendor to an outsourcing service provider, reaching 37 M € in fiscal year 2005 in HC management sales. Currently employs 500 professionals and has about 1,200 customers, mainly in the US. HROA (Human Resources Outsourcing Association) 2005 Provider of the Year.
MARKET PRESENCE	An excellent record of customer satisfaction, combined with visionary product to service business orientation. Business focus is driven primarily to the U.S., and some customers are from Canada and U.K.
FUNCTIONALITY	Its Ultipro Workforce Management Suite incorporates most required CM required process automation functions.
PRODUCT TECHNOLOGY	Open, scalable Web-based architecture. Eamed certification from HR-XML Consortium in 2003, creating HR-specific XML vocabularies.

Table 15. Standalone CM Products

Mindsolve

Evaluation Criteria	Considerations
COMPANY	Fast-growing company created in 1994, exclusively dedicated to the employee **performance management** business, licensing its Mind Solve Visual Product and providing associated required consultancy services. Last year business revenue estimated at 13 M €.
MARKET PRESENCE	Niche player, with consolidated HR expertise support to deploy PM functionality in heterogeneous U.S.-based (some outside US) medium- and large-size organizations. Product licence sales and MVP Express suite, tailored for outsourcing, easy to deploy Web-based solution.
FUNCTIONALITY	Includes end-to-end performance appraisals, 360-degree performance assessment, competency alignment and accountability, and talent and development planning. Skills and competency management support, requires interfaces with other external tools for full CM strategy deployment (e-learning, workforce management, etc.).
PRODUCT TECHNOLOGY	Open, scalable Web-based architecture. It uses proprietary technology (MindSolve's Visual Profiler™) of unique drag-and-drop system to deliver accurate, trustable information. Visual Profiler's ability to comparatively display multiple employees on a single screen produces ratings that better differentiate superior, good, and unacceptable performers.

Table 15. Continued

Geo Learning

Evaluation Criteria	Considerations
COMPANY	Geo Learning is an SME-type company, U.S. based, **dedicated to e-learning** and associated educational activities. It sells learning products (LMS, authoring tools, etc.) and other stand-alone SW products, as its *competency plus* CM tool. Started business in 2000; last 3 years, annual growth rate of 125%; has more than 300 SME-type clients, mainly in government and financial services.
MARKET PRESENCE	Good record of customer base. Works with small reseller and systems integrators partners.
FUNCTIONALITY	Exxceed competency plus is a stand-alone CM product that includes competency modeling (using profiles matching jobs, projects, etc.), career management (job profiles matching employee's competencies), individual development planning (based on competency gaps, assigning learning objects, imported from external LMS), and comprehensive 360 competency assessment process. The foundation of Exxceed functionality is based upon a competency dictionary wherein individual competencies are stored and organized in the form of families, identifying assessable behaviours linked to competencies. Typically records and employee information is obtained using crystal reports or other Web-based reporting tools.
PRODUCT TECHNOLOGY	Microsoft, PC, SQL-type application, thin client Web-based architecture. Low cost and maintenance. Delivered with preconfigured competency DB (10,000 competencies in areas such as business, management, engineering, etc, and 400-plus industry predefined job profiles).

Chapter 6.6
Becoming a Learning Organization in the Software Industry:
Is CMM the Silver Bullet?

Dev K. Dutta
Richard Ivey School of Business, The University of Western Ontario, Canada

ABSTRACT

This chapter examines to what extent the implementation of Software Engineering Institute's Capability Maturity Model (CMM) of software process improvement enables a firm to transform itself into an learning organization (LO). It argues that even though the CMM does lead the software firm forward on the route to learning, it does not go far enough. By recognizing organizational knowledge and organizational learning as the twin pillars of the LO, the author develops a conceptual framework against which the five maturity levels of CMM can be mapped and examined. This allows for an assessment of whether the CMM serves as a silver bullet in achieving the software firm's goal of reaching the visionary state of the LO.

INTRODUCTION

Today, across the world, business firms are exposed to increased environmental turbulence and uncertainty. There is rapid change in technology and its usage, and competition in the marketplace has intensified, with customers becoming highly knowledgeable and demanding. With economic realities and priorities shifting constantly, there is now the emergence of a new global economic order in which knowledge or intellectual capital—rather than labor, machine power and capital—constitutes the most critical factor of production as well as a source of competitive advantage (Zack, 1999). Nowhere is this more evident than in the software industry. By its very nature, a firm engaged in developing software applications as its primary product shares all the features of what Alvesson terms as "knowledge-intensive" firms. These firms depict the following characteristics:

1. "Highly qualified individuals doing knowledge-based work, using intellectual and symbolic skills in work;
2. A fairly high degree of autonomy and the downplaying of organizational hierarchy;
3. The use of adaptable, ad hoc organizational forms;

4. The need for extensive communication for coordination and problem-solving;
5. Idiosyncratic client services;
6. Information and power asymmetry (often favoring the professional over the client);
7. Subjective and uncertain quality assessment." (2004, p. 21)

To survive in such a turbulent business environment and achieve global standards with respect to quality, cost and customer expectations, a software firm must not only treat knowledge as its most critical resource but also learn to be highly adaptive in everything it does with the knowledge. It must proactively anticipate emerging trends and directions with regard to the business environment, customers and technology. It must assimilate the knowledge and use it effectively to best meet the customer requirements. Therefore, the software firm must work towards building for itself an all-pervasive learning culture. It must become what is termed as an LO (Senge, 1990).

The CMM, developed by the Software Engineering Institute (SEI) at Carnegie Mellon University, is suggested to be a step in this direction (Levine, 2001). The CMM enables firms to view software development as an engineering discipline and ensure its progression from being an immature, ad-hoc process to a mature, managed process (Paulk, 1998a). Ramanujan and Kesh (2004) note that the last few years have seen a significant investment on the part of software firms to implement the CMM; in most cases, firms also a report a spectacular improvement in financial performance after they have gone through the implementation process. However, the question that remains unanswered is, how sustainable is this improvement effort? That is, does adoption of the CMM enable the software firm into becoming an LO? The aim of this chapter is to investigate this research question. This is important because after the initial fanfare associated with the CMM has died down, the initiative will continue to prove useful only if it enables a software firm to develop an organization-wide learning culture and derive sustainable competitive advantage based on knowledge.

ESSENTIAL CHARACTERISTICS OF THE LO

The idea of an LO is difficult to grasp. This is because not only is it is far from a homogeneous concept but also because the terms "LO" and "organizational learning" are used interchangeably in literature. In tracing the concept of organizations as learning systems, Yeung, Ulrich, Nason and von Glinow (1999) identify eight properties that they suggest constitute the "basics" of LOs: (1) they focus not only on learning but also in meeting organizational goals; (2) they follow a systems logic and engage in out-of-the-box thinking; (3) they build upon but are not limited by individual learning; (4) they follow the learning continuum that stretches from superficial to substantial; (5) they recognize that learning comes from many small failures; (6) they adopt a process approach to learning, understanding that learning often evolves along a predictable set of processes; (7) they give cognizance to both direct experience and vicarious experience as being useful inputs to learning; and (8) they treat learning as being important, not only for "exploiting" existing opportunities but also for "exploring" new opportunities. This suggests that the LO is an ideal or visionary state that firms aspire to reach and one that requires them to engage in transformational, organization-wide, real-time learning.

Senge defines the LO as one where "people continually expand their capacity to create the results they truly desire, where new and expansive patterns are nurtured, where collective aspiration is set free and where people are continually learning how to learn together" (1990, p. 17). Even though this gives an idea of the philosophy behind an LO, Mumford provides a definition that is more practice oriented: "The LO is one that

creates an environment where the behaviors and practices involved in continuous development are actively encouraged" (1995, p. 12). In turn, then, OL refers to "a variety of practices and values that enable a company to explore continually new directions and anticipate, or even lead, change in the marketplace and in society at large" (EIU & IBM, 1996, p. 11).

Even though the LO appears to be an ideal or visionary state that a firm endeavours to reach, it is clear that its foundations rest on two specific organizational characteristics: (1) organizational knowledge, and (2) organizational learning. The former denotes the unique resource available to firms to use in order to progress. It can usefully be represented as the *content* aspect of the LO. Similarly, the latter can be referred to as the *process* aspect of the LO; that is, the specific mechanisms that actually allow learning to happen. In the next few paragraphs, I examine these two pillars of the LO and develop a theoretical framework that elaborates on how and when a firm truly becomes one.

Organizational Knowledge

Organizational knowledge is not static. It is created within the firm as a continuous dialog between its constituents; that is, explicit and tacit forms of knowledge available with employees and within organizational artefacts. Though such an exchange arises primarily among individuals, it is the organization that creates the facilitating mechanisms that lead to emergence of dialog. According to Nonaka (1994), the organization manages the four constituent processes of dialog: socialization (creating tacit knowledge through sharing of tacit experience), combination (creating explicit knowledge by combining different explicit knowledge), externalization (conversion of tacit knowledge into explicit knowledge) and internalization (converting explicit knowledge back into tacit knowledge). When all four modes of knowledge sharing occur as a continual shift, organizational knowledge is generated (Nonaka, 1994). Thus, close cooperation among organizational members is necessary for organizational knowledge to develop. This view endorses that organizations are social entities populated by individuals who have an interest and desire to share and learn from each other, and it is through the organizational platform that knowledge and expertise of individuals get converted into economic products and services that have an economic value in the marketplace (Kogut & Zander, 1992). In other words, it is in the organizational space that situated learning occurs between individuals, and which leads to a dynamic evolution of organizational knowledge. This is what is also called the distributed knowledge system (Tsoukas, 1996), where individual knowledge is constantly getting merged, shaped and reshaped as an organizational resource.

The firm's base of explicit knowledge can be expanded in several ways. For example, the firm's current knowledge position may be benchmarked vis-à-vis what are viewed as world-class practices; the firm can also focus on learning as a visible and central element of its strategic intent (by making explicit mention of it in the mission or vision statement); also, the firm can actually go for concrete investments in learning (through adoption of "hard" mechanisms, such as sponsoring employees to training programs, or through "soft" mechanisms, such as devising creative ways and means of employee feedback and suggestions, and by sharing best practices across vertical/horizontal divisions within the firm). Organizational learning does not happen by chance; nor does it happen overnight. Thus, LOs must exhibit "a purposeful learning approach designed to create knowledge and translate it into effective action" (Bohlin & Brenner, 1996, p. 2). By experimenting with collective learning, most firms engage in work practices that generate "ideas with impact." This is possible through continuous improvement, competence acquisition, experimentation and boundary spanning. Accord-

ing to Ulrich, Von Glinow and Jick, "combining the ability to learn by going outside a business' boundaries (i.e., boundary spanning), coupled with a culture focused on internal management processes such as empowerment and teamwork, is most conducive to competitiveness" (1993, p. 64). Firms also generalize ideas that have impact by creating an organizational infrastructure that moves ideas across boundaries. This can be through building up organizational competence (staffing, training and organizational development), management action (appraisal, rewards), governance (management style, policies, organization design, communication, feedback) and work processes (systems, processes, teams).

However, given that the firm competes in a radically shifting and turbulent environment, the knowledge it draws upon is not only inherently indeterminate but also continually emerging (Tsoukas, 1996). This requires that knowledge be viewed as being more than simply tacit or explicit or a sum of the two. Rather, it brings into focus an alternate view of knowledge as "knowing." Cook and Brown (1999) have suggested that if the former (i.e., knowledge) constitutes an "epistemology of possession" (with knowledge being treated as something people possess), the latter (i.e., knowing) calls for an "epistemology of practice" (where the focus is more on people knowing). The authors further suggest that knowledge and knowing are not competing but mutually enabling; together, they constitute a "generative dance" that leads to continuous innovation on the part of the firm. Orlikowski (2002) notes that "knowing in practice" is a social activity that has as its core several important attributes, such as sharing identity, interacting face-to-face, coordinating across time and space, learning by doing and supporting participation. Similarly, using a structuration perspective, Hargadon and Fanelli (2002) suggest that organizational knowledge arises as a recursive outcome of interaction between knowledge as action and knowledge as possibility. In that sense, by its very nature, knowledge is uncertain and never completely revealed.

Organizational Learning

Organizational learning has been defined as the process by which: (1) the organizational knowledge base is developed (Shrivastava, 1983), (2) organizational action is improved through better knowledge and understanding (Fiol & Lyles, 1985),(3) organizational inter-subjective meaning is changed (Cook & Yanow, 1993), or(4) change is effected in individual and shared thought and action (Crossan, Lane & White, 1998). Thus, by its very nature it is suggested to effect both cognitive and behavioral change among organizational members. In a general sense, the cognitive perspective regards organizational learning to be the summation of learning of individuals. It suggests the organization is a cognitive or information processing system (March & Simon, 1958). Any requirement of learning or strategic change is viewed in terms of cognitive maps of managers and employees, as a gap between actual and desired results measured in terms of business performance. Knowledge is taken to be primarily resident in the minds of individuals and from where it can be extracted, packed and stored in repositories for future use or transferred to others (Nidumolu, Subramani & Aldrich, 2001). In other words, the cognitive view takes learning to be primarily an individual activity separate from and, in some sense, even opposed to other activities individuals engage in within organizations (Gherardi, Nicolini & Odella, 1998). However, such an extreme position also seems to suggest that viewing organizational learning exclusively based on the cognitive perspective brings about its own inadequacies.

Though Kolb's (1979) cyclic model of individual learning (concrete experience, reflective observation, abstract conceptualization and active experimentation) has been applied in the organizational setting (Carlsson & Martin, 1976), individual learning forms only a necessary but not a sufficient condition for organizational learning. Huysman (1999) notes that current literature on organizational learning suffers from several

biases: (1) it tends to treat the individual as the actor in learning; (2) it considers environmental adaptation as the primary motivator for why organizations learn; (3) it suggests that learning primarily is a planning activity; and (4) it focuses on improvement as the only expected result of learning. While organizational learning necessarily must incorporate these elements, the question that arises is whether fulfilling these conditions will transform the firm into a LO. It is impossible to see cognition occurring at the level of the organization (Cook & Yanow, 1993). Also, most of the time, organizational members cannot agree on common cognitive models to interpret information or take action (Mirvis, 1996). Even if all individuals in the firm engage in learning, does it ensure learning at the organizational level? Again, does planning necessarily ensure optimal learning?

To mitigate these difficulties, researchers have proposed an alternate view of organizational learning based on the social, behavioral cultural and interpretive characteristics of organizations, with the recognition that context is an important parameter in learning (Fiol & Lyles, 1985; Daft & Huber, 1987). Under this perspective, organizational learning occurs when a group of learners (as social beings) engage in joint construction of reality and shared meaning-making, based on social interaction within specific socio-cultural settings (Gherardi et al., 1998; Miner & Mezias, 1996; Nicolini & Mezner, 1995). Thus, learning is a process that is socially constructed and "… focuses on the way people make sense of their experiences at work" (Easterby-Smith & Araujo, 1999, p. 4). When the individual learns, learning gets linked to changes in an individual's interpretation of events and action (Daft & Weick, 1984). Proponents of the social view of learning suggest that individual knowledge is possible only because of the social practices individuals find themselves in (Tsoukas, 1996). Therefore, the social view on learning not only endorses the active participation of individuals in the joint sense of making and learning, but also suggests the extremely important role context plays in this endeavor. The idea of socially constructed knowledge recognizes it as closely following a socio-historical context, made available through the everyday experience of individuals (McAdam & McCreedy, 1999). An ongoing, circular interaction between individually held latent knowledge and the knowledge manifest in the surrounding environment is what enables organizational knowledge to emerge (Hargadon & Fanelli, 2002). Specific mechanisms that may aid in this process of interaction include situational factors, such as the unit's tasks (process or content orientation) and domain of learning (focused or broad) (Becerra-Fernandez & Sabherwal, 2001).

In fact, Lave and Wenger (1991) go a step further. They suggest that not only is learning *situated* in practice, it is in fact hidden from the other regular mechanisms of the organization. Therefore, studying it systematically is extremely difficult (Brown, Collins & Duguid, 1989; Richter, 1998). According to the situated or social learning view, the learning context and relationship of the learners are as important as learning itself. As new members get inducted into the process of collaborative learning and meaning-making, individual schemata, scripts and beliefs get institutionalized into organizational knowledge structures (Cook & Yanow, 1993; Daft & Weick, 1984; Schank & Abelson, 1977; Weick & Bougon, 1986).

At the same time, apart from the individuals engaging in knowledge sharing and exchange, the team/group as well as the whole organization are influenced by organizational knowledge structures. Socialization of individuals in the learning process helps in the dynamic transfer of knowledge from the individual to the organization, as described in Nonaka's knowledge spiral (Nonaka &Takeuchi, 1995). Following this process, the knowledge structure and form of the organization also undergoes changes. It becomes a product of complex relations and interaction between individual beliefs and perceptions and organizational routines (Garud & Rappa, 1994), thus creating an appropriate collective for knowl-

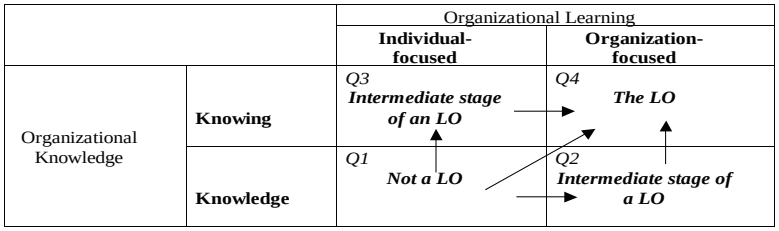
edge sharing across the community of practice (Nonaka & Konno, 1998). Crossan, Lane, and White (1999) suggest that the core processes that constitute organizational learning can be depicted as the 4I (Intuiting, Interpreting, Integrating and Institutionalizing), with intuiting and interpreting focused on the individual level, interpreting and integrating focused on the group level, and integrating and institutionalizing focused on the organizational level. The authors further suggest that a system of feed-forward and feedback learning flows characterizes a back-and-forth flow of knowledge across each of these three levels.

In view of the preceding discussion, I suggest that each of the two pillars of the LO—organizational knowledge and organizational learning—can be usefully looked upon as captured in two distinct states. For organizational knowledge, this state varies from "knowledge" to "knowing." Similarly, for organizational learning, the states vary from "individual-focused" learning to "organization-focused" learning. By identifying each of these two states of organizational knowledge and organizational learning, I arrive at a 2x2 framework that describes the different stages of a LO. This is depicted in Figure 1. Quadrants 1, 2 and 3 are intermediate stages that the firm finds itself in during its journey towards an LO. In my depiction, a true LO comes into existence in Quadrant 4, where the focus is on knowing over knowledge and organizational learning over individual learning. While it is expected that a firm in Q1 would reach Q4 by either traversing through the intermediate stage of either Q2 or Q3, it is possible that it may reach Q4 directly. This rare event would happen under a visionary change agent within the firm, who pulls up the organization from Q1 directly into Q4, thus by-passing the intermediate stage. Finally, it is important to remember that in Figure 1 the categorizations "knowledge" vs. "knowing" and "individual" vs. "organizational" are merely stylized ways of representing the two orthogonal dimensions. In practice, a firm will describe elements of both knowledge and knowing simultaneously, just as it will depict both individual and organizational learning at the same time. Rather, what I suggest is that in each of the four cells, one of the two forms of organizational knowledge focus will predominate, just as one of the two forms of organizational learning will assume greater importance.

Quadrant 1: This quadrant represents firms that focus on organizational knowledge over organizational knowing. In other words, these firms focus on knowledge possession over knowledge practice. While these firms may also accord importance to tacit knowledge in addition to explicit knowledge, they do so with the idea of possession rather than practice. In effect, these firms seem to adopt a rather static view of how knowledge is acquired, exchanged, utilized and updated. Similarly, these firms tend to lay a greater emphasis on explicit knowledge over tacit knowledge. If they do focus on tacit knowledge, they tend to view it as knowledge that is possessed rather than practiced.

Quadrant 2: This quadrant represents firms that give emphasis to organizational learning over

Figure 1. The LO framework



individual learning. Thus, they recognize that organizational learning is more than the sum of learning of individuals. However, by continuing to focus on the idea of knowledge as possession rather than practice, these firms fall short of the target of becoming a true LO.

Quadrant 3: Like Quadrant 2, this quadrant represents firms that are at an intermediate stage in their journey towards becoming an LO. While these firms do focus on knowing—that is, the idea of knowledge as practice rather than as possession—they continue to believe that learning in organizations is simply synonymous with learning efforts of individuals. As such, these organizations miss out on certain important linkages of how individual learning can expand into learning at the organizational level.

Quadrant 4: This quadrant represents firms that not only accord higher emphasis to knowing (i.e., knowledge as practice) over knowledge (i.e., knowledge as possession) but also focus on developing organizational mechanisms, processes and practices that expand individual-level learning into organizational learning. By doing so, these firms transform them into LOs in the true sense of the term.

Having described the essential characteristics of a firm's journey towards becoming an LO based on its understanding of organizational knowledge as well as organizational learning, I now examine to what extent adoption of SEI CMM enables the software firm to achieve this vision of transforming itself into an LO.

THE CAPABILITY MATURITY MODEL OF SOFTWARE DEVELOPMENT

The CMM was developed by SEI to enable software firms to treat the process of software development as an engineering discipline, and develop "reliable and usable software that is delivered on time and within budget … The progression from an immature, unrepeatable software process to a mature, well-managed software process also is described in terms of maturity levels in the model." (Paulk et al., 1993a, pp. 0-1). SEI commenced work on the model in 1986, based on an initial request on the part of the United States (U.S.) federal government, to provide the latter with a method for assessing the capability of its software contractors. The model was first released in 1991. Thereafter, periodic improvements on the model have been continued to be made, based on feedback from organizations that adopted the CMM.

Immature vs. Mature Software Firms

A computer software firm, assessed on the basis of robustness and maturity of the processes used by it to develop software, can be placed along a continuum that progresses from immature to mature. The immature software firm is characterized by an overall ad-hoc, reactive approach to software development. Not only does the firm not have consistently followed processes and procedures for production, testing and quality assurance of software, but whatever processes that may be in place are also thrown to the wind whenever the firm is in the throes of a crisis. In contrast, a mature software organization ushers in a certain consistency and uniformity of approach in the development of software. It possesses established, consistent processes for software development. Planning forms an integral part of the process cycle. Periodic re-evaluation and improvement of currently adopted processes is also institutionalized within the organization. In view of these measures, the mature software tends to produce software that is relatively less prone to defects and errors. To summarize, while immature software firms operate on a reactionary basis, mature software firms display a proactive approach towards managing the processes used to develop software products (Paulk et al., 1993b).

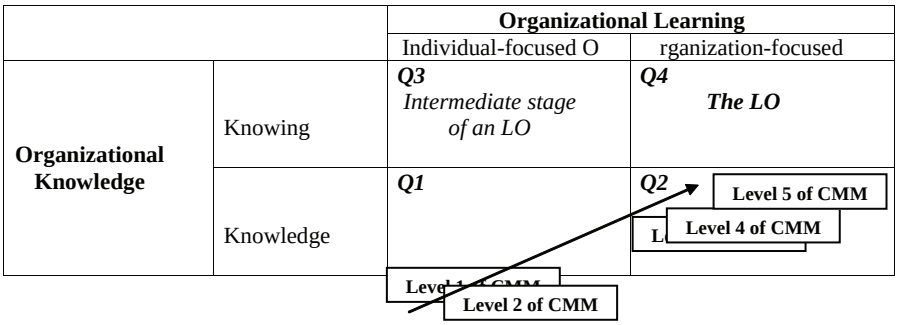
CMM Process Maturity Framework

When it adopts the CMM, the software firm demonstrates a commitment that it intends to move from a software development regime characterized by ad-hoc, immature, reactive processes to one that is disciplined, mature and proactive. The CMM process maturity framework has been conceptualised at five maturity levels (1 to 5), which "define an ordinal scale for measuring the maturity of an organization's software process and for evaluating its software process capability" (Paulk et al., 1993b, p. 7). Each of the five maturity levels of the CMM exhibit certain behavioral attributes. At Level 1, the software process is an amorphous black box that generates a software product when provided with certain specifications; however, it is unable to define or use any process controls whatsoever. This situation improves somewhat in Level 2, where both customer requirements and work products are controlled. At this level, the organizational software process can be visualized as a succession of black boxes that "allows management visibility into the project on defined occasions" (Paulk et al., 1993b, p. 21). Internal structure of the black boxes, the tasks in the project's defined software process, becomes visible in Level 3. This is, therefore, the level at which the software development process is viewed as an organization-wide activity, even though it is broken down into individual projects, and common routines and standards are applied to ensure both process and product quality. Level 4 is a further improvement; processes are instrumented and controlled quantitatively, and ability to predict outcomes and initiate corrective action is high. This culminates in the organization progressing into Level 5, where it initiates a culture of continuous process and product improvement. At this stage, "disciplined change is a way of life" (Paulk et al., 1993b, p. 21). Since each level builds a foundation for the next level, it is preferable for a software firm to progressively go up the maturity hierarchy; skipping levels is counterproductive.

SOFTWARE FIRMS AND CMM IMPLEMENTATION: A JOURNEY TOWARD THE LEARNING ORGANIZATION

Being an organization-wide change initiative based on the principles of total quality management (TQM), adoption of CMM provides an organization with many benefits. Some of the tangible benefits of CMM implementation include "… shorter development cycle, reduced rework, higher development productivity and higher-quality systems" (Duggan, 2004, p.9). The CMM concentrates on developing an organization-wide process architecture that enhances some aspects of both knowledge management and organizational learning through easy acquisition, storage, management and utilization of knowledge on the part of software firms. CMM plays this enabling role

Figure 2. CMM and its overlaps with the LO framework



mainly through transformation of the processes associated with the software development life cycle, making them less person-specific and based more on robust institutional systems, processes and practices. As a result, the firm necessarily progresses from "ad hoc, chaotic processes to mature, disciplined processes … [which reflect a culture of continuous process and product improvement, and where] disciplined change is a way of life" (Paulk et al., 1993b, pp. 3, 21).

In attempting to map each level of the CMM (with its associated challenges and benefits) onto the 2x2 LO framework, I arrive at Figure 2, which is a depiction of the extent to which the CMM actually helps a software firm to become an LO.

Under Levels 1 and 2, the firm continues to focus on individual training and learning, with little effort being taken to bring these processes up to the level of the entire organization as a common unit of analysis. Therefore, firms that are either at Level 1 or have progressed to Level 2 cannot be termed as LO at all. For instance, Level 1 firms may produce quality software from time to time, but if this happens, it is due to the personal initiative and heroics of the firm's managers rather than the firm's process architecture. When a firm has progressed to the stage of Level 2, it has initiated a system of managing development of software by imitating and implementing a repeatable set of software development processes. It is expected that at this level the firm has been able to articulate and share most of its explicit knowledge with other organizational members. However, even here the firm is focused too much on the present, with little efforts being made toward learning from the current set of experiences and applying it the future.

Figure 2 also suggests that Levels 3, 4 and 5 emerge as shifting positions within Quadrant 2. In these successive stages of software process maturity, the firm is clearly focused on adopting the entire organization as the unit of analysis. Thus, when it is in Level 3, the firm has already begun to use a set of standard software processes. In addition, under Level 4 the firm begins to practice a quantitative orientation as far as measuring and managing projects are concerned. Further, it has developed the requisite repositories for knowledge storage and retrieval. Finally, at Level 5 the firm is focused on managing and improving the processes on a proactive basis, with the objectives of defect prevention, innovation, knowledge sharing and dissemination of lessons learned across the organization. It is expected that at this stage there will be interplay of tacit knowledge among members, just as there is high emphasis on explicit knowledge exchange.

Even though the CMM and, especially, upper Levels 3, 4 and 5 make a software firm engage in organizational learning, by its very structure it also acts as a constraint in holding back the firm from becoming a true LO. This is because the CMM essentially over-emphasizes the structural and process aspects of an organization's journey towards becoming the LO and neglects the equally important people aspects. The framework essentially accords importance to the process and capability aspects of learning at the organizational level. It even emphasizes the skills and behavior aspects of learning at the individual level. In doing all this, however, the CMM continues to follow and emphasize an "epistemology of possession" (Cook & Brown, 1999) with respect to knowledge and learning. It is silent on what further must be done to usher in an organizational culture that values an "epistemology of practice" (Cook & Brown, 1999) with regard to knowledge and learning. In fact, the CMM seems to foster a notion within the firm that whatever gets measured is managed. While this is true with regard to many of the structured, relatively simple aspects of organizational life, it is well known from mainstream theories of the organization that this may not completely represent the totality of the firm's existence. Not only is organizational reality highly complex and ambiguous, but also managers are boundedly rational. This makes managers go for a strategy of satisficing rather than optimizing most of the

time. Unfortunately, the CMM does not recognize any scope for ambiguity within its processes.

In his study of what he terms as "high maturity organizations," Paulk (1998b) finds that these firms address several organizational issues that go beyond the scope of the CMM. These relate to developing a culture of openness and communication, commitment to quality, customer responsiveness and other "peopleware" issues. In contrast, the CMM seems to overemphasize what may be termed as the "hard" aspects of management and, in doing so, neglects its "soft" aspects. For example, process and capability mainly denote the structural or harder constituents of learning at the organizational level, whereas leadership and climate denote the visionary, style and cultural or softer constituents. Similarly, at the individual level skills comprise the harder constituent while behaviors and, to a greater extent, values constitute the softer components. The CMM implicitly assumes that the softer prerequisites are given or already existing within the firm. For example, top management vision, foresight and commitment are taken for granted, assumed as being exhibited by the decision to implement the model. Similarly, individual values may be said to exist, in the desire to use the model, achieve error-free software programs and continuous improvement, and thus ensure teamwork, transferability and sharing of knowledge.

According to Elkjaer (2001), a problem that plagued the initial efforts of organization towards becoming an LO related to the ways in which learning was understood. It was supposed that if individual learning was taken care of, organizational learning was bound to result. It is only later that specific concern, such as the assimilation of individual learning into organizational learning, began to be examined. In her study, Levine (2001) finds that learning and a program of adoption of technical change (such as the CMM implementation) mutually reinforce each other. Yet, it can be said that though adoption of CMM takes the software firm forward towards becoming the LO, it does not go far enough. Mathiassen and Pourkomeylian (2003) find that to become effective at managing knowledge, a software process improvement (SPI) initiative (such as the CMM) must strike a balance between personalized and codified aspects. This is because the organization in which information systems development occurs is essentially a socio-technical system in which technical processes combine with social ones and involve stakeholders at multiple levels of the organizational hierarchy (Robey, Welke & Turk, 2001; Sawyer & Guinan, 1998). Therefore, not only does the SPI need to be flexible and amenable to change over time, but it must also maintain a tension between dialectical opposites—codified vs. tacit, individual vs. the organization, informal vs. formal. Unless it is able to do this, the knowledge management efforts engaged in through the SPI will achieve adequate results but certainly not transform the firm into an LO. This is an area where the CMM leaves much to be desired.

Ravichandran and Rai believe that "… many software process improvement frameworks, including the CMM, do not pay adequate attention to the organizational factors that enable or constrain process improvements" (2000, p. 401). In fact, even with respect to knowledge management, which is only a part of the organization's overall journey towards becoming an LO, the CMM has further to go (Ramanujan & Kesh, 2004). Though adoption of the CMM does position the software firm on the road to transforming itself into an LO, to ensure sustainability of collective learning within the firm, its leadership must continually demonstrate in no uncertain terms the commitment to organizational learning. This will need to be reinforced through creation of an organizational climate that fosters innovative behavior on the part of employees and adoption of the essential "epistemology of practice" (Cook & Brown, 1999) based on adoption of an organization-wide enabling value system (trust, spirit of sharing and respect for the individual).

Table 1. SEI-CMM process maturity framework (adapted from Paulk et al., 1993a, 1993b)

Level	Name	Process Qualifier	Behavioral Characterization
1	Initial	Ad hoc	• Unstable internal environment for software development • Planned procedures abandoned during crisis • Quality of output depends on maturity and resilience levels of staff • Schedules, budget, functionality and quality remain unpredictable
2	Repeatable	Disciplined	• Policies established for managing the processes • Repetition of successful practices developed earlier • Basic software management controls exist • Software project standards are defined and adhered to • Software costs, schedules and functionality are tracked and monitored
3	Defined	Standard, consistent	• Standard software engineering/management processes documented and integrated • Adequate training programs imparted to staff to use software engineering concepts • Individual projects use baseline, standard software processes already available with the organization
4	Managed	Predictable	• Productivity and quality standards measured for all important software activities across projects • Organization-wide process database used to collect, store and analyze information on projects • Quantitative measurement standards available to evaluate projects' software processes and products • Meaningful variation in process performance can be distinguished from random variation
5	Optimizing	Continuouslyimproving	• Focus on organization-wide continuous process improvement • Means available for identifying and strengthening process weaknesses proactively • Software engineering innovations identified and adopted across the organization

CONCLUSION

In this chapter, my main aim has been to synthesize the growing body of literature on knowledge and learning with the primarily practitioner-driven framework of software quality assurance and process improvement—that is, the CMM. I have done this to identify whether the CMM process framework indeed acts as a silver bullet in the software firm's quest for becoming an LO. My analysis reveals that even though adoption of the CMM does take the software firm forward on the route to learning, it does not go far enough. Being a quality assurance framework, the CMM mainly concentrates on strengthening the structural or "hard" issues of ensuring collective learning based on predominantly codifiable or explicit knowledge. Therefore, it falls far short of concomitant changes in behavior, beliefs, values and culture that are required of employees if the firm is to truly transform itself into the LO. Future research efforts could concentrate on exploring how to build these "softer" concepts of the LO into the CMM.

This discussion on explaining to what extent the CMM transforms a software firm into an LO has several limitations. I have restricted the scope of the discussion to include only the CMM. It must be recognized that there are other associated/variant models also available with the SEI and adopted by software firms—for example, the People CMM, CMMI, PSP and IDEAL. However, these are outside the scope of the present discussion. To conclude, it is fair to suggest that even though the CMM has become the most popular TQM framework currently being adopted across the software industry, it has certain inherent limitations that do not take the software firm adopting the CMM to go far enough on the road to becoming an LO. The quest for becoming an LO, thus, continues to remain a journey along an arduous path, and one that the software organization must traverse with a great deal of foresight, experimentation and humility.

Chapter 6.7
Agile Practices in Project Management

John Gómez
Ericsson Chile, Chile

Alejandro Núñez
Practia Consulting S.A, Chile

ABSTRACT

This chapter introduces agile project management as a way to improve the processes for software development in small organizations. The chapter contains a description of the main concepts and techniques used along with practical recommendations for their application in real situations. The chapter also analyzes the relationship between these practices and recognized process improvement models like the CMMI and the PMI PMBOK and presents case studies to illustrate implementation.

INTRODUCTION

Most of the reasons behind failure in software projects lie in the lack of sound project management practices. The results of many industry studies and surveys show that the absence of appropriate strategies for scope management, risk handling, or project planning are frequently found in challenged projects.[1] For that reason, process improvement (PI) initiatives start with the project management discipline. For example, the maturity level 2 of the Capability Maturity Model Integration (CMMI®[2]) model is focused on the development of basic project management capabilities (CMMI Product Team, 2006, p. 55). This means that although an organization should improve the project management and the engineering process, beginning with the first one may allow it to obtain better results.

Nevertheless, starting process improvement is an overwhelming endeavor no matter the size or nature of the organization. The improvement initiatives have to compete with "delivery projects" that always seem to be more important (or urgent) especially from the business user's point of view. The benefits of a PI initiative are usually difficult to perceive or measure in the short term. This causes the organization motivation to decline progressively and lead the initiative to failure. This situation is even worse for small or medium organizations where resource limitations are higher. Small and medium organizations must approach process improvement in a way that benefits are realized sooner.

Another aspect of PI projects that reinforces the situation previously described is that many times PI teams replace the absence of good practices with over-engineered processes where formalism and control exceed what is needed due the nature of the work on the project or organization. Managers, users, and practitioners start to perceive these new processes as obstacles and not as tools and refer to the new way of doing things as bureaucratic, rigid, or heavy-weight. Product quality may be improved (initially), but team productivity and motivation remain low which is going to impact product quality in the long run. Also, team focus deviates from reaching project objectives to blindly follow procedures. Small and medium organizations are also more affected by this situation since usually their environments (team size, product size, project duration, cost, etc.) are smaller, and over-engineered methods may have a greater impact on project delivery.

The application of agile practices for project management addresses these common problems and may allow an organization (especially small and medium ones) to manage effectively a process improvement initiative. The development of project management capabilities facilitates the establishment of the environment to control not only project delivery but also the improvement project itself. The agile approach (by definition lighter and goal-oriented) may reduce the effort (and cost) and contribute to realize benefits sooner, keeping high morale and motivation. Our intent is to describe briefly how agility is understood and applied within the project management context and how this may benefit a process improvement initiative.

There has been a lot of discussion between agile and traditional methods authors and supporters. We do not adhere to any of them, and our purpose is not to contribute to any side of that polemic. What we see is that the limits known as the usual home grounds for agile and traditional methods are blurring creating environments where no one of them is enough or complete. A mixed approach is needed to find the best solution. Also, as many other disciplines, agile project management (APM) may be enhanced by a proper use of tools. Choosing the right tool and deciding how to use it is not easy, so we created a special section to make some recommendations on that subject.

Agile Project Management

Origin of APM

APM has its roots in the agile methodologies for software development created specially during late 1990s and publicly formalized as a movement with the formation of the Agile Alliance and subsequent publication of the Agile Manifesto (see Figure 1. *Manifesto for Agile Software Development*) in 2001 (Beck et al., 2001). Every agile method adheres to the declaration of values and principles stated in the manifesto, but the approach to deliver the solution varies from one to another; however, since agile methodologies are designed to handle a product development project, project management practices are present in most cases. We took our main references from the work of Jim Highsmith who recently published a book on agile project management, the SCRUM method created by Ken Schwaber

Figure 1. Manifesto for Agile Software Development

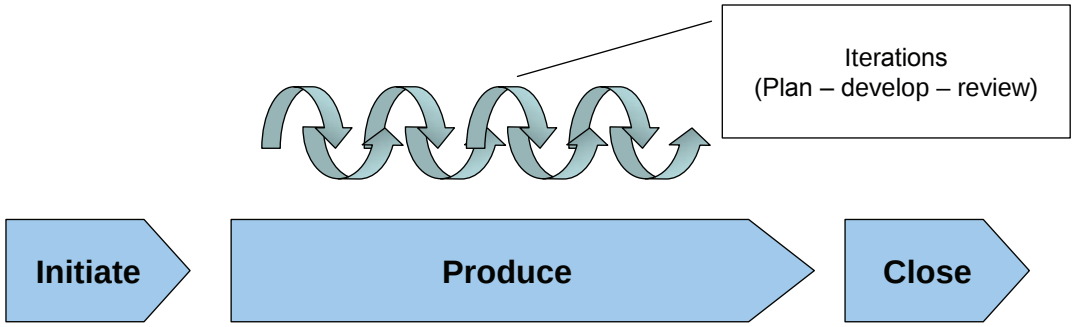
Manifesto for Agile Software Development

We are uncovering better ways of developing software by doing it and helping others do it.

- Through this work we have come to value:
- Individuals and interactions over processes and tools
- Working software over comprehensive documentation Customer collaboration over contract negotiation Responding to change over following a plan

That is, while there is value in the items on the right, we value the items on the left more.

Figure 2. Agile project life cycle



and Jeff Sutherland, and the Crystal Clear method developed by Alistair Cockburn.

Since its official birth in 2001, agility has grown beyond software development, and one of these areas is project management. This means not only that practices that were initially used for software development projects are currently applied for nonsoftware projects but also that there is an ongoing effort within the agile community to improve and extend the current state of the practice. The formation of the Agile Project Leadership Network (APLN[3]) and the publications of books on agile project management like the one from Highsmith (2004) mentioned before showed that work.

Agility Defined for Project Management

For the purpose of the chapter agility in project management is defined by:

- Keeping the team focused on reaching project goals oriented by customer objectives
- Use of a risk-oriented approach to accomplish project goals based on frequent delivery of functional solutions
- Creating and maintaining a healthy environment for team interaction and development, enhancing self-management, transparency, and visibility
- Use of balanced project management processes to allow the appropriate mix of flexibility and control, enhancing team productivity

The APLN also published a declaration of values and principles of agile and adaptive approaches to project management (see Figure 3. *Declaration of Interdependence*). Note how for APLN the appropriate term is "leadership" and not management. We talk about this topic later when discussing the role of the project manager in an agile environment.

Life Cycle of an "Agile-Managed" Project

There are three major phases of an agile managed project:

- Initiate phase, where product vision is defined, initial scope is established, a high level plan is elaborated, and the team and environment are set up.
- Produce phase, which is conformed by a successive set of iterative and incremental deliveries of functional product that ends in a product release.
- Close phase, which ends the project and gathers lessons learned.

Figure 3. Declaration of Interdependence

Declaration of Interdependence

Agile and adaptive approaches for linking people, projects and value

We are a community of project leaders that are highly successful at delivering results. To achieve these results:

- We **increase return on investment** by making continuous flow of value our focus.
- We **deliver reliable results** by engaging customers in frequent interactions and shared ownership.
- We **expect uncertainty** and manage for it through iterations, anticipation, and adaptation.
- We **unleash creativity and innovation** by recognizing that individuals are the ultimate source of value, and creating an environment where they can make a difference.
- We **boost performance** through group accountability for results and shared responsibility for team effectiveness.
- We **improve effectiveness and reliability** through situationally specific strategies, processes and practices.

The produce milestone may be divided into more than one release and each release in more than one milestone to establish different levels of control. The most important concept on this stage is the iterative-incremental approach that aims to reduce risk and uncertainty by delivering fully functional portions of the product to the customer. Every iteration has an internal cycle of plan (reviewing and updating scope and high-level plans and elaborating a detailed plan for the iteration), develop (building functional increments of the product), and review (team self-assessment on project performance and customer reviews of the product). In the next section, we will be seeing practices that fit into this life cycle.

Agile Project Management Practices

Product and Project Envisioning

Establishing a shared vision is critical in an agile environment. This is based on the belief that people work better when they are motivated for the long-term effects of the job. This is done by making the team realize the benefits that the project results will bring to the customers and the performing organization. A product or project vision statement is declared using workshops as team-building tools. Defining the product vision must include:

- Description of customer needs, motivations, or problematic situations
- Expected benefits or value added to customer business (problem solving, reducing costs, increasing revenue, or enhancing competitive advantage)
- Expected benefits for the organization performing the project

Highsmith (2004) suggests the use of a technique called the product vision box, where the team and customer representatives participate in a workshop to design the box that will contain the product. The team designs the front and back of the box and defines a set of statements that should be on the box to help sell the product. This may end with an "elevator test statement" containing the product vision (Chapter VI). For Crystal, this is part of a workshop is called "The Exploratory 360º." The product/project vision is defined in project initiation but is reviewed and communicated along the project to assure that objectives are still on target and that the team is oriented by those goals. The project vision normally ends with some charter of the project that contains the product vision, business objectives, project organization, and environment definitions.

Environment Setup

Enhancing team interaction is one of the goals of an agile managed project. This practice refers to establishing the environment when interaction happens. Environment definition covers essentially:

- **Interaction rules:** Agile methodologies are oriented by principles and values. These two, in combination with the product/vision, have a function within the agile environment: they allow team self-management. In agile environments many decisions on how to accomplish the work are left to the team who uses this rules to keep the work oriented to goals.
- **Processes and tools:** Agile teams should select the processes and tools that allow them to accomplish the objectives. A methodology workshop may be conducted to decide on this topic that results in a set of roles, practices, work products, and tools that the team will use on the project.
- **Physical environment:** Co-location is frequently suggested in many forms within agile environments to facilitate communication and interaction. This can be seen explicitly as a practice in extreme programming (XP) (Beck, 2000, chap. 13) and slightly modified with the osmotic communication property of Crystal Clear (Cockburn, 2005, p. 24). Face-to-face conversation is the most effective way of communication and the physical environment must facilitate that. Also the environment is designed to promote transparency, so it is common to use dashboards with task or feature cards where critical information like issues or progress are published and made visible to the whole team. A very good description of this practice is the information radiators strategy in Crystal Clear (Cockburn, 2005, p. 54). In projects with virtual teams, other collaborative tools are available and frequently used. The use of these kinds of tools will be commented on later.

Scope Management Strategy

Scope creep is one of the most common causes related to project failure, so strategies to handle this are a must. The degree of uncertainty is key in defining an adequate strategy for scope management. Uncertainty leads to change, and agile teams recognize that change is unavoidable and even beneficial. In that sense, change requests are allowed anytime in pursuit of maximizing the value that a customer may get for the product. Anyway, implementing changes as they are requested leads exactly to scope creep, so there must be some sort of change control. This is how it works:

- Scope is established using backlogs of scope elements. A scope element is a requirement (functional and nonfunctional), feature, use case, user story, defect, or change request.
- Changes to scope elements are received anytime but added at the end of the backlog.
- At the beginning of each iteration, the backlog is prioritized to decide which elements are to be developed during the iteration. Change requests are in the backlog so the customer has the chance to include them for the next iteration if they are considering more important that previous elements.

Engagement rules are established at the beginning of the project to manage customer expectation, and roles are defined to accomplish the scope management tasks. Normally, a customer representative owns the backlog and is in charge of prioritizing. This customer representative act also as an official provider of scope definitions. This way, uncontrolled changes from unofficial channels are prevented.

With this approach, the customer does not have to wait too long to include a change if he/

she really wants it. When the time of prioritizing comes, many change requests are dismissed because they add little to no value compared to other features previously defined. Iteration duration is critical to the success of this strategy. The iteration duration establishes the "lag" or "waiting time" for the customer to introduce changes to the project. A high change rate suggests a shorter iteration time. Anyway, sometimes changes are critical and must be included right away. When this situation happens, there is no sense to continue the iteration: the iteration is stopped and a new iteration is planned.

The backlog is usually maintained with as little detail as possible to facilitate updates. Scope elements definition may be detailed some more with feature cards or use cases/user stories descriptions. Detail information is usually added only for elements to be developed in the next iteration. Scope definition is also complemented with release or milestone plans. At the beginning of the project, the initial scope is established and release or milestone plans are elaborated to organize the project within a schedule. A release or milestone plan is usually a high level plan that describes which scope elements will be developed for each release or milestone. Release and milestone plans are based on the backlog and are reviewed and updated each iteration. This subject will be covered next.

Layered Planning

The focus on the planning process is to keep it the most cost-effective as possible. According to the scope management strategy, there are scope elements that are really committed (the ones that will be developed the current iteration) and others that are not. Detailed planning for items not committed or with low priority may be a waste. However, there should be a mechanism to elaborate a schedule for the whole project. A common misunderstanding of agile projects is that since changes are always allowed, the project is not able to commit for a fixed date. This is not true. A finish date is required to organize the work. This seems to be a paradox but has a simple solution. At the beginning of the project, an initial scope is established, and with that initial scope, a project plan is elaborated. This plan is kept at high level and its purpose is to establish a base schedule with some levels (or layers) of control. A large project with more than one delivery (release) to production environment may be organized by releases (every six months or more). A release is an organized set of scope elements associated with a date in the schedule. This primary level of control may be decomposed into a second one (milestones, from one to three months) that are also defined in terms of scope elements and dates. The work to accomplish a milestone is then divided in iterations (from one week to one month). The iteration is the minimum unit of work and is where the scope management strategy is fully applied. The iteration work is fixed, and the team is able to focus on that work. Then, predictability for the iteration work is higher, and detailed planning is cost-effective. The plans for the primary (releases) or secondary (milestones) layers are reviewed and updated each iteration.

Iteration planning is usually done in workshops where the customer and the whole team interact. This workshop is present in most of the agile methods (Beck, 2000; Cockburn, 2005; Scwhaber, 2004) and usually works like this:

- During the first part of the workshop, the customer representative explains the scope elements to be developed during this iteration.
- The team raises technological or environmental issues that may affect priorities which are adjusted.
- Based on previous performance results, the team estimates the effort to develop the scope elements. Restriction analysis (resource availability, risk identification, etc.) are incorporated to the estimations to allow

contingencies. Based on estimation, the scope for the iteration is agreed and committed. The whole team participates in the estimations, produced taking into account the complexity and size of the requirement, using a relative scale and assigning "points." This way, the simplest requirement takes one point and so on. The concept of relative scale refers to a predefined set of the amount of points that a requirement may get: 1, 2, 3, 5, 8, 13, 20, 40, 80 (Cohn, 2004, chap. 8). This kind of scale facilitates discussion among team members considering that for more complex or larger requirements uncertainty is higher and may reveal the need for further information or more decomposition.

- The team takes scope elements and breaks them down into tasks; tasks are assigned and effort is estimated. Task estimation is verified against scope element estimation to verify consistency.
- Resource load is reviewed and leveled.
- Team decides on task dependencies and sequencing and defines priorities. Tasks for the first day of work are agreed on and communicated.

The planning workshop is usually time boxed (Schwaber & Beedle, 2002).[4] The tasks are listed in another backlog. To facilitate control, tasks are always mapped to scope elements. This allows the team to keep the focus on the commitments for the iteration.

Frequent Inspection

The purpose of frequent inspection is to detect any obstacles before they can cause a major impact on project goals. The frequency of the inspection is left to be decided by the team, but most of the agile methods detect and remove obstacles on a daily basis. There are two more objectives of frequent inspection: set up a space for team interaction and communication and provide visibility on work progress to the team and project stakeholders. There are two main strategies related to frequent inspection: daily team meetings and daily task re-estimation and burn-down charts.

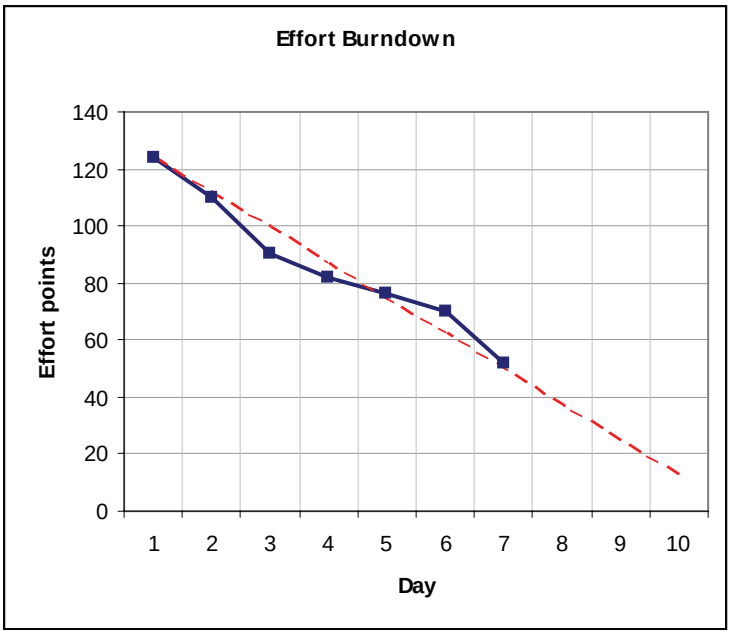
In the daily team meeting, the whole team gathers together for a maximum of 15 minutes with the main purpose of detecting any obstacles that may prevent the team from accomplishing the iteration goal. Each member of the team participates in the meeting, answering three questions:

- What tasks was I working on since the previous daily meeting?
- What tasks am I going to be working on until the next daily meeting?
- What obstacles or problems are or may be on the way?

No other subjects are allowed at the meeting, and problems are scheduled for further discussion later, commonly right after the meeting. Many soft aspects are related to this meeting: the team usually forms a circle (of peers) and is standing up. When a team member speaks, everyone else is listening. No interruptions are allowed, but questions may be asked to clarify some subject. The team leader conducts the meeting but only to keep the focus and register issues. Issues are registered for further action. It is expected that a defined response action must be in place for every issue before the next meeting.

The second strategy is to re-estimate the remaining effort of every not-completed task daily. Based on the daily information of total remaining effort, a "burn-down" is calculated. This information is graphically represented in "burn-down" charts as seen in Figure 4. Burn-down chart. In the figure, the blue/continuous line is plotted between the points of total remaining effort for each day. The trend of this line represents the "velocity" of the team. This actual velocity may be compared against an ideal or planned velocity (the red-dashed line) to obtain daily information

Figure 4. Burn-down chart



about progress and make performance forecasts. The graphics may be interpreted as follows:

- If at any given point, the actual velocity line is over the planned velocity line, the team is advancing slower than expected; probably, there are issues impeding the team progress or maybe the team underestimates the work to be done, so adjustments may be needed.
- If the actual velocity line is below the planned velocity line, the team is advancing faster. Assumptions may have changed, or the team overestimates effort.

With the value of actual velocity, the team is able to forecast its performance and make adjustments to assure that it will meet the iteration objectives. Burn-down information is public, and graphics are printed and published in a dashboard or any other place that everyone can see.

Product Review

Product review is present in agile environments with different techniques. For software projects, the use of automated unit testing linked to a disciplined procedure is frequent. Therefore, customer involvement in reviews is required and techniques like acceptance testing, technical reviews, or customer focus groups are common (Highsmith, 2004, chap. 8). These customer reviews occur normally at the end of every iteration. In SCRUM, there is a practice named sprint (iteration) review, the main focus of which is to review the product developed during the sprint; the sprint review is a meeting time boxed to three or four hours where the team presents the product to the product owner and other stakeholders. Defects and change requests are added to the product backlog to be prioritized at the next sprint (Schwaber, 2002, p. 54). The purpose of this practice is to show the actual progress on the product development and allow the customer to make changes and recom-

mendations if the product does not match stated requirements and expectations.

Team and Environment Tuning

Not only is the product reviewed to verify conformance to requirements and expectations; the performance of the team is also evaluated. At defined moments or at the end of every iteration, the team meets and reflects on its performance trying to find essentially what things worked well (and should be maintained), what did not (and should be adjusted or removed), and what improvements may be made to the team interaction or environment to enhance performance. In SCRUM, this is called the sprint retrospective (Schwaber, 2002, p. 54). Crystal Clear named it the reflection workshop (Cockburn, 2005, p. 65).

Time Boxes

The use of time boxes has a wide range on agile environments and that is why we decided to include a special part on this technique. A time box is a fixed duration time frame assigned to an event in the project. The most important time box is for iterations: once the iteration starts, the finish date is not changed. Time boxes are also applied for the daily meetings and the planning and reflection workshops.

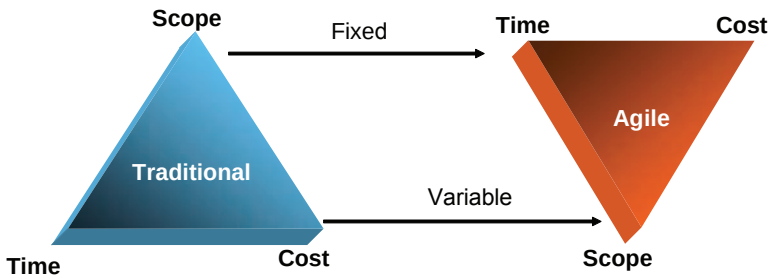
Role of the Agile Project Manager

First of all, it is appropriate to state that the word "manager" is rarely used in agile environments to refer to the person that conducts the project planning and execution. Team self-management is a fundamental concept of agile projects, and having that in mind, there is no place for a traditional "project manager." Instead, the agile project manager's main responsibilities are:

- Facilitating team interaction, removing obstacles from the path of the team to allow goal accomplishment and enhance performance
- Coaching and serving as change agents, promoting the values and principles, and encouraging discipline on the defined processes and rules
- Leading the team by keeping the team focus on customer objectives and the defined product vision and project goals
- Coordinating the work, helping in decision making and problem solving

One of the most interesting aspects of this role is the difference between self-management and self-direction. For authors like Highsmith (2004), agile teams are self-managed since they organize their own work and decide how to accomplish the goals. However, the team is not self-directed: there is a leader that keeps the work on track of the vision and objectives (Chapter III).

Figure 5. Agile vs. Traditional PM paradigms



Relating APM and Traditional PM Models

Agile vs. Traditional Paradigms for Managing a Project

Figure 5[5] shows the way the triple-restriction of projects is managed in agile and traditional environments. From the agile point of view, traditional project management aims to maintain the scope fixed by strict control of changes. When a scope is committed, the project tries to deliver it allowing some variations of time and cost. If the scope changes significantly, then the time and cost are adjusted. In an agile project, the time restriction is fixed (using time boxes), and the scope is allowed to change in benefit of the customer objectives, which is facilitated by the prioritizing practice in the scope management strategy.

Agile Project Management and the CMMI[6]

The CMMI model is one of the most important references in process improvement, especially for the software development industry. The CMMI establishes a set of recognized best practices for product development at the project and organizational contexts. The model is organized in 25 process areas, six of them dedicated to project management. Therefore, there is a cross-sectional focus on project management for the maturity level 2 and capability levels 1 and 2. That is why we decided to comment on the relationships be-

Exhibit 1.

Process Area	Specific Goal	Compatibility of Agile Practices
Requirements Management	SG1 Manage requirements	In an agile environment, there is a defined scope management strategy. There is a documented backlog of scope elements. Understanding is assured by the definition of official providers and the customer involvement in the development. Commitments are made and established in the iteration plan. Normally, there is traceability between scope elements and tasks. Changes are managed.
Project Planning	SG1 Establish estimates	Scope is established trough the development of the scope elements backlog and the release/milestone plan which also contains the defined lifecycle. Rationale for estimations is present and usually scope elements receive an assignation of attributes of size and complexity. Effort estimation is realized at ROM for the project and detailed for each iteration.
	SG2 Develop a project plan	Explicit planning of some parameters is missing (i.e., data management) and may be analyzed for each project. A schedule, budget, and resource plan exists. There are artifacts that represent the planning process.
	SG3 Obtain commitment to the plan	Planning is usually made at workshops when the customer participates. Resource leveling occurs by iteration.
Project Monitoring and Control	SG1 Monitor project against plan	During the daily meeting, issues that may cause deviations are detected. During iteration planning, the parameters for the whole project are reviewed and adjusted. Progress is analyzed daily using burn-down charts.
	SG2 Manage corrective action to closure	Issues detected are analyzed and a corrective action should be initiated as soon as possible.

continued on following page

Exhibit 1. continued

Process Area	Specific Goal	Compatibility of Agile Practices
Integrated Project Management	SG1 Uses the project defined process	Normally, at the beginning of the project, a process is defined to manage the project. This process is reviewed at the end of every iteration and adjusted. Estimations are adjusted using velocity data of previous iterations or projects. Lessons learned are gathered and shared among teams.
	SG2 Coordinate and collaborate with relevant stakeholders	Stakeholders are identified and its participation defined from the beginning of the project.
Risk Management	SG1 Prepare for risk management	The priorities and the choosing of life cycle are driven by project risks.
	SG2 Identify and analyze risks	Risks are identified and monitored as potential blocks in the daily meetings.
	SG3 Mitigate risks	Potential blocks are detected and preventive actions initiated using the same rationale as issues.

tween the CMMI and APM. We are not trying to prove that an organization may achieve a CMMI maturity or capability level using agile practices. Our purpose is to show how the agile practices we commented are related to some key elements of the project management discipline on the CMMI model. The table shows the goals process areas of the project management category until maturity level 3. Supplier management was out of the scope of this work, so the supplier agreement management process area was not included; instead the requirements management process area was included due its relevance to the project management discipline; although for the CMMI, it belongs to the engineering category.

Note how there are many agile elements that give some level of support to the specific goals of this process areas. Considering the nature of the SCAMPI method is difficult to affirm that an organization may achieve a capability or maturity level using only agile practices. In most cases, a refinement or addition is needed. Further, in this chapter, we comment on a case were a CMMI level 3 organization used some agile practices in a project without sacrificing the CMMI implementation.

Agile Project Management and the Project Management Body of Knowledge (PMBOK[7])

The PMBOK (Project Management Institute, 2004) is recognized as one of the top standards in the project management profession. As many traditional methods are usually misunderstood as heavyweight processes that are unsuitable for small environments, the PMBOK contains a series of best practices that are recognized as successful for a wide range of projects, and it is not expected that every one of them should be applied for every project. One statement says that quality should be planned into the project from the beginning and defining adequate processes is part of that definition. The adequate processes should address the objectives and nature of the project and this does not mean that every practice in the PMBOK is adequate for every case.

Exhibit 2.

Knowledge Area	Compatibility of Agile Practices
Scope management	Scope is defined using the scope elements backlog and the release plan, which when combined are equivalent to the WBS. The scope management strategy is defined from the beginning of the project and most of its rules (prioritizing as a key one) are performed every iteration.
Time management	Activity definition and dependency analysis for sequencing occur every iteration. There is not usually a bar (Gantt) chart or network diagrams to show the schedule. Also, techniques like resource leveling, theory of constraints, and rolling wave planning are frequently applied in agile environments. Schedule control also uses time boxes and is supported by burn-down charts.
Cost management	ROM (rough order of magnitude) estimations occur at initiation. Detailed task effort estimations occur every iteration. Effort control is based on daily re-estimation and burn-down charts.
Risk management	The whole life cycle of the project and the priorities are driven by project risk. Quantitative risk analysis is not commonly used. Mitigation occurs at the project level with time boxing and prioritization and at the iteration level with definition of corrective and preventive actions to avoid or remove obstacles
Quality management	Adequate processes are selected at the beginning of the project. Normally, there are quality control techniques in place like acceptance testing, product reviews, or customer focus groups.
Human resource management	The team is the most important factor in agile environments. Ground rules are explicitly established at the beginning of the project and maintained along the way. Team development is enhanced with reflection on causes of good or bad performance. The daily meeting allows for team management and interaction.
Communications management	The PMBOK states that the best way of communication is the face-to-face conversation which is also an agile principle. Communication is key on agile environments and frequently promoted through the workshops, daily meetings, and even the physical environment (i.e., with information radiators). Stakeholder identification and analysis is also conducted.
Integration	Chartering occurs at the beginning of the project by establishing a vision of the product and the project. The project is managed with integrated perspective of the scope, release plan, and iteration plans, which are maintained consistently through the project.

We can start analyzing compatibility with the groups of processes of project management in the PMBOK (initiating, planning, executing, monitoring and controlling, and closing) and the agile project life cycle. The process groups do not happen in a cascade in the project; instead they occur many times in different project phases. In an agile project, initiating and closing are related to the initiate and close phases, and the produce phase are continuous cycles of planning, executing and monitoring, and controlling the iterations. For that reason, most of the planning processes occur every iteration. The following table shows some compatibility of agile practices within the context of PMBOK areas:

Lessons Learned (Tales from the Trench)

Managing a Project Without a Gantt Chart

Power Games Co. (PGC) is a small game development studio[8] with just three years on the market. PGC works for larger game publishers developing small products oriented to the casual gamer segment. A typical project at PGC takes about six months with a team of five to six people integrated by designers and engineers. In the game industry, the product are built incrementally. This is explained since most of the features need to be

tested to prove not only that the software works as specified but also that the gaming experience is fun. PGC delivers a product increment each month or so. The culture is informal, and people are very talented.

PGC has a product manager who is in charge of all projects, and from previous work experiences, she firmly believes that the best way to eliminate risk or uncertainty is to plan up-front the activities with as much detail as possible. The team writes a project plan and produces a detailed schedule of the whole project tasks. Preparing this plan usually takes from two to three weeks. The team is not very comfortable with this way of doing things that, by the way, does not seem to be consistent with the culture and the iterative product development cycle; however, it seems to work for PGC: products are delivered on time and usually exceeding customer expectations. Publishers give PGC bigger contracts which implies developing more exciting games and making people feel happy. There are no complaints.

This success opens new opportunities for PGC, and one shows up quickly: a very important publisher contracts PGC for a new game. This project is different from any other PGC has executed in the past. It is a nine-month project that requires at least 15 people; most of the visual design of the game has to be outsourced and the game involves the use of technology that is unknown to people at PGC. Another challenge rises up: contract and franchise negotiations took almost two months, but the delivery dates remain fixed. A nine-month project is now a seven-month one. The product manager decides to start planning the project right away, as usual: the team takes about three weeks to build a detailed schedule with fine-grained tasks for the seven months of the project plotted in a Gantt chart. The first production iteration starts, and three weeks later (one before the first delivery), the project is completely challenged. Tasks seem to be advancing, but no real progress is visible. Team interaction is difficult: status meetings are held weekly but are not effective. Morale is very low. By this time, many tasks in the schedule do not make sense anymore, and the schedule has to be updated. This sole fact worries the team a lot because they know that it may take at least a week.

It is evident that the management approach is not working in this case, and a change is needed. The team decides to use an agile approach. First, the team is divided into three mini-teams of five people each. Each team has an assigned leader and is self-sufficient in terms of the required skills; this means that each team has at least a game designer, an illustrator, an animator, and a programming engineer. The product is also divided into two major components and assigned to the first two teams. The third team receives the responsibility of integrating the game. Regarding the planning process, considering the business and technology uncertainty, it is recognized that full up-front planning is not useful so a high-level milestone plan is prepared, and it is defined that detailed planning will be conducted iteratively. The iteration's duration is established in two weeks. Every iteration will start with a planning session when the scope is analyzed and tasks are identified and estimated. Tasks will be re-estimated daily, and progress will be reported with burn-down charts. Each team will hold daily inspection meetings. Team leaders will hold a daily meeting too. Agile principles and philosophy are communicated to the team, and ground rules are established. To support this transition, a coaching strategy is launched.

The results for this project improve significantly. After the first iteration pitfall, commitments with the customer are always fulfilled on time. Technology issues are common, but they are handled by the team and the product is delivered with high quality levels. There is also another big gain: people at the company have acquired competencies to lead a team and manage a project. The company feels more confident in taking bigger and more challenging projects. There is a paradox in this case that must be noticed. What

we can call a natural agile environment (small new product developed iteratively by a co-located team of highly talented people) was performing well using a traditional method. However, when they needed to scale-up, agile practices supported that better.

Mixing Approaches

Real Insurance Corp. is a large CMMI maturity level 3 company for which the project management methodology is based on the PMI framework. IT projects are managed using a strong matrix organization and the project management discipline is supported by the establishment of a project management office (PMO). There are senior project managers with more than eight years of experience. The company wants to develop two products for a business unit. The first one is a traditional product that is going to be re-engineered in a 12-month project that is partially outsourced. The second one is a new product which is going to be based in the framework developed for the first one. This second project will start three months before the first one ends and is planned to last about nine months (the first release in the sixth month). The first project starts and is challenged from the beginning: deliveries are always late; the primary supplier is changed twice and deliveries are normally rejected. The progress is very slow and schedules change frequently. The second project starts as planned by the ninth month of the first one with a six-person team. After two months, the first project is cancelled. A quality assurance audit is then conducted on the second project, but no significant methodology issues are detected. Knowing that this project was going to use components developed for the first one (that are not ready), six more people are added to the team. The team struggles trying to use the portions of components previously built, but the first partial delivery is late and rejected. This fact raises alarms to IT management which has been highly committed to the business unit since the first project failure. Now its three months to the first release, and the team realizes that it is less costly to stop trying to work around the half-developed components and start from scratch.

The decision was to include some agile practices to facilitate team interaction and improve morale. Scope management artifacts were maintained but change control procedures were slightly modified to allow fixed scope iterations. The scope of the first release was renegotiated by prioritizing items. The work was divided into four fixed-duration iterations: the first three finishing with a fully functional increment of the product and the fourth dedicated only to refinements and tuning. The project schedule was updated, leaving only milestones and high-level descriptions. The formal estimation method was maintained, but estimations were reviewed according to the defined iteration plan. Iteration planning workshops were conducted to create task backlogs. Daily meetings and burn-down charts were used. The main project management artifacts, like the project charter and project plan, were updated to reflect these changes. The project status reports required weekly by the PMO were maintained and also the risk management processes. Nevertheless, the main focus was not the process itself. A detailed communication plan was put in place and a coaching program was launched to facilitate change. The team was trained in agile principles and values, and workshops to establish ground rules were conducted. The team was co-located. The customer was involved in the methodology changes, and the acceptance testing plans were modified to fit the new approach.

The first iteration was the most difficult. The planning workshop lasted almost three days (not the day that was expected for the three-week iteration). Initially, the 12-person team was separated into two functional groups which was believed to be the most appropriate approach, but this was confusing for the people who decided to create groups by architecture layer. Initial daily meetings were also longer than expected. After

a week, the first integrations started with some suffering, but by the end of the second week, the team solved most of the problems allowing them to finish the iteration on time. Due the slow procedures to release a product to the acceptance testing environment, the result of the first iteration was presented in the development environment. Despite the customer's surprise, there was not too much to see but the team was able to accomplish a goal and deliver for the first time on the project a product that was functional. The team interaction improved a lot, but some political factors were present always and required a lot of attention along the project. The next iterations were less difficult but not exempt of challenges. The team was able to finish the development of all functionalities committed for the first release two weeks before the deadline, which was normally considered too short. However, since acceptance testing was conducted incrementally too, the first release went to production on time. Quality assurance reviews were conducted on the project, and no deviations from the CMMI process were noted. The management approach and practices were registered as lessons learned and made part of the organizational process assets.

Software Tools for APM

Software tools have been around us, helping to achieve goals since the beginning of the computer age. We can easily recall the different approaches to word processing of the late 1980s, the endless race of database engines of the mid-1990s, and the overpopulation of support software for whatsoever one may like in the present day. We may remember many enterprise resource plans (ERPs), customer relationship management (CRMs), operating systems (OSs), information managers, to-do lists, reminders, Web development, CAD tools, 3D modelers, and so on, but something amazing has revealed, in the continuous (and chaotic) race towards the future, that project management has received help from project management support packages. The offer is wide: they come in many flavors and some are more appealing to some clients (organizations) than to others. We will try to give a perspective of the present status of agile-focused project management tools or, to put it in the right way, tools that can be used to assist agile project management, and possibilities of their use in agile organizations, giving hints of alternate uses and warnings when risks are identified. In our search, we have recognized four flavors in which tools fit:

- Plan-based/traditional
- Wiki
- Web (2.0)
- Methodology-specific

As tools evolve and are fed with industry trends, new ideas, or customer feedback, they start to share some inspiration, leading ultimately to the fact that no tool can be allocated exclusively to one of these flavors, but the most influential one will represent its type. We will approach these tools with APM in mind, trying to relate their specific functions to components of APM.

Plan-based/Gantt Chart-Driven Software Tools

This is maybe the most overcrowded segment of consideration. There are many tools available, ranging from feature rich and quite expensive packages to free Gantt drawers. All these tools seem to have a strong bond to the traditional paradigm of project management, but some allow a degree of flexibility to adapt to the principles of APM.

Primavera Project Planner (Primavera) and MS Project (Microsoft) are the top of mind tools for many people, both are being used for a long time, and are the "de facto" standard for certain industries. Both tools are usually perceived as Gantt drawing tools, but they are feature rich and very helpful giving assistance to the project manager.

For product and project envisioning, Primavera Project Planner offers embedded forums on which the envisioning can take place as text post. These posts are published inside the application and are visible for all project members. Another possibility is to put the envisioning documents shared and access them through the embedded file manager. MS Project allows shared documents using project server's collaboration abilities.

For the layered planning, both tools use the traditional planning, so it is possible to specify milestones for the releases and some referential tasks to give a view of the project as a whole. Due to the inherent volatility of the tasks to be performed on an iteration, its inclusion on these tools would result in task/resource administration overhead. A parallel tool to maintain the feature list, task list, and estimations would be recommended. It must be said that a XP (template/extension) is available for MS Project on the Microsoft Web site (http://www.microsoft.com). Both products have an issue manager (in the case of Project, using Project server's collaboration capabilities) that allows tracking issues that might rise during product development.

Some other tools that have the same focus but with different implementations are eGroupware and TUTOS, both Web based, both open source. Each of these collaborative tools have a project module in which tasks and milestones are added with explicit task precedence and assignment. It is able to form a Gantt chart from the data set. Again, changing the content to be developed on the iterations can be a painful experience, especially when page loading time matters.

Wiki

Wikis have radically transformed the collaborative documentation works as we know them; its simplicity of concept has allowed many different implementations on many languages and platforms. Some people are using wikis as a project documentation repository; others are integrating tools around wikis to enhance planning and collaboration capabilities. Inside this group, the numbers point to open source as the most common licensing method. Among the best qualified applications is Trac (Edgewall Software), a software development project management tool with configuration management capabilities. Trac consists on a wiki integrated to an issue tracker and a subversion repository viewer for configuration management.

During the life cycle of the project, the wiki functions will allow the product and project envisioning development and organization in a collaborative way. Using the tool configurations, it is possible to define expected releases for the product. For each planned release, the project members have the chance to link any issue (or requirement) to any release, in such a way that the project features are organized based on the release in which they are expected. The wiki pages can act as concentrators, allowing linking from documentation to issues, change sets, files, including past versions of the project files (stored in a subversion server). The issue tracker provides configurable reports to check the project status according to the defined tasks.

A very lightweight alternative is TiddlyWiki and its branches, particularly d3, an implementation of GTD (Getting Things Done) by David Allen. D3 is a stand-alone wiki with the advantage of having certain tiddlers (wiki pages) with special behaviors, like projects or tasks that can be tracked as pending or checked as completed. Each tiddler has tags that will give us another way to search for them. Although this is not an APM tool, the flexibility that modern wikis give can empower a tool to handle more complex tasks. In this case, for the early stages of the project, the wiki inherent features can be very useful for the envisioning and project setup. Each task resides in a context; for our use, each context will be a release. In that way, a release will have many tasks that fulfill it. Using the task review, it is possible to see a list of all tasks pending, associated to its

particular release. In this case, we can use tags to assign the tasks to a particular team member. Any issue can be inserted into an issues context for its tracking.

Web

In the last year, the Internet community has seen the blooming of the Web 2.0 trend, the principles of which try to serve as a group of guidelines for Web applications towards a better user experience, where collaboration and social interactions are very strong concepts and tend to take applications out of the desk and onto the Net. Web 2.0 has brought some fresh air into project management tools, and some companies are actively working towards a better and more agile project management tool, and the results so far look promising.

Maybe the best example for this category comes with BaseCamp (37 signals), a Web application (service) for project management with an appealing user interface and simple but highly effective design. A BaseCamp project is a group of task lists, milestones, messages, and files. Its use for an APM project would be as follows: For envisioning, messages or files can contain the envisioning results that, in later phases, will become a major input for the planning; the release plan would consist of milestones marking approximate dates for each release; features are created in the form of task lists containing the actions to be performed in order to achieve the feature. Each feature can be assigned to a particular release, so it is possible to have a wide vision of the tasks needed to complete each release. This service was thought to handle many projects simultaneously and has access control features to give specific permissions to administrators, project members, and clients.

An open source clone is available under the name ProjectPier; it presents the same functionality of BaseCamp, with a less polished user interface. This tool can be installed into an organization's intranet (beating some of the fears that rise when one thinks of maintaining projects on the Web) and allows tagging for any element that is created. Although it is in active development, its available version has enough to carry a full project.

Stepping away from Web 2.0 and back to the traditional Web tools, another important referent is TargetProcess which can be used as a service or downloaded and installed in the organization's intranet. Its design denotes a profound knowledge of agile practices for project management and tries to cover the software life cycle in full. It has a user stories management module with mass import capabilities (from comma separated values files [CSV]), layered planning for releases and iterations, effort planning helpers, and team velocity estimation. It also includes per release burn-down charts based on the planning and daily status report. Additionally, it integrates its own bug tracking and test definition tools.

Methodology-Specific

Many of the APM tools available have a strong focus on a particular methodology. Among the more popular are Scrum and eXtreme Programming. In some cases, as we have seen in the past categories, we will notice mixtures of them. In this category, we discuss some tools with a scope limited to the methodology that may help to institutionalize their practices.

Wikiscrum is an open source wiki, adapted to support the Scrum project management methodology. Inside of a wiki page, the planned sprints are listed along the product backlog. Each sprint is clickable, leading to the task list for that sprint, having the opportunity to attach new tasks to it or to the product backlog, assigning the effort estimations for each task and the specific project member involved. One noticeable aspect of this tool is the charting capabilities included to show the burn-down chart for each sprint, based on the daily estimation variations for that sprint's

tasks. These are very basic but enough to get a team on track.

IceScrum is a basic tool for Scrum that lacks advanced functionality like planning support or resource estimating but achieves good works on giving order to releases, sprints, features, and tasks. It has security management that allows the daily review of the project, based on the team information about tasks. It is currently on active development.

On the road of eXtreme Programming, Xplanner is an open source tool made to simplify the project management using eXtreme Programming. The early stages of the project are supported in the way of a user stories management module; these user stories can be assigned to each planned iteration and, from these iterations, can be linked the tasks to perform. Among other aspects, the integration queue can be highlighted as a specific help for the project team, along with its time tracking module with special support for the tracking of pairs, like in pair programming.

CONCLUSION

The application of agile principles and value will continue its expansion to other disciplines. The next step from the project management point of view is the use of agile practices in multiproject environments and even more important in portfolio management. The portfolio management discipline by nature have many similarities with the agile context: a close relationship with business goals, prioritizing opportunities and enhancing resource productivity. Application of concepts like time boxes is starting at the project portfolio level in some companies, and we can expect many other applications in the next years.

We told before about the polemic raised between supporters of agile and traditional methods. For us, much of that discussion was based on misunderstandings. Many times, misusing a method is far more harmful than not having any. This is true for traditional and agile methodology implementations. A misunderstanding on the traditional planning paradigm may lead to the belief that fine-grained (one or two hour's tasks initiating 10 months from today) schedule elaboration is appropriate. A misunderstanding of the agile paradigm may lead to not having any plans at all.

Also it has been said that agile and traditional paradigms have home grounds where their principles and practices are appropriate, but outside of that zone, they are no longer valid. We agree that there is not any single method that may be applied to every context: there are no silver bullets. However, we do not believe that home grounds are mutually exclusive. In today's environments, the characteristics are crossing those limits. In those environments, neither agile nor traditional methods are able on their own to provide the best solution. The most effective solution is obtained by taking the best the two worlds can offer for that specific context. We truly believe that organizations may benefit from knowing how to apply best practices for their process improvement initiatives no matter the origin or philosophy behind them.

Chapter 6.8
Project Management in Enterprises:
IT Implementation Based on Fuzzy Models

ABSTRACT

The article discusses how the knowledge of management and artificial intelligence can be used for controlling the budgets and schedules of software projects. The first part of this paper gives an outline of the problems involved in software project management regarding the planning and control of processes and project teams. Next, an overview of changes in management is presented, followed by a description of a method for how these ideas can be used to solve software engineering problems. Consequently, an example is presented of a decision-support system, designed to aid project-team managers in planning and controlling budgets and schedules and helping the team members to adjust.

INTRODUCTION

In this paper, suitable methods for *Software Project Management* (*SPM*) are discussed. New possibilities of modelling SPM processes are indicated as well as an example concerning the issue of building a fuzzy model of a project team is presented. The scope of our research has been focused on specific project implementation performed by international project consortia. Such an ensemble can consist of several or more *project teams*, understood as those "distinguished from the structure of the organisation, commissioned for a defined period and consisting of specialists from various fields, whose knowledge and experience have a bearing on the problem" (Stoner, 1994, p. 143).

PROBLEMS OF MODELLING SPM

With the purpose of building on an SPM knowledge-based model, an appropriate *state of the art* has been established. The knowledge obtained in this way concerns the management techniques used by managers to support a project implementation and, based on process models, to allow for suitably assessing the states of both project processes and human teams (Figure 1). The consequences of these issues can be found in the budget, deadlines, and functionality of the project.

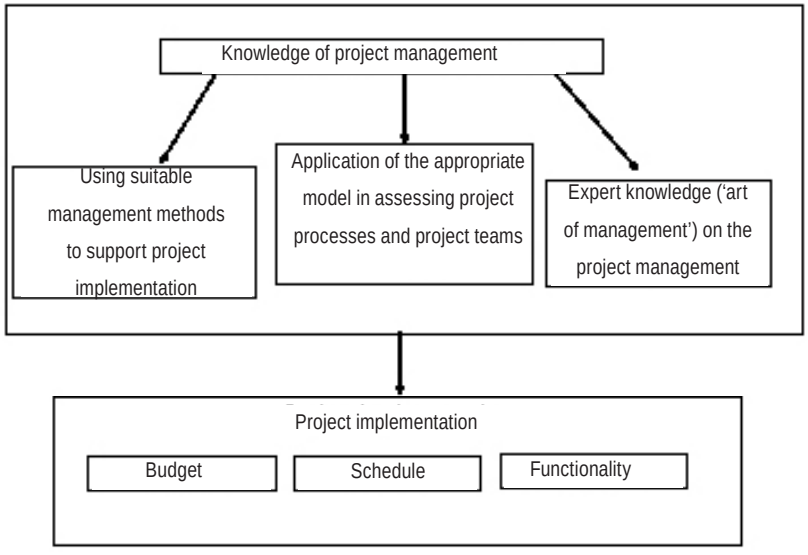
Expert Knowledge of Project Management

According to the SPM experts, scope, time, communication between team members, and risks of project changes are inter-related management knowledge factors. "Recycling" such knowledge in new projects is difficult. Those difficulties often result from an incomplete documentation of the project processes and from the lack of adequate knowledge, both on the factual project management mechanisms and way of describing SPM. They are also conditioned by the commercial nature of the projects (concerning the knowledge about implementations and their management). For given project experts (managers), the source of knowledge may be placed in the know-how of implementing previous projects. It is clear that such knowledge depends both on the specific characteristics of the performed projects and on the manager's ability to make suitable predictions, for example, to make use of this experience in implementing new projects.

