Buy and sell signals are generated according to the behavior of moving averages in the short and longer term. A buy signal is produced when the short average crosses above the longer one. When the short average moves below, a sell signal is generated. This technique is called the *double crossover method.*

The 10 commonly used indicators that we have employed in this work are detailed in Appendix 1.

METHODOLOGY

Genetic Algorithms

Genetic Algorithms (GA) were introduced by Holland (1975) as a general model of adaptive processes and have been widely applied as an optimization technique. They were inspired by natural genetic processes and employ a population of "chromosomes" (represented by binary strings) that are analogous to the DNA of a natural organism. Unlike traditional optimization methods that require well-defined mathematical representations of the objective, GA can solve optimization problems that are far less well described mathematically. This makes them very useful for trading models, which cannot easily be expressed in terms of mathematical formulas and functions.

In the original GA formulation, a population of possible solutions is encoded as a set of bit strings (known as parameter strings), each of the same fixed length. The fitness of each string in the population is estimated and the basic GA operators are then applied as described below. This provides a second generation population whose average fitness is greater than that of the initial population. The GA operators are now applied to the second generation population and the process is repeated, generation after generation, until some stopping criterion is met. The string with maximum fitness in the final population is then selected as the solution.

In applying a GA to FX trading, each string represents a possible solution for the trader — adopt a short, long or neutral position.

Decisions made by the trader are based upon the values of a set of market indicators. These values can be incorporated into the GA bit strings as binary variables. For instance, in the case of the double-crossover method mentioned in the previous section, the indicator generates a sell signal when the short average moves below the longer one. The indicator corresponding to this signal is called "MASell" and it takes on the binary value 1 when the condition for the sell signal is met. It has the value 0 otherwise.

An example of a rule employing this and two other indicators (described in the Appendix) is shown in Table 1. This rule instructs the trader to adopt a short position (i.e., sell) and is encoded as a bit string in the table. The rule states "IF MASell = 1 OR (MomentumSell =1 AND StochasticBuy = 0) THEN adopt a short position." Thus the connectives in the table are the Boolean operators AND and OR which have binary values 1 and 0 respectively.

Note that the instruction to sell in this rule is encoded as a zero at the right-hand end of the

Table 1. A sell rule and its associated bit string

MASell	Connective	MomSel	Connective	StochBuy	Sell
1	0	1	1	0	0

Table 2. An example of an exit

RSI Buy	Connect	Mom Sell	Connect	LW Sell	Connect	PO Sell
1	0	1	0	1	1	0

bit string. Rules that instruct the trader to adopt a long position (i.e., to buy) have a "1" in this position.

Rules for adopting a short or long position are called *entry* rules because they instruct the trader to participate actively in the market. There are also exit rules under which the trader returns to a neutral position. An example is shown in Table 2. Note that there is no explicit binary value for the instruction to exit. No such value is necessary because the exit action is always the same — that is, to return to a neutral position.

The rule in Table 2 rule states "IF RSIBuy = 1 OR (MomentumSell = 1 OR (Larry WilliamsSell = 1 AND Price OscillatorSell = 0) THEN adopt a neutral position."

The rules and their binary strings are obviously significantly longer than these, when a large number of indicators have to be coded.

The rules in Tables 1 and 2 together can be considered as a *strategy*. This strategy states that if the trader enters under the rule in Table 1, the rule for exiting is the one in Table 2. Our objective is to use machine learning methods to determine the best possible strategy for given market conditions.

In a typical implementation, a population of 150 rules of each type (entry and exit) is generated randomly. Then out of these 300 rules we randomly combine 150 pairs consisting of one entry rule and one exit rule. This therefore gives us 150 trading strategies. These strategies are ranked according to their profitability and are then stochastically chosen to participate in the creation of a new population. Those strategies with greater profitability (or *fitness*) are more likely to be selected to participate. The process of generating a new population employs rules that are analogous to processes involved in natural reproduction. The exchange of genetic material is reflected in the *crossover* operation which combines a pair of rules to form two "children" by swapping sub-strings. A form of *mutation* is also occasionally applied in order to broaden the mix of bit strings. This is implemented by simply inverting bit values. A low probability is used for this so that bit values are only infrequently inverted.

Crossover and mutation are applied only to rules of the same type (entry or exit). If rules derived in this way are unique (differing from all other rules in the population), they are used to replace low-ranked rules. This is done in such a way that the number of rules in the population remains constant. The process is continued until a stopping criterion is met upon which the best pair of rules (the best strategy) is chosen to be the output of the genetic algorithm. The best strategy is the one that gives maximum profitability.

Reinforcement Learning

Another Machine Learning framework that is helpful in the implementation of a financial market model is reinforcement learning. The general reinforcement learning problem addresses the following: an agent must explore its environment

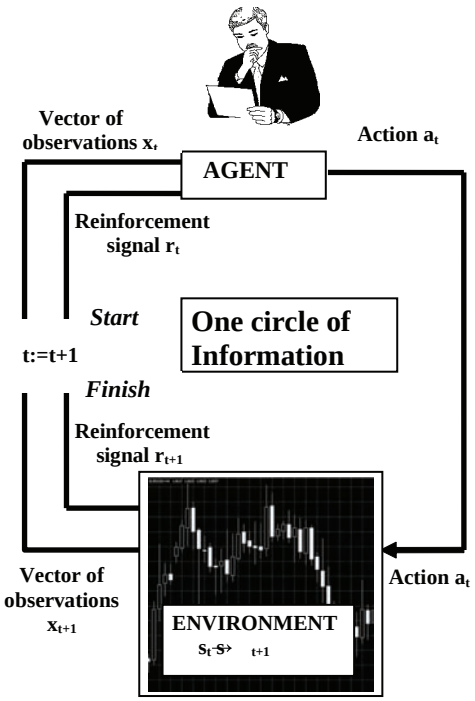
and make decisions in different situations based on incomplete knowledge about this environment. The only feedback that the agent receives from the environment is a scalar reinforcement signal which is positive if its actions are beneficial and negative otherwise. The objective of the agent is to choose its actions so as to increase the long-term sum of the reinforcement signals (Kaelbling & Littman, 1996). Besides the reinforcement signal the agent also receives information on the current state of the environment (in the form of a vector of observations). On the FX market a trader (machine or human) has insufficient knowledge about the environment to choose the times at which buy and sell decisions should be made in order to maximize profit. The only information available is the gain (positive or negative) generated by trading decisions and this provides the reinforcement signal that drives our system.

Figure 2 illustrates the principles of reinforcement learning (RL). At time *t* the agent receives inputs $\boldsymbol{x}_t$ (a vector of observations) and r_t (a reinforcement signal) and based on these it chooses an action, a_t. The action a_t changes the state of the environment from s_t to s_{t+1}. The process then repeats.

For our software implementation, we have developed an RL-engine based on the Q-learning algorithm proposed by Watkins (1989) for partially observable Markov decision processes. The Q-learning algorithm, which can be used online, was developed for the optimization of a strategy based upon experience gained from the unknown environment.

In general, the Q-learning algorithm works as follows. The value Q(*s*, *a*) is defined to be the expected discounted sum of future reinforcement signals when action *a* is taken in state *s* and an optimal policy is then followed. The state *s* belongs to *S*, the discrete set of states of the environment and the action *a* belongs to the set *A* of possible agent actions. Once we have the Q(*s*, *a*) values, the optimal action from any state is the one with the highest Q-value. This means that we obtain

Figure 2. Reinforcement learning cycle



the policy by executing the action with the highest Q-value. At the first step we initialize $Q_0(s_0, a_0)$ by arbitrary numbers and improved estimates of the Q-values are then obtained from incoming signals using the following procedure:

1. From the current state s_t, select an action a_t. This takes us to the next state s_{t+1} and provides the reinforcement signal $r_{t+1.}$
2. Update $Q_t(s_t, a_t)$ based on this experience:

$$Q_{t+1}(s_t, a_t) := Q_t(s_t, a_t) + \alpha \left(r_{t+1} + \gamma \max_a Q_t(s_{t+1}, a) - Q_t(s_t, a_t) \right) \quad (1)$$

   where α ($0 < \alpha \leq 1$) is a learning-rate parameter and $0 <$ ãð < 1 is the discount factor used to place more emphasis on reinforcement signals that are received earlier.
3. Go to 1.

Note that we have to store each value $Q(s,a)$ for all $s \in S$ and $a \in A$. They are stored in a table

called a Q-table. An illustration of Q-learning algorithm is given in Appendix 2.

The objective of the agent is to find the optimal policy $\pi(s) \in A$ for each state of the environment to maximize the long-run total reward. The Q-learning algorithm uses optimal Q-values $Q^*(s_t, a_t)$ for states s and actions a. The optimal Q-value function satisfies Bellman's optimality equation:

$$Q^*(s_t, a_t) := \sum_{s_{t+1}} P(s_t, a_t, s_{t+1}) \left[R(s_t, a_t, s_{t+1}) + \gamma \max_{a'} Q^*(s_{t+1}, a') \right] \quad (2)$$

where $P(s_t, a_t, s_{t+1})$ is the probability of a transition from state s_t to s_{t+1} with action a_t is taken.

$R(s_t, a_t, s_{t+1})$ is an immediate reward obtained from taking action a_t when the environment state changes s_t to s_{t+1}.

$\gamma (0 \leq \gamma \leq 1)$ is a discount factor to weight future rewards.

Given the optimal Q-values $Q^*(s,a)$ it is possible to choose the best action:

$$a^* = \arg\max_a (Q^*(s, a))$$

A major advantage of using Q-learning is that there is no need to know the transitive probabilities $P(s_t, a_t, s_{t+1})$. The algorithm can find the $Q^*(s,a)$ in a recursive manner. The Q-values are adjusted according to equation (1).

If equation (1) is repeatedly applied for each pair (s_t, a_t) and the learning rate α is gradually reduced toward 0 over time, then $Q(s,a)$ converges with probability 1 to $Q^*(s,a)$.

A HYBRID TRADING SYSTEM

Our hybrid system involves a combination of the two techniques of machine learning described in the previous section.

Combining the Two Techniques

It is important to realize that, because of the vast number of combinations of indicator values and connectives, the GA is unable to search the whole space of strategies to find the optimum. To see this, note that if we have m indicators per rule and N indicators in total, the number of possible rules is $P(N, m)*2^{m-1}$, where $P(N, m)$ is the number of permutations of N objects taken m at a time. In our system, the ten indicators we use are applied to both buying and selling, giving a total of 20 indicators in all. Our average rule length is eight indicators, so the above formula gives the approximate number of possible rules as 6.5×10^{11}.

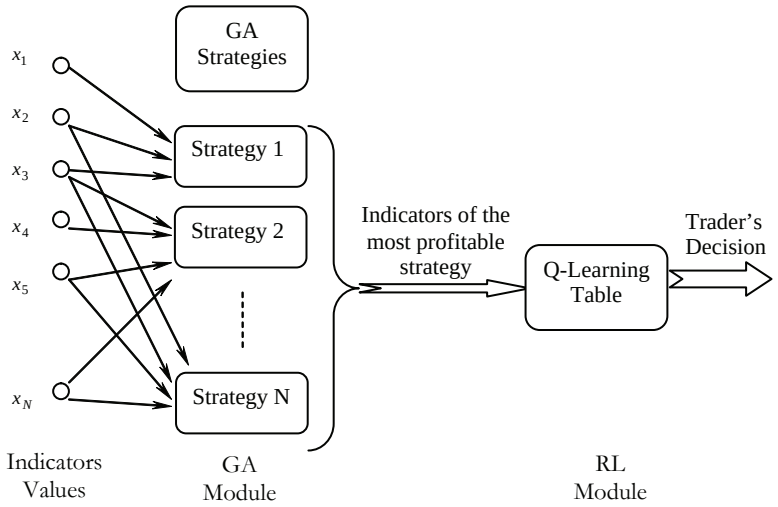
To illustrate our procedure a little further, suppose that the strategy given by Table 1 has been selected by the GA as the most profitable one. (Note that this could only occur in a market where prices are falling.) Because of the combinatorial complexity, the GA will, with very high probability, have only considered one set of instantiations for the indicators and connectives making up this rule (i.e., the ones in Tables 1 and 2). And this is where reinforcement learning comes in.

The fact that the GA identified this strategy as a profitable one shows that the indicators used in the strategy are capable of making useful market predictions. Because of this, it is worthwhile to consider the other possible instantiations of the rule values in the strategy, and this is the role of the Q-learning algorithm. Figure 3 shows the basic structure of the system. Once we have the set of the most useful indicators, they can be used to represent states of the environment and in this way we can take into account all possible combinations of the indicators.

Consider the theoretical situation where the GA module has identified the two indicators RSIBuy and CCISell as useful predictors. They provide the following set of states of the environment

$$\begin{cases} s_1 = \text{RSIBuy} = 1, \text{CCISell} = 1 \\ s_2 = \text{RSIBuy} = 1, \text{CCISell} = 0 \\ s_3 = \text{RSIBuy} = 0, \text{CCISell} = 1 \\ s_4 = \text{RSIBuy} = 0, \text{CCISell} = 0 \end{cases}$$

Figure 3. The hybrid system



At each moment of time the trader has to make a decision whether take a short, long or neutral position. Thus, the set of actions is {buy, neutral, sell}.

This set of indicators and actions gives a Q-table of the form in Table 3. The entries in this table contain Q-values that are calculated and updated using the method explained in the Reinforcement Learning section. A detailed example is given in Appendix 2.

Since a trader on the FX Market tries to maximize profit, the reinforcement signal r_t is set to the difference between portfolio values at times *t* "1 and *t*. For instance, if at time *t* "1 the trader took a long position, and then it was found that the portfolio at time *t* has a lower value than at time *t* "1, the reinforcement signal would be negative. This provides the basic mechanism for adopting long and short positions. But the third position, the neutral position, must also be properly dealt with. This requires the allocation of a threshold to avoid spurious shifts from the neutral position caused by minor market fluctuations. The major effect of this is to avoid the cost of insignificant transactions.

Table 3. Q-learning table consisting of 3 actions and 2N states where N — number of indicators

	RSIBuy=1 CCISell=1	RSIBuy=1 CCISell=0	RSIBuy=0 CCISell=1	RSIBuy=0 CCISell=0
Buy				
Neutral				
Sell				

Related Methods

Previous work with similar objectives includes Dunis, Gavridis, Harris, Leong and Nacaskul (1998) who used a genetic algorithm (GA) to optimize indicator parameters. Their trading model was based on two indicator — *viz.* the Momentum Oscillator and the Relative Strength Index (both are described in the Appendix). Their data covered only a relatively brief trading period. Many experiments were carried out and their best results were 7.1% of the annualized return for the period 20/3/1996 – 20/5/1996. This is approximately equal to the interest rate at that time and so the gains were not particularly impressive.

Yao and Tan (2000) used Neural Networks to perform technical forecasting on the FX. The only technical indicators they used were moving averages of different orders and these were employed as inputs to the neural network. The best results

achieved were 8.4% annualised return trading the USD/CHF exchange rate.

Dempster, Payne, Romahi and Thompson (2001) used a method based on an ensemble of indicators. They compared genetic algorithms and reinforcement learning to a simple linear program characterizing a Markov decision process and a heuristic. The best result achieved for trading over a 15-minute interval was around a 5% return.

Dempster and Romahi (2002) introduced a hybrid evolutionary reinforcement learning approach to constrain inputs to the RL system. The GA here aims to choose an optimal subset of indicators and then feeds them to the RL module. The annualised return gained from the implementation of this approach varied from 5% to 15% at a 15-minute trading frequency.

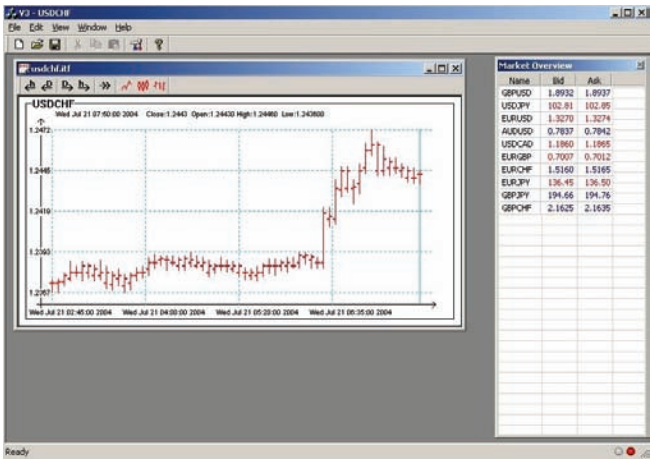
Moody and Saffell (2001) proposed the use of *recurrent* reinforcement learning to optimize risk-adjusted investment returns. Their system is based on price series returns rather than technical indicators. The recurrent RL trading system achieves an annualised 15% return on the USD/GBP exchange rate and they concluded that the recurrent RL system is superior to Q-Learning.

Note that although these results appear excellent, one must be careful in extrapolating them to real trading. Note also that Q-learning on its own is very susceptible to over-fitting but, as will become clear below, it can perform very well in a hybrid system.

THE SOFTWARE

The human trader makes use of online data to take a short, neutral or long position. Usually traders start with a set of concepts based upon indicators and then turn those concepts into a set of rules. The rule creating process requires a subjective choice to be made of which indicators to rely on and further subjectivity is needed in order to define rules for interpretation of the indicator signals. The trader then has to program the rules to create software for technical analysis. This is a difficult task, even for experienced traders. The market is changing all the time so that different rules and concepts work in different situations. Hence a trader has to determine the times at which the program should be changed, and obviously program modifications cannot be made online. Another problem for the trader is that different indicators are successful on different financial markets. For example, indicators that are profitable on one set of exchange rates could lead to catastrophic losses on another. Therefore a trader's strategy must be tailored to a particular situation. A software system that is able to adapt

Figure 4. Software for trading on the FX market



automatically to changing conditions avoids most of these problems and therefore has the potential to outperform a human in online trading. Our hybrid approach provides such an automated adaptive system and Figure 4 provides a snapshot of our system in operation.

When a trader uses our system, the software automatically connects to the broker's server, downloads data from the server and analyses the situation in the market. When using the "online trading" mode the trader does not require any knowledge of the state of the market " the software system automatically sells and buys assets and follows the market whilst updating system parameters. In the "off-line trading" mode, the trader can himself (or herself) place orders to sell or buy based upon analysis and advice provided by the system. When the software connects to the server at the first time, initial learning based on historical data occurs and then one of the modes can be selected.

The engine of the software consists of a genetic algorithm module and a reinforcement learning module based on Q-learning as described above. This system draws upon available information to determine the optimum strategy for the trader. Unlike the human trader, it is capable of working online and around the clock so its parameters are updated continuously over time to achieve the highest returns. Our system makes its decisions and predicts the future market using a combination of different market models. It recognizes the state of the market by simultaneously examining signals from each market indicator (rather than examining indicator signals one–by-one).

The fitness evaluation, crossover and mutation mechanisms are repeated until the fitness function cannot be improved any longer or a maximum number of iterations is reached. The fitness function is considered maximized if the average performance of the most profitable ten pairs of rules does not change more than 3% over several iterations. When the GA module is finished we feed the indicators from the most profitable strategy to the RL module.

Our method of choosing the indicators to feed to the RL module is an improvement on the one in Dempster & Romahi (2002) where the RL algorithm is itself employed to determine which of the indicators have the greatest fitness. This is computationally much more demanding than our method in which the fitness function is simply calculated in terms of the Sharpe ratio (Sharpe, 1966).

MAIN RESULTS

The data employed for testing our system is the intra-day Foreign Exchange (FX) rate EUR/USD. This currency pair is highly liquid since it is traded by a large number of market participants in all time zones. The data we employ relate to the period from 02 June 2002 to 31 December 2002 with a five-minute frequency 'off-line trading' mode and were obtained from the CQG Data Factory (www.cqg.com). They consist of 43,700 intra-day records with each daily record containing seven data fields. Figure 5 illustrates a sample of this data.

The first row of entries in the table in Figure 5 indicates that in the five-minute period commencing 1600 on 02 June 2002 the rate was 1 EURO = 0.9238 USD and at 1605 it was 1 EURO = 0.9331 USD. The highest and lowest rates in this period were 0.9335 USD and 0.9222 USD respectively. There were 41 trades between 1600 and 1605. A typical plot of the EUR/USD exchange rate that would provide a data entry identical to the first row of Figure 5 is shown in Figure 6.

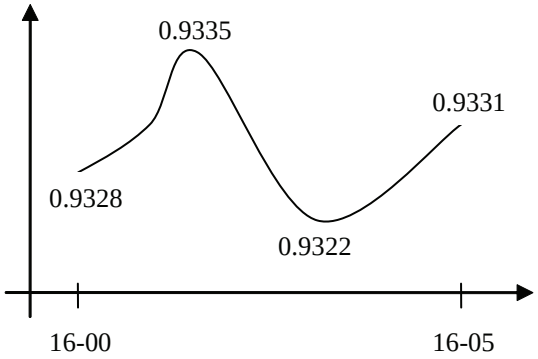
Using historical data our system learns to implement online trading. New training data is provided every five minutes and using this, the system learns to take a position - buy, sell or neutral.

Note that the software is able to work in any financial market where generally accepted market

Figure 5. Samples of 5 minute EUR/USD data extracted from 2 June 2002

Date	Time	Open	High	Low	Close	#Ticks
20020602	1600	9328	9335	9322	9331	41
20020602	1605	9324	9334	9320	9330	30
20020602	1610	9326	9334	9320	9333	32
20020602	1615	9323	9334	9320	9330	46

Figure 6. Illustration of the first row of Figure 5



rules are applicable. Transaction cost here is 2 pips per trade where a pip is the minimum unit of currency movement in the FX market. The initial trading capital was 10,000 Euros. Following training on 2.5 months of data the system achieved a profitability of about 6% on 3.5 months of test data. The annualised return achieved was therefore about 20%, which is clearly superior to the results quoted above for other approaches.

CONCLUDING REMARKS

A hybrid GA-RL system has been described that is aimed at optimizing trading strategies in the FX market. The system was trained and tested on historical data and was shown to be capable of achieving moderate gains over the tested period. Based on this system, real-time software has been designed that is capable of replacing a human trader. There are still some important features that are to be designed in future versions of the system. Some of these include stop-losses, different contract sizes, and the possibility of trading through different brokers simultaneously.

APPENDIX 1: THE INDICATORS

Besides the Moving Average (MA) indicator described in the Statistical Approach to Technical Analysis section, our system employs nine other indicators as described below. Here we add a little technical detail to the description of the MA indicator before detailing the other nine. All ten indicators provide the two signals: buy and sell. We consider standard indicator parameters that are usually used in the calculation by traders as advised in Murphy (1999).

Moving Average (MA)
The nine-day and 40-day moving averages can be written

$$MA_9(n) = \frac{1}{9}\sum_{i=0}^{9} C(n-i)$$

$$MA_{40}(n) = \frac{1}{40}\sum_{i=0}^{40} C(n-i)$$

where $C(n)$ is the latest closing price.
MABuy(n) = 1 if ($MA_9(n\text{-}1) < MA_{40}(n\text{-}1)$) AND ($MA_9(n) > MA_{40}(n)$).
MASell(n) = 1 if ($MA_9(n\text{-}1) > MA_{40}(n\text{-}1)$) AND ($MA_9(n) < MA_{40}(n)$).