Methods of Supporting Management Processes

Apart from expert knowledge, an important source of the education on project management can be found in the spectrum of the methods applied

Figure 1. Relationships between the knowledge of project management and project implementation



in project organisation. They constitute formal guides to proper behaviour in SPM. For example, *KADS* presented in the work of Hickman and Killin (1994) and *Pragmatic KADS* from the study of Kingston (1992) propose to divide projects into implementation phases and indicate solutions for these phases of the project. Adaptation of several known methods in the project management can be found in the works of Coleman and Somerland (1994) and Nerson (1992).

Individual methods created by certain large project teams can also be applied. As an example, the method of *Project Management Methodology* (*PMM*), discussed for instance by Łopaciński and Kalinowska-Iszkowska (1999), can be mentioned as being worked out by the IBM company. The main feature of PMM lies in planning the processes of the project and using a packet of *WS-DDM* (*Worldwide Solution Design and Delivery Methods*) supporting knowledge acquisition and project management.

There are also other methods which support project management in respect to costs, composition, and size of teams as well as labour intensity, as follows:

- *Estimation by analogy* — meaning an assessment of the project analysed on the basis of earlier implemented and documented projects;
- *Expert assessment* carried out by a group of independent experts;
- *Initial estimation* based on elementary work units (*Work Breakdown Structure* [*WBS*]);
- *Top down estimation* — the method of design within the limits of a given cost (*Design to Cost*) — introductory decomposition into simpler tasks (*Workpackages*) and definition of the necessary outlay of work, further decomposition to tasks, and exact processes;
- *Estimation based on parametric models* — the relationship between the productivity and the duration of the project as well as other factors directly bearing on them; and
- *Estimation in order to win* (*Price to Win*) — an assessment of the project is conducted in a way to outdo potential competitors.

For the purpose of managing time and material/human resources, the method of functional points analysis is applied. This method was worked out by Albrecht of the IBM company in 1979 and later perfected by the *IFPUG* (*International Function User Group*).

The method of functional points analysis, like *COCOMO* (Pfleeger, 2001), is characterised by the influence of subjective judgment, and not by objective indicators in the assessment of project productivity. This means the assessment of the projects productivity by the use of considerable experience and quite complicated algorithms.

Description of Project Teams

SPM demands a considerable involvement of human resources. As most beneficial solutions co-operation with an external organiser of the project and suitable definitions of the tasks of the team members are generally recommended. During team organisation, an attention should be given to the changes that may occur in the organisational structure of the consortium. New teams can be seen as complex systems in which information tools and management techniques are directly connected with each other (*Workflow Management, Groupware Process Reengineering, Computer Supported Co-operative Work*). It is also assumed that the project teams, brought together to implement a team task, can bear both formal and informal organisational structures. Such a project team is assembled by an appointed project manager. It is clear that the compiled team is usually interdisciplinary, which calls for using appropriate solutions to co-ordination problems.

Models for Assessing Team and Project Processes

Assessing teams and project processes needs appropriate models. A number of models, such as CMM (Capability Maturity Model) (Paulk, 1997), SPICE (Standard for Software Process Assessment) (Spice, 2000) and the norms of ISO 9000 have been elaborated. The models of process maturity (CMM) supply useful solutions making possible the handling of project processes. Their application supports the assessment of basic team management processes and defines their level of maturity. They also identify critical elements of the processes. The SPICE model constitutes a complement to other international standards of process assessment and other models for assessing the capacities and effectiveness of both teams and processes.

NEW POSSIBILITIES FOR CREATING THE SPM MODELS

There is an opinion in the subject literature (Pfleeger, 2001) that SPM is more an art than a systematic strategy of action. This judgment reflects the fact that, in the course of the project, the manager makes various decisions which can hardly be modelled and anticipated. They can, for instance, concern the running changes in the make-up of the team enforced by human and social factors (as best programmers may be "tempted" by a rival business). For these reasons, many managers consider the art and experience of SPM as being the principal source of knowledge about project management. Generally, the project success is connected with the manager's ability to appropriately forecast changes and react to the risks appearing in SPM. Many managers assert that it is not possible to successfully plan, organise and control a project without applying formal SPM procedures and methods.

Several methods of assessing projects in fuzzy categories (*Fuzzy Projects*) are discussed in the works of Słowiński and Hapke (1999), Węglarz (1999), and Hapke and Jaszkiewicz (1999). There are methods of scheduling projects with the use of *metaheuristic algorithms,* which are basically founded on genetic or evolutionary algorithms, simulated annealing, and taboo search. Such methods are widely used in solving problems of continuous, non-linear, multi-dimensional, multiple criteria, or combinatory characteristics. A multi-faceted version of this algorithm called *Pareto-Simulated Annealing* (*PSA*) makes it possible to search for representations of competitive (not dominated) solutions. It is also possible to use an *interactive search method* named *Light Beam Search* (Mesarovic & Takahara, 1989) to support the effort of the manager in choosing one of many solutions found by PSA.

A different group of system models are those concerning *management in uncertain conditions* as presented by Pawlak (1997) and Kacprzyk (1997). Their characteristic feature consists within incomplete or lack of information. Examples of this type can be observed within *relational, probability, game, and fuzzy models.*

Application of Fuzzy Set Theory

Fuzzy models of a linguistic type (*LM, Linguistic Models*) are based on a set of rules of type *IF-THEN* concerning undefined conditions and inference mechanism. They are profitably used in modelling social systems (Yager & Filew, 1995). Paradigms containing logical rules with fuzzy conditions and functional conclusions are marked as *Takagi-Sugeno-Kanga* (*TSK*) models (Tong, 1979). Nevertheless, the most commonly used model is the one of Mamdani (1974).

The following exemplary rule presents the process of fuzzy modelling for the case of two input variables and one output variable:

IF (u_1 is A_i) AND (u_2 is B_j) THEN (y is C_k) (1)

where the symbols represent:

A_i, B_j, C_k — fuzzy sets,
u_1, u_2, y — input and output variables, and
i, j, k — indices of fuzzy sets.

The TSK model differs from the Mamdani's one by the form of the rules.

IF (u_1 is A_i) AND (u_2 is B_j) THEN (y is $f(u_1, u_2)$) (2)

where:

$f(u_1, u_2)$ marks the function of the output (which can assume a linear or non-linear form).

The processes of fuzzy modelling for the case involving two inputs and one output are presented in Figure 2 (Zadeh, 1978).

These processes include: *fuzzification, inference*, and *defuzzification*. In the fuzzification process, the degrees of membership of crisp, model-input values (u_1, u_2) to the definite fuzzy sets (A_i, B_j) are calculated. Within the inference process, the membership function for the output value ($\mu_{Ck}(y)$) is computed based on the input degrees of membership ($\mu_{Ai}(u_1)$, $\mu_{Bj}(u_2)$). Finally, creation of the membership function for the output variable (y) takes place in the following stages:

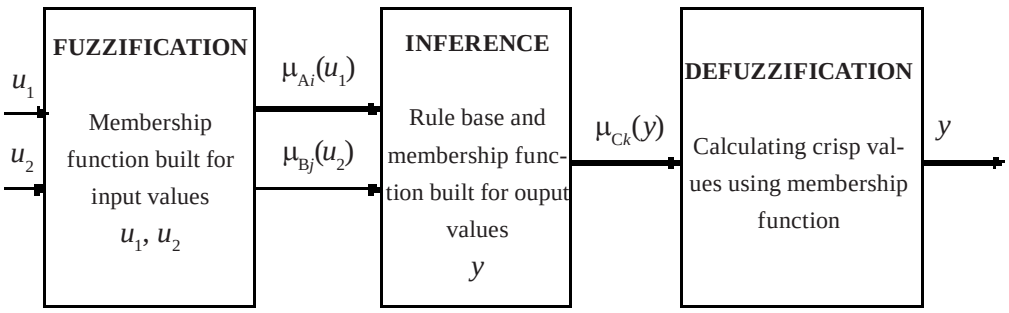
- Construction of the rule base;
- Activation of the conclusion mechanism;
- Definition of the degree of membership for the output value of the fuzzy model; and
- Calculation of the crisp value for the output value.

FUZZY *SPM* MODEL CONSTRUCTION

It is, thus, assumed that fuzzy models are constructed using the knowledge of SPM and project modelling. In the first case, the knowledge is acquired from project managers, while the latter one results from the specialists in the field of systems modelling. The knowledge of SPM can be applied in constructing formal methods of description, and, in particular, in building fuzzy models.

We also assume that a strategic milestone for the modeller lies in the selection of methods of formalising the knowledge of SPM. The famous statement of one of the originators of the fuzzy sets theory announces that "if the complexity of

Figure 2. Processes of fuzzy modelling for a case involving two inputs and one output



the system increases, then our ability to formulate accurate and also meaningful views of its behaviour decreases, until we reach a threshold value, beyond which precision and meaning become almost mutually exclusive features" (Yager & Filew, 1995, p. 167).

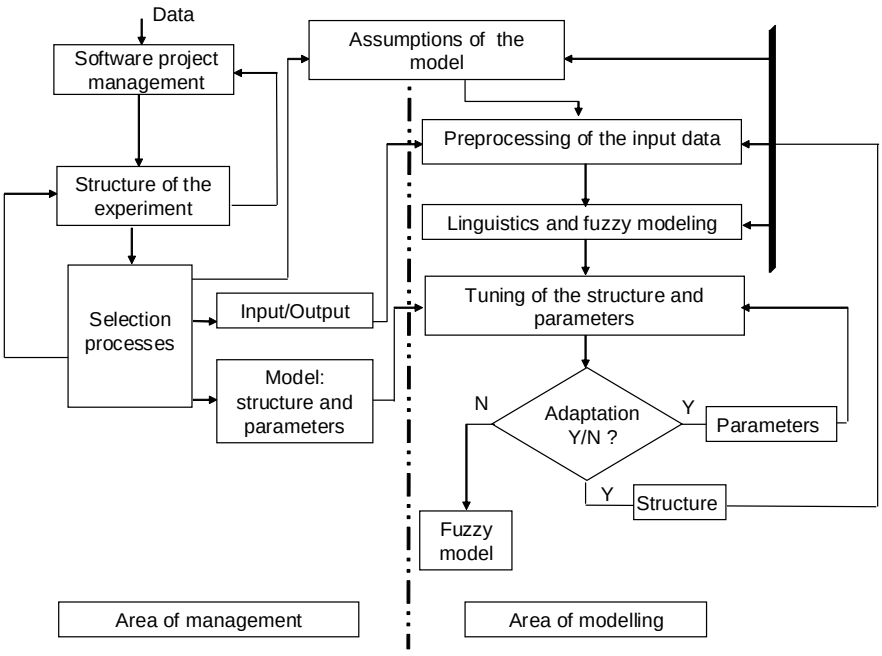
Making use of complex mathematical apparatus gives the possibility of precise description of repeatable processes mainly for technical systems (mechanical, electric). Whereas in the case of social systems, a departure from such precise descriptions is recommended by Łopaciński and Kalinowska-Iszkowska (1999), along with the use of techniques based on fuzzy logic. Therefore, also in the case of modelling socio-technical systems such as SPM, the apparatus of fuzzy set theory may be used both in the processes of formalising the knowledge and adapting the model. Then, the construction of *the fuzzy model of SPM* (Figure 3). can be treated as a process of continuous modelling with the use of fuzzy algorithms.

Keeping in mind the earlier assumptions, we have used the knowledge of the project manager (expert knowledge, methods and models) and the one of the modeller (basics of modelling and simulation, theory of fuzzy sets and regulators) in constructing a new prospective SPM model.

The aggregated knowledge of manager and modeller enables the processes of modelling SPM to be conducted along the lines of continuous modelling with the use of fuzzy sets. A detailed concept is presented in Figure 3, taking into account:

- Preparation of data concerning the structure and parameters of the model;
- Structural modelling on the linguistic level;

Figure 3. Continuous modelling of SPM with the use of fuzzy algorithms



- Basic tuning of the values of the parameters; and
- Possible adaptation of the parameters and structure.

Data Concerning the Structure of the Model

On the basis of the managerial knowledge, it is accepted that SPM can be implemented in four areas of management: knowledge, project processes, infrastructure, and supporting technologies (KPIT).

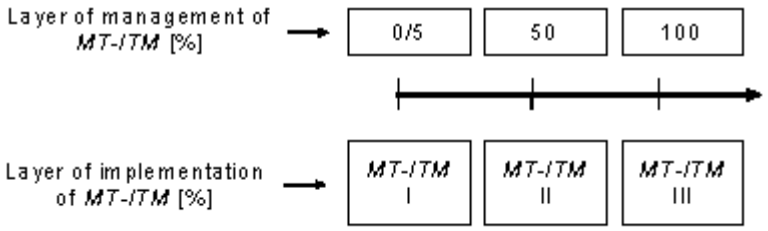
The SPM should also be analysed taking into account particular running phases of the project. Moreover, the scope of activity of managers should concern planning, selection, organisation, and monitoring of the *methods and tools of information technology and management* (*MT-ITM*). With regard to the crucial dynamic changes in MT-ITM, the use of the concept of variable states in describing those changes seems to be necessary, which needs also to be estimated by an expert of the MT-ITM according to the practice applied in SPM.

Three values of the level of exploitation of MT-ITM (in terms of management and implementation) are proposed, as shown on a linear scale in Figure 4. This distinction is applied to all the previously mentioned areas (KPIT).

1. The state of the MT-ITM management layer is described by a *scalar state variable*, which assumes one of three values. In the case of methods, they are within the range of 5% to 100%, and in the case of tools, from 0 to 100%. The choice of the scale for the methods (starting from 5%) results from the fact that the managing projects, without any method, is not possible. The choice of particular state values on the scale concerning the methods and tools of management depend accordingly:
   - On the number of team members who apply MT-ITM in relation to the number of all project team members (a composition co-factor, *ks*) at a given stage (in the case of managing infrastructure and knowledge);
   - On the number of implemented processes in which MT-ITM is applied in relation to the overall number of processes implemented (a process co-factor, *kp*) at a given stage (in the case of managing processes and supporting technologies).

On the basis of a weighted sum of the scalar states of the management layer concerning both methods and tools, we determined *a generalised scalar state of management of KPIT.* Note that

Figure 4. Defining the management states based on a linear expert scale for the two layers of KPIT



in calculating the generalised scalar states of management, we use weights, whose values are established on the basis of expert assessment.

2. Similarly, the TM-ITM implementation layer (determined by experts on the basis of the best practice in managing this type of projects) also covers the KPIT fields, but in terms of their implementation, and is assessed within three discrete values symbolised by MT-ITM I through MT-ITM II.

Using the Scale to Define the Generalised Scalar State of Knowledge Management

If the project manager achieves knowledge by means of direct talks with experts and formalises it with the use of diagrams or a rule description, the application of this method has considerable influence on planning the collection of knowledge. For the method of direct talks with experts, the scalar state of information and management methods is defined at the value of 5%, the formalisation of knowledge with the use of diagrams at 50%, and the rule description at 100%. The scalar state of information and management tools is defined similarly. Correct values are connected with the use of the co-factor *kp* resulting from the membership of the team. Next, the generalised scalar state of knowledge management (being the weighted sum of both values) is calculated.

In developing a concept of the model, several factors (such as "hand steering" of the composition of the team) have been ignored. Equally irrelevant appeared the so-far-identified phases of the project (definition and specification of demands, construction of the model, and its implementation). This could be easily justified because the manager initially chooses MT-ITM for all phases of the project and (if necessary) conducts a team training stage (Szczerbicki & Orłowski, 2003). With this, we assume that the manager is a specialist in a given field of IT and can appropriately select, exploit, and assess the information solutions applied in project management.

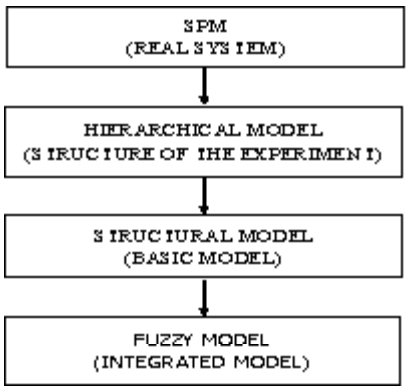
Data Concerning the Parameters of the Model

A concept of tuning the fuzzy model has been accepted, making use of SPM expert knowledge. The team manager collects the knowledge about the project management in suitable experimental knowledge base and records them in the form of rules whose structures correspond to the rules of the fuzzy model. The experimental knowledge base is classified with regard to the type of projects (e.g., successful, unsuccessful). It is clear that such a classification is performed by an expert in project management. Successful projects are defined as completed in the allotted time, with the agreed finance and aim. By using this kind of solution, we avoid misleading "averaging", which results in creating useless models.

The rules recorded in the experimental knowledge base are grouped according to the phases of the project. Such ordering influences a procedure of identifying clusters and creates the conditions for calculating the coordinates of the centres of gravity of the clusters, identified as coordinates of the peaks of membership functions. Adding new rules to the experimental knowledge base has an effect on a change of the centres of gravity of the clusters and, in consequence, on a change of the peaks of membership functions.

In the presented concept of the model construction, we also assume the processes of tuning the model parameters. The knowledge necessary for tuning should be gained from the managers and coordinators of the teams involved in the project realisation. The sources of knowledge are simply project documentations.

Figure 5. The process of constructing the fuzzy model



Structural Modelling on the Linguistic Level

A four-stage construction of the fuzzy model is proposed as shown in Figure 5. The first step is the analysis of the real system. It covers the management of the project consortium consisting of several or more project teams. In this paper, the management of the consortium is characterised by a basic structure of modelling experiments and a resulting *hierarchical model*. Next, a *structural model* is obtained, referring to the management concerning (the level of) the project team SPM_z. According to the theory of system modelling, this corresponds to a *basic model*. Next the *fuzzy model* is built (reflecting the so-called *integrated model*), which portrays the management processes based on the fuzzy rules. The applied concept of fuzzy modelling by giving a simple mathematical description of SPM_z , allows for obtaining a full hierarchy of management for the project consortium.

Tuning the Model Parameters

We have proposed a concept of tuning the membership function according to the project phases. The membership functions are tuned separately for the system input and output variables, while in the case of the state variables, the membership functions are fixed (in terms of the forms and the peak parameters). The construction of the membership function is controlled with the use of the clustering methods with the data from the concluded projects.

Adapting the Parameters

With the approach described earlier, it is easy to perform the adaptation of the model/system on two levels: (1) the management of the project and teams SPM_z and (2) the adaptation of the parameters of model SPM_z - *RFM* (*Software Project Management - Rule Fuzzy Model*). The first level of adaptation depends on the selection of "better" solutions of higher scalar values of the generalised management states, while the second level depends on the qualification of the output variables by the team manager according to the quality of team management.

As has been mentioned previously, with the proposed procedure and a great variety of the methods of implementation and various levels of quality in managing project teams and implementing information projects, we could easily finish off with "over-averaged" and, therefore, useless models. For this reason, in the concept of adaptation on the first level, we recommend a pre-selection of all projects carried out by an expert in SPM_z. The pre-selection can be done according to the quality of the project and team management, for example, leading to "successful" and "unsuccessful" projects based on the experimental knowledge base (see subsection, *Data Concerning the Parameters of the Model*). In

the second level, this influences the classification of input and output variables to appropriate models and the position of the apexes of the membership function. In conclusion, the method of modelling and adapting the model presented in this work *SPM$_z$ - RFM* allows us to:

1. Model various (established by the expert) types of processes, and
2. Create conditions for the project manager to use a *proper* model fitting to his knowledge about the level of managing the project team.

Finally, it can be worth mentioning that no adaptation of the model structure is assumed.

CONCLUSION AND ASSESSMENT OF EXISTING SOLUTIONS

The methodological solutions (methods PMM and KADS, models CMM and SPICE) provide formal approaches to supporting SPM by focusing on a collection of procedures for assessment of teams (the CMM model) or processes (the SPICE model). In the case of methodological solutions (PMM and KADS), we can use the project tools to implement IT systems, but not to manage them. The *SPM$_z$ - RFM* model indicate possibilities for managing the knowledge of IT projects and for using of IT methods and tools.

In the first case, the model *SPM$_z$ - RFM* (Kowalczuk & Orłowski, 2004) gives the possibility of selecting qualified solutions (on the basis of generalised management states) to the problems of realising project processes and functioning project teams. The latter case creates an integrated environment for ongoing assessment of both teams and processes. The criteria of MT-ITM for project teams increase the probability of selecting the best solution (on the basis of strict assessment). It also creates conditions for gaining knowledge, more effective rule-based processing, and increases the efficiency of the mechanism of cooperation between members of the project team. At the same time, it shortens production time (making group work mechanisms more efficient) and raises product quality (constant control of the produced software using *SPM$_z$ - RFM*).

ABSTRACT

Virtual teams are an important work structure in software development projects. However, little is known about what constitutes effective virtual software team leadership, in particular, the amount of leader delegation that is appropriate in a virtual software-development environment. This study investigates virtual software team leader delegation and explores the impact of delegation strategies on virtual team performance mediated by team motivation, team flexibility and team satisfaction with the team leader. This research is a report of a pilot study run on student teams

carried out to refine and test the research constructs and research model for a larger study run in corporations. The study found that virtual team leaders delegate more to competent virtual teams and that such delegation is positively correlated with team member satisfaction with their leader and with team member motivation. Overall, the work provides important information for software-based organizations interested in developing virtual team leadership skills.

INTRODUCTION

Virtual teams are composed of geographically distributed coworkers linked though information technologies to achieve an organizational task (Townsend, DeMarie, & Hendrickson, 1998). Virtual teams are a popular structure in software development for several reasons: they provide access to lower-cost labor as well as access to a range of disciplines and technical specialties (Curtis, Krasner, & Iscoe, 1988). While software team leaders and managers are now frequently given virtual teams to manage, they have not been given clear directions on how to effectively manage such teams. One important issue regarding virtual software team management is when and how team leaders should *delegate* authority and responsibility to the team.

Delegation means that one has been empowered by one's superior to take responsibility for certain activities, which were originally reserved for the superior (Ashton & Kramer, 1980; Bass, 1990). In traditional leadership studies, delegation is widely acknowledged to be an essential element of effective management (Yukl, 2002), and effective delegation offers a number of potential benefits, both to the manager and the subordinates. However, to the authors' knowledge, only a few studies have been conducted to investigate delegation as a distinct component of global virtual team leadership. In the limited number of conceptual works and empirical studies in which delegation is not the direct focus, delegation has been a controversial issue. Some researchers argue for the benefits of delegation: Eveland and Bikson, (1988); Jarvenpaa, Knoll, and Leidner, (1998); Jarvenpaa and Leidner, (1999) report that an effective leader of a virtual team needs to be more flexible to accommodate the complexities and volatility of the virtual team environment, and to be willing to let others take the lead when necessary. Furthermore, they suggest that virtual team leadership should focus on facilitating and empowering team members to take action on their own. In contrast, Paré and Dubé, (1999) argue that, due to the distributed nature of virtual teams, management by observation is simply not possible, and that much more discipline and control is required in a virtual setting. Additionally, team effectiveness in virtual environments may be hindered by excessive autonomy coupled with exclusive reliance on electronic communication and lack of face-to-face interaction.

This article aims to address the research gap regarding delegation to a virtual software team by investigating the occurrence and effects of leader delegation in such teams. Finding out how and why leaders do or do not delegate to virtual teams and the impact of the leaders' delegation behaviors on the teams will help industry practitioners to better frame their strategy for managing distributed software teams and will also add to the field's knowledge about virtual team leadership.

The focus of the article is on software teams, in part, because it is felt that the global software team phenomenon has several unique characteristics that may not apply to virtual teams in general. Unlike other activities that have been outsourced or offshored, work activities cannot be as easily compartmentalized because of the high integration of the software product. Thus, there is a need for communication and working together in a structured fashion, which demands good leadership. In addition, software developers expect to have a high degree of independence in their work. Therefore, the degree of delegation

by a leader may differentially affect these virtual teams.

Collaboration in software development also demands the ability to communicate highly detailed specifications and questions. This requires communication skills that may not be needed in other types of virtual teams, skills which may be influenced by a team member's knowledge of English, the common language for many of these teams. Therefore, good management of the communication structure and media is likely to be an important leadership trait. Finally, the new countries that are now being included in global software development have relatively young team members. As such, the distribution of corporate knowledge and software skills is uneven. Thus, leadership and delegation in this type of environment is likely to be different for software than for other tasks carried out by virtual teams.

The article is structured as follows: first, an overview of the research model is presented to give readers a sense of the focus of the article; then, based on a review of the literature, conceptualizations of leader delegation are presented and specific research hypotheses regarding virtual team leader delegation are explained; finally, the pilot study testing the model is presented. A discussion section presents the contributions and limitations of this research, and a final section discusses the implications for virtual team management.

RESEARCH MODEL

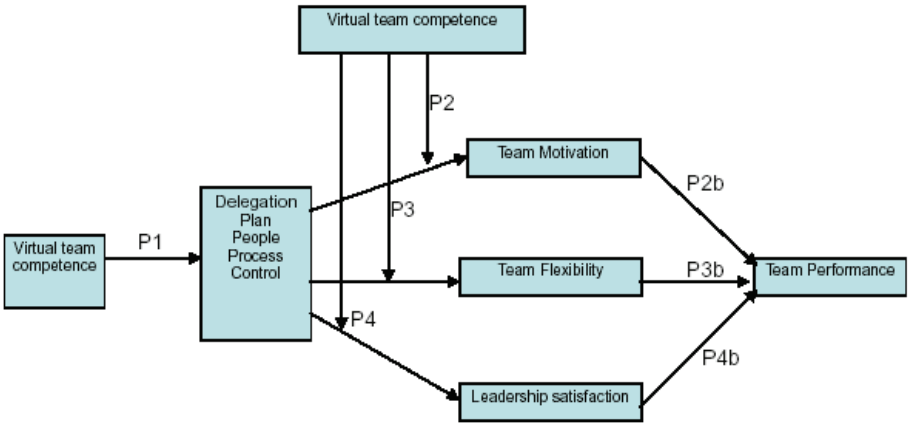
Before beginning a detailed discussion of the variables used in this study, we present the overall research model and briefly describe the relationships that are hypothesized to exist between the variables. A key focus of the model is the amount of delegation that virtual software teams receive from their leaders. It behooves us, therefore, to describe the management structures that are being studied.

When we talk about virtual teams, the structure that is typically in place does not constitute virtuality for each and every team member but, rather, distributed teams in which some subsection of the software development team is co-located and other sections are virtual. For example, a portion of the team may be located in the United States and a second and third portion in India and China, respectively. The overall team is working on the same software product, but the work has typically been compartmentalized in some way so that each co-located portion of the team has specific assignments. However, the work is such that there is a need for continued communication between each of the non-co-located portions of the team to resolve integration issues.

Management of these teams comes from several sources. First, there is typically a local manager who handles personnel issues. Then, there is a technical manager who oversees the project. Finally, there is a technical head of the particular subsection of the project who is directing the work of both virtual and co-located sub teams. Management of the work is the purview of this leader, and this is where delegation typically occurs. This management is located with one sub team and virtual to the other sub teams. Traditionally, management is located in the home of the parent company, but it also may be at a customer site.

Because at least, one part of the software team is distant from the manager, less is likely to be known about the competence of that part of the team by the manager, and therefore, he or she is likely to delegate in a manner so that majority control of the technical issues rests with that portion of the team that is co-located with the manager. The research model being put forward in this paper suggests that perceived team competence predicts the amount of delegation that will occur but that this delegation will have an effect on key team variables such as satisfaction, motivation and flexibility. It is argued that these three variables

Figure 1. Proposed model of delegation effects on global software teams



are primary in affecting team performance. Figure 1 presents our research model.

An elemental part of this model is that team competence not only affects the decision of the team leader on whether to delegate or not, but also affects the impact of the delegation. That is, teams with less competence, are likely to desire less delegation and to be unhappy and unmotivated with less direction from the leader. This occurs primarily because the team members do not know how to perform their tasks completely, yet wish to succeed in these tasks. However, the only way they can succeed is if they receive tighter direction from the leader. As we shall see with our analysis, we did not necessarily find that less competent teams wanted more delegation. The measure of perceived competence that we used had difficulties with the student teams used in this research. All student teams perceived themselves to be highly competent. Rather than treating this as a problem, it is a result that we believe has an impact on virtual team management.

Virtual subteams are not able to ascertain their competence in comparison to their distant counterparts because they lack the proximity required for an accurate comparison. They are, therefore, likely to perceive themselves as competent and desire more delegation. Culture may also have an impact in that many cultures worry about "face," that is, how they appear to others. These cultures would also perceive themselves as competent, possibly due to team members' advanced education in their country or membership in a high social class. Whatever the reason, they are likely to desire more delegation even when it is unwarranted. This issue will be further addressed in the paper's discussion section.

The next sections present prior research on the relations posited in our model and detailed definitions of each of the variables used in the model plus support from the literature on the validity of the constructs we have developed for the variables.

LITERATURE AND HYPOTHESES

Delegation

As mentioned earlier, delegation is a state or condition in which one has been empowered by one's superior to take responsibility for certain activities, which were originally reserved for the superior (Ashton & Cramer, 1980). There is a rich body of studies in traditional leadership research investigating delegation, mostly as a feature of leadership style or as a combination of related leader behaviors. Very few studies investigated delegation as a distinct management practice (Yukl & Fu, 1999; Zhang, Tremaine, Fjermestad et al., 2006). Because of this, we cannot ascertain the effect size of delegation (as a distinct leadership component) on possible variables of interest.

Another major limitation of previous delegation and leadership studies is the failure to focus on what types of responsibilities and activities a leader delegates. Only the global delegative style of the leader was assessed. This limitation seriously undermines the practical value of these studies, as their findings do not inform software team managers where they can and cannot delegate nor does it tell them what they can delegate. Leadership is a multi-faceted process, particularly so in virtual teams, given the technological, cultural and organizational complexities of a virtual team environment. Therefore, it is important to examine the leadership and managerial functions originally assigned to leaders to determine which of these can be delegated to followers. To that end, studies that describe leadership and managerial functions are reviewed in this section, and a list of leader delegation categories is generated.

For classical management theorists like Davis (1942) and Urwick (1952), the functions of the manager-leader in a formal organization were orderly planning, organizing and controlling. To address the overlapping needs of the organization, team and individuals, Coffin (1944) modified the classical functions as follows: formulation (planning), execution (organizing), and supervision (persuading).

MacKenzie (1969) proposed a well-known leader-manager model that illustrated the great variety of activities that a typical manager performs. He proposed that the central management functions relate to the management of people, ideas and things, which form the three basic components of every organization with which managers must work. Three functions (the analysis of problems, decision-making and communications) are important at all times and in all aspects of the jobs held by managers, and therefore permeate the entire work process. To carry out these functions, the leader-manager needs to execute these leader activities: planning, organizing, staffing, directing and controlling. A factor analysis reported by Dunnette (1986) of 65 managerial activities yielded seven factors: monitoring the business environment, planning and allocating resources, managing individual performances, instructing subordinates, managing the performance of groups, representing groups and coordinating groups.

Janz, Colquitt, and Noe (1997) identified four distinct facets in which a leader could give the team autonomy: planning (e.g., scheduling the team's work), product (e.g., suggesting new products or services), people (e.g., recruiting and hiring members) and process-related (e.g., specifying the development method a team should use).

Hertel, Geister, and Konradt (2005) reviewed a collection of empirical works on the management of virtual teams and summarized the management functions of virtual team leaders at various phases in the team's lifecycle. They proposed that virtual team leaders are generally engaged in such activities as *personnel selection, task design, team initiation, performance management, training and team development, and disbanding and re-integration.*

These studies categorize leader functions in different ways and use different labels for these leader functions. Integrating these different

Table 1. Four-dimensional leader delegation framework

Delegation Aspects	Key Activities
Planning-related	Scheduling the team's work Setting the team's long-term goals Setting the team's short-term objectives Setting the team's budget
People-related	Selecting team members Removing members from the team Determining team members' training needs
Process-related	Assigning work to team members Selecting the tools team members will use in their work Determining the team's operating procedures and work instructions
Control-related	Evaluating the progress of the team's work Evaluating team product quality Determining corrective actions when performance objectives are not met

categorizations, Table 1 summarizes four major leader function categories which can be delegated to virtual team members. These four areas are the overlapping important leader-manager functions identified in the mentioned studies. The first leader delegation category consists of *planning-related* team management and leadership activities that a virtual team leader can possibly delegate to the team. The second category consists of *people-related* team management and leadership activities that a virtual team leader can delegate, such as team staffing and team member training. The third category consists of *process-related* team management and leadership activities (or teamwork process management). The fourth is *control-related* team management and leadership activities. This category relates to the leader's functions and activities that control the work progress and quality of a virtual team.

To keep the categorization parsimonious, the key activities in each delegation category may incorporate more than one of the leader functions identified in the previous studies. For example, "determining operating procedures and work instructions" incorporates two virtual leader functions in MacKenzie's model: standardize methods and decide how to achieve goals. Some of the manager activities are not included because they either cannot be assigned to the team through leader delegation or are already tasks that are done by team members, for example, suggesting new products or services.

Delegation in Virtual Software Teams

The issue of productivity loss is very important when global software team leaders weigh the benefits and costs of delegation. A software team

is often formed for completing certain tasks within a limited time period. The short-term nature of the project requires avoidance of any productivity loss. In a longitudinal study using 18 student information system development (ISD) teams, Nicholson et al. (2002) confirmed the importance of avoiding productivity loss in distributed teams. The researchers attempted to identify the characteristics/behaviors of effective ISD project team leaders/managers. Their exploratory analysis revealed that face-to-face (FTF) and virtual ISD team members valued different ingredients of leadership in different phases of the ISD project. They found that a key ingredient for virtual team leadership was having a realistic leader who managed time efficiently. Global virtual teams involved in ISD are temporary structures that are very focused on the development of the information system application. These teams have tremendous time constraints. Hence, the role of a virtual project team leader is to remain practical in terms of the goals set and the deliverables promised, and to manage the time allocated to each task efficiently. Therefore, to avoid productivity loss, global software leaders are likely to delegate more to competent teams than to incompetent teams. A competent virtual software team has the knowledge, attitudes and expertise required to perform the team tasks and is more likely to plan well and manage their work efficiently (Faraj & Sambamurthy, 2006). A competent team can quickly apply their expertise to the delegated task and reduce productivity loss to a minimum. In contrast, delegation to incompetent teams means that leaders have to spend additional time giving feedback and monitoring the execution of delegated tasks to ensure that performance standards are met. Otherwise, managerial anxiety over loss of control can be overwhelming. However, in the distributed global team environment, close monitoring and timely feedback is difficult as "management by walking around" can not be used as a strategy (Paré & Dubé, 1999). Due to increased temporal distances, possible increased cultural distances and the lean nature of computer-mediated communication in virtual teams (Bell & Kozlowski, 2002), leaders will need to spend much more time and effort in coordinating, monitoring and coaching team followers in the delegated tasks.

Besides the need to manage time efficiently, the matrix organizational structure of global software teams is often another reason why team leaders delegate more to competent team members. Developing subordinates' skills and confidence is the biggest reason why leaders delegate or consult their followers, especially when followers' skill sets are still to be developed (Yukl & Fu, 1999). The potential growth of the followers is likely to be the major benefit leaders obtain from delegation to an incompetent team. However, virtual teams are often designed to cross geographical and organizational boundaries to allow dispersed organizations to maximize their expertise without having to physically relocate individuals. The required expertise for a given task or project may be dispersed at multiple locations throughout the organization; however, a global software team may facilitate the 'pooling' of this talent to provide focused attention to a particular problem without having to physically relocate individuals (Kayworth & Leidner, 2000). Therefore, global software teams are often dispersed in cities or even countries and, very commonly, the team followers do not report to the team leader in a direct organizational line. Due to the typically short-term nature of the team and the complexity of the reporting relationship, global software team managers are more likely to be evaluated on their success in achieving project goals, rather than on their development of team members. In delegating to incompetent teams, global software team managers—unlike line managers who may treat the costs of delegation as an investment to be redeemed later—are faced with the cost of sacrificing team performance, which determines the manager's own promotion and career growth. As managing a matrix structure is already chal-

lenging for virtual team leaders (Oertig & Buergi, 2006), the costs associated with delegating to an incompetent team would tend to deter virtual team leaders from this management strategy. Based on these arguments, the following hypothesis is proposed:

Hypothesis 1: *Leader delegation will be positively correlated with global software team competence.*

The Effects of Team Leader Delegation

In this section, three variables, motivation, team flexibility and team member satisfaction with their software team leader are each discussed. An argument is made as to why each of these variables is expected to be affected by team leader delegation and also why each of these variables is a primary determiner of overall team performance.

Motivation: According to Herzberg's (1968) motivation theories, recognition fulfills workers' esteem needs and can significantly improve employee's performance. A competent virtual team typically expects the team leader to recognize the team's competency by delegating more responsibility. Leader delegation will then improve the team's sense of self-worth and motivate the team to work more effectively. An empirical study found that the autonomy of virtual team members in determining work objectives and methods improved the intrinsic motivation of the team (Kirkman, Rosen, Tesluk, & Gibson, 2004). They investigated the relationship between team empowerment and virtual team performance and the moderating role of the extent of face-to-face interaction using 35 sales and service virtual teams in a high-technology organization. They found that team members are more intrinsically motivated when they believe they have high *performance capability* (**competence**), *high responsibility* and *authority* to carry out work (**delegation**), and *a meaningful task* that could impact the organization. Piccoli and Ives (2003) found that student virtual teams were more motivated and satisfied with less behavior control. Also, a team's acceptance of a decision is highest when the decision is made by the group (Curtis et al., 1988). Therefore, we posit that delegation to a competent virtual team would increase the team's motivation

On the other hand, delegation to less competent virtual teams will put the team in a difficult situation. Due to their low competence level, they need close monitoring and constant coaching from the leader or other experts, which is difficult and costly to obtain in dispersed virtual teams. Kayworth and Leidner's (2002) observation of a dichotomy between inexperienced members wanting and expecting strong directive leadership and team leaders who, faced with the practical constraints of distance and the lack of a direct management line, would prefer members to be self-managing. Such dichotomy hurts the team members' motivation and performance. In addition, the relatively short-term nature of virtual teams, which are often formed dynamically to cope with emerging projects or tasks, also means that the team has less time to learn on the job. Instead of desiring delegation, less competent virtual teams want detailed directions from the leader.

Therefore, we posit that delegation to less competent virtual teams may not improve team motivation. Based on these arguments, Hypothesis 2a is put forth:

Hypothesis 2a: *Delegation to competent virtual software teams will improve team motivation more than delegation to less competent virtual software teams.*

Team performance, as with individual performance, is a function of ability and motivation (Jarvenpaa et al, 1998). Sridar, Nath, Paul and Kapur (2007) have shown that team member motivation and trust affect performance in student teams

distributed between the United States and India. Significant improvement in team performance is therefore expected from motivated teams. Based on this argument, Hypothesis 2b is put forth:

Hypothesis 2b: *Virtual team leader delegation indirectly improves team performance through improving virtual team motivation.*

Flexibility: Team flexibility refers to how flexible a virtual team is in responding to environmental and personnel changes. Most virtual teams are knowledge-based teams which are formed to solve customer problems or to develop new products (Kirkman et al., 2004). The complex, knowledge-based tasks many virtual teams perform require behaviors such as planning and executing, managing team performance, improving team processes, and influencing organization-level direction and resource allocations (Mohrman, Cohen, & Mohrman, 1995). In conducting these activities, teams have to make sense of their tasks, improvise their work processes, and adjust how they make progress toward agreed upon goals. Therefore, flexibility is important to virtual team performance and team leaders should delegate to competent virtual teams to allow them to flexibly adapt to their immediate situations and opportunities. Remote team leaders may not be able to understand the work context or to appreciate the consequences of the changes occurring in the distributed locations. Delegation, therefore, puts this task in the hands of the competent virtual team members. These members can also make decisions in a more timely matter than the leader. Having appropriate authority delegated to them, they can proactively influence team leaders' decisions or even their own decisions instead of passively waiting for managerial permission before taking actions. Therefore, delegation to competent virtual teams will increase team flexibility. In contrast, delegation to less competent virtual teams may not improve team flexibility since less competent team members may not have the skills to make decisions and form action plans. Based on this argument, Hypothesis 3a is put forth:

Hypothesis 3a: *Delegation to competent virtual software teams will improve team flexibility more than delegation to less competent virtual software teams.*

When a virtual team flexibly adapts to its work situations and is free to respond to situations in at timely manner, it will be more risk-taking and learn from experience to continuously improve its work processes and to perform in more efficient ways. Based on this argument, Hypothesis 3b is put forth:

Hypothesis 3b: *Virtual team leader delegation indirectly improves team performance through virtual team flexibility.*

***Satisfaction with Software Team Leader*:** Delegation to competent virtual teams represents the leaders' recognition of their competence. Delegation allows the competent team to utilize their capabilities to adapt to the immediate opportunities and changes without waiting for decisions to be made by the distant leader. Therefore, delegation to a competent virtual team should improve the team's satisfaction level with the leader.

On the other hand, delegation to a less competent virtual team may decrease the team's satisfaction with the leader. In a global virtual team study consisting of undergraduates as followers and experienced MBA graduate students as team leaders, Kayworth and Leidner (2002) found that the inexperienced undergraduate followers were more satisfied with leaders who gave clear, detailed instructions and feedback. Faraj and Sambamurthy's (2006) study of 65 software development teams found similar results. Their study showed that empowering leadership has an important positive impact on team performance

but only under conditions of high task uncertainty or high team expertise. In the software teams they studied, when team members have significant levels of professional experience with software development, they are more likely to possess the relevant expertise and experience for managing their project activities. For such teams, an empowering leadership approach might be more appropriate since members may need less direct control and coordination and possibly possess as much relevant task expertise as the team leader. In contrast, when teams have low professional experience, a directive leadership might be more appropriate because the members look to the leader to provide needed directions and guidance about their work activities.

As software team distance increases, the work context exhibits increased complexities, for example, cultural misunderstandings, communication difficulties, and so forth. This makes virtual teamwork more daunting for a less competent team. Under such circumstances, the team needs to attain confidence and a sense of direction from a strong leader. Based on this argument, Hypothesis 4a is put forth:

Hypothesis 4a: *Delegation to a competent virtual team will improve the team's satisfaction with their team leader more than delegation to a less competent virtual team.*

When the virtual software team members are satisfied with the team leader, the team leader will be more able to influence the members to work towards team goals and therefore to improve team performance. This has been confirmed in empirical studies (e.g., Zeffane, 1994).

Based on this argument, Hypothesis 4b is put forth:

Hypothesis 4b: *Virtual team leader delegation indirectly improves team performance through improving virtual team's satisfaction with the team leader.*

RESEARCH STUDY

Study Design and Sample

A full-scale study with industry software development teams is currently underway to explore the presented research hypotheses. We report here on the pilot study conducted to test the validity and reliability of the constructs that were formed for this research and the viability of our research model. Although many of the questions that were used came from studies that had already tested their validity and reliability, there were modifications made to the questions to (a) fit the virtuality nature of the teams being studied and (b) to fit the software development environment. For example, the constructs of team competency and leader delegation were adapted to describe competency in terms of software skills and portions of leader delegation in terms of the assignment of software tasks

Student teams were used to pilot the research survey because the diversity of the student teams closely matched the software development team populations that the final survey is intended for. The student teams are part of a computer science and information systems program at an American, east coast university that has one of the most diverse student bodies in the United States. The students are primarily from China, India, the Middle East, Brazil, and Pakistan.

Forty-eight students in 30 software-development teams took an online survey that requested information about the variables presented in the hypotheses. Thirty-two males and 16 females; three graduate students and 45 undergraduate students participated. All participants were involved in teams that were engaged in developing a single software program for the entire semester. The software teams are part of the ABET accredited Capstone course designed to have students working in teams on real software projects before they matriculate. This is a course most students take in their last year of school. Companies are

solicited for software projects and present their projects to the class. A team leader volunteers for a software project and then interviews and accepts members for his or her team. Teams normally have four members but some teams have three or five members. Teams then meet with the company representative and develop requirements, a budget, a design and a deliverable tested product. Reports are due, including a management report with assigned team roles, at regular intervals. Thus, the teams are set up to behave as much as possible like typical software development teams. Our interviews with corporate management in software companies indicates that projects rarely last for more than six months and that when new teams form, the membership is also new, so our student teams represent this type of project assignment.

The research instrument is designed to work with virtual teams. Thus, it may be asked, how can this student population constitute a virtual team? Almost any team at the university studied is partially virtual because of the nature of the university. All capstone classes are held in the evenings because team members usually are part time students. The university is a commuter university with many classes online or partially online so that students may come to the university once a month. Thus, many of the teams meet virtually and much of the team work is done by e-mail, instant messaging and teleconferencing. It was felt that with the more mature students, seniors, the partial virtuality and member multiculturism presented a population suitable for piloting the research.

The survey was given near the end of the semester so the team members had worked together for about three months.

In a second administration of the survey, 34 graduate students from 14 report-writing teams took the online survey. The team task was to analyze an industry case study and write a team report based on the case study results. The teams consisted of five to six members with team leaders elected by the team members. The survey was given after the team finished their first case study project. These 14 teams were taking a two-month summer online management information systems course.

Only two of these teams reported meeting face-to-face once a week. The other teams did not report meeting face-to-face during the team project and may never have met each other face-to-face. This second set of teams was also different from the first in that they were working on a report rather than developing software. Thus, they met the requirement of being virtual for our pilot study but not of being a software development team. We use this second team to determine if the difference in virtuality might have an influence.

After the survey, open-ended interviews with six members from two software-development teams were conducted face-to-face. Each interview was conducted by two researchers and videotaped with the interviewee's permission. The interview results are reported in section 4.4 and 4.5.

Survey Measurement

In this section, each of the constructs used in the research is described in more detail, in particular, its source for validity and reliability verification are cited along with a sample question that presents the intent of the measure.

Delegation: The four categories of virtual team leader delegation were measured by 13 7-point Likert-scale items in the survey. Section 3.1 introduced the conceptualization of the four categories. A sample question statement is "how much is your team able to schedule team work?" (completely – not at all)

Team Competence: In the first round of the survey, six questions were used, which are adapted from the situational leadership measurement of follower ability (Hersey & Blanchard, 1988) and Hardin, Fuller, and Valacich's instrument of virtual team efficacy (2006). A sample question is

"The team has past experience related to the team job" (strongly agree – strongly disagree). In the second round, six 7-point Likert scale questions were used to assess specific skills important to team tasks. A sample question is "how do you evaluate your team on its critical analysis skills?" (extremely high – extremely low)

Team Motivation: Four 7-point Likert scale items measuring this construct are adapted from situational leadership theory (Hersey & Blanchard, 1988). A sample questions is "The team is motivated to take on additional responsibilities if needed to finish the project" (strongly agree – strongly disagree).

Team Flexibility: Three 7-point Likert-scale items were created by the research team consisting of five researchers with extensive virtual team research experience to measure this variable. A sample question is "This team quickly responds to new opportunities" (strongly agree – strongly disagree).

Team's Satisfaction with the Team Leader: Three 7-point Likert-scale items were created by the research team to measure this variable. A sample question is, "I am dissatisfied with the way the team leader manages this project" (strongly agree – strongly disagree).

Team Performance: Team performance is measured by five 7-point Likert-scale items adapted from Henderson and Lee's (1996) study. This is a composite measure which reflects five important areas of software team work outcomes including: the amount of work the team produces, the efficiency of team operations, the team's adherence to schedules, and the team's adherence to budgets, the quality of work the team produces. This measurement was examined by five experienced researchers and three IT managers with extensive virtual team experience and was considered by them to provide a valid and comprehensive view of software team outcomes. A sample question of this measurement is "Compared to other projects you have served on or observed, how do you evaluate your team's performance on adherence to schedules" (Extremely high – extremely low).

Other Contextual Variables: In addition to these constructs, the study also captured data on another two variables: trust towards other team members, and interdependence of tasks performed by team members, which were found to moderate the impact of leader delegation (Yukl & Fu, 1999) Trust is measured with four 7-point Likert scale items from Jarvenpaa et al.'s study (1998). A sample question measuring trust is "If I had my way, I would not let the other team members have any influence over issues that are important to the project" (strongly agree – strongly disagree). Task interdependence is measured by two items adapted from Campion, Medsker, and Higgs (1993). A sample question is "To what extent do the team members have to share work materials to get the project done?" (strongly agree – strongly disagree). Finally, team background information such as team member's age, year in school, how often the team met and how they met (remotely or face-to-face) was also gathered. This information is used in the post-hoc analysis to help us in our interpretation of the resulting relationships uncovered in the research model.

Preliminary Data Analysis

Delegation Construct Structure: A principle component analysis (PCA) was conducted to test if delegation is a four-dimensional variable. However, in the pilot study, the student teams did not have budget constraints and were not allowed to change their membership once the teams had been established. Therefore, the four leadership and management function measurements are not included in the data analysis done with PCA because students answered these questions as not applicable. PCA results show that all the remaining nine items measuring delegation load on one component instead of three unique components. This indicates that virtual team leader delegation

in the student teams is not multi-dimensional counter to our predictions.

Measurement Validity: The numbers in the study were too small to conduct a factor analysis, but wherever possible, the questions used for the constructs were drawn from previously validated surveys. We also checked the constructs for face validity by reviewing the questions with twenty experts from the countries where the virtual teams for the full study were located. In addition, a card sorting test was performed on the constructs using 20 respondents. Ninety-five percent of the questions were sorted correctly supporting a case for acceptable construct validity. Finally, external validity is a concern because students were used in the study. We treat this issue in the discussion on this research's limitations.

Measurement Reliability: Except for trust (α=0.409), the Cronbach Alphas of other construct measurements are above the level of 0.8. Trust is therefore not included in further data analyses.

Within-Team Agreement: Due to the small sample size, a simple measure was used to judge within-team agreement level: individual team members' responses were considered to have an adequate level of within-team agreement and were averaged to obtain a team score if the difference between the highest score and the lowest score in a team was less than 2.5 (half the scale range). There was a high level of within-group agreement in more than 85% of the 44 teams on all constructs in the research model. Therefore, individual team member's responses are averaged to get team-level data.

Test of Hypotheses

Multiple regression testing was chosen to analyze the data as the data met normality and homogeneity of variance requirements (An arcsine transformation was carried out on the team competence and performance measure to achieve these assumptions). Structured equation modeling was not used because of the small sample size and the intent of the study (pilot). Although a PLS model is more likely to have more accurate beta scores, it also has a greater chance of a Type I error (Goodhue, Lewis, & Thompson, 2006). Since this was a pilot study, we wanted to bias it against possible spurious results.

Hypothesis 1 Test: Hypothesis 1 predicts that virtual team leaders delegate more to competent virtual teams than to less competent virtual teams. A multiple regression analysis was conducted to test this hypothesis. The test results shown in Table 2 support Hypothesis 1. Delegation is positively correlated with team competence.

Hypotheses 2, 3, and 4 Tests: Hypothesis 2a predicts that leader delegation to competent virtual teams will improve team motivation more than delegation to less competent virtual teams. Hypotheses 3a and 4a predict the effects of virtual team leader delegation on team flexibility and on a team's satisfaction with team leader respectively. The three hypotheses were tested by stepwise regression with the outcome variables regressed on delegation, team competency and the interaction term of delegation and team competency.

Table 3 presents the test results in the *software-development teams. Hypotheses 2a and 3a* are not supported, as no significant interaction effects were found. Therefore, the effects of delegation on team motivation and team flexibility were not found to change as team competence varied. Regarding *Hypothesis 4a*, the results show that leader delegation improves the team's satisfaction but such effects do not change as team competence varies. In addition, team competence was found to significantly improve team motivation, flexibility, and team satisfaction with the leader (p<0.05).

Table 4 shows the Hypotheses 2a, 3a, and 4a test results in *the report-writing teams.* Regarding *Hypothesis 2a*, Team leader delegation significantly improves team motivation (p=0.006). However, the effects of leader delegation on team

	Motivation	**Flexibility**	**Satisfaction**
Delegation	0.782***	0.216	1.502***
Competency	0.126	0.069	1.708***
Delegation X Competency	-0.433	0.102***	-0.231***
R-Square	0.531	0.687	0.561
F-Overall	12.263***	21.912***	11.502***
*p < 0.10, ** p < 0.05, *** p < 0.01			

motivation did not differ as team competence level varied. *Hypotheses 3a_and 4a* are supported by the regression results. The interaction effects of delegation and team competence are significant such that leader delegation to competent virtual teams improves team flexibility and team satisfaction with the leader more than delegation to less competent virtual teams.

Hypotheses 2b, 3b, and 4b Tests: Hypotheses 2b, 3b, and 4b predict leader delegation indirectly improves virtual team performance through improving team motivation, flexibility and satisfaction with leader respectively. A Sobel test determines the significance of the indirect effect of the mediator by testing the hypothesis of no difference between the total effect and the direct effect. This method is used because its superiority of reducing Type 1 error and increasing power (Mackinnon, Lockwood, Hoffman et al., 2002). Due to the small sample size of the study, a bootstrapping Sobel test was performed.

For the ***software development teams***, the tests did not find delegation improved motivation and flexibility. Consequently, the effect of delegation motivation and flexibility improvements on virtual team performance was not testable and therefore, *Hypotheses 2b* and *3b* are rejected. *Hypothesis 4b* is supported by Sobel test results, as shown in Table 5. Therefore, delegation improves team performance partly through improving team satisfaction with the leader.

For the ***report-writing teams***, *Hypothesis 2b* is not supported by regression test results, as shown in Figure 2. Regression tests did not find that motivation had a significant positive impact on performance. Therefore, delegation was not found to improve team performance indirectly through improving team motivation. Previous tests on *Hypotheses 3a* and *4a* did not find that delegation improved team flexibility and satisfaction with the leader. Consequently, delegation cannot be tested as to whether it improves virtual team performance through improving team flexibility and satisfaction with leader. Therefore, *Hypotheses 3b* and *4b* are not supported either.

Interview Data Analysis

The interviews were analyzed in two steps. First, two PhD students and two professors with ex-

tensive research experiences watched the videos of the interviews and discussed what they found relevant to this study in a group meeting. Each of them explained his/her findings to the group and the group discussed the validity and implications of these findings. These discussion results were recorded in writing. Second, one PhD student summarized these group discussion results and combined them into a set of statements. Then, she watched the interview videos for the second time. She put down quotes from the interviewees related to each statement, examined these quotes to judge how they supported or disproved the categories of findings and modified the results of the analysis accordingly. This two-step procedure does not transcribe the interview data but roughly follows the process of creating a coding scheme, coding the data, iteratively improving the coding scheme and drawing conclusions. This procedure uses insights made by multiple researchers who separately viewed the interview videos and therefore should be adequately rigorous for a small-scale pilot study.

The interview data analysis found overall that delegation was an important part of team leadership and affected team outcomes in various ways. The following paragraphs present the detailed findings.

First, team leaders were aware of the importance of delegation, and engaged in delegation for a variety of reasons. One team leader learned from his previous military training that leaders should teach their subordinates to do their job so that they can take over if the leader is not available. The other reason both team leaders gave for delegating to the team was a belief that the team had the capabilities to perform the work. This belief in the team's competence came from knowledge about team members' past performance and their professional experiences. Also, one team leader recognized that competent team members have egos and decided that being too controlling would hurt such egos. Lastly, at least one team leader felt that delegating tasks to incompetent team members with the added support of fellow team members could be a way to build up a team member's self-confidence and skills.

Second, as the team develops, a leader's delegation style may change. In both teams the author interviewed, the leaders' style changed from one of controlling to that of delegating as team member's competence increased. In one team, members reported that at the beginning of the project, the team leader "tried to control everyone and everything in the project." When the leader was traveling, he sent team members detailed e-mails that specified the work to be done and the precise methods to use. As his team members demonstrated their capability and produced several deliverables ahead of deadlines, the leader "eased off in the middle." Near the end of the project, the team leader was very trusting and allowed the team members to self-lead. One of the most competent members in the team even led the team for two weeks when the leader was on vacation in a foreign country.

Third, delegation happened with monitoring and coaching. After certain tasks or functions were delegated, the leaders monitored how the team performed and coached the team members when needed. One team leader, for example, suggested books for the team members to read and advised the team on available development tools.

Fourth, delegation affects team motivation and a team's satisfaction with the leader. Within one team, a team member missed the first deadline and produced very low-quality deliverables. The team leader took action and became very directive setting detailed work schedules for the team, making detailed work assignments to team members and closely monitoring the work quality and progress of the team. Such non-delegation drove the team members to work harder. In this case team members appreciated the team leader's direction and effort to get their project started. In the other team, team members had adequate professional experience and the skills needed to perform the project tasks. In the beginning the

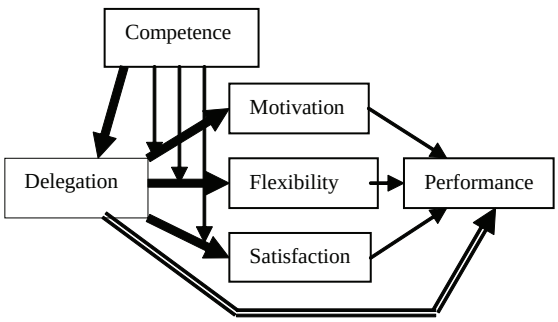
team leader was very controlling and the team members complained and even had a confrontation with the leader. However, as the team leader became aware that he was directing a competent team, he switched to negotiating with team members when making decisions. With this change, the team members felt his trust in their abilities and became more satisfied with the leader.

DISCUSSION

The following hypotheses were supported by the study. First, virtual team competence predicted leader delegation behaviors. This implies that virtual team leaders should carefully evaluate a team's competence before delegating tasks, especially before delegating important tasks. Second, leader delegation improved the satisfaction and motivation of team members. The effects of delegation on flexibility and satisfaction were more prominent in competent report-writing teams than in less competent report-writing teams but these effects were small. Other hypothesized results were not found. None of the intermediate outcome variables (flexibility, motivation, satisfaction) mediated the effects of delegation on team performance. Instead, tests results indicated that delegation directly improves virtual team performance. Figure 3 presents the model supported by the study results.

Comparing the results found in the two types of teams, one will observes that first, delegation exerted deeper influence on the report-writing teams than the software-development teams. It is suspected that the differences in delegation effects may arise from the differences in the number of times the teams met face-to-face or, as suspected, the degree of virtuality of the team. In contrast to the software development teams, which met face-to-face at least once a week, the report-writing teams barely met. Students in the report-writing teams were in an online summer course and, throughout the project, only two teams met face-to-face once a week. As collaboration and communication processes suffer from lack of face-to-face contact, the leader's role in team coordination and communication becomes more important. Therefore, leader delegation produced deeper effects in the more virtual report-writing teams. This suggests that leader delegation is likely to be a very significant factor in managing virtual teams.

Figure 3. Delegation effects on student teams. (Bold lines indicate supported hypotheses. The double line indicates a new result showing a direct link between delegation and team performance.)



Limitations of Study

One of the major limitations of this study is that the teams were student teams working on class projects. In particular, some of the questions that were designed for corporate virtual teams were not applicable. Student teams do not typically assign salaries, manage finances or hire and fire personnel. Only the planning part of the delegation construct showed differences between teams. The other parts were scored as not applicable (one of the possible answers) so that the results were pooled into one construct called Delegation which consisted mostly of items that addressed planning delegation.

In addition, the software and report writing teams did not represent the distributed teams that the survey was prepared for. There were some examples of distributed teams, for example, one-half of the team lived in the southern part of the state and the other half lived in the northern part, but, by and large, teams consisted of members who were individually virtual but also met face-to-face occasionally. The report writing teams were the most virtual with some team members never having seen each other.

It can also be argued that student teams do not give representative answers that parallel those of individuals working in companies although there is evidence that this is not always so. Hughes and Gibson (1991) found that MBA students made decisions comparable to managers in an Executive MBA program, but Ashton and Kramer (1986) in their literature review, note that attitude questions are answered differently by individuals in the workforce than by students. Briggs, Balthazard, and Dennis (1995) found students to be valid predictors of managerial technology adoption and Remus (1989) found graduate students to be more representative of industry personnel than undergraduates. In particular, studies show that students are not representative because of their lack of experience in the workforce and because of their youth. Because most of the students in our study were part time students and had full-time jobs, because the age of the students in the teams was higher than normal for university undergraduates and because the students represented the cultural mix that we wanted to assess, it was felt that this study's population was representative of the industry group our study targeted.

We did find, however, evidence that suggests that students were responding differently than a workforce population might. Student groups uniformly evaluated their team competence and team performance highly with more spread on this evaluation in the report-writing teams (Master's students). We also found that we were not able to obtain any viable reliability on what is considered a highly reliable trust measure that we borrowed from the literature. We therefore did not include trust in our models. We also remade the competence measure into a formative construct for the survey of the report writing team. This helped to fix the skew in the distribution of these results.

As mentioned earlier, the skewed evaluations of team competence and performance may be an artifact of student teams, but they also might be an artifact of virtual teams in some cultures. Thus, an additional variable to collect and compare to self report of team performance is a team leader's report of team performance in addition to other related variables such as subproject completion times. We continue to strive to obtain measures of performance from team leaders, but, to date, the descriptions of how management scores performance for their distributed teams lead us to believe that self-report of perceived performance is not any worse a measure than managerial reports. In particular, the cultural and temporal distances are likely to affect a leader's perception of performance.

The trust measure may have been highly unreliable because student team members have a different social relationship than workforce team members. One trust question asked if a team member would like to control the work of the other team members. This is socially out of the question

in a student team where fellow team members are independent individuals more than members of some greater whole such as a company. Thus, team members are likely to respond negatively to this question. A second question asked if a team member felt uncomfortable with the work of the other team members. A team member could answer positively in a socially acceptable way to this question. Thus, the reliability of a construct that works fine in a company environment falls apart in the student context. However, this failure of the trust construct could be applicable to virtual teams where their non-colocated counterpart may also feel that they have no right to control or monitor the work that the distant team performs even if they feel uncomfortable with this lack of control. This is likely to be true of teams in China and India where new hires are continually being added to the workforce. None of these younger team members would feel that they should control the work of their team members in Europe or North America, but their recent training may also make them feel uncomfortable with the work being done in these places.

These discussion notes that the literature demonstrates that student teams can provide reliable answers that represent industry situations if the groups are appropriately chosen, but it also suggests that the very nature of student teams might be more appropriate for studying virtual teams across cultures in that their responses might represent similar cultural responses.

The small sample size also limits the generalizability of the study findings. We analyzed the teams separately because of inherent differences in their virtuality and work assignments. We also performed a separate analyses so that we could examine the effects of virtuality although confounded with task and a more senior student population. This made the sample sizes small. Approximately 200 software teams were asked to fill in the survey but only 30 responded. The response rate was extremely low, in particular, because many of the students were in their final year, already had jobs that reduced the importance of the payment incentive we offered and were quite busy with class projects. The response rate was significantly higher for the report writing teams (about 50 percent) but the class size was small. We also choose to analyze all of the teams, even those with only one respondent because the response rate was low. Thus, there were 12 software teams that only had one member. For the report writing teams, only teams with two or more respondents were used in the analysis. The problem with a single team member responding constitutes another analysis problem because that single member could have been an outlier generating data unrepresentative of the team. Studies now in progress with a larger number of industry teams will yield more conclusive findings related to virtual team leader delegation.

CONTRIBUTIONS AND FUTURE WORK

This study addressed an important yet under-researched area regarding leader delegation practice in virtual software teams. It provides statistically sound conclusions which reduce the confusion arising from the conflicting findings of prior case studies. Some virtual software team managers claim that the increased distance make self-management necessary while others question whether excessive autonomy will produce negative effects in a complex virtual team environment. A pressing question for industry practitioners is when and how much authority and responsibility should be delegated to remote team members. Our findings suggest that delegation is an important virtual team management strategy that positively affects team performance. In particular, the results from the student teams imply that a team leader will delegate in response to his or her sense of how competent the team is. However, the real world situation affects this delegation with a push and pull effect, that is, management will want to

delegate more because the task of managing a global virtual team means more communication, odd hours of work scheduled for communication and care needed to avoid miscommunications. This is the push to delegate. However, the pull effect is that a team leader because of the lack of information on the global virtual team stemming from language difficulties, cultural differences and simply not being able to observe team behavior because of the distance will not want to delegate to the team. The findings suggest that team leaders need to be trained to ignore these effects and perform their delegation based on real information about the team, perhaps by visiting the virtual team or setting up viable measures for team performance.

The tendency of the student teams to give self-reports of high competence and high performance suggests leadership guidelines for industry. In particular, it would be wise to give team leaders training in the cultures they are interacting with so that they can better judge the self-reports they are obtaining.

Our findings also suggest that delegation is a good thing in that it increases a team's satisfaction with its leader, a team's flexibility to adjust the project to local needs and a team's motivation. The findings, however did not find a strong mediating relationship between these values and team performance Earlier discussion on the limitations of the study suggest that the performance measures captured were corrupted by the use of student teams. Flexibility, motivation, and satisfaction have been shown to affect performance in face-to-face teams so there is good reason to believe that obtaining better measures of performance would find moderation by these variables. This is future work that needs to be performed.

Overall, more delegation was found to be a positive behavior for a team leader, but with the youth and newness of team members joining virtual teams in many of the companies that offshore or outsource, this is likely to be a poor strategy unless measures are taken to bring up the skill sets of the offshore team members.

Due to high team member turnover in some countries, especially with the constantly increasing wages in these countries, companies are reluctant to invest in training for these team members. However, as we have been told by team managers from India, this training is precisely one of the mechanisms used to reduce turnover. This is another variable that clearly needs evaluating in future work.

Overall, the pilot study findings suggest useful recommendations for virtual software team leadership as to when and how much they should delegate to the team based on the team's degree of virtuality and competence. However, the hypotheses of this study were mainly based on software team literature and the pilot study was done mainly with student software teams. Future work with real industry teams with varied types of companies and a variety of organizational models needs to be performed to verify these findings. Currently a full-scale survey and interview has been conducted with the global software testing teams of a Fortune 100 company. Future data analysis will be performed to compare the industry team findings with the findings of this pilot study.

Chapter 6.10
Cultural Diversity Challenges: Issues for Managing Globally Distributed Knowledge Workers in Software Development

Haiyan Huang
The Pennsylvania State University, USA

Eileen M. Trauth
The Pennsylvania State University, USA

ABSTRACT

This chapter discusses cultural diversity challenges in globally distributed software development and the implications for educating and managing the future global information technology workforce. It argues that the work practices of global software development are facing a variety of challenges associated with cultural diversity, which are manifested in and can be analyzed from three dimensions: the work environment of global software development, the globally distributed knowledge workers, and the global software development work. It further articulates how cultural diversity is manifested in these three dimensions. Furthermore, it highlights the importance of developing cultural awareness and cultural diversity understanding as important skills for the future information technology workforce.

INTRODUCTION

In this chapter, we explore the cultural diversity challenges of managing globally distributed knowledge workers who engage in global software development work practices. This topic is important to information technology personnel management and knowledge management for three reasons. First, there has been a significant increase in global software development work practices in recent years. Such work practices not only adopt the conventional characteristics of knowledge intensive work, but also generate a set

of distinct features, which call special attention to managerial researchers and practitioners. Second, in global software development, the information technology (IT) professionals are globally distributed in the forms of global virtual teams and represent a wide range of nationalities and, thus cultures. Therefore, we should not only acknowledge the existence of cultural diversity of globally distributed knowledge workers, but also explore how such cultural diversity may affect global software development work, and how to explore, assess, and manage this cultural diversity. Third, although cross-cultural issues have been one of the major concerns of the global information systems discipline, there are still on-going debates about how to assess culture and cultural diversity. As a result, different views of culture and cultural diversity will have impacts on the related human resource strategies used in managing global IT personnel. Consequently, evaluation and reflection on those issues in global software development work environments are very important.

As knowledge work is increasingly outsourced globally, we would like to take the opportunity in this book chapter to consider the cultural diversity challenges of managing globally distributed knowledge workers. The objectives of this book chapter are: (1) to propose a framework to address the cross-cultural aspects of managing IT personnel in globally distributed software development work; and (2) to discuss some managerial implications that are derived from this framework. We believe both professionals and academics working in the field of global information technology and information systems (IS) management will benefit from these discussions.

The organization of the book chapter proceeds as follows. In the Background section, we introduce the concepts of global software development and virtual teamwork. Then we present our research framework, which focuses on articulating how cultural diversity is manifested in global software development workplaces, workers, and work practices. In the following section on recommendations, we discuss how we may address the cultural diversity challenges in managing globally distributed knowledge workers who are engaged in global software development activities, particularly from the perspectives of IS/IT education and organizational human resource management.

BACKGROUND

Global Software Development

Global software development as one type of information technology offshore outsourcing activities (Lacity & Willocks, 2001), has become an established practice for software and information systems development (Carmel & Agarwal, 2002; Herbsleb & Moitra, 2001). Global software development can be defined as software and information systems development practices that are knowledge intensive and involve the work arrangements between two or more organizations across the national boundaries.

Software and information systems development has been widely conceived as knowledge-intensive work (Henninger, 1997; Swart & Kinnie, 2003) with three characteristics. First, knowledge as intellectual capital is an important input to a software development project, and an important output as well (Swart & Kinnie, 2003; van Solingena, Berghoutb, Kustersc, & Trienekensc, 2000). Second, Waterson, Clegg, and Axtell (1997) pointed out that software development work is "knowledge intensive" in the sense that building a complex software system demands selecting and coordinating multiple sources of knowledge (Shukla & Sethi, 2004). Drucker (2004) argued that the specialized knowledge in knowledge work indicates that knowledge workers need to access the organization—the collective that brings together a diversity of specialized knowledge workers to achieve a common goal. For example, a software development project may

involve a variety of IT personnel such as designer, analyst, programmer, tester, implementer, and manager. Therefore, collaborations of team work are necessary and critical for software development projects. Third, knowledge associated with software development is rapidly changing as the complexity and diversity of the application domain is increasing (Henninger, 1997). Therefore, software development knowledge is not static but, rather, is evolving with the changing needs of the customers and business environments (Henninger, 1997). Drucker (2004) pointed out that knowledge workers not only need formal education to enable them to engage in knowledge work in the first place, but also need continuous learning opportunities through the work practice to keep the knowledge up-to-date. These three characteristics of software development work usually refer to the work practices within a single organizational domain. As software and information systems development work is increasingly outsourced globally, how to manage the knowledge workers to facilitate effective software development work practice in the cross-cultural context has become a great challenge.

Since the 1990s, software development and IT services have become dominant in global sourcing, which includes application packages, contract programming, and system integration (Lee, Huynh, Kwok, & Pi, 2002). And the global IT outsourcing market is continuously growing (Sahay, Nicholson, & Krishna, 2003; Trauth, Huang, Morgan, Quesenberry, & Yeo, 2006). It was projected that the IT outsourcing revenue would reach $159.6 billion by 2005 (Laplante, Costello, Singh, Bindiganaville, & Landon, 2004). The U.S. is the primary user of the global software and systems development market, followed by Western European countries such as the UK and Germany (Sahay et al., 2003). Countries such as India, Ireland, and Israel, have dominated the offshore outsourcing supplier market (Gopal, Mukhopadhyay, & Krishnan, 2002). A news release (*InformationWeek*, June 3, 2004) indicated that India's revenues from exports of software and back-office services is at $12.5 billion in the latest fiscal year and with growth of 30% compared with $9.6 billion in the previous year. Another news release (Friedman, 2005) reported that 7 out of 10 top software designers have operations in Ireland.

When compared to the traditional characteristics of software development work, globally distributed software development knowledge work has three additional characteristics. First, it is mainly conducted through a virtual environment that is supported to a great extent by networking technologies. Such virtual space is global by nature and transcends national and organizational boundaries. Second, it is situated within different complex, multi-leveled socio-cultural contexts. Walsham (2000, 2001) argued that the distinct cultures of different local contexts are critical factors in mediating the globalization process in the specific contexts. Therefore, the globally distributed workplace has a global-local duality. Third, the work practices of global software development are facing a variety of challenges associated with the difficulties of temporal and spatial distance, and cultural diversity.

Global Virtual Team

The globally distributed virtual team is the basic unit engaged in software development work. A global virtual team can be defined as a collection of individuals who are organizationally and globally dispersed, and culturally diverse, and who communicate and coordinate work activity asynchronously or in real time primarily through information and communication technologies (ICTs) (DeSanctis & Poole, 1997; Jarvenpaa & Leidner, 1999).

A variety of strategic and catalytic factors have contributed to the increasing trend of using globally distributed virtual teams for software and information systems development (Carmel, 1999; Herbsleb & Moitra, 2001). These include:

24/7 around-the-clock development activities, the desire to reduce development costs and have access to a global resource pool, and the proximity to the customer. In addition, some authors have further emphasized the contribution of diversity of heterogeneous teams to work performance brought about by globally dispersed team members (Adair, 1986; Harrison, McKinnon, Wu, & Chow, 2000; Hartenian, 2000; Maugain, 2003; Trauth et al., 2006). For example, Maugain (2003) argued that the different thinking modes and dissimilar problem solving methods brought in by diverse team members in multicultural R&D (Research & Design) teams will stimulate novel ideas and creativity. Hartenian (2000) pointed out that diverse groups have a tendency to make higher quality decisions, to be more creatively motivated, and have a higher productivity potential than less diverse groups.

However, research also shows that the absence of regular face-to-face interactions and the breakdown of traditional communication and coordination mechanisms are negatively associated with the effectiveness of globally distributed software development teams (Cameral, 1999; Herbsleb & Mockus, 2003). Systems development tasks, particularly front-end activities, require formal and informal communication and coordination (Audy, Evaristo, & Watson-Manheim, 2004) to facilitate knowledge exchange and learning (Curtis, Krasner, & Iscoe, 1988). According to Herbsleb and Mockus (2003), the change of communication patterns and the lack of effective communication channels (formal or informal) in globally distributed software development teams can lead to delays in global software development projects. The study by Cramton and Webber (2005) shows a negative relationship between geographic dispersion and perceived team performance with respect to complex and interdependent tasks.

The cultural difference may further exacerbate the communication problems (Herbsleb & Moitra, 2001). Carmel (1999) pointed out that the barriers of time, space, and cultural distances may be detrimental to building trust and achieving team cohesiveness in global virtual teams. Nicholson and Sahay (2004) argued that the barriers of knowledge sharing among knowledge workers in offshore software development are related to the embeddedness of knowledge in the local cultural context, and should be investigated at the interconnected societal, organizational, and individual levels of analysis.

While cultural factors may influence global virtual teams engaged in a variety of activities in general, they are particularly important to software development work for three reasons. First, compared to other activities such as new product developments in manufacturing sectors, the processes of software development are more complexly interdependent and iterative, the products of software development are less tangible, and knowledge perspectives involved in software development are more tacit and fast changing in nature (Sahay et al., 2003). Second, a number of studies have shown that culture is a critical influential factor in global software development work and has impacts on a variety of issues. While some issues are general issues faced by global virtual teams engaged in other activities in general (e.g., managing conflicts—Damian & Zowghi, 2003), building trust (Zolin, Hinds, Fruchter, & Levitt, 2004), some issues are specific to software development, such as managing IT outsourcing relationships (Krishna, Sahay, & Walsham, 2004; Nicholson & Sahay, 2001; Sahay et al., 2003), preference of software development methods (Borchers, 2003; Hanisch, Thanasankit, & Corbitt, 2001), preference of computer supported collaborative technologies (Massey, Hung, Montoya-Weiss, & Ramesh, 2001), knowledge transfer and management related to software development (Baba, Gluesing, Rantner, & Wagner, 2004; Nicholson & Sahay, 2004; Sarker, 2003), and the process and performance of globally distributed software development teams (Carmel, 1999; Olson & Olson, 2003). Third, as more and more countries are now entering the IT outsourc-

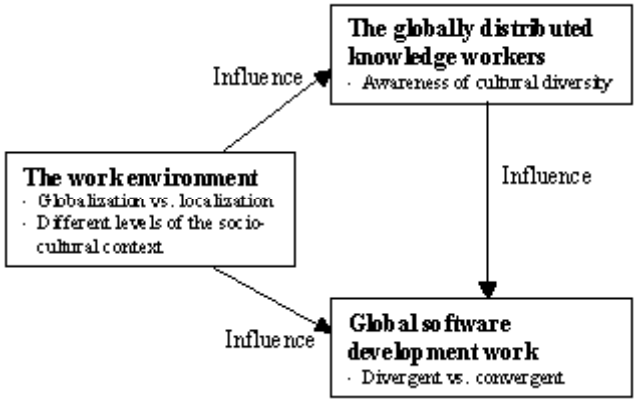
ing market, global software development work practices are facing more cultural diversity (Sahay et al., 2003; Trauth et al., 2006). Companies in Japan and Korea join those of the U.S., Canada and other western European nations in outsourcing their software or information system development and services activities to other countries. Besides the current leading outsourced countries such as India, Ireland, and Israel, Russia and China are now establishing their capabilities as outsourcing providers (Sahay et al., 2003).

Globally distributed software development efforts, thus, must deal with trade-offs between taking advantage of the global resource pool and cultural diversity while managing the cultural and distance barriers to effective communication and coordination in a geographically dispersed environment. How to make sense of cultural diversity and its impact on managing globally distributed knowledge workers who are engaged in global software development work activities are becoming the primary concerns of global IT personnel management and knowledge management.

In the research framework (Figure 1), we propose that cultural diversity is situated and manifested in three interrelated dimensions of global software development activities: the virtual workplace, the workers, and the work (Trauth, 2000). These three main constructs reflect what dimensions of global software development may be affected by cultural diversity. And the bullets under each main construct further indicate how cultural diversity is manifested in each of these dimensions. Trauth (2000) studied the information economy development in Ireland and pointed out that culture is one of the major influential factors. More specifically, she addressed the cultural influences from three perspectives: multinational workplaces, knowledge workers, and knowledge work. These three perspectives are interrelated and serve as our analytical lenses to study how the cultural factors influence IT work, and in this chapter, how cultural diversity is manifested in and affects global software development.

The virtual workplace of global software development is situated within a multi-leveled socio-cultural context with the global-local duality characteristic, which constitutes a unique work environment. Being engaged in global software development activities within such a work environment, globally distributed knowledge workers should be aware of the complexity and dynamics

Figure 1. Research framework: Situating cultural diversity in global software development



of cultural diversity, and constantly make sense of and negotiate meanings of such diversity. Global software development work, which includes both divergent and convergent perspectives is affected by the effectiveness of the sense-making processes and the management of cultural diversity. This framework adopts a situated approach and emphasizes the importance of studying globally distributed knowledge work as socially negotiated work practices by situating it within the both the global and local contexts (Avgerou, 2002; Trauth, 2000; Weisinger & Trauth, 2002, 2003). In the following sections, we discuss in detail how cultural diversity is manifested in each dimension of the framework, respectively.

THE WORK ENVIRONMENT

Globalization vs. Localization

Globally distributed software development work can be seen as a result of the globalization process—the IT industry is becoming more and more globally interconnected. According to Castells (1996), the globalization process involves the flows of capital, commodities, technology, cultural influences, and human resources across national boundaries, thereby creating a networked society. One stream of sociological and cultural research considers processes of globalization and flows of cultural elements across frontiers as a global "cultural homogenization" (Kellner, 2002; Schuerkens, 2003). Schuerkens (2003) criticized such "cultural homogenization" arguments of globalization by pointing out that they usually ignore the existence and active role of local cultural perspectives. Castells (1996) also pointed out that the globalization process is selective and segmented with many imbalances, and the networked society is both centralized and decentralized, which shows heterogeneous and global-local duality characteristics.

Sahay et al. (2003) argued against the "cultural homogenization" assumption of globalization and proposed that global software development work relationships can be seen as "models of" globalization process and "models for" globalization as well (p. 27). They emphasized the dynamic reciprocal relationships between the local cultural contexts and the globalization processes. Similarly, Walsham (2001) used Giddens' structuration theory (1990) and Castells' network society theory (1996) to study global IT development and stressed that the existing socio-cultural context of a country is a critical factor in mediating the globalization process in the specific context and, in turn, will have an impact on the complexity of globalization. They both acknowledge the uniqueness and importance of local contexts to globally distributed software development.

To illustrate the continuous interactions of local cultural elements and global cultural influences, Schuerkens (2003) cited Long's (1996) discussion: "Local situations are transformed by becoming part of wider global arenas and processes, while global dimensions are made meaningful in relation to specific local conditions and through the understandings and strategies of local actors" (p. 217).

Therefore, the local cultural context is neither a passive recipient of globalization and external cultural influences as indicated by the "global homogenization" argument, nor is it a static and deterministic factor that remains unchanged during the globalization process. The local cultural forms and meanings are constantly reconstructed (Schuerkens, 2003; Walsham, 2001).