Moving Average Convergence/Divergence (MACD)
The MACD is one of the most popular indicators. Two lines are used in its calculation. The MACD line is the difference between two exponentially smoothed moving averages of closing prices and responds very quickly to trend movements. The signal line is the exponentially smoothed average of the MACD line and it responds more slowly to trend movements. To calculate the MACD we need to compute 12 and 26 period Exponential Moving Averages (EMA).

$$EMA_{12}(n) = \frac{2}{12+1}C(n) + (1-\frac{2}{12+1})EMA_{12}(n-1)$$
$$EMA_{26}(n) = \frac{2}{26+1}C(n) + (1-\frac{2}{26+1})EMA_{26}(n-1)$$
$$MACD(n) = EMA_{12}(n) - EMA_{26}(n)$$
$$EMA_{12}(1) = EMA_{26}(1) = C(1)$$

The Signal Line is given by the nine-day exponentially smoothed average of the MACD line.

$$SignalLine(n) = \frac{2}{9+1}MACD(n) + (1-\frac{2}{9+1})SignalLine(n-1)\ SignalLine(1) = MACD(1)$$

Signals:
MACDBuy = 1 if (MACD(n-1) < SignalLine(n-1)) AND (MACD(n) > SignalLine(n))
MACDSell = 1 if (MACD(n-1) > SignalLine(n-1)) AND (MACD(n) < SignalLine(n))

The Stochastic (Slow Stochastic)

This is based on the observation that as prices go up, closing prices tend to be closer to the upper end of the price range and vice versa when trend goes down the closing price tends to be near the lower end of the range. The Stochastic consists of two lines: the %K line and the %D line.

$$\%K(n) = 100 * \frac{C(n) - L14(n)}{H14(n) - L14(n)}$$

where
L14(n) – the lowest low for the last 14 periods
L14(n) = min (Low(n), Low(n -1), …, Low(n - 13))
H14(n) – the highest high for the same 14 periods
H14(n) = max (High(n), High(n - 1), …, High(n - 13))
where Low and High are respective components of price bar in Figure 5.
%D is a three-period moving average of the %K

$$\%D(n) = \frac{1}{3}\sum_{i=0}^{2} \%K(n-i)$$

%Dslow is a three-period moving average of the %D

$$\%Dslow(n) = \frac{1}{3}\sum_{i=0}^{2} \%D(n-i)$$

Signals:
StochasticBuy(n) = 1 if (%D(n) < 20) AND (%Dslow(n) < 20) AND (%D(n - 1) < %Dslow(n - 1)) AND (%D(n) > %Dslow(n)).
StochasticSell(n) = 1 if (%D(n) > 80) AND (%Dslow(n) > 80) AND (%D(n - 1) > %Dslow(n - 1)) AND (%D(n) < %Dslow(n)).

Relative Strength Index (RSI)

This is considered to be a very powerful and popular indicator among traders. It is used to identify overbought and oversold market conditions.

$$RSI(n) = 100 - \frac{100}{1 + RS(n)}$$

$$RS(n) = \frac{\left[(Average\ Gain(n-1)) * 13 + Current\ Gain(n)\right]/14}{\left[(Average\ Loss(n-1)) * 13 + Current\ Loss(n)\right]/14}$$

where
Current Gain(n) = max (C(n) – C(n - 1), 0)
Current Gain(n) = max (C(n - 1) – C(n), 0)

$$Average\ Gain(n) = \frac{1}{14}\sum_{i=0}^{13} \max(C(n-i) - C(n-i-1), 0)$$

$$Average\ Loss(n) = \frac{1}{14}\sum_{i=0}^{13} \max(C(n-i-1) - C(n-i), 0)$$

Signals:
RSIBuy(n) = 1 if (RSI(n - 1) < 30) AND (RSI(n) > 30))
RSISell(n) = 1 if (RSI(n - 1) > 70) AND (RSI(n) < 70))

Commodity Channel Index (CCI)
This was designed to identify cyclical turns in exchange rates movements.
Most traders use CCI as an overbought/oversold oscillator. CCI is based upon the comparison the current price with a moving average over a selected time frame.

$$TypicalPrice(n) = \frac{C(n) + High(n) + Low(n)}{3}$$

$$SMATP(n) = \frac{1}{20}\sum_{i=0}^{19} TypicalPrice(n-i)$$

$$MeanDeviation(n) = \frac{\sum_{i=0}^{19} abs(SMATP(n) - TypicalPrice(n-i))}{20}$$

$$CCI(n) = \frac{TypicalPrice(n) - SMATP(n)}{0.015 * MeanDeviation(n)}$$

Signals:
CCIBuy(n) = 1 if (CCI(n - 1) < 100) AND (CCI(n) > 100))
CCISell(n) = 1 if (CCI(n - 1) > -100) AND (CCI (n) < -100))

Momentum Oscillator
Momentum measures velocity of price changes as opposed to the actual price level.

$$Momentum(n) = C(n) - C(n-10)$$

Signals:
MomentumBuy(n) = 1 if (Momentum(n - 1) < 0) AND (Momentum(n) > 0)
MomentumSell(n) = 1 if (Momentum(n - 1) > 0) AND (Momentum(n) < 0)

Price Oscillator
This is based upon the difference between two moving averages. The moving averages can be exponential, weighted or simple. Here, we consider the exponential moving average. Averages are calculated based on closing prices.

$$PO(n) = \frac{EMA_{10}(n) - EMA_{20}(n)}{EMA_{20}(n)}$$

where EMA_k is calculated using the same principle as for MACD calculation.
Signals:
POBuy(n) = 1 if (PO(n - 1) < 0) AND (PO(n) > 0)
POSell(n) = 1 if (PO(n - 1) > 0) AND (PO(n) < 0)

Larry Williams
This is an indicator that works similarly to the Stochastic Indicator and is especially popular for identifying overbought and oversold markets.

$$LW(n) = -100 * \frac{H14(n) - C(n)}{H14(n) - L14(n)}$$

L14(n) = min (Low(n), Low(n - 1), …, Low(n - 13)
H14(n) = max (High(n), High(n - 1), …, High(n - 13)).

Signals:
LWBuy(n) = 1 if (LW(n - 1) < -80) AND (LW(n) > -80)
LWSell(n) = 1 if (LW(n - 1) > -20) AND (LW(n) < -20)

Bollinger Bands
This is based on two trading bands placed around a moving average. Upper and lower bands are three standard deviations above and below the moving average.

$$UpperBand(n) = Average\,\mathrm{Pr}\,ice(n) + 3 * StDev(n)$$

$$LowerBand(n) = Average\,\mathrm{Pr}\,ice(n) - 3 * StDev(n)$$

$$AveragePrice(n) = \frac{1}{20}\sum_{i=0}^{19} C(n-i)$$

$$StDev(n) = \sqrt{\frac{\sum_{i=0}^{19}\left(C(n-i) - AveragePrice(20)\right)^2}{20}}$$

BBandBuy(n) = 1 if (C(n - 1) < LowerBand(n - 1)) AND (C(n) > LowerBand(n))
BBandSell(n) = 1 if (C(n - 1) > UpperBand(n - 1)) AND (C(n) < UpperLowerBand(n))

On Balance Volume
OBV can be used either to confirm the price trend or notify about a price trend reversal.

$$OBV(n) = OBV(n-1) + \frac{C(n) - C(n-1)}{abs(C(n) - C(n-1))} * V(n)$$

where V(n) is #Ticks component of the price bar in Figure 5.

The direction of OBV is more important than the amplitude. The OBV line should follow in the same direction as the price trend otherwise there is a notification about a possible reversal.

OBVBuy(n) = 1 if (OBV(n - 3) > OBV(n - 2)) AND (OBV(n - 2) < OBV(n - 1)) AND (OBV(n - 1) < OBV(n)) AND (C(n - 3) > C(n - 2)) AND (C(n - 2) > C(n - 1)) AND (C(n - 1) > C(n))
OBVSell(n) = 1 if (OBV(n - 3) < OBV(n - 2)) AND (OBV(n - 2) > OBV(n - 1)) AND (OBV(n - 1) > OBV(n)) AND (C(n - 3) < C(n - 2)) AND (C(n - 2) < C(n - 1)) AND (C(n - 1) < C(n))

APPENDIX 2: ILLUSTRATION OF Q-LEARNING

In Figure 7 we consider a real but simplified situation where a trader has two indicators for a financial market and has to make a decision based on the indicator signals. In this simplified situation, we assume that each indicator can advise either to buy or sell only. That is, we ignore the possibility of indicators advising that a neutral position be adopted. Since we have two indicators that can have two values each, we have in total four states of the environment. In any state of the environment a trader can make two decisions - either to buy a security or to sell it. Thus, writing the set of actions available in state i as A(state i), we have A(state i) = {buy, sell}for i = 1,2,3,4. After taking an action the trader makes a transition from one state of the environment to another according to a set of probabilities determined by the market situation.

The state of the environment is determined by the values of the indicators and, whatever the state, the trader must decide whether to buy or sell. To understand the meaning of Figure 7, consider the arrow at the upper-left of the figure. The rectangle attached to this arrow contains the following: "Sell, R.S. = 20, Pr = 12%." What this means is that this particular transition from state 1 to state 2 will take place if the trader, in state 1, decides to sell and that this decision will result in a transition to state 2 with a 12% probability, upon which the trader will receive a reinforcement signal of 20. Note that the decision to sell while in state 1 could also result in a transition to state 4, with probability 88%. Note also that the probabilities of these two transitions add to 100%, indicating that there is zero probability of a decision to sell when in state 1 causing a transition to state 3.

The values of the reinforcement signals and the transition probabilities in Figure 7 have been chosen arbitrarily for the purposes of this illustration. In practice, these values would change due to the non-static nature of the market, but we keep them fixed here so that the key features of Q-learning can be clearly understood. If we did not do this, the origin of some of the numbers in the example would become unclear unless we included frequent updates to Figure 7.

Suppose that the initial values of $Q_0(s, a) = 0$ for all s, a, discount rate $\gamma = 0.85$ and learning rate $\alpha = 0.15$. Also assume that the following sequence has taken place: (state 1, sell) → (state 3, buy) → (state 2, sell) → (state 3, sell) → (state 4, buy) → (state 3, buy)→ (state 2, buy) → (state 1, buy) → (state 2, sell) → (state 3, …) → … For this state-action sequence, equation (1) gives the following sequence of Q-value updates:

1) (state 1, sell, 20, state 3)

$$Q_1(state\,1,\ sell) = Q_0(state\,1,\ sell) + 0.15\left[20 + 0.85\max_a Q_0(state\,3,\ a) - Q_0(state\,1,\ sell)\right] =$$
$$0 + 0.15[20 + 0.85\max\{0,0\} - 0] = 0 + 0.15 * 20 = 3$$

2) (state 3, buy, 70, state 2)

$$Q_2(state\,3,\ buy) = Q_1(state\,3,\ buy) + 0.15\left[70 + 0.85\max_a Q_1(state\,2,\ a) - Q_1(state\,3,\ buy)\right] =$$
$$0 + 0.15[70 + 0.85\max\{0,0\} - 0] = 0 + 0.15 * 70 = 10.5$$

3) (state 2, sell, -30, state 3)

$$Q_3(state\,2,\ sell) = Q_2(state\,2,\ sell) + 0.15\left[-30 + 0.85\max_a Q_2(state\,3,\ a) - Q_2(state\,2,\ buy)\right] =$$
$$0 + 0.15\left[-30 + 0.85\max\{10.5, 0\} - 0\right] = 0 + 0.15 * (-30 + 0.85 * 10.5) = -3.16$$

4) (state 3, sell, 10, state 4)

$$Q_4(state\,3,\ sell) = Q_3(state\,3,\ sell) + 0.15\left[10 + 0.85\max_a Q_3(state\,4,\ a) - Q_3(state\,3,\ sell)\right] =$$
$$0 + 0.15\left[10 + 0.85\max\{0, 0\} - 0\right] = 0 + 0.15 * 10 = 1.5$$

So after the first four steps of the state-action sequence the Q-table looks like: (see Table 4)

Now consider the remaining values in the sequence:
(state 4, buy) → (state 3, buy) → (state 2, buy) → (state 1, buy) → (state 2, sell) → (state 3, …) → …

5) (state 4, buy, 30, state 3)

$$Q_5(state\,4,\ buy) = Q_4(state\,3,\ buy) + 0.15\left[30 + 0.85\max_a Q_4(state\,3,\ a) - Q_4(state\,4,\ buy)\right] =$$
$$0 + 0.15\left[30 + 0.85\max\{10.5, 1.5\} - 0\right] = 0 + 0.15 * (30 + 0.85 * 10.5) = 5.84$$

6) (state 3, buy, 70, state 2)

$$Q_6(state\,3,\ buy) = Q_5(state\,3,\ buy) + 0.15\left[70 + 0.85\max_a Q_5(state\,2,\ a) - Q_5(state\,3,\ buy)\right] =$$
$$10.5 + 0.15\left[70 + 0.85\max\{0, -3.16\} - 10.5\right] = 10.5 + 0.15(70 + 0.85 * 0 - 10.5) = 19.43$$

7) (state 2, buy, 50, state 1)

$$Q_7(state\,2,\ buy) = Q_6(state\,2,\ buy) + 0.15\left[50 + 0.85\max_a Q_6(state\,1,\ a) - Q_6(state\,2,\ buy)\right] =$$
$$0 + 0.15\left[50 + 0.85\max\{3, 0\} - 0\right] = 0 + 0.15 * (50 + 0.85 * 3) = 7.88$$

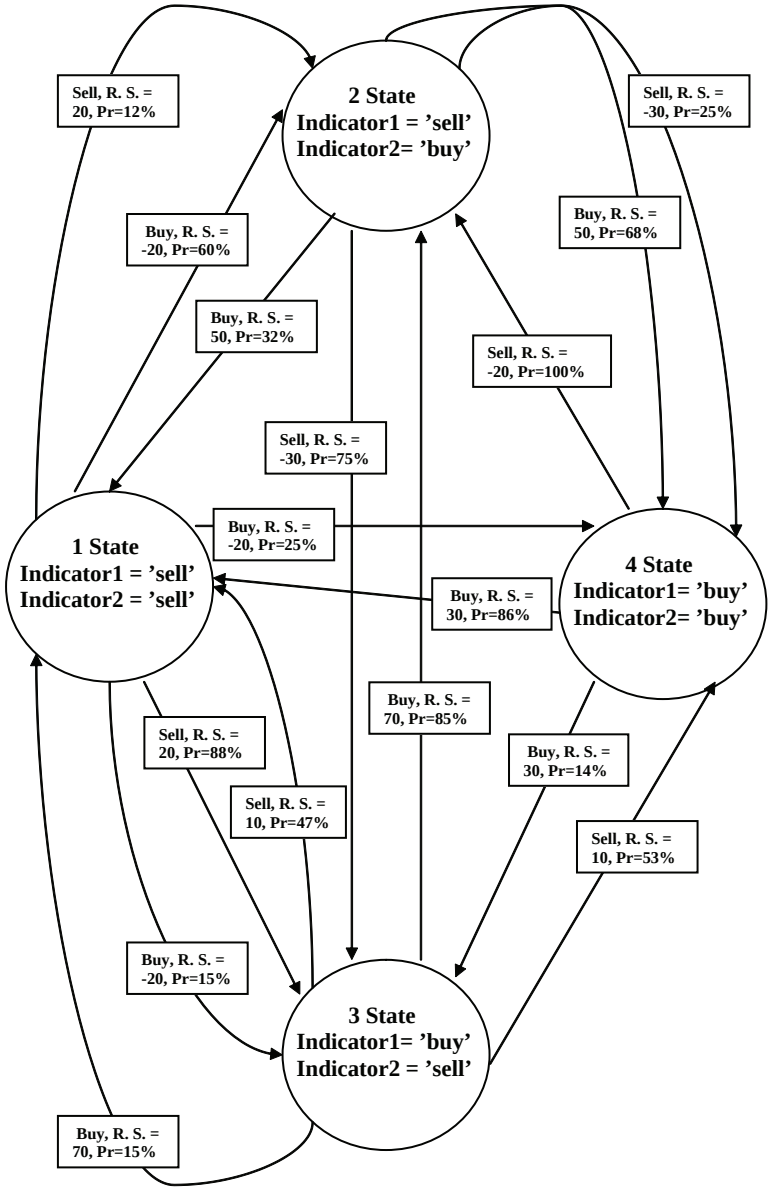
8) (state 1, buy, -20, state 2)

$$Q_8(state\,1,\ buy) = Q_7(state\,1,\ buy) + 0.15\left[-20 + 0.85\max_a Q_7(state\,2,\ a) - Q_7(state\,1,\ buy)\right] =$$
$$3 + 0.15\left[-20 + 0.85\max\{7.88, -3.16\} - 3\right] = 3 + 0.15 * (-20 + 0.85 * 7.88 - 3) = 0.55$$

Table 4. Q-learning table after 4 steps

$Q_4(s, a)$	Buy	Sell
state 1	3	0
state 2	0	-3.16
state 3	10.5	1.5
state 4	0	0

Figure 7. Example of Q-Learning



9) (state 2, sell, -30, state 3)

$$Q_9(state\,2,\ sell) = Q_8(state\,2,\ sell) + 0.15\left[-30 + 0.85 \max_a Q_8(state\,3,\ a) - Q_8(state\,2,\ sell)\right] =$$

$$-3.16 + 0.15\left[-30 + 0.85 \max\{19.43, 1.5\} - (-3.16)\right] = -3.16 + 0.15 * (-30 + 0.85 * 19.43 + 3.16)$$

$$= -4.71$$

After nine steps of the state-action sequence the Q-table looks like (see Table 5).

Table 5. Q-learning table after 9 steps

$Q_9(s, a)$	Buy	Sell
state 1	0.55	0
state 2	7.88	-4.71
state 3	19.43	1.5
state 4	5.84	0

And the optimal policy after nine steps is given by equation

$$\pi^*(s) = \arg\max_a Q_9(s, a).$$

Thus, at every state of the environment the trader will be able to determine the appropriate action. It can be shown (Watkins & Dayan, 1992) that the Q-table converges with probability 1 to the optimal set of Q-values.

Chapter 2.10
Architecture of an Information System for Personal Financial Planning

Oliver Braun
Saarland University, Germany

Günter Schmidt
Saarland University, Germany

ABSTRACT

We present a reliable application architecture and a corresponding system architecture of a system for personal financial planning. The application architecture is related to the business requirements, and the system architecture is related to information technology. We will present an analysis model as part of the application architecture, showing the granularity of an industry model. An intrinsic part of the proposed system architecture is the usage of Web technologies.

INTRODUCTION

The architecture of an information system influences just about everything in the process of developing an information system. The *system architecture* gives the rules and regulations by which the information system has to be constructed. The architecture's key role is to define the set of constraints placed on the design and implementation teams when they transform the requirements and analysis models into the executable system. These constraints contain all the significant design decisions and the rationale behind them.

The mission and concern of this chapter is to present a reliable *application architecture* and a corresponding *system architecture* of a system for *personal financial planning.* The application architecture is related to the business requirements, and the *system architecture* is related to information technology. We base the discussion of the business requirements on the application architecture, LISA, where four views on models are defined in Schmidt (1999):

1. The granularity of the model differing between industry model, enterprise model, and detailed model
2. The elements of the model differing between data, function, and coordination
3. The life cycle of modelling differing between analysis, design, and implementation
4. The purpose of modelling differing between problem description and problem solution

We will present an *analysis model* as part of the application architecture showing the granularity of an industry model. It contains *data*, *function*, and *coordination models* related to the purpose of modelling. The language we use to develop the analysis model is the Unified Modeling Language (UML). An intrinsic part of the proposed system architecture is the usage of Web technologies, as the global Internet and the World Wide Web are the primary enabling technologies for delivering customized decision support. We refer to the reference model as a combination of the analysis model and the system architecture. We believe that combining analysis model and system architecture could enhance the usability of the reference model.

We understand *personal financial planning* as the process of meeting life goals through the management of finances (Certified Financial Planner's (CFP) Board of Standards, 2005). Our reference model fulfils two kinds of purposes: First, the analysis model is a conceptual model that can serve financial planners as a decision support tool for the analysis of requirements. Second, system developers can map the analysis model to the system architecture at the design stage of system development. Furthermore, the reference model serves as a capture of existing knowledge in the field of IT-supported personal financial planning. The model also addresses interoperability assessments by the concept of platform-independent usage of personal financial planning tools.

STATE OF THE ART

Personal Financial Planning

The field of personal financial planning is well supplied with a lot of textbooks, among them: Böckhoff and Stracke (2003), Keown (2003), Nissenbaum, Raasch, and Ratner (2004), Schmidt (2006), and Woerheide (2002), to name just a few. Most books can be used as guides to handle personal financial problems, for example, maximise wealth, achieve various financial goals, determine emergency savings, maximise retirement plan contributions, and so forth. There are also papers in journals ranging from the popular press to academic journals. Braun and Kramer (2004) give a review on software for personal financial planning in German-speaking countries.

We will start our discussion with some definitions related to the world of personal financial planning. Certified Financial Planner's (CFP) Board of Standards defines *personal financial planning* as follows:

Definition 1: *Financial planning* is the process of meeting your life goals through the proper management of your finances. Life goals can include buying a home, saving for your child's education, or planning for retirement. Financial planning provides direction and meaning to your financial decisions. It allows you to understand how each financial decision you make affects other areas of your finances. For example, buying a particular investment product might help you pay off your mortgage faster, or it might delay your retirement significantly. By viewing each financial decision as part of a whole, you can consider its short and long-term effects on your life goals. You can also adapt more easily to life changes and feel more secure that your goals are on track. (Certified Financial Planner's (CFP) Board of Standards, 2005)

The draft ISO/DIS 22 222-1 of the Technical Committee ISO/TC 222, Personal Financial Planning, of the International Organization for Standardization, defines *personal financial planning* as follows:

Definition 2: *Personal financial planning* is an interactive process designed to enable a consumer/client to achieve their personal financial goals. (ISO/TC 222, 2004)

In the same draft, *Personal Financial Planner, consumer, client,* and *financial goals* are defined as follows:

Definition 3: A *Personal Financial Planner* is an individual practitioner who provides financial planning services to clients and meets all competence, ethics, and experience requirements contained in this standard. A *consumer* is an individual or a group of individuals, such as a family, who have shared financial interests. A *client* of a Personal Financial Planner is an individual who has accepted the terms of engagement by entering into a contract of services. A *financial goal* is a quantifiable outcome aimed to be achieved at some future point in time or over a period of time. (ISO/TC 222, 2004)

Certified Financial Planner's (CFP) Board of Standards and the Technical Committee ISO/TC 222, Personal Financial Planning, of the International Organization for Standardization define the *personal financial planning process* as follows:

Definition 4: The *personal financial planning process* shall include, but is not limited to, six steps that can be repeated throughout the client and financial planner relationship. The client can decide to end the process before having passed all the steps. The process involves gathering relevant financial information, setting life goals, examining your current financial status, and coming up with a strategy or plan for how you can meet your goals given your current situation and future plans. The financial planning process consists of the following six steps:

1. **Establishing and defining the client-planner relationship:** The financial planner should clearly explain or document the services to be provided to the client, and define both his and his client's responsibilities. The planner should explain fully how he will be paid and by whom. The client and the planner should agree on how long the professional relationship should last and on how decisions will be made.
2. **Gathering client data and determining goals and expectations:** The financial planner should ask for information about the client's financial situation. The client and the planner should mutually define the client's personal and financial goals, understand the client's time frame for results, and discuss, if relevant, how the client feel about risk. The financial planner should gather all the necessary documents before giving the advice that the client needs.
3. **Analyzing and evaluating the client's financial status:** The financial planner should analyze the client's information to assess the client's current situation and determine what the client must do to meet his goals. Depending on what services the client has asked for, this could include analyzing the client's assets, liabilities, and cash flow, current insurance coverage, investments, or tax strategies.
4. **Developing and presenting financial planning recommendations and/or alternatives:** The financial planner should offer financial planning recommendations that address the client's goals, based on the information which the client provides. The planner should go over the recommendations with the client to help the client understand them so that the client can make informed

decisions. The planner should also listen to the client's concerns and revise the recommendations as appropriate.

5. **Implementing the financial planning recommendations:** The client and the planner should agree on how the recommendations will be carried out. The planner may carry out the recommendations or serve as the client's "coach," coordinating the whole process with the client and other professionals such as attorneys or stockbrokers.
6. **Monitoring the financial planning recommendations:** The client and the planner should agree on who will monitor the client's progress towards his goals. If the planner is in charge of the process, he should report to the client periodically to review his situation and adjust the recommendations, if needed, as the client's life changes.

Systems, Models, Architectures

Models are simplifications of reality. Models exist at various levels of abstraction. A level of abstraction indicates how far removed from the reality a model is. High levels of abstraction represent the most simplified models. Low levels of abstraction have close correspondence with the system that they are modelling. An exact 1:1 correspondence is no longer a model, but rather a transformation of one system to another. *Systems* are defined as follows:

Definition 5: A *system* is a collection of connected units organized to accomplish a purpose. A system can be described by one or more models, possibly from different viewpoints. The complete model describes the whole system. (Rumbaugh, Jacobson, & Booch, 2005, p. 635)

The personal financial planning process can be supported by financial *Decision Support Systems* (DSS). In general, a Decision Support System can be described as follows:

Definition 6: A *Decision Support System* (DSS) is an interactive, flexible, and adaptable computer-based information system, specially developed for supporting the solution of a non-structured management problem for improved decision-making. It utilises data, provides an easy-to-use interface, and allows for the decision-maker's own insights. (Turban, 1995)

Continuous interaction between system and decision-makers is important (Briggs, Nunamaker, & Sprague, 1997). Interactive decision-making has been accepted as the most appropriate way to obtain the correct preferences of decision-makers (Mathieu & Gibson, 1993; Mukherjee, 1994). If this interaction is to be supported by a Web-based system, then there is a need to manage the related techniques (or models), to support the data needs, and to develop an interface between the users and the system. Advances in Web technologies and the emergence of the e-business have strongly influenced the design and implementation of financial DSS. As a result, improvement in global accessibility in terms of integration and share of information means that obtaining data from the Internet has become more convenient. Growing demand in fast and accurate information sharing increases the need in Web-based financial DSS (Chou, 1998; Dong, Deng, & Wang, 2002; Dong, Du, Wang, Chen, & Deng, 2004; Fan, Stallaert, & Whinston, 1999, 2000; Hirschey, Richardson, & Scholz, 2000; Li, 1998; Mehdi & Mohammad, 1998).