We believe that such continuous interactions of globalization and localization processes have three implications for conceptualizing the cultural diversity of global software development work environments. First, global software development work is situated within a complex and dynamic global-local societal context. Second, cultural diversity is inherent in global software develop-

ment and is a critical influential factor affecting global software development work practices. Third, the emergent nature of both the local cultural context and the globalization process indicates that we should focus on the appropriation and transformation of local cultural elements to address the dynamic perspectives of cultural diversity of the global software development work environment.

Different Levels of the Socio-Cultural Context

Another important feature of the cultural diversity of the virtual workplace of global software development is the multi-levels of analysis ranging from societal (national) to regional, organizational, professional, and team. Different cultural factors at different levels coexist, interact with each other, and together produce different work environments of globally distributed software development work practices. However, the influence of different cultural factors at different levels is not equal and varies across work environments. Some cultural factors may be more visible than others and some may seem trivial compared to the predominant factors depending on different cases.

For example, Robey, Gupta, and Rodriguez-Diaz (1988) studied one multinational company's efforts to implement an account system in its subsidiaries in two Latin American countries: Chile and Panama. Their findings showed that cultural and political differences between Chile and Panama could not explain the significant differences in the implementation outcomes. They believed that those differences were due to the organizational cultural differences of the two subsidiaries. This case is an example of the dominance of organizational cultural influences while national and organizational cultural differences coexist. Barrett and Walsham (1995) studied the global software development relationships between a Jamaican insurance company and an Indian software company. They pointed out that although the Indian and Jamaican team members of this joint venture development shared a similar professional culture, there were major differences between the local work culture at the Indian software company and the Jamaican insurance company. This case demonstrates the dominance of national and organizational cultural influences. The case study by Kaiser and Hawk (2004) on a long-term alliance outsourcing relationship between a U.S. company and an Indian company showed that the mutual understanding of ethnic and corporate cultures was an important factor to build stable and trust relationships.

In global IT outsourcing research, the focus tends to be on the national level of analysis. Therefore in most cultural studies of global software development, the national culture is predominant while other factors such as regional, organizational, and team cultures are in the background. This is probably due to the high visibility of cross-national cultural differences. Another reason may be that the cultural elements at different levels interact with each other and somehow diffuse into some inseparable influential factors.

Some studies (Cougar, Adelsberger, Borovits, Zviran, & Motiwalla, 1990; Constantine, 1995) pointed out that while the national culture may show divergent characteristics across national boundaries, the professionalism of the knowledge workers will share certain common cultural elements that constitute the professional culture. As a result, the team culture of the global virtual team may show a different pattern from either the national culture or the organizational or the professional culture. Earley and Gibson (2002) pointed out that through communications and interactions, the highly heterogeneous global team may appear to develop a common identity over the course of a long-term project, which they referred to as the team culture.

The contemporary work environment of global software development is situated within

a complex multi-leveled socio-cultural context in which culture and its influences are emergent as the work practices evolve. The emergent perspective of cultural diversity indicates that it cannot be reduced to a set of variables and treated as unchanging inherited properties. In a sense, globally distributed knowledge workers are not passively embedded in their local context. Instead, they continuously and actively engage and negotiate with their work environment in everyday work practices.

The Globally Distributed Knowledge Workers

Brannen, Gómez, Peterson, Romani, Sagiv, and Wu (2004) pointed out that the concept of culture is by no means free of controversy. According to Worsley (1984), there are four ways of conceptualizing culture: the elitist view – culture implies superior power; the holistic view–culture implies the whole way of life; the hegemonic view – culture is a set of behaviors imposed by the majority; the relativist view – culture is localized and may bear different behaviors in different regions or communities from the same society.

There are two general doctrines of conceptualizing culture—the functionalist view and the interpretivist view (Schultz & Hatch, 1996). The functionalist view assumes that culture can be studied from several generalized dimensions and those dimensions are universal. As a result, the functionalist studies focus on categorizing cultural dimensions and predicting their influences. Hofstede's (1984) framework of five major national cultural dimensions is one example of the functionalist doctrine. The interpretivist doctrine, on the other hand, argues that culture may be ambiguous and unstable and should be studied within a specific local context instead of using general frames.

Schultz and Hatch (1996) studied the difference between the functionalist and interpretivist paradigms of cultural research. They proposed that these two paradigms can somehow interact to address the different perspectives of culture. To some extent, the mainstream of each of these doctrines can be integrated to a "multiparadigm" approach. They suggested that for example, to study national cultural patterns, the functionalist view uses predefined categories to provide a clear, generalizable and stable pattern, while the interpretivist view uses interpretation and symbolic representation to describe the ambiguous, situated and instable perspectives of culture. However, this approach may still be problematic since it assumes that there is a line between the stable and unstable elements of culture. In reality, the line itself may be ambiguous and dynamically changing.

The anthropological view of culture is a constructivist view which rejects the idea of culture as having hard and fast boundaries (Avison & Myers, 1995). On the contrary, culture is seen as contestable, temporal, and emergent, and is constantly interpreted and re-interpreted in social relations (Carrithers, 1992). Therefore, the anthropological cultural view rejects the notion of culture as a set of predefined variables peculiar to a certain society. In the information systems discipline, Walsham's notion of culture mediating the global process in specific local contexts (Walsham, 1993, 2000, 2001), Avegerou's proposal on relativism (2002), and the situated culture perspective suggested by Weisinger and Trauth (2002, 2003) are three approaches to studying culture through exploration, interpretation, and sense making, which reflect the anthropological perspective of conceptualizing culture.

We argue that when managing global software development practice, the functionalist approach may provide general guidance if cautiously adopted. However, it is lacking the capability to provide an in-depth understanding of cultural dynamics. Therefore, we take the following statement as a working definition of culture:

Culture is the sense making of different social structures and relations such as beliefs, values, and norms, attitudes, hierarchies by a group of people within a particular social context.

In this definition, we view culture as the "sense making" which actively strives for interpretation and re-interpretation of the relationships between the self-identity and the surrounding contexts. We believe that viewing culture as dynamic and emergent instead of static and predefined will provide the corresponding cross-cultural management the capability of accounting for the evolving and diversified nature of global software development phenomena.

Child (2002a, b) pointed out that the globalization trend and subsequent interconnectivity of networking technologies have pushed the traditional boundaries between nations and organizations to become somehow "borderless." At the same time, they enhance the people's awareness of their own identity and cultural distinctiveness as they have more and more opportunities to interact with a variety of cultural groups during the processes. In a sense, they interpret and reinterpret self-identity and the relationships between the self-identity and the surrounding contexts.

We argue that cultural awareness of globally distributed knowledge workers should have two levels—the self-awareness of their own identity and the mutual awareness of the existence of the cultural diversity and differences in others. Baba et al. (2004) pointed out that in order for team members of a globally distributed team to bring together and integrate the divergent knowledge, they should first develop the mutual awareness and shared cognition of the divergences. They further stressed (Baba et al., 2004) that the mutual awareness is not simply exchanging declarative or procedural knowledge—it requires: "…suspending our own judgment as we learn the cultural logic and rationality of others' divergent beliefs and values, while also allowing those others to call our own beliefs and values into question as they learn about us…" (p. 583).

The Global Software Development Work

Studies have shown that while cultural diversity may lead to advantages with respect to the divergent processes of knowledge work, it may also cause problems for the convergent processes (Miroshnik, 2002). Divergent knowledge work processes in software development refer to processes of generating and articulating different viewpoints by different team members, as well as challenging the existing assumptions in requirement analyses and systems designs, which are important for surfacing and exploring alternatives, thus promoting creativity and innovation in software development (Kryssanov, Tamaki, & Kitamura, 2001; Nickerson, 1999). Convergent knowledge work processes refer to processes of developing shared understanding and building common ground among team members with respect to different perspectives of software development, which are important to decision-making and effectiveness of teamwork (Potts & Catledge, 1996).

Knowledge intensive work, such as design and development of new software and information systems is usually characterized as highly ambiguous, uncertain, equivocal, and interdependent (Curtis et al., 1988; Herbsleb & Grinter, 1999; Hoegl & Proserpio, 2004). The analysis of systems requirements, which is a critical task at the front-end of software and information systems development, is highly dynamic, complex, fluctuating, and evolutionary in nature (Audy et al., 2004; Curtis et al., 1988; Mathiassen & Stage, 1990). Cultural diversity may provide benefit to the front-end of software development work by providing different perspectives, ideas, and approaches. Dafoulas and Macaulay (2001) pointed out that cultural diversity may be beneficial to

team performance, especially on tasks for which differing perspectives might increase team performance (Trauth et al., 2006). Miroshnik (2002) also argued that cultural diversity can be used as a resource to enhance creativity, flexibility and problem solving skills, all of which are important for knowledge-intensive work.

On the other hand, to bring the divergent perspectives into a convergent development practice, cultural diversity may become a barrier to knowledge sharing and transference since knowledge is contextually dependent and culturally contingent (Nicholson & Sahay, 2004). To a great extent, the convergent processes require both formal and informal communication and coordination mechanisms to exchange diverse knowledge perspectives and facilitate learning (Curtis et al., 1988), to surface conflicts and negotiate differences (Audy et al., 2004; Briggs & Gruenbacher, 2002; Curtis et al., 1988), and to build shared understandings and common ground regarding various issues such as how to represent the system requirements and which system development methodologies are more appropriate (Cramton & Webber, 2005; Damian & Zowghi, 2003). During these convergent processes, cultural diversity may create cultural distance and barriers to knowledge sharing and transference. Herbsleb and Moitra (2001) pointed out that while cultural diversity can be seen as an enriching factor by bringing together divergent bodies of knowledge, it can also lead to serious and chronic misunderstandings.

For example, in the case study of distributed software development between England and India, Nicholson and Sahay (2004) identified cultural difference in perceptions of time between India and England. In England, a 9 AM to 5 PM working routine and the separation of working life from personal life are encouraged. In India, the boundaries between working life and home life are less defined (Nicholson & Sahay, 2004). Thus, Indian employees may respond to personal or home needs during regular working hours and may spend extra time working later hours or on weekends (Nicholson & Sahay, 2004). Such cultural differences are implicitly embedded in each local cultural context. Without building corresponding mutual knowledge and awareness about these differences, team members from one site may have misconceptions about the availability of team members from the other site. Saunders, van Slyke, and Vogel (2004) argued that different global virtual team members may have different time visions, which may influence the management and performances of global virtual teams.

The interchange of benefits of cultural diversity and hindrance of cultural distance put forward special challenges of teaching cultural diversity to future IS/IT workforce and managing globally distributed knowledge workers. On one hand, we need to address issues related to bridging cultural distance to encourage knowledge sharing and transference across different cultures. On the other hand, we need to study how to cultivate and integrate cultural diversity in order to develop new organizational capabilities (Baba et al., 2004).

RECOMMENDATIONS FOR PRACTICE

As suggested by our research framework, it is very challenging to manage such a diverse workforce for global software development for three reasons. First, the culture of the virtual work environment is complex and dynamic. Second, the cultural diversity of globally distributed knowledge workers has the potential for both great accomplishments and great conflicts. Third, the cultural diversity of such a global workforce needs to be proactively managed, and cultivated in order to facilitate both the divergent and convergent perspectives of software development work activities.

To address these challenges, we recommend the following. First, treat cultural awareness and cultural diversity understanding as important and necessary skills for the future IS/IT workforce, provide IS/IT students opportunities to experi-

ence cultural diversity, and help them explore and develop a proper mind-set towards diversity. Second, adopt the sense-making approach in human resource practices to motivate and facilitate globally distributed knowledge workers' articulation of their self-identities and the identities of others during the social interactions of teamwork processes. Third, balance the tensions between the values and the conflicts of cultural diversity by encouraging contested, diverse thinking while building the trust and shared understanding among globally distributed team members. Finally, value cultural diversity knowledge as an important part of the organization's intellectual capital and strategic resources for competing in the global market.

IS/IT Education

The gap of critical skills and knowledge required for information technology professionals between academe and industry has been a major concern for IS/IT education (Lee, Trauth, & Farwell, 1995; Miller & Donna, 2002; Swanson, Phillips, & Head, 2003; Trauth, Farwell, & Lee, 1993). Academics and practitioners have called for assessing and expanding IT, IS, and MIS curricula to adapt to the needs of future global IS/IT workforces (Miller & Donna, 2002; Swanson et al., 2003). For example, Swanson, et al. (2003), and Noll and Wilkins (2004) discussed the growing needs for soft skills such as communication skills and teamwork skills in information technology professionals. Larsen and McInerney (2002) simulated the inter-organization virtual teamwork environment in course design to teach students certain skill sets needed in virtual work.

However, only a few of these programs specifically target the global IT environment and conceptualize diversity as one of the core elements in the global IT environment. One of those few examples is the online "IT Landscape in Nations" repository initiated by Carmel and Mann (2003) to facilitate students conducting comparative analyses of different nations and developing greater awareness of the global IT environment. Therefore, there is a great gap between current IS/IT education and the increasing demands of the global IS/IT workforce. Educators should focus on designing and implementing corresponding curricula, renovating and expanding current pedagogical approaches to bridge such a gap.

IS/IT Human Resource Management

Along with the focus shifting from capital resources to knowledge resources in modern economic development, the role of knowledge has been fundamentally changed (Drucker, 1994). As a result, the role of human resource management has become more and more important because "*people are the only sustainable asset in modern business*" (Schwarzkopf, Saunders, Jasperson, & Croes, 2004, p. 28). The strategies and implementations of human resource practices directly affect how knowledge workers will be continuously motivated and trained to perform their value creation tasks (Hill & Jones, 1998; Pfeffer, 1994). Trauth et al. (2006) pointed out that it is critical that researchers and practitioners take an active role in creating HR solutions and it is important to understand diversity issues in the global IT environment.

Kakabadse and Kakabadse (2000) pointed out that organizational outsourcing initiatives have both negative and positive effects on their employees. As more and more IT jobs shift offshore, it may hamper the employment relationship of belonging and dedication when employees feel unsafe with respect to job security (Kakabadse & Kakabadse, 2000). The cultural diversity and the lack of trust and cohesiveness of global virtual teams may influence team members' working experiences (Carmel, 1999). It is also argued that outsourcing and global software development arrangements may provide career enhancement and learning opportunities for employees and organizations provided that special expertise

and skills can be acquired and knowledge can be mutually shared and transferred across borders (Baba et al., 2004; Carmel, 1999; Kakabadse & Kakabadse, 2000). Therefore, one of the primary concerns of human resource management in global software development practices is how to mitigate the negative impacts and enhance the positive effects.

Given the complexity and dynamics of cultural diversity and its criticality in global software development work practices, it is important to emphasize the sense-making perspective in cultural training and provide employees proper and continuous cross-cultural training. When knowledge workers are involved in different virtual work environments, the stereotypically and culturally specific approach may fail to help them make sense of different cultural nuances from different cultural contexts (Goodall, 2002; Osland & Bird, 2004). Therefore, cross-cultural training should focus on how to develop and improve the cultural sense-making skills of employees.

Foster (2000) studied the cultural training for expatriates of multi-national companies and pointed out that most of those training programs focus on pre-departure training and fail to provide continuous training during the work processes. Krishna et al. (2004) pointed out that systematic cross-cultural training is less common than informal experience sharing in their case studies of global software development activities. And if in place, that cultural training is usually in one direction: for the outsourced companies to learn the culture of the outsourcing companies (Krishna et al., 2004). Osland and Bird (2004) advocated the sense-making approach for cultural training and stressed that there should be both formal and informal mechanisms for sharing cultural knowledge.

We believe that organizational human resource management together with knowledge management practices should value cultural diversity knowledge as an important part of the organizational intellectual capital and strategic resources for competing in the global IT market in the future. Cross-cultural sense making, understanding, and knowledge sharing are critical to develop flexible, competitive, and yet sustainable learning organizations (Garvin, 1998). In cross-cultural training and learning practices, we should allow distributed knowledge workers to have opportunities to continuously reflect on their cultural experiences in the course of accomplishing working processes and encourage them to take such reflections as learning opportunities.

CONCLUSION

To address the cultural diversity challenges of managing globally distributed knowledge workers in global software development, we proposed a research framework to articulate how cultural diversity is manifested in global virtual work environments and how the cultural diversity of distributed knowledge workers may influence global software development work practices. The main objective of the chapter is to promote the awareness of cultural diversity challenges to managing information technology professionals in the increasingly globalized IT environment. Our analyses show that we should critically examine the global-local context of the cross-cultural issues to overcome the obstacles of cultural diversity in convergent tasks of software development work and maximize its values in divergent tasks of the work activities.

As researchers and educators in academic settings, we believe that cultural awareness and cultural diversity understanding should be viewed as important skills for the future IS/IT workforce. We also believe that organizational human resource practices should adopt the sense-making approach for cross-cultural training and knowledge sharing. In order for organizations to compete in the global market in the future,

cultural diversity knowledge should become an important part of the organization's intellectual capital and strategic resources.

Chapter 6.11
Business Modeling in Process-Oriented Organizations for RUP-Based Software Development

Francisco J. Duarte

ABSTRACT

Several organizations nowadays are not particularly comfortable with their internal structuring based on a hierarchical arrangement (sub-divided in departments), where collaborators with a limited view of the overall organization perform their activities. Those organizations recognize the need to move to a model where multi-skilled teams run horizontal business processes that cross the organization and impact suppliers and clients. To develop software systems for any organization, the development process must always be appropriate and controlled. Additionally, for organizations that want to migrate to a horizontal business processes view, it is required to model the organizational platform where the organizational processes will run. This necessity is also true when the organization under consideration is a software house. In this chapter, a proposal of a generic framework for process-oriented software houses is presented. The way of managing the process model and the instantiation of their processes with the rational unified process (RUP) disciplines, whenever they are available or with other kind of processes, is recommended as a way to control and define the software development process. To illustrate the usefulness of the proposal, the chapter presents

how the generic reference framework was executed in a real project called "Premium Wage" and shows, in some detail, the created artifacts (which include several UML models) during the development phases following the RUP disciplines, especially the artifacts produced for business modeling.

INTRODUCTION

A generic reference framework for process-oriented organizations is presented in Fernandes and Duarte (2004). Here, that framework is specialized to the specific case of organizations that develop software (software houses) and we describe its main characteristics. From now on, the term "target organization" is used to refer to those organizations where the software is deployed and installed. The term "software house" is used to refer to the organization that develops software to run in the target organizations.

The main objective of this chapter is to present a reference framework based on processes and RUP disciplines for software houses and to show its usage in a real software development project, as a demonstration case to illustrate the applicability of the proposed model.

With the proposed framework, a holistic view of any software house is straightforward to obtain, allowing a more accurate definition of those processes directly related with the software development, without disregarding the management and support processes.

Process-Oriented Organizations

The concept of a process-oriented organization is a way of focusing the activities of an organization toward the clients needs (Hammer, 1996). These activities are oriented toward and validated by the clients, whose necessities must be satisfied efficiently and with quality. Reengineering, and its process orientation, must be applied to anticipate change and not as a corrective procedure when bad business indicators occur. In process-oriented organizations, clients' needs must be continuously satisfied, which mandates an easy and fast adaptation to changes. This favors and forces the continuous improvement of every aspect of the enterprise, being it process-, product- or organizational-related.

Information technologies are among the principal factors to permit a process-based restructuring of a given organization (Spurr, 1994). The development of a software application for organizations of this kind must consider their process framework. Thus, the software engineering processes must take into account the organization structure. With this model, the application becomes more useful to the target organization, and maintenance is facilitated since no major modifications and adaptations to the process framework are needed.

A process framework inside an organization contains processes, and these can be viewed as a set of activities that has as inputs and outputs a set of services and/or materials. This view must be oriented toward the necessities of the client and to the creation of added-value. This implies that the clients' requirements must always be considered, both in the design and in the performance of the system. In an organization, there are other processes rather than those that provide added-value to the clients. The existence of different types of processes is necessary to assure, for example, the strategic planning for the organization, the recruitment of the human resources or the fiscal duties. As illustrated in Figure 1, these processes are instantiated in Management and Support Processes.

Within an organization, the management by processes requires a structure that differs from the typical functional hierarchy. It is mandatory to synchronize the processes among them and to fulfill the strategic objectives of the organization. For a process-oriented organization, a structure with the following elements should exist:

- **Process management top team:** This team includes the top managers, all process owners and, if existing, the process management structural responsible. Its mission is to revise all the processes according to the strategic objectives of the organization, to analyze the effectiveness of the process-oriented management and to decide about unsolved problems at the processes' interfaces.
- **Process sponsor:** The mission of this top manager is to help and instruct the process owner, to decide when there is a problem of interface among processes, to determine the strategic orientation of the process and to assure that the process is uniform within the organization.
- **Process owner:** For each process, its owner must have know-how on managing processes and persons and competency in the areas associated with the process. His mission is to lead the process' multi-disciplinary team.
- **Multi-disciplinary team:** This team must be created for each added-value process, since they represent the most important processes for the clients. The mission of this team is multi-fold: to monitor its process, to define and analyze the key indicators and the process objectives, to ensure that the process documentation is updated, to decide when and how to use improvement teams and to coordinate them and to manage the process execution teams.
- **Execution teams and team leaders:** These teams and their leaders represent the instances of a given process (Scheer & Nüttgens, 2000). Therefore, during the execution of a process, some teams will use it with a specific focus. For example, for a given production process, one team may be responsible for producing parts for industrial clients, while another team may produce them for individual clients.

To align a process-based organization with its strategic objectives, it is crucial that the goals are based on the organization mission and vision, and also on its principles and values. Based on those strategic objectives and in the business plan, the priority when deciding the key business processes within the organization can be perceived and included in the process landscape. This action may imply that some processes, activities or tasks can be eliminated if they do not add any value to the clients or to the organization. These eliminated (or redefined) processes, activities and tasks, and their respective consequences in terms of reorganization and impact in human resources, are the essence of re-engineering (Hammer, 1996).

Demonstration Case

The proposals made in this chapter were tested in a real industrial environment, more specifically in the first author's organization.

The project, titled "Premium Wage," consists of the development of a software application to calculate the payment of extra money to employees, based on their productivity, quality and absenteeism (Fernandes & Duarte, 2004). This project was considered critical, since it is likely to have important social and behavioral impacts on the organization, namely, if the amount is badly calculated or if it is impossible to explain how it was obtained. This premium was introduced with the aim of ameliorating the organization's overall productivity and quality, and to return the excellence to the workers.

Besides its criticality, the business process is also complex since it depends on other processes. In this case, the payment of a premium depends on three main factors: individual absenteeism, quality of the products made in the employee's line and individual performance. The first two sub-processes were extended in order to support new functionalities. For the third, a complete

reengineering was carried out. Finally, a new process was designed, modeled and implemented to the premium wage calculation.

In the project, the proposed reference framework, namely RUP's business modeling discipline, is extensively used and we evaluate the capacity of the process to cope with complex organizations.

Structure of the Chapter

This chapter is structured in five main sections. The second section presents the main characteristics of the reference framework for Process-Oriented software houses, namely the processes they are composed of. In the third section we describe RUP's business modeling core discipline, which implements an added-value process. In the fourth section we describe and discusses in detail the produced artifacts for the demonstration case during the execution of the business modeling discipline. In fifth section, future trends and work along with the conclusions are presented.

REFERENCE FRAMEWORK FOR PROCESS-ORIENTED SOFTWARE HOUSES

A reference framework, also called PSEE (process-centered software engineering environment), does not support the notion of a predefined process model that is supposed to be applied in every development project, but instead supports a wider variety of processes based on parameterization (Engels et al., 2001). SPADE (Bandinelli et al., 1994), EPOS (Conradi et al., 1994), MELMAC (Gruhn & Jegelka, 1992), OIKOS (Montangero & Ambriola, 1994), OPEN (Henderson-Sellers, 2000), ESF (Gasch et al., 1987) and APPL/A (Sutton et al., 1995) are well-known examples of PSEE systems or process modeling formalisms.

A reference framework for process-oriented organizations is presented and justified in Fernandes and Duarte (2005). In this chapter, an updated version of this particular framework (Figure 1) includes a new process, called *change management*, that allows a more explicit management of continuous improvement and changes. This framework has some of its processes consubstantiated with RUPs disciplines. Since RUP is a process meta-model, we can obtain a specific process model by tuning some of the parameters, allowing our reference framework to be tailored for each kind of project.

According to the classification described in Fettke et al. (2005), the framework in Figure 1 has the following main characteristics:

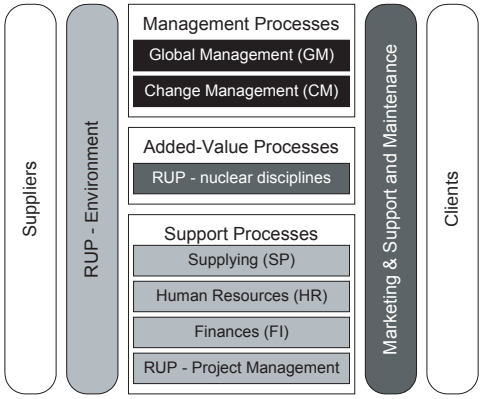
- **Construction:** domain differentiation (institution), domain description (software houses), modeling language (graphical, UML activity diagrams and RUP business use cases), modeling framework (yes) and evaluation (demonstration case)
- **Application:** method (procedure model), reuse and customization (customization of model contents)

The reference framework intends to cope with all issues related to software development processes and potentially can be used with the following purposes: documentation, analysis and improvement of software process models (Bandinelli et al., 1993), software process improvement (Avrilionis et al., 1996) and software process execution (Deiters & Gruhn, 1998).

Figure 1 represents a top-level view of the process landscape, which is useful to show and discuss with top managers and process owners. Afterwards, this view must be further refined by the process owner and the multidisciplinary team, to present the process at the appropriate level of detail for each software house professional.

It is also important to notice that Figure 1 corresponds to a specialization of the general framework presented in Fernandes and Duarte (2005) for the particular situation of organizations whose

Figure 1. Reference framework for software houses



main activity is to develop software. The execution of the TTM process by the software house produces an instance of the general framework that models the organization where the software will run. This fact makes the general framework valuable in two senses: (1) as a reference for the software house to model itself, and, (2) as a reference for the software house to model the target organization.

In software houses, we propose the business processes to be organized into two different groups: (1) the first one includes processes that exist in any organization independently of its relation to the software development business; (2) the second group includes processes that present specific characteristics due to the fact that the organization's main activity is the development of software-based solutions.

Management and Support Processes

We can observe several processes in the context of the management and support issues that are common to any type of organization.

The *global management* process includes the sub-processes *global strategy* (GS), *policy deployment* (PD) and *business plan* (BP). This process is equivalent to that of any other organization, although we must take into account the particularities of the software market, such as the rapid changes in technology and the competition in worldwide markets when defining, for instance, an organizations' business and vision.

Once stable process models have been obtained, they should be released and afterwards it is desirable to manage their changes, according to the change requests made by process stakeholders (Gruhn & Wellen, 2000). The *change management* (CM) process allows the software house to collect, organize and manage the output data and experiences that are the basis for processes self improvement. This new process should exist in any software house aiming to reach the highest CMM (*capability maturity model*) levels (Paulk et al., 1995). To reach the highest CMM levels, the concern about the constant improvement of the development processes must be part of each process, instead of being only a matter of the CM

process. CMM level 3, which is considered the minimum when discussing the software process (Henderson-Sellers, 2000) is reachable with RUP if it is extended accordingly, for example, to the proposals made in Manzoni and Price (2003). Also, rules and procedures should be defined previously to cope with the introduction of significant changes in the organization.

The *supplying* (SP) process consists essentially in creating copies of an application. In contrast with more traditional industries, where it represents probably the most important process, in software, due again to its intangible nature, this is a trivial process. The usual outsourcing of this process comes from the fact that it is considered to be secondary for an organization that develops software. Therefore in this kind of organization, this process is a support one.

The *human resources* (HR) process for software factories is the same as for other types of organizations. We must, however, point out that software development requires highly specialized people, making their hiring a critical issue for the success of the organization. It is impossible to produce quality software without skilled people.

The *finances* (FI) process is the typical fulfillment of the fiscal obligations, which is common to all types of organizations and may also include controlling activities.

The processes *marketing* and *maintenance and support*, represent the typical *customer relationship management* (CRM) process. This ensures that when a software application is delivered to the final clients, its life-cycle does not end at that time, but instead continues by incorporating changes and corrections, providing training to the users, while the application is being used by the clients. Hotline support activities can also exist as an included sub-process.

Added-Value Processes

In the context of added-value processes, the proposed reference framework is influenced by the fact that RUP constitutes a systematic approach to assign tasks and responsibilities to its members. The main aim of RUP is to construct quality software that meets the requirements of the stakeholders, within a typical engineering context (Machado et al., 2005). RUP identifies and defines the activities needed to map user requirements into a software application and is accepted to be a generic/customizable process that can be adapted for a wide range of contexts, namely organizations with distinct CMM levels, different skills and tools and unequal number of team members.

Since software is an intangible product, it is obvious that no raw materials are needed to produce it. For organizations that develop software, RUP's *environment* discipline can instantiate the *supplier relationship management* (SRM) process, since it furnishes the working environment (e.g., development tools) and the development guidelines to be followed by the teams.

The RUP's core disciplines (*business modeling, requirements, analysis and design, implementation, test and deployment*) represent the most critical activities for an organization that develops software and can be seen as the *time-to-market* (TTM) process of the organization. This set of activities, or sub-processes, run in parallel for the same development project.

The RUP's discipline *project management* implements the *data management* (DM) process. In this discipline, some activities lead to the production of indicators of the project status. Its existence is the foundation to take decisions based on facts, related to the advance of the project aiming to adjust and improve the software development process.

Business Modeling in RUP

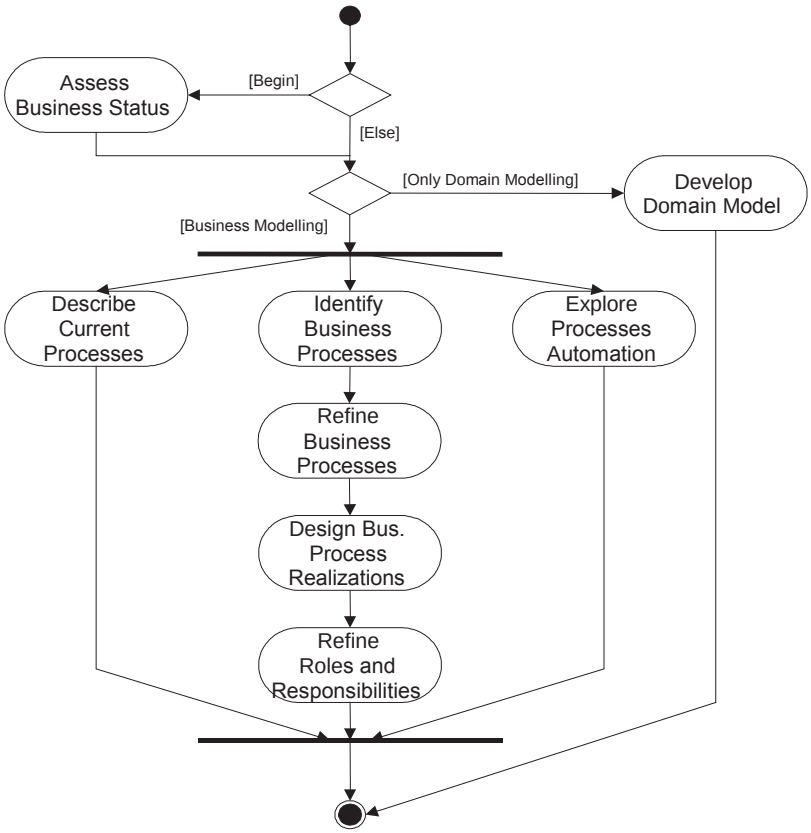
RUP's core disciplines implement added-value process. These disciplines are sub-divided in activities, which can be viewed as sub-processes. The description of those sub-processes is made with UML activity diagrams, complemented

optionally with other kinds of diagrams, such as interaction and business object diagrams.

This representation is also valid for all other processes of a generic organization. Any time a software house starts a new project, the TTM process is executed. Since we propose this process to be implemented by the six RUP's core disciplines, it implies that *business modeling* will also be executed. Among the recommended diagrams by this discipline for modeling purposes are included activity diagrams. Thus, a target organization will be modeled also by a collection of these diagrams. Additionally, within the software house, the discipline *business modeling* itself can also be modeled by activity diagrams, since it is a sub-process of the TTM process (Figure 2).

During software development, all the stakeholders must have a common understanding of the business processes that exist in the target organization. This reality is not circumscribed to the obvious organizational information systems. If the development of applications does not take into account the current business processes (or those to be implemented), the result will be probably unsuccessful. This may be caused by the fact that end users do not employ correctly the application, since it does not support directly the activities under their responsibility.

Figure 2. Activity diagram to help the execution of RUP's business modeling discipline in TTM process



The main activities of *business modeling* are centered on the identification, refinement and realization of the business processes and in the definition of the roles of people associated to the business. Each role in this RUP's discipline has under its responsibility the execution of several activities that will have as deliverables several artifacts (Table 1).

The activities of Table 1 are at a detailed level than those of Figure 2. For example, the activity *refine business processes* includes the activities *structure the business use case model*, *review the business use case model* and *detail business use cases.*

Among all the activities and their respective artifacts, only some are mandatory. This flexibility permits the configuration of RUP, so that it can be adapted to a specific project executed in a given organization.

Table 1. Roles, activities, and main artifacts for business modeling in RUP

Role	Sub-Activity	Activity (Figure 2)	Main Artifacts
Analyst of the Business Process	Assess target organization	Assess Business Status	Business rules Business use case model Business glossary Business object model Business vision Supplementary business specification Target organization verification Business architecture
	Set and adjust goals		
	Capture the business vocabulary		
	Find business actors and use cases	Describe Current Processes	
	Maintain the business rules	Assess Business Status & Identify business processes	
	Structure business use case model	Refine Business Processes	
	Define the business architecture	Identify Business Processes	
Reviewer of the Business Model	Review the business use case model	Refine Business Processes	
	Review the business object model	Refine Roles and Responsibilities	
Designer of the Business	Detail business use cases	Refine Business Processes	Organizational units
	Find business workers and entities	Describe Current Processes	
	Define the automation requirements	Explore Processes Automation	
	Detail business entities	Refine Roles and Responsibilities	
	Detail business workers		

BUSINESS ARTIFACTS FOR THE DEMONSTRATION CASE

Nowadays, the technology-planning horizon for big companies is a synthesis of software and process engineering (Smith & Fingar, 2002). Additionally, the success of a project depends heavily on the correct perception of the business process to be modeled. Taking into account these two aspects, the RUP's *business modeling* discipline assumes a critical role in the software development process. The artifacts that can be generated by this discipline have the following objectives:

- To understand the structure and dynamics of the organization where the system will be executed
- To comprehend the current problems of the target organization and to identify potential improvements
- To assure that clients, final users and developers have a common understanding about the target organization
- To capture/deduct the requirements of the system necessary to support the target organization

RUP can be parameterized and used both in small and complex projects; next we discuss what artifacts were produced for the demonstration case. For this parameterization to occur, it is necessary, during project execution, to choose which artifacts to use and their level of detail. This choice was validated by quality assessments contained in the process model as milestones between phase transitions. Thus, both the subset of used artifacts and also its degree of detail can not be anticipated with rigor, but must be selected based on experience and knowledge of the development team in relating the characteristics of each project with the functionalities offered by the artifacts. The criteria to fulfill this choice are related with:

- Characteristics of the project itself (e.g., criticality of the modeled business processes, type of target organization)
- Characteristics of the organization that develops software (e.g., team size, level of knowledge about internal rules)
- Temporal restrictions. Since resources are limited in engineering projects, it is always a necessary balance between the quantity and detail of the produced artifacts and the deadlines for implementing the project.

The produced artifacts result from a set of activities that occur inside those disciplines. In this demonstration case, we identified the need for the artifacts to represent two distinct situations in terms of business: One part of the project represents reengineering activities of some business processes, while the other part represents the introduction of a new business process. In several diagrams (e.g., business use case model), the standard UML is augmented with the stereotypes defined by RUP, thus allowing the creation of RUP-like artifacts.

Business Rules

The business rules correspond to policy statements and conditions that should be fulfilled from the business perspective. They are similar to systems requirements, but they focus on the business core, expressing rules related to business, and also its architecture and style. Its modelling must be rigorous, one possibility being the use of the object constraint language (OCL) as specified in UML. Alternatively, business rules can be modeled with structured English, using some fixed constructors (Odell, 1998).

The usage of structured natural language with fixed constructs and with a pseudo-programming language syntax was chosen due to the necessity to validate directly with key users the perception of the development team about stated business rules, and also because key users have a generic engi-

Table 2. Business rules examples for Premium Wage

Rule #	Description
1	**If** worker_has_conflict_inside_team **or** worker_is_under_disciplinary_process **then** premium(worker) = 0
2	**Switch** absenteeism(worker) **case** = 0h: premium(worker) = premium(worker) * 1 **case**]0-4h]: premium(worker) = premium(worker) * 0.75 **case**]4-8h]: premium(worker) = premium(worker) * 0.5 **case** >8h: premium(worker) = premium(worker) * 0
3	**If** line_productivity_not_available **or** absenteeism_not_available **or** quality_factor_not_available **then** premium(worker) = 0

neering background. This way, in the particular situation of the demonstration case, the usage of natural language was preferred over OCL.

Table 2 shows, as examples, three rules for Premium Wage system.

Rule 1 describes a situation where no premium payment is due when the worker has conflicts in its team or is under a disciplinary process, even though productivity, quality and absenteeism are at good levels for that worker. Rule 2 assigns a weight factor to the final premium based on the worker's absenteeism. Rule 3 states that if there is no information available from one of the three premium factors, no payment will be made for that worker.

Business Use Case Model

The main goal of this artifact is to show how the business is being perceived and run by stakeholders. This is achieved by modeling the business processes and their interactions with external parties, based on business use case diagrams (with stereotypes for business use cases and business actors) (Fernandes & Machado, 2001; Machado & Fernandes, 2002).

Business processes models should specify how added value is created for the business actors. Activity diagrams, possibly extended with the representation of organizational units interfering in the business process and with the distribution of the activities by those organizational units, can support this modelling. The knowledge about "who is doing what" should be obvious when reading this model.

Business use case model is the first description of the business functionalities and actors inside the target organization. For Premium Wage, one artifact was created to model the current situation (Figure 3) and another for the desired future situation (Figure 4).

The existence of these two models shows to all stakeholders, using the same notation and same detail level, the first perspective of effort amount

needed to reach a future situation, and more important, acts as a base for the target organization's management to decide on business re-engineering and improvement. A special emphasis should be given to explain to the target organization's management that an information system is not the complete business reality, but an abstraction of it. Real business processes, such the ones stated in *business modeling* discipline, are far more extent than the ones implemented inside the information system. This may be caused by people's activities because they do not act similarly every day, and mainly because people like to have their own special information systems (e.g., spreadsheets or personal databases) to make decisions and cause the *starvation* of the organization business information system with missing data. This is a crucial success factor at the present time because the work is no longer only individual or departmentally related, but exists through horizontal business processes that cross the entire organization and reaches external partners.

Figure 3 shows the current situation, where only three business use cases exist and only two business actors take part. The line productivity is calculated by the controller-based master data lines' team member and products maintained by the team manager. This situation shows that no information was available on how and where to collect quality data and absenteeism. Next, in Figure 4, the desired extensions and new business use cases can be seen. For the future situation, six business actors are needed, and special care should be put on this situation because some of them may not be directly related with project activities and may not understand the business value of the new activities (stated in the business use cases) if no proper involvement and education is provided.

In this situation, line productivity is *triggered* also by the controller, but to be useful, it first has to be transformed into individual performance (because one employee can work in several production lines for the premium calculation

Figure 3. Business use case model: As-Is situation

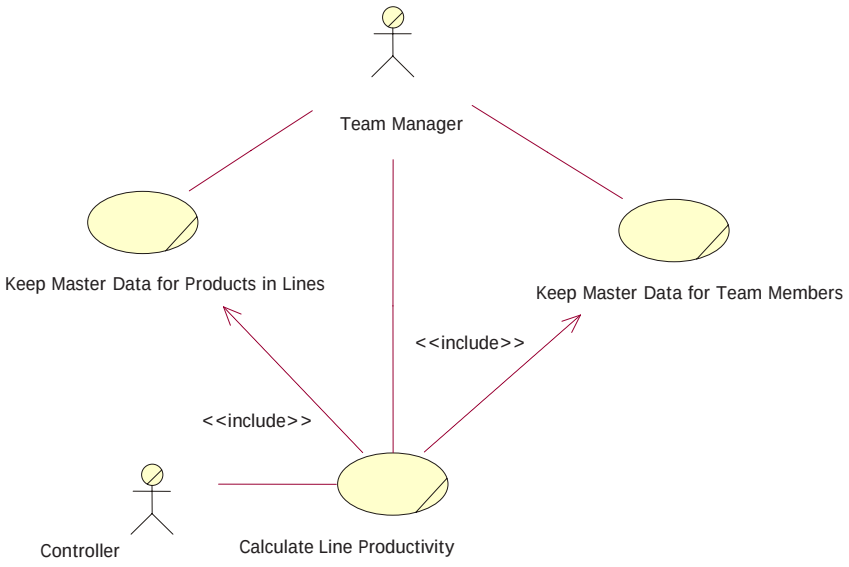


Figure 4. Business use case model: To-Be situation

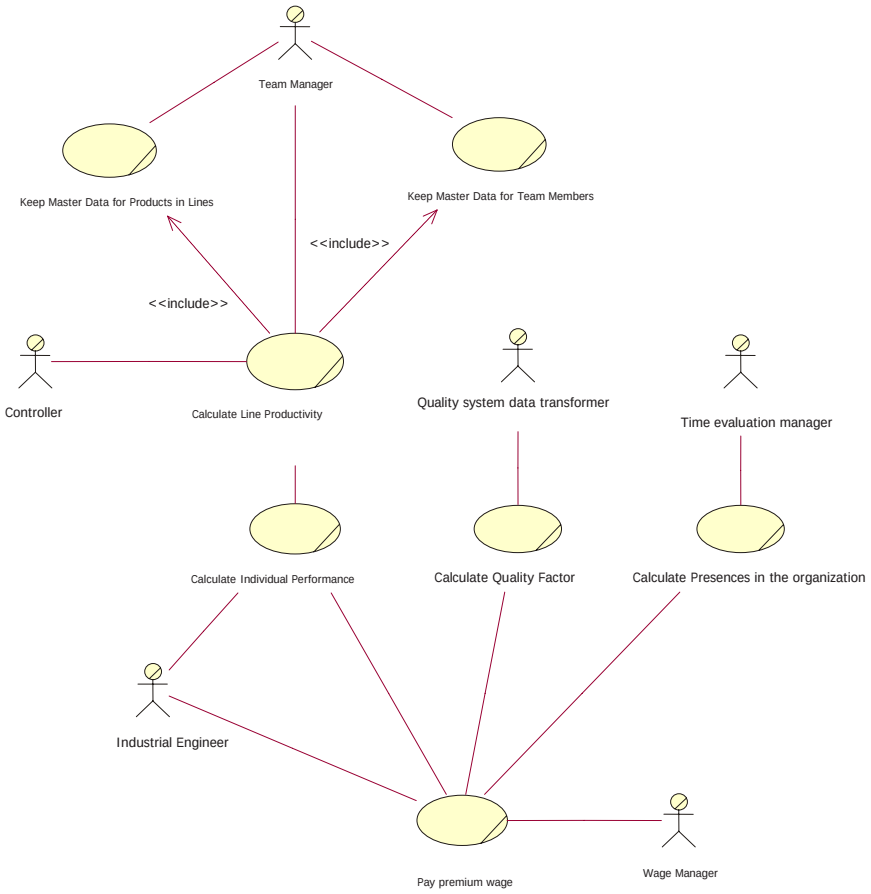


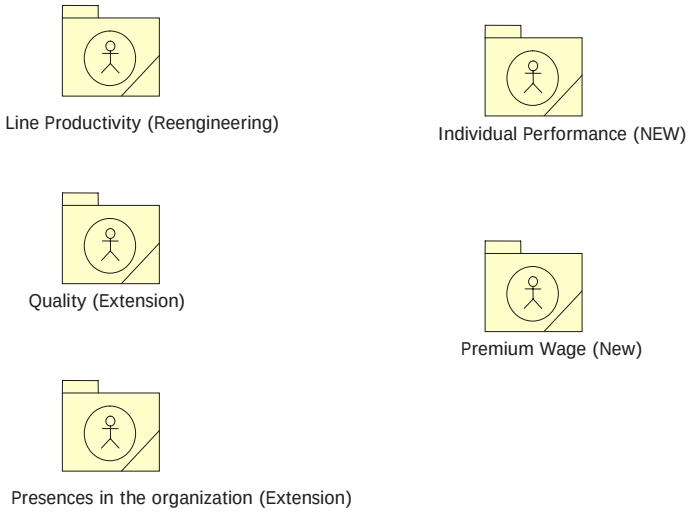
time frame). Additionally, the remaining two premium factors (quality and absenteeism) are stated, thus allowing the industrial engineer to calculate the final values and the wage manager to handle them.

Organizational Units

This artifact is used to reduce the complexity and structure of the business object model by dividing it into smaller parts. For the demonstration case, five organization units where created (Figure 5), each one representing a collection of business workers, business entities, relationships, business use-case realizations, diagrams and other organization units.

The organization unit *line productivity* includes the re-engineered activities for the productivity calculation, *quality* and *presences in the organization* where extended to cope with premium calculation. The *individual performance* and *premium wage* calculation organizational

Figure 5. Organizational units



units were newly created in the organization, because none of the existent capabilities could handle it.

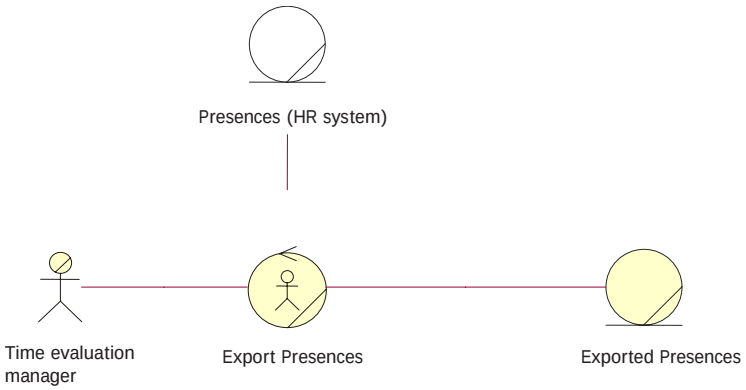
Business Object Model

This artifact is an object model describing the realization of business use cases. It serves as an abstraction of how business workers and business entities need to be related and how they need to collaborate in order to perform the business. In Figures 6 and 7 the realizations of some To-Be situation business use cases are presented, namely *Presences in the organization* and *Pay premium wage*.

The importance of this artifact comes also from it being a basis for identifying future information system actors and use cases, and in addition, to identifying classes for analysis and design models. First modelling the business and afterwards the information system is a crucial practice to correctly align the business reality with the abstraction the information system implements. If the software information system development only starts with the modelling of a software system, a quality software product can be obtained (being the quality perceived as the degree of correctly implementing requirements) but that may fail completely to cope with the business reality of the organization in which it will run. Although business information systems implement a large percentage of the business practices, there are always some parts of the organization's business processes that are not implemented in software systems. The modeling of such business practices by the software development team is a wise and safe procedure to avoid future inconsistencies when introducing the information system in the organization.

To calculate the presences in the organization (Figure 6), the business worker *Time evaluation manager* uses business entity *Export presences*

Figure 6. Business object model: Calculate presences in the organization



to pick the business object *Presences* available in the HR system and generate a new business object *Exported presences* containing the presences in the organization in a proper format to use inside the Premium Wage information system.

In Figure 7, business entity *Calculate Premium Values* uses several business objects representing final premium factors, such as *Compiled Quality System data*, *Exported presences* (generated in Figure 6, business object model) *Individual Performance* and also business objects representing levels and limits (acting as data supports to implement business rules (Table 2) to generate the business object *Premium to Pay.* Afterwards, this business object will be used and transformed by several business entities, with and without the intervention of business actors, until the final Employee Total Wage (Wage + Premium) is loaded and calculated in the HR system, as shown in Figure 7.

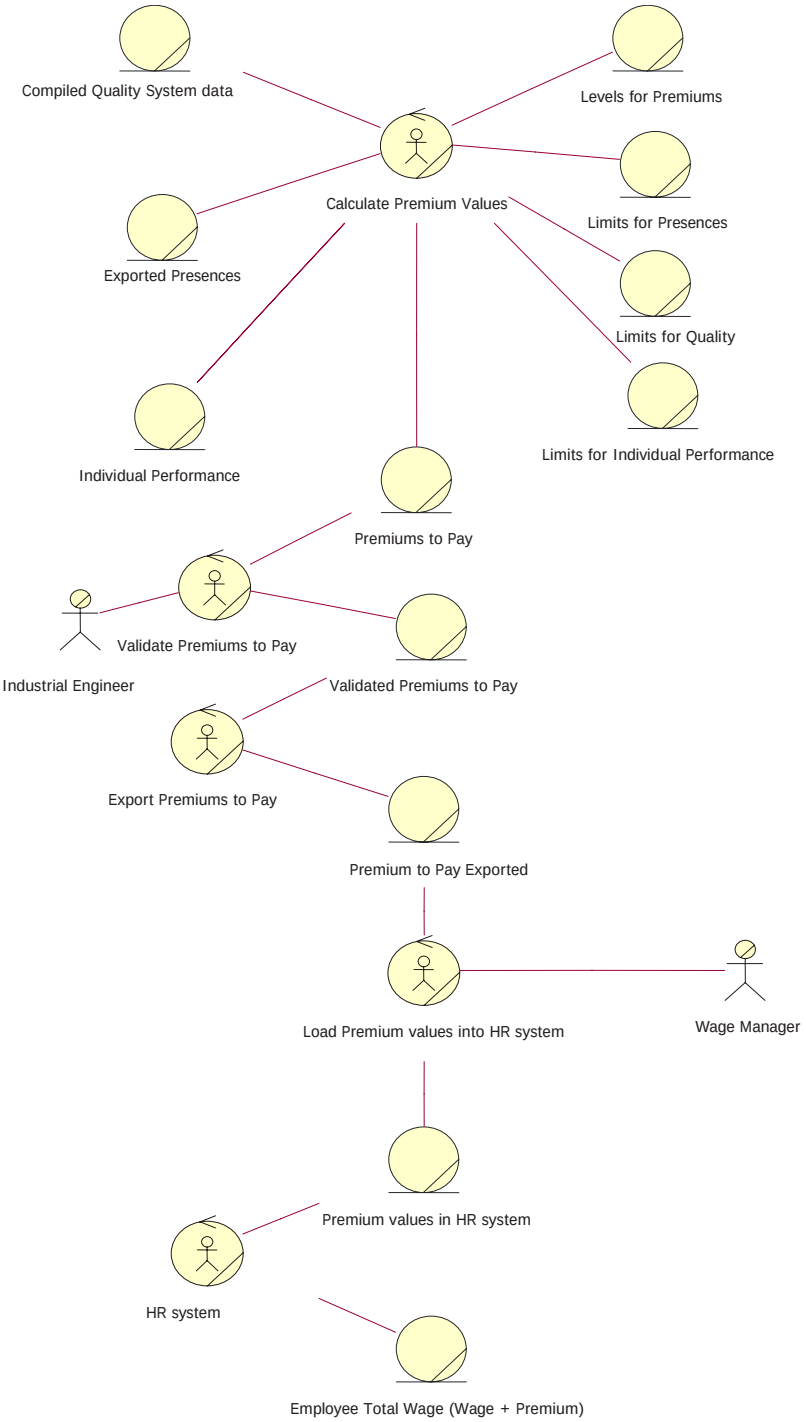
The business object model exposed in Figure 7 is not fully contained in Premium Wage information system. The business object Premium to Pay Exported is generated by Premium Wage to be used inside the organization's HR system. This is an example where some of the business actors, business entities and business objects will not be part of the information system required by the software development team, but they were modeled to guarantee a proper integration of current information systems (e.g., HR system) with newly developed ones (e.g., Premium Wage).

Other Business Artifacts

From all of the proposed artifact in RUP for business modeling, some were not used in the Premium Wage demonstration case. Next, we present the reason why they were not needed in the instance of the RUP we used for this project:

- **Business glossary:** In this artifact all business terms and expressions are kept. They are necessary for a good understanding among all project stakeholders. In our situation, the business terms are common to the target and to the software developing organization because they both are sub-organizations of the same organization.

Figure 7. Business object model: Pay premium wage



- **Business vision:** This artifact captures the goals of a particular business modeling activity, stating what is to be modeled and the reasons why. It also serves as an oracle to all future high-level decisions. We did not use business vision because it is common to the target and software development organization due to the same reasons as those of business glossary.
- **Supplementary business specification:** No need for extra-detail than that available in the business use case and the business object models.
- **Target organization verification:** The target organization is perfectly known by the software developers. The current processes are modelled by the business use case model, As-Is situation.
- **Business architecture document:** The detail level presented in the business use case model and in the business object model is sufficient to understand the business architecture.

CONCLUSION AND FUTURE TRENDS

In this chapter, we have presented a revised version of a reference framework for process-oriented software houses which serves as a foundation to model organizations. This specific framework is based on a more generic one, which is also used as a template to model the target organization in which the software product is to be executed. Additionally, we also show the way of managing the framework and the instantiation of its processes with RUP disciplines whenever feasible.

We also discuss in detail the usage of the framework within a demonstration case, and more particularly, the produced artifacts during the execution of the RUP's business modelling discipline. The modeling capabilities of a graphical modelling language (such as the UML) and the understanding that it gives to all the stakeholders was a crucial factor in the demonstration case to avoid communication and interpretation errors and to improve the solution utility and correctness.

As future work, we plan to model the reference framework with UML (Fettke et al., 2006) and formalize the processes of the framework by using colored Petri nets (Jensen, 1992). Similar approaches also based on Petri nets were also experienced with results (Gruhn & Wellen, 2001; van der Aalst, 2003).

By adopting a formal language, it is possible to model, animate, simulate and formally verify the properties of each single process. Additionally, we intend to explicitly model the interfaces between the business processes in our reference framework, which allows the complete framework to be analyzed, verified and validated.

We intend to automatically generate CPN skeletons from business requirements models. A semantic layer in the Arena environment (Kelton et al., 2002), capable of accepting CPN-based business specifications, will also be developed to allow the stochastic execution of workflow scenarios as a complement to some current validation approaches based on CPN/Tools (Beaudouin Lafon et al., 2001).

After formally describing the reference framework processes, we can use them in every organization (in this case, software houses) to compare with current processes. This comparison (based on the same Petri net formalism) should allow a quick assessment of the organization against world-class processes and consequently permit the re-engineering and improvement of its own processes. In this way, the reference framework acts as a To-Be model to be compared with the As-Is model of the software house. The detected mismatches show the improvement areas for the software house to proceed accordingly within the organization vision and mission.

Chapter 6.12
Improvement of Software Engineering by Modeling Knowledge-Intensive Business Processes

Jane Fröming
University of Potsdam, Germany

Norbert Gronau
University of Potsdam, Germany

Simone Schmid
University of Potsdam, Germany

ABSTRACT

The Knowledge Modeling and Description Language (KMDL®) allows analysts to identify process patterns, which leads to improvements in knowledge-intensive processes. After modeling the business processes, knowledge and process potentials in daily business processes can be unleashed. The following contribution presents a specification of KMDL® for software engineering (KMDL®-SE). A real-life example is used to explain KMDL®-SE.

INTRODUCTION

Software development is a knowledge-intensive business process. Until now, no adequate methods were available to improve knowledge management in software engineering by appropriate models, analyses, and concepts. It seems useful to combine more than 10 years of experience in the modeling and analysis of information processing tasks, applying methods like event-driven process chains and establishing a new modeling paradigm focused on knowledge creation. Its application in

the area of software engineering is described in the following contribution.

The main focus of the contribution refers to two principal objects: First, knowledge-intensive business processes in software engineering can be identified and improved using an adapted modeling language. Second, the specification of the Knowledge Modeling and Description Language (KMDL®) is used to model an exemplary software engineering processes. In the section "Theoretical Foundation of KMDL®," the theoretical framework of KMDL® is presented. The modeling language is used to describe knowledge-intensive business processes, tacit and explicit knowledge, and knowledge and information flows. In the section "Analysis of Potentials with KMDL®-SE," potential improvements for software engineering processes are proposed. In the section "Real-Life Application of KMDL®-SE," a real-life example of using KMDL® is described. "Identification of Process Patterns" describes the conclusions and identified process patterns that can be found and used to reorganize the software engineering processes in software engineering companies as well as for the specification of KMDL®. The last section gives future prospects of further developments of KMDL®-SE.

QUESTIONS AND PROBLEMS OF KNOWLEDGE MANAGEMENT IN SOFTWARE ENGINEERING

The dynamic behavior of the actual business environment will gain speed and complexity. The market for software products will transform very quickly, and the pressure due to competition is expected to increase massively. Especially small and medium-sized enterprises have to cope with the high pressure in the software engineering sector consisting in the rivalry between themselves and major players (Groff & Jones, 2003). Therefore, methods and applications are needed to identify potentials in daily business processes (Hamel & Prahalad, 1990). The knowledge and use of these potentials can be a decisive competitive advantage. The management and processing of organizational knowledge increasingly are being viewed as critical to organizational success (Inkpen & Dinur, 1998).

The contribution is based on the central thesis: The productivity of software engineering will be increased using appropriate knowledge management applications.

Software engineering processes have to be improved in a way that relevant information and knowledge have to reach the appropriate employee at the right time. If so, employees reduce unnecessary waiting time for information and knowledge; therefore, tasks can be completed more quickly. Another way to increase the productivity of software engineering is a constant documentation and optimization of recurring subprocesses and a reuse of these as patterns in other projects. Knowledge management activities in software engineering can be effective only if they are implemented and applied consequently throughout the company. Even the greatest strategies will be unsuccessful without the support of employees. Staff members have to deal with knowledge management, and its advantages have to be made clear.

In the following sections, the central thesis will be discussed, applying it to a real-life example of software engineering in a small and medium-sized enterprise. A German software engineering firm was analyzed within the research project M-Wise[1]. M-Wise is based on the German federal government's software engineering research initiative 2006. The interdisciplinary organized project aims to promote knowledge management in software engineering. Existing methods and applications to model knowledge-intensive business processes were improved, and a new specification of a modeling language in software engineering could be developed and tested in a real-life environment.

MODELING OF SOFTWARE ENGINEERING PROCESSES WITH THE KNOWLEDGE MODELING AND DESCRIPTION LANGUAGE

In the following section, the Knowledge Modeling and Description Language KMDL® is introduced. KMDL® is currently under development at the University of Potsdam in Germany. The theoretical framework of KMDL® as well as a general procedural model for its implementation is described. Finally, this article will point out the use of KMDL® especially for software engineering, for which a new specification (KMDL®-SE) is introduced. Further references to the modeling method are available in Gronau and Weber (2004) and Gronau and Weber (2004a).

Knowledge-Intensive Business Processes in Software Engineering

Within process-oriented knowledge management, the knowledge-intensive business process is the primary perspective (Remus, 2002). Several attempts have been made in the literature to define knowledge-intensive business processes. Heisig (2002) points out the opportunity to schedule the knowledge demand and evaluates knowledge intensity according to the existence of variability and exceptions (Mertins et al., 2000). Other sources define a process as knowledge-intensive if an improvement with conventional methods of business reengineering is not or is only partially possible (Remus, 2002). Davenport recognizes the knowledge intensity by the diversity and uncertainty of process input and output (Davenport & Prusak, 2000). A process is knowledge-intensive if its value can be created only through the fulfillment of the knowledge requirements by the process participants. Several properties that are typical of knowledge-intensive business processes are introduced in the following list (Gronau et al., 2005):

- In knowledge-intensive processes, knowledge contributes significantly to the values added within the process. Innovation and creativity plays a major role in such processes (Eppler et al., 1999). People within the process have a large scope in the freedom of decision, meaning that they can decide autonomously.
- The event flow of knowledge-intensive business processes is not clear in advance, as it can evolve during the process (Davenport & Prusak, 2000).
- The participants in the process have different experiences and bring in knowledge from different domains with a varying level of expertise (Heisig, 2002).
- The lifetime of knowledge involved in the process is often very short (Eppler et al., 1999). It quickly becomes obsolete. It is usually very time-intensive to build up this knowledge.
- Usually knowledge-intensive business processes do not follow structured working rules and often lack metrics to evaluate the success of the process (Davenport & Prusak, 2000).
- IT-tools for knowledge-intensive business processes are generally not very sophisticated, because the knowledge usually is transferred through socialization and an informal exchange of knowledge.
- Often the costs of knowledge-intensive processes are very high.

Software engineering consists of different knowledge fields such as requirements analysis, software design, software testing, and software configuration management (Abran et al., 2004). These fields can be analyzed and evaluated in terms of their knowledge-intensive characteristics. Except for the software configuration management, all the mentioned fields of applications are affected by a high degree of innovation and

autonomy. They do not follow structured working rules, and various individuals with different expertise are involved in the process. All that the knowledge fields have in common is that there is great variety of sources and media, a high demand for communication, a short half-life period of knowledge, and high process costs; therefore, it can be defined as knowledge-intensive processes.

In order to successfully create knowledge-intensive business processes in software engineering, a method to reflect knowledge flows is necessary. This dimension cannot be brought out adequately by methods like event-driven process chains (Van der Aalst, 1998), because the ability to display the essential elements of knowledge flows are missing, especially the description of tacit knowledge. The process-based approach can provide an efficient way to capture and navigate knowledge (Kim et al., 2003).

Theoretical Foundation of KMDL®

The first version of KMDL® was developed by Professor Gronau at the University of Oldenburg. The motivation for the development was the lack of appropriate methods to model knowledge-intensive business processes. At the University of Potsdam, KMDL® is improved continuously by the Knowledge Management Group. A procedural model is developed as well as a mechanism for the process analysis. KMDL® is a description language that is suitable to model knowledge-intensive business processes. It has the ability to identify available knowledge that exists in or is necessary for the process, including its origin and application. The following section introduces the theoretical concepts that are used to define the Knowledge Modeling and Description Language. The first paragraph outlines the tacit and explicit knowledge defined by Nonaka and Takeuchi. In the second paragraph, the concept of knowledge conversion will be introduced.

Tacit and Explicit Knowledge

KMDL® uses the understanding of tacit knowledge according to Nonaka and Takeuchi (1995). They follow the thoughts of Polanyi (1958), who introduced the terms of tacit knowledge and explicit knowledge. Polanyi (1958) defines tacit knowledge as personal knowledge bound to humans. This type consists of mental models, beliefs, and perspectives (Nonaka & Takeuchi, 1995). It is partially unconscious and, therefore, difficult to be communicated and explained by the persons who possess it.

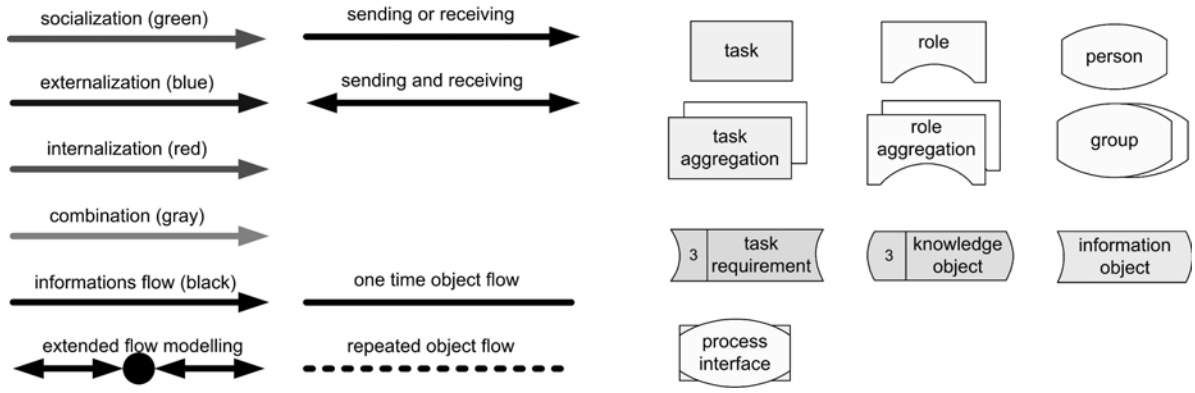
Explicit knowledge, on the other hand, easily can be expressed in handbooks, papers, patents, or software (Gronau & Weber, 2004). It is formal, codified, systematic, easy to communicate, shared, and can be articulated in writing and numbers (Schmidt et al., 1996). This also means that it can be transmitted and stored for reuse by other people.

Numerous life-cycle models adopt a similar staged view of knowledge flow (Nissen, 2002; Nissen & Levitt, 2004). Nonaka goes further still, as he introduces a model describing a spiral of five dynamic interactions between tacit and explicit knowledge along an epistemological dimension, and he characterizes four processes (socialization, externalization, combination, internalization) that enable individual knowledge to be amplified and to effect organizational knowledge crystallization along the ontological dimension (Nonaka & Takeuchi, 1995).

KMDL® Description Language

The basis for a software engineering specification of KMDL® is version 1.1 (see Figure 1). Tasks represent the frame of the KMDL® model description. They describe the logical sequence of the business process. The prerequisite for the execution of a task is certain information as

Figure 1. Associations and objects of KMDL® v1.1



input. The generated information is the result or the output of a task. The information flow connects these objects. Tasks are executed by roles. A role integrates textual or organizational-related activities of a task. For each role, requirements to execute the specific task in the desired manner in order to generate the required output using the given input are modeled. The person who performs a task is assigned to a role. The knowledge objects (tacit knowledge, see the section "Tacit and Explicit Knowledge") are attached to the person. These objects are required in order to execute a task. Each knowledge object is linked to a person and is personal. The attribute level describes the qualification of each knowledge object and task requirement. At present, the attribute level contains four degrees: 0 means no knowledge, 1 means basic knowledge, 2 means intermediate knowledge, and 3 means expert knowledge.

Attributes are used for more detailed descriptions of objects. For instance the attribute knowledge domain is provided for each knowledge and information object, assigning it to a specific topic. This enables the hierarchical assignment of knowledge and information objects and, hence, the description of used explicit and tacit knowledge within the considered process.

In addition, the description language enables the visualization of knowledge flows (see Figure 1). From the business process perspective, the flows of knowledge as well as the conversions of knowledge into other knowledge types are of significant importance. New objects of knowledge or information are created by the transformation of objects existing in the process. This transformation is performed by an interaction of knowledge and information objects. As an analogy to Nonaka/Takeuchi, KMDL® distinguishes between four types of knowledge conversion (Gronau & Weber, 2004):

- **Internalization.** Internalization means the conversion of explicit knowledge into tacit knowledge. It is related very closely to learning by doing. Experiences made through socialization, externalization, or a combination are internalized and integrated into the individual's knowledge framework.

The internalization is started by an information object and ends with a knowledge object.

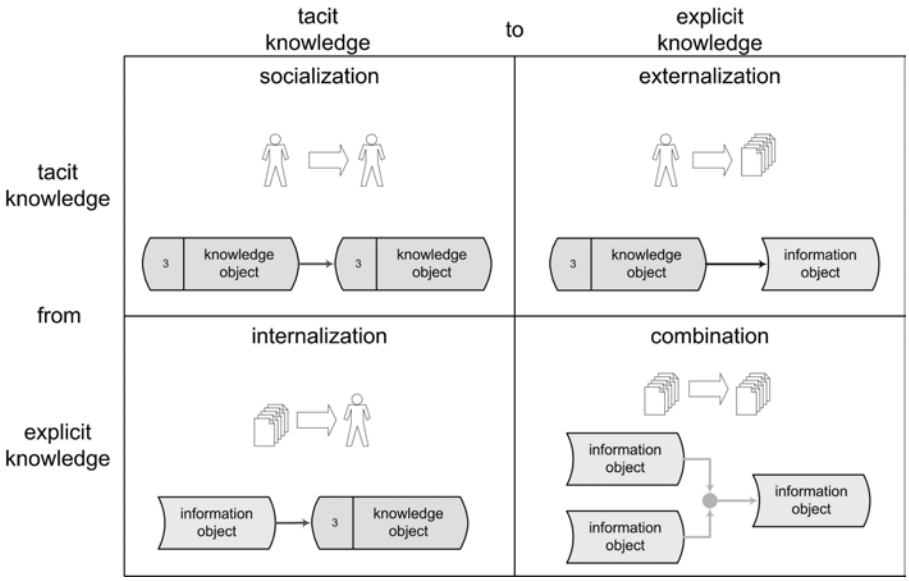
- **Externalization.** Externalization is defined as the transformation of tacit into explicit knowledge. The problematical aspect within this conversion is that important and person-bound parts will get lost, because it is difficult or, in some cases, impossible to externalize tacit knowledge. The externalization is modeled beginning with at least one knowledge object and ending with an information object.
- **Socialization.** Socialization is defined as a conversion from tacit to tacit knowledge. The most common way is by sharing experience: Just like apprentices of a craftsman learn skills by observation, a knowledge worker can learn required abilities through on-the-job training. The socialization does not demand for spoken or written words. Socialization is modeled starting with a knowledge object of one person to a knowledge object of another person.
- **Combination.** Combination is the conversion from explicit to explicit knowledge. During a combination, one or more information objects are used to create a new information object.

Unlike other process modeling tools, the main focus of KMDL® is to support all four expressions of knowledge conversion (see Figure 2). It allows a systematical description of process knowledge and the identification of all containing information. Origin and usage of knowledge and information can be defined as well. A conversion is either once (continuous line) or repeated (dashed line).

Specification of KMDL® for Software Engineering (KMDL®-SE)

Software engineering is a field of activity with a high percentage of knowledge-intensive business

Figure 2. Model of the dynamics of knowledge creation



processes. Competitive as well as sustainable software solutions have to be developed. In addition, there are factors like a fast-changing technical basis and a dynamic personnel situation. Modern software engineering processes have to find a way between these demands and conditions. An effective and efficient knowledge transfer within and between projects is an important factor for success, especially for an early identification and estimation of risks.

Besides the description of classical business processes, KMDL® provides the systematical identification and analysis of knowledge flows and transformations. This allows identifying knowledge monopolies, unused competencies, or unsatisfied demands. Thereby, actions to enhance knowledge-intensive processes can be taken. The development of a new knowledge management approach specifically for software engineering is based on the previous version of KMDL®, which was enhanced toward KMDL®-SE. It enables users to configure knowledge acquisition, storage, and transfer in software engineering effectively and efficiently. Starting points of the KMDL®-SE development were the complex and, to a high degree, knowledge-intensive software engineering processes of several business partners that accompanied the project. The project partners gave significant input in order to determine requirements and to evaluate the KMDL® methodology (Rombach et al., 1993). Simultaneously, the K-Modeler tool that supports the modeling of knowledge-intensive SE processes was developed and a prototype implemented.

Analysis of Potentials With KMDL®-SE

The K-Modeler automatically identifies and evaluates various design patterns in the modeled processes, which hence helps to analyze the process. These process patterns are derived from known disadvantageous process elements and structures found in knowledge-intensive processes (Brown et al., 1998). The concept of patterns was coined originally by the architect and mathematician Christopher Alexander. Patterns can be used to find solutions for recurring problems, reusing existing knowledge (Greenfield, 2004; Kirchner & Jain, 2004). During the 1990s, the concept of patterns and best-practice solutions was transferred in subareas of software engineering (Gamma et al., 1995). The principle of patterns is used in KMDL® to analyze knowledge-intensive business processes (KMDL, 2006). Thereby, a single process pattern describes a specific situation that repeatedly occurs during these processes. It is an indicator of hidden process potentials and points out opportunities for an alternative process design. During several projects, a multitude of patterns could be identified:

- **Occurrence Patterns.** The pattern of occurrence shows where specific objects appear with exceptionally high frequency in the business processes. If a specific person frequently occurs in a process, a knowledge monopoly might be present. The pattern can show that one person holds knowledge of high relevance for the process; hence, problems can surge when this person resigns. A better responsibility assignment can be a valid improvement. The occurrence pattern also can be used to determine the occurrence of information, knowledge, roles, tasks, and task requirements objects.
- **Multi-Step Patterns.** The multi-step pattern category describes a combination of two conversions, whereby transitions from tacit to the explicit process level and vice versa will be analyzed. There is also an examination of conversion doubling on the same level. Twelve different combinations of knowledge conversions are imaginable, but only some of the combinations can be used to improve the process design. The multi-step socialization pattern is one example of a multi-step pattern in which information gets

lost during a double socialization (Chinese Whisper).

- **Relevance Patterns.** Relevance patterns refer to tasks with a high degree of complexity and knowledge intensity. There are four types of relevance patterns that indicate tasks with a great amount of input (knowledge objects, information objects), output (knowledge objects, information objects), integrated persons, and task requirements. A suggestion for improvement can be task reorganization and, therefore, splitting up tasks.
- **Exclusive Patterns.** Two types of the exclusive pattern category are distinguished: exclusive information and exclusive knowledge pattern. Certain information or knowledge objects are requested very frequently in the business process. The loss of these information or knowledge objects can lead to a process disruption. Therefore, the information or knowledge has to be secured, for example, through externalization of specific knowledge objects.
- **Prerequisite Pattern.** The prerequisite pattern describes a person involved in the process who has the ability to fulfill a task only after the generation of knowledge through socialization with a noninvolved person. The informal acquisition of knowledge depends on personal preferences and the personal social network. A way of improvement can be the institutionalization of the knowledge transfer.

Usually, the mentioned patterns cannot be identified without modeling the business process. Therefore, modeling knowledge-intensive business processes with KMDL®-SE is an important step to detect strengths and weaknesses. As soon as the patterns are identified, proposals to improve the process can be made. This is an effective way to identify and unleash potentials systematically.

REAL-LIFE APPLICATION OF KMDL®-SE

In this section, the application of KMDL®-SE in a software developing company will be described. First, the company will be introduced, and then the main objectives of the real-life example will be explained. This will provide a better understanding of usage of KMDL® in software engineering.

The real-life application was carried out in a small software developing company with 25 employees based in Berlin, Germany. The company, founded in April 1999, today attends the entire middle European market. Since its establishment, the company has offered two browser-based content- and knowledge-management products based on the IBM Lotus Domino platform. These systems enable the maintenance of complex Internet, intranet, and extranet sites. Flexible integration modules provide interfaces and import and export functionalities. Beneath the permanent improvements of their standard software products, the firm also offers professional consulting, training, and individual development in conjunction with the product implementation. To cope with the changing market and client requirements, the company decided in 2003 to migrate the development environment of its content management system from IBM Lotus Domino Platform to IBM WebSphere.

Principal Objects of the Practical Example

For a reasonable design and analysis of software engineering processes, an adequate modeling is fundamental. Therefore, it is of great importance to consider the knowledge-intensive processes that occur during the development of new software products and even to build the main part of it. Based on the already existing Knowledge Modeling and Description Language (KMDL®), the practical example had two intentions:

- **Analysis of the Existing Software Engineering Processes**
  The complete analysis of the existing software engineering processes is the first step in order for a company to reorganize and, therefore, to improve these processes. All knowledge conversions and knowledge carriers have to be identified. Furthermore, the existent knowledge in the company should be identified, which could be useful for future developments. In this real-life example, the main focus was directed to the analysis of standard software engineering processes. As a result, the complete model of standard software engineering processes with the existing version of KMDL® could be presented. By mapping these standard development processes to one meta-model, critical points and risks as well as potentials in the existing software engineering processes could be identified. With the help of KMDL®, an effective redesign for the post migration processes became feasible.
- **Expansion of the Knowledge Modeling and Description Language (KMDL®) to a New Specification for Software Engineering Processes**
  The customization of the KMDL® for software engineering processes is the starting point for process reorganization. The existing version of KMDL® had to be adapted to the theoretical and practical requirements of the software engineering processes. The implementation in practice identified problems, which led to extensions and revisions of KMDL®. Putting KMDL® into practice allowed discovering critical points and insufficiencies in general. A further intention was to point out opportunities for improvement and to check the KMDL® approach for its relevance in software engineering. Thus, the drawing of profound conclusions for a new specification for KMDL® in software engineering became possible.

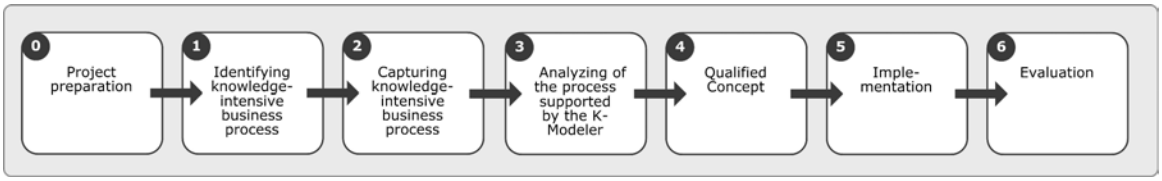
KMDL® Procedural Model

In order to determine the potentials for process improvements, a detailed analysis of knowledge-intensive business processes is required. The procedural model ensures the correct collection of data and information (see Figure 3). It is the basis for KMDL® process models and it was used in the following real-life example:

After project acquisition and preparation, it is necessary to identify knowledge-intensive processes. For this selection, a criteria catalogue can be used. It consists of more than 30 properties that are typical of knowledge-intensive business processes. In the next phase, current knowledge-intensive business processes are mapped. KMDL® offers a subprocedure within the six steps: definition of tasks associated with the process, identification of the information input and output, assignment of the persons to the specific roles, executing the task, specification of the role requirements, and assignment of the knowledge objects to the accompanying person. During the third phase, the modeling is realized with the K-Modeler tool. After going through the six steps, possible process improvements can be generated. The next step is to implement the recommendations in practice.

Detailed mapping of the knowledge-intensive business process is a requirement for the analysis and evaluation of potential improvements of the process. The analysis of the process contains the identification of knowledge intensity, the process scheme, and process potentials (weak spots). As-is models illustrate the ownership, demand, development, and use of knowledge. Further on, it is possible to visualize the knowledge intensity on a knowledge map for the entire process, a process part or for a single activity of the respective tasks. This procedure allows a classification of single tasks or the weighting of their relevance. The results are used for recommendations of technical and organizational improvements. The comparison of as-is models of different in-

Figure 3. KMDL® procedural model

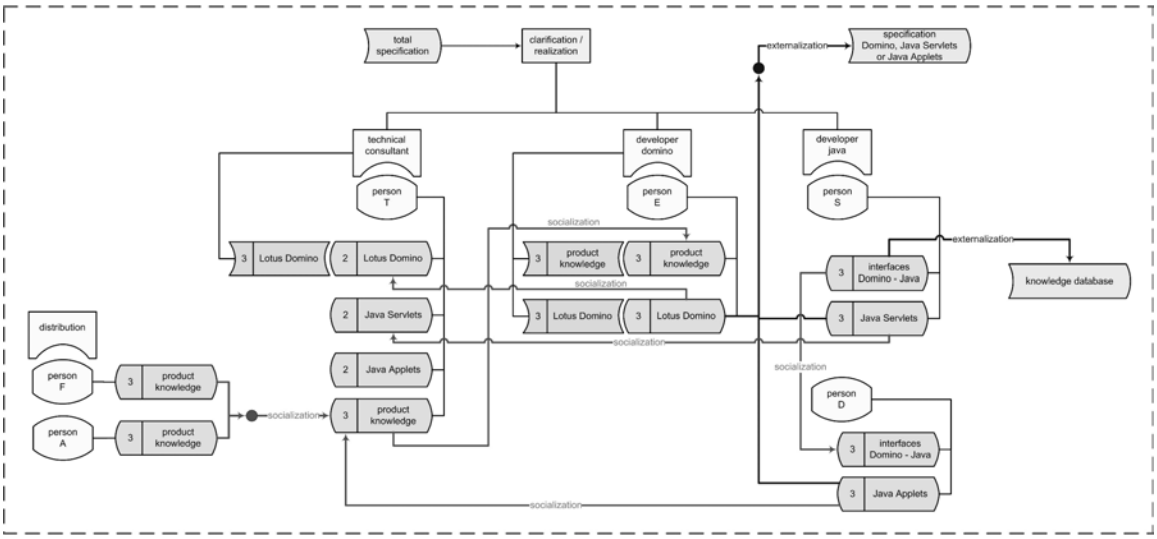


stances from the same process is useful in order to generate universally valid statements about process elements and element relations. Selected knowledge-based activities should be examined in order to identify specific patterns. It is recommended to extend the existing reference processes with this information in order to support future participants of the process.

Process Modeling in Software Engineering

In this case, three process instances of software engineering were modeled following the KMDL® procedural model. The individual process instances are used to derivate an organization-specific process model for the company. An organization-

Figure 4. Extended organization-specific process model



specific process model describes the approximated process flow and contains only all information objects and tasks, which can be found in most of the process instances.

In the next step, the organization-specific process model was enhanced with roles, persons, task requirements, and knowledge objects from the process instances in order to derivate conclusions for future software engineering processes. The resulting model is called extended organization-specific process model (see Figure 4). This model shows the process flow in the company containing all knowledge conversions. With ease, existing conversions within the software engineering process can be recognized. With these conclusions, the intended conversions can be supported directly.

Identification of Process Patterns

The following section describes the most important patterns that were identified several times in the business processes of the described software engineering company. They were used to optimize these processes as well as to improve the software engineering specification of KMDL®.

Person Occurrence Pattern

A frequent occurrence of a certain person in one process can be interpreted in two ways: First, frequent occurrence might indicate an unwanted knowledge monopoly. Second, frequent occurrence might classify the person as a specialist who supports his colleagues efficiently. Anyway, problems may surge if the specialist leaves the company and new employees are hired, because the new employees now might have the same expertise. A way to solve this issue can be the distribution of knowledge within the company. As a conclusion for the real-life example, newly hired employees socialized tacit knowledge from the specialist. In the future, the new employees are expected to take over the specialist's tasks, thereby replacing him. A major conclusion for modeling knowledge-intensive processes in software engineering is that important enterprise knowledge is frequently based on individual employees.

Figure 5 shows the KMDL® person occurrence pattern: person A is needed for all tasks within a subprocess. The person occurrence pattern (see Table 1) belongs to the family of occurrence pat-

Figure 5. Person occurrence pattern

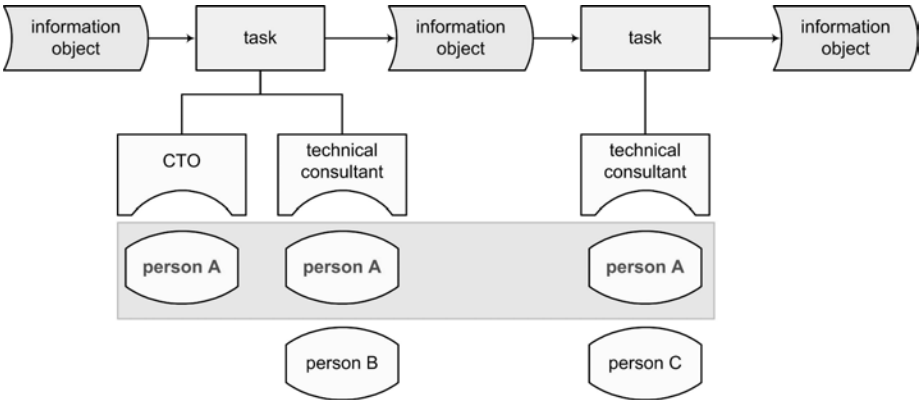


Table 1. Person occurrence pattern description

Purpose	Identification of monopolies and specialists
Description	A person is involved in many tasks within the process
Involved KMDL®-Objects	Person
Problem	Process-specific knowledge is held only by a single person. Problems can surge if this person is absent
Solution	Improved responsibility assignment

terns, such as task-, information-, knowledge-, role- and requirements-occurrence pattern.

Two-Step Socialization Pattern

The next pattern that could be identified within process modeling is a two-step socialization pattern (see Figure 6 and Table 2). This pattern is also known as Chinese whisper and belongs to the multi-step pattern family. It describes a transitive conversion between two persons (person A socializes person B, and person B socializes person C). Instead of a direct communication between person A and C, two socializations take place. Results of transitive conversion can be lost or modified information. This problem can be solved through a direct socialization. In the real-life example, German and English language skills were of significant importance. The software developers spoke only English, while the product

Figure 6. Two-step socialization pattern

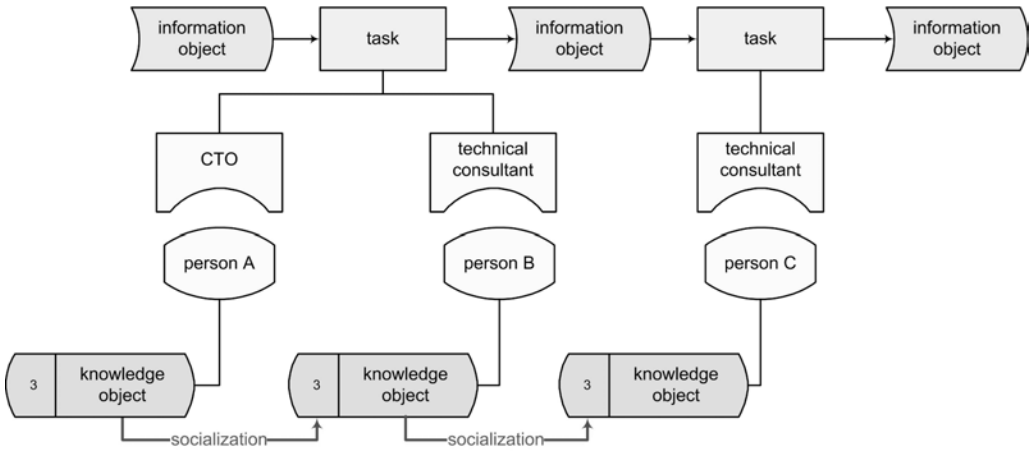

Table 2. Two-step socialization pattern description

Purpose	Identification of knowledge deformations
Description	Identical knowledge objects are transferred more than once on the tacit process level
Involved KMDL®-Objects	Persons, knowledge objects, socializations
Problem	Lost information due to indirect communication (Chinese whisper)
Solution	Support for direct communication, knowledge externalization

consultants spoke German. The consultants were the middlemen between customers and developers because the software developers could not communicate with the customers due to not being able to speak the German language. The software developers were instructed what consultants believed the customer wanted. This was one of the main sources of errors. To solve the issue, a new developer who spoke German and English was recruited. This enabled a correct translation of customer wishes into technical requirements, bypassing the consultants.

Team Relevance Pattern

The team relevance pattern (see Figure 7 and Table 3) describes the complexity of many tasks that cannot be completed by a single person. Therefore, the task requirements are very extensive and diversified. It is necessary that several persons

Figure 7. Team relevance pattern

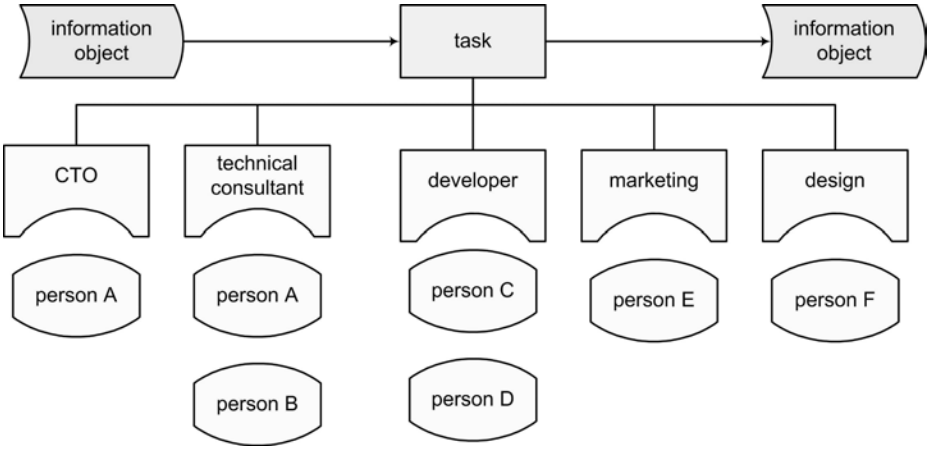

Table 3. Team relevance pattern description

Purpose	Identification of important teams
Description	Many persons are involved within one task
Involved KMDL®-Objects	Task, persons
Problem	A task is too complex to be worked out by a single person
Solution	A number of subtasks can reduce complexity

and roles be put together in order to fulfill the task successfully. It is not always a competitive advantage to reduce the number of persons within a process step. Especially knowledge-intensive business processes are characterized though complexity and often require a high degree of creativity and teamwork. Nevertheless, it can be useful to divide one task into subtasks, which can reduce complexity and make it easier to manage the task within the process.

Requirement-Oriented Team Building

Requirement-oriented team building can be realized through KMDL®. In order to guarantee a successful task realization, it is essential to build teams according to the requirements that have to be fulfilled. The team-building component is based on a term: taxonomy (see Figure 8). To clarify the functionality of the algorithm, Table 5 shows a repository including all the involved persons and their knowledge objects. These objects can be recovered in the taxonomy. Only red-marked terms are important for the real-life example; the remaining terms are relevant only in order to understand the full software engineering context.

A basic condition for the team-building component is a task. A task is defined by a couple of requirements that have to be fulfilled by a number of persons. In the practical example, a Linux server was purchased, and a Java-based application for Lotus Notes/Domino had to be developed. Therefore, the following requirements (see Table 4) had to be fulfilled by the team.

First of all, a matrix has to be set up consisting of task requirements and available knowledge objects (see Table 6). It can be recognized that Peter will not be considered, because he lacks the required knowledge object Java. Skills that are essential for all of the team members are marked (*). Requirements of particular importance and a high weighting will be indicated with (**).

Three teams were proposed to accomplish the task (see Table 7):

1. Mary (as a single person because she holds all the required knowledge objects)
2. Steve und Mary
3. Jane und Mary

The three proposed teams do not completely fulfill the requirements. More specialized or more general knowledge is available to close the gap.

Figure 8. Knowledge taxonomy (extract)

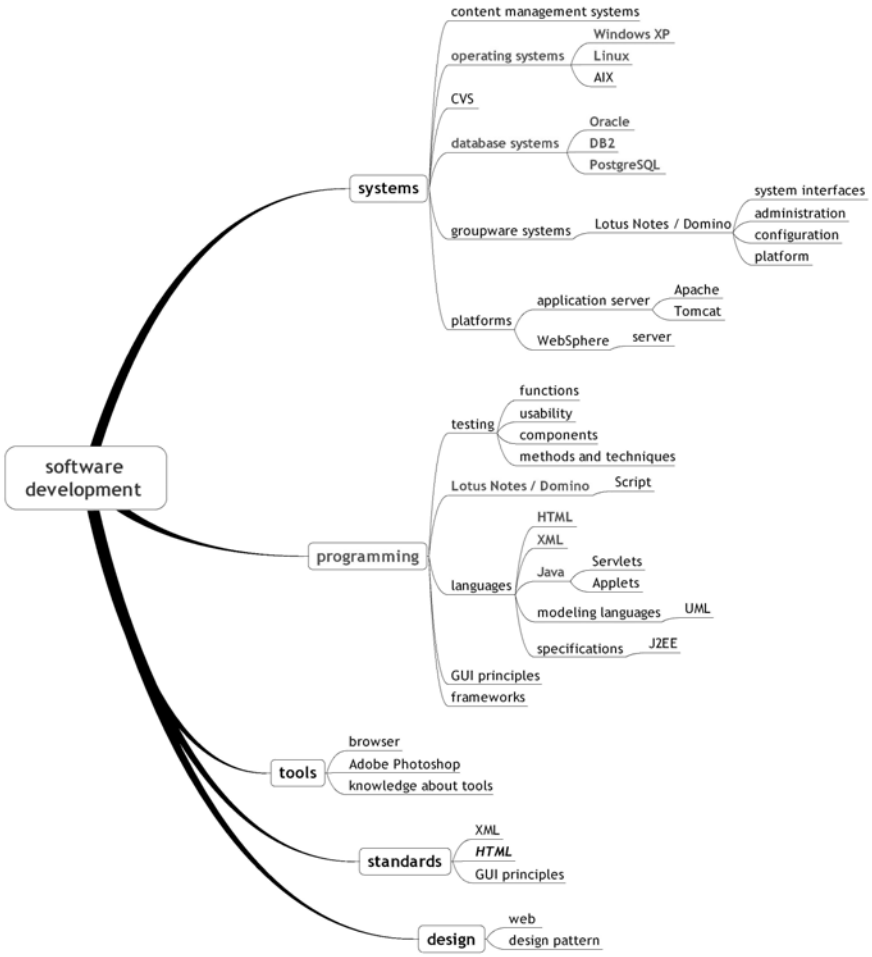

Table 4. Necessary requirements

	Necessary Knowledge (amount of persons)	Weight 8/8
Operating systems	at least one person	1/8
Linux	at least one person	1/8
Database systems	at least one person	1/8
PostgreSQL	at least one person	1/8
Lotus Notes/Domino	at least one person	2/8
XML	at least one person	1/8
Java	every team member	1/8

Table 5. Repository of persons

Steve	Peter	George	Jane	Mary
Operating systems, Windows XP, Linux, Lotus Notes/Domino, Java	Database systems, Oracle, DB2	HTML, XML, Java, DB2	Programming, Lotus Notes/ Domino, Java, Windows XP	Linux, database systems, PostgreSQL, Java, programming

Table 6. Team-building matrix

	Operating systems	Linux	Database-systems	PostgreSQL	Lotus Notes/ Domino**	XML	Java*
Steve	0	0	-5	-5	0	-5	0
~~Peter~~	~~-5~~	~~-5~~	~~0~~	~~-1~~	~~-5~~	~~-5~~	~~-5~~
George	-5	-5	+1	-5	-5	0	0
Jane	+1	-5	-5	-5	0	-2	0
Mary	+1	0	0	0	-1	-2	0

Table 7. Staffing algorithm results and team choice

	Expert Search	Team Search	Covering rate	Efficiency (covering rate/ persons)
1 person		Mary	4/8	**0,50**
2 persons		Steve, Mary	7/8	**0,43**
		George, Mary	5/8	0,31
		Jane, Mary	6/8	**0,37**
3 persons	Steve, Mary, George	Steve, Mary, George	8/8	0,33
		Jane, Mary, George	7/8	0,29
		Jane, Steve, Mary	7/8	0,29
4 persons	Steve, Mary, George, Jane	Steve, Mary, George, Jane	8/8	0,25

Within the expert search, only the team of Steve, Mary, and George are proposed.

GENERAL CONCLUSION AND FUTURE PROSPECTS

Applied to knowledge-intensive software engineering processes, KMDL® has proven to be a working concept. Current research focuses on the analysis of KMDL® process models in order to identify possible process improvements. The real-life example showed that the application of knowledge management can increase productivity in software engineering. By pointing out process patterns, potential improvements were identified. Therefore, long-winded coordination processes could be accelerated and optimized. But it has to be considered that knowledge management activities will be accepted by employees only if the advantages are clearly shown and the required effort is kept within a limit.

Based on the research results as well as the successful commercial implementation, KMDL® v1.1 now builds the backbone for the current development of KMDL® v2.0. The focus on knowledge conversions and the extension of the theory of Nonaka et al. leads toward a more powerful method that represents the actual conducted knowledge transfer, application, and creation. By introducing methods for the knowledge conversions, it is easy to distinguish the different knowledge conversions and to classify them. Therefore, they contribute to the expressiveness of the language. On the other hand, this can be used to identify best practice methods in the analysis of knowledge-intensive processes. In KMDL® v2.0 the introduction of information systems will extend the opportunities of the method and, thereby, consider technical aspects of the knowledge-intensive process. This provides an integrated view on the subject matter. The knowledge management strategy, therefore, can be arranged by considering the organizational, cultural, and technical aspects. The KMDL® v1.1 has been applied successfully in commercial and research projects. The next step with KMDL® v2.0 is the application of the method in real-life projects to measure the benefits of the improvements and to draw conclusions from the application of the method. Besides this, the analysis methods of KMDL® v1.1 that have been applied successfully in different projects have to test for KMDL® v2.0 now. Actual research in the field of KMDL® copes with skill management and staffing support for KMDL® v2.0, simulation of knowledge-intensive business processes, process-model-based configuration of knowledge management tools, interorganisational knowledge management, and semantic annotation of process models.

ABSTRACT

Supply Chain Management (SCM) has proven to be an effective tool that aids companies in the development of competitive advantages. SCM Systems are relied on to manage warehouses, transportation, trade logistics and various other issues concerning the coordinated movement of products and services from suppliers to customers. Although in today's fast paced business environment, numerous supply chain solution tools are readily available to companies, choosing the right SCM software is not an easy task. The complexity of SCM systems creates a multifaceted issue when selecting the right software, particularly in light of the speed at which technology evolves. In this paper, we use the approach of Analytic Hierarchy Process (AHP) to determine which SCM software best meets the needs of a company. The AHP approach outlined in this paper can be easily transferred to the comparison of other SCM software packages.

INTRODUCTION

A supply chain represents the veins of a business; it is a network of facilities and distribution options that perform the functions of material procurement, the transformation of materials into intermediate and finished products, and finally the distribution of finished products to customers. Supply chains are not specific to any one industry; they are inherent in both manufacturing and service based organizations. Supply chains do however vary in complexity from industry to industry and even firm to firm. The process of managing supply chains is a multi-billion dollar software industry; the worldwide market for SCM software topped an estimated $6 billion in 2006 and is expected to reach $10 billion by 2010 (a compound annual growth rate of 8.6%) (Trebilcock, 2007).

Supply chains are evolving to meet the changing requirements of the companies trying to manage them. A few years ago simply having full visibility of your own supply chain was seen as extraordinary. Now that visibility is no longer enough; companies need to be agile in respect to their supply chain (Croom, Romano, & Giannakis, 2000; Bartels, 2006). Companies need to make educated business decisions based upon the information captured in their information systems.

SCM systems are used to coordinate the movement of products and services from suppliers to customers (including manufacturers, wholesalers, and retailers). The system's main objective is to manage warehouses, transportation, trade logistics and various other issues concerning facilities and the movement and transformation of materials en-route to customers.

The components of SCM include (but are not limited to) supply chain event management and optimization, warehouse management, radio frequency identification (RFID), transportation management, demand management, supplier relationship management, and service parts planning. Beyond the traditional elements, SCM software has also incorporated modules for international management; this is the direct result of the growing need for businesses to manage supply chains that include a mix of global suppliers, manufacturers, and company owned plants. In fact, the bursting demand for global SCM has led the upsurge in the worldwide market for SCM systems (Aksoy & Derbez, 2003; Das & Buddress, 2007; Hill, 2007).

Why Compare?

Research has found that the typical U.S. manufacturer is managing an average of more than 30 contract relationships (Trebilcock, 2007). Wholesalers are distributing to worldwide retailers and jobbers for resale; and retailers now staff virtual storefronts that service customers globally. The growing supply chain requires a management system that is efficient and caters to the needs of each enterprise. The benefits of implementing an appropriate SCM system include: Increased top-line profit growth through supplier teamwork; Reduced inventory carrying costs and stock-outs; Increased customer service; Supply chain visibility; Optimization of the value chain respective to cost reduction and bottom-line improvement; Reduced corporate-wide operating costs; Increased competitiveness; and Quick adaptation to changing markets without detriment to customers.

However, since SCM system implementation is typically not a small scale operation, there are inherent managerial risks. For example, within businesses with several facilities, partners, and departments etc., a legacy or manual SCM system can lead to bottlenecks. There are cases where the appropriate SCM application is chosen but it does not sufficiently integrate with the rest of the enterprise software applications. In some cases, the wrong SCM application is chosen (perhaps to cut costs or due to poor information); the result is that the whole business from sourcing to distribu-

tion is negatively affected. Efficient SCM provides immense benefits; a well-run value chain should positively impact an organization's profitability and success.

SUPPLY CHAIN MANAGEMENT SOFTWARE

While there are a number of SCM software providers, the major players have maintained their top positions. For example, in 2005 the top 5 ranked providers were Manhattan, RedPraire, SSA Global, Swisslog, and SAP AG (O'Neill, 2005); in 2007 the top 5 spots were manned by Manhattan, RedPraire, SAP, Oracle and Infor (who swallowed up SSA) (Trebilcock, 2007). In selecting SCM software vendors to compare for this study, the following criteria were utilized:

- Limited to those providers offering world-wide solutions
- Limited to vendors whose SCM systems include the following minimum components: Warehouse Management Systems (WMS), Transportation Management Systems (TMS) and Warehouse Control Systems (WCS),
- Limited to 7 software vendors in the study (use of Expert Choice limited us to 7 alternatives).

Based on criteria outlined above we have elected to compare the following 7 software vendors:

- Aldata – Aldata SCM
- HighJump - HighJump SCM
- Infor – Infor SCM
- Manhattan Associates – Integrated Logistics Solutions
- Oracle – Oracle E-Business Suite Supply Chain Management - R12
- RedPrairie – E2e
- SAP – SAP SCM

Decision Tool

To aid in the comparison of our selected SCM systems, we have relied on Expert Choice 11.5 (EC11.5). The key functions of EC11.5 are: to structure by identifying objectives and criteria for evaluating the decision at hand and the potential alternatives; to evaluate the objectives and alternatives; to synthesize by combining hard numbers and intuitive judgments (math and psychology) to value the alternatives via sensitivity analyses and exploring "what if" scenarios (Expert Choice Inc., 2007). By relying on EC11.5 we can understand the trade-off of weighing certain choice criteria differently.

It is possible to yield the best alternative via EC11.5 using the Analytical Hierarchical Process (AHP). AHP is based on mathematics and human psychology; the process deals with complex decision making by providing a framework for arranging the criteria, quantifying them, and relating the elements to the overall goal. The AHP method breaks down the decision into a hierarchy of more clearly stated sub-issues (where each issue is treated independently); once the hierarchy is built, the numerous alternatives are reduced to a series of pair-wise comparisons for synthesis. Those judgments are converted to numerical values that are processed, evaluated and compared over the whole scope of the issue. Because a numerical priority (weight between 0 and 1) is assigned to each element, AHP allows non-comparative elements to be compared in a consistent way. Finally, AHP produces numerical priorities and the choice of the best alternative simply becomes ranking the software packages in order of preference (Saaty & Vargas, 2006; Saaty, 1980; 1996; 2001; 2005).

In the following section, we briefly discuss features offered in each of our seven chosen soft-

ware alternatives. Based upon this information, each alternative software package will be scored with respect to our evaluation criteria; these scores form the basis for pair-wise comparisons used in the AHP.

Aldata (Aldata SCM)

Aldata is one of the global leaders in supply chain software for retail, wholesale and logistics companies. The company's comprehensive range of SCM and In-Store solutions enable more than 300 customers across 50 countries to enhance productivity, profitability, performance and competitiveness. The majority of Aldata's customers are located in Western Europe; they primarily service small and medium size supermarket chains but also provide service to larger companies including Bosch and Merck. Aldata has won the IT Europa's European IT excellence award (General Business News, 2008).

Aldata invests heavily in research and development within the SCM unit. The G.O.L.D. product family is being further developed and the current version six of the software will remain the core platform for the coming years. Major launches were the new G.O.L.D. Track modules, a federation module for providing integrated traceability across business networks, and G.O.L.D. Mobile, a module providing mobility in the retail store and enabling store operations such as stocktaking, receiving and price control using PDAs or radio frequency terminals (IHL Group, 2006). The company does not provide any other enterprise management solutions.

HighJump (HighJump SCM)

HighJump, a 3M Company, offers standard functionality but leverages best practices in order to meet the clients' immediate operational disciplines while increasing efficiencies. HighJump software highlights its vertical-specific adaptability which enables solutions to fit a variety of customer requirements in industries that include aerospace, automotive, consumer goods, direct store delivery (DSD), discrete manufacturing, food and beverage, wholesale distribution/industrial production, document management, and publishing.

HighJump implants a best-practice advantage implementation methodology which focuses on budgeting and aligning clients' interests. HighJump offers in-depth training courses aimed at preparing clients to administer their software solutions and 24/7 staffed customer support. Furthermore, HighJump organizes an annual user conference where HighJump industry analysts, employees, partners and customers meet to brainstorm the latest trends in execution; customers get the opportunity to learn how to leverage SCM solutions to achieve increased efficiencies and maintain competitive advantage.

The software architecture and hardware platforms include the following: Main Languages: C++; .net; C-sharp; DMBS; SQL Server; Oracle; and a 4GL: HighJump adaptability tool set. The software pricing ranges from $100,000 to $250,000 and is dependent on the number of concurrent users. The target market for HighJump includes logistics/distribution, batch, repetitive, job shop, discrete, process, continuous flow, and project manufacturing which translates to industries that include health care, pharmaceuticals, automotive, grocery, food, apparel, 3PL, and audio.

HighJump integrates source-to-consumption solutions that contain four critical elements including rapid return on investment, a global execution platform that allows all applicants to work together seamlessly, ease of configuration to empower strategic competitive advantage, and best practices based functionality to solve core logistic challenges

Infor (Infor SCM)

Infor is a large size software developer that provides very strong management resource solutions. The company offers its products as separate

modules for various enterprise functions, including: Manufacturing, Supply Chain Management, Financials, Project Management (PM), Human Resources, and Customer Relationship Management. Infor also offers an all-inclusive Enterprise Resource Planning Suite (ERP). Their products are implemented worldwide.

Built on Open SOA (service-oriented architecture), Infor's logistics software provides advanced customization, which is not limited to any specific platform.

Due to high levels of customization, there are high setup costs in switching to the Infor's software. Due to high setup costs, Infor has historically targeted medium and large size businesses with sales in excess of $50,000,000. Recently, Infor announced a new ERP solution targeting small to medium size distributors (ERP FACTS). In targeting smaller firms, Infor has developed numerous industry specific basic modules that do not need costly customization; this has put them in a very cost advantage position when compared with their industry competition. Infor's SCM solutions range from $2,000 to $100,000+; solutions at the higher end of the price range tend to be solutions that have been extensively customized.

Manhattan Associates (Integrated Logistics Solutions)

Manhattan Associates is a leading supply chain solutions provider. The company's supply chain planning, supply chain execution, business intelligence, and business process platform capabilities enable its more than 1200 customers worldwide to enhance profitability, performance and competitive advantage. Unlike some of the other companies that provide SCM tools in addition to other non-SCM solutions, Manhattan Associates is engaged almost exclusively in the SCM solutions field. Much of their operational results company acquisitions.

Manhattan Associates targets companies in the retail, distribution, transportation, and manufacturing industries; their modules include warehouse, transportation, trading partner, distributed order, and reverse logistics management applications. Manhattan also offers performance management and radio-frequency identification tools designed to enhance the functionality of its other products. Manhattan's "Atlanta facility lets customers evaluate technology and equipment before adding RFID to supply-chain operations" (Malykhina, 2005, P.1). The company sells third-party hardware, including bar code scanners and printers, and also provides professional services. Manhattan Associates has been expanding their operations through new product offerings. According to Trebilcock (2007), "In 2001 Manhattan was the No.1 provider of warehouse management systems, with just more than $100 million in revenue. Today, Manhattan is a nearly $300 million company, offering transportation management, supplier collaboration and supply chain planning" (P. 47). Manhattan offers customer service on a 24 hour /7 days a week basis.

Oracle (Oracle E-Business Suite Supply Chain Management - R12)

With Oracle SCM (OSCM), companies can build and operate world class value-chains for profitable growth. The Oracle E-Business Suite Supply Chain Management (R12) family of applications integrates and automates all key supply chain processes, from design, planning and procurement to manufacturing and fulfillment, providing a complete solution set to enable companies to power information-driven value chains. Companies can anticipate market requirements and risks, adapt and innovate to respond to volatile market conditions, and align operations across global networks. A unified data model provides a single, accurate view of your entire supply chain. Companies can implement lean, demand driven principles and manage their increasingly complex, global supply chains.

OSCM consists of a variety of separate applications which are categorized by supply chain segments. Depending on a company's needs, a wide variety of applications are available. Some of the basic benefits of OSCM include real time supply chain measurements as a result of a direct connection with suppliers and customers, expense management for all categories of goods and services, analytical support to monitor the performance of a company's supply and the ability to make adjustments.

Oracle has been rapidly expanding its SCM software business, primarily through the acquisition of smaller, more specialized businesses. Oracle has adopted an acquisition strategy in order to accelerate its software innovations. Previous acquisitions include People Soft and Demantra. As a result of the acquisitions, Oracle is focusing its next generation of products on integration and the ability for these programs to communicate and share information with each other.

RedPrairie (E2e TM Suite)

E2e offers customers supply chain execution, store management, logistics, and warehouse management software that can assist or manage all facets of their business. E2e allows for monitoring and control from inbound logistics and inventory management to order fulfillment and transportation. Collaboration tools are included to assist in a company's daily efforts to collaborate or interact with trading partners.

Every industry is being challenged with increasingly complex multi-channel demands, especially from the end consumer of their products. The ability to respond to create perfect, customized, and timely orders is a critical competitive advantage to meet consumer expectations, reduce inventory and storage costs, and streamline operations (Report, 2006).

RedPrairie considers themselves unique in the SCM software industry in their effort to incorporate change management, learning management, interactive training, comprehensive online help, and customized learning and reference materials into their offerings. Companies implementing their suite of tools can leverage real ROI, minimize downtime due to obstacles, and move toward near 100% efficiency which increases companies core advantage. RedPrairie's support centers are located globally and offer full language capabilities in addition to leading-edge call tracking capabilities for reliability.

RedPrairie's ability to configure their software suites into practical groupings and components allows them to offer build-to-order manufacturing solutions that include sophisticated in-line sequencing which can lead to reduced cost and increased efficiency. The result is that all component levels can be tracked, revised and/or updated keeping all elements in synchronization. This capability is enhanced when used in conjunction with RedPrairie's warehouse management system (WMS).

SAP (SAP SCM)

SAP is the world's largest business software company and the world's third – largest independent software vendor. By building the strongest technology, services and development resources, SAP is positioned to deliver a superior business platform that can access valuable information resources, while improving overall process efficiencies and strong customer relationships including end users, suppliers and vendors. SAP's integrated packages allow customers' needs to be identified quickly and precisely while comprehensive and personal solutions are developed and rolled out.

SAP's services assists companies in maximizing their success through a combination of SAP experts, methodologies, tools, and certified partners. Users of SAP SCM can benefit with the following: Faster response to changes in supply and demand that will give customers the chance to quickly capitalize on new opportunity; Increased customer satisfaction- SAP SCM enables clients

to better adapt to changes and meet customer demand; Compliance with regulatory requirements; Improved cash flow; and Higher margins- SAP SCM helps companies lower operational expenses with more timely planning for procurement, manufacturing and transportation. Using SAP SCM companies can also improve their overall performance and quality through better order, product, and execution synchronization.

SAP SCM delivers a complete set of futures and functions for building adaptive supply chain networks. SAP SCM includes features and functions to support collaborative supply chain planning processes, including strategic, tactical, and operational planning as well as service parts planning. By using SAP SCM, a company can optimize a full range of planning activities including: demand planning, safety stock planning, supply network planning, distribution planning, and supply network collaboration. The company can also handle service parts planning activities, which includes: parts demand planning, parts inventory planning, parts supply planning, parts distribution planning, parts monitoring. With SAP SCM the company can manage order fulfillment activities, support end-to-end procurement, manage key transportation processes, manage warehouse activities, support all production processes including engineer-to-order, make-to-order, and make-to-stock manufacturing. SAP SCM also supports supply chain visibility design and analytics with features and functions that enable supply chain design and analytics processes. Planners and key decision makers can perform strategic and tactical business planning.

RELATIVE COMPARISON

Criteria Revisited

In order to conduct our analysis we will use selected quality criteria to assess software characteristics. With the help of Expert Choice software, we will first compare the relative importance of each of the criteria against each other.

- Ease of Integration: the ability to integrate with any third party software platforms (vendors, government clearance computers, ocean carriers, etc.) and any other proprietary software or legacy systems.
- Reliability and Stability: any warranties provided by the vendor in addition to the degree of completeness, accuracy, and consistency of the package. The availability of any templates or custom models available for specific aspects of the supply chain.
- Efficiency: the level of accessibility and efficiency; how well the software functions are aligned with the general business objectives as well as the number of tools available.
- Customization and Expansion potential: the degree to which the product supports the specific business goal assumptions and the tools available for SCM respective to the specific needs of the client company. Also, the degree of augmentation ability and the ability to evolve over time and expand as well as any expert options or limitations.
- Service and Support: the availability of support services coupled with the time it takes to have a technician to be available on site or on the network. The availability of technicians that are specialized in the particular industry the SCM is being utilized (transportation versus warehouse management, retail versus wholesale etc.). Any extra perquisites such as annual conferences.
- Mobility and Portability: is a measure of platform independence; the number of support platforms and supported architecture as well as any software requirements needed to run the software.
- Ease of Interface: shows how well the software communicates with the outside world, the quality of human machine interface, and how results are displayed.

- Pricing: the base price of the product, and/or range of the price for "basic" packaging respective to the SCM applications.

Evaluation Model

Our evaluation criteria, as entered in Expert Choice, are as follows:

- Ease of Integration – evaluated in terms of:
  - Time
  - Number of platforms supported
  - Support for open source developers
  - Reliability and Stability – evaluated in terms of:
  - What classes of models does the application support?
  - If the application allows custom model creation, templates or both.
  - The reputation of the vendor supplying the tool
- Efficiency – measured in relation to:
  - How well the software supports the general business objectives?
  - Data processing capacity and speed.
- Customization – evaluated in terms of:
  - How well the product supports the general business goal assumption?
  - Specific tools available respective to the specific needs of the client company.
- Expansion – evaluated in terms of:
  - The degree of augment ability
  - The ability to evolve over time and expand (i.e. available upgrades)
  - Any expert options or limitations
- Service and Support – evaluated in terms of:
  - Any available demos
  - Turnaround time for on site or network tech availability
  - Specialization of the techs in the respective industry
  - Any additional perks (i.e. annual conferences, 24/7 service etc.)
- Mobility and Portability – evaluated in terms of:
  - Hardware platform
  - Software architecture
  - Software requirements
- Ease of Interface – evaluated in terms of:
  - Simplicity of human machine interface
  - Result displays
  - Graphical layout
- Price (where available) – evaluated in terms of:
  - The price range provided – the lower of the range and the mean served as the rating criteria.

PROCEDURE OF EXPERT CHOICE: SHORT EXAMPLE

Providing an example of Expert Choice on a small scale helps to describe the method behind pair-wising and making the best decision regarding which SCM Software to choose contingent on our criteria. To provide a small scale example we implemented five criteria against our objective and compared three SCM software applications.

The pair–wise weights were assigned to the criteria initially chosen; the decisions were based on available information and which criteria outweighed their pair. The result is the prioritized listing of criteria respective to the objective – in this case selecting the best SCM software. Expert Choice allows for normalization in order to better understand the weighting scheme – in other words these small scale results recommend that Pricing is more than twofold the importance of Portability. In addition, the inconsistency is very low at only 2%; the logic behind assigning weights (importance) to each criterion remained consistent within each pair-wise comparison.

Figure 1. Presents the prioritized criteria after the initial weight assignments

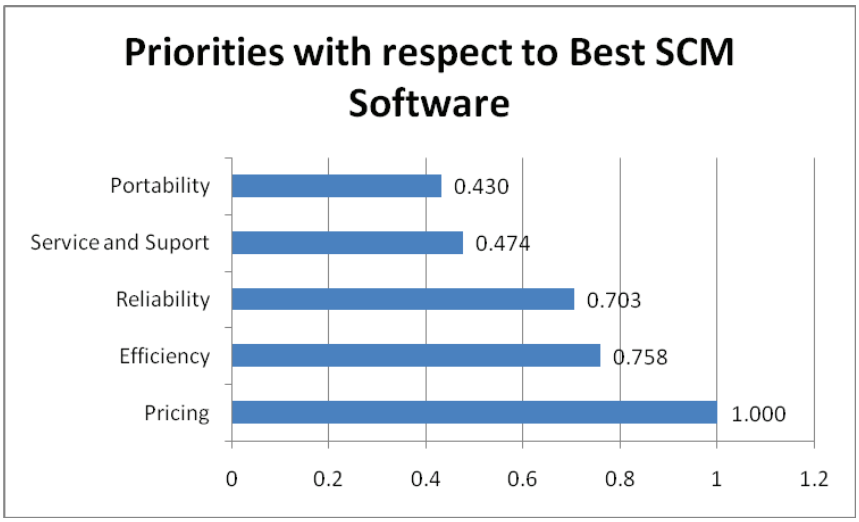

Figure 2. Presents the introduction of alternative SCM software packages analyzing pricing

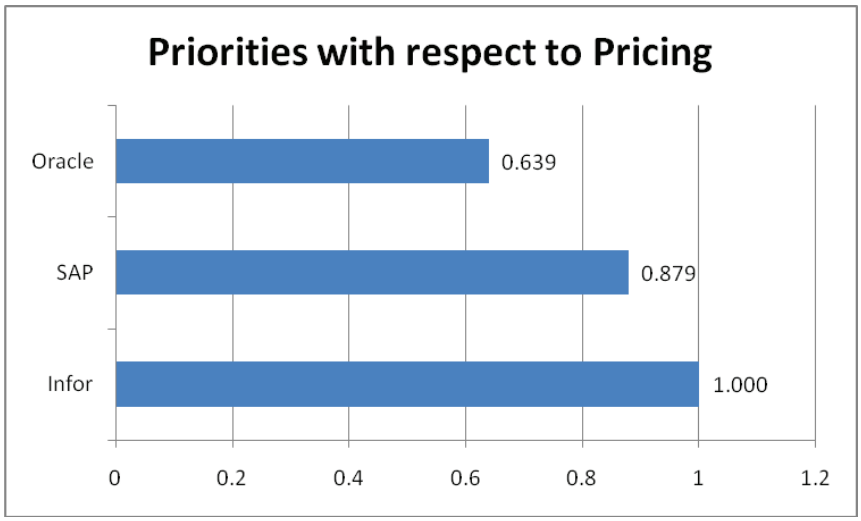

We chose three alternative SCM Software packages (Infor, SAP & Oracle) for the short example to exhibit the functions of AHP relied on by Expert Choice. We proceeded to perform a pair-wise comparison of all our software solution alternatives based on each established criteria. Based on strengths and weaknesses determined about each software; we analyzed the components

of each criterion on a case by case basis. The detailed level of analysis allowed us to obtain informative results about each software solution tool. The logic provided a prioritized listing of the software packages according to the criteria which held the highest weight. As an example, Figure 2 displays results obtained from Expert Choice when analyzing Pricing criteria.

However, this is minimal information when making a decision – sensitivity analysis provides a technique for determining the outcome of a decision if a key prediction turns out to be wrong. The analysis is a tool for analyzing the impact of key criteria; sensitivity blocks are used to generate tables and/or plots of simulation results as functions of feed stream, block input, or other input variables. Since there are various criteria, the following charts demonstrate the outcome of each SCM package against the chosen criteria. Expert Choice offers a variety of alternatives which facilitates the decision making process and offers alternatives for assessing the outcomes according to user preference.

We found that the dynamic sensitivity analysis tool can prove to be very useful when trying to estimate overall impact of each criterion on the final decision. The program allows users to graphically manipulate the relative weight of each criterion against one another by simply clicking and dragging. Furthermore, the program would simultaneously change the graphically presented outcome. Thus, if for the purposes of presentation, we assigned an unrealistically high weight to the price criterion in the example above the overall outcome would change from SAP being the best option to Infor software as the ultimate solution.

SCENARIO ANALYSIS

In this section, we compare the seven chosen SCM applications based on the seven criteria previously defined. The decision of optimal software choice involves multiple-objectives and will vary among customers based upon individual needs. It is not often that one SCM application suits the expectations of every industry, institution, or customer; therefore the integration of scenarios is an important tool of the decision making process.

In order to make the simulation realistic, various scenarios were examined that altered the size, needs, and global presence (amongst other aspects) of potential customers for the available SCM applications. We proceed with the hypothetical situations and demonstrate techniques and procedures to establish the best available alternative based on our set of defined criteria. In examining the importance of various criteria, size stood out as a decision making factor. In order to emphasize the importance of size as a decision making factor, we went further to implement three specific scenarios that visit opposite ends of the spectrum; large global presence versus small regional existence. Note, however, that when the size was manipulated, only certain criteria proved to be dependent on that factor, therefore the results below exhibit how other criteria were weighted similarly, despite the variations in size.

The number of SCM applications compared coupled with the number of evaluation criteria results in a significant number of pair-wise comparisons used in the AHP process. The following table summarizes the relative weights of each criterion in addition to the direct relationship between the synthesized weights in each column with their respective criterion. The higher the synthesized weight, the more a particular sized company (Large vs. Small) views that particular SCM software alternative.

When comparing above scenarios, the notable changes were the relative weights of each criterion when the size of the company is accounted for in the scenario. It is important to take into consideration that a real business environment comprises many different industries, as well as an array of different company types with different needs, goals and business objectives; all of which

would impact relative weights and the ultimate SCM software decision.

The selection of the best software for a specific company should be based on the individual needs of the organization making the choice. The same software package will not be the best choice for every buyer. Different SCM solutions will provide the best fit depending on the applicable situation or

Table 1. Synthesized weights with respect to criteria or goal

Synthesized Weights with Respect to Criteria	Pricing		Service & Support		Reliability & Stability	
	Large	Small	Large	Small	Large	Small
Manhattan Associates	0.138	0.162	0.140	0.090	0.143	0.143
RedPrairie	0.165	0.103	0.159	0.186	0.119	0.119

0.097	0.086	0.122	0.122	0.043	0.043	0.124	0.124
0.068	0.062	0.042	0.042	0.116	0.116	0.044	0.044

Overall Synthesized Weights with Respect to Goal		
	Large	Small
Manhattan Associates	0.179	0.156
RedPrairie	0.135	0.133
SAP	0.176	0.169
Oracle	0.186	0.199
Infor	0.135	0.122
Aldata	0.094	0.070
HighJump	0.096	0.152

scenario. Creating different hypothetical scenarios can be useful in the selection process.

To illustrate this point, we have created different scenarios which demonstrate the relevance of the individual organization's environment and objectives in the selection process. In addition to size, the best SCM software package for an organization can differ based on characteristics like industry or sector, geographic diversity of operations and vertical or horizontal integration of the supply chain. We found that sector can be a crucial factor in the decision making process; we believe that an organization's sector will drive the decision for an optimal SCM software package.

In addition to a total of 144 basic pair-wise comparisons in order to compare all alternatives with respect to all of the criteria, each scenario also requires an additional 21 pair-wise comparisons. Once all pair-wise comparisons are made, Expert Choice is used to synthesize the weights of all the criteria with the weights of all the alternatives to determine the best solution for each scenario. In illustrating the impact of each scenario of the final decision, we have chosen different sets of SCM software packages for a more complete comparison.

Table 2 lists the weights of the pair-wise comparisons for government versus business entities. There is a direct relationship between the individual criterion and the weights displayed in each column. The higher the number displayed, the greater the weight placed on the criterion for that type of organization.

Table 2. Weights assigned to alternatives for both business and government use

Synthesized Weights - with respect to criteria	Portability		Reliability		Efficiency		User Friendliness	
	Business	Gov't	Business	Gov't	Business	Gov't	Business	Gov't
i2 Solutions	0.149	0.147	0.167	0.167	0.154	0.154	0.159	0.153

ILOG	0.107	0.107	0.106	0.110	0.105	0.105

Based on the results of the weighted criteria calculations done by Expert Choice, the top three alternatives for a business entity would be Oracle, Manhattan Associates and i2 Solutions. This was in line with our expectations. We had expected Oracle and Manhattan Associates to be prime solutions for business and government operations, since they were the software solution tools that excelled in the areas of Efficiency and Reliability.

Table 3 summarizes the overall results obtained through Expert Choice for our case scenario. We previously placed emphasis on efficiency and reliability for which the weights obtained were very close to each other when comparing the three top alternatives. However, when the rest of the criteria are considered, the weights obtained under each business entity change influencing the type of software solution that best suit each type of organization. For example: under a business entity Oracle obtained the highest weight of .202 overall, as opposed to .180 under a government entity. Picasso on the other hand, although obtained the lowest weight for both type of entities, it obtained a better rating from the government sector with a weight of .092 as opposed to .086 from the business sector.

As demonstrated by the tables previously shown above, different entities have different preferences and priorities which leads to differences in optimal software selection. The following scenarios will further support this conclusion.

Scenario 1: A&D Wholesale Distributors, Inc

Let us assume this is a mid-size distribution company that operates throughout the United States, with 550 employees and operations in 20 different states. A&D is looking for SCM software that will support a distribution intensive type of business and assist them in reducing transportation and inventory retention costs leading to increased revenue and customer satisfaction. Based on this company's goals and objectives, we decided that the criteria they would focus on would be: Customization Flexibility, they need a software solution tool that would be able to customize to support their specific needs and Efficiency, their main objectives are to reduce transportation costs and inventory retention time.

Table 3. Summary of synthesized results for government vs. business entities

Synthesized Weights -- with respect to goal	Business	Government
i2 Solutions	0.157	0.156
Logility	0.145	0.144
SYSPRO 6.0	0.113	0.117
Picaso	0.086	0.092
Manhattan Associates	0.189	0.189
Oracle	0.202	0.180
ILOG	0.109	0.121
Overall inconsistency ratio	**0.03**	**0.05**

Scenario 1.

Criteria	Weights
Efficiency	0.232
Customization Flexibility	0.228
Reliability	0.138
Report Interpretation Ease	0.126
User Friendliness	0.117
Training and Support	0.091
Portability	0.069

Alternative	Ranking
Logility	0.192
i2 Solutions	0.186
Manhattan Associates	0.156
Oracle	0.156
Syspro 6.0	0.115
ILOG	0.102
Picaso	0.093

Scenario 2: Start Up Online Company

Let us assume this is a small retail oriented start up internet company with 10 partners, no fixed location, no fixed relationship with outside parties and limited knowledge on the industry. This is a company that would need a software solution alternative that would offer them a high level of support with relation to hardware platform and software architecture, and one that would be able to provide a high level of training and support, since they are new in the industry and have a flexible SCM structure. Based on this company's needs, we decided that the criteria they would focus on would be: Portability, because they need a software solution that would support their internet based business, across different platforms and operating systems and Training and Support, because they need a software solution that will provide them with intensive training about the software as well as with aids to gain a better understanding of their flexible supply chain structure and demands.

Scenario 2.

Criteria	Weights
Portability	0.239
Training and Support	0.183
Customization Flexibility	0.176
Efficiency	0.138
Reliability	0.103
Report Interpretation Ease	0.094
User Friendliness	0.067

Alternative	Ranking
Manhattan Assoc	0.195
Oracle	0.191
I2 Solutions	0.166
Logility	0.159
Syspro 6.0	0.109
ILOG	0.095
Picaso	0.085

In the following tables, results for a number of additional scenarios are presented.

CONCLUSION

The SCM software industry is gaining an increasing amount of attention as companies try to maximize return on investment and gain a competitive edge in their markets. The increasing focus on the industry is resulting in greater investment in SCM software and fueling innovation. In order to choose the best alternative among all of the choices available, potential users must clearly identify and prioritize their needs and preferences.

Expert Choice's technology, which utilizes AHP analysis, allowed us to compare seven SCM software alternatives according to seven select criteria in order to determine which software best meets the needs of each scenario. All of the potential factors involved in the selection process must be determined by the organization making a decision on an individual basis. We expect continuous improvements and competition from

the companies we have examined as well as new entrants into the marketplace looking to fill niches. The natural caveat to all this software is from the human side; the software is only as good as the users who truly understand how to properly use the application. Most logistics professionals and senior level management lack the knowledge or training to fully exploit the potential of their systems (Hannon, 2005). This ties in to a recent emphasis in moving away from pure planning and focusing on the execution aspects of managing a supply chain (Parker, 2007).

Since problems, criteria, needs, alternatives and other variables will vary from one entity to the next, there is no universal solution. In order to support an optimal choice, all of the key factors in the decision process must be identified and quantified. The methods and processes relied on in our research transfer easily to the comparison of other SCM software packages. The future for SCM software solutions is endless.

Chapter 6.14
How E-Entrepreneurs Operate in the Context of Open Source Software

Ambika Zutshi

Amrik Sohal
Monash University, Australia

ABSTRACT

The Internet has become an integral part of our everyday lives and it is often difficult to imagine how we ever functioned without it. This chapter presents experiences of two entrepreneurial companies, one of which has survived the 'dot-com bubble burst.' The chapter identifies current and future online business environments especially in light of open source software (OSS) being accepted globally. Unlike proprietary software (such as Windows), OSS comes with its internal implementation details (source code) visible both to its developers and users, along with the freedom to change and redistribute this source. The significant implications of this unique style of software distribution for e-entrepreneurs are examined. Having a flexible strategic plan; possessing management skills; providing excellent service; and having patience are some of the recommendations provided by interviewed e-entrepreneurs. When made part of the decision-making process, these recommendations would enhance current and future e-entrepreneurs in sustaining their business.

INTRODUCTION

The aim of this chapter is to explore the usage of OSS in e-entrepreneurship and to identify the attributes and skills necessary for an e-entrepre-

neur. **E-entrepreneurship** is defined as the notion which principally uses the Internet to strategically and competitively achieve vision, business goals, and objectives. **E-entrepreneurs** use the World Wide Web (WWW) to interact and complete virtual transactions both with other businesses (B2B) and their consumers/customers (B2C).

The notion of an e-entrepreneur has recently gained recognition amongst both academics and practitioners. An e-entrepreneur has many similarities with that of an 'entrepreneur,' especially with respect to the attributes and traits required to be successful. Concurrently, the major differences between the two are primarily in the resources (such as infrastructure and setup costs) required to start the business.

Over the last two decades, most businesses have experienced substantial change brought about as a result of globalisation and the Internet. Maintaining a competitive advantage to simply survive is a continued battle for many businesses. The Internet, however, has provided companies with numerous opportunities irrespective of the nature of the products and services offered to customers. Many companies now make use of the Internet and provide customers through their Web site information such as store opening hours, store locations, contact details, and listing of their products and services. However, for a majority of these businesses a large proportion of the sales revenue is still generated through activities conducted at the physical stores. One example is **Telstra**, which in addition to having nationwide physical stores also does sales and online billing (Telstra, 2004).

The number of companies performing their business activities through the Internet is increasing rapidly while still maintaining a physical store presence to enable customers to 'see and feel' their products before making a purchasing decision. Satisfying the needs of conventional customers who prefer to complete 'face-to-face' transactions is recognised by many businesses. One example being the Borders bookstores (Borders, 2004). Then, there also are companies who only have a virtual presence and complete all their advertising, marketing, and transactions through the Internet. Amazon.com (Amazon.com, 2004) is a perfect example of this type of organisation. Brand recognition, customer service, and customer satisfaction are the main ingredients for any company, whether operating solely as 'bricks and mortar,' 'online,' or a mix of the two (Mottl, 2000).

The concept of '**entrepreneurship**' has been in existence and researched by academics for some time. Due to the lack of literature in the area of e-entrepreneurship, the authors have sought guidance and direction from the entrepreneurship literature to realise the following objectives:

- Identify attributes of e-entrepreneurs.
- Identify the similarities and differences between entrepreneurship and e- entrepreneurship.
- Identify if being an e-entrepreneur is more advantageous than simply being an entrepreneur.
- Examine open source software in the context of e-entrepreneurship.

Chief executives of two e-entrepreneurial organisations were interviewed to obtain insights into the concept of e-entrepreneurship. Some of the issues explored in the interviews included:

- attributes of an e-entrepreneur,
- role played by **open source software (OSS)** in the information technology sector,
- impact of OSS on existing and future e-entrepreneurs, and
- role played (if any) by government in supporting e-entrepreneurs.

The next section presents an overview of the literature examining the dot-com crash, entrepreneurship, and open source software (OSS). This is

followed by the section that describes the research methodology used to conduct the interviews. Case studies of the two companies interviewed is then presented identifying the various aspects of being an e-entrepreneur with respect to the current technological environment including OSS. The last section presents the conclusions and future research directions.

THE DOT-COM CRASH: DID IT CHANGE THE WORLD?

The arrival of the 21st century was accompanied by the 'dot-com crash' with hundreds of companies around the world laying off thousands of employees and filing for bankruptcies. Competition amongst the remaining companies, however, has not diminished. Companies that have survived have merely "shifted their value propositions to meet (or chase) new marketplace needs" (Spiegel, 2002, p. 30). Success stories of companies that have survived and moreover thrived following the crash are no less amazing (see Anonymous, 2003; Spiegel, 2002).

A number of parties have been blamed for the 'dot-com crash' that include but are not restricted to venture capitalists, investment banks and brokerages, and the Federal Reserve Bank (Mills, 2001). Another factor that has been attributed to the dot-com crash was that the majority of these businesses were established and run by young entrepreneurs who lacked the "essential experience in planning, organising, and managing businesses" (Foster & Lin, 2003, p. 456). These arguments also have been substantiated by *The New York Times* and *The Industry Standard* studies (Infante, 2001) where lack of human resource planning has been noted as a contributing factor leading to sexual harassment and legal suits against the companies, further crippling them following the crash (see also Dvorak, 2001). Duck (2004, p.14) listed seven mistakes that resulted in the crash: "too many competitors; short-term mentality; undisciplined growth; unrealistic revenue projects; inexperienced management; underestimated costs of establishing a national brand; and lack of customer-centered focus." It is the authors' view that as opposed to the traditional models, entrepreneurs and investors alike failed to foresee long-term funds allocation and put in place contingency plans.

The '**dot-com crash**' has not meant that the Internet is no longer used for undertaking business transactions, rather it is being used more than ever before. Whether a company started using e-technologies before or after the crash, it is imperative that they offer security to their customers and avoid hackers from their Web sites. Conry-Murray (2001) and Dvorak (2001) have highlighted security issues that companies should address to protect their customers such as debugging their sites regularly, minimum use of cookies, and not putting too many advertisements on their Web sites.

Over the past decade there has been a substantial increase in the uptake of the Internet by businesses primarily as a marketing tool. The Internet has enabled even small businesses with limited resources to instantly communicate their products and services to their target markets and audiences globally. Worldwide companies are being encouraged to join this phenomenon. For instance, speakers at the Dubai Strategy Forum mentioned a number of attributes required to improve economic performance. This included the need for accepting information technologies and a "strategic structure that wipes out bureaucracy and encourages entrepreneurialism, where managers manage, innovators innovate, and the teams are rewarded for their successes" (Anonymous, 2002, p. 1).

The next section identifies the attributes of entrepreneurs and reviews the relevant literature in the area of e-entrepreneur(ship).

ENTREPRENEURSHIP AND ITS RELATIONSHIP TO E-ENTREPRENEURSHIP

The concept of entrepreneurship has been evident in economics and sociology studies since the early 18th century (Becker & Knudsen, 2004). A number of entrepreneurship definitions have been mentioned in the literature. Mulcahy (2003, p.165), while citing the *Oxford Dictionary* defines an entrepreneur as "a person who undertakes or controls a business or enterprise and bears the risk of profit or loss." Thompson and Randall (2001, p. 290) describe entrepreneurs as those individuals who "sense opportunities and take risks in the face of uncertainty to open new markets, design and develop new and improved products and processes" (see also Legge & Hindle, 1997; Kuratko & Hodgetts, 2001).

A number of traits and skills that entrepreneurs possess are cited in the literature. According to Chris Dyson, a business analyst, there are nine traits that depict a person's entrepreneurial characters. These traits include: "personality, integrity, initiative, commitment, drive and determination, directiveness, confidence, self-direction, selling, and leadership" (cited in Tams 2002, p. 399). Cherwitz and Sullivan (2002, pp. 24-25) similarly comment that an "intellectual entrepreneur" is depicted by having attributes such as "realistic and attainable vision, taking risks and seizing opportunities, using available resources to achieve the vision by using collaboration, teamwork, and innovative strategies" (see also Jablecka, 2001, p. 376). From these definitions, it can be inferred that successful entrepreneurs need to possess attributes such as vision, opportunity-seeking, leadership, and management skills.

As highlighted earlier, for the purpose of this chapter, the authors have defined e-entrepreneurship as a concept which principally uses the Internet to strategically and competitively achieve vision, business goals, and objectives. e-entrepreneurs have been defined as those individuals who use the World Wide Web (WWW) to interact and complete virtual transactions both with other businesses (B2B) and customer (B2C) (see Thompson & Stickland, 2003). E-entrepreneurs have come under focus after the dot-com crash that resulted in the closing of hundreds of businesses and thousands of people left unemployed. Practitioners, consultants, academics, and governments are investigating the causes behind this crash that left many other industries dependent on information technology crippled for months. Contingency measures are now being put in place to avoid similar crashes in the future. A study of 42 entrepreneurs based in the Greater London Business area who survived the dot-com crash was conducted during the last quarter of 2002 by the London School of Economics and Political Science (Steinberg, 2004). Using a triangulation method, the study found that businesspeople were "in the process of jointly developing a new [under]standing of what success and decision-making means via e-business networks" (Steinberg, 2004, p. 4) and, accordingly, developing coping strategies to avoid similar downfalls in the future.

One of the factors that contributed toward the demise of many e-entrepreneurial companies was the lack of human resources and communication between sellers and customers. To address such issues and provide potential e-entrepreneurs with an understanding and practicalities of the business world, many multinational organisations are now working with their prospective employees with the aim of providing them with an in-depth understanding of business operations. "Media entrepreneurship" is one such program that has been launched by Hewlett-Packard (Canada) Ltd. (Bolan, 2002). The program primarily uses Linux as being open sourced, allowing users (students) to acknowledge that there are no limitations in software development. Robert Miller, national business development manager responsible for education and healthcare at HP, commenting on the program said (Bolan, 2002, p. 19):

*The **dot-com boom**/bust saw a lot of technologically astute people become empowered with vast amounts of capital funding, but they lacked the business sense or financial management skills to fully exercise their plans. Some of them were smart enough to bring in business people that had that kind of savvy, but it was a very awkward culture mix because there were two totally different kinds of mindsets.*

Globally, companies and individuals are being encouraged to embrace the Internet as a means of developing a business advantage. For instance, the e-Business Forum Working Group D5 (WG D5) in June 2003 identified the key challenges (including those encountered in communication and policy formulation) to encourage Greek companies to enter the area of e-business (Neofotistos & Yagoulis, 2003). WG D5 consulted with a number of Greek private and public sector companies involved in e-business and provided a number of recommendations to smooth the process of conducting business through the Internet. These included being aware of issues of privacy, protection of personal information, promoting communication, and the training the e-entrepreneurs (Neofotistos & Yagoulis, 2003).

An individual's prior understanding and knowledge in business studies and cultural background affects how much new knowledge and information is required to develop a collaborative business plan. This finding was realised by Foster and Lin (2003) when exploring the impact of individual students' learning in e-business and e-commerce environments. By using cognitive perspective in the study of students from different cultural backgrounds, Busenitz and Lau (1996) found that people from some cultures produced more entrepreneurs than others (see also Thornton 1999). Similar results have been found in a recently completed study across eight countries including Australia, Slovenia, Mexico, North America, Finland, Scotland, South Africa, and Kenya (Morrison, 2000). Business plans of new ventures in New Zealand in 2000 were compared to identify the percentage of Internet usage as part of the e-entrepreneurship competition based on the Mckinsey model (McQueen, 2004). At the end of the phase two of the competition, it was found that individuals with pervious IT background, education, business experience, or personal interest had a much higher Internet component in their business plans than participants with traditional business experience such as those for the fields of accountancy, retail, entertainment, and games.

OPEN SOURCE SOFTWARE (OSS) VS. PROPRIETARY SOFTWARE

Proprietary Software Model

In the recent past, much high-profile software (including Microsoft products such as Word and Windows XP) have been distributed under a license that treats the software as a 'black box.' The software is supplied in 'compiled' or 'binary' form, meaning that a computer can read and execute it directly. However, programmers are unable to study the internals of the program. They are forbidden to understand in detail how the program works, they are not permitted to modify its working and they can redistribute neither the software in its original form, nor in any derived or modified form. Typically, a single company or an individual holds copyrights on **proprietary software** (Anonymous, 2004). These copyrights are used in conjunction with licensing agreements to deny the "freedom" or "openness" to modify and redistribute the software. "Proprietary software is software that is not free or semi-free. Its use, redistribution, or modification is prohibited, or requires you to ask for permission, or is restricted so much that you effectively can't do it freely" (FSF 2004).

From the point of view of the software vendor, the proprietary software model utilises restrictive licensing and secrecy to safeguard **intellectual**

property (IP). It is possible that the development of the software could be regarded as entrepreneurship.

However, from the point of view of an e-entrepreneur looking to leverage existing technology, proprietary software may not seem like an attractive option, since modification and redistribution of existing proprietary software is forbidden. Furthermore, providing key services related to deployed proprietary software may not be possible due to the unavailability of the internal source code. Another problem is what is commonly referred to as 'vendor lock-in.' A proprietary software vendor by definition is the only organisation with the legal capacity to improve and enhance their proprietary software products. Hence, an e-entrepreneur wishing to deploy proprietary software is "locked in" to the vendor. No other organisation or individual (including the e-entrepreneur) can provide improvements or custom modifications. For instance, Microsoft is the only organisation that can provide security updates and bug fixes for the proprietary Windows operating system. In effect, any user of Microsoft Windows faces vendor lock-in. Unless and until Microsoft decides to issue a security update or a bug fix, users must helplessly use the software in whatever condition it is in. This argument is developed further under the discussion of OSS below.

Free and Open Source Software Model

When referring to OSS, the authors have used the Open Source Initiative (OSI) definition (OSI, 2004a). OSS involves access to the underlying source code. In addition, for a license under which software distributed is to be considered open source, it must permit redistribution of the software without requiring a royalty. Redistribution must be permitted in source as well as compiled (ready-to-run) form. Modification of the software and creation of derived works must be permitted. There are some other clauses that must be satisfied for a particular software package to qualify as OSS (OSI, 2004b). However, the criteria are arguably the most fundamental and, to someone not familiar with the OSS paradigm, perhaps the most revolutionary. Many organisations and Web sites use the term "free software" (FSF 2004) whose meaning and interpretation is very similar to OSS, with 'free' implying freedom to access and modify the source as well as redistribute unmodified and modified versions. Strictly speaking, the definition of 'free software' might preclude certain software from being considered "free" even though it might be considered OSS. Since all 'free' software would be considered OSS, we will use that term for simplicity and to avoid the confusion that comes from 'free,' meaning 'at no charge.' Interestingly, while it is possible that OSS and 'free' software can be obtained for no or very little cost, e-entrepreneurs should note that it is entirely possible for OSS and 'free' software to be 'commercial' (i.e., a source of revenue). For instance, Red Hat produces an open source product called Red Hat Enterprise Linux, an open source operating system that is sold by annual subscription. Subscribed customers are entitled to receive ongoing security updates, errata fixes, and new features as they become available for the duration of their subscription.

RESEARCH METHODOLOGY

In this chapter, we have adopted the exploratory methodology (see Peil et al., 1982; Spencer, 1982) to identify the trends of how OSS has been and would impact the entrepreneurs as the usage of Internet and other technological methods to conduct business continues to increase. Conducting interviews as a method of exploratory research has been accepted in academia. For instance, Murray (1996) used case study methodology to identify the role of venture capital investments in newly established technological firms. Conduct-

ing interviews as a research methodology offers a numbers of advantages: giving flexibility to both interviewers and interviewees in setting up a mutual time; increasing the interviewers' control on the direction of the questions and an opportunity to further explore issues; providing undivided attention of the interviewees; and, last but not the least, providing insight into non-verbal observations such as body language (see May, 1993; Burns, 1998; Peil et al., 1982; Spencer, 1982; Reddy, 1987; McNiff, 1988; Yin, 1994).

As previously mentioned, e-entrepreneurship is a new and under-researched area, hence, the authors were working in unfamiliar terrains. Case study as a research methodology has been accepted when attempting to overcome the uncertainty of having clear measuring instrument (see Wallace, 1984; McCutcheon & Meredith, 1993; McGuire, 1995; Palmer & France, 1999; Corbett & Cutler, 2000).

Chief executives from two entrepreneurial organisations were interviewed in September 2004 for their experiences of setting up, running, and maintaining their businesses in light of growing technological changes. According to the Australian Bureau of Statistics (ABS) classification, Company A can be classified as "micro" with only four employees, while Company B can be classified as "small" with 25 full-time employees (see Steinberg, 2004). The focus of the interviews was on the role of OSS in today's entrepreneurial world where considerable focus is being placed on functions of the Internet for completing business transactions. After receiving consent from the interviewees, the interviews were tape-recoded and subsequently transcribed and written up as case studies. These were then sent back to the interviewees for verification of the content, and any changes as required, were accordingly made. This step was undertaken to reduce limitations (e.g., generalisation, reliability, information overload, validity, rigour) accompanied by the case study methodology (see McNiff, 1988; McGuire, 1995; Burns, 1998; Kitazawa & Sarkis, 2000).

Please note that to protect the confidentiality of the interviewees and their respective organisations, their names have not been disclosed and are referred to here as Company A and Company B, respectively. Nonetheless, as far as possible, direct quotes from the interviewees have been incorporated in the following sections.

CASE STUDY FINDINGS

Company A

With its head office currently based in regional New South Wales (NSW), Australia, the company was established and registered as a partnership business in early 2003 and then become a proprietary limited company in January 2004. The company is "focused on developing and deploying Web commerce and Linux-based network solutions" (Company A Web site) and has successfully secured and completed projects in both the open source area and commercial world projects for both Australian and foreign-based companies including in the UK and the United States. The company's open source content management product has been ranked in the top 2% of the active projects at the SourceForge dot-net site which has over 8,000 projects and downloads listed on its Web site (Company A Web site). Even though the company and its members have a strong background and focus on Linux, it also provides software solutions for pocket PCs, the Palm Operating System (Palm OS), and Microsoft Outlook.

The mission and vision of Company A, in addition to generating and increasing its revenue, is to move toward the area of "embedded media." Interviewee A considers embedded media to "employ devices and solutions on single chip computers running on open source software." Each of the Company A directors have expertise in areas of programming, administration, and management, respectively, and are on the path of expanding the company.

The motivation and flexibility offered by working for oneself was one of the driving forces for the interviewee to establish his own company. The interviewee also wanted to have the flexibility to adjust quickly as changes in the external environment and technology took place without going through the bureaucratic levels often found in a large organisation. Technology itself is also the passion of the company. This is still a motivating factor for all the personnel involved, which is steadily pushing the company forward. The interviewee believes that this is true of other companies such as Adobe and Apple, where he feels that the vision of the company and the passion of its technologists had kept them going despite management changes.

One of the themes that intrigued the interviewers was how the concept of OSS that involves freely distributing your knowledge can result in generating business for the company. Under an open source license the 'source code' is distributed along with the ready-to-run version of the software product. The interviewers were keen to ascertain how this apparent giving away of intellectual capital could result in profit for the person/organisation involved. It appears that OSS is gaining momentum and acceptance around the world, and these issues are becoming more relevant, especially for e-entrepreneurs.

To answer the query, interviewee A commented that the writers of a program are generally accepted as having the authoritative knowledge. To elucidate his point he gave the following example: If a program is released as OSS, the writer not only shares, but also demonstrates, his or her knowledge in a manner that can be subject to scrutiny by experts. In addition, other organisations that require tailoring of the program to their specific needs may contact the writer to do the customisation for them.

This is where dollars come into the picture. The interviewee has had similar experiences. A London-based company contacted the interviewee when they wanted him to make changes to their program source code so that it was compatible with the company's accounting system. Since the company's experts had the source code of the product available to them, they could, in theory, do the customisation themselves. However, this would involve them first becoming familiar with the internal details of the software and then modifying it. Cost-benefit analysis by the company showed that it was easier and more economical for them to ask the interviewee to utilise his knowledge and expertise to deliver the modified code. The interviewee estimates that the work took him approximately 20 hours to complete while his customers might have had to spend several man-days to achieve the same result. So, the interviewee was able to acquire highly specialised, lucrative business without having invested in marketing or publicity services. The client, on the other hand, was able to procure a software system that fitted their needs in less time and for less money than if they had done it by themselves. So, it was a win-win situation for both parties involved.

In interviewee A's view, the Internet, due to its ubiquitousness and near universal accessibility, can be very effectively used as a marketing medium and MySQL AB, the popular open source database product vendor, is a classic example. In less than a decade, the MySQL database server has become internationally recognised and widely used, including in customised forms. High-profile clients include Sony, Suzuki, and Sabre Holdings (MySQL, 2004).

It should be noted that not all the software produced by Company A is OSS. Some software is released under the "general public license" (GPL) (Derekgnu, 2004) and qualifies as OSS. In other cases, clients may purchase software under a "commercial licence agreement" from Company A. This agreement allows the client to use the product and to view the source code and covers the provision of regular service by Company A such as providing further customisation and enhancements. Under this license, the clients are

not allowed to modify the source. Essentially, this is Company A's strategy to be able to effectively support their clients. If too many modifications are made to the code, Company A would have to extensively study the modified version before being able to provide enhancements. It also can be seen as a precaution taken by Company A to avoid legal repercussions arising from claims of failing to provide adequate support as per the license agreement of the customised program. However, if the buying organisation changes the source code without obtaining prior consent from Company A, the latter is under no legal obligation to be able to support the changed version of the code. Of course, the client is free to approach Company A and/or other software solution providers to collaborate on customised versions subject to additional costs.

During discussions with Interviewee A, an interesting point emerged: Company A does produce open source software but also utilises open source software tools. Company A has obtained commercial services from Red Hat Linux related to their open source Linux-based operating system. They also are developing some software for embedded systems which may turn out to be a derived and open modification of existing open source software.

If an individual is contemplating to become an entrepreneur or change himself or herself from an entrepreneur to an e-entrepreneur, they have to first consider a number of alternatives and subsequently take appropriate decisions. One needs to decide whether they would be deploying new software or leverage the existing software. Further considerations regarding licensing agreements (OSS or proprietary or a mix of both) also would be required.

In views of Interviewee A, "Open source [should be considered] as a serious alternative for people [who] are trying to do [something new]. Statistically, more than 50% of the Web servers in the world run open source software, which is generally […] Apache, […] the most popular Web server in the world.[1]MySQL is the best or the most popular database for Web-based projects." Company A does still utilise proprietary software, such as MYOB for its accounting needs since it helps them conform to the appropriate standards and legislation. MYOB runs on the proprietary Microsoft Windows operating system. Except in instances where the clients request that supplied programs remain closed source, Company A generally licenses its software as OSS and believes that other organisations should do the same.

Interviewee A commented that the decision whether or not to go OSS for their software is a business decision and dependent on its vision, current position in the market, current/existing new code development, and future plans. One needs to keep in mind that like any other material product, software and code have their own life cycle and the business decision should incorporate the potential life of the code, accordingly.

Interviewee A also made two points of direct relevance to e-entrepreneurship. First, as an e-entrepreneur, if you are trying to develop a novel solution, you can focus on the entrepreneurial aspects by using existing, reliable, open source software to avoid "re-inventing the wheel." Second, as a provider of innovative IT solutions, an e-entrepreneur faces a more level playing field since organisations are not "locked-in." Hence, they can turn to the e-entrepreneurs to provide support, maintenance, and enhancement of OSS.

The interviewers also were interested to know the support, if any, provided by the government to Company A and whether being based in a regional area it was eligible for any specific government funds. Interviewee A indicated that he had approached the state government for assistance and there had been some progress. The response, however, has not always been very speedy which sometimes is a challenge for small, struggling firms looking for assistance as they may not be operating after a few months. The problem is sometimes further compounded by the bureaucratic structure of the governments.

The difficulty experienced by regionally based organisations is convincing the officials of their innovative ideas who are sometime reluctant to provide capital for new ideas that may be regarded as being too risky. A classic example is trying to get funds for OSS projects as the question raised by government officials is the same as the authors: How can one make money by giving away their knowledge and expertise?

Company B

The company has been providing innovative, competitive solutions based on open systems and open source technology to its customers since the late 1980s. The company aims to "develop strong, ongoing relationships with its clients and long-term partnerships, based on mutual growth and respect with industry vendors" (Company B Web site). Services provided by the company fulfil customers' needs in areas of: consulting; application development; and training in software programs such as Unix, Linux, Windows systems administration and network management, and Web-based solutions to name a few. In addition to serving a number of small and medium-sized Australian-based customers, Company B also has successfully completed projects and provided training to a number of large organisations including Hitachi, Telecom Australia, Kodak Australasia, University of Melbourne, Mobil Oil Australia, CSIRO, RACV Insurance, Rockwell Areospace, ANZ Bank, Ericsson Data Australia, and VDO Instruments (Company B Web site).

When the interviewee first started working in the computer industry, not only was the industry in its infancy with huge-sized computers, a much smaller percentage of people had access to computers as compared to today. The majority of people involved in the industry at the time were young males generally categorised as 'geeks.' Only large professional organisations such as insurance companies and banks were using computers. The interviewee's introduction to the potential for online collaboration and the spirit of OSS occurred in the late 1980s. At the time, only a small team of professionals had access to the Internet. He recalls participating in an online newsgroup where he would ask questions about the C++ programming language and on occasion receiving advice from Bjarne Stroustrup — the creator of C++. However, the state of the technology at the time meant that only technically skilled people could take advantage of this online community and near-instantaneous communication. Interviewee B realised that there was a "great business opportunity" in this area if people at large could access the Internet using tools that they could learn to work with relatively easily. Unfortunately, initial feasibility studies indicated that the level of capitalisation available was not sufficient to fund the infrastructure needed to realise such an opportunity. The way to make an entry into the field was by doing consulting work based on the emerging Internet technologies and the related open standards and software.

One of the areas in which Company B has competitive advantage is in the area of OSS as it was one of the pioneering companies. The company also has a very high reputation in providing superior client service and catering to clients' specific needs. Hence, the company receives many of its projects through referrals as has happened in one of its recent projects when an Australian University on recommendation from another university contacted the company to tailor its student database to comply with the federal government's reporting guidelines by using the ERP system. In this instance, the company made use of existing codes from "open source framework called Open for Business," along with their expertise in programming to successfully complete the project in less than half of the time and cost than if the company had to write the source code from scratch. By using existing codes on the OSS, the company can reduce the price of their products and accordingly is more competitive than its counterparts. By having

access to codes and research and development (R&D) at their disposal, the company also is able to provide prompt service as compared to other large software companies who may not have their respective service offices in Australia. The company does not bind its clients into a lifetime contract and the latter have full access to their codes that they can decide to move to another vendor/company if they wished without being penalised/disadvantaged in any way.

Working toward the "betterment of the mankind" by sharing his knowledge and expertise with others while operating in an exciting, dynamic sector are the motivations for Interviewee B to remain as an e-entrepreneur. One of the challenges encountered by the company and others in the information technology sector is when trying to market their products to third parties and businesses. It has been noted that most technology experts do not have marketing and business skills that can often disadvantage them in the marketplace.

Interviewee B and his company had different experiences while interacting with the government sector. At the time of the interview, Interviewee B had been working with the federal government to create a document/database that would provide access to all government "agencies on the procurement of open source software." The document would explain legal ramifications if the third party decides to take up the OSS modules from the document. The database also would act as a networking site for individuals and organisations who wish to safely use OSS modules. The federal government is consequently working to "remove impediments towards the adoption of open source." At the state government level, the focus is still at industry development. The New South Wales (NSW) government recently announced a US$40m Linux project which is one of the largest in the world.

Company B had been in operation long before the dot-com crash, and the authors were interested in understanding how the company had survived it as opposed to many other unfortunate competitors. Interviewee B noted that unlike other new companies emerging at the time with hundreds of people being employed in the company within weeks, the number of employees had remained more or less the same in Company B. Many people contemplating to expand their wealth also had invested huge funds in their newly established companies. Company B, however, did not receive any such funds. This does not imply that Company B's products and services were any less reliable or competitive. Nonetheless, its experience had cautioned them against investing or accepting impulsive projects and funds alike. Thinking and operating strategically as well as employing experienced staff saved the company while other businesses vanished within days after the dot-com crash. In an attempt to capture the already saturated market, new information technology companies spent huge amount of resources and was another reason for their failing: not conducting sufficient market and competitive analysis, a prerequisite for establishing and running any type of business.

Interviewee B cautioned existing and new entrepreneurs of being aware of globally existing patents for various programs and software codes as even without their knowledge the programmer could be held liable for potentially plagiarising other patented softwares. He proposed that for emerging economies and businesses to be successful, it was essential that the software patent system be either made redundant or more flexible with clear guidelines with a database for searching all the existing patents.

When asked about the future of e-entrepreneurship, Interviewee B commented that this was going to expand in the coming years. To emphasise his point, he gave the example of the music industry. Until very recently, popularity in the music industry was gained by singing face-to-face to a wider audience and generally it took years to get a reputation and make money. In this current era, however, by using the technology

and the Internet, the singer can make hundreds of copies of the music on CD and simultaneously distribute it worldwide capturing the global music market. This would not have been possible using the traditional manufacturing and distribution system.

Interviewee B strongly believes that for existing and future e-entrepreneurs and information technology companies it is essential that laws relating to patents should be changed, otherwise the progress could come to a standstill. Entrepreneurs also need to be aware and cautious of the situation and take comprehensive legal consultation and protection.

DISCUSSION

For an e-entrepreneur, the software tools used are likely to be the enabling factor of the novel service being provided. In fact, the entrepreneurial product may be software or a combination of hardware equipment and software. Given that such is the case, how should various entrepreneurs decide whether to use software solutions and/or which model to use for development?

To become a successful entrepreneur, it is essential that a person learns from the experience of others and avoids making the same mistakes. The reoccurring themes within the literature and interviewees complement each other. Halloran (1991), for example, discussed the 20 commonly experienced pitfalls which should be avoided, including: having unrealistic expectations; shortsighted financing arrangements; missing the target market; buying costly and ineffective advertising; and inconsistent and chaotic management.

Explaining the similarities and differences between an entrepreneur and an e-entrepreneur, Interviewee B viewed that both have similar attributes and skills. Both need to be able to "visualise future potential [that is] above and beyond just the vision for making money." One major difference between the two is that while working in the information technology sector, an e-entrepreneur requires comparatively less funds and infrastructure when starting a business and, consequently, less total investment dollars. Once a comprehensive market and competitor analysis has been undertaken and the service that would be delivered has been finalised, only access to the Internet is required to start the business, which can be done from any location.

Andal and Yip (2002) postulate that companies should combine traditional and new-economy bases of competitive advantage into their business models in order to be successful in e-business. The generally accepted "e-bases" (Andal & Yip, 2002, p.1) include community effects, first mover advantage, fulfilment/delivery, technology, teamwork, and scalability. They also suggest that some e-business start-ups failed to implement these advantages effectively or found that they needed to be augmented with traditional bases of competitive advantage. For instance, the e-base first mover advantage should be combined with traditional product/service advantages. Getting to the market first with a novel product or service can result in significant benefits such as in the case of Amazon.com and Yahoo. Also, while the use of new and emerging technologies is considered an e-base of competitive advantage, realistically, most technology can be easily replicated. Despite this, some companies, notably Google, have been able to convert technology into an asset and sell it.

The interviewees' comments indicate that they are at least intuitively aware of such implications. Both Interviewees A and B perceived a business opportunity in connection with an emerging technology, namely, embedded devices and the Internet, respectively. At the same time, they also realised that over-committing themselves merely on the basis of new technology did not make business sense, and they relied on other sources of revenue such as consulting work and Web development to acquire the infrastructure and capital to develop their e-entrepreneurial ideas.

Interviewee B mentioned that the fact that they were the pioneers in the industry of open source solutions was a major source of competitive advantage, thus, underscoring the first-mover e-base of competitive advantage. However, Interviewee B regards their use of OSS as another — and perhaps less traditional — source of competitive advantage. By candidly disclosing to their clients the fact that a solution is based on open source software, the clients are reassured that they can, should the need arise, go to other vendors for maintenance, support, and development. There is also an undercurrent of transparency at work; when a company agrees to provide an OSS solution, their entire system is potentially subject to scrutiny by their clients. This may give the clients a sense of confidence; a vendor supplying a completely open solution that can be verified by independent technical staff must surely believe in the technical quality of their product.

A possible interpretation of the comparative ease with which certain technological functionality can be replicated is that the intrinsic value of the software that provides such functionality does not amount to much. In cases like these, OSS offers the opportunity for an e-entrepreneur to focus on services that are enabled by or based on technology rather than wasting resources developing technology which will soon be replicated and widely available anyway. Certainly, it is still possible to try and sell technology, as Google has done. But this involves ensuring that one's technology is constantly evolving at a rapid enough pace to consistently stay ahead. As pointed out by Interviewee B, such research and development (R&D) can be prohibitively expensive for e-entrepreneurs, particularly in the Australian market where capitalisation can be harder to come by than, say, in the United States.

Teamwork amongst a diverse mix of people with varied skill sets and experience is another commonly cited e-base of competitive advantage (Andal & Yip, 2002). Apart from the contributions from team members within the organization, making software available in open source form allows participation from the wider community. One of Interviewee A's open source projects has built up a virtual community of users, some of whom are able to contribute by asking questions and reporting errors that enabled Company A to enhance the quality of their product. In some cases, they are even able to offer "patches" — snippets of software code that add functionality or repair an error. Interviewee B also is aware of this effect and mentioned that Company B is an organization that tries to contribute its expertise and knowledge to the improvement and enhancement of OSS that they deploy. Interviewee B considers the process a way of "bartering IP." In this sense, releasing software developed by an e-entrepreneur as OSS is not giving away something at no charge, it is an offer to exchange and share expertise, knowledge, and time with the possibility of mutual benefit to the developer(s) of the software and the wider community. Successfully trading IP with the global community is potentially a very powerful way of harnessing the synergy arising from a team of diverse backgrounds and abilities.