The application of DSS to some specific financial planning problems is described in several articles. In Schmidt and Lahl (1991), a DSS based on expert system technology is discussed. The focus of the system is portfolio selection. Samaras, Matsatsinis, and Zopounidis (2005) focus on portfolio selection. They propose a DSS which includes three techniques of investment analysis: Fundamental Analysis, Technical Analysis, and Market Psychology. Dong, Du, Wang, Chen, and Deng (2004) also focus on portfolio selection,

and report on the implementation of a Web-based DSS for Chinese financial markets. Zahedi and Palma-dos-Reis (1999) describe a personalised intelligent financial DSS. Zopounidis, Doumpos, and Matsatsinis (1997) give a survey on the use of knowledge-based DSS in financial management. The basic characteristic of such systems is the integration of expert systems technology with models and methods used in the decision support framework. They survey some systems applied to financial analysis, portfolio management, loan analysis, credit granting, assessment of credit risk, and assessment of corporate performance and viability. These systems provide the following features:

- They support all stages of the decision-making process, that is, structuring the problem, selecting alternative solutions, and implementing the decision.
- They respond to the needs and the cognitive style of different decision-makers based on individual preferences.
- They incorporate a knowledge base to help the decision-maker to understand the results of the mathematical models.
- They ensure objectiveness and completeness of the results by comparing expert estimations and results from mathematical models.
- Time and costs of the decision-making process is significantly reduced, while the quality of the decisions is increased.

Special emphasis on Web-based decision support is given in Bhargava, Power, and Sun (in press). Even though the above efforts in developing DSS have been successful to solve some specific financial planning problems, these do not lead to a general framework for solving any financial planning problem. There is no DSS which covers the whole process of financial planning. *Models* can be defined as follows:

Definition 7: A *model* is a semantically-complete description of a system. (Rumbaugh, Jacobson, & Booch, 2005, p. 461)

According to that definition, a model is an abstraction of a system from a particular viewpoint. It describes the system or entity at the chosen level of precision and viewpoint. Different models provide more or less independent viewpoints that can be manipulated separately. A model may comprise a containment hierarchy of packages in which the top-level package corresponds to the entire system. The contents of a model are the transitive closures of its containment (ownership) relationships from top-level packages to model elements. A model may also include relevant parts of the system's environment, represented, for example, by actors and their interfaces. In particular, the relationship of the environment to the system elements may be modelled. The primary aim of modelling is the reduction of complexity of the real world in order to simplify the construction process of information systems (Frank, 1999, p. 605). Mišić and Zhao (1999) define *reference models* as follows:

Definition 8: A *reference model* describes a standard decomposition of a known problem domain into a collection of interrelated parts, or components, that cooperatively solve the problem. It also describes the manner in which the components interact in order to provide the required functions. A reference model is a conceptual framework for describing system architectures, thus providing a high-level specification for a class of systems. (Mišić & Zhao, 1999)

Reference modelling can be divided into two groups (Fettke & Loos, 2003): Investigation of methodological aspects (e.g., Lang, Taumann, & Bodendorf, 1996; Marshall, 1999; Remme, 1997; Schütte, 1998), and construction of concrete reference models (e.g., Becker & Schütte, 2004; Fowler, 1997; Hay, 1996; Scheer, 1994). To the

best of our knowledge, there is no reference model for personal financial planning. Our reference model for personal financial planning consists of an analysis model for the system analysis of a personal financial planning system and of corresponding system architecture of an information system for personal financial planning.

Analysis Model

Surveys of reference models at the analysis stage of system development (i.e., conceptual models) are given in various papers, for example, Scholz-Reiter (1990), Marent (1995), Mertens, Holzer, and Ludwig (1996), Fettke and Loos (2003), and Mišić and Zhao (1999). For the construction of models, languages are needed. We will use the *Unified Modeling Language* (UML) for our analysis model.

Definition 9: The *Unified Modeling Language* (UML) is a general-purpose modelling language that is used to specify, visualize, construct, and document the artefacts of a software system. (Rumbaugh, Jacobson, & Booch, 2005, p. 3)

UML was developed by the Rational Software Corporation to unify the best features of earlier methods and notations. The UML models can be categorised into three groups:

- **State models** (that describe the static data structures)
- **Behaviour models** (that describe object collaborations)
- **State change models** (that describe the allowed states for the system over time)

UML also contains a few architectural constructs that allow modularising the system for iterative and incremental development. We will use UML 2.0 (Rumbaugh, Jacobson, & Booch, 2005) for our analysis model.

System Architecture

In general, *architecture* can be defined as follows:

Definition 10: An *architecture* is the organizational structure of a system, including its decomposition into parts, their connectivity, interaction mechanisms, and the guiding principles that inform the design of a system. (Rumbaugh, Jacobson, & Booch, 2005, p. 170)

Definition 11: The term *system architecture* denotes the description of the structure of a computer-based information system. The structures in question comprise software components, the externally-visible properties of those components, and the relationships among them. (Bass, Clements, & Kazman, 1998)

IBM (Youngs, Redmond-Pyle, Spaas, & Kahan, 1999) has put forth an *Architecture Description Standard* (ADS), which defines two major aspects: functional and operational. The IBM ADS leverages UML to help express these two aspects of the architecture. This standard is intended to support harvesting and reuse of reference architectures.

For a comprehensive overview of architectures, languages, methods, and techniques for analysing, modelling, and constructing information systems in organisations, we refer to the Handbook on Architectures of Information Systems (Bernus, Mertins, & Schmidt, 2005)

The reference architecture we use to derive our *system architecture* is a service-oriented architecture (SOA) proposed by the World Wide Web Consortium (W3C) (Booth, Haas, McCabe, Newcomer, Champion, Ferris, et al., 2005) for building Web-based information systems. According to the Gartner group, by 2007, service-oriented architectures will be the dominant strategy (more than 65%) of developing information systems. The architecture we propose supports

modular deployment of both device-specific user interfaces through multi-channel delivery of services and new or adapted operational processes and strategies. Service-oriented architectures refer to an application software topology which separates business logic from user interaction logic represented in one or multiple software components (services), exposed to access via well-defined formal interfaces. Each service provides its functionality to the rest of the system as a well-defined interface described in a formal mark-up language, and the communication between services is both platform- and language-independent. Thus, modularity and re-usability are ensured, enabling several different configurations and achieving multiple business goals. The first service-oriented architecture relates to the use of DCOM or Object Request Brokers (ORBs) based on the CORBA specification.

A *service* is a function that is well-defined, self-contained, and does not depend on the context or state of other services. Services are what you connect together using Web Services. A service is the endpoint of a connection. Also, a service has some type of underlying computer system that supports the connection that is offered. The combination of services, both internal and external to an organisation, makes up a service-oriented architecture. The technology of Web services is the most likely connection technology of service-oriented architectures. Web services essentially use XML to create a robust connection.

Web Services technology is currently the most promising methodology of developing Web information systems. Web Services allow companies to reduce the cost of doing e-business, to deploy solutions faster, and to open up new opportunities. The key to reach these goals is a common program-to-program communication model, built on existing and emerging standards such as HTTP, Extensible Markup Language (XML - see also Wüstner, Buxmann, & Braun, 2005), Simple Object Access Protocol (SOAP), Web Services Description Language (WSDL) and Universal Description, Discovery and Integration (UDDI). However, the real Business-to-Business interoperability between different organisations requires more than the aforementioned standards. It requires long-lived, secure, transactional conversations between Web Services of different organisations. To this end, a number of standards are underway (e.g., Web Services Conversation Language (WSCL), and the Business Process Execution Language for Web Services (BPEL4WS)). With respect to the description of services' supported and required characteristics, the WS-Policy Framework is under development by IBM, Microsoft, SAP, and other leading companies in the area. On the other hand, no other standard languages and technologies have been proposed for composing services and modelling transactional behaviour of complex service compositions. Such proposals include the Unified Transaction Modeling Language (UTML) and the SWORD toolkit.

Requirements for a Reference Model for Personal Financial Planning

Our reference model for personal financial planning should fulfil the following requirements concerning the *input*, *data processing*, and *output*: The input has to be collected in a complete (that is, adequate to the purpose) way. The *input* data have to be collected from the client and/or from institutions that are involved in this process. Such institutions may be Saving Banks, Mortgage Banks, Life Insurance Companies, Car Insurance Companies, Providers of Stock Market Quotations, Pension Funds, and so forth. This stage is time-consuming, and the quality of the financial plan is dependent on the completeness and correctness of the collected input data. *Data processing* (i.e., data evaluation and data analysis) have the task to process the input data in a correct, individual, and networked way. Correct means that the results have to be precise and error-free according to accepted methods

of financial planning. Individual means that the concrete situation with all its facets has to be centred in the planning, and that it is forbidden to make generalisations. Networked means: All of its data's effects and interdependencies have been considered and structured into a financial plan. The *output* has to be coherent and clear.

Analysis Model

The main task of an analysis model for personal financial planning is to help financial planners to consult individuals to properly manage their personal finances. Proper personal financial planning is so important because many individuals lack a working knowledge of financial concepts and do not have the tools they need to make decisions most advantageous to their economic well-being. For example, the Federal Reserve Board's Division of Consumer and Community Affairs (2002) stated that "financial literacy deficiencies can affect an individual's or family's day-to-day money management and ability to save for long-term goals such as buying a home, seeking higher education, or financial retirement. Ineffective money management can also result in behaviours that make consumers vulnerable to severe financial crises".

Furthermore, the analysis model should fulfil the following requirements:

- **Maintainability** (the analysis model should be understandable and alterable)
- **Adaptability** (the analysis model should be adaptable to specific user requirements)
- **Efficiency** (the analysis model should solve the *personal financial planning* problem as fast and with the least effort possible)
- **Standards-oriented** (the analysis model should be oriented at ISO / DIN /CFP- board standards; it should fulfil, for example, the CFP financial planning practice standards (Certified Financial Planner's (CFP) Board of Standards, 2005)

System Architecture

An architecturally-significant requirement is a system requirement that has a profound impact on the development of the rest of the system. Architecture gives the rules and regulations by which the software has to be constructed. The architect has the sole responsibility for defining and communicating the system's architecture. The architecture's key role is to define the set of constraints placed on the design and implementation teams when they transform the requirements and analysis models into the executable system. These constraints contain all the significant design decisions and the rationale behind them. Defining an architecture is an activity of identifying what is architecturally-significant and expressing it in the proper context and viewpoint.

The system architecture for an IT-based personal financial planning system should fulfil the following requirements:

- **Maintainability** (the architecture should be understandable and alterable)
- **Adaptability** (the architecture should be adaptable to specific user requirements)
- **Efficiency** (the architecture should deliver a framework that allows a Personal Financial Planner to solve *personal financial planning* problems as fast and with the least effort possible, for example, by automatic data gathering)
- **Standard-oriented** (the architecture should be oriented at well-established standards, for example, service-oriented architectures)
- **Reliability and robustness** (the architecture should support a reliable and robust IT-system)
- **Portability** (the architecture should support a platform-independent usage of the personal financial planning system)

In the following sections, we describe a reference model for personal financial planning which

meets the requirements specified in this section. The whole reference model is elaborated in more detail by Braun (2006b).

ARCHITECTURE OF A RELIABLE WEB APPLICATION FOR PERSONAL FINANCIAL PLANNING

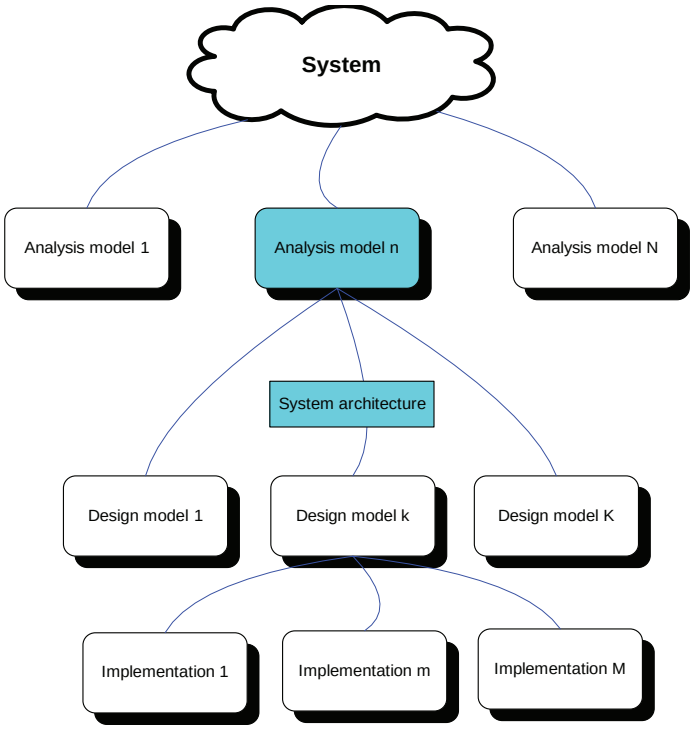
Our architecture for personal financial planning consists of two parts (see Figure 1):

1. **Analysis model** as part of the application architecture, which can help financial planners to do personal financial planning; and
2. **System architecture**, which can help system developers to develop logical models at the design stage of system development.

Our reference model for personal financial planning has two purposes: First, the analysis model can help financial planners to do personal financial planning in a systematic way. Second, at the design stage of system development, system developers can take the analysis model produced during system analysis and apply the system architecture to it. An intrinsic part of our reference model at the architecture level is the usage of Web technologies, as Web technologies have already and will strongly influence the design and implementation of financial information systems in general.

Design starts with the analysis model and the software architecture document as the major inputs (q.a. here and in the following Conallen, 2002). Design is where the abstraction of the business takes its first step into the reality of software. At design level, the analysis model is refined such that it can be implemented with the components that obey the rules of the architecture. As with analysis, design activities revolve around the class and interaction diagrams. Classes become more defined, with fully qualified properties. As this happens, the level of abstraction of the class

Figure 1. Analysis model and system architecture



shifts from analysis to design. Additional classes, mostly helper and implementation classes, are often added during design. In the end, the resulting design model is something that can be mapped directly into code. This is the link between the abstractions of the business and the realities of software.

Analysis and design activities help transform the requirements of the system into a design that can be realized in software. Analysis begins with the use case model, the use cases and their scenarios, and the functional requirements of the system that are not included in the use cases. The analysis model is made up of classes and collaborations of classes that exhibit the dynamic behaviours detailed in the use cases and requirements.

The analysis model and the design model are often the same artifact. As the model evolves, its elements change levels of abstraction from analysis to detailed design. Analysis-level classes represent objects in the business domain. Analysis focuses on the functional requirements of the system, ignoring the architectural constraints of the system. Use case analysis comprises those activities that take the use cases and functional requirements to produce an analysis model of the system. Analysis focuses on the functional requirements of the system, so the fact that some or all of the system will be implemented with Web technologies is beside the point. Unless the functional requirements state the use of a specific technology, references to architectural elements should be avoided. The analysis model is made up of classes and collaborations of classes that exhibit the dynamic behaviours detailed in the use cases and the requirements. The model represents the structure of the proposed system at a level of abstraction beyond the physical implementation of the system. The classes typically represent objects in the business domain, or problem space. The level of abstraction is such that the analysis model could be applied equally to any architecture. Important processes and objects in the problem space are identified, named, and categorised during analysis. Analysis focuses on the functional requirements of the system, ignoring the architectural constraints of the system. The emphasis is on ensuring that all functional requirements, as expressed by the use cases and other documents, are realised somewhere in the system. Ideally, each use case is linked to the classes and packages that realise them. This link is important in establishing the traceability between requirements and use cases and the classes that will realise them. The analysis model is an input for the design model and can be evolved into the design model.

SYSTEM ARCHITECTURE

Architecture influences just about everything in the process of developing software. Architecture gives the rules and regulations by which the software has to be constructed. Figure 2 shows the general architecture of our prototype FiXplan (IT-based Personal Financial Planning), and the data flow between the *User Interfaces*, the *Application Layer*, and the *Sources* (Braun & Schmidt, 2005).

Basically, the system contains the following components:

- **Clients:** Used by Personal Financial Planners or clients to access our main financial planning system and our Web Services; User Interfaces may be Web browsers such as the Internet Explorer or Mozilla, or applications such as Microsoft Excel.
- **Server:** As described in detail in the analysis model; the Web Services Toolbox provides useful tools for personal financial planning.
- **Sources:** Used as a repository for the tools of the personal finance framework.

The three-tier architecture of FiXplan supports modular deployment of both device-specific user

interfaces through multi-channel delivery of services and new or adapted operational processes and strategies. All connectivity interfaces are based on standard specifications.

Reliable Messaging

One of the first attempts to deliver guaranteed and assured delivery for Web Services was Reliable HTTP (HTTPR) from IBM. HTTPR aimed to provide reliable message delivery for Web Services, providing a “send and forget” facility through a guaranteed messaging model. It provided guaranteed delivery because it automatically retried requests if a link or a server was down. However, "OASIS WS-Reliability and WS-ReliableMessaging proposed by IBM, BEA, TIBCO, and Microsoft (submitted to the W3C) are the new competing protocols for reliable messaging" (Watters, 2005, p.24).

At the client side, the Web browser and PHP-scripts handle the user interface and the presentation logic. At the server side, the Web server gets all *http* requests from the Web user and propagates the requests to the application server, which implements the business logic of all the services for personal financial planning. At the database server side, transactional or historical data of the day-to-day operations are stored in the system database by RDBMS. The application server sends the query to the database server and gets the result set. It prepares the response after a series of processes and returns to the Web server to be propagated back to the client side. A registered user can log in and pick an existing session or create a new session of his preference, such as a level of user protection, access rights, and level of complexity. Based on the three-tier structure, FiXplan can run on both Internet and intranet environments. The user can, for example, use a Web browser to access a Web server through HTML language and HTTP protocol. The kernel of the system is placed on the web server. FiXplan uses a collection of Web Services. These services communicate with each other. The communication can involve either simple data passing, or it could involve two or more services coordinating some activity. Some means of connecting services to each other is needed.

Figure 3 illustrates a basic *service-oriented architecture*. It shows a service consumer below, sending a service request message to a service provider above. The service provider returns a response message to the service consumer. The

Figure 2. General three-tier architecture of FiXplan

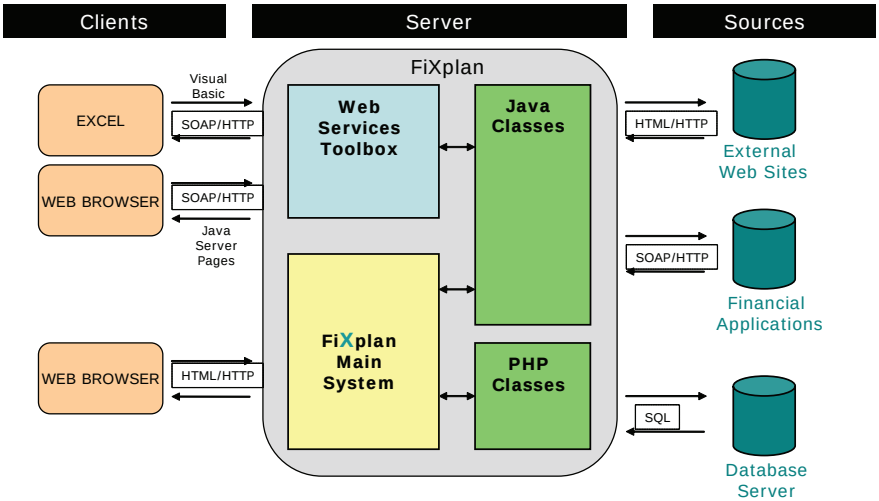


Figure 3. Basic service oriented architecture

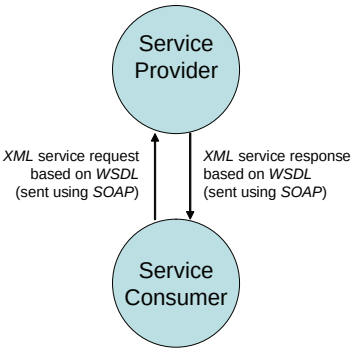


request and subsequent response connections are defined in some way that is understandable to both the service consumer and the service provider. A service provider can also be a service consumer.

All the messages shown in the above figure are sent using SOAP. SOAP generally uses HTTP, but other means of connection such as Simple Mail Transfer Protocol (SMTP) may be used. HTTP is the familiar connection we all use for the Internet. In fact, it is the pervasiveness of HTTP connections that will help drive the adoption of Web services. SOAP can be used to exchange complete documents or to call a remote procedure. SOAP provides the envelope for sending Web Services messages over the intranet/Internet. The envelope contains two parts: an optional header providing information on authentication, encoding of data, or how a recipient of a SOAP message should process the message; and the body that contains the message. These messages can be defined using the WSDL specification. WSDL uses XML to define messages. XML has a tagged message format. Both the service provider and service consumer use these tags. In fact, the service provider could send the data shown at the bottom of this figure in any order. The service consumer uses the tags and not the order of the data to get the data values.

FiXplan is both Web Service Provider and Web Service Consumer, as shown in Figure 4.

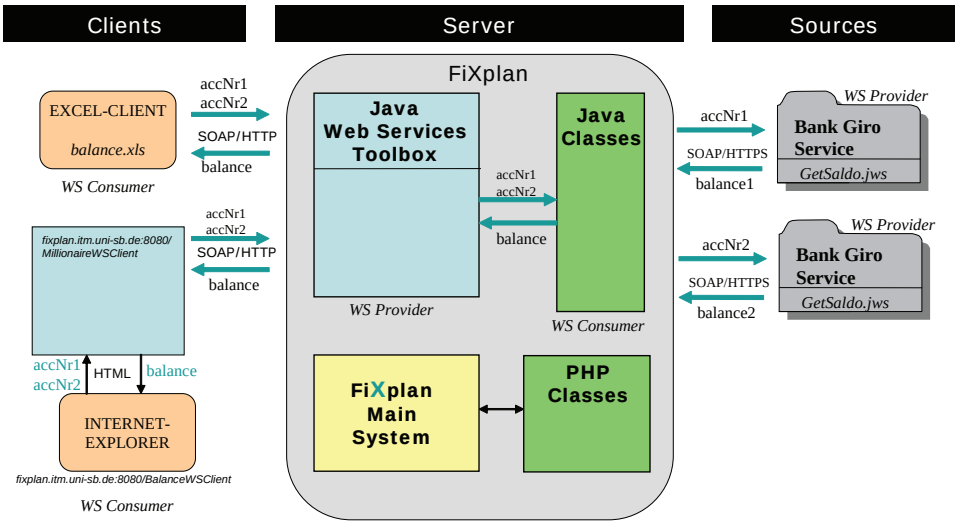
In this example, a browser (e.g., INTERNET EXPLORER) requests a static Web page with a form from a Web server (e.g., TOMCAT). After submitting the form, the Web page containing the desired results will be dynamically generated using Java Server Pages (JSP). In order to build up the Web page from JSP, the JSP calls a special Java method in a proxy class. As a result of this call, a SOAP message is sent to the corresponding Web service of the JAVA WEB SERVICES TOOLBOX. The Web service extracts the input data (in our example *accNr1, accNr2*) needed to compute the output data (in our example *balance*) from the received SOAP message. Because of the fact that our Web services are written in Java, looking for an answer means calling one of the methods of our JAVA CLASSES.

The design allows the Web service to be a consumer of another Web service: One of the Java classes called by the Web service to calculate the output data (in our example *balance*) is a proxy class which sends SOAP messages to external Web services (in our example a BANK GIRO SERVICES) and receives the results from these Web services (in our example *balance1* and *balance2*). In our example, this Java class computes also the sum of *balance1* and *balance2*.

The output data of the Java method (in our example *balance*) is packed in a new SOAP message and sent back. On the client side, the searched result is extracted from the SOAP message and given to the JSP by the proxy class. Finally, the JSP code includes the result in the Web page which is sent back to the browser.