Based on the understanding developed from the experiences of the interviewees, the authors have identified the following three key requirements for being a successful e-entrepreneur in the field of OSS.

1. **Being Technically Competent**
   Both interviewees recognised the critical importance of technical ability. Interviewee B mentioned the depth of knowledge required and the "wizards" on Company B's staff. Interviewee A also is emphatic on the need to be "technically sound." By definition, e-entrepreneurial activities are strongly dependent on the underlying technology. The e-entrepreneur must not only be thoroughly familiar with the state of the art of the relevant technology but also possess a deep understanding of the underpinning principles in order to be able

to analyse trends and foresee opportunities. Interviewee B does caution that in the context of Company B, high quality technical ability is often found in people who are unable to liase well with customers, and it can be a challenge to find staff that strike the right balance between being "tech" and "suit." Hence, the latter can act as a marketing challenge when "tech experts" need to explain their product in layman's language to their customers.

2. **Taking the Customer Service Perspective**

   Interviewee A, while emphasising technical ability of the product, insisted that the focus should be on what the technology can do for the consumer. Ideally, the technology should be transparent and the customer should see the benefits of the technology without needing to understand the details. In many cases, they should not even have to care whether the solution is open source or not. What should be clear to the consumer is what the technology can enable them to do and what the e-entrepreneur can make possible for them via the services related to the technological product. These views hold for Interviewee A's e-entrepreneurship plans in embedded media – small, portable devices which must, by their very nature, be consumer specific. They are also relevant to Company A's online content management system products. The base product itself is available to everyone, but the true source of revenue comes from consumers wanting services based on the existing product. These services include maintaining the customers' online presence and customisation of the base product to deal with customer-specific requirements.

   Interestingly, while Company B operates in a slightly different arena, the customer service and technology transparency issues are the ones that they strongly identify with. For instance, they have a product called the small business server. This is meant to be a turnkey solution that can be set up quickly and easily. It provides small businesses the most commonly needed functionality such as Internet connection sharing and acceleration, e-mail, anti-virus, fire walling, and file and printer sharing. It so happens that the software installed on the server is all OSS. However, in Interviewee B's experience, the customer does not necessarily care — or need to know — that this is the case, as long as they are instructed on how to use and administer it. Further, Interviewee B asserts that the open source nature of the software in this product ensures that they have full access and complete control over all aspects of the software functionality, thus placing them in a position to provide maintenance and service as long as the customer is willing to pay for such services.

3. **Being Clear on the Reasons for Going OSS**

   Neither interviewee recommends OSS as a panacea. It is clear from both their interviews that a number of factors influence their choice of whether a solution is made OSS or not. In fact, while doing some consulting work, Interviewee B recalls being specifically asked to provide proprietary software-based solutions, which Company B was comfortable providing. Hence e-entrepreneurs should not perceive OSS as the next "bandwagon" or something to be done purely out of ideological reasons. The interviewers, as well as some existing literature (see Cusumano, 2004), caution against this. Still, there can be solid business reasons for focussing on OSS as evidenced by the activities of big business such as IBM, Sun, Red Hat, and Novell (Mahoney & Naughton, 2004). In fact, both Companies A and B produce or have produced offerings and services based on proprietary and

open source software. One or more of the following reasons have been compelling enough for both Companies A and B to go open source:

- *To harness the distribution and marketing power of the Internet* Interviewee A decided to release Company A's content management system under an open source license over the Internet. The idea was to make it easy and obligation free for prospective customers to download and use the product. If they were technically inclined, they also could inspect the source and assure themselves that the product was technically sound. While there are a large number of people who have chosen to use this for free, they have at least become aware of the existence of the product and Company A. Further, some of the users have requested services and support for which they have paid Company A. Interviewee B made the observation that in order to get commercial entities to try out one's software, the fact that it is open source gives them further incentive. This is because a potential customer is ensured that they can make some use of the software even if the original vendor is not readily available because they have the code and can modify it to suit their purposes, if the need arises.
- *Avoid re-inventing the wheel.* When the functionality of the product and the services are paramount (such as Company B's turnkey product), the software itself is the means to an end. Therefore, it makes sense for an e-entrepreneur to make use of the readily available OSS rather than having to devote valuable resources to rebuild what has already been done (and often done well). For e-entrepreneurs seeking to move quickly and offer novel services, this can be a major motivation. Interviewee B finds that by avoiding a lot of duplicated R&D, they are able to provide cost-effective solutions.
- *Interaction with the community.* Interviewee A acknowledges that Company A has indeed benefited from the questions, suggestions, and contributions of the online community that uses their open source content management product. Interviewee B views his Company B's building solutions based on existing OSS as bartering IP. Company B benefits from the IP of the developers of existing OSS and in turn feeds back expertise to these open source projects.
- *Get an edge over proprietary software vendors.* An e-entrepreneur may have an idea for a new product or service that can be enabled by a software package (or, indeed, the product may be a software package itself). It is often the case that the e-entrepreneur would struggle against the big businesses that offer similar products/services based on proprietary software. By releasing their product as OSS, the e-entrepreneur can get the attention of some potential customers who are deterred by the higher prices or the closed nature of the proprietary vendors. These potential customers could become a source of revenue based on custom modifications and other support-related activities. Of course, if there are already a number of OSS solutions available, then the e-entrepreneur should try to come up with a different idea.

Apart from the discussed business reasons, a strong ethical undercurrent did seem to underlie some of the issues outlined by the interviewees. For instance, Interviewee A saw releasing a proprietary product as OSS after it had reached its end of life as one way of letting customers know that they were not being left in the lurch. By granting access to software that Company A had previously developed under a proprietary license, users of that software would be able to continue to use and maintain the product well after Company A declared it as discontinued, if they so wish. For Interviewee B trying to "make the world a better place" is more important than "making a buck."

Another common factor is the passion for technology and the excitement that comes from developing new technology or watching the technology evolve by following and perhaps collaborating with the open source software community.

As a result of these findings, we agree with Mahoney and Naughton (2004) when they say that for some companies, OSS can be a strategically valuable weapon. However, the idealistic tendencies of both interviewees would cause us to stop short of agreeing completely with them when they say that it is difficult to find the "ideals of freedom, volunteerism, and a shared community of values in today's world of Monetized Open Source."

CONCLUSION

In this chapter, we have examined the increasing usage and growing acceptance of open source software within the technological world. E-entrepreneurship is a growing field and the experiences of two e-entrepreneurs trying to survive in this competitive field were presented. The underlying attributes and skills necessary for an e-entrepreneur are very similar to that of becoming an entrepreneur. These include: being a visionary; the ability to develop short- and long-term strategic plans; providing leadership; developing flexible structures; and remaining responsive to changing environmental and market demands.

Presented next are the recommendations we have elicited from the interviewees that can enable e-entrepreneurs to be successful in their ventures.

Flexibility in Strategic Planning and the Work Environment

There is a need for maintaining flexibility when doing business irrespective of the organisational size. Especially in this technologically-dominated business world, the organisation needs to have a flexible structure so as to be able to respond to the ever-dynamic and ever-changing environment. At the same time, long-term strategic decisions should be made which reinforce the vision of the company.

Provision of High Levels of Service

A high emphasis needs to be placed on providing regular and outstanding service to clients. A company's reputation (communicated though "word-of-mouth") plays a major part in obtaining repeat business from existing clients and attracting new clients.

Developing Basic Management Skills

A successful e-entrepreneur must acquire basic management skills and attributes such as leadership, negotiation, and business planning. Furthermore, a balance needs to be maintained between the technical demands and the business demands of the company, especially those relating to people management — customers, suppliers, and employees. Motivating employees will remain a key task for managers regardless of the type of organization.

Taking the Long-Term Perspective

Establishing a new business requires significant commitment in terms of effort and financial resources over a significant period of time. Hence, returns in the short-term should not be the motivating factor. Building a robust and stable business requires patience. One way of maintaining motivation over a long period is to ensure that all individuals involved keep an open mind and enjoy the journey that can provide numerous challenges and highly satisfying outcomes.

Listening to Technologists

In order to maintain a competitive advantage, it is imperative that managers regularly communicate with their technical personnel since they are ones who will have firsthand knowledge of what is happening in the technological world.

This chapter has contributed to our understanding of OSS and e-entrepreneurship. The literature highlights the need for further research in this area, particularly to do with small businesses with Internet usage (Steinberg, 2003). Gaps in the existing literature in the area of OSS and e-entrepreneurship needs to be filled with more studies. One way this could be initiated is by more qualitative studies incorporating both in-depth case studies and focus-group discussions exploring experiences of e-entrepreneurs in the current technological environment. The experiences of entrepreneurs who have now become e-entrepreneurs also need to be further explored.

Chapter 6.15
Channel Optimization for On Field Sales Force by Integration of Business Software on Mobile Platforms

Rishi Kalra
Symbiosis International University, India

Amit Nanchahal
Symbiosis International University, India

ABSTRACT

Marketing and sales channels are a significant lifeline for the sales force of a business. Sales professionals work on the concept of creating and widening channels that are then fed by the supply chain and distribution network of the businesses. Sales teams are constantly pushed to meet customer expectations while generating revenue for the company. As companies grow, these pressures increase. Sales teams are now looking at Mobile Sales Force Automation technologies to handle the ever increasing customer demands. Companies want to keep costs low, increase productivity and efficiency through mobile devices for the much needed edge on the field. This chapter is based on literature review of channel optimization as well as mobile software platforms and challenges faced by the sales force. This chapter discusses the need for integrating business software on mobile platforms that will optimize and enhance the performance of sales processes.

INTRODUCTION

The concept of the mobile enterprise is growing[a] in today's corporate world taking interest in tools supporting enterprise mobility for their sales force. These mobile enterprise solutions promise efficiency and productivity gains resulting from the sales function optimization. The change in mindset towards mobile applications in business has created a strong opportunity for companies to

extend their core data and applications through smart phones, cell phones, and personal digital assistants (PDAs). This extension of the business process applications results in creation of location independent links between the office (or a centralized location) with an increasingly dispersed workforce – notably the sales force which is continuously on the move.

The reason why companies are looking at incorporating such small handheld devices in their business processes is because by increased usage of mobile phones, PDAs and laptops, the company can keep in constant touch with its staff and managers who are spending more and more time away from the corporate network. These devices also provide vital access to these staff for email and the Internet. Istart Technology research found that:

- 27% of e-mail requires immediate action[b]
- 40% of the workforce is mobile
- 60% of senior management time is spent away from the desk[c]

Sales force management is the art of managing sales team on the field that enable an organization to generate revenue by selling their products to customers and increase customer satisfaction.

Companies are spending huge resources on their sales force and incorporating the new systems and applications into their operations management that help automate business processes. These applications are combined with the existing CRM functions in the organization which help enhancing the selling tactics of the on field sales force across industries by providing up to date information helping them win in the global business battlefield.

On field sales force for any company is concerned with all the stages of the sales process, starting from contact management, sales forecasting, recording sales, product solution details, integration of the various departments companywide.

A sales force personnel on the field requires constant communication with the home office for sales leads, invoicing, inventory[d] tracking, order fulfillment, and other supporting information. Recent advances in wireless technology field staff had to make do with laptops that required a physical connection and voice-based mobile phones neither providing the added value of mobility.

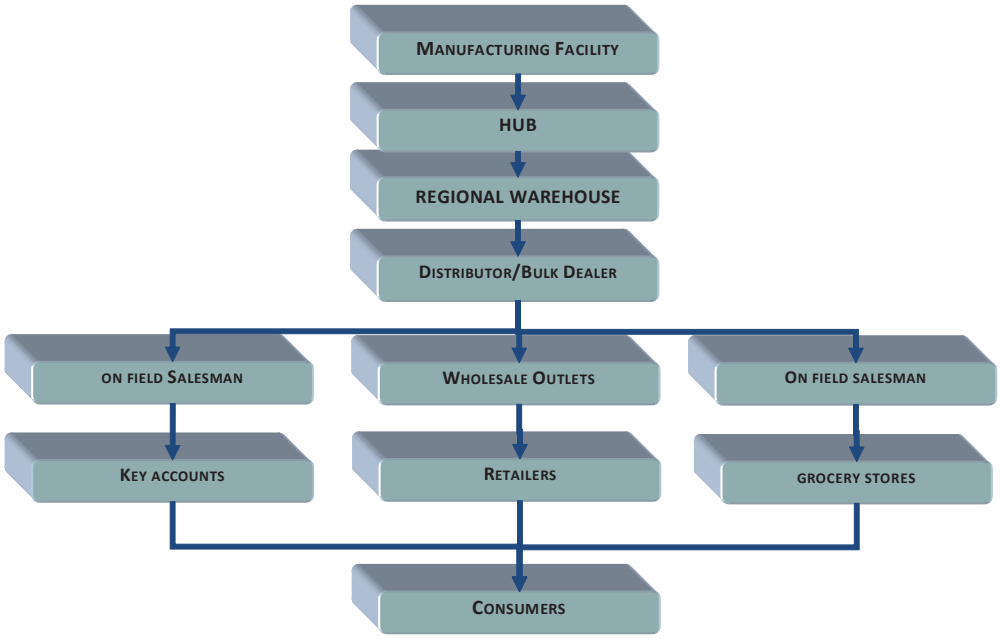
A new breed of user friendly Internet capable applications on smart phones and mobile devices are freeing the traditional sales force from their desks and allowing them to be incredibly effective. Sales personnel now have access to the same information and tools as their peers back at the office. This chapter discusses the various aspects in the channel for sales in an organization and the intervention of mobile devices to increase productivity.[e]

CHANNEL OPTIMIZATION CHALLENGE

Distribution channel is the structure that the company uses to reach its products/services to customers through intermediaries at the right place, at the right time with special consideration for profit and effectiveness. As shown in *Figure 1* products of a company may be passed from one intermediary channel member to another after keeping a certain margin for their services. The optimization of the distribution channel poses a challenge to organizations with different entities trying to transfer the product title and risk to the next successive channel member. The coordination and smooth working for optimum output for the company is the job of the sales team.

Distribution channels basically provide three functions: *information flow* (outward information about the supplier's offering and inward flow about customers' needs), *logistics* to get the supplier's product to the end customer, and *value-added services* that augment the supplier's product (local selling, financing, customization, after-sales parts

Figure 1. Distribution channel for a packaged goods industry



Reference: Report by Rishi Kalra on "Entry Stratefy for Haats/Shandies as a distribution channel in Orissa" at ITC Ltd Vizag Branch in June 2007.

Figure 2. Physical flow of goods in a distribution channel

and service, etc.). When improved alternatives for providing these functions evolve or when customer expectations rise, the failure of existing channels to respond prevents the supplier from adequately satisfying the customer. *Figure 2* describes the flow from the manufacturer to the retail point in Fast moving consumer goods category.

The shortcomings in a distribution channel are shown below:

- Excessive time taken for order processing due to lack of proper and effective communication between order procuring and order processing.[f]
- Inefficient forecasting techniques as calculated using past data rather than current on field inputs from sales force.
- Insufficient information supplied by sales personnel to retailers while pushing for sales; due to incomplete product knowledge and changing product lines.
- Increased threat of cannibalization and market fragmentation by inefficient order tracking and stock management techniques.
- Demographically heterogeneous consumers with changing habits, behavior and wants which are ineffectively monitored and stored by the sales force.
- Declining margins due to price erosion and increased costs due to excessive paperwork for completing the sales process leading to lost sales time.

Sales team for a company requires a lot of data support from the office or central location to close a deal or sell the company's products to demanding clients. The systems available now as shown in *Figure 3* incorporated on mobile devices enable the sales person to re-quote proposals, negotiate prices, manage orders and constantly update product knowledge on the move. Today the requirements from the sales force are more demanding and focused on monitoring all new business opportunities in the area, client reviews, marketing activities, competitor analysis and strategies for business development.

The various roles of a sales person are:[g]

- **Generate Sales:** Pre sales call planning, prospecting, presentations, entertain, closing sales, arrange delivery, collect payment.
- **Provide Service:** Technical consulting / solution formulation, arrange & oversee installation, train users, testing & monitoring.
- **Territory management:** Gather & analyze industry data – on customers & competitors, map distribution coverage, forecast.
- **Professional development:** Take part in sales meetings, trade shows, update product knowledge, upgrade skills, changing sales plan.
- **Other services:** Train new sales persons, counseling juniors, prepare manuals, and

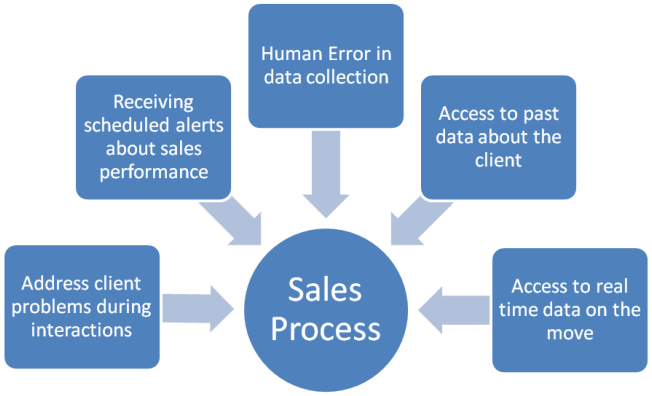
Figure 3. Process flow followed by sales force

represent company in sponsored civic/social events.

The shortcomings of the **on field sales force** are mentioned below:[h]

- *Figure 4* shows the various challenges faced by the on field sales force.
- Faster decision making required at the time of sales, access to information about price, product and stock to help close the sale on the spot.
- Need to remain as one point of contact for the company and the customer.
- Inefficiently addressing customer requirements and problems during interactions due to lack of proper negotiation and problem solving support on field.
- Challenge in identifying new sales opportunities at existing client accounts and at noncustomer, or whitespace, for companies due to lack of access to market data and current trends.
- Improper communication for receiving scheduled alerts about sales performance leading to inefficient planning and managing sales activity.
- Lack of access to customer/channel partner requirements and payment track record to manage the clients better on field.
- Inefficient use of field time[i]: A manual system requires a lot of time for data capture leading to lower efficiency. Moreover, loss of time is the most important edge against competition; increased efficiency allows sales force more time to generate sales.
- Possibility of human error: There are multiple jobs being performed by the sales force personnel while on the field which require manual data entry or estimation. Human error is critical when the decisions are made by the sales force for stock, sales forecasting, order due date, recording sales, and competition benchmarking.
- Lack of effective coordination during preparation of sales proposal due to improper flow of information between the various departments and the central database to on field agents making sales.

Figure 4. Challenges with the existing sales process system



- Inefficient monitoring and coordination of channel partners and sales force personnel on the field due to dispersed data.

The goal of Small Handheld Devices (SHD) is to streamline the entire sales process by integrating business software on the mobile devices to make businesses function efficiently, improve customer interaction, increase customer satisfaction, and save time.

Key research findings of mobile device management leader Mformation Technologies, Inc: [j]

- US enterprises reported more than half of managers using company-supplied mobile devices and nearly one-third of staff, with 56 percent reported increased usage among managers and 60 percent reporting increases in staff usage. [k]
- Mobile email, Internet and calendar applications are already pervasive, with more than 90 percent of companies using them, and businesses are set to significantly increase the use of new mobile applications such as sales force applications and company file share systems.
- 81 percent of respondents reported significant productivity increases from current mobile investments, with more than one-third of these reported increase higher than 20 percent.
- Four-fifths of CIOs interviewed look for improved management of mobile devices, applications, and data to accelerate the productivity trend, and more than 8 out of 10 US CIOs believe the mobile operator should take the lead in providing these device management services.

The major benefits of **Small Handheld Devices** for the on field sales force are:

- Data capture process optimization by pre drafted e-forms instead of manual filling of sales orders, reports, activity reports, and/or call sheets by on field sales people[l].
- Seamless information transmission from field to the central location rather than printing out reports and taking them to the sales manager. [m]
- Efficient response to client queries by use of hand held devices rather than waiting for paper based product inventory data and sales prospect lists resulting in long-lasting, profitable customer relationships.
- Ease of data entry mechanisms improve sales staff morale by reducing the amount of record keeping and/or increase the rate of closing.
- Sales staff can be easily trained with product information and sales technique training using SHD tools faster and more efficiently.
- Better communication and co-operation between sales personnel facilitates successful team selling.
- More and better qualified sales leads could be automatically generated by the software.
- This technology increases the sales person's ratio of selling time to non-selling time. Non-selling time includes activities like report writing, travel time, internal meetings, training, and seminars.
- Mobile technology providing instant access to information, applications, and services anytime and anywhere. This saves a lot of time most important business commodity.
- Improved supply chain efficiency by integrating various levels of corporate activity[n]
- Digital catalogue of products (including pictures) with sales representatives at all times.
- Orders placed by sales representatives can be automatically assigned to the sales representative that placed the order, thus streamlining the commission calculations and incentives.

Table 1.

Sales Process	Challenges	SHD Optimizations
Contact Management	1. Inefficient classification of contacts on the field 2. Cumbersome to develop new contacts from prospects with improper data capturing. 3. Difficult to remember old transactions with the contacts.	1. Efficient classification using the central database and parameters 2. Ease of recording data from prospects 3. Complete access to all transactions with the contact and customization of solution.
Order Management	1. Increased lead time in order processing due to time lag in information flow 2. Inefficient cumbersome order booking 3. Human error in recording data leading to incorrect demand estimation 4. Lack of real time access to client orders	1. Faster delivery due to reduced lead time 2. Effortless order capture 3. Increased accuracy in order processing 4. Access to past data of client orders and delivery dates.
Sales Forecasting	1. Micro level knowledge and view of the sales in the region. 2. Outdated information about targets of the served region	1.Integrated timely sales forecast generation from on field sales force (hourly, daily etc) 2. Coordinated updating of data from all mobile devices providing a holistic view of the database to sales force.
Recording Sales	1. Sales recorded manually on sale books and transferred to the database at the end of the day. 2. Human errors while recording data due to time constraints	1. Directly transferred to the database on a periodic basis synchronizing with the central database. 2. Less chances of human error due to efficient data entry mechanisms.
Charting Proposals	1. No data available from past interactions 2. Lack of access to latest sales data (product details, pricing, schemes, etc) available to field agents for preparing proposal.	1. Quicker access to past client interactions. 2. Access to latest sales data from the central database to give the client the most competitive quote.
Negotiation and Re-quote	1. Inefficient support on the field from the office during negotiations. 2. Decision making postponed till approved from higher authorities thus delaying the sales cycle,	1. Instant access to relevant sales data on the move. 2. Decision making and approval process streamlined.

- Improves cash flow by accelerating payments from customers – increasing efficiency of gathering data needed to create and deliver invoices customers.
- Since the data is collected in an electronic format the chances of errors are considerably reduced. These devices reduce human error by instructing the user with logic structure-based informational questions.

- Due to the compact form factor it can easily carried by the field work force. Handheld devices also score over notebooks as they are lightweight and fit easily into pockets. An SHD can provide quick, convenient, discreet Internet access.

MOBILE PLATFORMS REVIEW

With any new technology/solution, it is important to match requirements` with the benefits and limitations of the solution. The operating system determines a phone's features, performance, and security, providing APIs for add-on applications and technical hooks to manage it all. Decision makers face a tough choice when weighing which mobile platform or operating system to deploy to mobilize the workforce. There's BlackBerry, Windows Mobile, Palm OS, Symbian, Linux and J2ME.

Blackberry

BlackBerry offers the best combination of mobile phone, server software, push e-mail, and security from a single vendor. It integrates well with other platforms, it works with several carriers, and it can be deployed globally for the sales force which is on move. It is easy to manage, has a longer than usual battery life, and has a small form-factor with an easy-to-use keyboard. BlackBerry is good for access to some of the simpler applications, such as contact list, time management, and field force applications. It's a good device for doing e-mail, but it would be a bad choice if what you're looking for is a way to deploy business-critical applications to mobile workers.

Windows Mobile

Windows Mobile comes in two flavors. A smart phone edition is good for wireless e-mail, calendaring, and voice notes. A Pocket PC edition adds mobile versions of Word, Excel, PowerPoint, and Outlook. Palm's Treo 700w, with the full functionality of the Pocket PC edition, is a better choice for sales force professionals.

The main draw of the Windows Mobile operating system is its maker Microsoft. For a Windows or Microsoft shop, it's a wise decision, since it's fairly easy to add into the mix if a company has an affinity to other Windows applications, like Word and Excel. Windows Mobile also actively syncs to the Exchange and SQL servers. This augurs very well for use by the sales force.

Mobile sales force solutions for Windows Mobile are available from companies like SAP, Siebel, PeopleSoft, and Salesforce.com as well as other leading solution providers.

Palm OS

Palm OS is the most sensibly laid out and easy-to-use operating system on a smartphone today. This might suit the business requirement of some sales force implementations. Palm brings an open approach to business with two enterprise-ready, non-proprietary operating systems: classic Palm OS platform and the familiar Windows Mobile platform. Both platforms deliver secure mobile email, Palm's ease of use, access to thousands of industry-specific enterprise applications, and the ability to build custom applications using your existing development resources. The Palm OS does not allow for multitasking, which many enterprises could find a great hindrance. For example, if a user is working in an application and the phone rings, the application has to be closed down in order to take the call.

Symbian

Symbian[o] is one of the most widely used platforms. Its plug-in architecture makes it easier for manufacturers to add technology of their own which hastens delivery of new and in-demand features. Although Symbian is feature rich, it doesn't inte-

grate well with corporate back-end systems such as VPN connections and other enterprise-oriented tools. These devices work well for many traveling professionals, managers, knowledge workers and sales teams, but enterprise IT departments may find Symbian OS devices to be too expensive and too feature rich for verticalized field-force applications. Symbian has a strong feature set and is relatively easy to use. Its main stumbling blocks are the limited number of Symbian devices and its lack of support for CDMA. However, Symbian will start making its way to mobile workforces, even if it can't conquer the enterprise market.

Linux

Mobile Linux is not really a mobile operating system, but a kernel that can be a central part of any number of different operating systems. Mobile Linux cannot really be weighed against other mobile operating systems like Palm OS and Windows Mobile, simply because there are many flavors of Linux. Linux has an advantage over other mobile operating systems: a far-reaching community of developers ready to write smartphone applications. One can say things like 'Palm OS has an intuitive user interface' or 'Windows Mobile requires a more powerful processor,' but these generalizations can't be made about mobile Linux because it can have many different user interfaces depending on the distribution.

J2ME

J2ME is also not an operating system, it is a platform. The main selling point for J2ME is that it's lightweight and has a simple methodology for designing applications. Because it is lightweight, it requires very little storage. There are a few key applications that perform well in a J2ME environment, namely those from SAP AG, Oracle Corp. and IBM. What holds Java back is similar to what keeps Linux from infiltrating the enterprise as a viable mobile platform. The issue is there's no single party in charge of Java. In a company with a deployment of several different devices, that could create issues, since applications written to Java would have to be tested and tweaked for each, creating more work and potentially introducing performance issues if it is not tweaked just right.

Google's Android Mobile Platform

Google's Android Mobile platform is the latest mobile platform on the block. This open-source development platform is built on the Linux kernel, and it includes an operating system (OS), middleware stack and a number of mobile applications. Enterprises will benefit from Android because the availability of open-source code for the entire software stack will allow the existing army of Linux developers to create special-purpose applications that will run on a variety of mobile devices. If Android makes it into phones designed specifically for the enterprise, those products will have to include technology from the likes of Sybase, Intellisync or another such company to enable security features like remote data wipe functionality and forced password changes.

BUSINESS SOFTWARE INTEGRATION

The heart of the SHD device is its software and companies want employees on the field to get a feel of familiar applications they are trained to use on their mobile devices. Applications being developed in the SHD space depend upon the companies' requirements. There are industry-specific applications being developed; for instance, applications for an FMCG sales force, for insurance agents, the police, the military, and for e-governance. However, the applications have to be simple and effective. A salesman capturing information during a sales call has to complete all information, then and there, in a short span of

time. Hence it is very important for the applications to be simple and effective.

SHDs have proved to be a boon for the sales force of many organizations. Prior to having a handheld device the sales force had to depend on manual, paper-based systems. It used to take a month to compile data collected from different sources such as dealers, distributors etc. Software loaded in the SHD enable each member of the SF to maintain, store and feed information, and then transfer the same to central location. There are several protocols that sales people have to meet in different set-ups when they contact a distributor or retailer during their visits. They have to get information about products based on re-launch, regular purchase and different schemes. A salesperson does not spend much time with each channel partner and the challenge of recording all the parameters is automated and this has reduced the time required.

We'll understand the business software integration through an example from Insurance industry[p]. Gathering assets through partnerships and affiliations is critical for insurers to increase revenue. Third-party distribution continues to dominate the distribution of insurance products. Sales personnel spend most of their workday in the field in prospecting the customers. These sales personnel come back to home office periodically to update the office records which in turn would trigger the processing cycle. This often induces delay in the policy processing and increases the chances of data related errors. These work customs compel insurance carriers to seek cost-effective ways to deliver "anytime, anywhere" interactions between sales personnel, their home office, and their clients.

Mobile solutions[q] are being adopted in areas of new business acquisition and claims processing. It can improve day-to-day service levels for sales field force as it thwarts the need for duplicate data recording. Mobility lessens the need for multiple local offices in the same city which are frequently established for convenience of sales personnel[r]. Instead of sales personnel shuttling between local offices and client they can assess the insurability on site and immediately communicate with the carrier.

Exhibit illustrates a typical new business acquisition process flow using mobile devices to move data and information from the field to the home office of the agent. By instantly notifying underwriting[s] office of a new customer application and assigning them the case dynamically, Insurance[t] companies could expedite new policy processing. Through secure mobile environment, carriers can transmit applicant's demographics information, health information and other key details. The sales personnel can accept the business in real time, thereby improving the continuity between the sales activities and underwriting office.

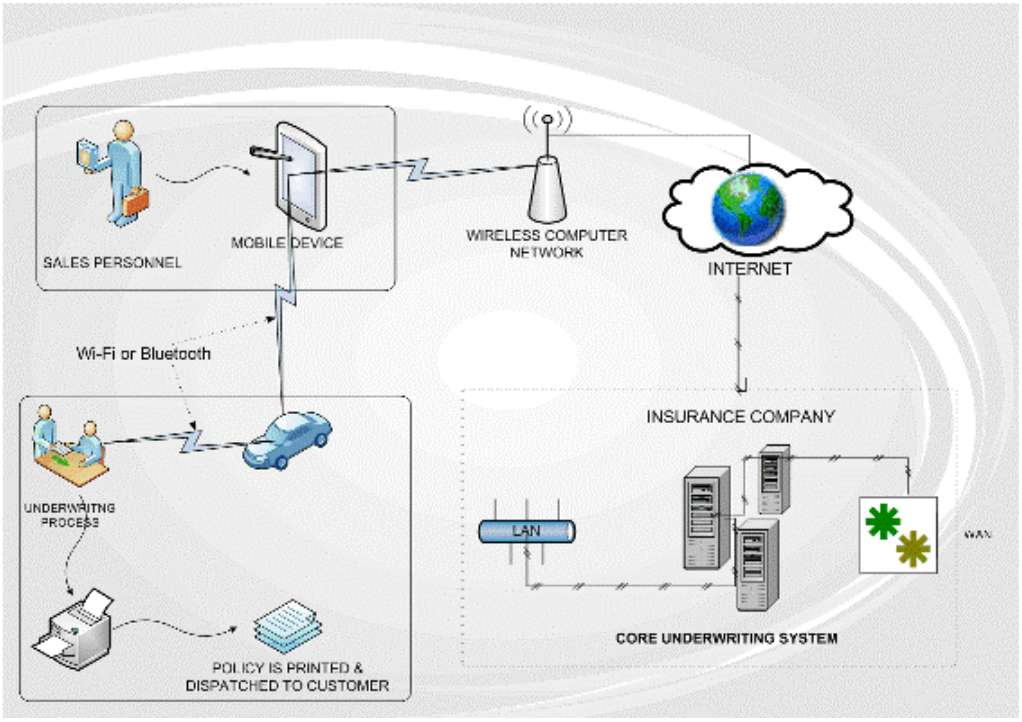
As the sales agent can collect detailed information on the spot, it often improves the accuracy of data and transactions. Mobile technology streamlines new business acquisition; increasing productivity in the process and reducing the potential for delayed policy processing and causing discontent among newly acquired customers. Both life and P&C carriers need to examine how a business process will work with handheld devices and then optimize these processes. Companies will have to do this optimization in perspective of the mobile wireless existing infrastructure available with the company and in the country, and how much is the company willing to spend on new mobile devices and wireless networks.

VALIDATION CASE

To illustrate the effectiveness of Mobile handheld devices in Sales-force management the following case has been chosen.

In a typical Consumer packaged goods company the sales force of the distributor typically perform the functions of Order Capture, Order Entry, Business Development and transfer of promotions designed by the company to the dealer. A

Figure 5. Architecture for a possible mobile sales force application



typical day of the sales force is spent visiting outlets making calls, booking orders manually, collection of pending claims, checking display efficiency. After covering his beat the sales person returns to the office to make the order entry for the day and plan the dispatch for the next morning. In addition to this he prepares invoices to be handed out to the retailers once Pros are dispatched. Since there is a time lag of 7-10 days between the dispatch and payment of the invoice the sales person also needs to keep a track of pending claims which is currently done manually and then fed into the system. If we analyze the current system there are gaps in terms of: duplication of effort when the order entry is done both at the dealer's premises and the office, manual entry of figures which can be mishandled. Moreover additional effort needs to be undertaken in terms of preparing statement claims, interpreting these and analysis of the offtake levels is adhoc.

Let us consider a scenario when handheld devices are used by the organization. The sales-force of the organization is equipped with portable devices. The first capability of the device is towards enhancing the order booking process. The device can either be 'always on' – permanently connected to office servers wirelessly – allowing users to dispatch their orders real-time. Or it can connect and synchronize at various times during the day – sending orders and receiving relevant sales information and emails etc. The order process will in many ways mimic what was

once done with paper orders, however, instead of faxing them in or delivering them to the office by hand, the orders are sent wirelessly. The suite of tools & information available in a mobile sales application include sales orders, customer sales history, corporate email, (typically synchronized with Microsoft Outlook or Lotus Notes), sales opportunities and promotions, often with the ability to record proposals and quotes, and marketing information like special trade promotions relevant to that particular customer. These modules contain potentially useful information about past promotions, their effectiveness with the customer and various options which may be customized to the buying pattern of the concerned customer.

This means the order dispatch process begins almost as soon as the order is taken, and it also means office bound order entry staff don't have to re-key orders (and potentially make mistakes while doing so) which ultimately means less credits and more satisfied customers. This is a significant improvement over the manual process where in the sales person had to replicate the effort in order booking and order entry which doubled the time required and the risk of inaccurate entries. Moreover when linked with the database maintained at the distributor/stockist premises reports related to the claims pending, off-take levels, success of promotional schemes can be tracked and used seamlessly by the company to make decisions. Another application is the automatic replenishment of stocks at the distributor level once the stocks reach a certain level. This helps in seamlessly integrating information across the supply chain and improving efficiency of channel partners and the manufacturing organization

This apart one major benefit is better utilization of a sales rep's time. The new operation enables the sales representative to undertake more calls, enhance the value of each order and gather competitive intelligence with the saved time.

We attempt to evaluate the benefit of investing in mobile technology. Let us assume the hypothetical example of a team of 20 sales reps, making an average of eight sales calls a day. Assuming that a sales person spends 15 minute per outlet visited to transfer the order information into an order sheet and this plus the travel time spent in driving to the office premises at the end of the day would amount to two hours wasted in a day. Even if the additional time generated by using as mobile application allowed the sales representative to make an additional sales call each day, or an additional $40 profit per sales (including the additional profits made due to better service) call made, this would amount to a staggering additional profit of $41,600 made in a year by the team. Add to this the additional benefits of better reporting, information synergies which help in designing strategies by the company and the reduced chances of stock unavailability at the distributor premises and the application brings excellent value. Assuming an investment of $800 per mobile device and the additional cost of altering the IT infrastructure the fixed one time cost would amount to $20000; thus illustrating the profitability of the technology.

CONCLUSION

An integral part of any mobile device system trying to automate the company's processes is companywide integration among different departments. If the systems aren't adopted and properly integrated to all departments, there might be a lack of communication which could result in different departments contacting the same customer for the same purpose. In order to mitigate this risk, sales force mobile devices must be fully integrated and kept up to date from all departments that deal with customer service management. The applications that are transferred or made mobile ready should be chosen such that they provide the most relevant, effective and up to date information to the on field sales force rather

than over burdening the sales team member with other administrative tasks.

Some of the applications available for the mobile devices are:

- There is a growing breadth of specialist applications on or coming to the market which enable fast efficient interface with your customers.
- These include specialist Sales Force Automation, Field Service Automation, Job dispatch and Tracking, Mobile Sales Force Management, Easy Order Software and Transport and Logistics Management. These applications all ensure delivery of a higher customer service level or increase the efficiency of the remote team your company has on the ground.
- To attain a sustainable advantage over competition, as the geographical boundaries become redundant, it is medium like telecommunication which will define the rules of the game.

Chapter 6.16
Revenue Models in the Open Source Software Business

Risto Rajala

ABSTRACT

Profit-oriented business behavior has increased within the open source software movement. However, it has proved to be a challenging and complex issue due to the fact that open source software (OSS) business models are based on software that typically is freely distributed or accessed by any interested party, usually free of charge. It should be noted, however, that like all traditional software businesses, the business models based on OSS ultimately aim at generating profits. The aim of this chapter is to explore the key considerations in designing profitable revenue models for businesses based on OSS. We approach the issue through two business cases: Red Hat and MySQL, both of which illustrate the complexity and heterogeneity of solutions and options in the field of OSS. We focus on the managerial implications derived from the cases, discussing how different business model elements should be managed when doing business with OSS.

INTRODUCTION

Whereas the business models of the traditional providers of proprietary software are grounded in one way or another on the distribution of access to the use of software-related intellectual property (IP) protected by copyrights, business models within the open source movement have to rely on other types of revenue models. This is due to the fact that open source software (OSS) business models are based on software that typically is freely distributed or accessed by any interested

party, usually free of charge. OSS is often mistaken for shareware or freeware, but there are significant differences between the licensing models and the processes between and within these types of software. It should be noted, however, that like all traditional software businesses, the business models based on OSS ultimately aim at generating profits. However, profitability and business models of OSS are still poorly understood phenomena, and there is no single framework that would explain the potential determinants of firm-level revenue model choices.

In this chapter, we make an attempt to identify key considerations in designing successful revenue models in the OSS business. We explore the revenue models of two selected OSS business cases. Through these cases, we aim at identifying the firm-specific business model elements that guide, enable and constrain the choice of revenue model options in OSS business. As a limitation to the analysis presented in this chapter, we leave the exogenous factors (such as competition and other environmental factors) beyond the scope of our consideration.

BACKGROUND

In this chapter, we discuss the background of the OSS business, typical licence OSS choices, and the potential for conducting for-profit business with OSS.

Development of OSS Business

The history of the open source movement goes back to the early ages of computing. In the 1960s and 1970s, it was common for programmers in certain academic institutions (e.g., Berkeley, MIT) and corporate research centers (e.g., Bell Labs, Xerox's Palo Alto Research Center) to share computer program source codes with other programmers. It was not until the early 1980s that proprietary software became very popular, thus causing problems with cooperative software development (Lerner & Tirole, 2002). The predecessor of the open source movement, the Free Software Foundation (FSF), was founded in 1983 by MIT employee Richard Stallman in his attempt to formalize cooperative software development and create a complete free[1] operating system with necessary software development tools. This project was called the GNU Project. Stallman's general concept of free software possesses four essential freedoms (Stallman, 1999):

- Freedom to run the program
- Freedom to modify the program
- Freedom to redistribute the program
- Freedom to distribute modified versions of the program

Stallman didn't want to release software with restrictive copyright terms because it would prevent certain forms of valuable cooperation. On the other hand, releasing software to the public domain would leave it vulnerable to be copyrighted and included in proprietary packages. Thus, Stallman came up with the idea of copyleft, or protecting the freedom of software with the means of copyright laws. In addition, copyleft ensures that the modified works are also released under copyleft terms and, therefore, to the use of the community. Stallman, (2002) argues, "Proprietary software developers use copyright to take away the users' freedom; we use copyright to guarantee their freedom. That's why we reverse the name, changing 'copyright' into 'copyleft.'" To implement this idea, the FSF developed the GNU General Public License (GNU GPL), the first of the now extensive selection of copyleft licenses that are used to protect free/OSS. Meanwhile, the open anticommercialism of FSF led to a group of free software movement leaders deciding to find new ways to strengthen their cause, but with less radical means. They came up with the term "open source," which they thought would better describe the software ideals, and founded the Open Source

Initiative (OSI). The idea of the organization was to promote the Open Source Definition (OSD), a set of terms for licences, which is more adaptable to commercial use than the approach FSF took. OSI has since registered a certification mark, and there is a variety of OSI-certified licenses (including GNU GPL and other copyleft licenses).

What motivated the birth of OSI was the way free software was being developed in such projects as the Linux operating system since the beginning of the 1990s. The new development model introduced in the Linux project was first described in "The Cathedral and the Bazaar," an essay written by Eric Steven Raymond, one of the founders of the OSI (Raymond, 2001). The Linux development model was seen as a better way of software development that could lead to higher quality and rapid advancement. Cooperational software development was not only for the ideologists and community-spirited anymore, but rather something also to be used in more commercial projects. The new emphasis born with the OSI made it possible for the business world to intensively embrace OSS. Before 1998, relatively few people in the IT industry knew about free software; however, a couple years later, open source was on many people's lips. With the participation of big IT companies such as IBM, Hewlett Packard, and Nokia, open source has become a credible player in the IT field.

OSS Licensing

OSS, exactly defined, is software fulfilling the terms of distribution given in the OSD and adopting a license approved by the OSI (Open Source Initiative, 2004). Summarizing the ideas behind the terms in OSD, the software license must generate the following effects:

- Source code must be readable and available, either included with the binary code or publicly downloadable
- Free distribution of the software by any party, on any medium, to any party, gratis or for a fee
- Derivative works must be allowed, either under similar license or not, depending on the specific OSS license type
- No discrimination against persons, groups, or fields of endeavor

The nature of OSS is in the licensing terms and not just the accessible source code, which is just one part of the features the licensing terms generate. In addition, the licensing terms allow the free use, redistribution, and modification of the software. The copyright owner preserves the moral rights and some economic rights, such as the right to dual-license the software, but transfers many important rights to the users and developers of the software in order to enable the development of the software and to increase its adoption. It is important to understand that the OSD licensing terms allow the creation of many types of OSS licenses, each with different qualities. Välimäki (2005) categorizes OSS licenses into three functionality classes, ranging from the most liberal to the most restrictive. The categories are permissive licenses, licenses with standard reciprocity obligation, and licenses with strong reciprocity obligation. Standard reciprocity means that the distribution terms of the source code must be maintained in further developed versions, which is also called the "copyleft" effect. Strong reciprocity obligation means that in addition to standard reciprocity effects, derivative works and adaptations must keep the licensing terms intact, also called the "viral" effect.

Välimäki (2005) has studied the prevalence of different OSS license types. Table 1 presents the most popular licenses as surveyed in his study at SourceForge.net in 2004 (Välimäki 2005), together with their functionality and relative popularity in project licensing.

In Table 1, the popularity percentage refers to the occurrences of these license types among

Table 1. Most popular OSS licenses and their functionality (Source: Adapted from Välimäki, 2005)

License	Functionality	Popularity
GNU GPL	strong reciprocity	66.50%
GNU LGPL	standard reciprocity	10.60%
BSD	permissive	6.90%
Public domain	permissive	2.70%
Artistic	permissive	2.00%
MIT	permissive	1.70%
Mozilla	standard reciprocity	1.50%
Common Public License	strong reciprocity	0.60%
Zlib	permissive	0.50%
QPL	strong reciprocity	0.40%
Open Software License	strong reciprocity	0.40%
Python License	permissive	0.40%
Academic Free License	permissive	0.30%

all OSS licenses (surveyed at the SourceForge.net in late 2004).

Special Characteristics of OSS Business

One of the most critical issues for OSS business is that the licensing terms allow free redistribution of the licensed software (i.e., the licenser doesn't necessarily gain any revenue from these copies of the software). In fact, charging a fee for OSS is usually not feasible, because (1) any buyer may start to resell the software or give it away and (2) fees could severely diminish the rate at which both developers and users adopt the software product (De Laat, 2005), which often is the motivation behind licensing a product as OSS. Therefore, it is usually not feasible to base the revenue logic on licensing fees. It is also possible to use OSS as part of a firm's other products; namely, software packages, hardware, and/or services. This approach is not free of challenges either, since the unique licensing of OSS may create risks as well as opportunities.

Many firms conducting business with OSS are in some way dependent on the OSS community for developing software in their product offerings, for support, or for customers. However, the OSS community is outside the hierarchical control of the firms since there are normally no contractual agreements between them. In addition, the idea of exploiting the financial value of a jointly developed community might go against the values of the community (Dahlander & Magnusson, 2005) in which the code is actively protected from being appropriated by commercial firms through the use of legal and normative mechanisms (O'Mahony, 2003). However, the attitudes and policies toward the commercial exploitation within the OSS community range from the critical attitudes of FSF

Table 2. Firm-community relationship (Source: Modified from Dahlander & Magnusson, 2005)

Approaches	Description	Nature of Relationship
Parasitic approach	Focuses on firm's own benefits without considering possible damages to the community	Search for useful input without obeying norms, values, and rules
Commensalistic approach	Firm aims to benefit from the community	Search for useful input from the community
Symbiotic approach	Firm tries to codevelop itself and the community	Give something to the community, often through a firm-established community

and copyleft licensing to the more liberal attitude of OSI and permissive licenses.

Dahlander and Magnusson (2005) propose three approaches a firm can use to relate to the OSS community. In question is the parasitic approach in which the firm focuses on its own benefits without considering possible damages to the community. Since the firm doesn't share the norms, values, or rules of the community, the possibility to influence community development does not exist. The commensalistic approach is about benefiting from the community while leaving it otherwise indifferent. Since the firm isn't considered hostile, influencing the community is possible but difficult. Also in question is the symbiotic approach in which the firm tries to co-develop itself and the community. This demands heavy involvement in community development and sharing of norms and values but also allows influencing community development in a desired direction. These approaches are illustrated in Table 2.

MAIN FOCUS OF THE CHAPTER

According to recent studies, the business-model concept includes some elements of business strategy and aims to describe the business as a manifestation derived from strategy (Rajala, Rossi, & Tuunainen, 2003; Osterwalder, 2004; Morris, Schindehutte, & Allen, 2005). It has also been defined as an abstraction of business (Seddon & Lewis, 2003), which characterizes revenue sources and specifies where the company is positioned in its value-creating network in a specific business. The essential elements of various business models are defined in different words by several researchers (Rajala et al., 2003; Hedman & Kalling, 2003; Osterwalder, 2004; Morris et al., 2005, Rajala & Westerlund, in press). Many of the studies identify a number of elements that are characteristic of various business models. These elements, expressed in different words by different authors, include the following: (1) offerings; (2) resources needed to develop and implement a business model; and (3) relationships with other actors (Timmers, 2003; Osterwalder, 2004; Morris et al., 2005). Finally, these elements are interconnected with (4) the revenue model, including sources of revenue, price-quotation principles, and cost structures, which is characteristic of a particular business. Grounded on the previous review and summation of the prior research literature, we identify three business model elements in order to describe the revenue models in the OSS business. These

business model elements are key considerations on which firms should focus after the decision to participate in an OSS business. In the following we discuss these elements in detail.

Offering

In the literature of business and management, the concepts of product strategies and product offerings are discussed widely (Cravens, 1987; Kotler, Armstrong, Saunders, & Wong, 1996). We see that offerings embody several aspects within the concept of a business model and, thus, affect the revenue model. Generally, type of offering, target market, product vs. service orientation, licensing model, and so forth, can be considered as aspects related to the product strategy. Likewise, the product offering includes aspects such as complexity, the essential benefit that the customer is really buying, and product features, styling, quality, brand name, and packaging of the product offered for sale (Kotler et al., 1996).

From the business model perspective, a defining characteristic of OSS as a product is that it is not a physical but rather an information product. Information, or digital, products have unique characteristics that differ largely from physical product characteristics. However, certain open source business models, such as widget-frosting and accessorizing (see the following), consist also of physical products. In addition, OSS revenue models such as support selling, service enabling, and software franchising, are comprised mostly of service components, which also have a very different nature.

In addition to the type of offering, license types are considered part of the offering element in our conceptual model as a determinant of revenue model choices. Indeed, the licensing issues and commitment to the principles of OSS licenses (GPL, etc.) are key issues related to information products such as OSS solutions (Lee, 1999).

Resources

The development of resources in the industrial-network perspective is linked to its strategy (Håkansson & Snehota, 1995; Gadde & Håkansson, 2001; Sallinen, 2002). According to this view, resources vary according to the business and product strategy. The resources and capabilities of a firm are among the central issues in understanding and analyzing its business. This accentuates the essence of resources in core competencies (Selznick, 1957; Prahalad & Hamel, 1990), as they are generally seen as firm-specific property that is subordinate to the core competencies. The resource-based view of the firm originated from the work of Penrose (1959) and was further developed by Wernerfelt (1984). According to Penrose (1959), bundles of resources that are activated in different ways lead to incoherent performance and heterogeneous outputs in various organizational settings.

In our analysis of the resources in the OSS business, we share the view of Metcalfe and James (2000), who define tangible and intangible assets as physical and nonphysical resources, and capabilities as intangible knowledge resources. Furthermore, we see that the increasing complexity of OSS markets makes it difficult for firms to have all the necessary resources in their possession to compete effectively. This view is consistent with the research of Ariño and de la Torre (1998). These resource-related approaches provide us with a basis on which to identify key resources in various types of OSS business models. They deepen our understanding, especially of how resources are applied and combined by a firm, and take inimitable resources as a basis for the creation of sustainable capabilities as described in other technology-intensive industries such as those by Hart (1995) and Gabrielsson (2004).

Relationships

We see that the elements in our conceptual model are interrelated with each other and, therefore, are consistent with Håkansson and Snehota (1995) and Rosenbröijer (1998) that capabilities of a company reflect its success in combining resources to perform activities through internal and external relationships.

As pointed out in the previous discussion, we need to consider the interaction of companies with other actors as an inseparable part of a business model, similar to offerings and resources. Timmers (2003) points out that in the context of business models, the focus shifts from creating value through internal activities to creating value through external relations. He identifies these relationships within the value-creating network as an important element in the development and distribution of offerings. In addition to being an important intangible company asset, a firm's network offers access to the resources of other network actors (Foss, 1999; Gulati, Nohria, & Zaheer, 2000; Chetty & Wilson, 2003, Möller & Svahn, 2003).

Revenue Model

Discussion of the revenue models in the context of OSS has traditionally been problematic since the OSS movement emphasizes free distribution of intellectual property. However, since the emergence of the OSS movement, there has also coexisted a favorable attitude toward earning money and, more generally, toward profit-oriented behavior based on the OSS (Raymond, 2001).

Concerning open source as an economic phenomenon, De Laat (2005) argues that whether an enterprise involved in the open source business chooses to license its own software product as open source or tries to benefit from existing OSS products, the ways of making money with open source are basically the same. These ways include selling services to facilitate OSS use, selling connected hardware, and selling commercial closed applications to use with OSS. However, Hecker (1999) has identified eight possible revenue models to be applied in conjunction with OSS. These models are described in Table 3.

Although Hecker's list of OSS revenue models (summarized in Table 3) was published as early as 1999, it still remains one of the most comprehensive classifications of OSS revenue models. It clearly points out that a company has a multitude of options to capture revenue with OSS.

CASE EXAMPLES

In our literature review, we identified three endogenous business model elements (i.e., offering, resources, and relationships) that affect the revenue models in the OSS business. In this chapter, we illustrate these determinants and their interconnectedness with the revenue model in two empirical examples: MySQL and RedHat. We see that these case examples improve understanding of the interrelatedness of these business model elements, and especially their role as determinants in setting up the revenue model. Furthermore, the cases illustrate the complexity and heterogeneity of solutions and options related to revenue models in the field of OSS business.

MySQL

The MySQL trademark and copyright are owned by the Swedish company MySQL AB. Two Swedes, David Axmark and Allan Larsson, founded MySQL AB, together with Michael "Monty" Widenius, a Finn who is broadly appreciated as the chief designer and developer of the system. The company develops and maintains its key product offering, the MySQL open source database system, in close collaboration with the

Table 3. Summary of OSS revenue models (Source: Modified from Hecker, 1999; Välimäki, 2005)

Revenue Model	Description	License Types	Revenue Sources
Support selling	A for-profit company provides support for a software that is distributed free of charge.	Any	Revenue comes from media distribution, branding, training, consulting, custom development, and post-sales support for physical goods and services.
Loss-leader	A no-charge open source product is used as a loss leader for traditional commercial software (i.e., the software is made free by hoping that it will stimulate demand for a related offering of the company).	Varies	Complementary offerings (e.g., other software products)
Widget-frosting	Companies that are in business primarily to sell hardware can use this model to enable software such as driver and interface code. By making the needed drivers open, the vendor can ensure that they are debugged and kept up to date.	Any	The company's main business is hardware. This is quite similar to the loss-leader model.
Accessorizing	Companies that distribute books, computer hardware, and other physical items associated with and supportive of OSS.	Any	Supplementary offerings
Service enabler	OSS is created and distributed primarily to support access to generating revenue from consulting services and online services.	Any	Service fees
Brand licensing	A company charges other companies for the right to use its brand names and trademarks in creating derivative products.	Strong reciprocity	Copyright compensations
Sell it, Free it	A company's software products start out their product life cycle as traditional commercial products and then are converted to open source products when appropriate.	Alteration of license type	Initial revenue from software product offerings converted into other models (e.g., the loss-leader model)
Software franchising	A combination of several of the preceding models (in particular, brand licensing and support sellers) in which a company authorizes others to use its brand names and trademarks in creating associated organizations doing custom software development; in particular, geographic areas or vertical markets.	Strong reciprocity	The franchiser supplies franchisees with training and related services in exchange for franchising fees of some sort

OSS community over the Internet. Unlike projects such as Apache, MySQL is owned and sponsored by a single for-profit firm, MySQL AB. In addition to providing the database product under the GPL license, the company sells support through service contracts as well as commercially-licensed copies

of the MySQL database software, and employs people all over the world to communicate about the use and development of the product.

Offering

The offering of MySQL AB is a multithreaded, multiuser SQL (structured query language) relational database server (RDBS) software. The software is available either under the GNU GPL or under other licenses when the GPL is inapplicable to the intended use. MySQL provides database products for integrating software vendors and original component manufacturing (OCM) partners, enterprise organizations, and private users in the OSS community. To distribute its offering to a large number of users worldwide, MySQL AB has applied a dual licensing principle by making the MySQL database software available for free on the Internet under the GPL and selling it under proprietary licenses when the GPL is not an ideal option and in situations such as inclusion of MySQL technology in closed source products. In summary, the core offering of MySQL AB embodies an in-house developed software product and related services.

Resources

As a symbol of the key resources of MySQL AB, chief technology officer Widenius began programming databases in 1981. He worked previously in Tapio Laakso Oy developing systems that needed data storage. Similarly, Axmark and Larsson, his two colleagues and later cofounders of MySQL, collaborated in programming projects from 1983 to 1995 and accumulated knowledge about database systems. By licensing the MySQL product under an OSS license, the company transferred some of its internal intellectual property resources to the open source community, thus gaining possible future clients as well as developers and enthusiasts to support its offering. The internal programming resources can still be considered the key element in the MySQL business model. Currently, 80% of the source code in the MySQL core database product (version 4.0) is programmed by in-house programming resources; the company has systematically invested in professional management resources to successfully manage its growing for-profit business.

Relationships

As already described, the collaboration based on personal relationships between key individuals can be seen as the key determinant of success in the early phases of the MySQL product development. This open atmosphere and knowledge-sharing culture between the cofounders of MySQL AB provided a sound base for enlarging the network to OSS-oriented Internet communities. At present, partners in the business network of MySQL include companies such as suppliers, distributors, outsourcing service providers, other key companies in the OSS field, commercial research institutions, and other strategic partners. Relationships with these actors are based on commercial multi- or bilateral activity. Furthermore, relationships in the business network include collaboration with public (government) organizations, research institutes, and so forth.

Relationships within the OSS community are a multifaceted phenomenon. According to the company CEO, the community of 5 million MySQL users includes several groups that produce MySQL books and articles as well as conduct courses and presentations. Furthermore, these ecosystems develop applications in different OSS projects. Currently, MySQL AB is balancing between the OSS community and commercial business networks that have somewhat disparate needs and values. We see that MySQL AB depends on the OSS community for its ecosystems and even more for the customer base, but they mostly conduct the product development in-house. However, the company also has made a significant contribution to the OSS community by licensing the database as

an OSS. Therefore, we define MySQL's approach toward the OSS community as a symbiotic one.

The Revenue Model

MySQL AB is often cited as the champion of the second generation of open source projects. These projects are open source but are directed by for-profit companies. The revenues of these corporations derive from selling consulting services for their products. MySQL AB makes MySQL available under the GPL for free and sells it under proprietary licenses for clients when the GPL is not an ideal option (e.g., inclusion of MySQL technology in a closed source product). Currently, MySQL AB receives more income from proprietary license sales than from its other income sources, branding, and services. Its main income seems to come from embedded commercial users (Välimäki, 2003). In terms of Hecker (1999), the revenue models of MySQL AB include features from support selling and dual licensing, both of which can be considered incarnations of the loss-leader model.

Red Hat

The U.S.-based Red Hat is one of the world's leading Linux software provider and one of the highest profile companies employing OSS in its business model. Red Hat's offerings resemble those of a classical software vendor: software distributed on CDs or over the Internet, deployment support, add-on products, and so forth. The unique aspect of the business model is that, for the most part, Red Hat has neither developed the software offering itself nor paid the development for suppliers. The role of Red Hat in its value network is related to its main activities in packaging, branding, and distributing the open source Linux operating system, thus making it usable for those who are not familiar with the ins and outs of the constantly evolving project.

Offering

Red Hat offers Linux and open source solutions into the mainstream by making high-quality, low-cost technology accessible (Rappa, 2005). In particular, Red Hat provides operating system software along with middleware, applications, and management solutions. In recent years, the target market has shifted mainly to corporate customers, thus influencing the heavy emphasis on enterprise Linux and network tools. Major parts of the software offering are provided under the GPL, which governs the redistribution of source code as well as monetary licensing rights for the binaries (Microsoft, 2005). In addition, Red Hat offers support, training, and consulting services to its customers worldwide and through top-tier partnerships. These services range from complete Linux migration to client-directed engineering to custom software development, especially in industry-specific solutions.

Resources

From the perspective of Red Hat's business model, it is obvious that key resources are related to brands and their development and management, as well as to marketing and business management. The funding provided by investors has enabled Red Hat to systematically develop these resources. In addition to marketing and management capabilities, relationships with OSS communities as the supplier network form a key resource in Red Hat's business model. Indeed, the company makes an extensive use of external resources for developing the software in its offering. The internal production resources include personnel and technology aimed at producing services.

Relationships

Red Hat has succeeded in establishing strong ties with large enterprise and academic custom-

ers such as Amazon.com, AOL, Merrill Lynch, Credit Suisse First Boston, DreamWorks, VeriSign, Reuters, and Morgan Stanley. In addition, its customer portfolio includes local, state, and federal governments in various countries. The company also maintains key industry relationships with hardware and middleware suppliers. In June 2002, Red Hat, Oracle, and Dell formally launched a combined Linux effort that includes joint development, support, and hardware and software certification. It was considered as an emphatic declaration in the strategy of Red Hat to focus on enterprise customers. Due to the inherent sharing nature of OSS, Red Hat considers balance as a key aspect in building a successful business without sacrificing customer trust, and in creating shareholder value without severing ties to the open source community.

Red Hat is gaining significantly from the software produced in the OSS community. It participates in OSS and Linux development by collaborating in standards creation as well as sponsoring the Fedora Project. According to the classification of Dahlander and Magnusson (2005) presented in the theoretical part of the study, the company's approach toward the OSS community could be defined as a symbiotic relationship, although the emphasis on enterprise customers embodies commensialistic elements.

The Revenue Model

Despite the release of software under the GPL-license mode, the services employed by Red Hat for commercial viability places a layer of restriction upon the binary and source code usage based on support contracts. This hybrid approach enables the company to provide OSS solutions in a commercial way (Microsoft, 2005). Thus, the primary revenue model is currently what Red Hat calls "subscriptions," which allows the company to effectively develop and deliver its technology based on customer feedback, as well as to provide support to customers over the life of an agreement. In terms of Hecker (1999), we identify this revenue model as support selling.

It has been claimed that this is a high-margin activity demanding only a little investment (Mantarov, 1999). On the other hand, little investment means lower entry barriers, and support offers a very weak basis for differentiation to gain sustainable competitive advantage. Microsoft clearly has nearly a monopoly on desktop operating systems, but its market share in services related to desktop operating systems is much smaller. Thus, there is potential for revenue models based on service provisioning, as in some OSS-based businesses.

CONCLUSION

This chapter aims at identifying the key determinants of OSS revenue model choices. On the basis of our literature review and through our case studies, we see that there are several motives for firms to participate and contribute to the OSS movement.

In this chapter, we identify three business model elements that affect firms' revenue model choices. These identified elements are offering, resources, and relationships. The type of offering in terms of the user environment and, thus, the target market of the software (private vs. enterprise applications and desktop vs. server applications) constrain the possibilities to form a revenue model. Furthermore, the licensing model affects the revenue model choice through defining the free and commercial components, as well as the use and further development terms and conditions of the software.

In addition to the type of offering, we argue that a firm's resources are an important factor affecting the revenue model. We see that the internal resources and capabilities of firms are essential determinants of the actor-driven devel-

Table 4. Summary of the cases

Business Model Elements	MySQL	Red Hat
Offering	Core offering embodies an in-house developed database software product and related services.	Operating system software maintenance and services along with operating system software.
Resources	The internal programming resources and professional management resources.	Resources related to the development and management of brands, as well as to marketing and business management.
Relationships	Balancing between the OSS community and commercial business networks that have somewhat disparate needs and values. Dependence on the OSS community mainly as a user community.	OSS community as significant product developer.
Revenue model	A majority of revenue originates from proprietary license sales, and a smaller proportion stems from other sources such as services. The main income seems to come from business users. The revenue model includes features from support selling and dual licensing, both of which can be considered incarnations of the loss-leader model.	The primary revenue model is currently what Red Hat calls "subscriptions," which allows the company to effectively develop and deliver its technology based on customer feedback, as well as to provide support to customers over the life of an agreement. The revenue model is identified as support selling.

opment activity in the collection and integration of divergent OSS components into commercial offerings. Our cases illustrate that they strongly enable and constrain the possibilities to collect revenue based on OSS. Furthermore, relationships between business actors and the OSS community form the essential external resource and capability base of the firm. The importance of relationship management is emphasized in balancing between the noncommercial culture of OSS communities and the for-profit business networks. The objectives and characteristics of these two networks differ in terms of the development of loyalty, trust, and motivation of actors into activities in which some actors may benefit economically.

The managerial implications of this chapter suggest that profit-seeking firms in the field of OSS must maintain a balance between their profit-oriented business objectives and the noncommercial principles of the OSS community. This is consistent with Dahlander and Magnusson (2005), who argue that an intention to control the community development may allow a firm to manipulate the development toward its strategic goals, but might also diminish the creativity and general interest of the community toward the project.

Our empirical observations from the two case examples indicate that the selection of the revenue model is dependent on other business model elements. The case of MySQL illustrates

that the need to maintain relationships with both the OSS community and the business network has led to a revenue model based on dual licensing. In this model, the community has access to the software for free, but business users may buy a software license for their commercial purposes. Furthermore, the dual-licensing model used by MySQL illustrates that a change in any of the elements of the identified key determinants may affect the revenue model choice. In this model, the company owns all copyrights to the software and, therefore, can license the software with two licenses, one allowing gathering of revenue from sold copies of the software and the other based on the principles of the loss-leader model.

The lesson learned from the Red Hat case is that internal resources (e.g., well-known brands) and superior commercialization capabilities allow a company to benefit from the development efforts of the OSS community. The business model of Red Hat is based on the ecosystem developing the core product collaboratively. The role of Red Hat in this collaboration is to deliver the results of the development work commercially added with service elements essential for the users of software.

KEY TERMS

Business Model: An abstraction of business, or the manifestation of strategy, that characterizes the business and specifies in which the company is positioned in its value-creating network.

Offering: An inseparable part of a business model that includes aspects such as complexity; the essential benefit that the customer is really buying; and product features, styling, quality, brand name, and packaging of the product offered for sale.

Relationships: The ties and interaction of companies with other actors.

Resources: Specific properties that are subordinate to the core competencies of companies.

Revenue Model: The method of value capturing that includes the description of the sources of revenue, price-quotation principle, and cost structure.

Software Licensing: The definition and agreement of rights to use, redistribute, or modify software.

Source Code: The programming that allows software to perform a particular function or operation.

ENDNOTE

[1] The adjective "free" refers to freedom, not price.

Chapter 6.17
Knowledge Management and Organizational Performance in the Egyptian Software Firms

Ahmed Seleim
Alexandria University, Egypt

Omar Khalil
Kuwait University, Kuwait

ABSTRACT

Management research has often overlooked the role of knowledge and knowledge management (KM) in the analysis of organizations and their performance. Also, the literature on KM is short of empirical evidence on the likely interrelatedness of the KM processes. This investigation adopted a research model and used data from 38 Egyptian software firms to examine: (1) the relationship of the KM processes of knowledge acquisition, documentation, transfer, creation, and application to organizational performance, and (2) a number of relationships within the KM processes themselves. The results suggest that knowledge application influences organizational performance, knowledge acquisition and knowledge creation influence knowledge application, and knowledge acquisition and knowledge transfer influence knowledge creation. Although they provide a limited support to the research mode, the results signify the value of continued examination and enhancement of such a model.

INTRODUCTION

Knowledge is an asset that needs to be effectively managed (Davenport & Prusak, 1998; Drucker, 1993). Interest in knowledge management (KM) has grown dramatically in the recent years, as more researchers and practitioners have become aware of the knowledge potential to drive innovation and improve performance (e.g., Cavaleri, 2004; Machlup, 1962, 1983; Penrose, 1959). For an organization to remain competitive, it must effectively practice the activities of creating, acquiring, documenting, transferring, and applying

knowledge in solving problems and exploiting opportunities (e.g., Sambamurthy & Subramani, 2005; Zack, 1999).

Argote and Ingram (2000) argue what the organization comes to know explains its performance. The ultimate test of any business concept, such as KM, is whether it improves business performance. If organizations cannot use knowledge to improve performance, knowledge does not have measurable value (Gorelick & Tantawy-Monsou, 2005). However, management research has often overlooked the role of knowledge and KM in the analysis of organizations and their performance (Nonaka, 1994; Spender, 1996). Most of KM research consists of either theoretical analyses of KM issues or case-based reviews of organizations' KM practices. Consequently, KM research is short of offering an unambiguous understanding of the role of KM in improving organizational performance (Kalling, 2003).

On the other hand, effective KM entails an understanding of the interrelationships that may exist among KM processes such as knowledge acquisition, knowledge creation, knowledge documentation, knowledge transfer, and knowledge application (e.g., Lee, Lee & Kang, 2005; Seleim, Ashour & Khalil, 2005a). These processes are not necessarily sequential but rather iterative and overlapping (Holsapple & Joshi, 1999, p. 7-1; Lee & Choi, 2003). Furthermore, an analysis for the purpose of understanding the relationship of the KM processes to organizational performance is incomplete if it does not also include the analysis of the interrelationships among the KM dimensions themselves. In other words, effective KM requires an understanding of the direct and indirect influence of KM processes on organizational performance.

Thus far, the literature on KM is short of a cohesive theoretical framework that provides a structure that can be used to understand how to enhance KM within an organization as well as to assess the potential impact of KM efforts on organizational effectiveness (Hoffman, Hoelscher & Sherif, 2005). This research proposes and tests a model to explore the interrelationships among the KM processes as well as the relationship of the KM processes to organizational performance in the Egyptian software industry. The exploration of the possible interrelationships among the KM processes is believed to be an extension to the absorptive capacity theory (Cohen & Levinthal, 1990), which attends to the organizational processes and activities by which organizations acquire, absorb, transfer, and exploit organizational knowledge, and the SECI— socialization, externalization, combination, and internalization—model of knowledge creation (Nonaka & Takeuchi, 1995).

The article is organized accordingly. A background on KM is presented first, followed by the research method, research results, implications, and conclusions.

BACKGROUND

KM Processes

KM is a natural function in human organizations. Gorelick and Tantawy-Monsou (2005) view KM as a system or framework that integrates people, processes and technology to achieve sustainable results by increasing performance through learning. Therefore, effective KM requires viewing knowledge as a process rather than a resource (e.g., Alavi & Leidner, 2001; Davenport & Prusak, 1998; Lee & Choi, 2003; Spender, 1996).

Researchers have adopted different views of what the KM process entails. Johnston and Blumentritt (1998), for example, define the KM process to comprise knowledge identification, acquisition, generation, validation, capture, diffusion, embodiment, realization, and use. Zack (1999) asserts that KM includes the acquisition, refinement, storage, retrieval, distribution, and presentation of knowledge. Bennett and Gabriel (1999) view KM as a process that involves the cap-

ture, storage (i.e., documentation), dissemination, and use of knowledge. Also, Gold, Malhotra, and Segars (2001) view KM as a knowledge process capability that consists of knowledge acquisition, conversion, application, and protection. More recently, Salojarvi, Furu, and Sveiby (2005) view KM as a perspective on the management of the firm as a whole that encompasses activities in all relevant managerial areas.

Based on the aforementioned varying views of KM, these researchers classify the five fundamental dimensions of the KM process as knowledge acquisition (KA), knowledge creation (KC), knowledge documentation (KD), knowledge transfer (KT), and knowledge application (KAP). These five KM processes are likely interdependent (e.g., Darroch, 2003; Lee et al., 2005). Successful KM systems, which can be IT or non-IT based and aim to manage organizational knowledge, should support the performance of these KM processes (Alavi & Leidner, 2001; Edward, Feng & Liou, 2005; Jennex & Olfman, 2005). Moreover, organizational outcomes are a function of how well organizations can use, apply, and leverage what they know.

KM and Organizational Performance

The conceptualization of the relationship between KM and organizational performance can be traced back to the resource-based theory of the firm, the knowledge based theory of the firm, and the organizational learning theory. These schools of thought view organizations as systems for creating, using, and distributing knowledge (e.g., Grant, 1996; Spender, 1996); the success/performance of a firm is attributable to superior capabilities in knowledge processing (e.g., Hedlund, 1994; Reinmoreller & Chong, 2002).

According to the resource-based theory of the firm, the possession of unique resources such as knowledge within organizations is an important source of competitive advantage (Barney, 1991; Penrose, 1959; Prahalad & Hamel, 1990). Also, the knowledge-based theory of the firm focuses on applied knowledge as the most strategically significant resource of the firm. It postulates that the primary rationale for the firm is to produce, create, and transfer knowledge (e.g., Bierly & Chakrabarti, 1996; Choi & Lee, 2003; Demsetz, 1991; Grant, 1996; Nonaka, 1994; Nonaka & Takeuchi, 1995; Spender, 1994). Consequently, differences in the firms' performances are attributed to differences in the rules that the firms apply to knowledge creation, development, distribution, and usage.

Similarly, the organizational learning theory emphasizes the need for an organization to build its learning capabilities. Organizational learning is the process by which firms develop new knowledge and insights (e.g., Davenport & Prusak 1998; Garvin, 1994; Huber, 1991; Tippins & Sohi, 2003). From this perspective, KM is viewed as a process of capturing an organization's knowledge and using it to foster innovation through organizational learning (Nonaka, 1994; Nonaka & Takeuchi, 1995).

Scholars argue that the acquisition, creation, documentation/codification, transfer, and application of knowledge are the keys to achieving competitive advantage (e.g., Argote & Ingram, 2000; Connor & Prahalad, 1996; Darroch & McNaughton, 2002; Davenport & Prusak, 1998; Grant, 1996; Powell & Dent-Micallef, 1997; Rastogi, 2002; Spender, 1994), to improving organizational performance (e.g., Bassie, 1997; Teece, 1998), and to fostering innovation (e.g., Antonelli, 1999; Nonaka & Takeuchi, 1995). Holsapple and Jones (2004, 2005) propose a knowledge chain model that links KM to organizational performance. The model identifies five primary activities (acquisition, selection, generation, assimilation, and emission) and four secondary activities (leadership, coordination, control, and measurement) as focal points in improving organizational competitiveness. However, the model has yet to be empirically validated.

A number of researchers investigated the relationship between KM and different performance outcome measures. Gold et al. (2001) reported that KM capability, including knowledge acquisition, conversion, application, and protection are related to organizational effectiveness. Wiig (2002) empirically investigated how KM enhances decision making in public services, aids the public in participating effectively in decision making, builds competitive societal intellectual capital capabilities, and develops a knowledge management work force. Wiig's findings suggest the importance of having a comprehensive KM function in support of a public administration that allows the society to prosper and increase its viability by making its people and institutions work smarter.

Jennex and Olfman (2002) found information systems that incorporated organizational memory and knowledge improve productivity. Kremp and Mairesse (2004) found KM to influence a firm's innovative performance and productivity. Also, Liu, Chen, and Tasi (2004) found a positive and significant correlation between KM capability factors—for example, obtaining knowledge, refining knowledge, storing knowledge, and sharing knowledge—and competitiveness. Cavaleri (2004) underscores that reports of major cost reductions and performance increases as a result of KM initiatives have helped KM gain the attention of managers worldwide.

More recently, Edward et al. (2005) found that the adopters of KM systems gain a competitive advantage over the nonadopters. Salojarvi et al. (2005) examined the relationship between sustainable sales growth and KM activities in Finnish small and medium-sized enterprises, and found higher levels of KM maturity to be positively correlated with long-term sustainable growth. Lee et al. (2005) found a significant correlation between the KM activities of knowledge creation, accumulation, sharing, utilization, and internalization and three financial performance measures. In addition, Zhang, Tian, and Qi (2006) suggest a conceptual model describing the impact of organizational memory on organizational performance. The model was tested using data from Chinese manufacturing companies, and the results confirmed that organizational memory had a strong positive impact on organizational performance.

The Interrelationships among KM Processes

An understanding of the interrelationships among the KM processes is essential to the discovery of knowledge gaps, unused knowledge, and the development of knowledge maps in organizations (Liebowitz, 2005). This understanding helps organizations avoid randomized and unsystematic knowledge processes so that organizational knowledge is consistently and systematically developed (Ichijo, Krogh & Nonaka, 1998, p. 197). In addition, the coordination of KM dimensions is critical, since the shortage of any dimension may result in less than optimum outcomes of KM efforts (Darroch, 2003). Such coordination, however, requires a thorough understanding of the strength and direction of the relationships among the KM processes from a holistic perspective (Lee & Choi, 2003).

A number of scholars have conceptually deliberated on the interrelatedness of the KM processes. KM is viewed as a cross-functional, multifaceted phenomenon (Lee & Choi, 2003), and therefore, KM processes appear to be interconnected. Each KM process seems to depend on one or more of the other processes (Darroch, 2003). Beckman (1999, pp. 1-7) asserts that the KM processes often work simultaneously rather than sequentially.

Gold et al. (2001) present an integrative view of KM as a one knowledge process capability, which implies that the KM processes are complementary. For example, once knowledge is acquired, it needs to be documented in knowledge repositories in order to be transferred/shared, combined with

other knowledge to create new knowledge, and applied. Also, documented knowledge constitutes an important input for creating new knowledge and facilitating knowledge transfer, which, in turn, fosters knowledge creation and application. Furthermore, knowledge transfer and knowledge creation are critical elements and inputs for successful knowledge application.

Besides, the SECI model of knowledge creation (Nonaka & Takeuchi, 1995), which focuses on socialization, externalization, combination, and internalization, can provide another theme to establish the interrelationships among the KM processes. The common factor of the four processes of the model is knowledge sharing. Socialization is the process of converting new tacit knowledge through shared experience that allows non communicated knowledge to be communicated (Nonaka & Takeuchi, 1995); therefore, it involves knowledge transfer. Externalization is the process of articulating tacit knowledge into explicit knowledge that can be shared with others.

Combination and internalization are the processes of converging explicit knowledge into more complex and systematic sets of explicit knowledge. In these processes, knowledge is exchanged and reconfigured through documents, meetings, or communication networks, and the focus is on knowledge utilization (Nonaka & Reinmoeller, 2000, p. 90). Lee and Choi (2003) add that the SECI model includes not only knowledge creation but also knowledge transfer. Knowledge transfer, which is enabled by knowledge acquisition and documentation, is seen as a key element towards a better understanding of the knowledge creation process (Marr, Gupta, Pike & Roos, 2003). Also, transferring and sharing of knowledge from various sources is essential for knowledge application.

On the other hand, Alavi and Leidner (2001) argue that knowledge creation and codification do not necessarily lead to improved performance, nor do they create value. Value is created only when knowledge is located and transferred from its previous site and applied where it is needed. The creation, codification, and storage of new knowledge without its exploitation (e.g., application) lead to its underutilization as a driver of performance (Alavi & Tiwana, 2000).

Empirically, however, only few investigations aimed at exploring the interrelatedness of KM processes. Liu et al. (2004) found a significant correlation among all knowledge management capability factors of obtaining, refining, storing, and sharing knowledge. Faraj and Sproull (2000), for example, investigated the importance of coordination of expertise knowledge in 69 software development teams, and the results revealed that expertise coordination correlated strongly with team performance. Syed-Ikhsan and Rowland (2004) found knowledge that was created and stored on paper and electronic documentation to be positively related to knowledge transfer. They also found a negative but nonsignificant relationship between the status of knowledge documentation and the accessibility of knowledge assets.

To summarize, the review of the existing KM literature reveals that the direct relationship between KM processes and organizational performance has yet to be empirically explored and validated (Lee & Choi, 2003). In addition, the literature on KM is short of empirical evidence on the probable interrelatedness of the KM processes. A significant number of the cited relationships within KM processes and between KM processes and organizational performance are hypothetical. Therefore, the validation of such relationships is deemed important. Empirical evidence on the strength and direction of the interrelationships among KM processes and between KM processes and organizational performance should enhance our understanding of the KM dynamics, enable knowledge managers to justify resources allocation to KM, and achieve the required effective integration of KM processes.

RESEARCH METHOD

The Research Model

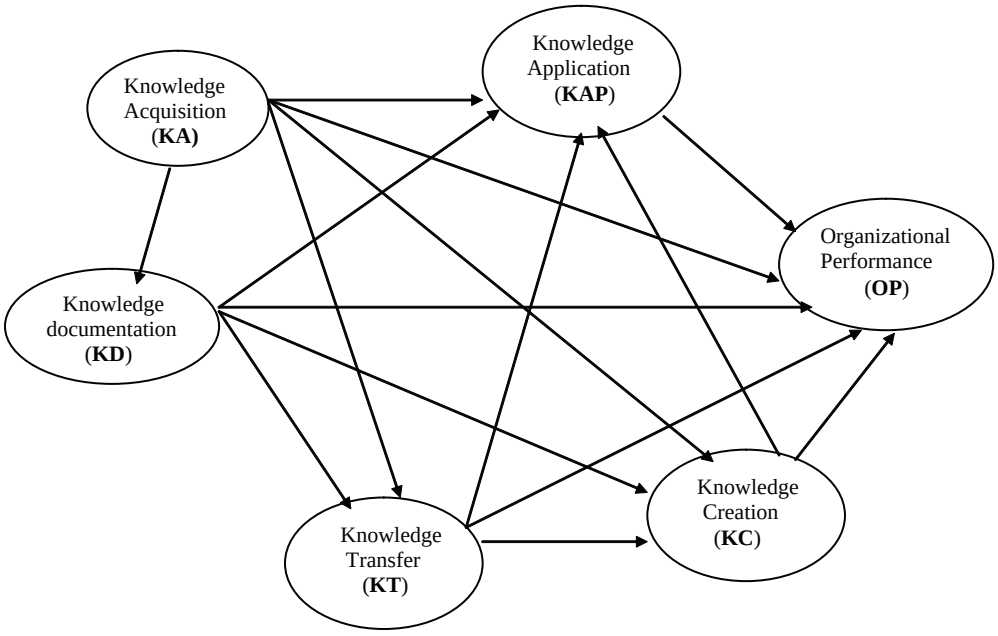
Figure 1 depicts the research model used in this study, including the research variables and the hypothesized relationships. The model is drawn based on the relevant KM literature reviewed in the previous section. The research model depicts two groups of relationships: (1) relationships between the five KM processes (KA, KD, KT, KC, and KAP) and organizational performance (OP), and (2) relationships among the five KM processes themselves. The model also implies indirect relationships between the KM processes and organizational performance.