If you have an Excel client, you have an Excel sheet instead of a Web page. When you want to calculate a result, you call a Visual Basic function which corresponds to the JSP in the example above. The Visual Basic function uses a Microsoft object which does the same as the proxy class: sending a SOAP message to the server and receiving the answer. The result is given to the Visual Basic function which writes it in the Excel sheet.

Figure 4. Service provider and service consumer



ANALYSIS MODEL AS PART OF THE APPLICATION ARCHITECTURE

The *analysis model* of our reference model for *personal financial planning* consists of the following parts: *Use Cases* build the dynamic view of the system, and *class diagrams* build the structural view of the system. Both are combined in the behavioural view of the system with *activity diagrams* and *sequence diagrams.*

Dynamic View on the System: Use Cases

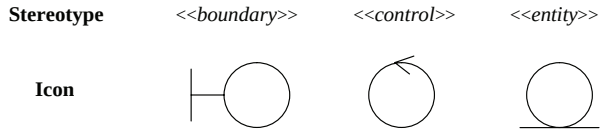
Use cases, *use case models*, and *use case diagrams* are defined as follows:

Definition 12: A *use case* is the specification of sequences of actions, including variant sequences and error sequences, that a system, subsystem, or class can perform by interacting with outside objects to provide a service of value. A use case is a coherent unit of functionality provided by a classifier (a system, subsystem, or class) as manifested by sequences of messages exchanged among the system and one or more outside users (represented as actors), together with actions performed by the system. The purpose of a use case is to define a piece of behaviour of a classifier (including a subsystem or the entire system), without revealing the internal structure of the classifier. A *use case model* is a model that describes the functional requirements of a system or other classifier in terms of use cases. A *use case diagram is a diagram* that shows the relationships among actors and use cases within a system. (Rumbaugh, Jacobson, & Booch, 2005, pp. 668-677)

Structural View on the System: Class Diagrams

The hierarchy of the dynamic view of the system (use cases) may provide a start but usually falls short when defining the *structural view* of the system (classes). The reason is that it is likely that certain objects participate in many use cases and logically cannot be assigned to a single use case package. At the highest level, the packages are often the same, but at the lower levels of the hierarchy, there are often better ways to divide the packages. Analysis identifies a preliminary mapping of required behaviour onto structural

Figure 5. Structural elements



elements, or classes, in the system. At the analysis level, it is convenient to categorise all discovered objects into one of three stereotyped classes: «*boundary*», «*control*», and «*entity*», as suggested by Jacobson, Christerson, Jonsson, and Overgaard (1992); see Figure 5.

Definition 13: *Boundary classes* connect users of the system to the system. *Control classes* map to the processes that deliver the functionality of the system. *Entity classes* represent the persistent things of the system, such as the database. (Jacobson, Christerson, Jonsson, & Overgaard, 1992)

Entities are shared and have a life cycle outside any one use of the system, whereas control instances typically are created, executed, and destroyed with each invocation. Entity properties are mostly attributes, although operations that organise an entity's properties can also often be found on them. Controllers do not specify attributes. Initially, their operations are based on verb phrases in the use case specification and tend to represent functionality that the user might invoke. In general, *class diagrams* can be defined as follows:

Definition 14: A *class diagram* is a graphic representation of the static view that shows a collection of declarative (static) model elements, such as classes, types, and their contents and relationships. (Rumbaugh, Jacobson & Booch, 2005, p. 217)

Use Case Realisation: Sequence and Activity Diagrams

Construction of behavioural diagrams that form the model's use case realisations help to discover and elaborate the analysis classes. A use case realisation is an expression of a use case's flow of events in terms of objects in the system. In UML, this event flow is expressed with *sequence diagrams.*

Definition 15: A *sequence diagram* is a diagram that shows object interactions arranged in time sequence. In particular, it shows the objects participating in an interaction and the sequences of messages exchanged. (Rumbaugh, Jacobson & Booch, 2005, p. 585)

A sequence diagram can realise a use case, describing the context in which the invocation of the use case executes. The sequence diagram describes the objects that are created, executed, and destroyed in order to execute the functionality described in the use case. It does not include object relationships. Sequence diagrams provide a critical link of traceability between the scenarios of the use cases and the structure of the classes. These diagrams can express the flow in a use case scenario in terms of the classes that will implement them.

An additional diagram that is useful for mapping analysis classes into the use case model is the *activity diagram*.

Definition 16: An *activity diagram* is a diagram that shows the decomposition of an activity into

its constituents. (Rumbaugh, Jacobson, & Booch, 2005, p. 157)

Activities are executions of behaviour. Activities are behavioural specifications that describe the sequential and concurrent steps of a computational procedure. Activities map well to *controller classes*, where each controller executes one or more activities. We create one activity diagram per use case.

Example Models

The basic analysis *use case* model (see Figure 6) is oriented to the Certified Financial Planner's (CFP) Board of Standards and ISO/TC 222 definition of the *personal financial planning* process (see Definition 4).

In the following, we will describe the subsystem *Core Personal Financial Planning* in detail. *Core Personal Financial Planning* includes three use cases, *determining the client's financial status*, *determining a feasible to-be concept*, and *determining planning steps*, that are elaborated in more detail in the following sections.

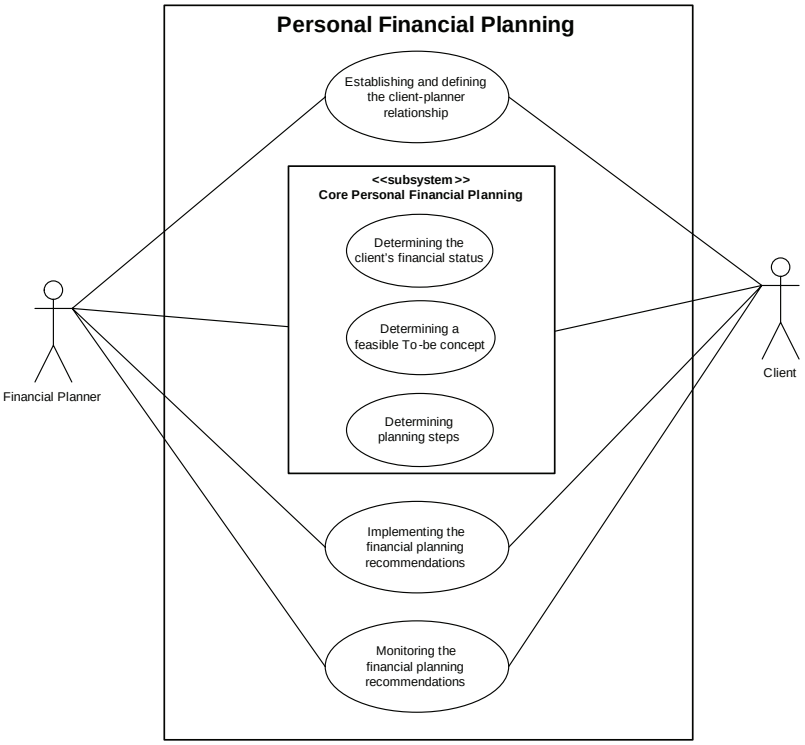
Determining the Client's Financial Status

Determining the client's financial status means answering the question "*How is the current situation defined?*" We will pick the following scenarios as the main success scenarios.

Determining the client's financial status includes:

1. **Data gathering:** The Financial Planner asks the client for information about the client's financial situation. This includes information about *assets*, *liabilities*, *income*, and *expenses*.
2. **Data evaluation:** The Financial Planner uses two financial statements: *balance sheet* and *income statement*.

Figure 6. Basic use case model



3. **Data analysis:** The Financial Planner analyses the results from balance sheet and income statement.

He can investigate, for example, the state of the provisions and pension plan, risk management, tax charges, return on investments, and other financial ratios.

In the following, the scenario is described in more detail:

- **Data gathering—assets and liabilities:** The first category of assets is *cash*, which refers to money in accounts such as checking accounts, savings accounts, money market accounts, money market mutual funds, and certificates of deposit with a maturity of less than one year. The second category of assets is fixed assets, fixed-principal assets, fixed-return assets, or debt instruments. This category includes investments that represent a loan made by the client to someone else. Fixed-return assets are primarily corporate and government bonds, but may also be mortgages held, mutual funds that invest primarily in bonds, fixed annuities, and any other monies owed to the client. The third category of assets is equity investments. Examples of equity investments are common stock, mutual funds that hold mostly common stock, variable annuities, and partnerships. The fourth category of assets is the value of pensions and other retirement accounts. The last category of assets is usually personal or tangible assets, also known as real assets. This category includes assets bought primarily for comforts, like home, car, furniture, clothing, jewellery, and any other personal articles with a resale value. *Liabilities* are debts that a client currently owes. Liabilities may be charge account balances, personal loans, auto loans, home mortgages, alimony, child support, and life insurance policy loans. In general, assets are gathered at their market value, and debts are gathered at the amount a client would owe if he were to pay the debt off today.
- **Data gathering—income and expenses:** *Income* includes wages and salaries, income from investments such as bonds, stocks, certificates of deposit, and rental property, and distributions from retirement accounts. *Expenses* may be costs for housing, food, and transportation. Expenses can be grouped by similarity; for example, one can choose insurance premiums as a general category, and then include life insurance, auto insurance, health insurance, homeowner's or renter's insurance, disability insurance, and any other insurance premiums one pays in this general category. The acquisition of personal assets (buying a car) is also treated as an expense.
- **Data evaluation—balance sheet:** A *balance sheet* has three sections. The first section is a statement of *assets* (things that one owns). The second section is a statement of *liabilities* (a list of one's debts). The third section is called *net worth*. It represents the difference between one's assets and one's liabilities. Businesses regularly construct balance sheets following a rigorous set of accounting rules. Personal balance sheets are constructed much less formally, although they should follow some of the same general rules incorporated into business balance sheets. The assets on a personal balance sheet may be placed in any order. The most common practice is to list assets in descending order of *liquidity*. Liquidity refers to an asset's ability to be converted to cash quickly with little or no loss in value. Liabilities are normally listed in order of increasing maturity. The *net worth* on a balance sheet is the difference between the total value of assets owned and the total amount of liabilities owed. Net worth is the measure of a person's financial wealth.

- **Data evaluation—income statement:** Where the personal financial balance sheet is like a snapshot of your net worth at a particular point in time, an *income statement* is a statement of income and expenses over a period of time. The time frame is usually the past year. The first section of an income statement is the *income*. The second section is a statement of *expenses*. Expenses are usually listed in order of magnitude, with the basic necessities being listed first. The third section is a summary that represents the *contribution to savings*. Contribution to savings is the difference between the total of income and the total of expenses. A positive contribution to savings would normally show up in the purchase of investments, a reduction in debt, or some combination of the two. A negative contribution to savings shows up in the liquidation of assets, an increase in debt, or some combination of the two.
- **Data analysis:** The *net worth* number is significant in and of itself, since the larger the net worth, the better off a person is financially; however, the balance sheet and the income statement contain even more useful information that a financial planner should consider. The traditional approach for analysing financial statements is the use of *financial ratios*. Financial ratios combine numbers from the financial statements to measure a specific aspect of the personal financial situation of a client. Financial ratios are used:

  1. To measure changes in the quality of the financial situation over time
  2. To measure the absolute quality of the current financial situation
  3. As guidelines for how to improve the financial situation

  We will group the ratios into the following eight categories: liquidity, solvency, savings, asset allocation, inflation protection, tax burden, housing expenses, and insolvency/credit (DeVaney, Greninger, & Achacoso, 1994; Greninger, Hampton, & Kitt, 1994). For example, the Solvency Ratio is defined as:

  Solvency Ratio = Total Assets / Total Liabilities

  and the Savings Rate is defined as:

  Savings Rate = Contribution to Savings / Income

Determining a Feasible to-be Concept

The use case scenario is as follows.

Determining a feasible to-be concept includes:

1. **Data gathering and feasibility check:** The financial planner asks for information about the client's future financial situation. This includes information about the client's *future incomes and expenses* and the client's assumption on the *performance* of his assets. Future incomes and expenses are determined by *life-cycle scenarios.*
   The financial planner asks the client for his *requirements* on a *feasible* to-be concept.
   A to-be concept is feasible if and only if all requirements are fulfilled at every point in time.
2. **Data evaluation:** The financial planner uses two financial statements: (planned) *balance sheets* and (planned) *income statements.*
3. **Data analysis:** The financial planner analyses the results from balance sheets and income statements. He can investigate, for example, the state of the foresight and pension plan, risk management, tax charges, return on investments, and other financial ratios.

Data evaluation and data analysis have to be done in a very similar way as in determining the client's financial status. In this section, we will concentrate our discussion at the first step: *Data gathering.*

Future incomes and expenses are determined by *financial goals*. Financial goals are not just monetary goals, although such goals are obvious and appropriate. Goals can be short-term, intermediate-term, and long-term.

Short-term goals refer to the next twelve months. What does a client want his personal balance sheet to look like in twelve months? What would he like to do during the coming year: Where would he like to spend his vacation? How much would he like to spend on the vacation? What assets, such as a new computer or a new car, would he like to acquire?

Intermediate goals are usually more financial in nature and less specific in terms of activities and acquisitions. As one thinks further into the future, one cares more about having the financial ability to do things and less about the details of what one will do. Most intermediate goals would likely include more than just wealth targets. For example, a client may target a date for buying his first home. Intermediate goals often address where one wants to be in 5 or 20 years.

For most people, *long-term goals* include their date of retirement and their accumulated wealth at retirement. What sort of personal balance sheet does a client want to have at retirement?

The *goals* of a system for personal financial planning consist in helping a personal financial planner to handle the financial situation of a client in a way that the client can maximise his/her quality of life by using money the best way for him/herself. Goals are about the management, protection, and ultimate use of wealth.

There is a strong propensity to associate wealth or standard of living with quality of life. Wealth is normally defined as assets owned less any outstanding debts. Standard of living is measured in terms of annual income. For some people, wealth or standard of living may be the correct measure of their quality of life. For many, that is not the case. First, many people give away substantial amounts of wealth during their lifetimes (places of worship, charities, non-profit organisations such as alma maters). People give gifts because they derive pleasure from it or because they have a sense of obligation. Second, many people hold jobs noted for low pay (religious professions such as priests) and earn low pay compared with what their level of educational training could earn them in other professions. A lot of people pass up lucrative corporate incomes in order to be self-employed. Some people seek jobs with no pay. Full-time, stay-at-home parents are examples of people who accept unpaid jobs based on the benefits they perceive from managing the household. Obviously, many people regularly make choices that are not wealth- or income-maximising, and these choices are perfectly rational and important to their lives. Proper financial planning seeks only to help people make the most of their wealth and income given the non-pecuniary choices they make in their lives, not just maximise their wealth and income.

Life-cycle scenarios (Braun, 2006a) are, for example, applying for a personal loan, purchasing a car, purchasing and financing a home, auto insurance, homeowner insurance, health and disability insurance, life insurance, retirement planning, and estate planning.

Requirements to a feasible to-be concept as introduced in Braun (2006a) are primarily requirements to balance sheets such as the composition of the entire portfolio, a cash reserve, and so forth. According to the financial goals of a company, a client may have the following two main requirements to a feasible to-be concept: assurance of liquidity (i.e., to always have enough money to cover his consumer spending) and prevention of personal insolvency (i.e., to avoid the inability to pay).

Assurance of liquidity (liquidity management) means that one has to prepare for anticipated cash

shortages in any future month by ensuring that enough liquid assets to cover the deficiency are available. Some of the more liquid assets include a checking account, a savings account, a money market deposit account, and money market funds. The more funds are maintained in these types of assets, the more liquidity a person will have to cover cash shortages. Even if one has not sufficient liquid assets, one can cover a cash deficiency by obtaining short-term financing (such as using a credit card). If adequate liquidity is maintained, one will not need to borrow every time one needs money. In this way, a person can avoid major financial problems and therefore be more likely to achieve financial goals.

Prevention of personal insolvency can be carried out by purchasing insurance. Property and casualty insurance insure assets (such as car and home), health insurance covers health expenses, and disability insurance provides financial support in case of disability. Life insurance provides the family members or other named beneficiaries with financial support if they lose their breadwinner. Thus, insurance protects against events that could reduce income or wealth. Retirement planning ensures that one will have sufficient funds for the old-age period. Key retirement planning decisions involve choosing a retirement plan, determining how much to contribute, and allocating the contributions.

If the *feasibility check* fails, personal financial planners can apply their knowledge and experience to balance the financial situation. They can take actions which adjust to the financial structure by changing requirements to a feasible to-be concept, by changing future expenses (such as expenses for a car), or by alternative financing expenses (for example, by enhancement of revenues). These actions may be necessary to ensure that the main financial goals are fulfilled.

Measures to Take

Financial goals of a client determine the planning steps as gathered in the section "Determining a Feasible To-Be Concept" and activities to achieve a feasible to-be concept.

UML Diagrams

In this section, we will elaborate the use case, *Determining the client's financial status: Data evaluation*, as an example of the UML diagram.

The *class diagram* in Figure 7 shows a first-pass analysis model for the use case, *Determining the client's financial status: Data evaluation*. The most important elements are the class names, the types, and the relationships.

This basic class diagram can be elaborated with the operations and attributes as described in

Figure 7. Basic use case analysis model elements

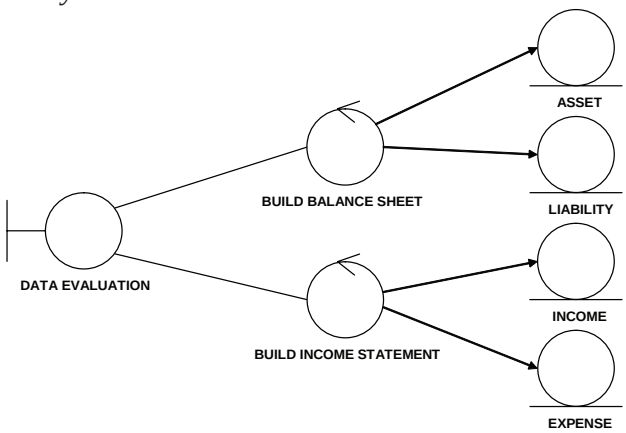


Figure 8. Elaborated analysis model elements

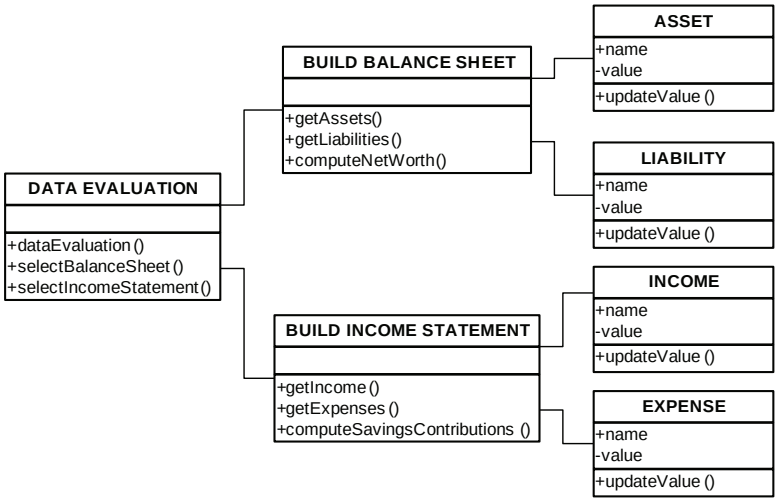

Figure 9. Basic sequence diagram

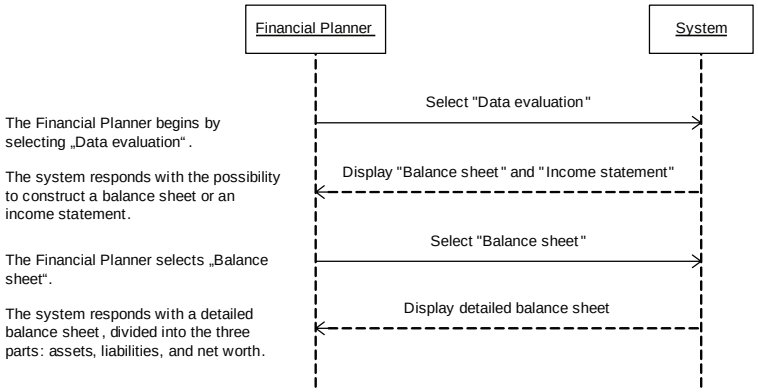

Figure 10. Sequence diagram elaborated with analysis objects

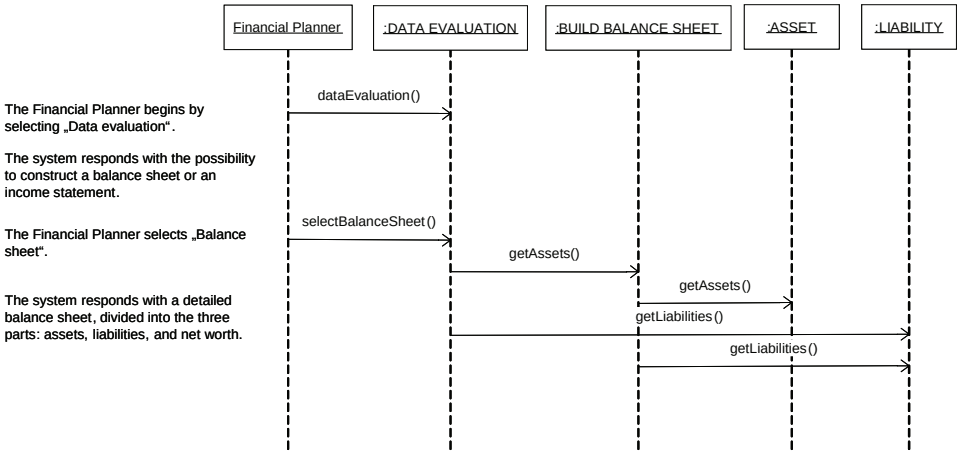

Figure 11. Basic activity diagram

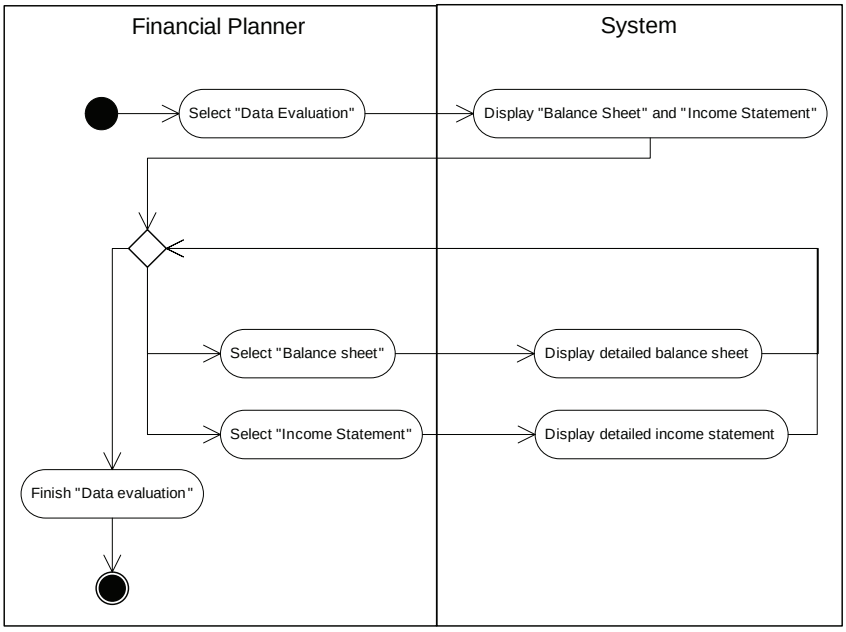

the use case specification to an elaborated class diagram (Figure 8).

Figure 9 shows a simple *sequence diagram* that indicates a basic flow of the use case, *Determining the client's financial status: Data evaluation.* Messages corresponding to operations on the classes are drawn to correspond to the main narrative text alongside the scenario.

Figure 10 shows the same use case scenario, *Determining the client's financial status: Data evaluation,* as depicted in the sequence diagram in Figure 9, with *System* expressed in terms of the analysis classes in Figure 7.

Figure 11 shows the basic *activity diagram* for the use case, *Determining the client's financial status: Data evaluation,* elaborated with classes from Figure 7.