Research Hypotheses

The KM Processes and OP Hypotheses (H1-H5)

1. KA and OP. KA was found to be related to innovation (Darroch & McNaughton, 2002). In addition, knowledge strategies (e.g., explorers, exploiters, loners, and innovators) were reported to influence organizational performance (Bierly & Chakrabarti, 1996; Pablos, 2002), where innovators and explorers tended to be more profitable than loners. In the international business field, Lyes and Salk (1996) found a significant relationship between KA and performance indicators.

Figure 1. The research model



Makino and Delios (1996) found that partnering with local firms could be a primary strategy for accessing local knowledge and improving joint venture performance.

KA activities—for example, active participation in professional networks or associations, regular attendance of courses, seminars or other training programs, collection of information about the needs of customers, hiring of consultants and new staff members, and so forth–are expected to enhance organizational performance. This expectation is formulated in the following hypothesis:

H1. KA positively influences OP.

2. KD and OP. KM research emphasizes KD as a critical KM process. Staff turnover is frequently cited as the main cause of the institutional memory loss (e.g., Mason & Pauleen, 2003), and the loss of organizational tacit knowledge (Stovel & Bontis, 2002). Therefore, KD is used as an important strategy to manage through the turnover dilemma, which could influence organizational performance (Hansen, Nohria & Tierney, 1999).

   Skandia Insurance Company, for example, was able to set up its office in Mexico in six months using formerly acquired and documented knowledge, whereas the task was expected to take seven years (Loermans, 2002). Documented knowledge is one form of the knowledge storage bins in the organizational memory that enables firms to avoid mistakes and capitalize on past experience (Walsh & Ungson, 1991). Therefore, KD is expected to be related to OP. This expectation is formulated in the following hypothesis:

H2. KD positively influences OP.

3. KT and OP. Wagner (2003) argues for the importance of knowledge transfer as a KM process. The foundation of knowledge transfer can be traced back to the past research on technology transfer, research and development (R&D) collaboration (Amabile, Nasco, Mueller, Wojcik, Odomirok, Marsh, et al. 2001), and strategic alliances (Borys & Jemison, 1989; Das, Sen & Sengupta, 2003). Such research provides evidence of the benefits of knowledge transfer. Bloodgood and Salisbury (2001) posit that knowledge transfer is beneficial to the organizations. Teece (2000) asserts that knowledge which is inside the minds of employees, the files, databases, and the like is of little value if it is not transferred to the right people at the right time. Also, Sveiby (2001) argues that knowledge transfer between individuals does not only benefit the organization but also improves the competences of the individuals that are involved in the process of knowledge transfer.

   Darr, Argote, and Epple (1995) found that knowledge transfer between the organizational units within the same corporation was essential to increased productivity. Tsai (2001) investigated the influence of knowledge sharing within organizations on outcome variables, and found that the absorptive capacity improved innovation and performance. Andersen Consulting saves millions of dollars a year in FedEx bills alone by using an intranet and other knowledge sharing tools (Stewart, 1997). Nelson and Cooprider (1996) found that increasing the level of shared knowledge between the information systems (IS) group and line groups improves IS performance. The ability to transfer and diffuse knowledge is expected to improve OP. This expectation is formulated in the following hypothesis:

H3. KT positively influences OP.

4. KC and OP. KC has become a critical element for organizational competitive advantage (Alavi & Leidner, 2001; Nonaka & Takeuchi, 1995; Syed-Ikhsan & Rowland, 2004). Linderman, Zaheer, Leidtke, and Choo (2004) speculate that quality management practices create knowledge that, in turn, contributes to organizational performance. Hussi (2004) adds that successful companies create sustainable value through the creation of knowledge. Kim and Kogut (1996) indicate that the capability of a company to improve its products relies on the accumulated knowledge from past experience, research, and experimentation.

   In addition, KC is perceived as an important element to new products development (Camelo-Ordaz, Fernandez-Alles, Martín-Alcázar, Romero-Fernández & Cabrera, 2004; Kim & Kogut, 1996), and an essential factor for the continuity and survival of the organization (Nonaka, Byosiere & Konno, 1994; Sharkie, 2003). Empirically, Lee and Choi (2003) found that KC was positively related to organizational creativity, which, in turn, was positively related to organizational performance. Therefore, organizations are expected to improve their performance outcomes through KC activities. This expectation is formulated in the following hypothesis:

H4. KC positively influences OP.

5. KAP and OP. The knowledge-based theory of the firm focuses on applied knowledge as the most strategically significant resource of the firm. In KM, emphasis should be on the application of knowledge, not merely on the acquisition and protection of such knowledge (Grant, 1996; Spender, 1994; Teece, 1998; Wiig, 1997). Demarest (1997) states that the application of knowledge should be the ultimate goal of any effective KM system. A firm that treats knowledge as a by-product of its operations rather than a purpose of those operations, especially in the knowledge intensive firms, will fail, not because it could not create knowledge, but because it could not apply it to create market-valued delivery in the marketplace.

   Hasan and Al-hawari (2003) speculate on the strong relationship between KM and organizational performance through making knowledge applicable to all organizational activities. Lopez, Peon, and Ordas (2004) add that the firm's ability to create and put knowledge into practice is a principal capacity in order to attain a sustainable competitive advantage. In addition, effective reuse of knowledge is frequently cited as an organizational concern that is related to organizational effectiveness (Markus, 2001). Therefore, organizations that emphasize the strategic value of managing the application of their knowledge (Bartlett & Ghoshal, 2000), and systematically apply their knowledge, are expected to capitalize on their performance. This expectation is formulated in the following hypothesis:

H5. KAP positively influences OP.

The KM Processes-Interrelationships Hypotheses (H6-H9)

The investigation of the interrelationships among KM processes is an extension to the absorptive capacity theory (Cohen & Levinthal, 1990) that stresses the organizational processes and activities, by which organizations acquire, absorb, transfer, and exploit organizational knowledge. The KM processes often work simultaneously rather than sequentially (Beckman, 1999, p. 1-7; Holsapple & Joshi, 1999, p. 7-1; Lee & Choi, 2003), are likely interrelated, and the ineffectiveness of

one or more of the processes may turn KM ineffective (Darroch, 2003).

The existing KM literature appears to be short of well-defined and broadly acceptable theories and frameworks that guide the formulation of hypotheses describing possible interrelationships among the KM processes. As a result, the researchers propose the following four hypotheses (*H6*-*H9*) in order to explore four sets of interrelationships among the KM processes.

6. The relationship of KA to KD. Once knowledge is acquired, it needs to be documented in knowledge repositories so that it can be transferred/shared and combined with other knowledge to create new knowledge (e.g., Nonaka & Takeuchi, 1995). When knowledge is acquired and becomes available (KA), it is expected to be codified and documented (KD) in order to be transferred and reused. This expectation is formulated in the following hypothesis:

H6. KA positively influences KD.

7. The relationship of KA and KD to KT. For knowledge to be transferred and shared (KT) by people and organizational units, the knowledge must exist (KA) in a form (KD) that facilitates its transfer. Syed-Ikhsan and Rowland (2004) found the knowledge that was acquired and documented positively related to KT. Therefore, KA and KD are believed to be important processes for KT. This expectation is formulated in the following hypothesis:

H7. KA and KD positively influence KT.

8. The relationship of KA, KD, and KT to KC. Knowledge cannot be created in a vacuum. To create new knowledge (KC) through experience, research, and experimentation, prior knowledge (KA) must be available in a form (KD) that can be transferred and shared (KT) by those who are responsible for performing tasks and/or conducting research. Nonaka and Takeuchi's (1995) SECI model of knowledge creation establishes the interrelationships among the KM processes. The common factor of the four processes of the model is KT (Lee & Choi, 2003), which is seen as a key element towards a better understanding of the knowledge creation process (Marr et al., 2003). The expected relationships of KA, KD, and KT to KC are formulated in the following hypothesis:

H8. KA, KD, and KT positively influence KC.

9. The relationship of KA, KD, KT, and KC to KAP. Knowledge application is the ultimate goal of KM. For knowledge to be used and applied (KAP), it must be acquired (KA) and/or created (KC), documented (KD), and transferred (KT). Value is created only when knowledge is located, transferred, and applied where it is needed (Alavi & Tiwana, 2000). Gold et al. (2001) add that knowledge transfer and knowledge creation are critical elements and inputs for successful knowledge application. Documented knowledge constitutes an important input for creating new knowledge and facilitating knowledge transfer, which, in turn, fosters knowledge creation and application. The expected relationships of KA, KD, KT, and KC to KAP are formulated in the following hypothesis:

H9. KA, KD, KT, and KC positively influence KAP.

Research Variables

a. Organizational performance (OP). OP is the dependent variable in the research model, and refers to an organization-level performance relative to the competition.

b. KM variables. The five KM variables are defined as follow:
   1. KA includes activities that select and acquire external knowledge (e.g., via journals, magazines, books, Web sites, professional meetings, etc.).
   2. KD involves activates that institutionalize knowledge in the form of an organizational memory so that it can be transferred and reused in the future.
   3. KT includes activities that enable the exchange of knowledge between individuals, groups, organizational units, and at the different organizational levels.
   4. KC comprises activities that develop and create insights, skills, and relationships in the organization as well as the generation of internal knowledge (e.g., through experience, experimentation, special groups such as R&D, etc.).
   5. KAP refers to the organization's use of the available knowledge in order to improve its processes, products and services, and organizational performance.

Measurement

1. OP. Measurement of organizational performance is one of the most difficult issues that researchers have to deal with. Performance measures can be obtained from either primary or secondary sources. Also, these measures can be objective or subjective. Subjective or indirect measures for OP may represent an adequate alternative for objective or direct measures, especially when the financial data are unavailable (Dess, 1987; Dess & Robinson, 1984; Powell, 1992; Powell & Dent-Micallef, 1997; Spanson & Lioukas, 2001; Tippins & Sohi, 2003).
   In addition, Venkatraman and Ramanujam (1987) demonstrate that managers tend to be less biased in their assessments of their organizational performance than what researchers had believed. They state that perceptual data from senior managers can be used as acceptable criteria for organizational performance. Other researchers found the measurements of perceived organizational performance to have positive and significant correlations with objective measures of financial performance (Delaney & Huselid, 1996; Dollinger & Golden, 1992; Hansen & Wernerfelt, 1989; Powell, 1992).
   Because objective measures of OP were unavailable in the investigated firms, the researchers had to use a self-reported item that asked each respondent to indicate the performance of the respondent's firm relative to the competitors in the software market. The question used a five-point Likert scale, whereas 1 = very low and 5 = very high.
2. The KM variables. A generally accepted measuring instrument for KM constructs is currently lacking. The scale used in this investigation is a modified version of the original survey of Filius, de Jong, and Roelofs (2000). The items that measure the five KM constructs use a 5-point Likert-type scale (1 = very low practice and 5 = very high practice). A number of items have been added in order to strengthen the original survey and fit it to the Egyptian context.
   In the course of modifying the instrument, one item (item 3, knowledge gap diagnostic) has been adopted from Hall and Andriani (2002) and added to the KA items. Another item (item 15, use of knowledge maps and networks) has been added to the KD items. In addition, four items (items 17, 18, 20, and 25) have been added to the KT part of the instrument. These four items include statements regarding extraction of experience and knowledge of experts, keeping knowledge and know-how away from others in the firm,

distributing knowledge in formal ways, and using methods and mechanisms for knowledge exchange among employees.

Furthermore, four items (items 30, 33, 35, and 36) have been added to modify the KC part. The added items cover the existing idiosyncratic knowledge resources in the firm, development of important knowledge at the industry level, conducting benchmarking analysis, and data mining. In addition, four items (items 43, 44, 45, and 46) have been added to strengthen the KAP section of the instrument. The four items address knowledge integration, leveraging and improving knowledge usage, discovering problems that cause gaps between targets and achievements, and the ability of the firm to use its knowledge in different projects.

The instrument was tested and revised a number of times in order to fit the context of the study. The final instrument (in Arabic) includes two sets of questions. The first set consists of 46 items to measure KM variables. The second set comprises questions that are designed to gather data on each firm's performance and the firm's background such as age, number of software developers, and the number of other employees in the firm. Appendix A includes an English copy of the adopted KM survey.

Sampling

A cross-sectional field survey strategy was chosen for this investigation. This investigation focused on the software companies in the Egyptian private sector as the primary population. Software firms were selected because of the relevance and usefulness of KM practice in software industry, which is a knowledge intensive industry (Mathiassen & Pourkomeylian, 2003). In addition, the software development in Egypt is a promising industry. With more than 200 software firms and over 2,000 programmers, Cairo, Egypt has established itself as the software development hub of the Arab world (Albrecht, 1996). In the year 2000, the software exports were estimated at $50 million, and expected to eventually reach as high as $600 million within a year (Howeidy, 1999). Moreover, Egypt has thousands of qualified software professionals and has become a major supplier of software products, services, and software developers to its neighboring Arab countries.

The research population consisted of 107 software companies which were members in the Egyptian Chamber of Software Industry. Upon an initial contact with these firms, which are located in the Cairo and Alexandria areas, 38 firms agreed to participate in this investigation. The firms' CEOs or their representatives were asked to answer the survey questions in a structured interview setting.

The research sample (n = 38) represents 35.5% of the total population. Most of the firms in the entire sample are relatively small, with averages of 62 total employees and approximately 26 software developers. The largest firm has 300 employees, 80 of whom are software developers, and the smallest firm has only 5 employees, 2 of whom are software developers. In addition, the firms in the sample are relatively young (the average age in the sample is less than eight years), with the oldest firm only seventeen years old, and the youngest two years old. However, the relatively high standard deviations suggest wide dispersions in the firms' number of employees and ages.

Tables 1 and 2 summarize the respondents' characteristics, including level and type of education and tenure in the firm and in the software field.

Reliability and Validity

The reliability of the KM scales was assessed by estimating the latent variables' composite scale reliability, which is a measure of internal consistency reliability analogous to Cronbach's alpha. Table 3 shows that all the composite scale

Table 1. The respondents' educational characteristics (N = 38)

Respondents' Characteristics	Frequency	Percentage
Level of Education:		
Graduate	7	18.4
Undergraduate	31	81.6
Total	38	100
Educational background:		
Engineering	18	47.4
Business	13	34.2
Computer and Information	4	10.5

Total	38	100

Table 2. The respondents' experiences

Years of experiences	Minimum	Maximum	Average	Standard Deviation
Tenure in the firm	1	22	5.28	4.88
Tenure in the industry/ field	1	32	10.86	7.36

reliability coefficients for the five KM variables were higher than .70, the criterion recommended by Fornell and Larcker (1981). Fornell and Larcker (1981) also recommend the use of average variance extracted (AVE) by the latent variables from the observed or manifest variables as another index of internal consistency reliability. In Table 3, the AVEs for the five KM variables (KA, KD, KT, KC, and KAP) are .468, 486, .447, .527, and .518, respectively. The AVEs are either greater than the recommended 0.5 (House, Spangler & Woycke, 1991) or close to it. In addition, the factor loading of the indicators associated with the five KM variables are all higher than the recommended level (0.55) for adequate practical significance (Hair, Anderson, Tatham & Black, 1998, p. 111).

This procedure has lead to the exclusion of 17 items in order to improve the reliability and validity of the KM instrument (Table 3). The final scale consists of 29 items that measure the five KM constructs.

To assess its content and face validity, the instrument was pretested and refined several times as a result of feedback received from a number of experts in software development in Egypt as well as from a number of academicians at Alexandria University, who were asked to comment on the clarity and the relevance of the measures. After

the preliminary test, a pilot study was conducted with the participation of six software firms in order to evaluate the instrument and its administrative procedures.

The convergent validity was assessed by examining the factor loading of each manifest variable on its latent variable. If the manifest variables load high on the latent variable, there is evidence for

the convergent validity of the measure (e.g., House et al., 1991). As shown in Table 3, all observed variables had factor loadings on their respective latent variables greater that .5, which has been traditionally accepted in principle component factor analysis and exploratory factor analysis.

The discriminant validity of the measures was examined following the recommendation of House et al. (1991); discriminant validity exists if the correlation between two composite constructs is not higher than their respective reliability estimate. Using this criterion, the comparison between the reliability estimates (Cronbach's alpha) for the research variables in Table 3 (.814, .789, .827, .868, .894, and 1, respectively), and the correlations among the variables (Table 4) shows that the correlation coefficient are not higher than the reliability estimates.

Discriminant validity can also be demonstrated if the square root of the average variance extracted in the measurement model is higher than the correlation between the construct and the other constructs in the correlation matrix (Fomell & Larcker, 1981). The diagonal elements are the square roots of the average variance extracted. Off-diagonal elements are the correlations between constructs. In Table 5, the square root of the AVEs for KA, KD, KT, KC, KAP, and OP are .684, .697, .668, .725, .719, and 1, respectively.

While KD and KT satisfy the discriminant validity criterion, the AVEs for KA, KC, and KAP are slightly lower than their correlations with

Table 4. The correlation matrix of the research variables

The Variables	KA	KD	KT	KC	KAP	OP
1. KA	1.000					
2. KD	.280	1.000				
3. KT	.393*	.212	1.000			
4. KC	.684**	.343*	.531**	1.000		
5. KAP	.706**	.282	.575**	.750**	1.000	
6. OP	.065	.331*	.168	.073	.255	1.000

**p <.05; **p < .01*

Con-structs	KA	KD	KT	KC	KAP	OP
1. KA	.684					
2. KD	.280	.697				
3. KT	.393	.212	.668			
4. KC	.684	.343	.531	.725		
5. KAP	.706	.282	.575	.750	.719	
6. OP	.065	.331	.168	.073	.255	1.000

some of the other KM variables in their respective rows and columns. Based on the results of the two discriminant validity tests, we may conclude that the KM measures used in this investigation have adequate discriminant validity.

RESULTS

Descriptive Statistics

Table 6 display a summary description of the mean, standard deviation, maximum value, and minimum value for each of the five KM variables and the organizational performance (OP) variable. The results indicate that the respondents generally agree that their firms moderately practice the five KM processes, and their practice of KD (mean = 3.51) and KAP (mean = 3.51) is slightly higher than their practice of KA (mean = 3.19). In addition, KC practice (standard deviation = .66) seems to be the most dispersed and KT practice (standard deviation = .48) to be the least dispersed practice in the investigated firms.

On the other hand, the respondents feel that, on average, their firms perform well (mean = 4.18), compared to the competitors, and the performance scores seem to slightly fluctuate from one firm to another (standard deviation = .69).

Testing the Research Hypotheses

The partial least squares (PLS) method was used to test the hypothesized relationships in the research model (Figure 1). PLS is a technique for estimating path models involving latent variables indirectly observed by multiple indicators (Fornell & Cha, 1994). It maximizes the explanatory power of a conceptual model by examining the R^2 values for the dependent (endogenous) variables (Hulland, 1999). PLS was chosen in the present study because it does not require multivariate normal data, and it is appropriate for the analysis of a small sample size (e.g., House et al., 1991).

Testing the Hypotheses on the Relationships of KM Processes to OP

Figure 2 displays the final research model in a structural equation map. The PLS results show that the KM processes explain 19.7% of the variance in OP, the endogenous variable. The explanatory power of the model is relatively reasonable for such new measures and phenomenon. This result also supports the significance of the KM processes to organizational performance.

The examination of the effect of each KM process on OP (Table 7) reveals that only the path from KAP to OP (*H5*) has a positive and significant

Table 6. Descriptive statistics for the research variables

Research Variables	N	Minimum	Maximum	Mean	Standard Deviation
KA	38	1.86	4.29	3.1955	.5592
KD	38	1.57	4.43	3.5075	.5404
KT	38	2.27	4.27	3.3852	.4761
KC	38	1.73	5.00	3.3876	.6616
KAP	38	2.00	4.80	3.5053	.5927
OP	38	3.00	5.00	4.1842	.6919

Figure 2. The research model results

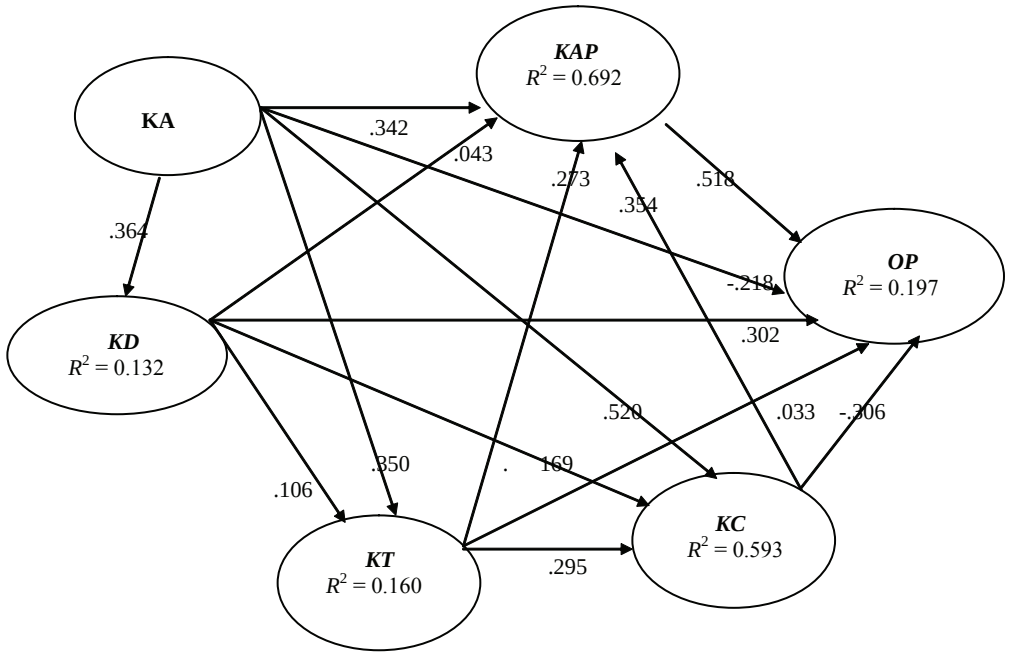

Table 7. The relationships of KM processes to OP

Dependent variable	Independent Variables	R^2	Hypotheses
OP	All KM variables	.197	*H1-H5*

Dependent Variables	Independent Variables	Hypothesis Number	Predicted Path Coefficient	Standardized Path Coefficient
OP	KA	*H1*	−	.218 T =. 8106
	KD	*H2*	+	.302 T = 1.1106
	KT	*H3*	+	.033 T = .1764
	KC	*H4*	−	-.306 T = .8784
	KAP	*H5*	+	.518 T = 2.1185

beta coefficient of .618 (T = 2.1185). These results suggest that, since KAP influences OP, there must be processes and systems that facilitate knowledge application in order to enhance organizational performance. Accordingly, the results support the acceptance of *H5*.

The other paths from KA, KD, KT, and KC to OP are not significant. There is a negative but insignificant beta coefficient of .218 (T = .8106) between KA and OP (*H1*), a positive but insignificant beta coefficient of .302 (T = 1.11106) between KD and OP (*H2*), a positive but insignificant beta coefficient of .033 (T = .1764) between KT and OP (*H3*), and a negative but insignificant beta coefficient of -.306 (T = .8748) between KC and OP (*H4*).

These nonsignificant paths suggest that KA, KT, and KC do not directly influence organizational performance, and therefore, the results do not support the acceptance of *H1, H2, H3,* and *H4*.

Testing the KM Interrelationships Hypotheses

- **The relationship of KA to KD (*H6*):** In Table 8, the PLS results show a positive but insignificant beta coefficient of .364 (T = 1.3063) between KA and KD. Although it has no significant influence on KD, KA explains 13.2% of the variance in KD, as the endogenous variable. Therefore, the results fail to support the acceptance of *H6*.
- **The relationship of KA and KD to KT (*H7*):** The PLS results in Table 9 confirm that KA and KD explain 16.1% of the variance in KT, as the endogenous variable. In addition, there is a positive but insignificant beta coefficient of .350 (T = 1.3929) between KA and KT, and a positive but insignificant beta coefficient of .106 (T = .3969) between KD and KT. KA and KD appear to have no influence on KT, and therefore, these results fail to support the acceptance of *H7*.
- **The relationship of KA, KD, and KT to KC (*H8*):** The PLS results of Table 10 indicate that KA, KD, and KT explain 59.3% of the variance in KC, as the endogenous variable. This model has a relatively high explanatory power. As to the effect of the individual processes on KC, there is a positive and significant beta coefficient of .520 (T = 3.6433) between KA and KC, a positive and significant beta coefficient of .295 (T =

Table 8. The relationship of KA to KD

The Dependent Variable	Independent Variables	R^2	Hypothesis Number
KD	KA	.132	*H6*

Dependent Variable	Independent Variables	Hypothesis Number	Predicted Path Coefficient	Standardized Path Coefficient
KD	KA	H6	+	.364 T = 1.3063

Table 9. The relationship of KA and KD to KT

Dependent Variable	Independent Variables	R^2	Hypothesis Number
KT	KA and KD	.161	*H7*

The Dependent Variable	Independent Variables	Hypothesis Number	Predicted Path Coefficient	Standardized Path Coefficient
KT	KA	*H7*	+	.350 T = 1.3929
	KD	*H7*	+	.106 T = .3969

Table 10. The relationship of KA, KD, and KT to KC

Dependent Variable	Independent Variables	R^2	Hypothesis Number
KC	KA, KD, and KT	.593	*H8*

Dependent Variable	Independent Variables	Hypothesis Number	Predicted Path Coefficient	Standardized Path Coefficient
KC	KA	*H8*	+	.520 T = 3.6433
	KD	*H8*	+	.169 T = 1.1403
	KT	*H8*	+	.295 T = 2.0413

Table 11. The Relationship of KA, KD, KT, and KC to KAP

Dependent Variable	Independent Variables	R^2	Hypothesis Number
KAP	KA, KD, KT, and KC	.692	*H9*

Dependent Variable	Independent Variables	Hypothesis Number	Predicted Path Coefficient	Standardized Path Coefficient
KAP	KA	*H9*	+	.342 T = 2.1549
	KD	*H9*	+	.043 T = .2713
	KT	*H9*	+	.273 T = 1.8014
	KC	*H9*	+	.354 T = 2.4152

2.0413) between KT and KC, and a positive but insignificant beta coefficient of .169(T = 1.1403) between KD and KC. Therefore, the results demonstrate that only KA and KT have a significant positive influence on KC, and consequently, the results provide support for a partial acceptance of *H8*.

- **The relationship of KA, KD, KT, and KC to KAP (*H9*):** From Table 11, the PLS results show that KA, KD, KT, and KC explain 69.2% of the variance in KAP, as the endogenous variable in this model. Therefore, this model appears to have a relatively high explanatory power.

The results of the individual effect of each of the four KM processes on KAP show a positive and significant beta coefficient of .342 (T = 2.1549) between KA and KAP, and a positive and significant beta coefficient of .354 (T = 2.4152) between KC and KAP. However, there is a positive but insignificant beta coefficient of .043 (T = .2713) between KD and KAP, and a positive but insignificant beta coefficient of .273 (T = 1.8014) between KT and KAP. Therefore, the results reveal that only KA and KC have a significant positive influence on KC, and consequently, provide support for a partial acceptance of *H9*.

To summarize, the PLS results lend support to the acceptance of *H5*, a partial acceptance of *H8*, and a partial acceptance of *H9*. The results, however, fail to support *H1*, *H2*, *H3*, *H4*, *H6*, and *H7*. These results are further discussed in the next section.

DISCUSSIONS

This investigation examined the relationship of the KM processes to organizational performance as well as the interrelationships within the KM processes in the form of nine hypotheses. The results of the final models, depicted in Figure 2, show that: (1) the five KM processes of knowledge acquisition (KA), knowledge documentation (KD), knowledge transfer (KT), knowledge creation (KC), and knowledge application (KAP) explain approximately 20% of the variance in the organizational performance (OP) of the investigated software firms; (2) KA, KD, KT, and KC explain 69% of the variance in KAP; and (3) KA, KD, and KT explain 59% of the variance in knowledge creation.

Although relatively low (approximately 20%), the explained OP variance is significant because it is the first empirically based evidence on the contribution of KM processes to OP in the Egyptian software industry. This finding can be interpreted in light of the assumption that knowledge is not always used, and does not always result in improved performance when used. As Kalling (2003) explains, if knowledge is not utilized, it will not contribute much to performance (e.g., profit); and even if knowledge is utilized, it might not contribute to improved performance. In order for knowledge to improve performance, knowledge application decisions should be made in light of the software firms' strategic processes and products-enhancement plans.

The relatively low explained variance in OP may be also attributed to the research design employed in this investigation. First, OP has been operationalized and measured using a subjective single-item measure. Such a measure may not effectively reflect all possible contributions that KM processes may have on OP. Second, the proposed causal relationship between KAP and OP is not necessarily straightforward. The effect of KAP may occur over several layers of causal relationships that should be identified and explicitly incorporated when modeling the relationships between KM processes and OP. Third, there may be other factors—such as environment, leadership, and organizational culture—that may as well influence OP (Yeo, 2003), and are not accounted for in the research model or the data analysis.

Among the KM processes, only KAP was found to directly influence OP. This finding

confirms the theoretical argument that knowledge application is a strategic resource of the firm, and that the primary rationale for the firm is to produce and apply knowledge (Choi & Lee, 2003; Grant, 1996; Nonaka, 1994; Nonaka & Takeuchi, 1995; Spender, 1994). It also supports Alavi and Leidner's (2001) argument that knowledge creation and codification do not necessarily contribute to improved performance or created value. Performance is improved and value is created only when knowledge is applied. In addition, this finding confirms Markus' (2001) assertion that knowledge usage associates with organizational effectiveness, and Alavi and Tiwana's (2000) observation that knowledge becomes underutilized as a driver of performance when it is not put into application.

Zack (1999) points out that the ability of an organization to create knowledge and to continue to learn from it may become a competitive advantage, since the innovative knowledge developed today becomes the core knowledge of tomorrow. However, the finding of no direct influence of knowledge creation on organizational performance may be attributed to the possible "gap" between knowledge creation and knowledge application. Components of the newly created knowledge in the software firms are perhaps still in an informational form and need to be further modified in order to become applied knowledge. Sveiby (1996) adds that newly created knowledge should be explored and used in order to find more appropriate applications for it.

Although they did not directly influence OP, KA, KT, and KC were found to indirectly influence organizational performance. KA indirectly influenced OP through its direct influence on both KC and KAP, which directly influenced OP. In addition, KT indirectly influenced OP through its direct influence on KC, which, in turn, influenced KAP. Also, KC indirectly influenced OP through its direct influence on KAP.

These findings are consistent with those of Gold et al. (2001), who found that knowledge acquisition, conversion, application, and protection are positively related to performance variables. They also confirm the research results of Kremp and Mairesse (2004), who found KM to influence innovative performance and productivity. These findings are also consistent with the other empirical studies that confirmed the importance of KM processes and activities in improving organizational performance or effectiveness (e.g., Edward et al., 2005; Jennex & Olfman, 2002; Kremp & Mairesse, 2004; Lee et al., 2005; Liu et al., 2004; Salojarvi et al., 2005).

As to the interrelationships among the KM processes, KA was found to positively influence KC and KAP. KT was found to positively influence KC. And KC was found to positively influence KAP. This means knowledge that is acquired from outside sources and transferred/shared within the firm facilitates the creation of new knowledge as well as the application of such knowledge to improve the performance of the software firms.

These findings support Nonaka and Takeuchi's (1995) SECI model of knowledge creation that establishes the interrelationships among the KM processes. Knowledge transfer is perceived to be the common factor that facilitates the four processes of knowledge creation in the model (Lee & Choi, 2003; Marr et al., 2003). These findings also agree with the argument that firms normally seek additional knowledge in the same area in which they already have a knowledge base and they may seek knowledge in a complementary area (Shenkar & Li, 1999), which is a prerequisite for knowledge search and use. In addition, these findings support the argument that existing knowledge bases facilitate new knowledge creation (Shenkar & Li, 1999; Cohen & Levinthal, 1990).

KA and KT appear to be essential processes to knowledge creation in the software firms. In order to create and build new knowledge, software firms need to acquire and transfer knowledge. Sources for knowledge acquisition and creation in the investigated software firms were found to include visitation with customers, secondary

information on demand and trends of software, market research, the Internet, individual initiatives of software developers, and R&D activities. Also, the firms were found to use e-mail, voice mail, forums, traditional meetings, groupware, on and off-the-job training, and education as methods for internal knowledge transfer (Seleim, Ashour & Khalil, 2005b).

On the other hand, KD is the only KM process that was found to have no direct or indirect influence on organizational performance and the other four KM processes of KA, KT, KC and KAP. This finding is inconsistent with the knowledge reuse theory (Markus, 2001), where organizational memory plays an important role in organizational success (Stein & Zwass, 1995).

One possible reason for the insignificant impact that KD had on OP and the other KM processes in the investigated firms is the lack of quality systems for knowledge documentation within the investigated software firms. Although the CEOs of a number of these firms recognize the important role of IT-based systems in building relationships, facilitating the exchange of information, and sharing experience and knowledge, the firms are currently not fully utilizing the capabilities of such systems (Seleim et al., 2005a).

IMPLICATIONS

The findings of this investigation contribute to the growing empirical KM research. Measuring scales for KM processes were adopted, revised, validated, and used to empirically examine the interrelationships between KM processes (in the form of antecedents and consequences) and their influence on the Egyptian software firms' performance. This is a step forward towards a future adoption, revision, and validation of a comprehensive KM measuring instrument and producing a generally accepted instrument that facilitates the accumulation of an empirically-based and consistent body of knowledge on KM.

Wiig (1999, p. 6) argues the need for a new theory of the firm in order to effectively manage knowledge and link it to the firm's strategy, tactics, and daily operations. The findings of this investigation extend and substantiate the absorptive capacity theory (Cohen & Levinthal, 1990) that emphasizes the organizational processes and activities, by which organizations acquire, absorb, transfer, and exploit knowledge. In particular, this research explored a number of relationships within the KM processes. Although they provide limited support for the proposed relationships, the findings indicate the value of continued investigation and refinement of the proposed research model in order to enhance our understanding of a phenomenon that is as complex as KM.

The findings of this research further support the significance of the knowledge-based theory of the firm as a paradigm to investigate and understand organizations in the knowledge economy context. It confirms the core of the knowledge-based theory of the firm because software firms not only create knowledge but also emphasize knowledge application (Grant, 1996; Spender, 1994).

For practitioners in the Egyptian software companies, the findings of this investigation demonstrate the importance of the KM processes, especially knowledge application to organizational performance. Software firms should adopt knowledge strategies in order to create value by generating and applying knowledge. These knowledge strategies may be guided by Hamel's (1991) recommended ways for creating value through knowledge utilization and application:

1. apply new knowledge to old or existing software products and services in order to add new functionalities and characteristics that better fulfill users' needs,
2. develop new software products and services through knowledge,
3. create value by globalizing or exporting deeply embedded local knowledge such as leading business practices, software prod-

ucts, software development techniques and methods, and the like to the other Middle Eastern countries, and

4. convert knowledge into strategic knowledge to create shareholders' wealth through effective leverage of organizational knowledge.

The Egyptian software firms need to adopt KM strategies—codification, personalization, or both—in order to guide knowledge acquisition, creation, and transfer practices in the software firms. Codification strategies should emphasize the systematization and storage of knowledge and make it available for software developers and other employees in the firms (Hansen et al., 1999). The development of comprehensive and formal KM systems that capture, edit, store, update, and disseminate knowledge is essential to improve the knowledge documentation process (Seleim et al., 2005b).

Software firms should also capitalize on the Egyptian national culture and adopt personalization KM strategies in order to develop a collaborative knowledge culture that allows knowledge creation and transfer within the firms. The Egyptian culture, which is rich in its social capital and interpersonal relationships (House et al., 2002; Javidan & House, 2001; Nahapiet & Ghoshal, 1998), encourages software developers and managers to assist each other and exchange experience and knowledge. It also encourages openness, trust, and mutual respect, which are vital in enabling knowledge transfer and learning (Kautz, Thaysen & Vendelo, 2002).

Finally, since the findings of this investigation provide some evidence on the interrelatedness of the KM processes, managers in the software firms need to manage knowledge from a holistic perspective that takes into consideration that KM processes are interrelated and transcend the departmental boundaries within the firm. Formal and informal integrating mechanisms must be adopted in order to facilitate a coordinated and balanced KM processes, since the deficiency of one or more of the KM processes may negatively affect the result in less than optimum outcome of the KM efforts in the firm.

RESEARCH LIMITATIONS AND FUTURE RESEARCH

Due to the lack of well-defined and broadly accepted theories and frameworks in the KM literature to guide the formulation of hypotheses describing possible interrelationships among the KM processes, only a selected number of interrelationships were included and tested in our research model. In addition, our results failed to detect a number of the hypothesized relationships. These undetected relationships may be due to possible measurement errors, the relatively small sample size, or contextual factors that were not accounted for in the research model. Future research should use research designs that employ larger samples to further validate the KM measuring instrument used in this investigation, hypothesize, and test new sets of relationships within KM processes, and investigate the role of the intermediary effect of the organizational context (e.g., organizational culture and climate, organizational size, organizational age, and business environment)on the relationships between knowledge application and organizational performance.

The use of an exclusive indicator to measure organizational performance represents a limitation to this research (de Pablos, 2002). Using multiple variables to measure organizational performance may help to get a more accurate representation of the relationship between KM and organizational performance. Future research may measure organizational performance as a function of multiple financial variables, such as return on investment (ROI), return on equity (ROE), sales growth, and profit growth. Or, since the financial measures may be confounded by other business, economic, and environmental factors, future research may adopt less confounded nonfinancial measures,

such as the fourteen-item scale developed by Gold et al. (2001), to measure KM contributions to organizational performance.

Furthermore, a cross-sectional data was used in this research with assumed causal flows within KM processes and from KM processes to organizational performance. There is, however, a possibility that the relationships may occur in reverse order. Therefore, future longitudinal investigations are recommended in order to conclusively replicate the findings presented in this research. In addition, future research may investigate alternative paths that connect KM processes and organizational performance. For instance, the application of knowledge may result in the creation of new knowledge (Gold et al., 2001), and the transfer of more knowledge among the individuals in an organization. Organizational learning may also mediate the relationship between knowledge application and organizational performance.

CONCLUSION

This investigation examined the relationship of the KM processes of knowledge acquisition, documentation, transfer, creation, and application to organizational performance and the interrelationships among the KM processes themselves in the form of nine hypotheses. Although the findings provide limited support for the proposed research model, they indicate the value of continued investigation and refinement of the model. Only knowledge application, among the KM processes, has a significant, direct and positive influence on organizational performance. This implies that KM is most effective in the Egyptian software firms when their employees not only receive and share knowledge but also apply it, and, thus, affects organizational performance.

Given the exploratory nature of this investigation, the proposed research model is considered adequate in explaining the variance in the organizational performance of the Egyptian software firms, as a function of the KM processes. Also, two submodels of the research model exhibit high power in explaining the variance in knowledge application and knowledge creation as functions of the other KM processes.

With the exception of knowledge documentation, the KM processes have either direct or indirect influence on organizational performance. Also, knowledge acquisition and knowledge creation directly influence knowledge application, while knowledge application and knowledge transfer directly influence knowledge creation. Therefore, KM processes within the Egyptian software firms should be viewed and managed as integrated, rather than separate, processes. Follow up research is warrant in order to validate and extend our research model.

APPENDIX A.

An English Form of the KM Practice Measuring Instrument Adopted in this Investigation*

(1 = very low practice, and 5 = very high practice)

Knowledge acquisition (KA):
1. To what extent the members in your firm actively participate in professional networks or associations.
2. To what extent your firm regularly collects information about the needs of its customers.
3. To what extent your firm regularly conducts knowledge gab analysis.
4. To what extent your firm hires consultants when important skills/information are not available in-house.
5. To what extent your firm hires new staff members who possess missing knowledge.
6. To what extent your firm conduct research (i.e., with universities and/or research centers) to explore future possibilities or to gain technical knowledge.
7. To what extent the employees in your firm regularly attend courses, seminars, or other training programs to remain informed.
8. To what extent your firm considers competitors as a source of inspiration for developing new methods and/or products.
Knowledge documentation (KD):
9. To what extent your firm uses brainstorming sessions for problem solving.
10. To what extent your firm evaluates failures and successes and "lesson learned" are set down.
11. To what extent your firm has available up-to-date handbooks, manuals, CDs, and so forth, which are frequently used.
12. To what extent your firm informs its members systematically of changes in procedures, handbook, and so forth.
13. To what extent your firm has documented the specific knowledge and skills of its individual members.
14. To what extent your firm encourages its experts to make explicit the methods they use in developing software products.
15. To what extent your firm keeps and maintains knowledge maps, knowledge networks, and data warehouses.
Knowledge transfer (KT):
16. To what extent your firm assigns mentors to the new hires to help them find their way in the organization.
17. To what extent your firm extracts the experiences of its experts and shares them with others in the organization.
18. To what extent the employees in your firm share with colleagues and others their knowledge/know how.
19. To what extent the knowledge in your firm is distributed in informal ways.
20. To what extent the knowledge in your firm is distributed in formal ways.
21. To what extent your firm holds regular business update meetings to discuss software development issues.
22. To what extent the members in your firm regularly inform each other about positive experiences and successful work methods.

23. To what extent your firm conducts intercollegual review in which members discuss their methods of working.
24. To what extent the members in your firm change jobs regularly in order to distribute their know-how.
25. To what extent your firm uses mechanisms and means for knowledge exchange across individuals, groups, and organizational levels.
Knowledge creation (KC):
26. To what extent Individual performances are assessed regularly and discussed in individual evaluative conferences.
27. To what extent problems, failures, and doubts are discussed openly in your firm.
28. To what extent that new ideas lead to re-design of work methods and processes in your firm.
29. To what extent members are assigned to new projects depending on know-how and availability.
30. To what extent your firm endeavors to find knowledge combination that contributes to its identity.
31. To what extent the members in your firm are rewarded for developing new knowledge and testing new ideas.
32. To what extent your firm promotes and stimulates a learning climate among employees.
33. To what extent your firm contributes to the development of the important ideas and knowledge in the industry.
34. To what extent the important issues in your firm are explored using scenario- or simulation techniques.
35. To what extent your firm analyzes benchmark at the industry level.
36. To what extent your firm conducts data mining to discover new knowledge and insights.
Knowledge application (KAP):
37. To what extent selling knowledge, products, or services gets explicit attention in your firm.
38. To what extent customer feedback is used to improve products/services in your firm.
39. To what extent your firm uses existing know-how in a creative manner for new applications.
40. To what extent your firm does marketing research among potential clients before developing new products or services.
41. To what extent your firm tries to conquer dysfunctional beliefs within the organization.
42. To what extent your firm utilizes multi-disciplinary teams to perform tasks and/or make decisions.
43. To what extent your firm has capabilities to integrate its knowledge across different areas.
44. To what extent your firm maximizes knowledge use through its organizational structure, management systems, and practices.
45. To what extent your firm attempts to discover the problems that cause gabs between targets and achievements.
46. To what extent your firm attempts to use its stocks of knowledge across different software projects.

** Note: The items that have been added to the original scale are written in italics.*

Section VII
Critical Issues

This section addresses conceptual and theoretical issues related to the field of software applications, which include ethics in software engineering, software piracy, and morality in free and open source software. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Overall, contributions within this section ask unique, often theoretical questions related to the study of software applications and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1
A Survey of Object-Oriented Design Quality Improvement

Juan José Olmedilla
Almira Lab, Spain

ABSTRACT

The use of object-oriented (OO) architecture knowledge such as patterns, heuristics, principles, refactorings and bad smells improve the quality of designs, as Garzás and Piattini (2005) state in their study; according to it, the application of those elements impact on the quality of an OO design and can serve as basis to establish some kind of software design improvement (SDI) method. But how can we measure the level of improvement? Is there a set of accepted internal attributes to measure the quality of a design? Furthermore, if such a set exists will it be possible to use a measurement model to guide the SDI in the same way software processimprovement models (Humphrey, 1989; Paulk, Curtis, Chrissis, & Weber, 1993) are guided by process metrics (Fenton & Pfleeger, 1998)? Since (Chidamber & Kemerer, 1991) several OO metrics suites have been proposed to measure OO properties, such as encapsulation, cohesion, coupling and abstraction, both in designs and in code, in this chapter we review the literature to find out to which high level quality properties are mapped and if an OO design evaluation model has been formally proposed or even is possible.

INTRODUCTION

In the last two decades there has been a growing interest and effort put after the idea of improving the quality of the software processes (Humphrey, 1989). This increasing trend had it origin in the application of statistical process control techniques (Oakland, 1990) from the manufacturing industry to our sector, thus creating a new discipline that has been called software process improvement (SPI) (Humphrey, Snyder & Willis, 1991). This discipline aids organisations to improve their software producing processes by, firstly, identifying all the broad areas of the process, their goals

and the activities and sub-activities needed to achieve them and secondly by establishing a path through which the process can be incrementally improved, this path is a set of quality levels, each of them defined by the areas and their associated goals to be accomplished. Fundamental to the SPI are the associated metrics (Fenton & Pfleeger, 1998) that are the tool by which the organisation can tell at each moment where it is in the path, each of the aforementioned goals has an associated set of metrics that help to tell if it has been achieved and to what extent. Although there are alternative SPI models and methods, like CMMI (Paulk et al., 1993) or SPICE (ISO/IEC, 1999), an organisation can always adhere to a concrete definition of process quality and a way to measure it and improve it.

However the product arena does not seem to be so established in terms of quality improvement models. A fundamental question that managers and developers often face is when it is worth to improve a software product by reengineering it or on the contrary start it all over from scratch. Fowler (2000) states that

There are times when the existing code is such a mess that although you could refactor it, it would be easier to start from the beginning ... I admit that I don't really have good guidelines for it. (p. 66)

In this case Fowler was talking about the refactoring technique but something similar can be said about other OO design knowledge elements. There is plenty of knowledge, more or less formalised, about identifying situations in which to apply an specific design improvement (Brown, Malveau, Brown, McCormick & Mowbray, 1998; Fowler, 2000; Gamma, Helm, Johnson & Vlissides, 1995; Riel, 1996), but is there a formal method to know which design transformations should be applied first or are more important? Is it possible to establish which design transformations, pattern applications, refactorings, and so forth, are more important in a certain quality level?

An organisation or a project could be interested in attaining only a moderate quality level that is acceptable for the time being and it is foreseeable that will consume only a limited amount of resources. Such an organisation could be interested in a guide that tells what quality indicators are really crucial to that quality level, to what extent, in terms of a measurable quantity, how to measure them and which design transformation affect the properties object of the measurements.

First of all it would be necessary to define what is design quality, by identifying what general properties or high level indicators comprise it; second, to organise those indicators in sets that constitute an incremental ladder of quality, so that depending on the situations, the (non-functional requirements and the resources a designer can choose the target level for his or her design; thirdly, choose the metrics that help in the assessment of the goals accomplishment; and finally, define the OO knowledge elements that apply in each case. We are talking here about something that we could call an *OO design maturity model* that would help designers to assess and improve a design before having to implement it.

Product quality has been defined in ISO 9126 (ISO/IEC, 2001) by external and internal attributes that describe the quality of the final software product and its intermediate subproducts, such as design; according to that, design quality should be measured through internal attributes that will predict, somehow, the final outcome of the external attributes. Some authors (Bansiya & Davis, 2002; Basili, Briand & Melo, 1996) have proposed numerical relations between some internal quality attributes and general OO properties, such as coupling or cohesion, for which there are already defined metrics. Other authors (Miller, Hsia & Kung) have proposed directly to measure the levels of accomplishment of certain OO knowledge elements like design principles,

using some of the existing OO metrics and map them to internal quality attributes. If the first approach was used then it would be necessary to establish how much each OO knowledge element impacts each OO property or, at least, know what design transformations are directed to which properties and re-measure after applying them and repeat the process until the level of quality is reached (see Figure 1). This chapter will review the state of the art to see whether there is an accepted set of internal quality properties as high level indicators or goals for the assessment of OO micro architecture design quality and if there are already assessment models that map metrics, OO properties and these high level indicators. A secondary objective of the review is the identification of what role the OO knowledge elements play in the assessment. There might be evaluation models based on the detection of the elements in the design so that they will not only be part of the improvement model but also of the appraisal. The sources of review will be journals, transactions, conference proceedings, and other periodicals published in the main areas of knowledge affected by this study which are object orientation design, metrics, and software maintenance.

In the next section a background on software product quality and OO metrics and OO knowledge will be presented, the method followed to perform the review will be explained one section later and the results exposed along with critical comments on the most relevant studies, and conclusions will be drawn in the closing section.

BACKGROUND

Software Product Quality

Quality can be measured at a process or product level, although there are obvious relationships among them, as Figure 2 illustrates. There are other quality aspects besides those two but are not of interest to us. ISO/IEC has issued two standards that refer to software product and process quality respectively, ISO 14598 (ISO/IEC, 1999) and ISO 9126. As is usual with these kind of standards the authors do not give an explicit assessment methodology nor do they give guidelines to achieve quality through specific software processes or development methodologies. Rather they simply put in places what is understood by quality, in terms of attributes that must be measured, in each

Figure 1. Measurement and improvement model for object-oriented design

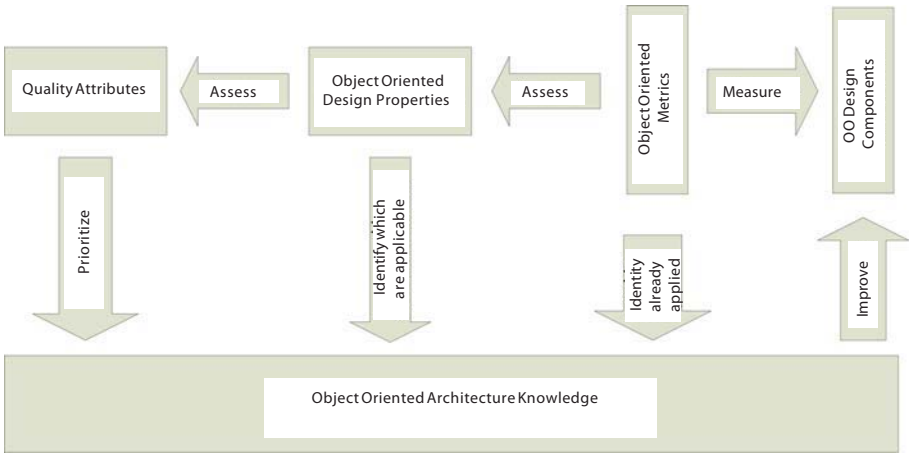

Figure 2. Quality in the software lifecycle

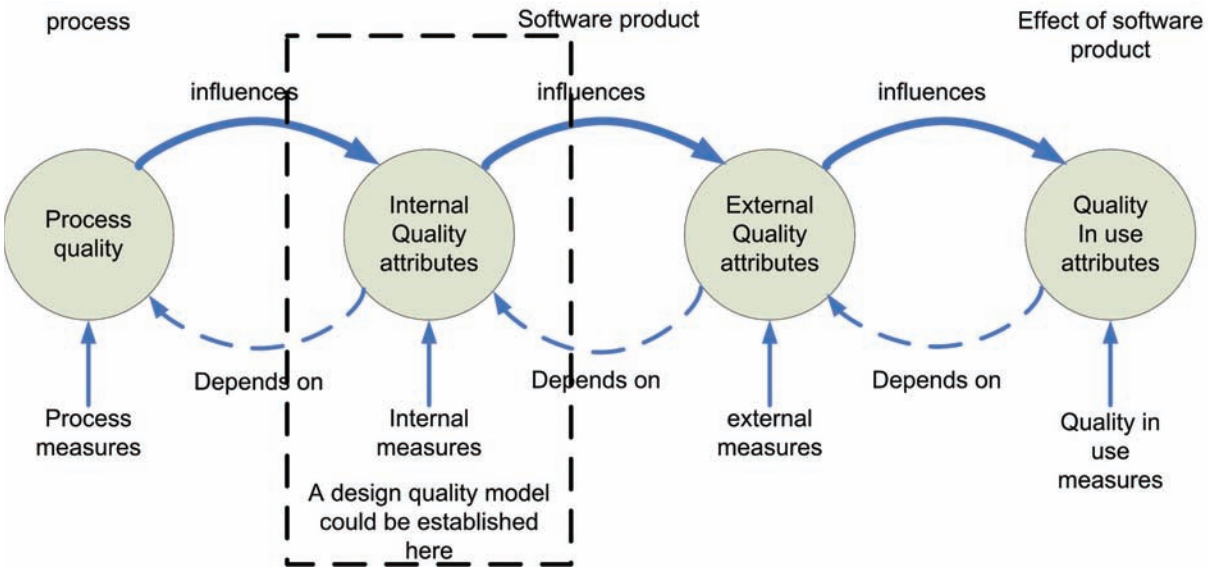


of the cases. The CMMI model connects with ISO 14598 in being a classification of maturity levels in the software process and giving a set of specific guidelines to assess and evaluate the quality of a software process.

ISO 9126 states that software product quality can be evaluated by measuring internal attributes, or by measuring external attributes; the former are obtained through metrics defined on intermediate products, such as design, and the latter are based on the behavior of the final executing code. It also takes in account "quality in use" which deals with the perspective of behavioral quality of the finished product in a speciûc environment under a user's perspective. In both cases, internal and external, quality is defined as a set of six characteristics:

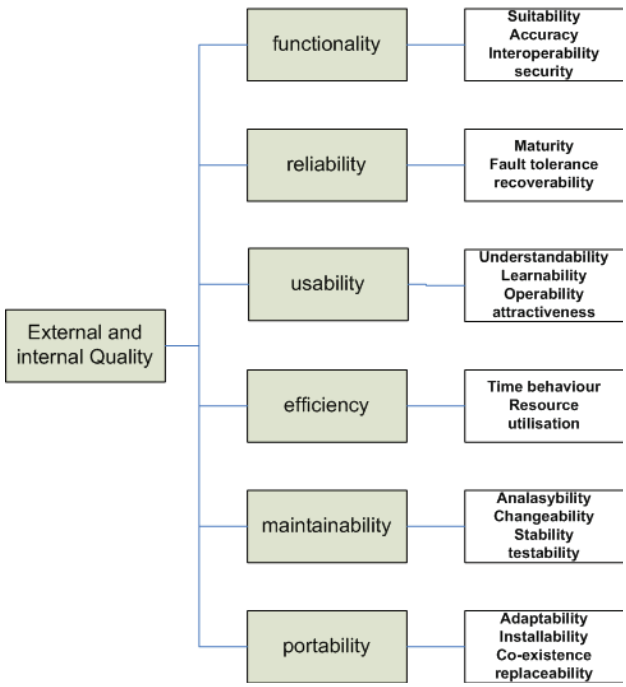
- **Functionality:** The capability of the software product to provide functions which meet stated and implied needs when the software is used under specified conditions.
- **Reliability:** The capability of the software product to maintain a specified level of performance when used under specified conditions.
- **Usability:** The capability of the software product to be understood, learned, used, and attractive to the user, when used under specified condition.
- **Efficiency:** The capability of the software product to provide appropriate performance, relative to the amount of resources used, under stated conditions.
- **Maintainability:** The capability of the software product to be modified. Modifications may include corrections, improvements or adaptation of the software to changes in environment, and in requirements and functional specifications.
- **Portability:** The capability of the software product to be transferred from one environment to another.

These characteristics are general for any kind of software product and being object-oriented or

structured does not affect the choice of characteristics, although it will affect the way to measure them. These characteristics are further divided in subcharacteristics as shown in Figure 3. But we are centered in the design quality in early stages of the development cycle and certain attributes in that list, apparently, should not be addressed yet. Let us see which of them are addressable at the design stage and which are not:

- The correct coverage of all user requirements should be addressed in previous phases of the life cycle, such as analysis, and verified during testing; therefore, it is logical to suppose that the quality of a design should not be measured by the functionality attribute, as defined in ISO 9126. In fact the OO design improvement techniques always state that to apply them, first the current design must behave "mostly" correctly (Fowler, 2000) (in terms of functionality and in terms of reliability). But how can we decide if a design is better than another, for the same requirements? If one of them does not implement the full set of requirements as described in the corresponding specifications then the design is not "worse" than the other, it is simply not correct or incomplete.
- Again we tend to suppose that reliability should not be one of the internal attributes that define design quality, given that reliability has been traditionally measured during testing; however, McCabe (1976) introduced the cyclomatic complexity (CC) metric which has been used to calculate, for a given, software program, the minimum set of tests that are necessary to ensure a certain level of test coverage and therefore a prediction of the ratio of defects yet uncovered. Later works (Chidamber & Kemerer, 1991) created equivalent metrics for OO software and there are certain studies that try to predict

Figure 3. ISO 9126 Quality characteristics and sub-characteristics



reliability (Basili et al., 1996; Briand, Wust, Daly, & Victor Porter, 2000; Brito e Abreu & Melo, 1996) from design. These and other works[1] establish a relationship between the complexity, as an OO property, and the defect density or fault prone-ness, which we interpret as synonyms for reliability.

- Usability deals with the way the final user feels about the finished product. No evidence was found in the sense of establishing usability as an internal attribute for design quality. Understandability is mentioned in the literature (Bansiya & Davis, 2002; Deligiannis, Shepperd, Roumeliotis, & Stamelos, 2003; Dumke & Kuhrau, 1994) as a desired property to have in a design. However, it is more than arguable that it refers to the ISO 9126 sub-characteristic of usability, and it must be understood as "analysability." However, other voices (Fowler, 2000) claim that the "user" of a design is not the same as the user of the ûnal product. He or she could be the developer that has to implement the specified design, or that same designer (or other) in the future when a new feature has to be introduced in the system or the design must be modified for whatever reason, the latter case is already contained under "maintainability," but the former is not so clear.
- Efficiency is divided into "time behavior" and "resource utilisation" which has made this attribute a clear measuring target in the testing phases; however, there are proposals, mostly in the real-time systems area, to measure efficiency, usually addressed as "performance," early in the design stage. This could be a good candidate quality attribute for a higher level of design quality and not for a basic one. Making an OO design more understandable by, for instance, introducing patterns, introduces indirections which in turn penalises performance, so it looks like they are opposite. However if a design is more understandable thanks to being decomposed in more entities, that allows a better isolation and identification of those spots where most of the performance issues tend to be (Fowler, 2000).
- Maintainability is a clear focus of most of the OO knowledge dedicated to improve designs as we will see, this is intuitive since most design efforts in OO paradigm are centred around ideas such as data hiding, encapsulation and abstraction which enhance a better understand ability (analysability) through domain concept representation, separation of components in testable units, and so forth.
- Portability looks completely out of the scope of the design stage since the design must remain conceptually separated from the actual implementation environment. In any case, we have not found sufficient evidence to support that this attribute is important, quality wise, during early design phases.

In Bansiya & Davis (2002), a set of six design quality attributes are derived from ISO 9126 quality characteristics, although they are not taken exactly but rather adapted to the particularity of design. Two are discarded as not measurable in design, two are changed for equivalent ones, and two are added from general concepts present in software design literature.

These quality attributes are abstract concepts and, therefore, not directly observable, so we need some properties that can be observed and quantified and that are particular of object-oriented design. In many of the OO metrics suites the speciûc metrics are implicitly mapped to general design properties as cohesion, coupling, encapsulation, complexity, and inheritance, although not all of them are specific to OO design and could be applied to modular design as well. Measurements are proposed in different works for those properties and in some cases there is an explicit mapping from the former to the latter, as in Bansiya & Davis (2002) where each design

property is measured by a single metric. In Miller et al. (1999), 11 properties were chosen. In fact, object-oriented design principles, which according to Garzás and Piattini (2005) are part of the OO architecture knowledge, as we previously said, and five measurements, all of them at class level, are used to assess their degree of fulfillment. On the contrary, Bansiya and Davis (2002) choose not only classes but also class attributes, methods, and packages.

A very sound set of object-oriented design properties could be:

- Design size
- Hierarchies
- Abstraction
- Encapsulation
- Coupling
- Cohesion
- Composition
- Inheritance
- Polymorphism
- Messaging
- Complexity

But these quality attributes and OO design properties must be measured on specific components or entities of the design (see Figure1), thus it is important to define what a design is or what components are in a design susceptible to be measured. Purao and Vaishnavi (2003) survey product metrics for OO systems and propose a framework and a formalism, according to which, the product goes through different "states" during the development process and in each of them different components that he calls "entities," are produced or modified. In his work, Purao, reviewed all the different metrics suites to see what entities where measured in each state and gathered an extensive set of which we only recall here those in the design state, along with the their attributes (see Table 1).

Object-Oriented Metrics

We are going to present a summary of the most important object-oriented metrics and identify which OO properties they can measure.

Chidamber and Kemerer's Metrics Suite

Chidamber and Kemerer (C&K henceforth) first proposed in 1991a suite of six metrics. All except one were applied to the class entity and measured complexity, coupling, cohesion, inheritance, and messaging (see Table 2).

Henderson-Sellers Metrics

Another important suite was given by Henderson-Sellers, Constantine, and Graham (1996) but it was related to coupling and cohesion. Only AID (average inheritance depth of a class) was an Inheritance measure. AID was defined as zero, for a class without ancestors and the average AID of its parent classes increased by one.

Conclusion on Metrics

In Purao and Vaishnavi (2003) and Briand et al. (2000), a detailed listing of metrics is presented. An important conclusion drawn after reviewing these metrics is that, although they claim, in many cases, to be OO design metrics they are not since they need source code to be analysed or measure code size. Another important conclusion is that most metrics suites focus just in a very constrained set of properties, namely, coupling, cohesion and inheritance. There are some exceptions like Briand et al. (2000), which gives a set of metrics taken partly from previous suites that cover all properties considered in their assessment model.

Table 2. Metrics of the C&K suite

Metric	Definition	Properties
Weighted methods per class (WMC)	Consider a class C_1 with methods $M_1, M_2, \ldots, M_n$. Let $c_1, c_2, \ldots, c_n$ be the static complexity of the methods. Then: $WMC = \sum_{i=1}^{n} c_i$ The static complexity can be measured in many ways, one of them being CC(McCabe, 1976).	Complexity
Depth of inheritance tree (DIT)	The DIT metric of a class A is its depth in the inheritance tree. If A is involved in a multiple inheritance the maximum length to the root of the tree will be the DIT.	Inheritance
Number of children (NOC)	NOC of a class is the number of immediate subclasses subordinated to a class in the class hierarchy.	Inheritance
Coupling between object classes (CBO)	CBO for a class is a count of the number of other classes to which is coupled. One class is coupled to another if it uses its methods or instance variables, excluding inheritance related couples.	Coupling
Response for a class (RFC)	$RFC = \lvert RS \rvert$ where RS is the response set for the class, given by $RS = \{M\} \bigcup_{\text{all } i} \{R_i\}$ where $\{R_i\}$ = set of methods called by method i and $\{M\}$ is the set of all methods in the class. The response set of a class is the set of all methods that can potentially be executed in response to a message received by an object of that class.	Messaging
Lack of cohesion in methods (LCOM)	Consider a Class C_i with n methods $M_1, M_2, \ldots, M_n$. Let $\{I_j\}$ be the set of instance variables used by method M_i. There are n such sets $\{I_1\}, \ldots \{I_n\}$. Let $P = \{(I_i, I_j) \mid I_i \cap I_j = \emptyset\}$ and $Q = \{(I_i, I_j) \mid I_i \cap I_j \neq \emptyset\}$. If all n sets $\{I_1\}, \ldots \{I_n\}$ are $\emptyset$ then let $P = \emptyset$. $LCOM = \lvert P \rvert - \lvert Q \rvert$, if $\lvert P \rvert > \lvert Q \rvert$ or 0 otherwise.	Cohesion

Table 3. Li and Henry's metrics

Metric	Definition	Properties
Message passing coupling (MPC)	MPC= the number of method invocations in a clas.s	Coupling/ Messaging
Data abstraction coupling (DAC)	The number of attributes in a class that have as their type another class.	Coupling/ Abstraction
SIZE1	It is a variation of traditional LOC (Lines of Code) defined specifically for the Ada language. We obviate its definition.	Design size
SIZE2	SIZE2 = number of attributes + number of local methods.	Design size

Table 4. Bansiya and Davis metric model

Metric	Definition	Properties
Design size of classes (DSC)	Total number of classes in the design	Design size
Number of hierarchies (NOH)	Number of class	Hierarchies
Average number of ancestors (ANA)	Average number of ancestors	Abstraction
Data access metric (DAM)	Ratio of the number of private (protected) attributes to the total number of attributes declared in the class	Encapsulation
Direct class coupling (DCC)	Count of different number of classes that a class is directly related to. The metric includes classes that are directly related by attribute declarations and message passing (parameters) in methods	Coupling
Cohesion among methods of class (CAM)	This metric computes the relatedness methods of a class based upon the parameter list of the methods. The metric is computed using the summation of the intersection of parameters of a method with the maximum independent set of all parameter types in the class.	Cohesion
Measure of aggregation (MOA)	This metric measures the extent of the part-whole relationship, realised by using attributes. The metric is a count of the number of data declarations whose types are user de?ned classes.	Composition
Measure of functional abstraction (MFA)	Ratio of the number of methods inherited by a class to the total number of methods accessible by member methods of the class	Inheritance
Number of polymorphic methods (NPM)	Number of methods that can exhibit polymorphic behaviour (virtual in C++ and non ?nal in Java)	Polymorphism
Class interface size (CIS)	Count of the number of public methods in a class	Messaging
Number of methods (NOM)	Count of methods de?ned in a class.	Complexity

CURRENT STATE OF THE ART IN DESIGN QUALITY ASSESSMENT MODELS

Review Questions

The objective behind this review is to find out if there is any solid research to relate software design high level indicators with OO design knowledge (patterns, heuristics, bad smells, best practices, rules, and principles). The future trend of research, on the one hand, is to relate current (or new) OO metrics with ISO 9126 internal characteristics, or establish a new set if necessary, and see if they can be measured through them. On the other hand, we are after the relation between the application of OO knowledge and the impact of those metrics, and therefore, the quality characteristics.

The review tries to determine if this gap exists or not in the OO area of knowledge. We are constrained exclusively to the design phase and more specifically to OO micro architecture.2 We are not interested in metrics or models for process quality, effort, estimation, or project tracking metrics. The area of research is always focused on metrics intended for design improvement.

The primary question of research is:

Research Question 1: Are there object-oriented design quality assessment models that use a set of metrics, based only in design entities,3 to measure levels of accomplishment in internal product quality attributes (as those in ISO 9126)? And what are those attributes or high level indicators?

Needless to say, we are interested in quantified models, so that those metrics are numerically related to the characteristics, directly or through other numerical relations with intermediate elements, such as OO properties, which, on the other hand, is what is found in all cases as we have advanced in the Background section.

The secondary question of research is:

Research Question 2: Do those models use any of the OO knowledge elements in Garzás & Piattini (2005) as part of that assessment model and how?

This secondary question leads necessarily to models where there is a detection of those elements in the design by using speciûc metrics. Since the future work will establish a way to improve the design through the application of design transformations based on those knowledge elements, it is very useful to know in advance how much that will impact the desired quality attributes and if those transformations are already present in the design.

Review Methods

A systematic review protocol following Kitchenham (2004) was used. The sources consulted were all digital, and the intention was to cover as many periodicals and conference proceedings related with metrics, software quality, OO knowledge, and software maintenance as possible. The sources chosen were IEEE Digital Library, ACM Digital Library, Journal of Systems and Software (Elsevier), Journal of Software Maintenance and Evolution (Wiley) and Software Practice and experience (Wiley).

Our search strategy was to compose queries that included in different Boolean expressions the following terms:

- Object-oriented design
- Metrics
- Quality
- High level indicators
- Assessment
- Method
- Patterns
- Heuristics
- Bad smells
- Principles
- Rules
- Refactoring
- Lessons learned
- Best practice

Different synonyms were chosen for some of the above terms like assessment for which we chose "assess," "assessing," "evaluation," "evaluate," and "evaluating"; also, "method" had different synonyms. The singular was chosen as in "pattern" instead of "patterns" in order to obtain expressions that included both variations, since the first is a substring of the second. Different queries were created with these terms and executed in the search engines. However, some of them had to be expanded, like in the case of the Journal of Systems and Software given to obtain a decent set of results and afterwards the selection had to be manually reviewed to exclude publications that were completely out of the scope. Several different queries were tried in both engines and the search was broaden more than initially thought given the initial low number of results, for instance in IEEE Digital Library the following query was executed:

"(metrics<in>metadata)<and>(object-oriented design<in>metadata)." Surprisingly enough, this query threw only 62 results (in IEEE Digital Library) which was less than other more restrictive ones. One first conclusion of the first round of searches was that, although there are many metrics suites for OO systems there are very few centered exclusively in the design phase and using only design entities as the measurable elements.

Repetitions were taken out since there were references to the same study from different sources (i.e., from IEEE and ACM Digital Libraries), the same can be said about those studies that were different publications of the same work, where we always took the most recent one, as Kitchenham (2004) advises. Once repetitions were taken out 481 studies remained. After obtaining this initial list of results we did a quick review of abstracts when available or the introduction of the paper and directly discarded those elements not having to do with object-oriented metrics. After that initial review we did a more thorough review by reading one by one the publications and using the exclu-

sion criteria explained in section "Included and excluded studies" to discard those not interesting to us. We recorded the reason for each discard whether it was in the first quick review or in the thorough one.

For the ones not discarded, that is, the primary sources object of our review, we recorded its type according to a set quality assessment levels suggested by Kitchenham (2004) according to the experimental data they included. The set of quality levels is given in Table 5.

After the review we could verify that all primary sources were below three (concurrent cohort). We decided not to establish a quality threshold and take into account all studies that passed the exclusion criteria regardless of their experimental (quality) level.

Included and Excluded Studies

The exclusion criteria used in the more thorough review were:

Exclusion criterion 1: *Study not focused on metrics for design improvement, like those too general and including effort and quality assurance.*

Exclusion criterion 2: *It does not propose an assessment model with quality attributes as target of the metrics*

Given the low number of studies (only 23) that passed the exclusion criteria we decided to record as well those studies that, not proposing a general assessment model, were focused on prediction of one or two quality attributes, recording those attributes as well.

Data Extraction

We were interested primarily in obtaining the high level indicators or internal quality attributes that could be utilised in a design improvement methodology, so we recorded all those indicators in the primary studies. We also recorded which of these studies, or "primary sources," were proposing an explicit model of assessment with a full mapping of metrics to intermediate properties and from there to high level indicators or attributes. Although the selected studies proposed a method for quality evaluation based on high level indicators and their associated metrics, only four of them proposed formally a complete mapping with explicit mappings or relations to the high level indicators, we called them "full models" (see Table 6). Later on we also recorded attributes for those discarded studies that were focused only on the prediction of one or two attributes, that we have indicated in Table 7 as "secondary sources"; in that table we can see all the indicators or attributes collected from both sources.

Table 5. Quality levels for primary sources, as in Kitchenham (2004)

Level	Name	Description
1	Randomised trial	Evidence obtained from at least one properly-designed randomised controlled trial
2	Pseudo-randomised trial	Evidence obtained from well-designed pseudo-randomised controlled trials
3	Concurrent cohort	Evidence obtained from comparative studies with concurrent controls and allocation not randomised, cohort studies, case-control studies or interrupted time series with a control group.
4	Historical control	Evidence obtained from comparative studies with historical control, two or more single arm studies, or interrupted time series without a parallel control group
5	Randomised experiment	Evidence obtained from a randomised experiment performed in an artificial setting
6	Case series	Evidence obtained from case series, either post-test or pre-test/post-test
7	Pseudo-randomised experiment	Evidence obtained from a quasi-random experiment performed in an artificial setting
8	Expert opinion	Evidence obtained from expert opinion based on theory or consensus

Table 6. Summary of data collected

Number of Studies			Accepted Studies		Primary Sources	
Total	Accepted	Discarded	Primary Sources	Secondary Sources	Full Model	Basic
481	584	232	3	354	1	9

Table 7. Collected high level indicators

Property Name	Full Model	Primary Sources	Secondary Sources
Adaptability	0	1	0
Analysability	1	1	0
Change proneness	0	0	1
Changeability	1	2	3
Completeness	0	2	0
Complexity	0	3	0
Comprehensibility	1	1	0
Consistency	0	2	0
Correctness	0	2	0
Effectiveness	1	1	0
Efficiency	0	0	1
Extensibility	1	4	3
Flexibility	1	1	2
Functionality	1	1	0
Maintainability	1	10	10
Performance	1	2	0
Realisability	0	1	0
Reliability	0	4	9
Reusability	2	5	5
Security	0	1	0
Stability	1	1	2
Testability	1	5	2
Traceability	0	1	0
Unambiguity	0	1	0
Understandability	1	4	3
Usability	0	1	0
Verifiability	0	0	1

It can be observed that there are many attributes that are really synonyms, as for example analysability, comprehensibility, and understand ability. As we expected, maintainability is the most referred in both kinds of studies by itself or adding their subcharacteristics, analysability, comprehensibility, changeability, stability, and testability. On the other hand, it must be taken into account that all these attributes refer to design and that, for instance, "understandability" means in this context that the design is easily understandable by a software developer other than its author; therefore it must not be taken as the sub-characteristic beneath "usability" in ISO 9126.

Results: Description of Primary Studies and Findings

From the data obtained in Table 7 we can conclude that, for the so called *full models*, maintainability, counting its subcharacteristics, was the highest

scoring quality attribute with a total of eight appearances. Maintainability is comprised of analysability, changeability, stability, and testability, and, in this context, an analysability, comprehensibility, and understandability are synonyms, or at least that was the semantic behind the word in the selected studies, and the same can be said about changeability, flexibility, and extensibility. Another important attribute or high level indicator is reusability.

In primary studies, those not stating explicit relation between OO properties and quality attributes, maintainability and reusability were the two most important indicators and reliability appears as the next one. In the secondary studies, reliability outperforms reusability. Apparently reliability and, in decreasing importance, performance and efficiency (and effectiveness as its synonym) take more importance as the studies try to predict a specific quality attribute instead of evaluating the overall quality.

Apparently, when trying to establish a quality evaluation method, reliability, defect proneness, and functional correctness and consistency are way less important than maintainability. On the other hand, there are many studies that try to predict and decrease defects early in the design phases. One possible interpretation is that quality evaluation methods, as we said before, are not seen as a replacement for software quality assurance and try to establish a way to measure and compare different designs that are semantically equivalent, that is, built for the same functional requirements, and mostly correct (defect-free).

Given the resulting figures, a statistical analysis was not considered relevant. Only four studies were considered relevant to our study and they will be summarised. In Table 8, a brief summary is shown about the use these studies make of the OO micro architecture knowledge; only those elements that have appeared in at least one of the studies is listed.

Bansiya and Davis's QMOOD

Bansiya and Davis (2002) propose a model for the assessment of high level design quality attributes in object-oriented designs called *quality model for object-oriented design* (QMOOD). It is decomposed in four levels, OO design components (level 4 or L_4), OO design metrics (level 3 or L_3), OO design properties (level 2 or L_2) and finally design quality attributes (level 1 or L_1), and links between adjacent levels, L_{34} (from L_3 to L_4), L_{23} (from L_3 to L_2) and L_{12} (from L_2 to L_1). This model is very similar to that depicted in Figure 1 and the quality attributes are taken partly from the ISO 9126 quality attributes: reusability, flexibility, understandability, functionality, extendability, and effectiveness.

In each of the links, Bansiya and Davis identify explicit relation between components of both levels, for L_{23} the mapping is exactly one to one, one metric for each of the properties (design size, hierarchies, abstraction, encapsulation, coupling, cohesion, composition, inheritance, polymorphism, messaging, and complexity), and in L_{12}

Table 8. Use of OO knowledge in the four full models

	Principles	Patterns	Heuristics	Bad smells
Bansiya & Davis	No	No	No	No
Miller, Hsia & Kung	Yes	No	No	No
Barber & Graser	No	Indirectly	Yes	No
Marinescu & Ratiu	No	Partially	No	Yes

the mapping is even more explicit because each quality attribute (from ISO 9126) is the result of the sum of each of the calculated metrics multiplied by its weight, for instance, Reusability equals 0.25*Coupling +0.25*Cohesion+ 0.5*Messaging +0.5*Design Size.

The weights can be positive or negative and were calculated somehow intuitively; in fact, the study states that the weights, as well as other mappings, can be changed to reflect the goals of the organisation.

On the other hand, relative importance of each quality attribute is not stated and is left to the designer's decision.

Finally, there is no use in the model of OO knowledge such as design patterns, principles, refactorings, or other such elements.

Miller, Hsia and Kung OO Architecture Measures

Miller, Hsia, and Kung (1999) define an OO architecture quality measurement method that fills, in a way, the gap that Bansiya and Davis had. They use quantitatively OO architecture knowledge, in the form of well known principles. Again there are defined design components, metrics (they call them measurements) and OO principles; they substitute the OO properties for these latter. Unfortunately, they stop there, not quantifying the impact of those principles in general quality attributes; in fact, they do not identify quality attributes or refer to ISO 9126, although they give high importance to the extendability, flexibility, and maintainability of the architecture.

The design components they use are hierarchies, relationship, classes, methods, and attributes (they call the operations) but in defining how to obtain the measures, they give a high importance to operations, and the impact on all of the measures. Their measurements are class abstractness, hierarchy chain brittleness, class abstraction cohesion, pure inheritance index, and relationship abstraction index. As for the principles used: open-closed, Liskov substitution, dependency inversion, interface segregation, reuse/release equivalency, common closure, common reuse, stable abstractions, least astonishment, deep abstract hierarchies, and Demeter (see Miller et al., 1999 for references).

In summary, this study is not really a quality evaluation model since it does not calculate (explicitly) internal or external software quality attributes. It does not use general OO properties either but it is interesting because it uses some OO knowledge in a quantitative way.

Barber and Graser's RARE

Barber and Graser's (2000) study is not, strictly speaking, a quality evaluation model or method but a tool for creating evaluation models by specifying which quality attributes are the target for the designer. This tool is called RARE (Reference Architecture Representation Environment). Barber and Graser state that quality attributes have an impact on each other and that not all of them can be maximised at the same time and, therefore, the designer must explicitly solve the conflicts that arise. The idea behind this study is that no single quality model can be established given that, for instance, flexibility or extensibility will negatively impact on performance and there are application domains where one or the other can be more important. As a matter of example, the study mentions reusability, extensibility, comprehensibility, and performance as the main quality attributes to work with, although it does not imply that others cannot be added.

As in the other models there are mappings that drive calculations from OO design metrics to quality attributes, but in this case the intermediate elements are OO knowledge elements: *heuristics* and *strategies* (as refactorings and design transformations that guide the application of heuristics). Thus, Barber and Graser incorporate OO knowledge not as a goal, as in Miller et al. (1999), but rather as a tool to achieve quality attribute

enhancement. The quality attributes chosen by the designer and their associated importance weights are quality goals; the metrics calculate the degree of achievement of the heuristics, which are used to calculate the level of achievement of the goals. This tool uses strategies to help the designer to change design in order to increase certain heuristics, and the order in which they are suggested to the designer is driven by the goals.

Unfortunately the study talks about a tool still under construction and, in our searches, we have not seen further notice of it. No quantitative measures are given in the paper about the calculation of each heuristic, nor a list of heuristics and strategies is given for it; although promising, we must discard this study as incomplete.

Marinescu and Ratiu's Factor Strategy Model

In Marinescu and Ratiu (2004),yet another perspective is given, this time an indirect measurement of the quality is proposed, instead of measuring the quality of the design, Marinescu and Ratiu measure the lack of quality by detecting common design flaws. The model is comprised of OO metrics, design flaws and, finally, quality factors and goals. The first two set of elements are tied together through principles, rules, and heuristics and with them design flaws are quantified through *detection strategies.* Each quality factor has an associated formula for calculating its level from the set of design flaws (quantified from metrics through detection strategies) and the total quality is given by the quality goals chosen (ISO 9126 quality attributes such as maintainability or reliability) and the weight given to each one. Quality goals are divided into factors exactly as in ISO 9126, and the study refers to it and gives two example formulae for maintainability from its sub-factors (changeability, testability, analysability, and stability) exemplifying that different weights could be used for each subfactor according to experience. There are similar formulae to associate factors and detection strategies and the relative weights must be provided by the designers.

This is probably the most promising of all the selected studies since it takes into account OO knowledge as a tool for improvement and measurement of the design quality and establishes that quality is decomposed in general software quality attributes that can be derived from those knowledge elements. OO properties are not quantitatively present in the model, although there is a table identifying which design flaws impact on what properties (only coupling, cohesion, complexity, and encapsulation are listed).

We see that, on the one hand, quantification of the different mappings must be provided by the developer and, on the other hand, the design flaws (and detection strategies) are categorised according to the design component they are tied to; however, we see that OO knowledge is not properly classified and there are missing elements (only "bad smells" and some "patterns" are used). Probably a better ontology could be used as rules used instead of detection strategies, for that Garzás and Piattini (2005) could be used.

CONCLUSION AND FUTURE WORK

With all the sources, primary, secondary, and discarded ones, we can conclude that studies dealing with OO quality evaluation and metrics can be classified as follows:

- True quality evaluation models based on quality attributes quantification
- Prediction models for a single or few OO properties or quality factors
- Design flaw detection methods and their associated refactorings or design transformations
- OO metrics suites

The first set is the one that interests us and can be further subdivided in models that favor

specific quality indicators or those that propose a flexible model in which the user (i.e., designer or other stakeholder) must set the quality factors and their weights.