CONCLUSION AND FUTURE TRENDS

We gave an architecture for a reliable *personal financial planning* system consisting of an *system architecture* and a corresponding *analysis model* (conceptual model) as part of the application architecture. An intrinsic part of our *system architecture* is the usage of Web technologies. Our model for personal financial planning fulfills two kinds of purposes: First, the *analysis model* is a conceptual model that can help financial planners to do their job. Second, at the design stage of system development, system developers can take the *analysis model* and apply the *system architecture* to them. The model combines business concepts of *personal financial planning* with technical concepts from information technology. We evaluated the model by building an IT system FiXplan (IT-based personal financial planning) based on the model. We showed that our model fulfills *maintainability, adaptability, efficiency, reliability,* and *portability* requirements. Furthermore, it is based on ISO and CFP Board *standards.*

Further research is needed to enlarge the model with respect to an automatisation of the to-be concept feasibility check. Here, classical *mathematical programming models* as well as *fuzzy*

models may deliver a solution to that problem. While in the case of classical models the vague data is replaced by average data, fuzzy models offer the opportunity to model subjective imaginations of the client or the personal financial planner as precisely as they will be able to describe it. Thus the risk of applying a wrong model of the reality, and selecting wrong solutions which do not reflect the real problem, could be reduced.

Chapter 2.11
Educational Theory Into Practice Software (ETIPS)

Sara Dexter
University of Virginia, USA

ABSTRACT

The ETIPS software is a Web-based learning environment that delivers cases that allow educators to practice instructional decision making. Here I recount its development but mainly emphasize the two key concepts that were central to our design process. The first was the Conceptual Assessment Framework, an evidentiary reasoning and design perspective that helped us to focus on which key attributes to build into the software and cases. The second concept is described as extreme programming, which is an iterative approach to software programming based upon user stories and rapid prototyping. The story of developing the ETIPS cases illustrates the need to know very clearly what the point is of the educational experience you are creating and to design software where form follows function.

INTRODUCTION

In this chapter, I recount the important aspects of the creation of the ETIPS software and its cases but mainly emphasize the two key concepts that were central to our design process. The first was the *Conceptual Assessment Framework*, developed by Mislevy, Steinberg, Almond, Haertel, and Penuel (2001); this framework helped us to focus on which key attributes to build into the software and cases. The second concept is described as extreme programming (Beck & Fowler, 2000), which is an iterative approach to software programming based upon user stories and rapid prototyping.

The story of developing the ETIPS cases illustrates the need to know very clearly what the point is of the educational experience you are creating and to design software where form follows function. The first generation of ETIPS

cases was created with existing case-authoring software; halfway through this four-year project our team realized that this software constrained the sort of learning experience we wanted the cases to provide. During the project's third year we began to create from scratch software for a second generation of cases and an interface that brought to fruition our case-based pedagogical approach. We used the *Conceptual Assessment Framework* (Mislevy et al., 2001) to guide the development and refinement of each user story for the software; this helped us to connect form to function in the second generation of software and to recognize how our case-based pedagogy could be used with other topic areas as well. Thus, a side benefit of using these conceptual approaches was that we increased our product's sustainability through broader user bases, potential co-authoring partnerships, and licensing.

EDUCATIONAL PURPOSE OF THE CASES

The purpose of the ETIPS project was to create teacher education cases that were learning exercises about educational technology integration and implementation. The primary audience for our cases was pre-service teacher education classes on either educational technology or pedagogical methods. Key premises upon which we based the software for our second generation of cases were that teaching is decision making—and decision making is a process that can be taught and requires practice in order to learn—and that instructional decisions are guided by schemas, or mental models.

The cases allowed students studying to be teachers to practice making instructional decisions about educational technology use in classrooms and schools using the Educational Technology Integration and Implementation Principles as a schema, or the basis of a schema, for those decisions. By providing instructors nine virtual yet realistic schools among which to choose to set these decision-making exercises in it allowed them to give their students multiple practice opportunities to see how these principles can guide instructional decision making about technology integration and implementation in a variety of school contexts.

The six principles summarize what research suggests are the conditions that should be present in order for educational technology integration and implementation to be effective (Dexter, 2002). The first three educational technology principles focus on integration, meaning teachers' instructional decision-making process when considering the use of educational technology resources in their classrooms. Discussion of these principles develops the premise that a teacher must act as an instructional designer and plan for the use of the technology to support student learning.

- **Principle 1:** Learning outcomes drive the selection of technology.
- **Principle 2:** Technology use provides added value to teaching and learning.
- **Principle 3:** Technology assists in the assessment of the learning outcomes.

The last three educational technology principles focus on the implementation of technology at the school level—that is, how a school setting can create a supportive context that provides teachers with the necessary access to technology, technical and instructional support, and a positive climate for professional collaboration about educational technology tools.

- **Principle 4:** Ready access to supported, managed hardware/software resources is provided.
- **Principle 5:** Professional development is targeted at successful technology integration.

- **Principle 6:** Professional community enhances technology integration and implementation.

UNIQUE FEATURES OF THE ETIPS CASE METHOD

ETIPS stands for Educational Theory into Practice Software. It is a Web-based learning environment in which students complete cases that are set in a K-12 school and focus on an educational theory. Unlike text-based cases, which are read in a linear fashion and emphasize the multiplicity of perspectives inherent in an event that is often told in chronological fashion, cases in ETIPS present learners with a scenario in which they need to make an instructional decision, and require them to select which information they think they will need to make that decision. The case is an opportunity to practice reasoning with a guiding theory that relates to the case topic and to develop an understanding of how the different school contexts in which the cases are set might influence how that theory is applied in practice.

This case approach emphasizes learners' metacognition—their thinking about their thinking—through a software feature called a PlanMap. The PlanMap asks students to check off what information they think they will need to make the decision posed in the scenario (see Figure 1); if they return to their PlanMap during the case, they will see that these choices are noted with a checkmark (see Figure 2). As students look at information in the case—and their choices are not limited to only what they checked while planning their search—the software records what they access and uses a different icon to record it on their PlanMap; in addition, experts' recommendations of which key items should be considered are indicated with yellow highlighting. Thus, the PlanMap provides feedback to the learners on their planned and actual progress as well as an in-progress check of their approach as compared to experts'.

Figure 1. The PlanMap page view initially explains to students the purpose of the PlanMap, and asks them to click in the box next to each category of case information they think will be necessary to access in order to complete the case

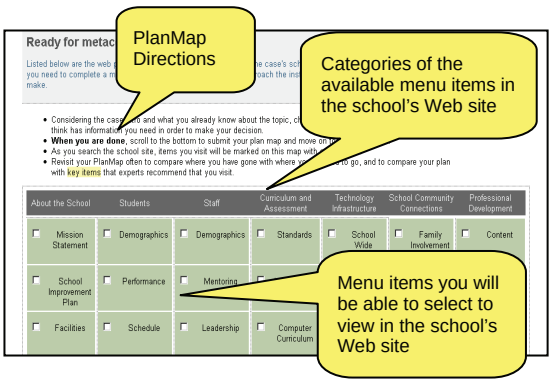

Figure 2. This close up of a PlanMap from a case in progress shows how checkmarks indicate items the user planned to visit; green arrows indicate what case information the user has viewed so far, and yellow highlighting shows which pieces of information experts deem as key for making a decision such as the case requires

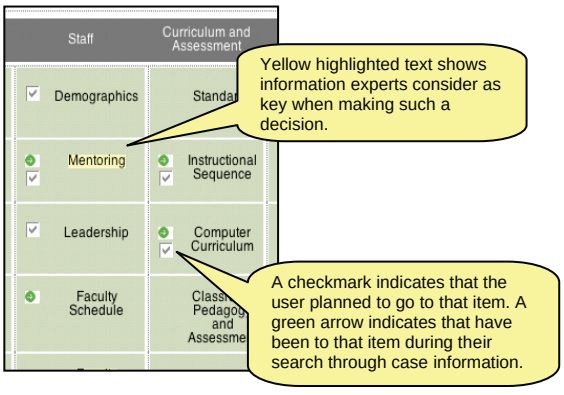

Figure 3. On the submit answer page, students can chose to save their work as a draft, use the automated essay scoring feature, or submit their response to their instructor as a final answer

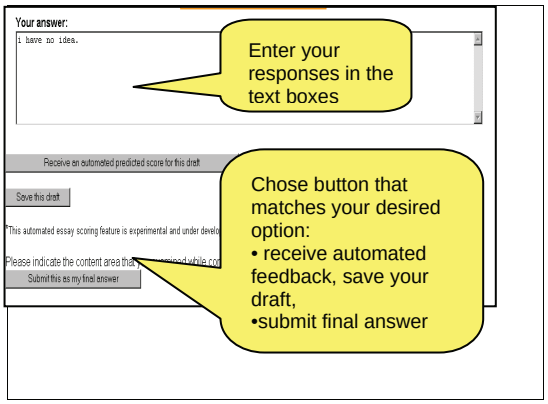
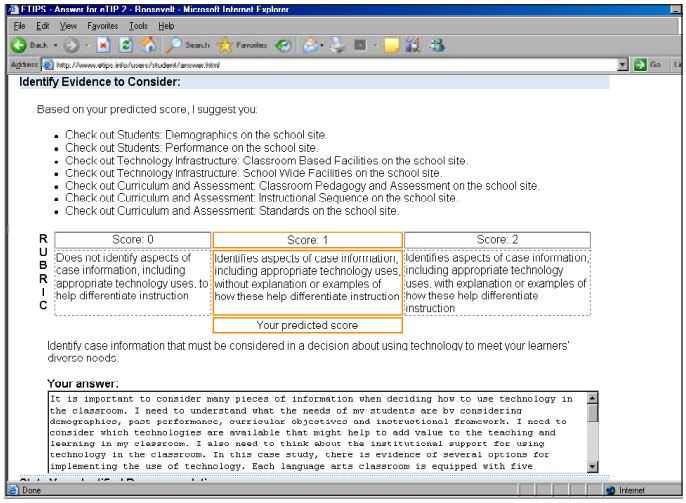


Another formative assessment tool in ETIPS is automated essay scoring, which students can use to get feedback on their decision; this feedback is in the form of a predicted score of their short answer responses against a rubric before they submit it to their instructor for a final grade (see Figure 3). The automated essay scoring engine software compares the student's response to other essays, which were scored by humans against the same rubric, predicts which score a student is most likely to receive, and presents it and the scoring criteria to them. In addition, if students have not yet been to the case information items that experts consider to be key, it suggests they review that information.

ETIPS PROJECT TEAM MEMBERS

The ETIPS project was funded by a grant from the US Department of Education through its Preparing Tomorrow's Teachers to Use Technology (PT3) initiative. A majority of the grants were made to colleges of education; consortiums were encouraged, and awardees were required to include a project evaluator to collect data for performance feedback. The initial ETIPS team represented a strategic alliance among the project lead, which was a college of education at a major research university, a software development lab based at a similar type of institution, and a non-profit organization with extensive experience developing software and delivering professional

Figure 4. The automated essay scoring engine shows the student their predicted score for that answer, the rubric criteria, and suggests any of the case's information items they should also take into consideration



development. Toward the end of the second year of the project, when the project director decided to create from scratch the software that was the basis for the second generation of cases, the software development lab agreed to bow out of the partnership.

At the lead university the team included the half-time project director, who had educational technology and teacher education expertise, a full-time project coordinator and two half-time graduate assistants who wrote case content and supported our test-bed of faculty members and their students, and a half-time project evaluator. At the non-profit organization there were two part-time collaborators who brought extensive assessment experience to the project as well as a software programming company with whom they had successfully worked and that we hired on an hourly basis.

PROJECT CHALLENGES

The major challenge that the project faced was articulating clearly the pedagogical purpose of the case-based learning experience we wanted to provide to learners. Because at the outset of the project we began to create cases using the software developed previously by the university-based software development lab in our consortium we initially assumed the learning experience functions inherent in that software. While aspects of the resulting learning experience worked well for this audience and these topics, other aspects were not well suited to practicing instructional decision making.

The first generation of cases was based upon the case approach pioneered by the IMMEX Software Development Lab at UCLA (Stevens, 1991). The IMMEX approach posed a problem to the learner and presented him or her with a menu-driven approach to selecting information necessary in order to solve it. The problem had a right answer, which—after having looked through sufficient case information—the user would select from a multiple-choice format. IMMEX software allowed case designers to elect to limit how much information the users could select through a points system. This rewarded learners who understood the correct problem solving approach and could recognize what information to seek out and how to interpret it because they could use the least number of points to determine the correct answer choice. The software tracked their information choices and graphically portrayed the sequence of their choices and the time spent at each using IMMEX's proprietary SearchPath Map. The SearchPath Map was designed to show learners' strategic responses to solving the problem. Each labeled icon on a SearchPath Map represents one menu item; the lines connecting the icons illustrate the path a student took in trying to solve the challenge presented in the case. Lines lead from the upper left-hand corner of an icon to the middle of the icon of the next menu item that was accessed. In this way, the SearchPath Map also illustrates the order in which students visited menu items.

The map on the left represents that the student explored many menu items and thus made a rather complete search of the problem space. The performance of the student at right shows only two general areas of the problem space were explored, indicating they do not have a firm grasp of the concepts underlying the problem that was presented

The IMMEX developers applied neural network analysis to determine the most common problem-solving approaches used by students who selected correct and incorrect answers, and to infer the likely student misconceptions that would lead to their taking such paths (Stevens, Johnson, & Soller, 2005; Stevens, Wand, & Lopo, 1996).

At the outset of the ETIPS project it appeared that the major change to IMMEX that would be required to create cases about technology integration and implementation for pre-service teachers would be to allow for short answer responses.

Adding a text box for responses was easy, but soon our test-bed faculty members wanted online modules for scoring essays, recording the scores, and then reporting them to students. We also saw that the instructional decision making exercise at the core of the ETIPS cases did not have a right or wrong answer and that scoring was a key point of the analysis of IMMEX cases. Further, students' searches through case information did not result in predictable, categorizable sequences that the SearchPath maps could help illustrate. Consequently, our test-bed instructors reported that they often did not use the maps with students, which reduced the case experience's potential for helping students become aware of their schema for their instructional decision making about technology integration.

User performances and faculty feedback made clear to the project leadership team which aspects of the emerging vision of the ETIPS case-based pedagogy were not compatible with the IMMEX software's features, and so we redirected a significant portion of the project's budget away from this partner and to the programming company associated with the non-profit organization. This mid-course redesign was thus a challenge to the project's budget, timeline, and consortium partner relationships.

In retrospect, the initial design of the ETIPS cases in the IMMEX software served as a fast way to create a prototype and proof of concept for an online case-based pedagogy that was focused on student reasoning and decision making. The downside to this rapid start-up was that by using an existing software to author the cases it let us skip over what we now would argue is an essential step of creating educational games or simulations: articulating what you want to learn about the student's knowledge and skills, and determining what tasks in the game or simulation will elicit that information.

The data we collected through the evaluation component of the project reinforced the project director's impressions that there were discontinuities between our users' intended and actual experiences with the cases. The evaluation process enabled us to attend in a rigorous way to our test-bed faculty members' experiences with the cases as an instructional resource and whether or not their students learned what we wanted them to learn about the case's use.

At the time project leaders decided to create our own ETIPS software some project leadership team members had been reading about assessment design, namely the Conceptual Assessment Framework developed by Robert Mislevy and his colleagues. Applying this framework forced us to articulate what we wanted the cases to help the user learn, and what task we would create in order to elicit that knowledge and skills, and then how to interpret and report their performance data. Through this process we determined how our software could be thought of as a general case-based pedagogy where the virtual schools could serve as the settings for cases on a variety of topics. We then began to think of ETIPS as standing for Educational Theory into Practice Software and that the Educational Technology Integration and Implementation Principles, for which the acronym was originally coined, would be just one topic about which we would offer cases. We enlisted two other organizations, chosen because of their large member bases and project leaders' connections to them, as co-authors of cases about urban teaching and digital equity.

At the outset of designing the software that would anchor the second generation of cases, the software programming company the project leaders hired (Green River; see http://greenriver.org), asked us to read *Extreme Programming* (Beck & Fowler, 2000) and to take that approach to our development work together. From the project leadership team's perspective as a client, this is a user-centered design process that is articulated through descriptions of desired functionalities called user stories that are then checked out

through usability testing and revised accordingly. Thus it was congruent with our on-going evaluation process.

Table 1 recounts the timeline of the key steps during the development of the ETIPS software that anchored the second generation of the cases.

The overall budget allocated for the software development, as well as the domain name and hosting costs, over this two-year process was approximately $450,000. The personnel costs for the project director and coordinator and graduate students at the lead institution and the team members at the non-profit organization were approximately $640,000. Additional costs were incurred for travel to project meetings and for dissemination and co-authoring work that was undertaken. All the personnel costs given are for the entire life of the grant; during the first two years this went mostly for case topic conceptualization and case authoring work and in the latter two years it was for test-bed member implementation support, co-authoring, and dissemination efforts. The portion

Table 1. Timeline for key development steps of ETIPS

Timeline	Key steps
2003	Project Year Two
April	Software development planning meeting with Green River
May	Consultations with Mislevy on Conceptual Assessment Framework Test-bed faculty meeting at end of Year 1 of generation 1 cases' use
June	Programming commences
July	Review of key elements in ETIPS engine with project leadership team
August	Alpha testing with students and faculty, usability expert's review
September	Programming meeting and beta testing with one test-bed faculty member's students
October	Planning for more responsive feedback to students on their case performance User interface planning for incorporating cases on multiple topics Co-authoring of cases on new topics begins with selected organizations Graphic re-design of interfaces for public part of site, post log-in, and cases
November	Programmer's meeting to develop PlanMap feature Systematic data collection on students' reaction to automated essay scoring
December	Begin discussion with publisher about bundling cases with book
2004	Project Year Three
January	New Web site interfaces deployed PlanMap deployed
March	Usability testing of new interfaces with faculty and students
May	Section 508 compliance review
July	Revise navigation scheme per users' and 508 report input
September	Implement revisions Design better feedback on answer to students per results from student data
October	Begin controlled experiments with students to determine impact of a student's use of the automated essay scorer on his or her essay's quality
2005	Project Year Four
February	Begin controlled experiments with students to determine impact of a student's use of the PlanMap on his or her essay's quality
June	Improve performance of automated essay scorer

of the budget allocated for the evaluation work was approximately $210,000. In addition, the direct cost for the training and travel to project meetings for the test-bed faculty members' was approximately $80,000.

LESSONS TO PASS ALONG TO OTHERS

Games and simulations produced for educational purposes in effect serve as a sort of formative, and perhaps summative, assessment. That is, they allow the user to practice doing something that is based upon some key premises that guide the operational rules of the game or simulation. It is likely that through his or her performance the software indicates, among other things, how well the user understands those key premises. From the outset, the ETIPS project leaders knew we wanted the cases to be an opportunity to practice instructional decision making while keeping an educational technology integration and implementation principle in mind. But when designing the specifics of the software—especially what feedback we could give to the learner during the case—Mislevy et al.'s (2001) Conceptual Assessment Framework helped us to work more efficiently, as well as with confidence since this framework draws upon contemporary learning and assessment theory.

The National Academy of Sciences report *How People Learn: Brain, Mind, Experience and School*, (Bransford, 1999) suggested that effective learning environments, among other things, are assessment-centered in the sense of providing multiple opportunities to make students' thinking visible so they can receive feedback and be given chances to revise and to learn about their own learning. The companion National Academy of Sciences report, *Knowing What Students Know: The Science and Design of Educational Assessment* (Pellegrino, Chudowsky, & Glaser, 2001), addresses principles of assessment design for learning situations aligned with the findings reported in *How People Learn*. According to Pellegrino et al. (2001), central to assessment is reasoning from evidence generated through a process consisting of three points: "a model of how students represent knowledge and develop competence in the subject domain, tasks or situations that allow one to observe students' performance, and an interpretation method for drawing inferences from the performance evidence thus obtained" (p. 2). Mislevy et al. (2001) incorporate these same three points into their Conceptual Assessment Framework by specifying it consists of a student model, task model, and an evidence model.

Almond, Steinberg, and Mislevy (2002) write that the student model is "the knowledge, skills, and abilities…to measure for each participant" (p. 35); the task model includes "the presentation material to be presented to the user…[and] a description of the work products that will be returned as a result of user interaction with the task" (p.24); and the evidence model acts as a bridge between the student and task models in that it describes how to analyze the evidence called for by the task model and so as to assess the student's understanding.

In writing about assessment designers, Mislevy et al. (2001) and Pellegrino et al. (2001) assert that networks, new media, and new methodologies have much to offer us in the way of support and enhancement of assessment but that technology has the potential to lure designers into creating complex tasks where substantial amounts of data are collected without any plan for analyzing how it can combine as an assessment of learner progress. To guard against this, Mislevy and colleagues (2001; Almond et al., 2002) promote using evidentiary reasoning and a design perspective during the development of instruction and assessment materials so that the focus remains on construct definition, forms of evidence in keeping with the construct, and the creation of tasks that would produce such evidence.

Extreme programming is an approach to programming developed by Beck and Fowler (2000) that describes how a team of software programmers works together with the client to efficiently create reliable code. Its creators describe it more as a set of values and disciplined approach than a strict set of steps. From our programmer's use of it and the project director's and other team leaders' experience designing ETIPS, this strategic approach was excellent for letting the design of a case-based pedagogy emerge. This included the focus on developing an overall metaphor to illuminate what you are creating and then expressing distinct aspects of functionality in user stories that are coded, reviewed by the client and users, and then revised as needed.

Extreme programming demands a lot of communication between the client and the programmers, often on a quick-turnaround basis. Further, to the degree the design process is driven by user testing, this requires advance planning for data collection, analysis, and reporting so that the code revisions can occur on a timeline that meets deadlines. Our team used a wiki to record our user stories and record notes from project meetings. The project director and programmers used a trouble ticket system to record the priority of the various user stories, recorded one per ticket, and their timelines and related communication. Working with the project evaluator, the project director and coordinator arranged for data collection from faculty and student users as needed. We also consulted experts on the usability of our site, including our compliance with disabled users' needs as specified Section 508 of the Rehabilitation Act.

Considering the Conceptual Assessment Framework during the design phase and following the approach advocated in *Extreme Programming* to bring that design into code can help creators of games and simulations work efficiently toward the educational purpose of their work. More importantly, it will encourage the development of assessment-centered learning environments, which we know will aid learning.

WHAT IS NEXT FOR OUR TEAM

At the time of this writing the project has about six months of funding left and so in addition to refining all features and user interfaces and support materials, we are focused on creating a revenue stream that will ensure the sustainability of our work. Over the last year we explored various models for generating income from the use of the cases. We have decided upon three related strategies.

The first is to consider the functionality of the software and the case-based pedagogy it supports as a separate product that can be marketed to developers of educational cases on various topic areas. Developers would pay to license the ETIPS engine, and any income could help to improve the software. This strategy involved setting up working arrangements with a company that is focused on marketing the ETIPS engine as well as other educational software.

A second strategy is that we will work with the membership networks and organizations that inspired the cases that we authored on additional topics. They, in turn, may promote the use of these cases to their members, who may then purchase access to the cases.

The third, and most promising, strategy pertains to just the ETIPS cases on technology integration and implementation. The project director and a long-time test-bed faculty member are writing a series of books on technology integration in secondary science, mathematics, social studies, and English language arts. The educational technology integration and implementation principles serve as an organizational framework for the books; in the chapters about each of the six principles the online ETIPS cases are presented as homework exercises that learners complete to practice applying the

main idea from that chapter. With this strategy the student who purchase the book is then very likely to purchase access to the cases, through an e-commerce functionality we have added. This model of students assuming responsibility for the costs of the educational materials associated with a class is familiar to students and faculty alike, and also allows our development team to leverage the publishing company's expertise in marketing, selling, and distributing the books, and their inherent relationship to some of the ETIPS cases.

Chapter 2.12
Engineering Reusable Learning Objects

Ed Morris
RMIT University, Australia

ABSTRACT

We adapt the object-oriented software engineering design methodology for software objects to engineering reusable learning objects. Our approach extends design principles for reusable learning objects. The resulting learning object class is a template from which individualised learning objects can be dynamically created for, or by, students. The properties of these classes refine learning object definitions and design guidelines. We adapt software object levels of cohesion to learning object classes. We demonstrate reusability increases when learning object lessons are built from learning objects, like maintainable software systems are built from software objects. We identify facilities for learning management systems to support object-oriented learning object lessons that are less predetermined in sequencing activities for each student. Our overall approach to the design of learning object lessons is independent of, and complementary to, instructional design theory underlying the learning object design process, and metadata standards adopted by the IEEE for learning object packaging.

PERSPECTIVE

We approach the shared aim to design reusable e-learning objects by adapting software engineering methodology, where it enhances the reusability of software objects. Our work (Morris, 2005) contributes software engineering techniques to the design and evaluation of learning objects with enhanced reusability.

We also provide a different perspective on the continuing pedagogical debate over granularity and context for optimal e-learning object reusability (Littlejohn, 2003) as we focus on the user interface and internal structure of a learning object to enhance its reusability.

OBJECTIVES

The objectives of this chapter are:

1. To explain how object-oriented software engineering design methodology can be applied to the design of a learning object to enhance its reusability. See the "Designing Learning Objects as Software Objects" subsection and the "Example Learning Object Classes" section.
2. To show how object-oriented software engineering extends and refines Boyle's (2002) design principles for authoring dynamic reusable learning objects by enabling individual learning objects to be dynamically created for or by students from a template learning object, which we call a learning object class. See the "Designing Learning Objects as Software Objects" subsection and the "Example Learning Object Classes" section.
3. To contribute toward a learning object lesson design methodology that will facilitate the design and implementation of larger scale lessons, courses, and educational programs. See the "Developing Learning Object Lessons as Software Systems" subsection and the "Object-Oriented Design Principles for Learning Objects" section.
4. To explain how the properties of a learning object class refine existing learning object definitions and design guidelines. See the "Criteria That Define Object-Oriented Learning Objects" subsection.
5. To show how reusability is further enhanced by standardising the interface of a learning object class to provide its learning activities as services that can be invoked by other learning objects. See the "Developing Learning Object Lessons as Software Systems" subsection and the "Example Learning Object Classes" section.
6. To explain how software object levels of cohesion can be applied to the design of a learning object class, such that the higher the level of cohesion, the more it is reusable. See the "Object-Oriented Design Principles for Learning Objects" section.
7. To identify facilities required in a learning management system to support learning object lessons that are less predetermined in their sequencing of activities for each student. See the "Support for Object-Oriented Learning Objects" section.
8. To explain how our object-oriented software engineering approach to the design of learning object lessons is independent of, and complementary to, (a) instructional design theory underlying the learning object design process, and (b) metadata standards adopted by the IEEE for learning object packaging. See the "Support for Object-Oriented Learning Objects" section.

INTRODUCTION

Early research and development of online learning materials did not focus on their reusability. For example, our previous research focussed on the cost effectiveness (Zuluaga, Morris, & Fernandez, 2002) and educational effectiveness (Morris & Zuluaga, 2003) of our online learning approach. This involved both online course development and online course delivery phases. We also addressed the deployment, management, and scalability of our online courses over a network of learning management system servers (Zuluaga & Morris, 2003).

Most of our early online courses (1999-2002) were developed for 100% online delivery, utilising mostly textual learning materials, plus (on average) four short multimedia supplements such as Java applets, Flash animations, voice overs, and video clips. During online delivery of such

a course we relied more on students interacting with staff via e-mail or chat than on building interactivity into the online course material during its development. We assumed these early generation online course materials would soon be replaced as multimedia and learning management systems matured and standardised. So we were not so much concerned with upgrading the original online materials over the years, repurposing them for new educational programs, or repackaging them for different media in the future. Nor were we particularly concerned with standardising the packaging of online course materials so that they could be reassembled with online materials from other institutions.

However, during this early period of research and development (R&D) it became increasingly clear that e-learning materials need to satisfy all the 'bilities': *interoperability* among different systems connected by the Internet, *accessibility* anytime from another location, *reusability* by other developers to save time and money, *discoverability* in repositories using metadata, *extensibility* of existing courses due to their modular construction, *affordability* due to reduced development costs, and *manageability* by allowing easy changes and updates to small chunks (Computer Education Management Association, 2001).

The concept of a unit of e-learning material or 'learning object' is central to these objectives. A range of definitions of *learning object* or 'instructional object' exist (Wiley, 2001). One that captures a common theme defines learning objects as "small but pedagogically complete segments of instructional content that can be assembled as needed to create larger units of instruction, such as lessons, modules and courses. Learning objects should be stand-alone, and be built upon a single learning objective, or a single concept" (Hamel & Ryan-Jones, 2002).

Boyle (2002) proposed learning object design principles synthesised from pedagogy and software engineering for authoring dynamic reusable learning objects. From pedagogy, a learning object should have a single learning objective. From software engineering, a learning object should do one thing and only one thing (strong cohesion). And a learning object should have minimal bindings to other learning objects (weak coupling).

Contents

In the second section of this chapter, we expand the above synthesis by applying object-oriented software engineering design methodology to the design of learning objects. We introduce the 'abstraction' of a learning object to enable a designer to produce a 'learning object class'. A *learning object class* is a template from which similar but individualised learning objects can be dynamically created during a lesson. (Object-oriented software engineering refers to similar 'objects' being 'instantiated' (created) from a 'class', which encapsulates their shared attributes and activities.) We introduce 'inheritance' so that a designer can evolve a 'child' learning object class from its 'parent' learning object class, extending and modifying its attributes and activities as desired. The instructional designer can use inheritance to reuse learning object classes or repurpose a lesson by extending and coupling inherently cohesive learning object classes. The instructional designer can use instantiation during a lesson to enable student interaction to determine the actual sequence of possible events in a lesson.

In the third section we illustrate the application of object-oriented software engineering design methodology to the design of two learning object classes. Broadly speaking, one is for the programming discipline, and the other is for psychology. The first is based on the Java programming language while-loop learning object of Boyle et al. (2003). The second is based on a conflict resolution learning object that explains Maddux's five styles of conflict resolution (Rathsack, 2001). These two learning object classes from different disciplines demonstrate the general applicability of our approach.

In the fourth section, we adapt to learning objects a scale for grading the cohesion of software objects. We show how to classify a learning object's level of cohesion and explain how each of the lower levels further reduces learning object reusability. This informs the design of learning objects, as we illustrate with the examples from the third section.

Finally, in the fifth section, we identify facilities required in a learning management system to support object-oriented learning object lessons. We point out that our object-oriented software engineering approach to the design of learning object lessons is independent of, and complementary to, the instructional design theory underlying the learning object design process, and the metadata standards adopted by the IEEE (LTSC, 2003) for learning object packaging.

APPLICATION OF OBJECT-ORIENTED SOFTWARE ENGINEERING TO LEARNING OBJECTS

Software engineering is concerned with the design and implementation of large scale, complex information processing systems that are robust, maintainable, modularly reusable, scalable, and extensible (Pfleeger, 2001). These properties overlap the 'bilities' required of learning objects. This observation underlies the application of software engineering design principles to the design of learning objects. Boyle introduced this approach with reference to coupling and cohesion principles for the design of learning objects (Boyle, 2002). We extend this approach by applying *object-oriented* software engineering design methodology to the design of learning objects. Object-oriented software engineering has evolved into a dominant 'branch' in the software engineering design methodology 'tree'.

In the "Designing Learning Objects as Software Objects" subsection we show how learning objects can be designed with essentially the same techniques used to design software objects. In the "Developing Learning Object Lessons as Software Systems" subsection we explain how flexible learning object lessons can be built from reusable learning objects in the same way that maintainable software systems are built from software objects with well-designed interfaces. Our application of object-oriented software engineering to the design of object-oriented learning object lessons leads us in the "Criteria That Define Object-Oriented Learning Objects" subsection to synthesise criteria that define a truly object-oriented learning object.

Designing Learning Objects As Software Objects

Object orientation is an approach to software development that organises both the problem and the solution as a collection of discrete 'objects' (Pfleeger, 2001). Each software object can be based on a physical or abstract object in the problem space. In the software system solution, the software objects collaborate to answer a user's requests.

- **Problem:** Model an employee-employer relationship. This could be a fundamental requirement of a software application to manage staff. Solution: We consider an employee software object below; the reader can similarly consider an employer software object later.

In the object-oriented approach to software design the nouns in the problem statement generally identify the software objects and their attributes. The 'has-a' relationship governs a software object and each of its attributes.

Let us say that an employee software object (at least) has a *name*, a social security (tax) *number*, and regular *pay*.

Other attributes of a software object can be discovered by asking "if I am an employee, what

should I know?" For instance the problem could indicate that an employment *history* is required.

In general the verbs in the problem statement identify the activities (behaviours, actions, responsibilities, operations) required of a software object.

An employee software object at the very least *works* and gets paid; the latter possibly comprising two activities: *receivePay* and *showPay*.

Other activities of a software object can be discovered by asking "if I am an employee, what should I be able to do?" For instance the problem could indicate that *reportWork* is also required.

The state of a software object at any time is given by the values of its attributes, as determined by the software object's activities. For instance showPay should show a higher pay value after receivePay provides a pay rise.

By analogy with a software object, we consider a learning object to have attributes and activities to deliver a single learning objective. Just as the users of a software system (solution) cause interactions between software objects to solve a problem, the students of a 'lesson' can cause interactions between learning objects to achieve the lesson's learning outcomes.

Adapting the above example of the object-oriented approach to software design, consider the overall learning outcome: understand the employee-employer relationship. A learning objective could be to know the responsibilities of employees in an employment hierarchy. We develop an employee learning object below in the same way that we developed an employee software object above.

Importantly, the attributes and activities of a learning object can be identified in the same manner as they were identified for a software object.

For the employee learning object we identify the exact same attributes and activities in the same manner as they were identified for the employee software object above.

By comparison with a software object, the activities of a learning object provide a form of explanation, rather than a computation.

For instance the receivePay activity in the employee learning object could explain that pay is in return for work.

In the object-oriented approach to software design a software object is an instance of a software object class. The process of abstraction enables software objects with shared attributes and activities to be defined as a single software object class. A *software object class* acts as a template from which individualised software objects are instantiated (created), as determined by the user's interactions with the software system.

As a user interacts with a software system that simulates the employee–employer relationship, let us say that employees, *bob*, *ted*, *carol*, and *alice* are instantiated. Each of these software objects has a distinct *name*, social security (tax) *number*, and *pay*. If bob's showPay activity is invoked, the pay value need not be that same as the other employees. If we define an extra *work* attribute and appropriate activities in the employee software object class, all these employee software objects could collaborate to perform their collective work.

Analogously, learning objects can be created as customised instances of a learning object class. A learning object class is not only a container of learning materials for a single learning objective (attributes), but also a container of operations defined on the materials (activities) that a student interacts with to attain the intended learning outcomes.

During a lesson, a student could create employees, *bob*, *ted*, *carol*, and *alice*. Each learning object has at least the distinct attributes identified above. These learning objects could collaborate to explain their *work*.

In general, a student initiates a lesson by interacting with a learning management interface that instantiates a learning object to service the

student's initial request. During the learning object lesson, other learning objects are likely to be instantiated from one or more learning object classes. The student interacts with these collaborating learning objects to attain their desired learning experience.

In the object-oriented approach to software design, abstraction promotes generality, and instantiation provides flexibility and individuality. We assert that the design of learning objects can similarly benefit from essentially the same approach.

The unified modeling language (UML) is a standard for diagrammatically depicting relationships between classes (software object classes), via class diagrams, and between software objects, via object diagrams (Priestley, 1996). Figure 1 shows the Employee software object class in UML and four (4) instance Employee software objects. The attributes and activities of the Employee class are also shown.

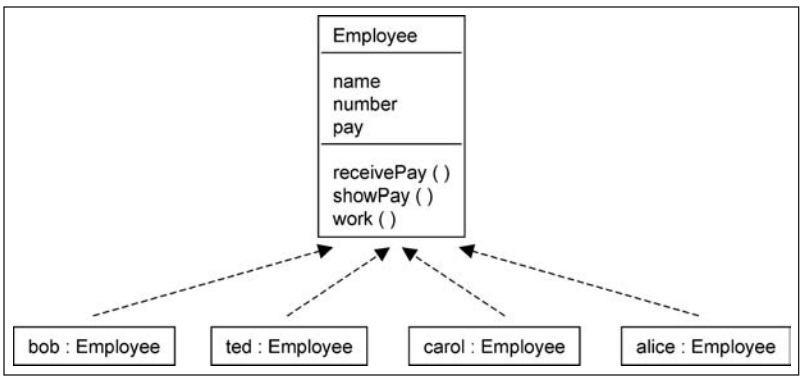
Figure 1 could equally show the Employee learning object class in UML and its four (4) instance Employee learning objects.

Access to the attributes and activities encapsulated by a software object is determined by its software object class. In general, attributes of one software object cannot be directly manipulated by another software object. Instead, the software object encapsulating the attribute in question performs the relevant activity in response to a request from another software object. For instance, an employee software object's pay cannot be directly accessed by other software objects; they can only request an employee software object to showPay or receivePay. Not all activities of a software object need be accessible to other software objects. The public activities supplied by a software object class define an interface that protects the private attributes and activities of its software objects. In effect, software objects request each others' 'services' via the public interface activities supplied by their software object classes. This allows the internals of a software object class to be modified by a programmer without affecting collaborating software objects, provided its interface remains unchanged; for example receivePay could incorporate a bonus without upsetting any software object that requests showPay.

Encapsulation can be equally applied to learning object classes. We assert that encapsulation enhances manageability by facilitating updates without requiring changes to collaborating learning object classes. Other 'bilities' such as reusability and affordability also benefit.

A software object class can be extended into a more specialised software object class without changing the original (parent) class. The 'child' software object class inherits the parent's attributes and activities while encapsulating extra

Figure 1. Class Employee and four instance objects



attributes and activities. The 'is-a' relationship governs a child as a specialised extension of its parent. The child can selectively modify its inherited characteristics too (called polymorphism). For example an Employee software object class could define employment *history* in terms of career achievements. A junior employee could reimplement its history in terms of final school courses and grades. Inheritance enhances reusability and adaptability of software object classes.

An *Employee* software object class can be extended to an *AirlineEmployee* software object class on the one hand, and a *HospitalEmployee* software object class on the other hand. An *AirlineEmployee* could add to its inheritance a knowledge of the *travelIndustry* and *airlinePolicies*. A *HospitalEmployee* could add to its inheritance a knowledge of *healthCareIssues* and *hospitalPolicies*. A *Nurse* software object class could further extend the *HospitalEmployee* with knowledge of *patientCare* and the activities to *takeBloodPressure* and *giveInjection*.

Figure 2. Class Employee and its 'child' classes

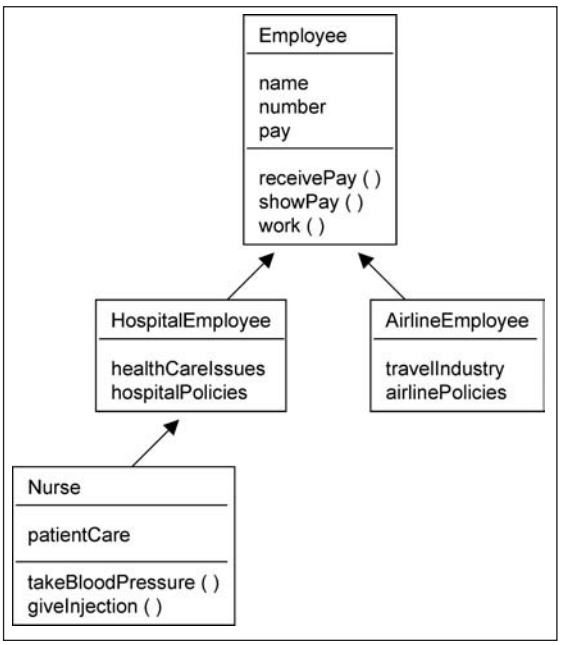


Figure 2 depicts the above inheritance hierarchy in a UML class diagram.

Figure 2 could equally depict an Employee learning object class inheritance hierarchy in a UML class diagram. We assert that inheritance can enhance reusability and extensibility of learning object classes.

Developing Learning Object Lessons as Software Systems

Software systems can be large and complex. Their design can comprise hundreds of software object classes and thousands of interactions of many kinds. Their implementation can amount to millions of lines of code. The software development life cycle (comprising requirements elicitation, analysis, specification, design, implementation, testing, and maintenance) can involve numerous teams of professionals of various kinds over many human years.

On the other hand, most learning objects are designed and implemented by one or two individuals, or a small team, over weeks or months, rather than years (Boyle et al., 2003; MIT OCW, 2005). No more than a handful of learning objects comprise a typical lesson. So there is at least an order of magnitude difference in the current scale of software systems design and learning object lesson design. However, software systems were originally far smaller. As the underlying hardware improved exponentially, it was still the advent of software engineering design methodologies that facilitated production of larger scale reliable software (Pfleeger, 2001). Hopefully, this chapter is a contribution toward a learning object lesson design methodology that will facilitate the design and implementation of larger scale lessons, courses, and educational programs.

An *interface* in object-oriented software engineering terms is the boundary around an object that defines which of its attributes and activities are accessible to other objects. An object's attributes remain private by default, but a public 'accessor'

activity can be defined in an object to return an attribute to any other object that requests it. An object may also define a public 'mutator' activity to enable an attribute to be altered at the request of other objects. Each interaction between two objects is in the form of a request and an answer. Data can be transferred in both directions—in and out. Such interactions in software systems are generally driven by the user(s). In general, objects are dynamically created to provide services in response to user requests.

This software object interaction model is also entirely applicable to a learning object lesson. An instructional designer can define the interface of a learning object class to provide certain learning activities as services. During a lesson, learning objects instantiated from several learning object classes can interact to provide a (student) user responsive learning experience.

The Java language also provides a special interface type that can be used to group a number of classes by insisting each class implements all activities specified by the interface. The grouped classes can be considered to have the same 'look and feel'. We think the Java interface type suggests a mechanism for combining learning object classes into learning object lessons. If a learning object class, L, implements interface I along with other learning object classes, all these learning object classes share a single look and feel. So a (student) user should experience an interactively integrated lesson. If the learning object class, L, also implements another interface, say J, then L can integrate with other learning object classes that implement interface J. This facilitates reuse of learning object class L in a new learning object lesson. Multiple interface types can act as 'wrappers' or 'skins' to provide different contexts for the one learning object class (and its learning objects) in different learning object lessons. This should aid the 'bilities', in particular, reusability and extensibility.

Criteria That Define Object-Oriented Learning Objects

Our above application of object-oriented software engineering design methodology to the design of learning object classes and learning object lessons leads us to synthesise the criteria that define a truly object-oriented learning object class. Our criteria (as follows) refine the learning object definition work of Wiley (2001) and others, and extend learning object design guidelines (Hamel & Ryan-Jones, 2002).

- Each learning object class has attributes and activities that meet a single well-defined learning objective and implement measurable learning outcomes in accordance with an instructional theory.
- Each learning object class and its attributes are identified by the nouns in its learning objective and learning outcomes. The verbs identify its activities.
- Each learning object class encapsulates learning activities that are stand-alone and achievable in a single sitting.
- Each learning object class's attributes and activities contribute packaging metadata (LTSC, 2003), to enhance the 'bilities' (see the "Determining Learning Object Cohesion" subsection).
- Each learning object class in general extends (specialises) its parent learning object class's attributes and activities. Inheritance enhances the 'bilities'.
- Each learning object class in general implements a Java-like interface type (see the "Developing Learning Object Lessons as Software Systems" subsection), which can also be implemented by other learning object classes. A single interface for multiple learning object classes provides the 'look and feel' for a learning object lesson. Implementing

multiple interfaces enables a learning object class to integrate into a different learning object lesson with other learning object classes. Learning object class interfaces enhance the 'bilities'.

Each learning object lesson involves student interaction to create learning objects on demand and to drive interactions between these learning objects to achieve the lesson's learning outcomes. The overall learning activity is necessarily interactive and in general involves (self-)assessment against the learning objectives.

EXAMPLE LEARNING OBJECT CLASSES

In this section we demonstrate our adaptation (see previous) of object-oriented software engineering design methodology to the design of learning object classes. The first example is based on the learning object developed by Boyle et al. (2003) for students to learn how while loops work in the Java programming language. The second example is based on a conflict resolution learning object that explains Maddux's five styles of conflict resolution (Rathsack, 2001).

We assert that our two learning object classes for different disciplines (programming and psychology) demonstrate the general applicability of our object-oriented software engineering approach to the design of learning object classes. Although we write each learning object class in Java, the design is our focus, and is language independent. In the "Cohesion of Example Learning Objects" subsection, we demonstrate the advantages of our design over the originals, as measured by the design principles of coupling and cohesion (elaborated in the "Learning Object Levels of Cohesion" subsection).

While Loop

The Java programming language while-loop learning object of Boyle et al. (2003) starts by showing the student how a program hammers a nail into wood: while (nail is not flush) hit the nail. Next, the Java code to move a car over a given distance is displayed, explained, and the student can animate the loop. The student can also step through the code, statement by statement. A second example shows a submarine submerging to a given depth. The code is displayed, explained, animated, and the student can step through. Then the student is asked to build the code from a given set of Java statements to move a horse a specified distance. Finally, the student is asked to spot errors in the code to move a lorry a given distance.

Our object-oriented software engineering design for a while-loop learning object class is shown (see Figure 3) as an incomplete class in Java. Class While has one attribute—the loop in question, represented as a string of characters. When an object of class While is instantiated, the loop can be initialised to an input string, or the default generic loop. Class While defines the following activities as operations on this loop—display, explain, animate, step_thru, build, and debug.

Figure 3. Class While

```
class While {

   String loop;

   While (String input) {
     // constructor given a loop
     loop = input
   }
   While ( ) {
     // default constructor with generic loop
     loop = "pre-action;" + "while (condition)" + "loop action;" + "post-action";
   }

   display ( );
   explain ( );
   animate ( );
   step_thru ( );
   build ( );
   debug ( );
}
```

The student interacts with a Java program that instantiates requisite While objects. For example, if the student follows the sequence intended in Boyle's learning object, the hammer object would be instantiated first. Its code would be displayed, explained, and animated. Next, the submarine object would be instantiated, its code displayed, explained, animated, and stepped through if desired. Next, the horse object would be instantiated, and the student would build its code. Finally, the lorry object would be instantiated, and the student would debug its code.

Note that another student, perhaps more advanced, could interact with class While to instantiate While objects (learning objects) in another sequence, bypassing some learning objects as desired.

Conflict Resolution

Rathsack's conflict resolution learning object explains Maddux's five styles for managing conflict. The learning object begins by stating that people can disagree, that this can be an opportunity for growth and learning, or it can be detrimental as conflict arises. The ability to manage conflict is important to succeed in one's career and life. The learning object then introduces Maddux's matrix depicting five styles for managing conflict: avoiding, accommodating, winning/losing, collaborating, and compromising. Each style is explained. Then the learning object explains that the matrix y-dimension shows increasing assertiveness and the x-dimension shows increasing cooperation, starting from zero at bottom left. This explains the location of each style in the matrix: winning/losing at top left, collaborating at top right, accommodating at bottom right, avoiding at bottom left, and compromise in the centre. The learning object then presents five conflict scenarios and asks the student to identify the style in use. Finally, the learning object explains that Maddux believes no one style is always best for all situations.

Figure 4. Class Conflict

```
class Conflict {

   String style;

   Conflict (String input) {
      // constructor given a style
      style = input
   }

   display ( );
   explain ( );
   animate ( );
   identify ( );
}
```

Our object-oriented software engineering design for a conflict resolution learning object class is shown (see Figure 4) as an incomplete class in Java. class Conflict has one attribute—the conflict style in question, represented as a string of characters. When an object of class Conflict is instantiated, the style is initialised to an input string. Class Conflict defines the following operations on this style—display, explain, animate, and identify.

The student interacts with a Java program that instantiates requisite Conflict objects. For example, if the student follows the sequence intended in Rathsack's learning object, the 'avoiding' object would be instantiated first. This style would be displayed on the matrix (in relation to the other four styles), explained, and animated on the matrix (in terms of the x and y dimensions). Next, the 'accommodating' object would be instantiated. Similarly, this style would be displayed on the matrix (in relation to the other four styles), explained, and animated on the matrix (in terms of the x and y dimensions). Next, the remaining three Conflict style objects would be instantiated. Finally, the Java program that instantiates Conflict objects would ask the student to identify the style in use in a conflict scenario. The Conflict objects could cooperate to randomise this test.

Note that another student, perhaps more advanced, could interact with class Conflict to instantiate Conflict objects (learning objects)

in another sequence, bypassing some learning objects if desired.

OBJECT-ORIENTED DESIGN PRINCIPLES FOR LEARNING OBJECTS

In a software system, *coupling* measures how cleanly objects are partitioned. And *cohesion* measures how closely activities in an object are related. Coupling and cohesion are interdependent measures—the less cohesive an object, the more likely it is coupled with other objects. The more coupled an object is with other objects, the harder it is to alter or upgrade the object in isolation, which lowers maintainability. A strongly coupled object is less reusable without significant maintenance (Pfleeger, 2001).

In our terminology, the 'objects' referred to above are software object classes, not individually instantiated software objects. Following Boyle (2002), we assert the above applies as much to learning object classes in a learning object lesson as to software object classes in a software system. Weak coupling between learning object classes in a learning object lesson promotes the 'bilities' in that the maintainability of software object classes is essentially the manageability of learning object classes. The more cohesive each learning object class is, the less coupling is required when learning object classes are reused in a new learning object lesson.