One important conclusion of our review is that maintainability is the most used high-level quality indicator, which is logical given that Object Orientation has been seen as a paradigm that favors flexibility and reuse. Other quality indicators or attributes, such as efficiency or portability are missing in the full models, which can be due to the fact that all the studies are biased by the fact that different application domains are not considered.

Surprisingly reliability is also very important in those studies that are just prediction models.

Only four studies establish a full quality evaluation model and, of them, no one establishes an explicit hierarchy between the high-level indicators. Two of the four studies are flexible models and three of the four use, partially, OO micro architecture knowledge.

In future works two main objective can be targeted, on the one hand, by trying to establish hierarchies between quality attributes, which may be according to different hierarchy sets corresponding to application domains, and on the other hand a better application of OO micro architecture knowledge in the construction of the evaluation methods through the use of ontologies.

Chapter 7.2
Software Quality and the Open Source Process

Sameer Verma
San Francisco State University, USA

ABSTRACT

This chapter introduces the open source software development process from a software quality perspective. It uses the attributes of software quality in a formal model and attempts to map them onto the principles of the open source process. Many stages of the open source process appear to have an ad-hoc approach. Although open source is not considered to be a formal methodology for software development, it has resulted in the development of very high quality software, both in the consumer and in the enterprise space. In this chapter, we hope to understand the open source process itself, and apply it to other methodologies in order to achieve better software quality. Additionally, this chapter will help in understanding the "Wild West" nature of open source and what it may hold for us in the future.

INTRODUCTION

The concept of quality is an abstract one. While quantity can be specified in standard terms such as a gram or a gallon, quality is usually a relative term. It is relative to the assessment of the product or process, as perceived by an individual or an organization (Barbacci et al., 1995). Quality is sometimes defined as compliance *to* a standard (Perry, 1991). It seems that the implications of quality vary from one task to another, and so does its assessment. However, generally speaking, we can agree on the direction it takes when the quality of an entity improves or degrades. In the case of software, the quality of software can be assessed by its characteristics. Several models exist that either measure software quality using a quantitative surrogate, or in terms of attribute sets. In this chapter, we use a model (Bass et al., 2000), where the quality of software is assessed by its attributes. These attributes include per-

formance, security, modifiability, reliability, and usability of a particular system. We will explore these attributes, the challenges they pose to the open source development process and how the open source community measures up to these challenges.

BACKGROUND

The importance of information systems and technology is well-established in our society, both in personal and professional space. It is difficult to imagine a society without access to information. Software forms an important cog of that system. While hardware such as desktops, laptops, and PDAs provide a platform for implementing computing power, software is the flexible component that is responsible for expression of innovation, creativity, and productivity (Lessig, 2005). Ranging from word-processing to number-crunching, the quality of software influences and impacts our lives in many different ways. It is no surprise that software quality has become the subject of many studies (Halloran & Scherlis, 2002).

Software Quality

While the quantitative side of software can be measured and optimized in terms of its capability to solve mathematical formulations and render graphics (Wong & Gokhale, 2005), it is the qualitative perception that matters to the end user and the organization (Bass et al., 2000). Quality is also harder to assess, so it is often ignored or replaced by quantitative measurements such as lines of code. Obviously, more lines of code do not always imply better quality (Samoladas et al., 2004).

In this chapter, we will use a model that uses five attributes, namely, performance, security, modifiability, reliability, and usability, to assess the quality of software. Performance involves adjusting and allocating resources to meet system timing requirements (Bass et al., 2000). Security can be described as freedom from danger, that is, safety. It may also be viewed as protection of system data against unauthorized disclosure, modification, or destruction (Barbacci et al., 1995). Modifiability is the ability of a system to be changed after it has been deployed. Requests can reflect changes in functions, platform, or operating environment (Bass et al., 2000). Reliability of a system is the measure of the system's ability to keep operating over time (Barbacci et al., 1995). Usability is a basic separation of command from data. It relies on explicit models for task, user, and system (Bass et al., 2001). These attributes put together can assist in assessing the quality of a software project. Of course, these attributes apply to all kinds of software, whether open source or proprietary.

Open Source Process

Next, let us examine the open source process. The purpose of looking at open source as a process, as opposed to a product, is that the open source ideology permeates well beyond software production (DiBona et al., 1999). The proponents of open source believe in a philosophy of open source more so than simply the software. They look upon software as an enabler of change in a society that increasingly relies on information technology for its survival and growth (Lessig, 2005). The following sections are by no means exhaustive, but should provide a substantial background to understanding the tenets of quality in the open source context.

Open source software (OSS) is largely developed by freelance programmers, who create freely distributed source code by collaborating and communicating over the Internet (Moody, 2001; Raymond, 1999; Sharma et al., 2002). A small, but significant proportion of the software is also developed in software companies such as IBM, Sun Microsystems, and Intel. Open source software is generally fashioned in what is often

classified as the *bazaar* style as opposed to the *cathedral* style, which is more commonly observed in proprietary software development. In his collection of essays, Raymond (1999) postulates that the proprietary style of software development follows the cathedral model, complete with plans, schedules, resources, and deliverables. In contrast, the bazaar model lacks an explicit blueprint. Work begins with an idea, followed by a series of short release cycles of software, which is prototypical at best. Over time this software development process gains momentum, in some cases, partly due to the availability of source code and partly due to common interest in the application of the software (Feller & Fitzgerald, 2002).

This development process is akin to shopping at a bazaar-like marketplace and purchasing ingredients as needed. Just as one would shop for olive oil, basil, pine nuts, lemons, parmesan cheese, and garlic to make pesto (Technorati, 2005), one could look for an operating system, a Web server, database server, and a programming language to build a Web application (Associates, 2005). The fact that this style of software development actually works comes as a pleasant surprise to many who are accustomed to working with traditional methods of software development[1]. A more subtle message from Raymond's essay is that while the *cathedral* approach may result in a grand and impressive application, it becomes somewhat outdated by the time it is completed (Raymond & Trader, 1999). The application may be complete, but the nature of the original problem may have changed significantly over time.

Failure to maintain a time schedule and contain the scope are often cited as reasons for the failure of information systems (Applegate et al., 2002). Open source's course-correction approach makes minor changes frequently to continually address the changing nature of the problem at hand. In some ways, the *bazaar* approach might alleviate the ills of the traditional software development process (Feller & Fitzgerald, 2000).

Proprietary vs. Open Source Software

Proprietary software, including the source code used to create it, is often protected by a patent (Perens, 2005). The patent, not to be confused with copyright, is not free of distribution restrictions, and is rarely free of cost. Proprietary software is also defined as the software whose source code is kept secret and belongs to a specific individual or a company (Barahona et al., 1999). In the case of proprietary software, the source code is not distributed. The software is only made available in the form of compiled, object files to end users (Feller & Fitzgerald, 2002). The ownership of the software belongs to a specific company, group, or individual. Software cannot be redistributed, modified, or sold without the explicit permission of the owner. This "permission" is usually specified in the end user licensing agreement, also called EULA.

Enterprises use similar licenses, except that enterprise licenses apply to all end users in an enterprise, and even if the source code is given to the client company for maintenance purposes, the client is not allowed to make it available to third parties, let alone the entire world (Goth, 2001). These descriptions are largely applicable to proprietary software, although many variations do occur and must be treated on a case-by-case basis (Rosen, 2005). The owner entity (usually a software company) decides on the release cycles of the proprietary software, which in most cases is based on market pressures and upgrade revenue (Applegate et al., 2002). Closely guarded source code becomes the basis of this revenue stream.

The development framework for open source leverages communication facilities of the Internet. Independent software developers examine existing source code and make modifications to fulfill immediate needs in their own environment. In the case of open source software, the licensing allows distribution in source code as well as object form. When a product is not distributed with its

source code, there is usually a well-publicized means of obtaining the source code for no more than a reasonable reproduction cost, preferably downloadable via the Internet.

Proprietary Licensing

Companies that practice the traditional software approach typically use proprietary software licenses. The EULA[2] assures that any software given to a customer cannot be copied, redistributed, or modified without the explicit permission of the company. Since commercial software products are in the form of object and not source code, software products can be licensed per-user, per-machine, per-processor, or for an entire organization under closed-source software licensing. A closed-source license may require a royalty fee, and in some versions it has an expiration date by which the customer should purchase the software again or upgrade to a new version of the product. Proprietary licensing is designed to generate a continuous revenue stream, while protecting the source code, and thereby controlling its use in the market.

Open Source Licensing

In contrast, the nature of the open source software is that no right-to-use license fee or right-to-redistribute license fee is solicited from the users. No royalty is charged for businesses or individuals if they sell the source code of any open source software. However, open source must not be confused with public domain (Rosen, 2005). When the developer releases the source code to the public under the terms of an open source license, he or she does not relinquish the copyright. Open source licenses grant conditional rights to members of the general public willing to comply with the terms of the open source license. Developers can still sell private licenses to individuals and companies that are unwilling or unable to comply with the terms of the open source license (Rosen, 2005).

THE OPEN SOURCE MECHANISM

The open source community is a collection of individuals who may have any level of interest in open source software. These interests may lead them to play different roles. The involvement varies from being providers of ideas and code to simply users of the code (Dotzler, 2003). Open source communities pattern their operations off virtual organizations. In most cases, virtual organizations refer to new organizational forms that rely on strategic alliances and external partners to collaborate to achieve business goals or to serve customer needs (Davidow & Malone, 1992; Grenier & Metes, 1995; Lucas, 1996).

In order to achieve "spatial and temporal independence" (Robey et al., 1998), information and communication technologies tend to be heavily utilized to facilitate the coordination across time and space boundaries (Mowshowitz, 1997). Gallivan (2001, p. 281) defines virtual organizations as "goal directed and consisting of geographically distributed agents who may or may not ever meet face to face", which is very apt in the case of open source communities. Additionally, the *gift culture* within the open source community features giving away source code (Bergquist & Ljungberg, 2001), voluntarily testing and debugging the software (Dotzler, 2003), and supporting fellow users by promptly answering their posted questions through mailing lists and Internet Relay Chat sessions (Raymond & Trader, 1999).

Producer of Software

Open source software development is often initiated by individuals or small cliques of people for their own limited purpose (Mui et al., 2005). A phrase often used to describe this approach is "Every good work of software starts by scratching a developer's personal itch" (Raymond, 1999, p. 23). The *itch* metaphor is indicative of a small, yet focused need that an individual developer may have, as opposed to a grand plan for soft-

ware development. If the software that results from this process (*scratch*) proves to be useful, then others join in and contribute. The producer community is usually made up of individuals who are bound together by an open source project and little else. Often, these "producers" never meet in person. It is a modern marvel that entire pieces of software projects are negotiated, developed, managed, and disseminated completely online (Dotzler, 2003).

Based on the control structure of most open source software projects, a handful of individuals are given write-access to the software repository. These are the producers of software, also called maintainers in OSS parlance. Projects in the open source world adopt the walled server approach (Halloran & Scherlis, 2002). The server that hosts the software repository is visible to the entire world. Anybody can read from it. However, only the maintainers hold the right to *implement* recommended changes. Information flows freely from the producers, but not all feature requests or bug fixes are necessarily implemented into the project itself.

This approach seems to work well for controlling software development practices of the project. It does not limit the behavior of developers in their own environment. It does limit changes that the maintainers can make on the project itself. The walled server idea embodies critical aspects of software best practices such as process, management, design, and architecture *as defined by* the project leaders. This enables effective engineering management despite the fact that the engineers are self-selected and largely self-managed. It also allows for a more rigorous approach to quality control and assurance.

Consumer of Software

Oddly enough, the primary consumer base of open source software is the open source community itself. Thus, one way to classify open source development is to study it as an innovation (Verma & Jin, 2004). Considering the traditional methods of software development, there is plenty of evidence that the open source methodology is indeed an innovation. Taking this idea one step further, we can look at this development as a process that happens where the consumers of software are from the same group as the producers. In most production and consumption-based economies, the producer group is quite different from the consumer group.

This holds true in the world of traditional software as well. The stack of communities is vertically connected from producer to distributor to consumer. Consumers of software are rarely skilled in the art and science of software production, hence the segmented innovation approach, where the innovators are different from the end users. However, the open source community is different. A large proportion of the open source community falls in an intersection of producers and consumers of the software (Feller, 2001). This is inherent in the open source process. Users are treated as co-developers. Both parties subscribe to the same community. These shared innovation networks have a great advantage over the segmented innovation systems. Furthermore, individual users do not have to develop everything they need on their own; they can benefit from innovations developed by others and freely shared within and beyond the user network.

Peer Review Process

The software development process is community-driven, where the community size may vary from a small group of 2, to a large group of over 100 developers. An interesting departure from other traditional approaches is that OSS users are treated as co-developers or peers (Dotzler, 2003). Since the source code is freely available, a community of peers is able to partake in a peer review process somewhat similar to the academic peer review process conducted to publish research (Raymond & Trader, 1999). The role of members

of the community varies based on their skill sets, interest, and availability of resources. Different roles can be approximately categorized into four groups, including project owners/core developers, patch submitters, source code testers, and end users (Verma & Jin, 2004). Project owners/core developers are a small group of people who contribute most of the code and control the software releases.

Let us look at two examples to comprehend the proportion of members across different functional roles. The first example is the Apache project, which is an open source project for developing a Web server. It began as a series of patches or fixes to the original Web server developed at National Center for Supercomputing Applications at University of Illinois, Urbana-Champaign (Audris, 2003). Eventually, the patches became so numerous that it was suggested the server be named a "patchy" server; hence the name Apache (Dotzler, 2003). The core developers of Apache account for over 80% of the coding. Patch submitters involve a relatively wider development community who examine the source code in detail and submit bug fixes (Mockus et al., 2000).

Source code testers are comprised of an even larger group who download and compile the source code and report the bugs. Lastly, end users, who may constitute the largest group of all, are only interested in using precompiled object code. End users may also report problems, but the problems are based on precompiled software. Another example is the Mozilla project, which came out of the original Netscape Web browser code (Dotzler, 2003). Mozilla developed into a significantly different browser since its inception in 1998. Mozilla has about 25 core developers, over 400 patch submitters, over 10,000 quality assurance testing contributors, and around over 500,000 end users involved (Dotzler, 2003).

Debugging and Feedback

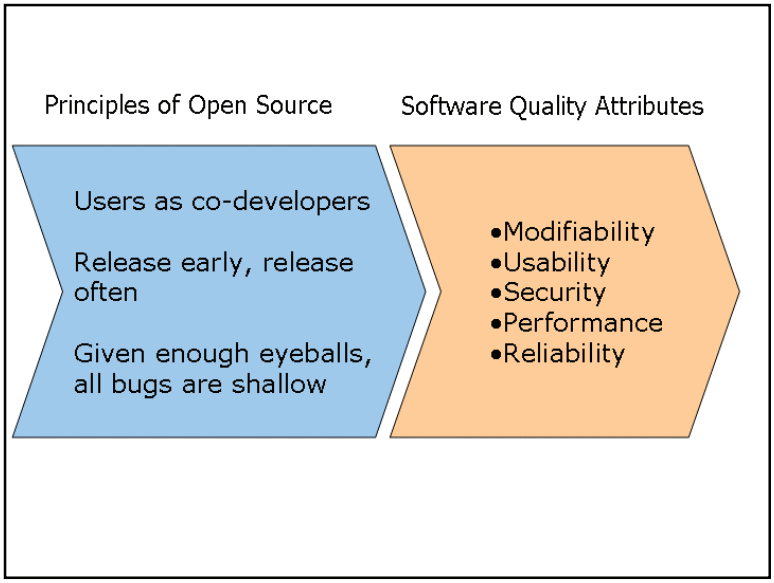
Bug reporting methods adopted by the open source community are designed for public view. All feedback is made public, thereby allowing someone on the outside to review the code and submit a change, usually called a fix or a patch. Such patches are usually maintained in parallel with existing software, so that users may pick and choose patches that are necessary for a particular scenario. The walled server approach (Halloran & Scherlis, 2002) mentioned before, provides an asymmetric channel for flow of bug-related information. The number of inputs from the community outnumbers the number of fixes implemented by the core group. Patches are usually written by one of the core members, or by patch submitters. Only core developers are allowed to make the decision to include a patch into the main software code base. Irrespective of the decision to include the patch into the main code base, the patch is always made available as an option. If a project requires some esoteric feature set provided by a patch, the developers can choose to include it at the time of compilation.

Evolutionary Survival

When the demands for features and bug fixes from the community go unanswered, the project may split or fork into a parallel development stream. Most open source licensing allows for a project fork, which is a split in the code development process into a new branch. A fork allows for independent and parallel development following two different approaches. It is theorized that the most useful branch will thrive while the less useful one will wither away (Torvalds & Diamond, 2001). This is similar to the process of genetic evolution where dominant traits get adopted and recessive ones diminish over generations.

A popular example is PHPNuke, a portal framework written in PHP, with a database back-

Figure 1. Mapping of open source principles and quality attributes



end to store content. PHPNuke started as a creation of one person to fulfill the need for a free and open source content management system. PHPNuke got popular very quickly. The application soon grew to a size that was beyond one person's ability to manage. The maintainer accepted help from other programmers but did not give them credit where it was due. He also failed to fix bugs they repeatedly pointed out, even when they submitted bug fixes. A number of these programmers became annoyed and disappointed with the general unresponsiveness of the project owner and decided to fork PHPNuke (Krubner, 2003). This version came to be known as PostNuke. With its own community, PostNuke implemented all the patches that were previously ignored. As PostNuke became more feature rich and less buggy, PHPNuke picked up momentum in order to compete with its forked creation. While forking does create a division of resources, it also creates a healthy competitive environment. Eventually, which version of the fork will dominate (i.e., used by the majority) will depend on the adaptability of the software to its environment[3].

QUALITY AND THE OPEN SOURCE PROCESS

To reiterate our approach to examining open source via the lens of quality attributes, we propose five key attributes: modifiability, usability, security, performance, and reliability. We would like to map these attributes to the primary principles of open source (Figure 1). Three most widely sited principles of OSS development include:

- Treating users as co-developers.
- Release early and release often.
- Given enough eyeballs, all bugs are shallow.

These three principles explain the essence of open source development model. Other observations are comparatively minor in their impact on the open source process as a whole.

Users As Co-Developers

The first principle of *treating users as co-developers* stems from the fact that many members of the open source community are also involved in the development process. They may be programmers or simply bug testers. Either way, the users are treated as an integral part of the development process. This approach makes it easier to communicate with the community on a deeper level of software development. For example, instead of telling users to wait for a month or two, a project member may simply ask members to download untested code from the software repository. Repeated testing and use by co-developers provides valuable feedback that plays an essential role in the quality assurance process. Often, co-developers test software on a variety of software and hardware combinations. For example, programs written for the 386 class of Intel processors running a form of Linux operating system will typically run without any problems on 486 and Pentium class processors as well. Similarly, software written for the 32-bit version of Windows (Windows 95) will typically run on Windows 98, Windows 2000, and Windows XP.

Each co-developer would often have different setup of software and hardware. The combinations of hardware and software as a testing platform make for a very rich testing process. Working with co-developers has other advantages. Every time a significant problem is solved, a patch is applied to the existing code which is re-released every night in versions dubbed as nightly releases (Dotzler, 2003). Each nightly release is based on the very latest improvements and is targeted toward the co-developer community. Each nightly build is tested and goes through a rigorous testing process conducted by the co-developers.

By treating users as co-developers, the open source community strives to create a better performing piece of software (fewer bugs) with higher levels of usability. A good example of improved performance is the Linux kernel. After its 624 iterative incarnations (Kendrick, 2005), the version 2.6.10 of Linux has come to support many form factors ranging from cell phones to mainframes (Pranevich, 2003). The performance of Linux is equally good in either of these environments. The availability of source code and feedback from co-developers has made it possible to get performance levels on par with industry giants from the proprietary world.

Similarly, the Mozilla Firefox project is an example of improved usability. The Mozilla project was started in 1998 as a spin-off of the Netscape Communicator product from Netscape Communications (Dotzler, 2003). The idea was to open source the code-base in order to foster innovation. Over the last seven years, the Mozilla project has evolved from a sluggish, bloated piece of software to a much more usable product in the stand-alone version of the browser called Firefox[4]. The usability of Firefox is considered so much better than the leading browser (Internet Explorer) from Microsoft that Firefox has been downloaded over 78 million times since its original release in 2004.

The OSS community follows an incremental model of quality and payoff. With each incremental change comes a change in quality. After all, a large proportion of the feedback comes from the user community. This high degree of involvement relies on a legal mechanism of the *right* to modify any piece of software. It is only under the auspices of an open source license, that software creators provide their source code and hence a large share of their intellectual property rights. This sharing is done for a greater good of a much better expected payoff in the long run.

Release Early, Release Often

Open source licenses are primarily designed to encourage modification and redistribution of software in source code form. The process of releasing several versions of the software in rapid cycles is aptly captured in the second principle: *release*

early and release often. For example, over its life cycle of almost 14 years, it is estimated that the Linux kernel has been released 624 times (Kendrick, 2005). Each release attempts to improve upon the previous one. In some projects, versions are released every week during rapid testing and bug fixing. The general thinking is that instead of providing the end user with a feature complete version of the software, the creators release very rudimentary versions to get the discussions going. Small changes are incorporated quickly and released often to the public.

Another such example can be seen with the NoCatAuth project (Ishii et al., 2002), a very visible project that provides open source routing for wireless networks. In its initial incarnation, the software was written in Perl. The first few versions did not even work. However, it presented the idea to a group of people who then worked on improving it. After over 25 revisions, the software was stable enough to run for months on end without a reboot. NoCatAuth gained this stability through rapid release cycles with simple bug fixes implemented in each cycle.

Most open source projects use version numbers that mirror the policy of rapid releases. For example, in case of the Linux kernel, the version numbers take the form of *x.y.z* where *x* begins at 0, and *y* and *z* are nested subcategories (Torvalds, 2005). The first release of Linux was dubbed version 0.01 and has reached version 2.6.10 today[5].

Such incremental versioning supports incremental changes and timely assimilation of feedback through the quality assurance process. Features are therefore implemented and bugs are fixed in a more organized fashion.

Another outcome of rapid release cycles is that over time, the proportion of critical system errors decreases. This observation has been tested using randomly-generated commands (called the Fuzz approach) on different operating systems, including Microsoft Windows Family, UNIX, and Linux (Miller et al., 2000). The outcome is interesting. It shows that over time, the reliability of Linux-based operating systems has improved tremendously. Better stability and increased time between crashes improves stability and reliability of the system as a whole.

The most visible downside of the rapid release process is that it does not allow for long-term thinking in some cases. For example, the Jabber project was initially created to address the problem of instant messaging (Adams, 2001). However, as the project grew, the developer community realized that the project could be extended to much more than just instant messaging. In its next major release beyond the 1.4 series, the Jabber Software Foundation decided to release a version 2.0, a complete rewrite of the design and its code (XMPP.org, 2005). Both series 1.4 and 2.0 co-exist and are actively used based on feature preferences.

Given Enough Eyeballs…

Feedback is a very important cornerstone of the OSS process. Since the source code is made available for peer review, skilled programmers not only find problems but also fix them on their own. Even the non-programmer community can contribute by looking for the odd behavior in performance and user interface design. This is the essence of the third principle: *given enough eyeballs, all bugs are shallow,* also called *Linus' Law* after Linus Torvalds, the founder of Linux (Raymond, 1999).

Easy access to source code facilitates rigorous peer review and parallel debugging among many geographically dispersed programmers, therefore enabling rapid evolution of *high quality* software (Koch & Schneider, 2002; Stamelos et al., 2002). In addition, the mass of software users are directly and actively involved in the development process. Their bug reports tend to be very detailed because they generally cover problems that originated in different kinds of systems with various hardware/software configurations. Their suggestions and feedback regarding features

Table 1. Comparing software methodologies (Adapted from Abrahamsson et al., 2002)

Entity	**A gile Methods**	**Open Source-based (bazaar style)**	**Plan-driven (cathedral style)**
Producers	Rapid, Localized, Collaborative	Geographically distributed, Collaborative, Rapid	Adequate skill-set, plan-oriented, usually localized
Consumers	Dedicated, Knowledgeable, Collaborative, Empowered	Dedicated, Knowledgeable, Collaborative, Empowered	Representative, plan-driven
Design approach	Based on current environment	Based on current environment, but open for change	Based on current and foreseeable environments
Team management	Smaller team dynamics, Face-to-face	Dispersed teams, loose team dynamics	Larger teams
Goal	Rapid Value	Challenging problem (itch metaphor)	High assurance
Time scale	Short	Short	Long

and solutions of the software also promote more functional and user-friendly design.

This approach also goes against the grain of the *security through obscurity* concept that is often leveraged by proprietary software companies (Hissam et al., 2002). This is a controversial principle in security since it attempts to use secrecy to ensure security (Wikipedia, 2005). The essence of this concept is that since proprietary software does not make source code available, the risk of discovering security vulnerabilities is minimized. However, this approach is also akin to the practice of hiding the key under the doormat, so that it remains hidden. It is almost universally known that the first place to look for keys is under the doormat. Once the vulnerability is discovered, all is lost, until the vendor chooses to fix the problem. With open source projects, vulnerabilities get fixed either by the vendor, or by someone in the community. It appears that the open source process fosters better notions of security from the code perspective.

COMPARISON OF SOFTWARE METHODOLOGIES

Many approaches within the open source community are similar to the ones followed within proprietary processes. It is important to understand that the programming language or framework that is used in either case is not significantly different. Programs written as open source or closed are essentially only instructions for a computer. What differs is its visibility and management. Closed source projects have programmers and reviewers, but these members are most likely paid employees of the same organization, where the goal is to maximize profit. OSS communities are not driven by monetary incentives. They are largely driven by ego, trust (Mui et al., 2005), and a desire to produce free code.

Open source software development has formalized in the last few years, but most of the work is done based on the direction from a very small core group as in the *benevolent dictator* model (Hamm, 2004) or by a group of developers who take on roles based on their quality of work and intentions as in the *meritocracy* model (Perens, 1997; Young, 1958). Linux is the primary example of a project where the central authority is Linus Torvalds, who relies on the consensus of a few other core contributors. Linus is therefore considered to be the benevolent dictator. On the other hand, a project like Debian, which is a community-driven distribution of Linux, chooses a team to lead the project every few years. The individuals elected to these positions are chosen based on their merit; hence the term meritocracy. In either case, the projects start with

a vested interest at solving a single problem (the itch metaphor), and then evolves into something larger, if found useful.

Similar methods exist that rely on quick cycles of feedback and very rapid development schedules. Agile methods are primarily fostered by groups that are customer-oriented, and prefer to work in face-to-face environments that are usually well-funded (Alliance, 2001). Extreme programming is perhaps the most well-known of all agile methods. Table 1 presents a side-by-side comparison of open source methods, agile methods, and the classic plan-driven methods (Abrahamsson et al., 2002).

FUTURE TRENDS

In the early days of open source, it was strongly believed that the entire open source movement was being shouldered by altruistic programmers who burned the midnight oil to keep their ideals intact, an ideal of software free from bugs and free from the clutches of the enterprise (Himanen, 2001). Those stereotypes are changing rapidly (Dahlander & Magnusson, 2005). It is no longer a fly-by-night operation. Large organizations such as IBM, Oracle, General Motors, and the U.S. Department of Defense are playing a major role in the creation and maintenance of open source software (MITRE, 2002). Companies such as Sun Microsystems, known for their proprietary software, are testing the waters with different business models. Sun Microsystems recently announced the OpenSolaris project (Sun Microsystems, 2005), which aims at releasing the Solaris version 10 operating system under an open source license. These are big steps for the software industry, and it looks like this trend is moving up.

Other companies are getting into the business of providing a test platform (often called a stack) where they test a combination of software for enterprise level performance and security. The primary complaint with open source software is its lack of a guarantee. The software is provided as-is. Companies such as SpikeSource test combinations of open source Web servers, databases, and scripting environments for performance and security. Such approaches bolster confidence by providing guarantees that enterprises need. In such cases, open source is no longer viewed as unwarranted code written by lone programmers.

Enterprise involvement brings with it the question of legality. Given that code is written by so many different people, it is very difficult to avoid the conflict with an existing patent. In recent cases, SCO has taken IBM and DaimlerChrysler to court over intellectual property claims (Groklaw, 2005). Given that the legal standing of open source software is still largely untested in court, some companies shy away from using open source.

CONCLUSION

While the open source approach is more along the lines of the untamed "Wild West", it presents a compelling alternative to developing high quality software. Projects such as Apache, Mozilla, and Linux have produced equal if not better quality software when compared with their proprietary counterparts. Apache commands over 65% of the world's Web server market share (Netcraft, 2005), while Mozilla Firefox and Linux have demonstrated very rapid growth in their own domains. In spite of the risks of a community-driven project, open source presents a favorable picture from a quality perspective. Over time, open source software improves in usability, performance, security, and reliability. Additionally, it is the *modifiability* of open source that stands out as the prime attribute. It would be well worth the effort to take a closer look at the open source world and attempt to accommodate its idiosyncrasies into more well-established, formalized methods to gain a "best of both worlds" advantage.

ENDNOTES

1. This document was authored using OpenOffice Writer, a component of the open source productivity suite available at http://www.openoffice.org/
2. EULA is the generic term used for proprietary software licenses. Open source licenses are classified based on one of the fifty-six different licenses as certified by the Open Source Initiative. There is no common body that certifies proprietary software licenses.
3. There appears to be some recent discussion amongst the core developers of PHPNuke to completely re-write the application and to avoid all the problems they faced with

the original design. This is a significant drawback of the open source model.

[4] Mozilla still exists as a complete suite (codenamed SeaMonkey), but is used by a smaller proportion of users. The larger and more visible component is the Mozilla Firefox product.

[5] As of version 2.6.11, Linus Torvalds has proposed the use of a quad notation, wherein a release will be versioned as x.y.z.a, thereby adding one more loop to the quality assurance process.

Chapter 7.3
Agile Software Development Quality Assurance:
Agile Project Management, Quality Metrics, and Methodologies

James F. Kile
IBM Corporation, USA

Maheshwar R. Inampudi
IBM Corporation, USA

ABSTRACT

Of great interest to software development professionals is whether the adaptive methods found in agile methodologies can be successfully implemented in a highly disciplined environment and still provide the benefits accorded to fully agile projects. As a general rule, agile software development methodologies have typically been applied to non-critical projects using relatively small project teams where there are vague requirements, a high degree of anticipated change, and no significant availability or performance requirements (Boehm & Turner, 2004). Using agile methods in their pure form for projects requiring either high availability, high performance, or both is considered too risky by many practitioners (Boehm et al., 2004; Paulk, 2001). When one investigates the various agile practices, however, one gets the impression that each may still have value when separated from the whole. This chapter discusses how one team was able to successfully drive software development quality improvements and reduce overall cycle time through the introduction of several individual agile development techniques. Through the use of a common-sense approach to software development, it is shown that the incorporation of individual agile techniques does not have to entail additional risk for projects having higher availability, performance, and quality requirements.

INTRODUCTION

Traditional software development approaches, perhaps best represented by the capability maturity model for software (SW-CMM) (Paulk, Curtis, Chrissis, & Weber, 1993) and its successor the capability maturity model for software integration (CMMI®) (Chrissis, Konrad, & Shrum, 2003), focus on a disciplined approach to software development that is still widely used by organizations as a foundation for project success. While the strength of traditional development methods is their ability to instill process repeatability and standardization, they also require a significant amount of organizational investment to ensure their success. Organizations that have done well using traditional approaches can also fall victim of their success through a strict expectation that history can always be repeated (Zhiying, 2003) when the environment becomes uncertain.

Agile development practices have frequently been presented as revolutionary. There is some evidence, however, that they can offer an alternative common-sense approach when applied to traditional software engineering practices (Paulk, 2001). Perhaps they can be used in part to improve the development processes of projects that do not fit the usual agile model (e.g., critical systems with high availability requirements)? Indeed, it has been suggested that project risk should be the driving factor when choosing between agile and plan-driven methods (Boehm et al., 2004) rather than overall project size or criticality. This implies that certain components of *any* project may be well suited to agility while others may not.

This chapter discusses how agile methods were used on one team to successfully drive software development quality improvements and reduce overall cycle time. This is used as a framework for discussing the impact of agile software development on people, processes, and tools. Though the model project team presented is relatively small (eight people), it has some decidedly non-agile characteristics: It is geographically distributed, it has no co-located developers, the resulting product has high performance and reliability requirements, and the organization's development methodology is decidedly waterfall having gained CMM® Level 5 compliance. Therefore, some of the fundamental paradigms that serve as the basis for successful agile development—extreme programming (Beck & Andres, 2005), for example—do not exist. Nevertheless, they were successfully able to implement several agile practices while maintaining high quality deliverables and reducing cycle time.

Chapter Organization

This chapter is organized as follows:

1. **Background:** Some history is given about our model project team and what led them to investigate agile methods. The concept of using a hybrid plan- and agile-driven method is also introduced.
2. **Approaching Selection:** How did our model project team decide which agile practices to use and which ones to discard? This section discusses the risk-based project management and technical approach used.
3. **Implementation:** This section presents how each selected agile practice was incorporated into the software development process.
4. **Impact:** How did the project team know the implemented agile practices were providing some benefit? This section talks generically about some of the metrics that were used to compare the project to prior projects performed by the same team and the impact the selected methods had on the project.
5. **Future Trends:** A brief discussion about what path will be taken to approach follow-on projects.
6. **Conclusion**.

BACKGROUND

How doth the little busy bee
Improve each shining hour,
And gather honey all the day
From every opening flower!

Isaac Watts, *Divine Songs, 20, Against Idleness and Mischief, 1715*

This chapter introduces several concepts about integrating agile software development techniques into a project that does not have typical agile characteristics. The information provided identifies the conditions that were present at the time our profiled project team began to incorporate agile practices into their decidedly traditional development approach. We begin with a history of a project development team that was unable to meet the expectations of its customer and was unsatisfied with the progress they were making toward meeting their goal of quickly developing a quality product that supported both high availability and high performance. Though the conditions identified are specific to this project and project team, one will most likely find them familiar.

Following an overview of the project and project team, a brief summary is given of some of the existing alternative development methodologies that formed the basis of the team's decision to attempt to integrate agile techniques. Though a short section, it provides some additional insight into the investigatory nature underway to improve the team's results.

This background presents the reader with a contextual overview that will serve to ground the topics discussed later in the chapter. It provides a starting point from which the remaining discussions are based. Because a real project team is being profiled, both the name of the project and the product has been obscured throughout the chapter.

Project and Historical Context

In 2003, a project was undertaken to replace an existing Web application used almost daily by a significant number of individuals (almost 450,000 users). This would not be an ordinary application rewrite, however. When the business analyzed how the product was being used and what its perceived shortcomings were, it became clear that the application needed to be taken in a whole new direction. A project was therefore undertaken to create an entirely new application—one that would incorporate the base functionality of the original application, yet include a significant number of functional improvements, usability enhancements, and external dependencies. This was not the first attempt at replacing this application (a prior attempt ended in failure), but it was certainly the most bold.

This original rewrite project became troubled as requirements seemed to never stabilize and critical milestones were continuously missed. Though it was a medium-sized project with approximately 18 individuals on the development team, there were almost as many analysts, testers, and reviewers and perhaps an equal number of stakeholders. It had the classic characteristics of what Ed Yourdon calls a "death march"—a project in which an unbiased risk assessment would determine that the likelihood of failure is extremely high (Yourdon, 2004). Though the project was considered a success both in delivery and quality, the personal sacrifices were extremely costly. It left the entire team feeling that there needed to be a change in how future projects would be managed and how to adapt to rapid change in the future.

Back to Basics

Interestingly, even though it was recognized that things would have to change, the first change that was made was to be sure the team adhered to what they did not hold fast to the first time: the traditional software engineering life cycle. Though

this may seem somewhat counterintuitive, part of the problems faced during the original "death march" project had to do with not maintaining proper control over changes, agreeing to a scope that could not possibly be contained within the time allotted for the project, and not properly evaluating risks and dependencies. In other words, the project team needed to be able to walk before it could run. Since traditional development methodologies were well known and had generally predictable results, they would provide the basis upon which any future process changes would be based.

Several Small Successes

In our experience, it is a common occurrence that several smaller upgrade releases follow large application enhancements or new application implementations—this was no exception. As the project team was re-learning the basics of the software engineering process, there were two opportunities to immediately put it to work and identify which areas were ripe for true improvement. The first was a 2-month cycle of enhancements. It was a small project, but there was still a significant staff on board to complete the work. Unlike the first project, this one adhered to the traditional software engineering process and was successful with respect to schedule, cost, and quality. The business customer was satisfied and somewhat relieved that the delivery was uneventful.

The second project of enhancements was slightly larger in scope, but used less staff and, therefore, had a longer duration. Again, a traditional software development process was followed and the project was successful with regard to schedule, cost, and quality. This second project became a true proof point for the team and was a source of confidence in their abilities. They proved that they could maintain control over these types of projects and deliver high quality work. On the other hand, even though requirements change activity was similar to what occurred in the original project, their ability to control the change was through rejection or re-negotiation—they were unable to accept late changes that might have improved the overall product. A prime example of this was in the area of end user usability. In the traditional software development process being used, ensuring that an application is usable had to be done after the application was essentially complete (during user acceptance). Unfortunately, this meant that there would be no time remaining in the development cycle to address any changes prior to releasing the upgraded product. The implication was that these types of "enhancements" would always have to wait for a follow-on release to be implemented.

The project team also began to recognize that their integration and subsequent testing phases consumed a significant part of the development schedule. Even though the project was generally under control, integration had become a time of heroic sleep deprivation to ensure the schedule was met. It was not the same situation as occurred in the original rewrite project, but it was significant enough that the team recognized that this part of the development process needed to be addressed differently.

Rapidly Changing Business Needs

Though our profiled project team could now be considered successful—after all, they were able to deliver on a set of scope within a defined period of time at a defined cost and with good quality results—the process modifications that they made did not allow them to keep up with the rapidly changing needs of the business. The business could not afford to have 6-9 month development cycles with no changes to the original scope. The releases they sought to put out were time sensitive. They also wanted the amount of functionality contained within each release to remain somewhat flexible. Instead, as new ideas arose, they would be added to a list of ever-increasing "future requirements" or handled as changes that would adjust the end date of the release. There was also the nagging

problem of not being able to incorporate usability defect corrections easily into the release where the defects were found without adding a separate "usability" test period with corrections prior to the final user acceptance test period. As it was, they were subjecting users to usability issues that would not be corrected until a follow-on release.

Finally, the business was looking for more out of the team and the team was looking for a better way to do things. Traditional software development practices appeared to be only part of the solution. They had learned to walk, but weren't sure yet how to run.

Delivery Challenges

As more and more functional enhancements were requested by the business, the team began to run into additional delivery challenges. Though quality, cost, and schedule were under control, they were unable to build in the most important features fast enough for the business. In fact, they found that their cycle time to complete a project had actually elongated. In essence, they had traded the chaos of the original schedule for its opposite and found that both didn't really solve their problem (though not being in chaos was infinitely better). They also found that just "following the process" had a chilling effect on their customer relationship. The practice of locking down requirements and stopping change made them appear unresponsive and prone to not delivering value. Though the initial releases following the large rewrite were successful, the sense of pending frustration was becoming palpable. Again, the team recognized that they needed to do something different.

Technical Challenges

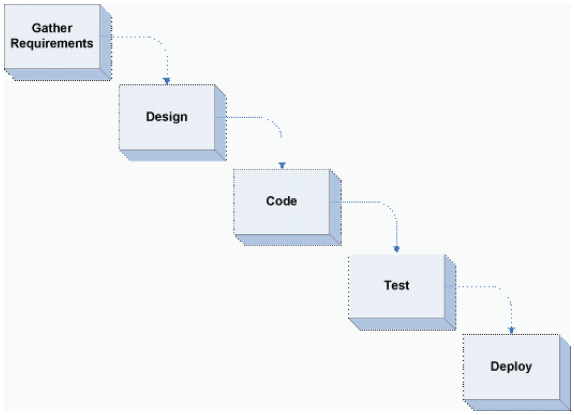
Technical challenges do not always get the same attention as other facets of software development when discussing the speed of delivery or quality for the final product, but it was a real concern to our profiled project team. Their customer was not only business-savvy, but had a keen interest in directing which technologies were used. This meant that some portion of the technical solution was imparted to the development team through the requirements gathering process. This could include individual technologies or, in one instance, the final production platform's specifications. To accommodate these types of requirements required a bit of experimentation to ensure they would work. This was something that the traditional development process did not easily support since some of the requirements themselves would derive additional requirements once investigated.

Hybrid Methodologies

Using a hybrid of adaptive and traditional software development methodologies is not as new and radical as it may at first appear. Though some of the concepts related to iterative development and other agile-like techniques can be traced back to at least two decades before the first mass-produced computer was even built (Larman & Basili, 2003), the "traditional" waterfall software development model had gained acceptance by the late 1960s when it was proposed that engineering disciplines should be used to tame wild software schedules (Naur & Randell, 1968). It derives its name from the fact that each step has distinct input and exit criteria that is supported by the surrounding steps (Figure 1). Unfortunately, the model assumes that a project goes through the process only once and that the implementation design is sound (Brooks, 1995).

Soon after being proposed, enhancements started to appear. Over time, several evolutionary techniques were developed as a compliment or replacement to the basic waterfall model including modified waterfalls, evolutionary prototyping, staged delivery, and the spiral model (Boehm, 1988; McConnell, 1996). Each enhancement recognized a failing in the original waterfall ap-

Figure 1. A traditional waterfall development model



proach and proceeded to address them within the replacement models.

Why Use a Hybrid?

Why use a hybrid development model and not adopt a single approach? The answer to this question is related to the amount of risk one can afford in their project schedule, cost, and quality. Pure waterfall models operate best with systems that require high reliability and need to be scaleable (McConnell, 1996). Our profiled project team and application has high reliability and high performance as key requirements, but they also have a highly volatile business environment in which the priority of functional enhancements frequently changes.

There is also a bit of a comfort factor in altering something one already understands; One need only learn the new techniques that replaces the original rather than an entirely new process. Over time as new techniques are introduced, the old process will no longer exist in its original form and the organization may be following a totally new methodology—one that meets their needs.

APPROACHING SELECTION

Guess if you can, choose if you dare.

Pierre Corneille, *Héraclius, act IV, sc. IV, 1674*

Great deeds are usually wrought at great risks.

Herodotus, *Histories, VII, 50, c. 485 – c. 425 B. C.*

One of the most difficult things when implementing process change is deciding which changes to make. The entire exercise is a study in risk management since choosing the wrong thing may impact the team's ability to deliver. Recall that after the tumultuous project of 2003, our profiled project team was able to deliver on time, on cost, and at a reasonable level of quality—though there was some room for improvement in the area of quality. Their challenge was to deliver faster and be more adaptable to changes that were brought forward within the development cycle. They recognized that changes needed to be made to make the team's delivery better, but they wanted to be sure that those changes did not undo the predictability they had worked so hard to attain.

The team approached these changes from two perspectives: Project management and technical. From a project management perspective, selected changes would need to be those that would enhance the delivery or quality of the project. From a technical perspective, the changes would need to be reasonable and able to enhance practitioner productivity and delivery. Making changes to one's development process is a unique experience; No two projects are the same. However, there seems to be at least two constants that we will address in the following sections prior to discussing process selection: Fear of change and overcoming that fear.

Fearing Change

Though our profiled project team recognized that there was something that needed to be done to make them a better team that could adapt to changes, deliver more quickly, and produce high quality results, some feared that tinkering with what was working could push them toward the ad hoc development process that they had already rejected. Even though they were not delivering quickly and the customer could not be characterized as completely happy, their projects seemed under control and they were no longer working 90-hour weeks.

The fear of change was manifest in several dimensions for our profiled project team. Each one, though, could be counterbalanced with a fear of not changing. This made for an interesting dance of conflicting emotions around what should be changed and what should be left alone. On one hand, they had proven their competence to their executive management. If they changed the way they do things and failed, they risked something that was tied directly to their self worth. Countering that emotion was the fear of not changing: If their customer was unhappy, the view of their competence may erode regardless.

Overcoming Fear

Fortunately for our profiled project team, their fear of not changing eventually outweighed their fear of change. They were able to recognize that if they did nothing, the situation they would find themselves in would be far worse than if they had not tried at all. Their customer was looking for something new and if the changes could be presented in that light, small bumps in the road may be looked upon more as a learning experience, than failure.

The project management and technical leadership team began to brainstorm. They came up with a plan that would make any change they implemented participative at all levels of the project and conservative so that they could assess the impact and determine if the change was good for the project. Agile practices seemed to make a lot of sense, but a piecemeal approach to change (advocated by those same agile practices) also seemed prudent. They decided that before they implemented any change, they would make sure their customer understood what they were doing and was supportive. In a sense, this approach helped them bridge the chasm between fear of change and the consequences of not changing.

It should be noted that although the project team was able to come to the conclusion that they should change and was able to overcome their fears by making some practical decisions, this was not an easy or quick process. It developed over time and with the help of the relationships they had built with others in the organization.

Process Selection

Implementing changes within any organization takes time and must be participative at all levels to be successful (Manns & Rising, 2005). To overcome the fear of making changes, the team had decided to do it in small steps—a conservative approach that would assist their evaluation of the change when the project was complete. They began by addressing two areas that seemed to cause the most trouble: Requirements prioritization and putting out a version of the release to the customer early so that initial tests—and more importantly usability tests—could be completed in time to provide feedback that could then be incorporated into the code base prior to deployment. Changes would still be controlled, but because there were to be multiple iterations, there would also be multiple integrations and system tests; they would have some flexibility to incorporate small changes from the first cycle into the second assuming they could keep the quality of the release high and they planned enough time for these anticipated changes.

When the team found they had some suc-

cess (see "Impact") with their initial changes, they became more emboldened. They suggested and implemented more changes. We discuss the areas that were addressed earliest in the next several sections. They are presented along with the reasoning behind each so that the reader can understand why each was chosen by the project team. Later in the chapter, a discussion ensues about how each practice was specifically implemented from a technical standpoint and the cycle time and quality impacts of each.

Prioritizing Requirements

One of the most difficult things facing our profiled project team was their joint ability with their customer to prioritize their requirements. On any given day, the priority may change. What seemed to be missing was a way to quantify the requirements in a manner that would permit a reasonable prioritization. In some cases, a requirement may be highly desired, but its cost would make implementation prohibitive. In other cases, a requirement may be somewhat desired, but its cost would make implementation highly desirable. A process was needed to quickly assess requirements and have the customer prioritize them so that the team was always aware of what features and functions were desired next.

Iterative Development

Partially to address their overall product quality and to gain early feedback on how a release was progressing, the team decided that some form of iterative development should be implemented. Creating products iteratively goes back to an invention theory from the 1920s and 1930s (Larman et al., 2003). It is a proven technique for addressing product quality and change. As you will see, the team's first foray into iterative development was only partially successful and required some additional process changes.

Continuous Integration

Perhaps the most frustrating part of the development process for our profiled project team was the "integration" cycle. This was where the system was put together so that it could be functionally tested as a whole. Part of the frustration with this process was that there was no easy way to see the entire system in operation from end to end without going through a lot of tedious build steps. To address this, the team decided that they would need to automate their builds and would need to permit any team member to create a locally running version of the full system at any time.

Addressing integration took on additional importance with respect to iterative development. If the team wished to create rapid iterations in the future, they could not do so without addressing the integration and build process.

Automation

One area the team thought they could gain improvements in both quality and cycle time was in the area of automation. It has long been understood that design and code inspections could significantly and positively impact the quality of a product, but the time to perform the inspections could be prohibitive for a large product. Indeed, testing also fell into this same category—large benefit, but time consuming. To address the latter concerns, the team identified automating critical reviews and testing as one of their top priorities. Tools such as JUnit, JTest, Rational Performance Tester, Findbugs (http://findbugs.sourceforge.net/), SA4J (http://www.alphaworks.ibm.com/tech/sa4j), and Parasoft's WebKing would be used (and re-used) to reduce their cycle time while improving quality.

IMPLEMENTATION

For the things we have to learn before we can do them, we learn by doing them.

Aristotle, *Nicomachean Ethics, II, 1, ca. 384-322 B. C.*

Deciding which processes to alter as discussed in "Approaching Selection" was only one facet of implementing change. Each area that was selected required a corresponding implementation action (or actions). This section of our chapter focuses on those actions that were taken to address overall quality and cycle time. Of interest are some of the reasons why certain actions were taken. As you will see, the way agility was worked into our profiled project team's project can serve as a model for other project using a hybrid development methodology where teams are looking for incremental or evolutionary (rather than revolutionary) process improvements.

Improving Quality

Perhaps one of the most vexing problems faced after the tumultuous 2003 project and even in the small step enhancement projects undertaken in 2004, was the fact that defects were being discovered and corrected late in the development cycle when they were most time consuming and most expensive to correct. Adjusting the defect detection curve such that it afforded an earlier indication into what was wrong and provided the ability to make early corrections was considered of paramount importance to improving overall code and product quality.

After taking a retrospective look back at how the product itself was developed, it became clear that not everything had been created in a manner that would be considered optimal. There were architectural and design flaws that were not necessarily apparent when the original version of the application was created, but began to impose limitations on development as enhancements were being considered—limitations that had the result of increasing the amount of time and money it would take to make those enhancements.

In addition, the original project team that worked on the first version of the product in 2003 was quite large. Due to the ad hoc nature of that project, no coding standards had been defined or adhered to. This meant that each functional area of the application was implemented and behaved differently. In effect, the application had internal vertical silos of discrete functionality.

Changes surrounding the quality of the application needed to address each of these issues: Defect detection and correction, architectural and design dependencies, and the silo effect of independently created functions. The sections that follow provide a general overview of what was implemented to address each of these concerns. We begin with a discussion about the project's quality management plan. From there, we introduce the concept of "technical stories" as a way the project team codified the refactoring of existing inefficient architectural and design constructs. Next is a description of what was done to move the defect detection and correction curve earlier in the development cycle. This is followed by a description of some of the methods and tools that would be used to enforce best coding practices. Finally, an explanation of how continuous integration might be used to improve overall code quality is given.

Quality Management Plan

Being a traditional waterfall project with a structured approach to development meant that our profiled project team had implemented a quality management plan for each of their projects. Typically, this plan would identify, along industry standard lines, the percentage and aggregated number of defects that one could expect by project phase, how those defects would be detected (e.g., inspection, testing, etc.) and how they would be

removed.

Rather than discard the quality management plan, the team thought it important to take the time to update it with the strategy they would employ to address the quality of the product. Though such a document may be derided as defying the "barely sufficient" nature of an agile project, the team found it useful to document an internal goal for the overall detection and correction of defects and the strategy they were going to use for their early elimination from the product. This document also gave them a baseline from which they could measure their intended results with their actual results.

The quality management plan, therefore, became a document that identified the goals the team would strive to achieve and the techniques they would employ to integrate agile practices into their development process. It no longer specified only industry standard information to which the project would attempt to comply, but a much higher standard to which the project team wished to be held. These changes are evident in each of he implementation practices outlined in the following sections. Each, however, was first identified as part of the project's quality management plan.

Technical Stories

One thing that was identified quickly by the profiled project team was that innovation could often be introduced into a project that would also satisfy a business requirement. In other words, the way new function was added began to have both a technical component in addition to the business component. These so-called "technical stories" became part of the requirements gathered after each release and, later on, iteration. They were influenced by a retrospective look at what went well and what did not go so well during each development cycle. As a result of these reflections, the architecture of the application was reduced and simplified through refactoring. This had the net effect of reducing the cost of ownership and change while improving the overall quality of the application by consolidating change points. The approach the team took is similar to the "user stories" concept in extreme programming.

A few possible outcomes of these "technology stories" include:

- Cost reduction as a result of simplification.
- Architecture simplification through refactoring.
- Improvement in the throughput or performance of an individual application module or area.
- Architectural changes that will re-align the application with the long-term strategy of the organization.

Defect Detection and Correction

The continuous feedback provided to the development team through the use of iterative development and continuous integration paired with automation and reuse supplied them with the opportunity to detect and correct defects earlier in the development cycle and improve overall quality. Recalling some of the difficulties the project team had with late usability changes and the difficulty they had integrating the system, two practices were introduced: Test case reuse and test case automation.

Test Case Reuse

When a project is undertaken to enhance an existing product, a common scenario that many developers face is the re-introduction of defects from prior releases when a new feature is added without understanding the overall purpose of the module (or function). One way to combat this is to retain the unit and functional test cases from release to release and execute them prior to and during each build of the system. By integrating

Figure 2. Technology-based proposals in release planning

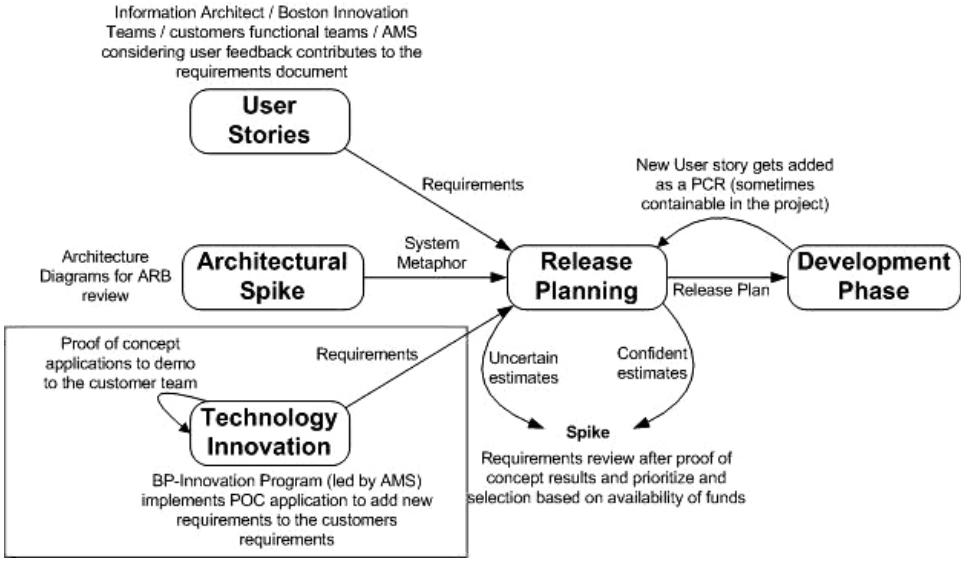


Figure 3. Test case reuse process

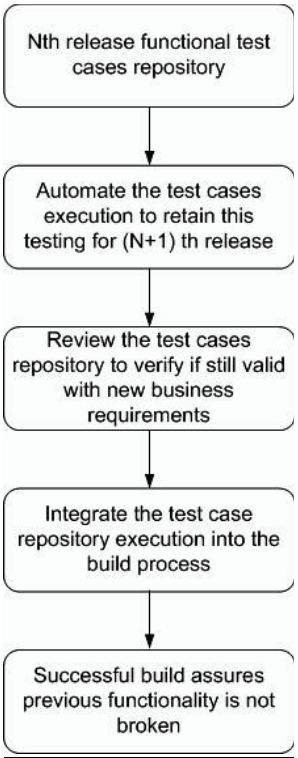
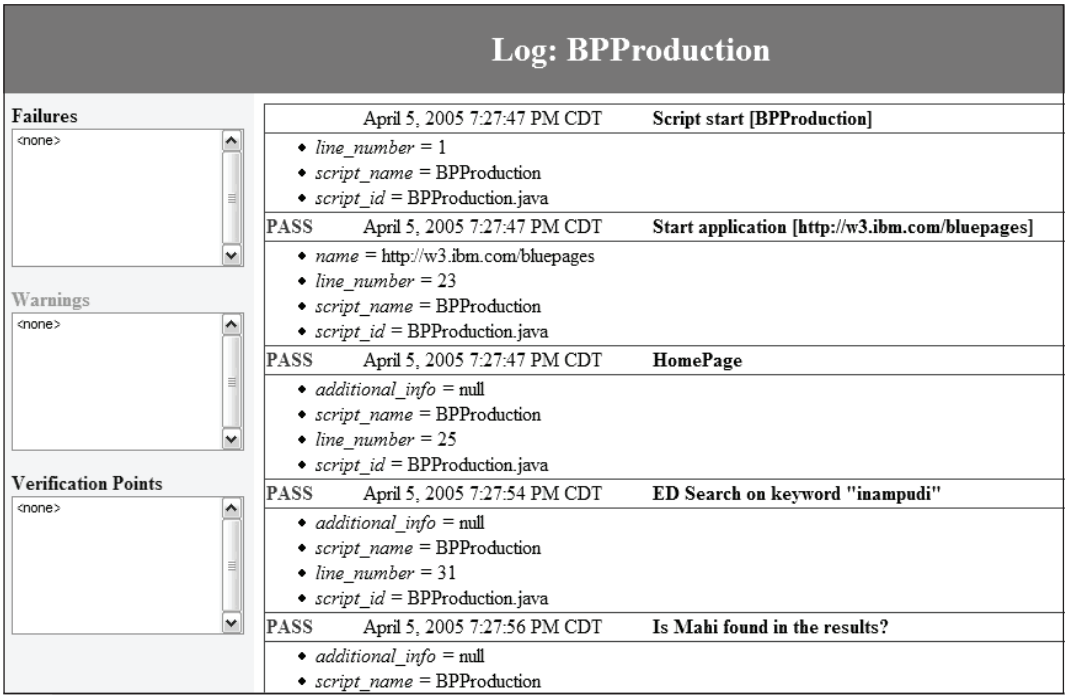


execution of the test cases with the build process, one can be assured that existing functionality is not compromised by changes made to the product; Either the new changes are incorrect or the test case is no longer valid. This reduces the number of undetected defects in a release and improves the overall quality of the application. Instead of finding issues during integration or system testing, they can be found and corrected prior to or during each system build. The theory is that the closer the defect is detected to when the change is made, the easier it will be to recall what was changed and fix it. An example of the process followed appears in Figure 3.

Automated Test Case Execution

Agile principles encourage developers to adopt test-driven development. Whether a project follows a pure agile approach, a hybrid approach (as was used here), or a traditional methodology, there is value in testing code in an automated fashion at the unit and function level. Retaining these test cases so that all developers can execute them in

Figure 4. Automated functional test cases using Rational Functional Tester



an automated fashion to ensure that their changes do not break the system is an agile principle that was implemented for this project team to measure project progress, address interim code quality, and assist in the development of new classes or methods. It should be noted that since these test cases were being built upon an existing product that did not have them initially, they were first built against those areas that required change. Those cases remained available as subsequent projects were undertaken.

Two tools were used to automate test case execution. The first, not surprisingly, was JUnit for unit testing. For functional testing, IBM's Rational Function Tester was used. This latter tool easily integrates with the build process and provides an automated functional regression testing platform for client-based and Web-based applications. A sample report appears in Figure 4.

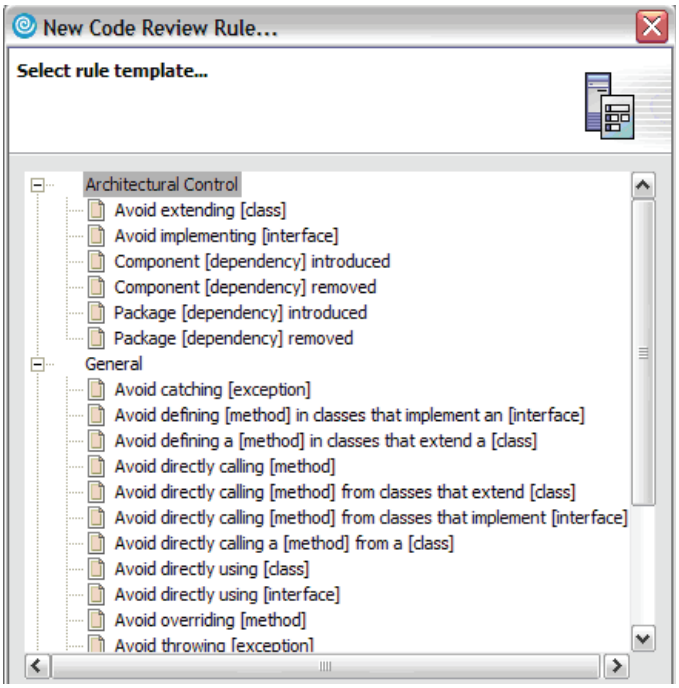
Enforce Coding Practices

One area of quality that is oftentimes not addressed by a project team is the way code will be written. Documenting the coding standards up front is helpful, but it will not ensure that an individual will not violate the project's standards or best coding practices in general. Rather than implement a series of manual code inspections, several tools were implemented to ensure best practice compliance.

Automated Code Reviewers

Tools such as Parasoft's JTest, RAD Code Reviewer, and WebKing can be plugged right into the developer's IDE. They help ensure that code is written according to a standard the team has set. They also can catch common mistakes and identify problem areas that may need to be ad-

Figure 5. Example automated code review rules



dressed. Each developer on the project team was required to install the plug-ins into their development environment and execute the review process prior to checking the code in or integrating it into the system build. An example of some of the rules used appears in Figure 5.

Tools such as IBM's Rational Application Developer Code review tool can be used to show the details and the nature of a violation including the class name and the line number of the code where the violation occurred (see Figure 6).

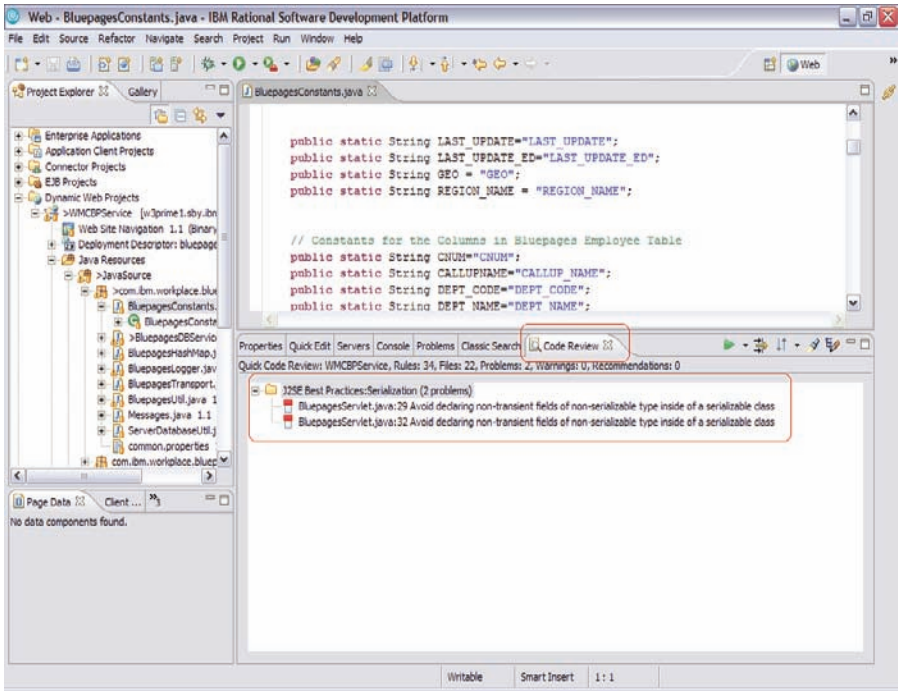
Automated Static and Stability Analysis

Static analysis tools such as Findbugs (http://findbugs.sourceforge.net/) and Structural Analyzer for Java (SA4J) (http://www.alphaworks.ibm.com/tech/sa4j) can be embedded into the build process to verify the quality of the build. These tools produce reports for the development team that help them understand potential run time defects either due to the way something was implemented or by finding architectural anti-patterns that can reduce the application's stability in the production environment.

"Continuous" Integration

One of the extreme programming practices that our profiled project team readily adopted was the concept of continuous integration. Recall that one of the most difficult project activities was the integration of created components into a functioning whole. It was felt that if the integration of the application could become more continuous—more agile—it would be possible to see the system working earlier, identify and remove integration defects in closer proximity to when they were introduced, and enforce the view that the system must always be kept in an operational state.

Figure 6. Example code review automation (IBM Rational Code Reviewer)



Automating the Build

The primary barrier to continuous integration was an onerous build process. One of the technical stories, therefore, was to automate the product build such that it could be started by any developer in their own workspace and in the integration environment (under the proper controls). Apache's ANT (http://ant.apache.org), as the de facto standard for build automation, would be used as the foundation for this automated build process. In addition to automating the build itself, the script would also incorporate several of the code verification steps identified earlier: functional analysis, structural analysis, functional test verification, coding practices, etc.

The Build Process

The following process provides a general overview of the steps to be followed by the automated build process identified in several technical stories for the application.

- Pull the latest checked-in source software from the library control system (CVS).
- Execute automated code analysis tools on the extracted code to verify the code's look and feel and identify any anti-patters violations of best practices in the code base.
- Build an EAR package and execute all existing JUnit test cases against the code package and push the results to a build status Web page.
- Install the application into the runtime environment.
- Execute the automated functional test cases using Rational Functional Tester and publish the results to the build status Web page.
- Execute an overall architectural quality check using structural analysis tools (e.g., SA4J).

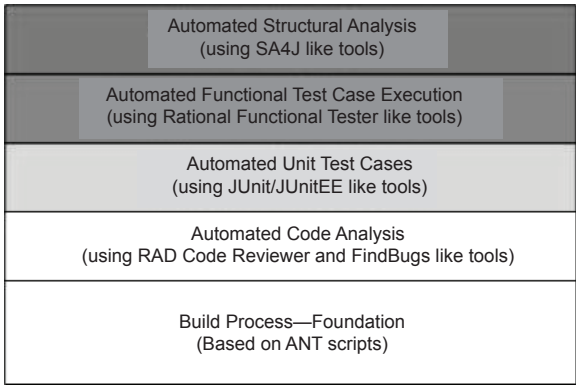

Figure 9. Continuous integration using automated tools

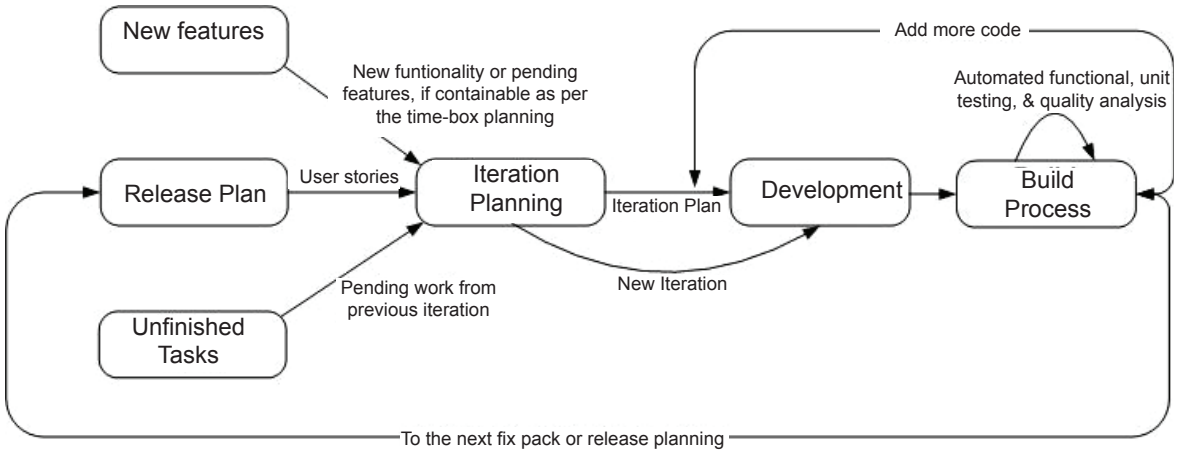


A graphical representation of this process appears in Figure 8.

Mapping the Build Framework to the Development Process

Every time a developer adds code to the system either as part of an iteration or as part of a release, the overall integration with existing code (and code written by others) is taken care of by the build process. This process is depicted in Figure 9.

IMPACT

Nothing quite new is perfect.

Marcus Tullius Cicero, *Brutus, 71, c. 106 B.C.-43 B.C.*

What was the overall impact of the changes that were made? By and large, the impact was positive. The team proved they could successfully integrate agile techniques into a traditional development process. What follows is a summary of some of the results. It should be noted that these are results from one team and that the experiment would need to be expanded to others to assess its validity in a broader context. Regardless, some of the results are rather remarkable.

Requirements Prioritization: Time Boxing the Schedule

As identified in the "Approaching Selection" section, instead of beginning with a fixed set of requirements from which a project sizing and project plan was derived, the most important requirements were identified and given a rough sizing. Based upon this rough sizing, the requirements were re-ordered. The schedule was broken down into discrete "time boxes" that dictated how much would be spent and how many features could be contained within a particular iteration or a project. Anything that could not fit would be re-prioritized into a follow-on project (or iteration). This method permitted the customer to introduce what they considered the most important features into the product and regularly deliver function to the business. Since the estimation at the beginning was by necessity a rough order of magnitude, as the team began the work additional adjustments would be made to the scope. If the size of a feature grew beyond what could be contained within a project, it would be discarded (or, if truly important, the date would change). If the size of a feature was smaller than what was originally anticipated, additional features would be added from the prioritized list (see Figure 10).

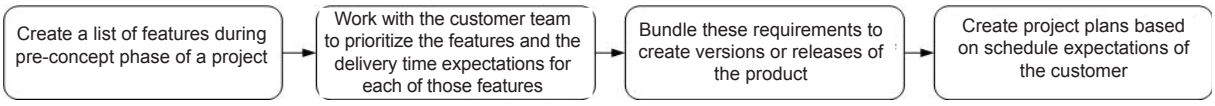
Using this approach, customer satisfaction increased from essentially failing on the first project to 97.3% on the first project that used this approach—they recognized that the project team was willing to help them meet their goals and change the way they do things in support of those goals. (Note: This satisfaction rating was for the entire release and most likely reflects the improvement in quality—discussed later—as well as the way requirements were prioritized.)

Iterative Development

Breaking each release into smaller iterations had a three-fold impact on the projects. First, the customer was able to see the results of built-in features earlier. This allowed them to re-assess the priority of the remaining requirements against changes that they may wish to implement. From a customer satisfaction perspective, the team was beginning to be seen as much more flexible—yet, the project was still under control.

The second area of positive impact area was the team's ability to have usability testing done on the parts of the application as they were produced. This meant that any usability defects identified could be rolled in to the next iteration and would be in the final build rather than waiting six months for a follow-on project to be commissioned. This had

Figure 10. Time boxed requirements prioritization



the net effect of improving end user satisfaction to above 85%—which was a significant improvement from 76% given the size of the population.

The third area of impact was in the quality of the final product. Since the system was being "put together" more frequently (also see the discussion on continuous integration results), the amount of time spent cleaning up integration errors was significantly reduced. While the initial 2003 project had greater than 400 user acceptance defects, less than a year later the user acceptance phase for all of the iterations combined had three defects (one of severity 3 and two of severity 4).

As we mentioned, not everything was positive. The way the team initially implemented iterations was not as clean as it could be. They were rushing at the end of the first iteration to get function working. This lesson learned was built into their second project—they more discretely planned the iterations so that they would have enough time to put the system together prior to the interim review by the customer. Interestingly, when they automated the build and began to use a more continuous form of integration, this additional planning was no longer required.

Continuous Integration

Perhaps one of the biggest gains the project team saw from a quality perspective was as a result of implementing their version of continuous integration. As previously discussed, this involved automating the build process such that testing occurred at each run and the system always remained in a workable state. Creating the build process cost approximately 100 labor hours to the team. The amount of time saved in integration and integration testing, however, was 300 hours and almost two weeks cycle time. On the project it was implemented in, the additional time was used to contain additional features that originally did not fit in the planned time boxes. For future projects, the additional time will be factored into the schedule as available for general development.

Automation

Although automation took on various forms including the creation of the automated build used for continuous integration, there were some additional positive impacts to cost and quality. For example, even though there was a cost to modifying automated test cases from release to release, that cost was minimal compared to creating a new test suite each time or executing all of the test cases manually. Some interesting statistics were gathered from project to project. The original project in 2003 used 12.7% of its overall budget (hours) to conduct functional and system testing (not user acceptance testing where most of the defects were eventually found). Through automation and reuse of the test case library, the two subsequent similarly sized projects consumed 5.8% and 5.2% of their budget on function and system testing respectively.

Recall that automation also added several tools that checked the stability and quality of the code. Perhaps the best measure of impact on the project is that after incorporating the recommendations for coding standard best practices and addressing structural weaknesses, the amount of time

required to maintain it was reduced by almost 10%. In a world where operation budgets are constrained, this was considered a significant under run. Most of it related to the reduced amount of call support from people who were having trouble using the application or finding obscure errors that had not been caught in the project team's own testing.

FUTURE TRENDS

In our opinion, the trend toward using agile software development practices in general and as a way to enhance the quality of products developed using traditional practices will continue. As with the profiled project team used as the basis for this chapter, we also see a trend toward using risk to identify which practices may work best in a particular environment. That will mean that projects that are not thought of as being able to easily use agile practices to enhance quality or reduce cycle time and cost today—such as those with high availability requirements or high performance requirements—may have an agile component in the future.

Smaller and More Frequent Releases

Developing a product in a piecemeal fashion predates computing by several decades. The concept of creating incremental releases to products initially grew from a desire to improve quality (Larman et al., 2003). Recent evidence has continues to show that smaller, more frequent releases have a positive impact on the overall quality of a software development project (see Madsen, 2005, for example). Several "heavier" methodologies such as the rational unified process always embraced iterations and even that has had its share of agile practices introduced as process improvements (Ambler, 2006). We expect this trend toward smaller, incremental releases with agile components to continue.

Reviews

Another future trend in agile quality management seems to be the return of peer reviews. Agile practices typically rely on up front test cases to ensure quality, but some of the current literature indicates that peer reviews still play an important role in software development. Some recent research has been conducted on focusing reviews on the most important aspects of a particular project based upon risk and the perceived value of a particular review (Lee & Boehm, 2005). This suggests that reviews themselves may also be moving toward a sufficiency model similar to agile. It will be interesting to see if a review structure will appear as part of pure agile practices.

More Hybrids

As with our profiled project team, not everyone is willing or able to move to completely agile approaches for their software development either due to perceived complexity or performance and availability requirements. We believe that the evolutionary introduction of agile practices into traditional organizations will continue, but alterations may be required for an organization to derive value as in Svensson and Host (2005). Perhaps the largest focus area in the next couple of years will be in project management. Project managers will need to not only drive the implementation of agile practices, but also need to understand their impact on their project(s) (Coram & Bohner, 2005). In all of these cases, we believe risk will most likely be the deciding factor for when agile methods are used and when they are not.

CONCLUSION

This chapter discussed how one team was able to successfully drive software development quality improvements while reducing overall cycle time through the introduction of several individual

agile development techniques. Through piecemeal change to their existing development processes, they were able to make significant improvements over time. This common-sense approach to software development showed that the incorporation of agile techniques does not have to entail additional risks for projects that have high availability, performance, and quality requirements.

Chapter 7.4
Teaching Agile Software Development Quality Assurance

Orit Hazzan
Technion–Israel Institute of Technology, Israel

Yael Dubinsky
IBM Haifa Research Lab, Israel
Technion–Israel Institute of Technology, Israel

ABSTRACT

This chapter presents a teaching framework for agile quality—that is, the way quality issues are perceived in agile software development environments. The teaching framework consists of nine principles, the actual implementation of which is varied and should be adjusted for different specific teaching environments. This chapter outlines the principles and addresses their contribution to learners' understanding of agile quality. In addition, we highlight some of the differences between agile software development and plan-driven software development in general, and with respect to software quality in particular. This chapter provides a framework to be used by software engineering instructors who wish to base students learning on students' experiences of the different aspects involved in software development environments.

INTRODUCTION

Quality assurance (QA) is an integral and essential ingredient of any engineering process. Though there is a consensus among software practitioners about its importance, in traditional software development environments conflicts may still arise between software QA people and developers (Van Vliet, 2000, p. 125).

Agile software development methods emerged during the past decade as a response to the characteristics problems of software development processes. Since the agile methods introduced a different perspective on QA, we will call the agile approach toward quality issues *agile quality*—AQ, and will focus, in this chapter, on the teaching of AQ. By the term AQ, we refer to all the activities (e.g., testing, refactoring, requirement gathering) that deal with quality as they are manifested and applied in agile software development environments. It is important to emphasize that the term

AQ does not imply that quality changes. To the contrary, the term AQ reflects the high standards that agile software methods set with respect to software quality.

Based on our extensive experience of teaching agile software development methods both in academia and in the software industry[1], we present a teaching framework for AQ. The teaching framework consists of nine principles, the actual implementation of which is varied and should be adjusted for different specific teaching environments (e.g., academia and industry to different sizes of groups). This chapter outlines the principles and addresses their contribution to learners' understanding of AQ.

In the next section, we highlight some of the differences between agile software development and plan-driven[2] software development in general, and with respect to software quality in particular. Then, we focus on the teaching of AQ. We start by explaining why quality should be taught and, based on this understanding, we present the teaching framework for AQ, which suggests an alternative approach for the teaching of AQ. Finally, we conclude.

Agile vs. Plan-Driven Software Development

In this section, we highlight some of the main differences between agile software development and traditional, plan-driven software development. Before we elaborate on these differences, we present our perspective within which we wish to analyze these differences.

Traditional software development processes mimic traditional industries by employing some kind of production chain. However, the failure of software projects teaches us that such models do not always work well for software development processes. In order to cope with problems that result from such practices, the notion of a production chain is eliminated in agile software development environments and is replaced by a more network-oriented development process (Beck, 2000). In practice, this means that in agile teams, the task at hand is *not* divided and allocated to several different teams according to their functional description (for example, designers, developers, and testers), each of which executes its part of the task. Rather, all software development activities are intertwined and there is no passing on of responsibility to the next stage in the production chain. Thus, all team members are equally responsible for the software quality. We suggest that this different concept of the development process results, among other factors, from the fact that software is an intangible product, and therefore it requires a different development process, as well as a different approach toward the concept of software quality, than do tangible products.

Agile Development Methods vs. Plan-Driven Development Methods

During the 1990s, the agile approach toward software development started emerging in response to the typical problems of the software industry. The approach is composed of several methods and it formalizes software development frameworks that aim to systematically overcome characteristic problems of software projects (Highsmith, 2002). Generally speaking, the agile approach reflects the notion that software development environments should support communication and information sharing, in addition to heavy testing, short releases, customer satisfaction, and sustainable work-pace for all individuals involved in the process. Table 1 presents the manifesto for agile software development (http://agilemanifesto.org/).

Several differences exist between agile software development methods and plan-driven methods. Table 2 summarizes some of these differences.

Table 1. Manifesto for agile software development

We are uncovering better ways of developing software by doing it and helping others do it. Through this work we have come to value:

- **Individuals and interactions** over processes and tools.
- **Working software** over comprehensive documentation.
- **Customer collaboration** over contract negotiation.
- **Responding to change** over following a plan.

That is, while there is value in the items on the right, we value the items on the left more.

Table 2. Several differences between agile and plan-driven software development methods

	Agile Software Development Methods	**Plan-Driven Software Development Methods**
Process orientation	The development process is formulated in terms of activities that all team members apply on a daily basis.	The development process is formulated in terms of stages, in which each team member has one defined role in the process.
Formulation of requirements	Requirements are formulated in a gradual process during which customers and developers improve their understanding of the developed product. This process enables natural evolution.	Requirements are formulated in one of the first stages of the project. Therefore, the cost of implementing a change in requirements increases the later in the process it is introduced.
Customer involvement	Customers are available for discussion, clarifications, etc., in all stages of the software development process.	Primary contact with the customers occurs at the beginning of the development process.

AQ vs. Plan-Driven QA

In plan-driven software development environments, the main concept related to software quality is quality assurance, which, according to Sommerville (2001), is "The establishment of a framework of organizational procedures and standards which lead to high-quality software" (p. 537). Though this definition inspires an organizational roof for quality assurance processes, in reality, in many software organizations quality assurance is associated with a specific stage of a typical software development process and is usually carried out by the QA people who are not the developers of the code whose quality is being examined.

To illustrate the agile software development approach toward quality, we quote Cockburn (2001), who describes quality as a team characteristic:

Quality may refer to the activities or the work products. In XP, the quality of the team's program is evaluated by examining the source code work product: "All checked-in code must pass unit tests at 100% at all times." The XP team members also evaluate the quality of their activities: Do they hold a stand-up meeting every day? How often do the programmers shift programming partners? How available are the customers for questions? In some cases, quality is given a numerical value, in other cases, a fuzzy value ("I wasn't happy with the team moral on the last iteration") (p. 118).

As can be seen, within the framework of agile software development, quality refers to the *entire team* during the *entire process* of software development and it measures the code as well as the actual activities performed during the development process, both in quantitative and in qualitative terms. Accordingly, the term qual-

Table 3. Some differences between AQ and plan-driven QA

	Agile Quality (AQ)	**Plan-Driven QA**
Who is responsible for software quality?	All development team members	The QA team
When are quality-related topics addressed?	During the entire software development process; quality is one of the primary concerns of the development process	Mainly at the QA/testing stage
Status of quality-related activities relatively to other software development activities	Same as other activities	Low (Cohen, Birkin, Garfield, & Webb, 2004)
Work style	Collaboration between all role holders	Developers and QA people might have conflicts (Cohen et al., 2004)

ity assurance does not appear in agile software development as a specific stage.

In Table 3, we summarize some of the noticeable differences between the attitude toward quality of agile software development methods and of plan-driven methods, as it is manifested in many software organizations.

We note that these previous perspectives are clearly also reflected in the cultures of the two approaches toward software development. While in the context of plan-driven development, conferences are held that are dedicated to QA issues, conferences that target the community of agile software developers subsume all aspects of the development process, including AQ. This difference might, of course, be attributed to the maturity of the plan-driven software development approach; still, the observation is interesting by itself.

TEACHING AGILE SOFTWARE DEVELOPMENT QUALITY

Why Teach QA?

Naturally, software engineers should be educated for quality. The importance of this belief is reflected, for example, in the Software Engineering volume[3] of the Computing Curricula 2001, in which software quality is one of the software engineering education knowledge areas (p. 20), and is described as follows:

Software quality is a pervasive concept that affects, and is affected by all aspects of software development, support, revision, and maintenance. It encompasses the quality of work products developed and/or modified (both intermediate and deliverable work products) and the quality of the work processes used to develop and/or modify the work products. Quality work product attributes include functionality, usability, reliability, safety, security, maintainability, portability, efficiency, performance, and availability. (p. 31)

Furthermore, the software engineering code of ethics and professional practice[4], formulated by an IEEE-CS/ACM Joint Task Force, addresses quality issues and outlines how software developers should adhere to ethical behavior. Table 4 presents the eight principles of the Code. Note especially Principle 3, which focuses on quality.

Based on the assumption that the concept of quality should be taught as part of software engineering education, the question that we should ask at this stage is, How should quality be taught? Later in this section, we present our perspective on this matter. We suggest that the nature of the software

Table 4. Principles of the software engineering code of ethics and professional practice

1. Public: Software engineers shall act consistently with the public interest.
2. Client and Employer: Software engineers shall act in a manner that is in the best interests of their client and employer, consistent with the public interest.
3. Product: Software engineers shall ensure that their products and related modifications meet the highest professional standards possible.
4. Judgment: Software engineers shall maintain integrity and independence in their professional judgment.
5. Management: Software engineering managers and leaders shall subscribe to and promote an ethical approach to the management of software development and maintenance.
6. Profession: Software engineers shall advance the integrity and reputation of the profession consistent with the public interest.
7. Colleagues: Software engineers shall be fair to and supportive of their colleagues.
8. Self: Software engineers shall participate in lifelong learning regarding the practice of their profession and shall promote an ethical approach to the practice of the profession.

development methods that inspire a curriculum is usually reflected in the curriculum itself. For example, in traditional software engineering and computer science programs, QA is taught as a separate course, similar to the way in which it is applied in reality in plan-driven software development processes. Based on our teaching experience of agile software development methods, we propose that when teaching the concept of quality is integrated into a software engineering program that is inspired by agile software development, quality-related issues should and are integrated and intertwined in all topics. This idea, as well as others, is illustrated in the next section in which we present the teaching framework we have developed for teaching agile software development and illustrate how AQ integrated naturally into this teaching framework.

Teaching Framework for AQ

This section is the heart of our chapter. In what follows, we introduce our teaching framework, which is composed of nine principles, presented in Table 5 as pedagogical guidelines. Each of the principles is illustrated with respect to the teaching of AQ.

As can be seen, all principles put the learners at the center of the discussion while referring to two main aspects—cognitive and social. Specifically, Principles 1, 2, 3, and 7 emphasize the learning process from a cognitive perspective while Principles 4, 5, 6, 8, and 9 highlight the learning process from a social perspective. We note that this is not a dichotomy, but rather, each principle addresses both aspects to some degree. Accordingly, in what follows, the principles are presented in such an order that enables a gradual mental construction of the learning environment that this teaching framework inspires.

Specifically, for each principle we first describe how it is expressed when agile software development concepts are taught, and then how it is applied in the teaching of AQ.

This presentation style is consistent with our perspective of the teaching of AQ. As mentioned previously, agile software development inspires a development environment in which all activi-

Table 5. Teaching framework

• **Principle 1:** Inspire the agile concept nature.
• **Principle 2:** Let the learners experience the agile concept as much as possible.
• **Principle 3:** Elicit reflection on experience.
• **Principle 4:** Elicit communication.
• **Principle 5:** Encourage diverse viewpoints.
• **Principle 6:** Assign roles to team members.
• **Principle 7:** Be aware of cognitive aspects.
• **Principle 8:** Listen to participants' feelings toward the agile concept.
• **Principle 9:** Emphasize the agile concept in the context of the software world.

ties involved in software development processes are intertwined, and the notion of a production chain is eliminated. Accordingly, when we teach AQ we do not separate it from the teaching of the software development process (in our case, agile software development) but, rather, AQ is taught as part of the software development process in the same spirit in which the entire agile development process is taught.

This section presents, in fact, the application of our teaching framework for software development methods (presented in Dubinsky & Hazzan, 2005 and in Hazzan & Dubinsky, 2006) for the case of AQ. In Dubinsky and Hazzan (2005), we also outline the evolutionary emergence of the teaching framework and describe its implementation in a specific course (including detailed schedule and activities).

Principle 1: Inspire the Agile Concept Nature

This is a meta-principle that integrates several of the principles described later on in this section and, at the same time, is supported by them. It suggests that complex concepts in software development, such as quality or a software development method, should not be lectured about, but rather, their spirit should be inspired. In other words, the teaching of a complex (agile) concept should not be based solely on lecturers but rather, the learning of the main ideas of such concepts is more valuable if a "learning by doing" approach is applied and the (agile) concept is applied, performed, and used by the learners. Such an experience improves the learners experience and skills in the said agile concept, and at the same time, provides the teacher with opportunities to elicit reflection processes.

The application of this principle is expressed by active learning (Silberman, 1996) on which the next principle elaborates, and should take place in an environment that enables the actual performance of the agile concept.

In the case of teaching AQ, this principle implies that the learning occurs in an environment in which it would be natural to illustrate and feel the interrelation between AQ and the other activities that take place in agile software development environments. For example, the extreme programming practice of *whole team*, which states that "a variety of people work together in interlinking ways to make a project more effective" (Beck & Andres, 2004, p. 73), should be applied in order to inspire agile software development. In such software development environments, when the teacher asks the learners to expose and reflect on the relationships between AQ and the other activities, connections between AQ and other activities performed in this environment become clear.

Principle 2: Let the Learners Experience the Agile Concept as Much as Possible

This principle is derived directly from the previous one. In fact, these two principles stem from the importance attributed to the learners' experimental basis, which is essential in learning processes of complex concepts. This assertion stands in line with the constructivist perspective of learning (Davis, Maher, & Noddings, 1990; Confrey, 1995; Kilpatrick, 1987), the origins of which are rooted in Jean Piaget's studies (Piaget, 1977).

Constructivism is a cognitive theory that examines learning processes that lead to mental constructions of knowledge based upon learners' knowledge and experience. According to this approach, learners construct new knowledge by rearranging and refining their existing knowledge (Davis et al., 1990; Smith, diSessa, & Roschelle, 1993). More specifically, the constructivist approach suggests that new knowledge is constructed *gradually*, based on the learner's existing mental structures and in accordance with feedback that the learner receives both from other people with whom he or she interacts and from the different artifacts that constitute the learning environments. In this process, mental structures are developed in steps, each step elaborating on the preceding ones. Naturally, there may also be regressions and blind alleys.

We suggest that quality in general, and AQ in particular, are complex concepts. Therefore, their gradual learning process should be based on the learners' experience. One way to support and enhance such a gradual mental learning process is to adopt an active-learning teaching approach according to which learners are *active* to the extent that enables a reflective process (which is addressed by another principle later on in this chapter).

We do not claim that lecturing should be absolutely avoided in the process of teaching AQ; in fact, some aspects of AQ can and should be taught by means of lectures. Our experience, however, teaches us that the more learners *experience* AQ and *reflect* upon it, the more they improve their understanding of the essence of the topic, as well as their professional skills.

To illustrate how this principle is applied in the case of AQ, we focus on acceptance tests. Here, active learning is expressed in several ways. First, learners are active in the definition of the software requirements. Second, learners define the acceptance tests and verify that they meet the requirements. Third, they develop the acceptance tests. And fourth, they are guided to reflect both on each individual step and on the entire process. Such a complete process provides learners with a comprehensive message that both highlights each element of the AQ process and at the same time connects each of its elements to the others.

Principle 3: Elicit Reflection on Experience

The importance of introducing reflective processes into software development processes has been already discussed (Hazzan, 2002; Hazzan & Tomayko, 2003). This approach is based on Schön's *Reflective Practitioner* perspective (Schön, 1983, 1987). Indeed, it is well known in the software industry that a reflective person, who learns both from the successes and failures of previous software projects, is more likely to improve his or her own performance in the field (Kerth, 2001).

According to this principle, learners should be encouraged to reflect on their learning processes as well as on different situations in the software development process in which they participated. We note that reflection processes should not be limited to technical issues, but rather should also address feelings, work habits, and social interactions related to the software development processes.

In order to elicit learners' reflective processes, learners should be offered verbal and written means for self-expression. The ability to express one's reflections and impressions gives learners the feeling that their thoughts and feelings are of interest to the instructors. Naturally, such reflective processes might also elicit criticism and complaints. In this spirit, learners should be encouraged to express not only positive ideas, but also negative feelings and suggestions for improvement.

The teaching of AQ is a good opportunity to illustrate this principle since it allows us to address the different facets of AQ. First, we can address the technical aspect of AQ, asking learners to reflect on the actual processes of applying AQ. Specifically, learners can be asked to describe the process they went through, to indicate actions that improved their progress and actions that blocked progress and should be improved, and to suggest how the AQ process itself could be improved. Second, affective aspects can be referred to during the reflection process. For example, learners can be asked to describe their feelings during the AQ process and specifically indicate actions that encouraged them, as well as actions that discouraged them, in their pursuit of the AQ process. Finally, social issues can be addressed in such reflection processes. For example, learners can be asked to indicate what teamwork actions supported the AQ process and which interfered with that process and to suggest how such interactions should be changed so as to support the AQ process. Furthermore, experience learners can be asked to reflect both during the AQ process and after it is completed—processes that Schön calls in-action and on-action reflection, respectively.

Principle 4: Elicit Communication

Communication is a central theme in software development processes. Indeed, the success or failure of software projects is sometimes attributed to communication issues. Accordingly, in all learning situations we aim at fostering learner-learner, as well as learner-teacher communication.

When communication is one of the main ingredients of the learning environment, the idea of knowledge sharing becomes natural. Then, in turn, knowledge sharing reflects back on communication. This principle can be applied very naturally in the context of AQ since it is a multifaceted concept. During the AQ learning process, learners can be asked to identify its different facets (such as, the developer perspective, the customer perspective, its fitness to the organizational culture) and to allocate the learning of its facets to different team members—first learning them, and then subsequently teaching them to the other team members in the stage that follows. In the spirit of agile software development, it is appropriate to assign the different aspects that are to be learned to pairs of learners (rather than to individuals) in order to foster learning processes. When the team members present what they have learned to their teammates, not only do they share their knowledge, but further communication is enhanced.

Another way to foster communication is to use metaphors or "concepts from other worlds." Metaphors are used naturally in our daily life, as well as in educational environments. Generally speaking, metaphors are used in order to understand and experience one specific thing using the terms of another thing (Lakoff & Johnson, 1980; Lawler, 1999). Communication, which is based on the metaphor's concept-world, refers not only to instances in which both concept-worlds correspond to one another, but also to cases in which they do not. If both concept-worlds are identical, the metaphor is not a metaphor of that thing, but rather the thing itself. Specifically, metaphors can be useful even without specifically mentioning the concept of metaphor. For example, the facilitator may say: "Can you suggest another concept-world that may help us understand this unclear issue." Our experience indicates that learners have no problem suggesting a varied collection of con-

cept-worlds, each highlighting a different aspect of the said problem and together supporting the comprehension of the topic under discussion.

Principle 5: Encourage Diverse Viewpoints

This perspective is based on management theories that assert the added value of diversity (cf. the American Institute for Managing Diversity, http://aimd.org). In the context of agile software development, it is appropriate to start by quoting Beck et al. (2004):

Teams need to bring together a variety of skills, attitudes, and perspectives to see problems and pitfalls, to think of multiple ways to solve problems, and to implement the solutions. Teams need diversity. (p. 29)

We argue that this perspective is correct also with respect to AQ, as explained next.

Naturally, the more diverse a team is, the more diverse the perspectives elicited are. These diverse viewpoints may improve software development processes in general, and the execution of AQ in particular. Specifically, in this context diversity has several benefits. First, learners are exposed to different perspectives that they can use when communicating with people from different sectors and of different opinions. Second, the developed software product itself may be improved because when different perspectives are expressed with respect to a specific topic, the chances that subtle issues will emerge are higher. Consequently, additional factors are considered when decisions are made. Third, the creation process is questioned more when diverse opinions are expressed and, once again, this may result in a more argument-based process based on which specific decisions are made. Finally, we believe that diversity reduces resistance to new ideas and creates an atmosphere of openness toward alternative opinions. In the case of learning AQ, which inspires different work habits than the ones most learners are familiar with, such openness to a different perspective is especially important.

Principle 6: Assign Roles to Team Members

This principle suggests that each team member should have an individual role in addition to the personal development tasks for which he or she is responsible. Based on our agile teaching and research practice, we have identified 12 roles, each of which is related to at least one aspect of software development, several of which are related to AQ (Dubinsky & Hazzan, 2004a). See Table 6.

The role assignment serves as a means for distributing the responsibility for the project progress and quality among all team members. The rationale for this practice stems from the fact that one person (or a small number of practitioners) can not control and handle the great complexity involved in software development projects. When accountability is shared by all team members, each aspect of the entire process is treated by single team member, yet, at the same time, each team member feels personally responsibility for every such aspect. Indeed, both the software project and all team members benefit from this kind of organization.

More specifically, our research shows that the accumulative impact of these roles increases the software quality both from the customer's perspective and from the development perspective, for several reasons. First, the roles address different aspects of the development process (management, customer, code) and together encompass all aspects of a software development process. Second, such a role assignment increases the team members' *commitment* to the project. In order to carry out one's role successfully, each team member must gain a global view of the developed software, in addition to the execution of his or her personal development tasks. This need, in turn, increases one's responsibility toward the

Table 6. Roles in agile teams

Role	Description
Leading Group	
Coach	Coordinates and solves group problems, checks the Web forum and responds on a daily basis, leads development sessions.
Tracker	Measures the group progress according to test level and task estimations, manages studio boards, manages the group diary.
Customer Group	
End user	Performs on-going evaluation of the product, collects and processes feedback received from real end-users.
Customer	Tells customer stories, makes decisions pertaining to each iteration, provides feedback, defines acceptance tests.
Acceptance tester	Works with the customer to define and develop acceptance tests, learns and instructs test-driven development.
Maintenance Group	
Presenter	Plans, organizes, and presents iteration presentations, demos, and time schedule allocations.
Documenter	Plans, organizes, and presents project documentation: process documentation, user's guide, and installation instructions.
Installer	Plans and develops an automated installation kit, maintains studio infrastructure.
Code Group	
Designer	Maintains current design, works to simplify design, searches for refactoring tasks and ensures their proper execution.
Unit tester	Learns about unit testing, establishes an automated test suite, guides and supports others in developing unit tests.
Continuous integrator	Establishes an integration environment, publishes rules pertaining to the addition of new code using the test suite.
Code reviewer	Maintains source control, establishes and refines coding standards, guides and manages the team's pair programming.

development process. Third, the need to perform one's role successfully increases the team members' *involvement* in all parts of the developed software and leads him or her to become familiar with all software parts. If team members have only a limited view and are aware only of their own personal development tasks, they will not be able to perform their personal roles properly. Alternatively, the proposed role scheme supports knowledge sharing, participants' involvement and enhanced performances.

The software quality and the quality of the development process are reflected by three measures that serve as AQ teaching-metrics. The first is the role time measure (RTM). The RTM measures the development-hours/role-hours ratio, or in other words, the time invested in development tasks relative to the time invested in role activities. The second measure is the role communication measure (RCM), which measures the level of communication in the team at each development stage. The third measure is the role management measure (RMM), which measures the level of the project management. Data illustration of these metrics, taken from a specific academic project, can be found in Dubinsky and Hazzan (2004b).

Principle 7: Be Aware of Cognitive Aspects

This principle addresses two issues. The first deals with the idea of inspiring a process of on-going

and gradual improvement. The second addresses the fact that software development should be addressed by the individuals involved on different levels of abstraction.

It is clear that software development is a gradual process conducted in stages, each one improving upon those preceding it. In many cases, this improvement takes place in parallel to an improvement in the developers understanding of the developed application. Indeed, this principle is closely derived from the constructivist approach presented in the previous discussion of Principle 2. Accordingly, the learning environment should specifically inspire that feeling of gradual learning and elicit reflection processes when appropriate (cf. Principle 3).

We briefly present two illustrative scenarios that describe how this principle can be applied in practice. When learners try to achieve a consensus with respect to a topic of which their current knowledge is insufficient, the instructor/facilitator should guide them to postpone their final decision until a later stage. Sometimes, the instructor should guide the team to make a temporary decision based on their current knowledge, and explicitly state that in the future they will be able to update, refine, and even change the decision just made. In other cases when learners are deadlocked the moderator/instructor can stop the discussion, reflect on what has transpired, and suggest to move on, explaining that it might make more sense to readdress the issue currently blocking the development progress at a later stage when the learners' background and knowledge can solve the said problem.

As mentioned before, this principle is also related to thinking on different levels of abstraction. In a previous paper (Hazzan & Dubinsky, 2003), we suggested that during the process of software development, developers are required to think on different abstraction levels and to shift between abstraction levels, and explain how several agile practices (such as, refactoring and planning game) support this shift between abstraction level. In other words, developers must shift from a global view of the system (high level of abstraction) to a local, detailed view of the system (low level of abstraction), and vise versa. For example, when trying to understand customers' requirements during the first stage of development, developers should have a global view of the application (high level of abstraction). When coding a specific class, a local perspective (on a lower abstraction level) should be adopted. Obviously, there are many intermediate abstraction levels in between these two levels that programmers should consider during the process of software development. However, knowing how and when to move between different levels of abstraction does not always come naturally, and requires some degree of awareness. For example, a developer may remain at an inappropriate level of abstraction for too long a time, while the problem he or she faces could be solved immediately if the problem were viewed on a different (higher or lower) level of abstraction. The required shift to that different abstraction level might not be made naturally, unless one is aware that this may be a possible step toward a solution.

This principle suggests that instructors or workshop facilitators who teach agile AQ should be aware of the abstraction level on which each stage of each activity is performed. Based on this awareness, they then should decide whether to remain on this abstraction level, or, alternatively, whether there is a need to guide the participants to think in terms of a different level of abstraction. For example, when learners are engaged in design activities and tend to move to details related to the code level, it is important to guide them to stay at the appropriate (higher) level of abstraction. It is further suggested that the instructor or facilitator explicitly highlight the movement between abstraction levels and discuss with the learners the advantages that can be gained from such moves.

We note that the role assignment mentioned in the discussion of Principle 6 can also be viewed

as a means to encourage learners to look, think and examine the development process from different abstraction levels. More specifically, if a team member wishes to perform his or her individual role successfully, that is, to lead the project in the direction that the role specifies, he or she must gain a more global (abstract) view of the developed application.

Principle 8: Listen to Participants' Feelings Toward the Agile Concept

The adoption of AQ requires a conceptual change with respect to what a software development process is. In practice, when learners express emotional statements against some aspect of AQ, we propose to take advantage of this opportunity and encourage participants to describe the subject of the said statement as it is manifested in their current software development environment. As it turns out, in many cases these descriptions elicit problems in the currently used approach. Then, we explain how AQ attempts to overcome the problematic issues just raised. For example, when a statement is made against the test-driven development approach, it is a good opportunity to ask the person making this statement to describe the testing process that he or she is currently using. In some cases, this in itself is sufficient: The question highlights the test-driven development approach toward the discussed issue, and consequently, in many cases, the facial expression of the person expressing the objection immediately changes.

In all teaching situations, we propose to try sympathizing with and legitimizing learners' feelings, and being patient until learners start becoming aware of the benefits that can be gained from the new approach. In many cases, learners' objections disappeared in part after a short while. One plausible explanation is that they begin to realize that the new approach might actually support their work and improve the quality of their developed products.

Principle 9: Emphasize the Agile Concept in the Context of the Software World

This principle closes the circle that opened with the first principle—Inspire the nature of the learned concept, in our case—AQ. We believe that part of this inspiration is related to the connections made between the concept taught and the world of software engineering. Since the world of software engineering has witnessed relatively many cases in which new terms emerged and shortly after turned out to be no more than buzzwords, when teaching a new concept that requires developers to adopt a different state of mind, it is preferable to connect the new idea to the world of software development, and in our case, to connect AQ to other agile ideas. This can be done, for example, by presenting the learners with specific problems faced by the software industry (for example, the high rate of software projects that do not fit customer requirements), illustrating how the taught idea may help overcome them. Learners will then, hopefully, feel that, on the one hand, they are being introduced to a new idea that is not detached from the software industry world and is not just a passing fashion, and on the other hand, that the new approach toward quality issues emerged as a timely answer to the needs of the software industry and that it will be useful to them in the future.

In the case of teaching AQ, the need for AQ may be first explained and some problems related to traditional QA processes may be outlined. Such a broad perspective enables learners to understand the place of the agile approach in the software industry in general, and in particular, to observe that AQ is a topic that is still undergoing development.

SUMMARY

The set of principles presented in this chapter aims to establish a teaching framework within which we teach agile software development in general, and AQ in particular. A closer look at the teaching framework reveals that, in fact, its nature is similar to that of agile software development environments. Specifically, as agile software development inspires the notion of a single comprehensive framework in which all activities are performed by all team members in short cycles, with the different activities mutually contributing to one another, the framework described in this chapter also inspires an integrative teaching framework in which all principles should be adhered to at the same time, with different focuses as appropriate. Furthermore, as the assimilation of agile software development takes place in stages, the adoption of this teaching framework should also be carried out gradually, according to the culture of the environments into which the teaching framework is assimilated.

Chapter 7.5
Software Quality Modeling with Limited Apriori Defect Data

Naeem Seliya
University of Michigan, USA

Taghi M. Khoshgoftaar
Florida Atlantic University, USA

ABSTRACT

In machine learning the problem of limited data for supervised learning is a challenging problem with practical applications. We address a similar problem in the context of software quality modeling. Knowledge-based software engineering includes the use of quantitative software quality estimation models. Such models are trained using apriori software quality knowledge in the form of software metrics and defect data of previously developed software projects. However, various practical issues limit the availability of defect data for all modules in the training data. We present two solutions to the problem of software quality modeling when a limited number of training modules have known defect data. The proposed solutions are a semisupervised clustering with expert input scheme and a semisupervised classification approach with the expectation-maximization algorithm. Software measurement datasets obtained from multiple NASA software projects are used in our empirical investigation. The software quality knowledge learnt during the semisupervised learning processes provided good generalization performances for multiple test datasets. In addition, both solutions provided better predictions compared to a supervised learner trained on the initial labeled dataset.

INTRODUCTION

Data mining and machine learning have numerous practical applications across several domains, especially for classification and prediction problems. This chapter involves a data mining and machine learning problem in the context of software quality modeling and estimation. Software measurements and software fault (defect) data have been used in the development of models that predict software quality, for example, a software quality

classification model (Imam, Benlarbi, Goel, & Rai, 2001; Khoshgoftaar & Seliya, 2004; Ohlsson & Runeson, 2002) predicts the fault-proneness membership of program modules. A software quality model allows the software development team to track and detect potential software defects relatively early-on during development.

Software quality estimation models exploit the software engineering hypothesis that software measurements encapsulate the underlying quality of the software system. This assumption has been verified in numerous studies (Fenton & Pfleeger, 1997). A software quality model is typically built or trained using software measurement and defect data from a similar project or system release previously developed. The model is then applied to the currently under-development system to estimate the quality or presence of defects in its program modules. Subsequently, the limited resources allocated for software quality inspection and improvement can be targeted toward low-quality modules, achieving cost-effective resource utilization (Khoshgoftaar & Seliya, 2003).

An important assumption made during typical software quality classification modeling is that fault-proneness labels are available for all program modules (instances) of training data, that is, supervised learning is facilitated because all instances in the training data have been assigned a quality-based label such as fault-prone (*fp*) or not fault-prone (*nfp*). In software engineering practice, however, there are various practical scenarios that can limit availability of quality-based labels or defect data for all the modules in the training data, for example:

- The cost of running data collection tools may limit for which subsystems software quality data is collected.
- Only some project components in a distributed software system may collect software quality data, while others may not be equipped for collecting similar data.
- The software defect data collected for some program modules may be error-prone due to data collection and recording problems.
- In a multiple release software project, a given release may collect software quality data for only a portion of the modules, either due to limited funds or other practical issues.

In the training software measurement dataset the fault-proneness labels may only be known for some of the modules, that is, labeled instances, while for the remaining modules, that is, unlabeled instances, only software attributes are available. Under such a situation following the typical supervised learning approach to software quality modeling may be inappropriate. This is because a model trained using the small portion of labeled modules may not yield good software quality analysis, that is, the few labeled modules are not sufficient to adequately represent quality trends of the given system. Toward this problem, perhaps the solution lies in extracting the knowledge (in addition to the labeled instances) stored in the software metrics of the unlabeled modules.

The above described problem represents the labeled-unlabeled learning problem in data mining and machine learning (Seeger, 2001). We present two solutions to the problem of software quality modeling with limited prior fault-proneness defect data. The first solution is a semisupervised clustering with expert input scheme based on the *k-means* algorithm (Seliya, Khoshgoftaar, & Zhong, 2005), while the other solution is a semisupervised classification approach based on the expectation maximization (EM) algorithm (Seliya, Khoshgoftaar, & Zhong, 2004).

The semisupervised clustering with expert input approach is based on implementing constraint-based clustering, in which the constraint maintains a strict membership of modules to clusters that are already labeled as *nfp* or *fp*. At the end of a constraint-based clustering run a domain expert is allowed to label the unlabeled clusters, and the semisupervised clustering process is iter-

ated. The EM-based semisupervised classification approach iteratively augments unlabeled program modules with their estimated class labels into the labeled dataset. The class labels of the unlabeled instances are treated as missing data which is estimated by the EM algorithm. The unlabeled modules are added to the labeled dataset based on a confidence in their prediction.

A case study of software measurement and defect data obtained from multiple NASA software projects is used to evaluate the two solutions. To simulate the labeled-unlabeled problem, a sample of program modules is randomly selected from the JM1 software measurement dataset and is used as the initial labeled dataset. The remaining JM1 program modules are treated (without their class labels) as the initial unlabeled dataset. At the end of the respective semisupervised learning approaches, the software quality modeling knowledge gained is evaluated by using three independent software measurement datasets.

A comparison between the two approaches for software quality modeling with limited apriori defect data indicated that the semisupervised clustering with expert input approach yielded better performance than EM-based semisupervised classification approach. However, the former is associated with considerable expert input compared to the latter. In addition, both semisupervised learning schemes provided an improvement in generalization accuracy for independent test datasets.

The rest of this chapter is organized as follows: some relevant works are briefly discussed in the next section; the third and fourth sections respectively present the semisupervised clustering with expert input and the EM-based semisupervised classification approaches; the empirical case study, including software systems description, modeling methodology, and results are presented in the fifth section. The chapter ends with a conclusion which includes some suggestions for future work.

RELATED WORK

In the literature, various methods have been investigated to model the knowledge stored in software measurements for predicting quality of program modules. For example, Schneidewind (2001) utilizes logistic regression in combination with Boolean discriminant functions for predicting *fp* program modules. Guo, Cukic, and Singh (2003) predict *fp* program modules using Dempster-Shafer networks. Khoshgoftaar, Liu and Seliya (2003) have investigated genetic programming and decision trees (Khoshgoftaar, Yuan, & Allen, 2000), among other techniques. Some other works that have focused on software quality estimation include Imam et al. (2001), Suarez and Lutsko (1999) and Pizzi, Summers, and Pedrycz (2002).

While almost all existing works on software quality estimation have focused on using a supervised learning approach for building software quality models, very limited attention has been given to the problem of software quality modeling and analysis when there is limited defect data from previous software project development experiences. In a machine learning classification problem when both labeled and unlabeled data are used during the learning process, it is termed as semisupervised learning (Goldman, 2000; Seeger, 2001). In such a learning scheme the labeled dataset is iteratively augmented with instances (with predicted class labels) from the unlabeled dataset based on some selection measure. Semisupervised classification schemes have been investigated across various domains, including content-based image retrieval (Dong & Bhanu, 2003), human motion and gesture pattern recognition (Wu & Huang, 2000), document categorization (Ghahramani & Jordan, 1994; Nigam & Ghani, 2000), and software engineering (Seliya et al., 2004). Some of the recently investigated techniques for semisupervised classification include the EM algorithm (Nigam, McCallum, Thrun, & Mitchell, 1998), cotraining (Goldman

& Zhou, 2000; Mitchell, 1999; Nigam & Ghani, 2000), and support vector machine (Demirez & Bennett, 2000; Fung & Mangasarian, 2001).

While many works in semisupervised learning are geared toward the classification problem, a few studies investigate semisupervised clustering for grouping of a given set of text documents (Zeng, Wang, Chen, Lu, & Ma, 2003; Zhong, 2006). A semisupervised clustering approach has some benefits over semisupervised classification. During the semisupervised clustering process additional classes of data can be obtained (if desired) while the semisupervised classification approach requires the prior knowledge of all possible classes of the data. The unlabeled data may form new classes other than the pre-defined classes for the given data. Pedrycz and Waletzky (1997) investigate semisupervised clustering using fuzzy logic-based clustering for analyzing software reusability. In contrast, this study investigates semisupervised clustering for software quality estimation.

The labeled instances in a semisupervised clustering scheme have been used for initial seeding of the clusters (Basu, Banerjee, & Mooney, 2002), incorporating constraints in the clustering process (Wagstaff & Cardie, 2000), or providing feedback subsequent to regular clustering (Zhong, 2006). The seeded approach uses the labeled data to initialize cluster centroids prior to clustering. The constraint-based approach keeps a fixed-grouping of the labeled data during the clustering process. The feedback-based approach uses the labeled data to adjust the clusters after executing a regular clustering process.

SEMISUPERVISED CLUSTERING WITH EXPERT INPUT

The basic purpose of a semisupervised approach during clustering is to aid the clustering algorithm in making better partitions of instances in the given dataset. The semisupervised clustering approach presented is a constraint-based scheme that uses labeled instances for initial seeding (centroids) of some clusters among the maximum allowable clusters when using *k-means* as the clustering algorithm. In addition, during the semisupervised iterative process a domain (software engineering) expert is allowed to label additional clusters as either *nfp* or *fp* based on domain knowledge and some descriptive statistics of the clusters.

The data in a semisupervised clustering scheme consists of a small set of labeled instances and a large set of unlabeled instances. Let D be a dataset of labeled (*nfp* or *fp*) and unlabeled (*ul*) program modules, containing the subsets L of labeled modules and U of unlabeled modules. In addition, let the dataset L consist of subsets L_nfp of *nfp* modules and L_fp of *fp* modules. The procedure used in our constraint-based semisupervised clustering approach with *k-means* is summarized next:

1. **Obtain initial numbers of *nfp* and *fp* clusters:**
   - An optimal number of clusters for the *nfp* and *fp* instances in the initial labeled dataset are obtained using the C_g criterion proposed by Krzanowski and Lai (1988).
   - Given L_nfp, execute the C_g criterion algorithm to obtain the optimal number of *nfp* clusters among $\{1, 2, \ldots, Cin\_nfp\}$ number of clusters, where Cin_nfp is the user-defined maximum number of clusters for L_nfp. Let p denote the obtained number of *nfp* clusters. Given L_fp, execute the C_g criterion algorithm to obtain the optimal number of *fp* clusters among $\{1, 2, \ldots, Cin\_fp\}$ number of clusters, where Cin_fp is the user-defined maximum number of clusters for L_fp. Let q denote the obtained number of *fp* clusters.
2. **Initialize centroids of clusters:** Given the maximum number of clusters, C_{max}, allowed

during the semisupervised clustering process with *k-means*,

- The centroids of p clusters out of C_{max} are initialized to centroids of the clusters labeled as *nfp*.
- The centroids of q clusters out of $\{C_{max} - p\}$ are initialized to centroids of the clusters labeled as *fp*.
- The centroids of the remaining r (i.e., $C_{max} - p - q$) clusters are initialized to randomly selected instances from U. We randomly select 5 unique sets of r instances each for initializing centroids of the unlabeled clusters. Thus, centroids of the $\{p + q + r\}$ clusters can be initialized using 5 different combinations.
- The sets of *nfp*, *fp*, and unlabeled clusters are thus,

$C\_nfp = \{c\_nfp_1, c\_nfp_2, \ldots, c\_nfp_p\}$,
$C\_fp = \{c\_fp_1, c\_fp_2, \ldots, c\_nfp_q\}$
$C\_ul = \{c\_ul_1, c\_ul_2, \ldots, c\_ul_r\}$

3. **Execute constraint-based clustering:**
   - The *k-means* clustering algorithm with the Euclidean distance function is run on D using the initialized centroids for the C_{max} clusters, and under the constraint that *the existing membership of a program module to a labeled cluster remains unchanged*. Thus, at a given iteration during the semisupervised clustering process, if a module already belongs (initial membership or expert-based assignment from previous iterations) to a *nfp* (or *fp*) cluster, then it cannot move to another cluster during the clustering process of that iteration.
   - The constraint-based clustering process with *k-means* is repeated for each of the 5 centroid initializations, and the respective SSE (sum-of-squares-error) values are computed.
   - The clustering result associated with the median SSE value is selected for continuation to the next step. This is done to minimize the likelihood of working with a lucky/unlucky initialization of cluster centroids.
4. **Expert-based labeling of clusters:**
   - The software engineering expert is presented with descriptive statistics of the r unlabeled clusters, and is asked to label them as either *nfp* or *fp*. The specific statistics presented for attributes of instances in each cluster depends on the expert's request, and include data such as minimum, maximum, mean, standard deviation, and so forth.
   - The expert labels only those clusters for which he/she is very confident in the label estimation.
   - If the expert labels at least one of the r (unlabeled) clusters, then go to Step 2 and repeat, otherwise continue.
5. **Stop semisupervised clustering:** The iterative process is stopped when the sets *C_nfp*, *C_fp*, and *C_ul* remain unchanged. The modules in the *nfp* (*fp*) clusters are labeled and recorded as *nfp* (*fp*), while those in the *ul* clusters are not assigned any label. In addition, the centroids of the $\{p + q\}$ labeled clusters are also recorded.

SEMISUPERVISED CLASSIFICATION WITH EM ALGORITHM

The expectation maximization (EM) algorithm is a general iterative method for maximum likelihood estimation in data mining problems with incomplete data. The EM algorithm takes an iterative approach consisting of replacing missing data with estimated values, estimating model parameters, and re-estimating the missing data values. An iteration of EM consists of an E or Expectation

step and an M or Maximization step, with each having a direct statistical interpretation.

We limit our EM algorithm discussion to a brief overview, and refer the reader to Little and Rubin (2002) and Seliya et al. (2004) for a more extensive coverage. In our study, the class value of the unlabeled software modules is treated as missing data, and the EM algorithm is used to estimate the missing values. Many multivariate statistical analysis, including multiple linear regression, principal component analysis, and canonical correlation analysis are based on the initial study of the data with respect to the sample mean and covariance matrix of the variables. The EM algorithm implemented for our study on semisupervised software quality estimation is based on maximum likelihood estimation of missing data, means, and covariances for multivariate normal samples (Little et al., 2002).

The E and M steps continue iteratively until a stopping criterion is reached. Commonly used stopping criteria include specifying a maximum number of iterations or monitoring when the change in the values estimated for the missing data reaches a plateau for a specified epsilon value (Little et al., 2002). We use the latter criteria and allow the EM algorithm to converge without a maximum number of iterations, that is, iteration is stopped if the maximum change among the means or covariances between two consecutive iterations is less than 0.0001. The initial values of the parameter set are obtained by estimating means and variances from all available values of each variable, and then estimating covariances from all available pairwise values using the computed means.

Given the *L* (labeled) and *U* (unlabeled) datasets, the EM algorithm is used to estimate the missing class labels by creating a new dataset combining *L* and *U* and then applying the EM algorithm to estimate the missing data, that is, the dependent variable of *U*. The following procedure is used in our EM-based semisupervised classification approach:

1. Estimate the dependent variable (class labels) for the labeled dataset. This is done by treating *L* also as *U*, that is, the unlabeled dataset consists of the labeled instances but without their fault-proneness labels. The EM algorithm is then used to estimate these missing class labels. In our study the *fp* and *nfp* classes are labeled 1 and 0, respectively. Consequently, the estimated missing values will approximately fall within the range 1 and 0.
2. For a given significance level α, obtain confidence intervals for the predicted dependent variable in Step 1. The assumption is that the two confidence interval boundaries delineate the *nfp* and *fp* modules. Record the upper boundary as *ci_nfp* (i.e., closer to 0) and the lower boundary as *ci_ fp* (i.e., closer to 1).
3. For the given *L* and *U* datasets, estimate the dependent variable for *U* using EM.
4. An instance in *U* is identified as *nfp* if it's predicted dependent variable falls within (i.e., is lower than) the upper boundary, that is, *ci_nfp*. Similarly, an instance in *U* is identified as *fp* if it's predicted dependent variable falls within (i.e., is greater than) the lower bound, that is, *ci_ fp*.
5. The newly labeled instances of *U* are used to augment *L*, and the semisupervised classification procedure is iterated from Step 1. The iteration stopping criteria used in our study is such that if the number of instances selected from *U* is less than a specific number (that is, 1% of initial *L* dataset), then stop iteration.

EMPIRICAL CASE STUDY

Software System Descriptions

The software measurements and quality data used in our study to investigate the proposed semisupervised learning approaches is that of a large

NASA software project, JM1. Written in C, JM1 is a real-time ground system that uses simulations to generate certain predictions for missions. The data was made available through the Metrics Data Program (MDP) at NASA, and included software measurement data and associated error (fault or defect) data collected at the function level.

A program module for the system consisted of a function or method. The fault data collected for the system represents, for a given module, faults detected during software development. The original JM1 dataset consisted of 10,883 software modules, of which 2,105 modules had software defects (ranging from 1 to 26) while the remaining 8,778 modules were defect-free, that is, had no software faults. In our study, a program module with no faults was considered *nfp* and *fp* otherwise.

The JM1 dataset contained some inconsistent modules (those with identical software measurements but with different class labels) and those with missing values. Upon removing such modules, the dataset was reduced from 10,883 to 8,850 modules. We denote this reduced dataset as JM1-8850, which consisted of 1,687 modules with one or more defects and 7,163 modules with no defects.

Each program module in the JM1 dataset was characterized by 21 software measurements (Fenton et al., 1997): the 13 metrics as shown in Table 1 and 8 derived Halstead metrics (Halstead length, Halstead volume, Halstead level, Halstead difficulty, Halstead content, Halstead effort, Halstead error estimate, and Halstead program time. We used only the 13 basic software metrics in our analysis. The eight derived Halstead metrics were not used. The metrics for the JM1 (and other datasets) were primarily governed by their availability, internal workings of the projects, and the data collection tools used. The type and numbers of metrics made available were determined by the NASA Metrics Data Program. Other metrics, including software process measurements, were not available. The use of the specific software metrics does not advocate their effectiveness, and a different project may consider a different set of software measurements for analysis (Fenton et al., 1997; Imam et al., 2001).

Table 1. Software measurements

Line Count Metrics	Total Lines of Code Executable LOC Comments LOC Blank LOC Code And Comments LOC

Branch Count Metrics	Branch Count

In order to gauge the performance of the semisupervised clustering results, we use software measurement data of three other NASA projects, KC1, KC2, and KC3, as test datasets. These software measurement datasets were also obtained through the NASA Metrics Data Program. The definitions of what constituted a *fp* and *nfp* module for these projects are the same as those of the JM1 system. A program module of these projects also consisted of a function, subroutine, or method. These three projects were characterized by the same software product metrics used for the JM1 project, and were built in a similar software development organization. The software systems of the test datasets are summarized next:

- The KC1 project is a single CSCI within a large ground system and consists of 43 KLOC (thousand lines of code) of C++ code. A given CSCI comprises of logical groups of computer software components (CSCs). The dataset contains 2107 modules, of which 325 have one or more faults and 1782 have zero faults. The maximum number of faults in a module is 7.

- The KC2 project, written in C++, is the science data processing unit of a storage management system used for receiving and processing ground data for missions. The dataset includes only those modules that were developed by NASA software developers and not commercial-of-the-shelf (COTS) software. The dataset contains 520 modules, of which 106 have one or more faults and 414 have zero faults. The maximum number of faults in a software module is 13.
- The KC3 project, written in 18 KLOC of Java, is a software application that collects, processes, and delivers satellite meta-data. The dataset contains 458 modules, of which 43 have one or more faults and 415 have zero faults. The maximum number of faults in a module is 6.

Empirical Setting and Modeling

The initial *L* dataset is obtained by randomly selecting *LP* number of modules from JM1-8850, while the remaining *UP* number of modules were treated (without their fault-proneness labels) as the initial *U* dataset. The sampling was performed to maintain the approximate proportion of *nfp*:*fp* = 80:20 of the instances in JM1-8850. We considered different sampling sizes, that is, *LP* = {100, 250, 500, 1000, 1500, 2000, 3000}. For a given *LP* value, three samples were obtained without replacement from the JM1-8850 dataset. In the case of *LP* = {100, 250, 500}, five samples were obtained to account for their relatively small sizes. Due to space consideration, we generally only present results for *LP* = {500, 1000}; however, additional details are provided in (Seliya et al., 2004; Seliya et al., 2005).

When classifying program modules as *fp* or *nfp*, a Type I error occurs when a *nfp* module is misclassified as *fp*, while a Type II error occurs when a *fp* module is misclassified as *nfp*. It is known that the two error rates are inversely proportional (Khoshgoftaar et al., 2003; Khoshgoftaar et al., 2000).

Semisupervised Clustering Modeling

The initial numbers of the *nfp* and *fp* clusters, that is, *p* and *q*, were obtained by setting both *Cin_nfp* and *Cin_ fp* to 20. The maximum number of clusters allowed during our semisupervised clustering with *k-means* was set to two values: $C_{max} = \{30, 40\}$. These values were selected based on input from the domain expert and reflects a similar empirical setting used in our previous work (Zhong, Khoshgoftaar, & Seliya, 2004). Due to similarity of results for the two C_{max} values, only results for $C_{max} = 40$ are presented.

At a given iteration during the semisupervised clustering process, the following descriptive statistics were computed at the request of the software engineering expert: minimum, maximum, mean, median, standard deviation, and the 75, 80, 85, 90, and 95 percentiles. These values were computed for all 13 software attributes of modules in a given cluster. The expert was also presented with following statistics for JM1-8850 and the *U* dataset at a given iteration: minimum, maximum, mean, median, standard deviation, and the 5, 10, 15, 20, 25, 30, 35, 40, 45, 55, 60, 70, 75, 80, 85, 90 and 95 percentiles. The extent to which the above descriptive statistics were used was at the disposal of the expert during his labeling task.

Semisupervised Classification Modeling

The significance level used to select instances from the *U* dataset to augment the *L* dataset is set to $\alpha = 0.05$. Other significance levels of 0.01 and 0.10 were also considered; however, their results are not presented as the software quality estimation performances were relatively similar for the different α values. The iterative semisupervised classification process is continued until the number of instances added to *U* is less than 1% of the initial unlabeled dataset.

Semisupervised Clustering Results

The predicted class labels of the labeled program modules obtained at the end of each semisupervised clustering run are compared with their actual class labels. The average classification performance across the different samples for each *LP* and $C_{max} = 40$ is presented in Table 2. The table shows the average Type I, Type II, and Overall misclassification error rates for the different *LP* values. It was observed that for the given C_{max} value, the Type II error rates decreases with an increase in the *LP* value, indicating that with a larger initial labeled dataset, the semisupervised clustering with expert input scheme detects more *fp* modules.

In a recent study (Zhong et al., 2004), we investigated unsupervised clustering techniques on the JM1-8850 dataset. In that study, the *k-means* and *Neural-Gas* (Martinez, Berkovich, & Schulten, 1993) clustering algorithms were used at $C_{max} = 30$ clusters. Similar to this study, the expert was given descriptive statistics for each cluster and was asked to label them as either *nfp* or *fp*. In (Zhong et al., 2004), the *Neural-Gas* clustering technique yielded better classification results than the *k-means* algorithm.

For the program modules that are labeled after the respective semisupervised clustering runs, the corresponding module classification performances by the *Neural-Gas* unsupervised clustering technique are presented in Table 2. The semisupervised clustering scheme depicts better false-negative error rates (Type II) than the unsupervised clustering method. The false-negative error rates of both techniques tend to decrease with an increase in *LP*. The false-positive error rates (Type I) of both techniques tends to remain relatively stable across the different *LP* values.

A *z-test* (Seber, 1984) was performed to compare the classification performances (populations) of semisupervised clustering and unsupervised clustering. The Overall misclassifications obtained by both techniques are used as the response variable in the statistical comparison at a 5% significance level. The proposed semisupervised clustering approach yielded significantly better Overall misclassifications than the unsupervised clustering approach for *LP* values of 500 and greater.

The KC1, KC2, and KC3 datasets are used as test data to evaluate the software quality knowledge learnt through the semisupervised clustering process as compared to unsupervised clustering with *Neural-Gas*. The test data modules are classified based on their Euclidean distance from centroids of the final *nfp* and *fp* clusters at the end a semisupervised clustering run. We report

Table 2. Average classification performance of labeled modules with semisupervised clustering.

Sample Size	Semisupervised			Unsupervised		
	Type I	Type II	Overall	Type I	Type II	Overall
100	0.1491	0.4599	0.2058	0.1748	0.5758	0.2479
250	0.1450	0.4313	0.1989	0.1962	0.5677	0.2661
500	0.1408	0.4123	0.1913	0.1931	0.5281	0.2554
1000	0.1063	0.4264	0.1630	0.1778	0.5464	0.2431
1500	0.1219	0.4073	0.1759	0.1994	0.5169	0.2595
2000	0.1137	0.3809	0.1641	0.1883	0.5172	0.2503
2500	0.1253	0.3777	0.1725	0.1896	0.4804	0.2440
3000	0.1361	0.3099	0.1687	0.1994	0.4688	0.2499

the averages of the respective number of random samples for *LP* = {500, 1000}. A similar classification is made using centroids of the *nfp* and *fp* clusters labeled by the expert after unsupervised clustering with the *Neural-Gas* algorithm.

The classification performances obtained by unsupervised clustering for the test datasets are shown in Table 3. The misclassification error rates of all test datasets are rather unbalanced with a low Type I error rate and a relatively high Type II error rate. Such a classification is obviously not useful to the software practitioner since among the program modules correctly detected as *nfp* or *fp*, most are *nfp* instances—many *fp* modules are not detected.

The average misclassification error rates obtained by the respective semisupervised clustering runs for the test datasets are shown in Table 4. In comparison to the test data performances obtained with unsupervised clustering, the semisupervised clustering approach yielded noticeable better classification performances. The Type II error rates obtained by our semisupervised clustering approach were noticeably lower than those obtained by unsupervised clustering. This was accompanied, however, with higher or similar Type I error rates compared to unsupervised clustering. Though the Type I error rates were generally higher for semisupervised clustering, they were comparable to those of unsupervised clustering.

Table 3. Data performances with unsupervised clustering

Dataset	Type I	Type II	Overall
KC1	0.0617	0.6985	0.1599
KC2	0.0918	0.4151	0.1577
KC3	0.1229	0.5116	0.1594

Semisupervised Classification Results

We primarily discuss the empirical results obtained by the EM-based semisupervised software quality classification approach in the context of a comparison with those of the semisupervised clustering with expert input scheme presented in previous section. The quality-of-fit performances of the EM-based semisupervised classification approach for the initial labeled datasets are summarized in Table 5. The corresponding misclassification error rates for the labeled datasets after the respective EM-based semisupervised classification process is completed are shown in Table 6.

As observed in the Tables 5 and 6, the EM-based semisupervised classification approach improves the overall classification performances for the different *LP* values. It is also noted that the final classification performance is (generally) inversely proportional to the size of the initial labeled dataset, that is, *LP*. This is perhaps indicative of the presence of excess noise in the JM1-8850 dataset. A further insight into the presence of noise in JM1-8850 in the context of the two semisupervised learning approaches is presented in (Seliya et al., 2004; Seliya et al., 2005).

The software quality estimation performance of the semisupervised classification approach for

Table 4. Average test data performances with semisupervised clustering

Dataset	Type I	Type II	Overall
LP = 500			
KC1	0.0846	0.4708	0.1442
KC2	0.1039	0.3302	0.1500
KC3	0.1181	0.4186	0.1463
LP = 1000			
KC1	0.0947	0.3477	0.1337
KC2	0.1304	0.2925	0.1635
KC3	0.1325	0.3488	0.1528

the three test datasets is shown in Table 7. The table shows the average performance of the different samples for the *LP* values of 500 and 1000. In the case of *LP* = 1000, semisupervised clustering (see previous section) provides better prediction for the KC1, KC2, and KC3 test datasets. The noticeable difference between the two techniques for these three datasets is observed in the respective Type II error rates. While providing relatively similar or comparable Type I error rates, semisupervised clustering with expert input yields much lower Type II error rates than the EM-based semisupervised classification approach.

For *LP* = 500, the semisupervised clustering with expert input approach provides better software quality prediction for the KC1 and KC2 datasets. In the case of KC3, with a comparable Type I error rate the semisupervised clustering approach provided a better Type II error rate. In summary, the semisupervised clustering with expert input generally yielded better performance than EM-based semisupervised clustering.

We note that the preference of selecting one of the two approaches for software quality analysis with limited apriori fault-proneness data may also be based on criteria other than software quality estimation accuracy. The EM-based semisupervised classification approach requires minimal input from the expert other than incorporating the desired software quality modeling strategy. In contrast, the semisupervised clustering approach requires considerable input from the software engineering expert in labeling new program modules (clusters) as *nfp* or *fp*. However, based on our study it is likely that the effort put into the semisupervised clustering approach would yield fruitful outcome in improving quality of the software product.

CONCLUSION

The increasing reliance on software-based systems further stresses the need to deliver high-quality software that is very reliable during system operations. This makes the task of

Table 7. Average test data performances with semisupervised classification

Dataset	Type I	Type II	Overall
LP = 500

software quality assurance as vital as delivering a software product within allocated budget and scheduling constraints. The key to developing high-quality software is the measurement and modeling of software quality, and toward that objective various activities are utilized in software engineering practice including verification and validation, automated test case generation for additional testing, re-engineering of low-quality program modules, and reviews of software design and code.

This research presented effective data mining solutions for tackling very important yet unaddressed software engineering issues. We address software quality modeling and analysis when there is limited apriori fault-proneness defect data available. The proposed solutions are evaluated using case studies of software measurement and defect data obtained from multiple NASA software projects, made available through the NASA Metrics Data Program.

In the case when the development organization has experience in developing systems similar to the target project but has limited availability of defect data for those systems, the software quality assurance team could employ either the EM-based semisupervised classification approach or semisupervised clustering approach with expert input. In our comparative study of these two solutions for software quality analysis with limited defect data, it was shown that semisupervised clustering approach generally yielded better software quality prediction that the semisupervised classification approach. However, once again, the software quality assurance team may also want to consider the relatively higher complexity involved in the semisupervised clustering approach when making their decision.

In our software quality analysis studies with the EM-based semisupervised classification and semisupervised clustering with expert input approaches, an explorative analysis of program modules that remain unlabeled after the different semisupervised learning runs provided valuable insight into the characteristics of those modules. A data mining point of view indicated that many of them were likely noisy instances in the JM1 software measurement dataset (Seliya et al., 2004; Seliya et al., 2005). From a software engineering point of view we are interested to learn why those specific modules remain unlabeled after the respective semisupervised learning runs. However, due to the unavailability of other detailed information on the JM1 and other NASA software projects a further in-depth analysis could not be performed.

An additional analysis of the two semisupervised learning approaches was performed by comparing their prediction performances with software quality classification models built by using the C4.5 supervised learner trained on the respective initial labeled datasets (Seliya et al., 2004; Seliya et al., 2005). It was observed (results not shown) that both semisupervised learning approaches generally provided better software quality estimations compared to the supervised learners trained on the initial labeled datasets.

The software engineering research presented in this chapter can lead to further related research in software measurements and software quality analysis. Some directions for future work may include: using different clustering algorithms for the semisupervised clustering with expert input scheme, using different underlying algorithms for the semisupervised classification approach, and incorporating the costs of misclassification into the respective semisupervised learning approaches.

Chapter 7.6
Integrating Quality Criteria and Methods of Evaluation for Software Models

Anna E. Bobkowska
Gdańsk University of Technology, Poland

ABSTRACT

Successful realization of the model-driven software development visions in practice requires high quality models. This chapter focuses on the quality of models themselves. It discusses context-free and context-dependent quality criteria for models and then moves on to methods of evaluation which facilitate checking whether a model is good enough. We use linguistic theories to understand groups of criteria and their impact on other models, software product and the process of software development. We propose a strict distinction of the impacts of visual modeling languages, models of the system and tools for quality criteria. This distinction is helpful when designing the methods of evaluation and making decision about the point in time, scope and personnel responsible for quality assessment. As the quality criteria and several methods of evaluation has usually been considered separately we propose a methodology which integrates them. Such an integrated approach provides the following benefits. It allows for designing methods of evaluation based on quality criteria and elements of the model (or modeling language) in the context of specific needs. It can be applied for management of the scope of evaluation with quality criteria as well as configuration of the method to a specific situation. It allows for flexible and efficient conduct of the evaluation with selection of the methods of evaluation. Finally, this chapter presents case studies which illustrate the approach.

INTRODUCTION

Models play the central role in model-driven software development approaches. However, only good models really support work of analysts, managers and developers. Only good models have the potential to facilitate dealing with complexity, direct micro-process of software development, enable more efficient performance of the difficult

tasks, facilitate management and increase satisfaction at work. On the opposite, "bad" models may cause mistake, waste time and be annoying in use. Despite that, much research has been done in the area of technology of model transformations and tools supporting this task. We argue that there is a need to focus on the quality of visual modeling languages (VML), which are used for creating the models as well as quality of models themselves.

This chapter takes a practical perspective to quality in modeling. In order to improve the quality of models one needs to understand quality criteria for models, know efficient methods for conducting evaluation and understand relations between them for effective configuration and management. The level of maturity of the technology is not satisfactory nowadays and one can observe several problems from the point of view of project and general knowledge.

From the point of view of the software project, there are several unrelated methods with limited scope of application. It is unclear what could be benefits of using them and how they could be integrated. Perhaps the most popular method for improving model quality are inspections or reviews with checklists. However, one often needs to customize the checklist provided with methodologies for a specific project. It is easy to remove unnecessary checkpoints, but the problem remains when deciding which checkpoints need to added. The problem of inflexible methods of evaluation appears even more clearly in the perspective of the current trend of software process configuration. It assumes that companies do not choose a process but rather they make a configuration of roles, artifacts and tasks for a given type of project within a framework. It means that model artifacts, modeling activities and model checking activities are objects of configuration. Thus, we need objective criteria to make decisions about the scope of modeling as well as methods of evaluation for software models.

From the point of view of maturity of modeling technology, some objective criteria and practical methods of evaluation are needed in order to provide frameworks for customization of the concrete software projects. There is a need to understand criteria why modeling languages should have such elements, diagrams, visualizations, etc. The methods of evaluation are useful for making efficient evaluation and quality criteria behind such decision allow for trade-offs when compromises are necessary. They could be applied by Object Management Group (OMG) members working on modeling standards, e.g., Unified Modeling Language (UML) and its profiles or Business Process Modeling Notation (BPMN). As these standards influence advances in practice, the increase of the maturity of modeling technology should result in better perception of this technology and more successful application in practice. This approach could be useful also for committees which work on application-type modeling languages, e.g., internet applications; special type of models, e.g., task models for user behavior modeling; and models for emerging technology, e.g., aspect-oriented technology. Finally, they could be applied in the area of domain specific modeling. The tasks of designing and evaluating modeling languages in this case are performed in software companies which means a universal application of the methods of visual modeling language evaluation.

The objective of this chapter is to present an approach to dealing with model quality in a way which integrates quality criteria and methods of evaluation. The quality criteria are useful for understanding which aspects are evaluated and for managing the scope of evaluation. The methods of evaluation are necessary for efficient conduct of evaluation. The integrated approach should provide the following benefits. It should allow for designing methods of evaluation based on quality criteria and elements of the model (or modeling language) in the context of specific

needs. It should be applicable for management the scope of evaluation with quality criteria as well as configuration of the method to a specific situation. It should allow for flexible and efficient conduct of the evaluation with selection of the methods of evaluation. The most important features of the solution include:

- Improved understanding of the quality of models in the perspective of selected linguistic theories and separating impacts modeling language, model and modeling tools for the quality criteria;
- Proposition of a methodology for designing methods of evaluation based on quality criteria and elements of the model (or modeling language).

BACKGROUND

Although several quality criteria and some methods for evaluating models have been already proposed, the practical integrated approach is still missing. They solve one kind of problems but fail to satisfy other requirements. This section discusses related work in the area of identifying quality criteria for both models and visual modelling languages, and then available methods of evaluation.

Traditionally, software engineering researchers proposed technical quality criteria for models and visual modeling languages (VML). It was typical, that they were related to modeling technology in general. It can be illustrated with the following examples. Models should be expressive enough to allow developers to capture all interesting strategic and tactical decision (Booch, 1994) and notation should allow to create complete, correct and consistent models (McGregor, 1998). The diagrams should be executable (Martin, 1993). A set of characteristics of a good notation include: clear and uniform mapping of concepts to symbols, ease to draw by hand, good look when printed, faxed and copied using monochrome images, consistency with past practice and self-consistency, simplicity of common case modeling, not-to-subtle distinctions, no overloading of symbols and suppressible details (Rumbaugh, 1999). More attempts to answer the question of the quality of models can be found (Firesmith et al. 1996; Hong, 1993). The set of desirable criteria for models also include: precision, constructability, expressiveness, executability, traceability, inspectability, and usability. A more recent research proposes the following key characteristics of engineering models (Selic 2003):

- Abstraction – possibility to remove or hide details irrelevant for a given viewpoint, it constitutes the means for coping with complexity;
- Understandability – presenting in a form that directly appeals to our intuition and thus reduces intellectual effort;
- Accuracy – true-to-life representation of the system;
- Predictiveness – possibility to predict system's features;
- Small cost – models should be significantly cheaper to construct and analyze than modeled system.

Analysis of the proposed criteria suggests that, in general, models should be easy to understand for software developers, integrators and maintainers, and on the other hand, they should be precise enough to allow for automatic transformations by the tools. However, it is not clear how these criteria could be satisfied. Separating impacts of visual modeling language, model and tools can be helpful in the analysis and allow for higher level of precision and more practical application. Not much work on systematic approaches has been done. The only exception was an attempt to distinguish between goals and means in conceptual

modeling and to define syntactic, semantic and pragmatic quality (Lindland et al. 1994).

Many factors have impact on the models. The process of creating them, education and experience of designers, their purpose of use, and developer's subjective decisions are just a few examples. However, models quality depends, first of all, on the quality of visual modelling languages, which define syntax of correct models, their semantics and notation. In the area of VML evaluation, several methods of evaluation or just evaluations has been described in the literature, e.g. a method based on cognitive dimensions (Cox, 2000), comparative studies (De Champeaux et. al. 1992; Gu et.al. 2002; Kutar et al. 2002), comparing to ontology of systems (Opdahl et al. 2002) or evaluation based on a set of model quality criteria for business process modelling notation (Hommes et.al. 2003).

Several approaches to checking model quality has been proposed, e.g. checklists (Rational Unified Process, 2001), heuristics (Grotehen), object-oriented metrics with thresholds (Lorenz et al. 1994). Usually when applying them one finds out they are not complete and one misses a kind of framework for checking completeness. The problem is one does not know according to which quality criteria evaluations are made. Another problem in current approaches is that it is difficult to manage scope of evaluation when scope of models in the documentation or type of system under development changes.

The level of understanding of the quality criteria for models and usefulness of the proposed methods of evaluation is not satisfactory nowadays and the progress in this area is expected. But even assuming that universal lists of the quality criteria for models are possible to be defined, it is very likely that concrete evaluation will require only limited scope of them. Therefore, instead of attempting to define yet another "final set of quality criteria", we want to present a kind of framework for dealing with these issues.

CONFIGURATION OF METHODS OF EVALUATION BASED ON QUALITY CRITERIA

The objective of our research was to provide a practical solution for increasing quality in the modeling technology. We assume that in order to achieve it one can manipulate on models or visual modeling languages. In this section we identify the requirements for the methods and their application area and then we describe a methodology for designing methods of evaluation.

With the current trend in the area of software processes to provide a framework with best practices, e.g. IBM Rational Unified Process, which could be customized and configurated for a given type of projects depending on its characteristics, particular models, modeling and model checking activities are just a result of decisions made by process engineer. This observation leads to formulation of the first requirement for the methods of evaluation. They should be configurable for artifacts under evaluation.

The practice of software project shows that most projects are performed in the tough market conditions, they must meet limitation of resources and increasing quality requirements. On the other hand, it is known that quality assessment activities are essential, but there is an optimal point on the curve describing cost-to-effect. This perspective leads to the next requirements for the methods of evaluation. They should be as effective and efficient as possible. Since more advanced methods require more time to be performed, the methods of evaluation should be additionally manageable with respect to the scope and time of evaluation.

Furthermore, process engineer should be delivered with a solid knowledge about the consequences of using a given method of evaluation. Such knowledge would enable making rational decisions instead of using a coincidental set of checkpoints.

The above requirements can be fulfilled when delivering a methodology for designing methods

of evaluation customizable for selected objects under evaluation which check out these objects against desired quality criteria. The methodology can be summarized operationally in the following steps:

1. Define objectives for your method of evaluation
2. Identify means you can manipulate – objects under evaluation
3. Define quality criteria
4. Make configuration of the method of evaluation.

This methodology applied to design of the method of evaluation for models during the software project can be used by software process engineers once during the configuration of the process for a given type of projects or when the changes to this process are introduced. Then, several evaluations of models can be made by members of the quality assurance group in several projects of this type. The methodology applied for designing methods of evaluation for visual modeling languages can be used by the members of the standard committees as well as language engineers working on visual modeling languages. The application in the area of support for improvement of the standard modeling languages is not a common activity but it has a great impact on usefulness of technology used by many users. With the increasing popularity of domain specific languages, the design of the modeling languages and methods of their evaluation becomes a more common activity.

Definition of the Objectives and Identification of Objects Under Evaluation

The first important thing when designing a method of evaluation is to define objectives. It requires making realistic decisions about expected results and elements to be manipulated. Hardly ever the process engineer has the freedom to make configuration of the process from scratch without any limitations. Without this specific point of reference, hardly any evaluation can be successful. The distinction between quality of language and quality of models increases precision in evaluation. It is useful to understand a language as an expression space and a model as a kind of expression. Thus, examples of objectives for models include:

- Find defects in the design diagrams,
- Analyze fit to the purpose of the documented system,
- Support domain expert in validation of analysis documents,
- Evaluate understandability of documentation for a project,
- Predict functional quality of a system on the basis of its documentation.

Depending on the expected results different methods would be useful.

As examples of objectives for visual modeling languages one can state:

- Evaluate application of a subset of UML for a given type of projects with respect to the fit to needs,
- Evaluate usability of UML diagrams,
- Compare expressiveness of several propositions for a domain specific language,
- Compare maturity of modeling technology using BPMN and business use case modeling including tool support and fit to software development process.

It is important to have realistic expectation what can be achieved by manipulating VML, models and tools. For example, in order to achieve "executable diagrams" one needs a VML which allows to make executable specifications, then models which are precise enough to deliver data for transformations, and finally the tools which make

the transformations to the executable form. When attempting to assess correctness with respect to syntax it is useful to understand that VML defines correct models, then one can check models against the syntax, and tools support checking correctness against the syntax. They can disable incorrect constructions but additional check is needed in order to assess lack of incomplete work-in-progress ones. When evaluating expressiveness, VML defines what is possible to express and it can be evaluated against the fit of the expression space to the domain or purpose of modeling; models are kinds of expression within VML and they can be evaluated against how they use possibilities of VML to represent a system, and the role of tools is neutral – they just facilitate making models. When evaluating inspectability, VML can be checked against ease of defining criteria for inspection and relating them the model elements, the most important for models is understandability for inspectors and tools can be evaluated whether they support making inspections. Depending on the quality aspect the role of VML, models and tools changes.

Quality Criteria

Once decided about objectives and objects under evaluation the next step is to define quality criteria. It is difficult to define an orthogonal and complete set of quality criteria. The solution depends on several circumstances as well as internal aspects of VMLs. In order to understand better impact of quality criteria for models we use the following linguistic inspirations:

- Distinction into content and expression areas - which enables to predict consequences of several types of defects;
- Model of syntax, semantics and notation - and its application to evaluation of several aspects of VML; and
- Pragmatics – a promising approach which allows to define context of model usage and make more precise context-dependent evaluation.

For describing the quality model one can use, for example, McCall's framework or Goal Question Metric (GQM) approach.

Content and Expression Areas

Distinction between content and expression areas was inspired by the work of Hjelmslev (semiotician and linguist living in 1899-1965). In his perception of a language, a sign is a function between two forms, a content form and an expression form and every sign function is manifested by two substances: the content substance and the expression substance. The content substance is the psychological and conceptual manifestation of the sign, whereas the expression substance is the material substance wherein a sign is manifested. In simple words, it is a distinction between what one communicates and the means one uses to do it, e.g. sound, text, pictures, sign language, gestures, etc.

The implication for model quality evaluation is we can evaluate separtely content of models from their expression form. It allows to split apart these characteristics which have impact on solution from those which are only concerned with understanding. In the first group there are: completeness, correctness with respect to goals of the system etc. While the second group includes understandability, precision, adequate symbols and simplicity.

The content has direct impact on the system and these criteria can be used in order to predict quality of software. For example, the lack of completeness of use case diagram will result in the lack of functions in the system, the consequence of incorrect class diagram will be incorrect structure of the system, incorrect dynamic models will propagate to incorrect interactions between the user and the system. The expression criteria are indirectly concerned with the system quality, but

they indicate for likely problems with understanding by their users and resulting defects.

Syntax, Semantics and Notation

The distinction between syntax, semantics, notation and pragmatics is inspired by the work of semioticians such as Morris and Peirce and chapters of contemporary books on linguistics which study separately syntax (grammar) when dealing with relations between signs, semantics concerned with relations between signs and reality, different forms of expressions and their rules (speech, writing, gestures) and pragmatics—dependence of communication on interpreters. The distinction between syntax, semantics and notation is successfully applied in formulation of UML description. An attempt to use distinction between syntax, semantics and pragmatics for understanding model quality has already been proposed (Lindland et al. 1994). However, this distinction has much greater potential for performing more precise methods of evaluation from the perspective of a given area as well as the perspective of relationships between given two areas.

Pragmatics

Pragmatics is the study of language which focuses attention on the users and the context of language use rather than on reference, truth, or grammar' (The Oxford Companion to Philosophy). It studies the use of language in context, and the context-dependence of various aspects of linguistic interpretation. Context is the situation in which language is used and it includes extralinguistic factors: social, psychological and environmental ones. One of the topics of debate in linguistics is the semantics-pragmatics distinction (Bach). Semantics concerns context-independent meaning (the relation of signs to objects) and pragmatics deals with context-dependent meaning (the relation of signs to their interpreters). This distinction is best reflected in the following pairs of expressions: sentence vs. utterance; meaning vs. use; context-invariant vs. context-sensitive meaning; linguistic vs. speaker's meaning; literal vs. nonliteral use; or saying vs. implying.

Pragmatics in linguistics allows to deal with the context of use. It enables understanding aspects dependent on people who take part in conversations and their situations. It could play similar role in research on modeling in software engineering. VMLs also have several kinds of users with different social, psychological and environmental factors. The perception of models might differ depending on expectations related to the roles they play in software development activities. Application of pragmatics in practice would require definition and description of pragmatics profiles and evaluation of VML in the context of these pragmatics profiles.

Design of the Method of Evaluation

The input for the method of evaluation are objectives, quality criteria and objects under evaluation which can be changed depending on the results of evaluation. The results depend on the objectives. They include: lists of defects, metrics, suggestions of improvement, comparison results etc. The essence of the design of the method of evaluation is combination of the all relevant quality criteria with objects under evaluation. This can be as simple as intersection of criteria and objects under evaluation or as difficult as using several basic methods supporting the quality improvement and integrating them.

In our opinion, the method of evaluation is basically a support for human information processing. Although some tools automatically collect diagram metrics or automatically discover some kinds of low-level defects, still majority of model evaluation tasks and almost all VML evaluation tasks must be performed by professionals.

Thus, it is useful to have a look at a cognitive inspiration (without going into details of cognitive modeling.) One can notice that within

an evaluation without any support two different types of information processing processes are performed:

- An organizational process – which is concerned with issues 'What shall I do next? What should be checked? How to do it? Is it enough?'
- A checking process – which performs several basic checks according to the organizational process.

These processes take place concurrently and can be informal, implicit and unordered. They might be more or less conscious and casual. Main problems and most of 'awaiting' are associated with the organizational process. The role of the method of evaluation is to deliver a pattern for the organizational process, and, thus, to make it more explicit, conscious, ordered and repeatable. As the most waste of time is concerned with this process, the method should result in improvement of the efficiency of evaluation.

Furthermore, modeling concepts and quality concepts are usually placed in different conceptual models in our minds. The role of the methods of evaluation which combine model elements with quality criteria is to drive evaluator's attention step by step to facilitate checking all important aspects. Any of these combinations is less prone for forgetting when there are lots of them or evaluator is working in hurry or has another motivation to finish the evaluation soon. Thus, the method supports effectiveness by forcing complete check.

Additionally, some strategies are useful when designing methods of evaluation, e.g. 'most important things first' which takes into consideration that people get tired during evaluation and their productivity can decrease, or the idea of 'building evaluators' knowledge' and thus checking related aspects together in time. A good practice is to design a space for 'other comments' just in case of finding by evaluators defects which are not covered by the method or to allow them to express their comments on the method.

One more important group of aspects to be taken into account when designing methods of evaluation are human factors: evaluators, their characteristics, their knowledge and their context of work. The differences might depend on culture or language. The evaluators might prefer e.g. command style or question style, long questionnaires with very simple questions or shorter questionnaires with more open and complex questions, discussions with authors or just formal reports from evaluation.

An interesting issue related to the design of the methods of evaluation is whether it is possible to automatically generate appropriate checklists. As tools can be designed to support any task, it is useful to pose additional questions about the quality of the generated checklists and effectiveness of generation, i.e. comparison of the effort required for the development of such tools and inserting necessary data with the effort required for re-designing the checklists when context of application or requirements change. Large benefits can be achieved with low-cost manually-made methods of evaluation. The tools can add the value of easy generation of multiple variants of checklists and allow for relating results of evaluation with the items of the method and processing them. However, one should be skeptical to automatically generated checklists and review them carefully for accuracy and style.

The main idea of the method to support organizational process during evaluator's work and to drive their attention seems to be universal, however more research on strategies and evaluator's preferences would be useful.

CASE STUDIES

In order to demonstrate the practical application of the methodology of designing methods of evaluation, we present three case studies with design of

diverse methods of evaluation. Two of them are related to models, but they have different objectives. The first method is a simple manageable checklist for the purpose of finding defects and the second uses every information on the models in order to deliver quality predictions (Bobkowska, 2001). The third case study summarizes a method for evaluating visual modeling languages from a cognitive perspective (Bobkowska, 2005).

Quality Criteria-Based Checklist

The objective of this method design was to provide a simple checklist for verification of analysis models to be applied in teaching classes of systems modeling and analysis. It was required that the method fits well to the diagrams under evaluation and quality criteria for models should be explicitly stated. Additionally, the method should be efficient and easy to modify.

The object under evaluation was documentation of the analysis, which consisted of the vision of the system (goals, scope, context) in the textual form, use case diagram for presentation of the system's functionality, class diagram and sequence diagrams for all use cases. Apart from the diagrams, non-functional requirements were specified in the textual form.

The quality criteria reflected the distinction between content and expression areas. The content group included: completeness, correctness, consistency and fit to the vision of the system. The expression group included: understandability of diagrams, their elegance, precision, simplicity and adequate level of abstraction.

While designing the method we have used additionally two 'strategies' which allowed for effective and efficient evaluation: 'direct users to check most important aspects first' and 'order questions around the diagrams not the quality criteria'. This resulted in a checklist to check content of the use case diagram, then content of the class diagram and sequence diagrams. Later consistency between all diagrams and fit to the vision were evaluated, and finally - expression criteria for all diagrams. The checklist ended with some space for summary. Each subsection related to checking a given diagram with a selected quality criterion included direct instructions for users informing them what they should do.

For example, section '1. Content of use case diagram' consists of two subsections '1.1 Completeness of use case diagram' with instruction to identify missing actors, missing use cases and missing relationships and subsection '1.2 Correctness of use case diagram' with instruction to identify incorrect actors, use cases and relationships, i.e. spurious, these with wrong scope, wrong labels, wrong directions of arrows in relationships. Section '6. Expression of use case diagram' consists of the following subsections '6.1. Precision and understandability of labels and descriptions' with instruction to identify unclear, vague and difficult to understand labels and descriptions, '6.2. Elegance of icon placement on the diagram' with instruction to find defects related to placements and aesthetics of the diagram, '6.3. Simplicity' with instruction to identify unnecessarily complex descriptions and constructions on the diagram and finally subsection '6.4 Adequate level of abstraction' with instruction to identify mismatch of elements in respect to level of abstraction, e.g. some elements too general or others too detailed.

This checklist satisfies the requirements formulated when stating objectives. It is simple, it fits exactly for the diagrams under evaluation and it explicitly indicates for the criteria of evaluation. It is as efficient as possible and easy to modify when documentation or quality criteria change. We collected opinions of users of this checklist who have also used fragments of general purpose RUP checklist for these diagrams. The users said that clear instructions in context of these subsections facilitate finding defects and give a good understanding according to which criteria evaluation is made. The checklist was leading them through the review and without it they

wouldn't find so many defects. They claimed it suited better to the diagrams under evaluation then the RUP checklist.

Software Quality Prediction

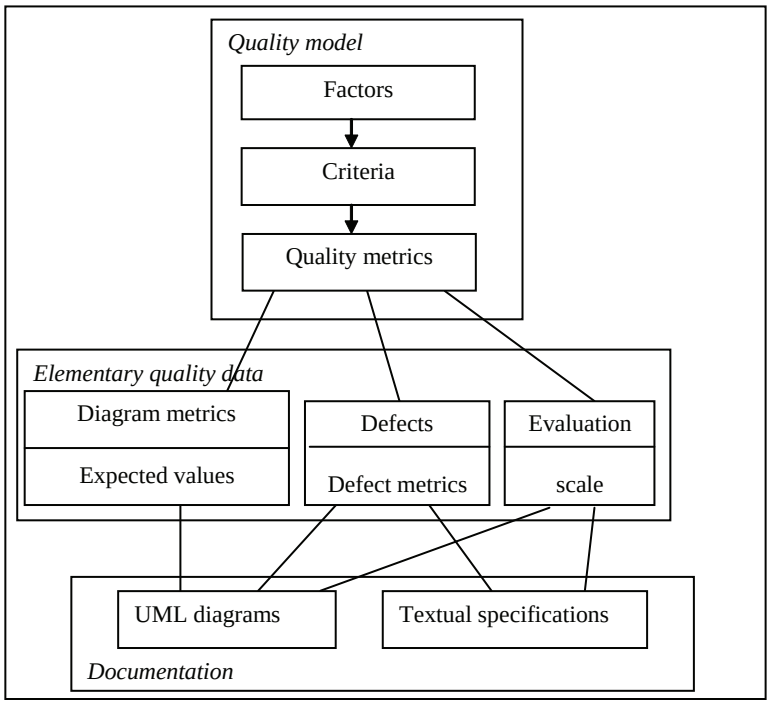
The objective of this method design was to use every information on the models indicating for quality of the final software to be developed and use it in order to make software quality predictions in early phases of software development. Such predictions should allow managers to control the development process with quantitative measures of software product (together with measures of software process taken from other sources).

The objects under evaluation were documents of software analysis and design. The scope of analysis was similar to one described in the previous section, and the documentation of design consisted of systems design which consisted of subsystem diagram and interactions between subsystems, decisions about environment, boundary conditions, style and trade-offs. Other documents contained user interface design, database design and subsystems design.

Since the objective was to predict quality factors of system under development, the meaningful attributes were functionality, maintainability and usability. They needed to be related to quality criteria of models such as completeness, correctness, precision, adequate structure, flexibility to probable changes, adequacy of designed algorithms etc. Additionally, the requirement of quantitative measurement leaded to introduction of quality metrics for both quality factors and quality criteria in scale 0.1.

The schema of the relationships between items of the method for software quality prediction is shown in Fig. 1. The design integrates the quality model (made with the use of McCalls framework

Figure 1. Elementary quality data in context of the quality model and documentation with UML (©2007 Anna Bobkowska. Used with permission)



with its terms of quality factors, criteria and metrics) with UML model elements and related textual specifications, e.g. these which describe vision of the system or system design decisions.

The link between them consists of elementary quality data, which can be diagram metrics and their expected values, model evaluation in a scale and the lists of defects together with their metrics. Diagram metrics cover the idea of measurement of the UML diagrams and use of this information to reason about quality by comparing the results of measurements with expected values, which can be derived from historical data about similar projects. Diagram metrics are also the basis for local size calculation which can be used for defect metrics calculation. The diagram metrics are example of optimal features, and expected values indicate the right range. Evaluations with comments are concerned with the criteria that are difficult to measure objectively. Evaluations are numbers that represent subjective feelings about some aspects of the work, e.g. ease of understanding, aesthetics, precision, etc. They can be given in the scale and described as comments. They represent positive features. Defect collection according to the defect classification is an instantiation of the negative features in the model. These defects can be then counted and combined with the diagram size metrics.

Two steps are performed during the quality prediction:

- Elementary quality data collection which allows to gather elementary quality data on the basis of documentation;
- Reasoning about quality, which allows to transform elementary quality data into quality metrics, which can be made manually by quality expert or can be calculated according to formulas with parameters which represent the impact of given metrics or evaluations.

This method requires more work comparing to the previous case study. However, it satisfies its goal of delivering quantitative predictions of the software quality in early phases of software development. It allows to see consequences of defects in the documentation for the software quality and supports the control of the process of software development. The problem of software quality prediction is quite complicated and when designing a solution one meets the questions of missing data and thus uncertainty of predictions as well as the problem of subjectivity of evaluations and reasoning. However, with questionnaires supporting elementary quality data collection and reasoning, even students of experimental group have performed predictions with satisfying results.

Evaluating VMLs from a Cognitive Perspective

The objective of this method design was to propose a tool for visual modeling language (VML) evaluation from a cognitive perspective and then evaluate with this method use case diagram. It is believed that cognitive fit of the technology to its users can increase efficiency, decrease cost, improve software quality and allow for easier learning, use and maintenance.

Since the methodology is configurable the object under evaluation can be any visual modeling language or any of its diagrams. In this case study we present customization for use case diagram, thus we operate are at meta-model level and objects under evaluation are UML model elements.

The quality criteria for this methodology were defined by a set of cognitive dimensions (Blackwell, Green, 2000):

- Viscosity - resistance to change,
- Visibility - ability to view components easily,
- Premature commitment - constraints on the order of doing things,

- Hidden dependencies - important links between entities are not visible,
- Role-expressiveness - the purpose of an entity is readily inferred,
- Error-proneness - the notation invites mistakes and the system gives little protection,
- Abstraction - types and availability of abstraction mechanisms,
- Secondary notation - extra information in means other than formal syntax,
- Closeness of mapping - closeness of representation to domain,
- Consistency - similar semantics are expressed in similar syntactic forms,
- Diffuseness - verbosity of language,
- Hard mental operations - high demand on cognitive resources,
- Provisionality - degree of commitment to actions or marks,
- Progressive evaluation - work-to-date can be checked at any time,

A schema of the approach to the design of the method is presented in Fig. 2. CD-VML template is a product of customization of the original cognitive dimensions (CD) questionnaire for visual modeling languages. It required some modification to increase precision of questions and their fit to visual modeling language terminology. Then, the next step in design is customization for the method of evaluation for a specific visual modeling language or one of its diagrams. We have designed a CD-VML-UC questionnaire - a product of the CD-VML methodology for the use case (UC) model in the default context of use of creating models, their usage and change.