Stevens and Myers devised a table (Yourdon & Constantine, 1978) to classify the level of cohesion of a software module—in our terminology, a software object class. (Although their work predated object-oriented software engineering design methodology, it is readily accommodated.) In the "Learning Object Levels of Cohesion" subsection we adapt their seven-level scale to learning object classes. In the "Determining Learning Object Cohesion" subsection, we show how to classify the level of cohesion of a learning object class. We explain how each of the lower levels further reduces learning object class reusability. We assert that awareness of cohesion levels can improve the design of learning object classes, as we illustrate in the "Cohesion of Example Learning Objects" subsection with the examples from the "Example Learning Object Classes" section.

Learning Object Levels of Cohesion

In Table 1 we adapt a seven-level scale of cohesion for software object classes (Yourdon & Constantine, 1978) to learning object classes. We describe a learning object class at each level and provide an example. The strongest level of cohesion is called *functional*, and the weakest cohesion is called *coincidental*. Each level in Table 1 is less cohesive that the level above it.

The reusability issue for each level below functional cohesion is explained in Table 2. Note that the issue at a given level is often in addition to reusability issues at higher levels.

Determining Learning Object Cohesion

The description or name of a learning object class may suffice to determine its level of cohesion, as shown in Table 3.

We note that the presence of any of the above key words could be a valuable indicator for metadata tagging purposes, but further research is required to evaluate reliability.

In Figure 5, we adapt a decision tree (Page-Jones, 1998) that enables the level of cohesion of a learning object class to be more accurately determined by asking and answering a few questions, starting at top left.

If all the activities in a learning object class share more than one level of cohesion, the learning object class has the highest (strongest) of the shared levels of cohesion—according to the 'chains in parallel' rule. If the activities in a learning object class exhibit various levels of

Table 1. Learning object class cohesion levels

Cohesion level	Description	Example
Functional (strongest)	Each activity in a learning object class contributes to a single learning objective related task or learning outcome.	Learn to calculate net employee salary. This could be one of many tasks an accountant learns. It comprises: getting the gross salary, subtracting legal deductions, computing taxes. Every step contributes to the single purpose outcome of this learning object class.
Sequential	The outcome (output) of each activity in a learning object class is the input to the next activity in the learning object class.	Learn to paint a picture. This learning object class could comprise: sketching, painting outlines, coloring shapes, adding texture, signing, and dating. Each activity uses the result of the previous activity on the canvas. The picture may be complete, but learning to paint could still be a life-long objective, so the learning object class is not functionally complete.
Communicational	The activities in a learning object class share the same attributes, or inputs and outputs.	Learn to summarise, say, a chapter of a book. This learning object class could comprise: reading the chapter, highlighting headings in the chapter, listi;ng key words in the chapter, writing sentences that connect key words in the chapter. Each activity uses the chapter, but not necessarily the result of the previous activity.
Procedural	Control flows from one activity to the next in the learning object class, i.e., the activities are related solely by their order of execution, which is arbitrary. Data passing in and out of the learning object class are unrelated.	Learn to dissect, say, a fish or mouse. This learning object class could comprise: cleaning the bench, arranging implements, preparing the specimen, starting experimental notes, using scalpel, recording observations. Each activity leads to the next, but it does not necessarily use the result of any previous activity.
Temporal	The activities in a learning object class are related in time only, i.e., the activities are executed at about the same time.	Learn to study. This learning object class could comprise: turning off the radio and TV, collecting pen, paper, and textbook, working at one's desk, ignoring phone calls and other distractions, making notes, etc. All these activities occur during study time, but they need not occur in this exact order.
Coincidental (weakest)	The activities in a learning object class are unrelated by any of the above.	Learn to tidy up a room. This learning object class could comprise: disposing of litter, hanging clothes, finishing a snack, making the bed, vacuuming, etc. Not all these activities need be done (together). The activities are not logically related, nor connected by flow of execution or data.

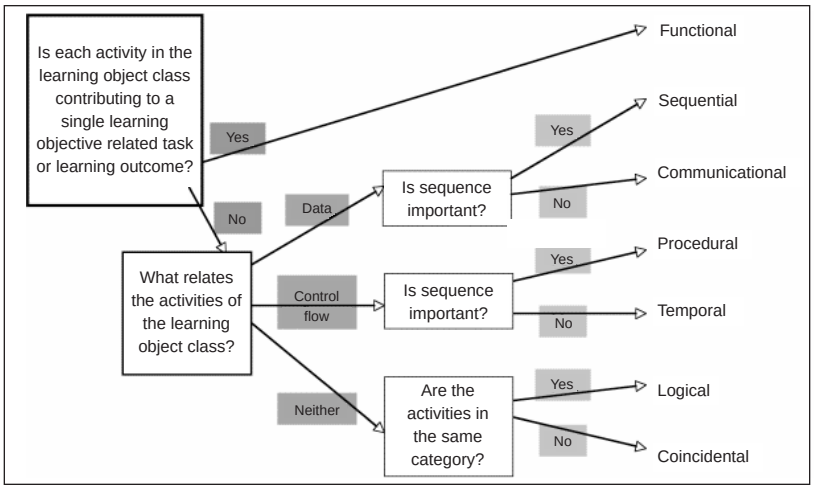
Table 2. Learning object class cohesion levels and reusability

Cohesion level	**Reusability issue**
Sequential	Not as reusable as a functional learning object class because the sequencing of its activities cannot be easily altered.
Communicational	Either the input or output coupling is generally broader than for the above levels of cohesion. Reuse often needs a subset of this coupling, hence redundant coupling; or a cut down version of the learning object class is created, which still duplicates functionality. A communicational learning object class can often be split into functional learning object classes.
Procedural	Intermediate or partial results are often passed into or out of a procedural learning object class, reducing reusability. It is tempting to combine distinct activities for 'efficiency' or 'convenience' further reducing reusability.
Temporal	Activities in a temporal learning object class tend to be related to activities in other learning object classes, increasing coupling. Activities in a temporal learning object class are often combined because they can occur together. But this compromises reusability in another situation where the activities can occur at different times.
Logical	Broad input coupling is required for a logical learning object class to select which activity to perform. The activities are typically combined because they share common parts. Reusability suffers.
Coincidental	A combination of inputs often determines the selected activity. As a result it can be hard to understand a coincidental learning object class unless its internal detail is examined. This reduces reusability.

Table 3. Determining learning object class cohesion by its name or description

Cohesion Level	**Name or Description**
Functional	Simple verb-object phrase.
Sequential	Commas often required.
Communicational	The word 'and' is often present.
Procedural	The word 'or' is often present, or words synonymous with repetition, e.g., 'while', 'until'.
Temporal	Time related words apparent, e.g., 'start', 'end', 'before', 'after'.
Logical	An 'umbrella' word is present, e.g., 'all', 'every', 'total'.
Coincidental	Description or name is meaningless, e.g., 'miscellaneous', 'X', 'Z-process'.

Figure 5. Cohesion decision tree



cohesion, the learning object class has the lowest (weakest) level of cohesion—according to the 'chains in series' rule.

Cohesion of Example Learning Objects

In this section we use Figure 5 to establish the cohesion of the learning object examples in the "Example Learning Object Classes" section. Similar analysis of other learning objects could establish their levels of cohesion, and hence their reusability.

When we address the first question (top left of Figure 5) for Boyle et al.'s Java while-loop learning object, the answer at first appears to be 'yes'—the While learning object appears functionally cohesive in that each activity contributes to understanding how while loops work, which is the learning object's learning objective. But on closer examination, the activities performed by the While learning object do not contribute to one and only one learning objective related task. The learning object performs two pairs of similar analysis activities in sequence (hammer and submarine, horse and lorry), followed by one synthesis activity. Data are not passed between the activities, so the sequence is program controlled (i.e., chosen by the instructional designer). So the learning object exhibits procedural cohesion at best. If we similarly address our object-oriented software engineering design for a while loop learning object class, shown in Figure 3, a learning object can be instantiated for each of hammer, submarine, horse, and lorry. The sequence is determined by the student (via input data), so at least the learning object class exhibits communicational cohesion, which is better than procedural cohesion.

The situation is similar for Rathsack's conflict resolution learning object and our Conflict learning object class shown in Figure 4. When we address the first question (top left of Figure 5) for Rathsack's learning object, the answer at first appears to be 'yes'—the learning object appears functionally cohesive in that each activity contributes to understanding Maddux's five styles for managing conflict, which is the learning object's learning objective. But after closer examination, the activities performed by the Conflict learning object do not contribute to one and only one learning objective related task. The learning object

performs five similar activities in sequence, one for each style. Data are not passed between the activities, so the sequence is program controlled (i.e., chosen by the instructional designer). So the learning object exhibits procedural cohesion at best. If we similarly address our object-oriented software engineering design for a Conflict learning object class, shown in Figure 4, a learning object can be instantiated for each of the five styles. The sequence is determined by the student (via input data), so at least the learning object class exhibits communicational cohesion, which is better than procedural cohesion.

Since each object-oriented software engineering designed learning object class exhibits stronger cohesion than the original learning object, our learning object class is likely to require weaker coupling with other learning object classes in a new learning object lesson, thereby enhancing its reusability.

SUPPORT FOR OBJECT-ORIENTED LEARNING OBJECTS

We henceforward refer to our above described object-oriented software engineering approach to designing learning objects and learning object lessons as 'object-oriented learning'. We claim benefits of object-oriented learning include the following, in addition to enhancing the 'bilities'. Dynamic instantiation of a learning object from its learning object class in response to a student's input/choice enables a learning object lesson to not only be more highly interactive but also far less predetermined in its sequence of activities for each student. Also the instructional designer need not build lessons as a predetermined sequence of learning object classes, as the student can be given more choices.

Below we investigate supports available for our object-oriented learning approach. We outline how object-oriented learning can be accommodated in a learning object development project from initial application of an instructional design theory to final implementation in a learning management system (e.g., Blackboard, WebCT, Moodle).

Object-Oriented Learning and Instructional Design Theory

It is reasonable that the design of learning objects and learning object lessons should be informed by an instructional design theory (Wiley, 2001). After these pedagogical choices are made, an instructional designer can apply our object-oriented learning approach, where the focus is on structuring the functionality provided by learning object classes. We assert that object-oriented learning is independent of, and complementary to, instructional design theory. Further research and development is needed to confirm this.

In fact we are presently using object-oriented learning to design a substantial learning object lesson, which is composed of several learning object classes. We intend to use UML during the design process in order to report on its usefulness as a tool for communicating the design of a learning object lesson. But the focus of our study will be on evaluating the effectiveness of our object-oriented learning approach on learning object class 'bilities'. We also expect to demonstrate most of the objectives of this chapter.

Object-Oriented Learning and Learning Management Systems

- Learning management systems like Blackboard, WebCT, and Moodle currently facilitate the development of e-learning courses, their collection in a repository, and their delivery to online students at anytime over any distance. Learning management systems are also starting to support standardised metadata tagging of learning objects to better facilitate the combination of learning objects into lessons, courses, and educational programs. Our object-oriented

learning approach contributes to learning object metadata tagging as explained in the "Determining Learning Object Cohesion" subsection. We contend that our approach is automatically accommodated within the pedagogically neutral standards adopted by the IEEE (LTSC, 2003) for learning object packaging.

- Learning management systems will also need to provide the 'programming language' that enables instructional designers using object-oriented learning and students to realise the full potential of the dynamics inherent in the design of learning object classes. Our use of Java in the "Example Learning Object Classes" section was not only to illustrate the application of object-oriented software engineering to the design of learning objects. Java can also be the programming language used in a learning management system to implement student-centered combination of learning object classes and the dynamic instantiation of their learning objects. However, the power of a general programming language environment such as Java is not necessary for this purpose. Indeed, further research is desirable to produce a complete yet simple programming tool for instructional designers to use across learning management systems. One avenue to explore is the programmability introduced into the computer aided instruction systems of the past (Gibbons & Richards, 2001). Fortunately, today's graphic user interfaces, more powerful computers, and faster connectivity will make the experience far more friendly for both today's instructional designers and students.

CONCLUSION

We have applied object-oriented software engineering design methodology to the design of learning objects. Our object-oriented learning approach extends and refines Boyle's (2002) design principles for authoring dynamic reusable learning objects as follows. The attributes and activities of a prospective learning object are first 'abstracted' into a learning object class. This facilitates dynamic instantiation of an individualised learning object for, or by, a student during a lesson; as we illustrated in the "Example Learning Object Classes" section with two example learning object classes for different disciplines. We introduced the unified modeling language to illustrate the learning object class design process (Figures 1 and 2). We showed how inheritance and polymorphism further enhance learning object class reusability in new lessons.

We explained how our object-oriented learning approach can benefit the design of lessons comprising several learning object classes. We identified a Java-like interface type as a useful mechanism to assist reuse and repurposing of learning object classes into new learning object lessons. This application of object-oriented software engineering design methodology led us to synthesise the criteria that define a truly object-oriented learning object class. Our criteria refine the learning object definition work of Wiley (2001) and others, and extend learning object design guidelines (Hamel & Ryan-Jones, 2002).

We adapted to learning object classes a scale for grading the cohesion of software modules (Yourdon & Constantine, 1978). We showed in the "Object-Oriented Design Principles for Learning Objects" section how to classify the level of cohesion of a learning object class, and described how each of the lower levels further reduces reusability. To illustrate we outlined two object-oriented software engineering designed learning object classes that exhibit stronger cohesion than the original learning objects. These learning object classes are likely to require weaker coupling with other learning object classes in a new learning object lesson, thereby enhancing reusability. Our adaption of cohesion levels to learning objects

further extends and refines Boyle's design principles for authoring dynamic reusable learning objects (Boyle, 2002).

We explained in the "Support for Object-Oriented learning objects" section how our object-oriented learning approach is independent of, and complementary to, (a) the instructional design theory underlying the learning object design process, and (b) the metadata standards adopted by the IEEE (LTSC, 2003) for learning object packaging. Pedagogical decisions can be made by the instructional designer before applying our approach to structuring the functionality of learning object classes. Our object-oriented learning approach is pedagogy neutral in this respect. Our approach also contributes to learning object metadata tagging by identifying attributes and activities for each learning object class.

We assert that our object-oriented learning approach expands and informs the options available to instructional designers for structuring and interfacing learning object. We believe our approach assists the systematic development of more complex, authentic lessons, composed of student-centered, dynamically created learning objects. We expect further contributions toward an object-oriented learning methodology will facilitate the design and implementation of larger scale lessons, courses and educational programs, composed of learning objects that increasingly exhibit the 'bilities'.

Chapter 2.13
Covert End User Development:
A Study of Success

Elaine H. Ferneley
University of Salford, UK

ABSTRACT

End User Development (EUD) of system applications is typically undertaken by end users for their own, or closely aligned colleagues, business needs. EUD studies have focused on activity that is small scale, is undertaken with management consent and will ultimately be brought into alignment with the organisation's software development strategy. However, due to the increase pace of today's organisations EUD activity increasing takes place without the full knowledge or consent of management, such developments can be defined as covert rather than subversive, they emerge in response to the dynamic environments in which today's organisations operate. This paper reports on a covert EUD project where a wide group of internal and external stakeholders worked collaboratively to drive an organisation's software development strategy. The research highlights the future inevitability of external stakeholders engaging in end user development as, with the emergence of wiki and blog-like environments, the boundaries of organisations' technological artifacts become increasingly hard to define.

INTRODUCTION

In today's environment of rapid business change facilitated by users with increased technical capabilities, there is a tacit understanding that end user development (EUD) activity is inevitable—development tools are more accessible, and end users are now technologically mature and expected to be proactive in their use of technology to enable enactment of their employment roles (Jawahar & Elango, 2001; Nelson & Todd, 1999). As the end user takes control of the development effort and develops systems with little or no input from information technology (IT) specialists so the ultimate level of end user involvement has arrived—the end user is no longer simply consulted, they have assumed the roles of the designer, developer and tester, they are the IT specialist for their software requirement (Cheney, Mann, & Amoroso, 1986; McGill, 2004).

To date, studies have focused on EUD that management is fully aware of and endorses, the assumption is that EUD activity is small scale and that it will ultimately be brought into the organisation's software development strategy.

However, due to the increased pace of today's organisations, EUD activity increasingly takes place without the full knowledge or consent of management. Such developments can be defined as covert rather than subversive, and it can be argued that they emerge in response to the dynamic environments in which today's organisations operate (Nelson & Todd, 1999; Ouellette, 1999; McLean, Kapperlman, & Thompson., 1993).

This paper reports on a field study on the effects of covert EUD activity in a publishing company. The paper aims to enhance our understanding of covert EUD activity using an interpretive approach. We draw on the literature on the social construction of technology (SCOT) and apply this to covert EUD activity identifying a technology "path" (MacKenzie & Wajcman, 1985). The "path" may be born from an individual vision, but the multifaceted nature of technology requires disparate actors to contribute to technology success. Whilst the paper does not purport to offer definitive solutions, the experiences reported suggest valuable lessons for organisations faced with the challenge of managing the dichotomous relationship of encouraging worker proactivity manifested in EUD whilst controlling maverick EUD activity.

LITERATURE REVIEW

Authors have begun to recognise the futility of attempting to align business strategy and technological infrastructures and have acknowledged that technological "drift" is inevitable, (Ciborra et al., 2000; Sauer & Burn, 1997; Ciborra, 1994; Orlikowski, 1996). This process of "drift" is largely assumed to be an overt process, management being aware that it is happening and either attempting realignment (usually futilely) or allowing the technology to develop a certain momentum of its own (for examples see Kanellis & Paul, 2005; Hanseth & Braa, 1998; Rolland & Monteiro, 2002). What is less frequently considered is the notion of, and rationale for, covert IT implementations that result in "drift," and the literature that does exist is primarily concerned with covert activity with the intention of sabotage (for examples see Gordon, 1996; Conti, 2005; Verton, 2001; Graham, 2004).

Such covert activity, whether for altruistic or subversive purposes, necessitates a degree of improvisation—using current resources to create new forms and order from tools and materials at hand, such an approach has been defined by anthropologists as "bricolage" (Levi-Strauss, 1966). When considering information systems bricolage, "materials at hand" are usually considered to be information technology hardware and software artefacts. However, it has also been suggested that the use of networking with preexisting professional and personal contacts is also a form of "network bricolage" (Mintzberg, 1994; Moorman & Miner, 1998; Baker, Miner, & Eesley, 2003).

RESEARCH DESIGN

To examine covert EUD activity within an organisation from multiple stakeholder perspectives requires an understanding of the social and contextual relationships that influence the organisation; there can be no single explanation of success. Our epistemological assumptions are that no individual account of social reality can be proven correct. Therefore, the research method employed has been interpretivist, with the aim being to understand the perspectives of the various stakeholders and the historical and socially situated contexts in which they reside (Hirschheim, Klein, & Lyytinen, 1996). The opportunity to gain access to a covert end user developer group emerged during the course of a wider longitudinal study that was undertaken by the author and a postgraduate student that examined the effect on various stakeholders of implementing IT solutions in small- to medium-sized enterprises (SMEs). The postgraduate student was employed by one

of the studied SMEs (PublishCo) and became one of the covert EUDs, simultaneously exploring the dynamics and rationale for EUD whilst repeatedly intervening and stimulating change. Therefore, the research employed participatory action research: "…members of the organisation we study are actively engaged in the quest for information and ideas to guide their future actions" (Whyte, Greenwood, & Lazes, 1991). The research largely complied with the major characteristics of information systems action research as identified by Baskerville (1999) and Baskerville and Wood-Harper (1996). However, there is one area in which the researchers did not fully conform to the established principles for action research: informed consent. Whilst formal consent from PublishCo's management to study the effects of the introduction of IT into the organisation was gained, as the research evolved into a more specific study on covert EUD the researchers were faced with a moral dilemma—whether to inform management of the covert activity or whether to abuse management confidence and collude rather than confess. During the rest of this paper we will discuss how this dilemma was accommodated, and it is up to the reader to decide if we acted morally.

Field Study: PublishCo

PublishCo is a small publishing house established in 1895, and it is involved in the publication of niche specialist magazines for the pet owning, breeding, and exhibiting community. Circulation is global, although the customer base at the start of the fieldwork was largely European. Over the course of 4 years data has been collected from multiple levels and perspectives across the organisation, from technology suppliers and from customers. The findings are the results from 4 years of field diaries, over 200 hours of transcribed interviews and numerous hours of observation.

This paper reports on the covert development of a Web-based portal that has resulted in system integration across the company, and has contributed to increasing PublishCo's revenue by approximately 60%, improved the efficiency of the company's processes, built better customer relations, and simultaneously improved the working lives and morale of its employees. A summary of

Table 1. Emerging characteristics, roles and influences for stakeholders in covert end user development

Stakeholder Groups	**Predevelopment**	**System Development**	**System Implementation**
Internal End User Developer	**Characteristics** Entrepreneurial Personal or financial reward **Role/influences** Participative approach Enrolling management Revision of organisation and IS, based on previous external experience, current education, etc. **Quote** *"Web publishing is the way forward for all niche magazines"* (Emp1). *"We've only got a single web page with our contact details… it's too dated"* (Emp2)	**Characteristics** Risk taking. **Role/influences** External stakeholders—developer /software vendor, customers, competitors Access to technology—beta-software, packages External promotional events and training **Quote***"There was so much to implement and limited resources so illegal software was the only solution"* (Emp3)	**Characteristics** Efficiency gains Technical rationalisation (networking, desktop, etc.) **Role / influences** Recognition of need to manage & integrate technology Upgrade to reflect changing use **Quote** *'as functionality was released customers started using it straight away, it was obvious immediately that the decision to move online was the right one … we're always adding new things, it changes almost weekly* (Emp2)

(continued on following page)

Table 1. continued

Management	May not be aware EUDs occurring **Characteristics** Willingness to listen to strategic technologist **Role/influences** Trust change agent—internal or external Change-friendly climate Encourage autonomous "can do" employees **Quote** *"We were really wary of the developing a comprehensive website, especially as the dotcom catastrophe was just happening"* (Man2)	**Characteristics** Radical change (large or small scale) Business-led development **Role/influences** Acceptance of new direction Commit to technology education Technology as +ve lever for social change within the organisation **Quote** *"We can not envisage our customers using a website, their largely older, we don't expect them to be interested in an online site … we regard the development as a necessary commercial distraction"* (Man1)	**Characteristics** Financial commitment Technology management **Role / influences** Availability of financial support for ongoing implementation Ensure legality of EUD systems Vision alignment with business, organization and technology strategies **Quote** *'the web site has made a significant difference to our business, the discussion forums keep all of us abreast of what's going on in* [the field] *and we're* [management] *now actively contributing to those discussions'* (Man2)
External IT Agencies	**Characteristics** Long term commitment to organisation End user focussed **Role/influences** Long term financial gain Participative approach **Quote***"We needed to develop a reference site, so PublishCo implementation was an ideal opportunity"* (Salesman3)	**Characteristics** Exploratory, risky development (large or small scale) **Role/Influences** Technology & training provider **Quote** *"At the time we didn't see the effect that using lots of different tools would have, we wanted a reference site and believed using those tools was a means to an end"* (Salesman3)	**Characteristics** Educator **Roles / Influences** Training Emerging technology vision **Quote** *'we expected to use the site as a sales example but the end users have been using all sorts of free resources to cobble together a site that's not as professional looking as we'd hoped for'* (Salesman2
External End Users/ Customers	**Characteristics** Innovators **Role/influences** Stimulate technology vision **Quote** *"Online dog breeding forums were starting to emerge but really very few dog breeders were talking on them"* (Customer2)	**Characteristics** Reviewers Testers **Role/influences** External influences	**Characteristics** Explorers **Role / influences** Technology 'path' leaders **Quote** *'the portal effectively gave a voice to the community'* (Customer5)

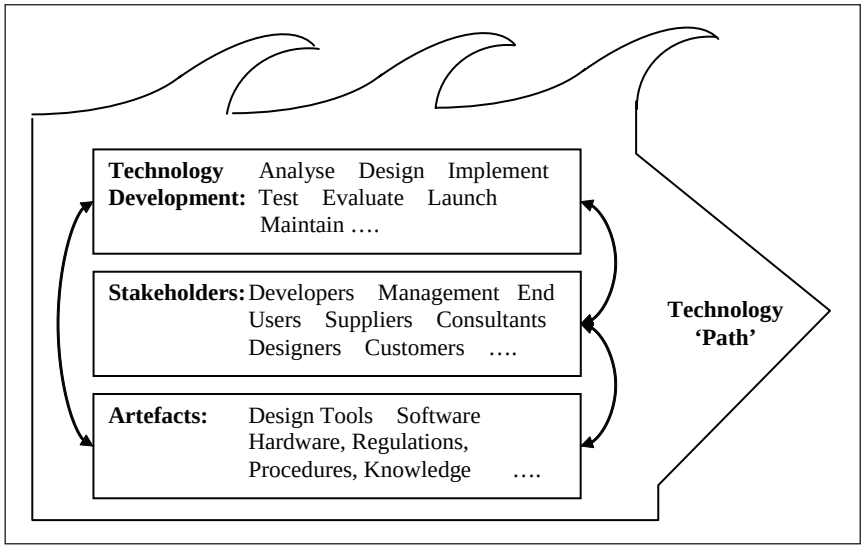
the various stakeholders' roles and perspectives is presented in Table 1.

IMPLICATIONS OF COVERT END USER DEVELOPMENT

Within the limitations of this field study, by considering the rationale and world views of these disparate groups who have all embraced EUD as a means of moving down a technology "path," a model for harnessing end user development activity emerges. The internal covert developers viewed the technology as emancipatory. They saw the technology as an opportunity to change the organisation's business model and introduce a new revenue stream, thereby potentially increasing sales turnover and hence commission. However, in the portal development the technical artefacts themselves became the technology path driver,

and as the end user developers gained enthusiasm and technical knowledge they introduced more, disparate functionality into the portal, and the technology developed a momentum of its own. These disparate elements now define the portal—its quirky, eclectic style clearly differentiates it from the competition and have made it the market leader. The IT consultants also assumed the role of covert developers. The usual assumption is that IT consultants view technical implementations as a source of income, yet in the presented study the implementation also provided them with a learning opportunity. They were prepared to work with internal, budding developers to provide them with the requisite skills to ensure the systems could evolve with the business. However, they also actively deceived management by presenting illusionary demonstrations and condoned or instigated the use of illegal software. Management's interpretation of the emerging technology was as a distraction and cost overhead. The end users and consultants perceived that they had limited understanding of the presentations and conversations that took place regarding technology, and subsequent interviews confirmed that members of management had sought advice from family members, personal friends, or peer networks rather than question their employees or contracted IT consultants. However, it emerged that they were aware that some covert development was occurring and chose to allow it to remain underground rather than stifle the proactivity that their employees were demonstrating. Customers' interpretation of the technologies has been as communication enabler. The portal facilitates communication in many directions: customer to customer, customer to journalist, customer to management, customer to advertiser. Indeed, it could be argued that the customer has become the final technology path driver: Functionality is added or removed from the portal dependent on customer use, editorial is driven by their discussion forum conversations, whilst the content of the online directories is created and uploaded by the customers themselves. As the portal develops so it is interpreted in different ways, including a sales forum (extensive online directories), an organisational tool (calendar of

Figure 1. Technology path



events), and a dating agency (putting readers with similar requirements in touch for the purposes of pursuing their niche interest).

Reflecting on the findings of the field study, our inquiry illustrates that (a) covert EUD may be driven by a wider stakeholder group than the end user developers themselves, and (b) although EUD activity is traditionally seen as a microlevel activity, the challenge is to harness the developing technical artefacts to achieve maximum business benefit without jeopardizing the stability of the organisation as a whole. We discuss these implications in turn.

The traditional view of EUD is that the activity is small scale and undertaken to satisfy end users' own needs. Yet as end users become more technically sophisticated and as technology itself becomes more homogeneous, user friendly and reconfigurable, so a wider set of stakeholder groups are gaining common or easily transferable technical know-how. This allows traditionally disparate stakeholder groups from both inside and outside organisations to act collectively in covert activity; in the field study, transferred technological know-how enabled the internal end users and the technology vendors to work together to covertly developed information systems solutions. Indeed, whilst the ultimate level of end user involvement has traditionally been seen as the end user taking ownership of the system and becoming the developer himself (Cheney et al., 1986), it is feasible for external stakeholder groups to effectively become the end user developer. In the field study, as the customer stakeholder group has gained technical know-how, it has become able to drive the portal's ever changing design, and it provides the content in the form of uploaded reviews, customer profiles, and commentary via discussion forums. Indeed, the portal could be viewed as an emerging wiki or blog-like environment owned by PublishCo (Leuf & Cunningham, 2001).

Chapter 2.14
A Social Ontology for Integrating Security and Software Engineering

J. Mylopoulos
University of Toronto, Canada

ABSTRACT

As software becomes more and more entrenched in everyday life in today's society, security looms large as an unsolved problem. Despite advances in security mechanisms and technologies, most software systems in the world remain precarious and vulnerable. There is now widespread recognition that security cannot be achieved by technology alone. All software systems are ultimately embedded in some human social environment. The effectiveness of the system depends very much on the forces in that environment. Yet there are few systematic techniques for treating the social context of security together with technical system design in an integral way. In this chapter, we argue that a social ontology at the core of a requirements engineering process can be the basis for integrating security into a requirements driven software engineering process. We describe the ***i**** agent-oriented modelling framework and show how it can be used to model and reason about security concerns and responses. A smart card example is used to illustrate. Future directions for a social paradigm for security and software engineering are discussed.

INTRODUCTION

It is now widely acknowledged that security cannot be achieved by technological means alone. As more and more of our everyday activities rely on software, we are increasingly vulnerable to lapses

in security and deliberate attacks. Despite ongoing advances in security mechanisms and technologies, new attack schemes and exploits continue to emerge and proliferate.

Security is ultimately about relationships among social actors — stakeholders, system users, potential attackers — and the software that are instruments of their actions. Nevertheless, there are few systematic methods and techniques for analyzing and designing social relationships as technical systems alternatives are explored.

Currently, most of the research on secure software engineering methods focuses on the technology level. Yet, to be effective, software security must be treated as originating from high-level business goals that are taken seriously by stakeholders and decision makers making strategic choices about the direction of an organisation. Security interacts with other high-level business goals such as quality of service, costs, time-to-market, evolvability and responsiveness, reputation and competitiveness, and the viability of business models. What is needed is a systematic linkage between the analysis of technical systems design alternatives and an understanding of their implications at the organisational, social level. From an analysis of the goals and relationships among stakeholders, one seeks technical systems solutions that meet stakeholder goals.

In this chapter, we describe the ***i**** agent-oriented modelling framework and how it can be used to treat security as an integral part of software system requirements engineering. The world is viewed as a network of social actors depending on each other for goals to be achieved, tasks to be performed, and resources to be furnished. Each actor reasons strategically about alternate means for achieving goals, often through relationships with other actors. Security is treated as a high-level goal held by (some) stakeholders that need to be addressed from the earliest stages of system conception. Actors make tradeoffs among competing goals such as functionality, cost, time-to-market, quality of service, as well as security.

The framework offers a set of security requirements analysis facilities to help users, administrators, and designers better understand the various threats and vulnerabilities they face, the countermeasures they can take, and how these can be combined to achieve the desired security results within the broader picture of system design and the business environment. The security analysis process is integrated into the main requirements process, so that security is taken into account from the earliest moment. The technology of smart cards and the environment surrounding its usage provides a good example to illustrate the social ontology of ***i****.

In the next section, we review the current challenges in achieving security in software systems, motivating the need for a social ontology. Given that a social modelling and analysis approach is needed, what characteristics should it have? We consider this in the following section. The two subsequent sections describe the ontology of the ***i**** strategic actors modelling framework and outline a process for analyzing the security issues surrounding a smart card application. The last section reviews several areas of related work and discusses how a social ontology framework can be complementary to these approaches.

BACKGROUND

Despite ongoing advances in security technologies and software quality, new vulnerabilities continue to emerge. It is clear that there can be no perfect security. Security inevitability involves tradeoffs (Schneier, 2003). In practice, therefore, all one can hope for is “good enough” security (Sandhu, 2003).

But how does one determine what is good enough? Who decides what is good enough? These questions suggest that software and information security cannot be addressed by technical specialists alone. Decisions about security are made ultimately by stakeholders — people who

are affected by the outcomes — users, investors, the general public, etc. — because the tradeoffs are about how their lives would be affected. In electronic commerce, consumers decide whether to purchase from a vendor based on the trustworthiness of the vendor's business and security practices. Businesses decide how much and where to invest on security to reduce exposure to a tolerable level. In healthcare, computerized information management can streamline many processes. But e-health will become a reality only if patients and the general public are satisfied that their medical records are protected and secure. Healthcare providers will participate only if liability concerns can be adequately addressed.

Tradeoffs are being made by participants regarding competing interests and priorities. Customers and businesses make judgments about what is adequate security for each type of business, in relation to the benefits derived from online transactions. Patients want their personal and medical information to be kept private, but do not want privacy mechanisms to interfere with the quality of care. In national defense, secrecy is paramount, but can also lead to communication breakdown. In each case, security needs to be interpreted within the context of the social setting, by each stakeholder from his/her viewpoint.

Current approaches to security do not allow these kinds of tradeoffs to be conveyed to system developers to guide design. For example, UML extensions for addressing security (see Chapter I for a review) do not lend themselves well to the modelling of social actors and their concerns about alternate security arrangements, and how they reason about tradeoffs. Access control models can specify policies, but cannot support reasoning about which policies are good for whom and what alternate policies might be more workable. They cannot explain why certain policies meet with resistance and non-compliance.

Each of the common approaches in security modelling and analysis focuses on selective aspects of security, which are important in their own right, but cannot provide the guidance needed to achieve "good enough" overall security. Most approaches focus on technical aspects, neglecting the social context, which is crucial for achieving effective security in practice. The technical focus is well served by mechanistic ontology (i.e., concepts that are suitable for describing and reasoning about automated machinery — objects, operations, state transitions, etc.). The importance of social context in security suggests that a different set of concepts is needed. From the previous discussion, we propose that the following questions are important for guiding system development in the face of security challenges:

- Who are the players who have an interest in the intended system and its surrounding context? Who would be affected by a change?
- What are their strategic interests? What are their business and personal objectives? What do they want from the system and the other players?
- What are the different ways in which they can achieve what they want?
- How do their interests complement or interfere with each other? How can players achieve what they want despite competing or conflicting interests?
- What opportunities exist for one player to advance its interests at the expense of others? What vulnerabilities exist in the way that each actor envisions achieving its objectives?
- How can one player avoid or prevent its interests from being compromised by others?

These are the kind of questions that can directly engage stakeholders, helping them uncover issues and concerns. Stakeholders need the help of technical specialists to think through these questions, because most strategic objectives are accomplished through technological systems.

Stakeholders typically do not know enough about technology possibilities or their implications. Technologists do not know enough about stakeholder interests to make choices for them. In order that stakeholder interests can be clarified, deliberated upon, and conveyed effectively to system developers, a suitable modelling method is needed to enable stakeholders and technologists to jointly explore these questions. The answers to these questions will have direct impact on system development, as they set requirements and guide technical design decisions.

We argue therefore that a social ontology is needed to enable security concerns to become a driving force in software system development. In the next section, we explore the requirements for such a social ontology.

APPROACH

If a treatment of security requires attention to the social context of software systems, can the social analysis be given full weight in a software engineering methodology that is typically dominated by a mechanistic worldview? How can the social modelling be reconciled and integrated with mainstream software modelling?

It turns out that a social paradigm for software system analysis is motivated not only by security concerns, but is consistent with a general shift in the context of software and information systems. The analysis of computers and information systems used to be machine-centric when hardware was the precious resource. The machine was at the centre, defining the human procedures and structures needed to support its proper functioning. Today, hardware and software are commoditized and distributed everywhere. Human practices and imagination determine how hardware and software are put to use, not the other way round. Pervasive networking, wired and wireless, has also contributed to blurring the notion of "system." Computational resources can be dynamically harnessed in ad hoc configurations (e.g., through Web services protocols in service-oriented architectures) to provide end-to-end services for a few moments, then dissolved and reconfigured for another ad hoc engagement. Even computational entities, in today's networked environment, are better viewed as participants in social networks than as fixed components in a system with predefined structure and boundary. Increasingly, the computational services that we desire will not be offered as a single pre-constructed system, but by a conglomeration of interacting services operated by different organisations, possibly drawing on content owned by yet other providers.

The questions raised in the previous section arise naturally from today's open networked environments, even if one were not focusing on security concerns. The relevance of a social ontology is therefore not unique to security. Competing interests and negative forces that interfere with one's objectives are ever present in every organisation and social setting. They are accentuated in an open network environment. In security scenarios, the negative forces are further accentuated as they materialize into full-fledged social structures, involving malicious actors collaborating with other actors, engaging in deliberate attacks, possibly violating conventions, rules, and laws. Security can therefore be seen as covering the more severe forms of a general phenomenon. Competing and conflicting interests are inherent in social worlds. Negative forces do not come only from well identified malicious external agents, but can be present legitimately within one's organisation, among one's associates, and even among the multiple roles that one person may play. It may not be possible to clearly separate security analysis from the analysis of "normal" business. We conclude, therefore, that a social ontology would serve well for "normal" business analysis, recognizing the increasingly "social" nature of software systems and their environments. A social ontology offers a smooth integration of the treatment of normal and security scenarios, as the latter merely refer

to one end of a continuum covering positive and negative forces from various actors.

Given this understanding, the social ontology should not be preoccupied with those concepts conventionally associated with security. For example, the concepts of asset, threat, attack, counter-measure are key concepts for security management. In the social ontology we aim to construct, we do not necessarily adopt these as primitive concepts. Instead, the social ontology should aim to be as general as possible, so that the concepts may be equally applicable to positive as well as negative scenarios. The general ontology is then *applied* to security. Special constructs unique to security would be introduced only if the expressiveness of the general constructs is found to be inadequate. The principle of Occam's razor should be applied to minimize the complexity of the ontology. If desired, shorthand notations for common recurring patterns can be defined in terms of the primitives. The premises behind a social ontology are further discussed in Yu (2001a, 2001b).

BASIC CONCEPTS OF THE *i** STRATEGIC MODELLING FRAMEWORK

The ***i**** framework (Yu, 1993, 1997) proposes an agent oriented approach to requirements engineering centering on the intentional characteristics of the agent. Agents attribute intentional properties such as goals, beliefs, abilities, commitments to each other and reason about strategic relationships. Dependencies give rise to opportunities as well as vulnerabilities. Networks of dependencies are analyzed using a qualitative reasoning approach. Agents consider alternative configurations of dependencies to assess their strategic positioning in a social context. The name ***i**** (pronounced eye-star) refers to the concept of multiple, distributed "intentionality."

The framework is used in contexts in which there are multiple parties (or autonomous units) with strategic interests, which may be reinforcing or conflicting in relation to each other. The ***i**** framework has been applied to business process modelling (Yu, 1993), business redesign (van der Raadt, Gordijn, & Yu, 2005; Yu et al., 2001), requirements engineering (Yu, 1997), architecture modelling (Gross & Yu, 2001), COTS selection (Franch & Maiden, 2003), as well as to information systems security.

There are three main categories of concepts: actors, intentional elements, and intentional links. The framework includes a strategic dependency (SD) model — for describing the network of relationships among actors, and a strategic rationale (SR) model — for describing and supporting the reasoning that each actor has about its relationships with other actors.

Actor

In ***i****, an *actor* () is used to refer generically to any unit to which intentional dependencies can be ascribed. An actor is an active entity that carries out actions to achieve its goals by exercising means-ends knowledge. It is an encapsulation of intentionally, rationality and autonomy. Graphically, an actor is represented as a circle, and may optionally have a dotted boundary, with intentional elements inside.

Intentional Elements: Goal, Softgoal, Task, Resource and Belief

The intentional elements in ***i**** are goal, task, softgoal, resource and belief. A goal () is a condition or state of affairs in the world that the stakeholders would like to achieve. A goal can be achieved in different ways, prompting alternatives to be considered. A goal can be a business goal or a system goal. Business goals are about the business or state of the affairs the

individual or organisation wishes to achieve in the world. System goals are about what the target system should achieve, which, generally, describe the functional requirements of the target system. In the ***i**** graphical representation, goals are represented as a rounded rectangle with the goal name inside.

A *softgoal* () is typically a quality (or non-functional) attribute on one of the other intentional elements. A softgoal is similar to a (hard) goal except that the criteria for whether a softgoal is achieved are not clear-cut and *a priori*. It is up to the developer to judge whether a particular state of affairs in fact sufficiently achieves the stated softgoal. Non-functional requirements, such as performance, security, accuracy, reusability, interoperability, time to market and cost are often crucial for the success of a system. In ***i****, non-functional requirements are represented as softgoals and addressed as early as possible in the software lifecycle. They should be properly modelled and addressed in design reasoning before a commitment is made to a specific design choice. In the ***i**** graphical representation, a softgoal is shown as an irregular curvilinear shape.

*Task*s () are used to represent the specific procedures to be performed by agents, which specifies a particular way of doing something. It may be decomposed into a combination of subgoals, subtasks, resources, and softgoals. These sub-components specify a particular course of action while still allowing some freedom. Tasks are used to incrementally specify and refine solutions in the target system. They are used to achieve goals or to "operationalize" softgoals. These solutions provide operations, processes, data representations, structuring, constraints, and agents in the target system to meet the needs stated in the goals and softgoals. Tasks are represented graphically as a hexagon.

A *resource* () is a physical or informational entity, which may serve some purpose. From the viewpoint of intentional analysis, the main concern with a resource is whether it is available. Resources are shown graphically as rectangles.

The *belief* () construct is used to represent domain characteristics, design assumptions and relevant environmental conditions. It allows domain characteristics to be considered and properly reflected in the decision making process, hence facilitating later review, justification, and change of the system, as well as enhancing traceability. Beliefs are shown as ellipses in ***i**** graphical notation.

Strategic Dependency Model

A strategic dependency (SD) model consists of a set of nodes and links. Each node represents an actor, and each link between two actors indicates that one actor depends on the other for something in order that the former may attain some goal. We call the depending actor the *depender*, and the actor who is depended upon the *dependee*. The object around which the dependency relationship centers is called the *dependum*. By depending on another actor for a dependum, an actor (the depender) is able to achieve goals that it was not able to without the dependency, or not as easily or as well. At the same time, the depender becomes vulnerable. If the dependee fails to deliver the dependum, the depender would be adversely affected in its ability to achieve its goals. A *dependency* link () is used to describe such an inter-actor relationship. Dependency types are used to differentiate the kinds of freedom allowed in a relationship.

In a *goal dependency*, an actor depends on another to make a condition in the world come true. Because only an end state or outcome is specified, the dependee is given the freedom to choose how to achieve it.

In a *task dependency*, an actor depends on another to perform an activity. The depender's goal for having the activity performed is not given. The activity description specifies a particular course

of action. A task dependency specifies standard procedures, indicates the steps to be taken by the dependee.

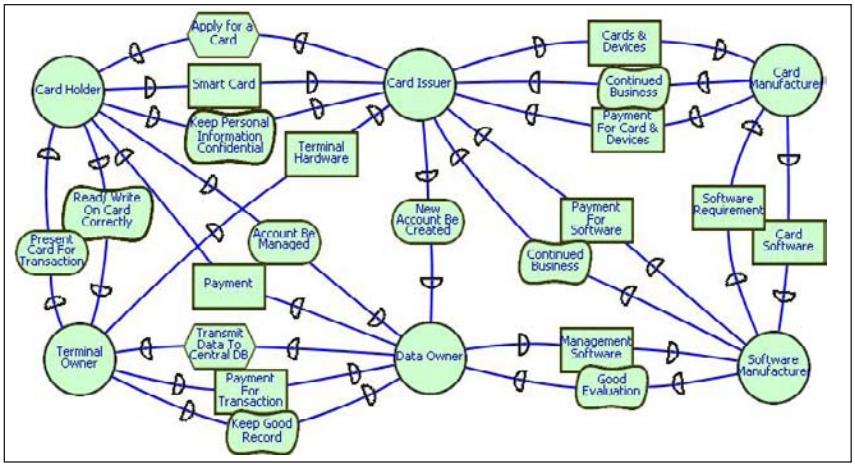
In a *resource dependency*, an actor depends on another for the availability of an entity. The depender takes the availability of the resource to be unproblematic.

The fourth type of dependency, *softgoal dependency*, is a variant of the goal dependency. It is different in that there are no *a priori*, cut-and-dry criteria for what constitutes meeting the goal. The meaning of a softgoal is elaborated in terms of the methods that are chosen in the course of pursuing the goal. The dependee contributes to the identification of alternatives, but the decision is taken by the depender. The notion of the softgoal allows the model to deal with many of the usually informal concepts. For example, a service provider's dependency on his customer for continued business can be achieved in different ways. The desired style of continued business is ultimately decided by the depender. The customer's softgoal dependency on the service provider for "keep personal information confidential" indicates that there is not a clear-cut criterion for the achievement of confidentiality. The four types of dependencies reflect different levels of freedom that is allowed in the relationship between depender and dependee.

Figure 1 shows a SD model for a generic smart card-based payment system involving six actors. This example is adapted from Yu and Liu (2001). A Card Holder depends on a Card Issuer to be allocated a smart card. The Terminal Owner depends on Card Holder to present the card for each transaction. The Card Issuer in turn depends on the Card Manufacturer and Software Manufacturer to provide cards, devices, and software. The Data Owner is the one who has control of the data within the card. He depends on the Terminal Owner to submit transaction information to the central database. In each case, the dependency means that the depender actor depends on the dependee actor for something in order to achieve some (internal) goal.

The goal dependency New Account Be Created from the Card Issuer to the Data Owner means that it is up to the Data Owner to decide how to create a new account. The Card Issuer does not care how a new account is created; what matters is that, for each card, an account should be created. The Card Issuer depends on the Card Holder to apply for a card via a task dependency by specifying standard application procedures.

Figure 1. Strategic dependency model of a generic smart card system



If the Card Issuer were to indicate the steps for the Data Owner to create a new account, then the Data Owner would be related to the Card Issuer by a task dependency instead.

The Card Issuer's dependencies on the Card Manufacturer for cards and devices, the manufacturer's dependencies on Card Issuer for payment are modelled as resource dependencies. Here the depender takes the availability of the resource to be unproblematic.

The Card Holder's softgoal dependency on the Card Issuer for Keep Personal Information Confidential indicates that there is not a clear-cut criterion for the achievement of confidentiality. In the Manufacturer's softgoal dependency on Card Issuer, Continued Business could be achieved in different ways. The desired style of continued business is ultimately decided by the depender.

The strategic dependency model of Figure 1 is not meant to be a complete and accurate description of any particular smart card system. It is intended only for illustrating the modelling features of ***i****.

In conventional software systems modelling, the focus is on information flows and exchanges — what messages actors or system components send to each other. With the social ontology of ***i****, the focus is on intentional relationships — what are the actors' expectations and constraints on each other. Since actors are intentional, strategic, and have autonomy, they reflect on their relationships with other actors. If these relationships are unsatisfactory, they will seek alternative ways of associating with others.

Security concerns arise naturally from this perspective. A social ontology therefore provides a way to integrate security into software system engineering from the earliest stages of conception, and at a high level of abstraction.

Intentional Links

Dependencies are intentional relationships between actors. Within each actor, we model intentional relationships in terms of means-ends, decomposition, contribution, and correlation links.

- **Means-ends** links (⊣▷⊢) are used to describe how goals can be achieved. Each task connected to a goal by a means-ends link is one possible way of achieving the goal.
- **Decomposition** links (—┼) define the sub-elements of a task, which can include sub-tasks, sub-goals, resources, and softgoals. The softgoals indicate the desired qualities that are considered to be part of the task. The sub-tasks may in turn have decomposition links that lead to further sub-elements. Sub-goals indicate the possibility of alternate means of achievement, with means-ends links leading to tasks.
- A **contribution** link (→) describes the qualitative impact that one element has on another. A contribution can be negative or positive. The extent of contribution is judged to be partial or sufficient based on Simon's concept of satisficing (Simon, 1996), as in the NFR framework (Chung, Nixon, Yu, & Mylopoulos, 2000). Accordingly, contribution link types include: *help* (positive and partial), *make* (positive and sufficient), *hurt* (negative and partial), *break* (negative and sufficient), *some+* (positive of unknown extent), *some-* (negative of unknown extent). *Correlation* links (dashed arrows) are used to express contributions from one element to other elements that are not explicitly sought, but are side effects.

Strategic Rationale Model

The strategic rationale (SR) model provides a detailed level of modelling by looking "inside" actors to model internal intentional relationships. Intentional elements (goals, tasks, resources, and softgoals) appear in SR models not only as external dependencies, but also as internal ele-

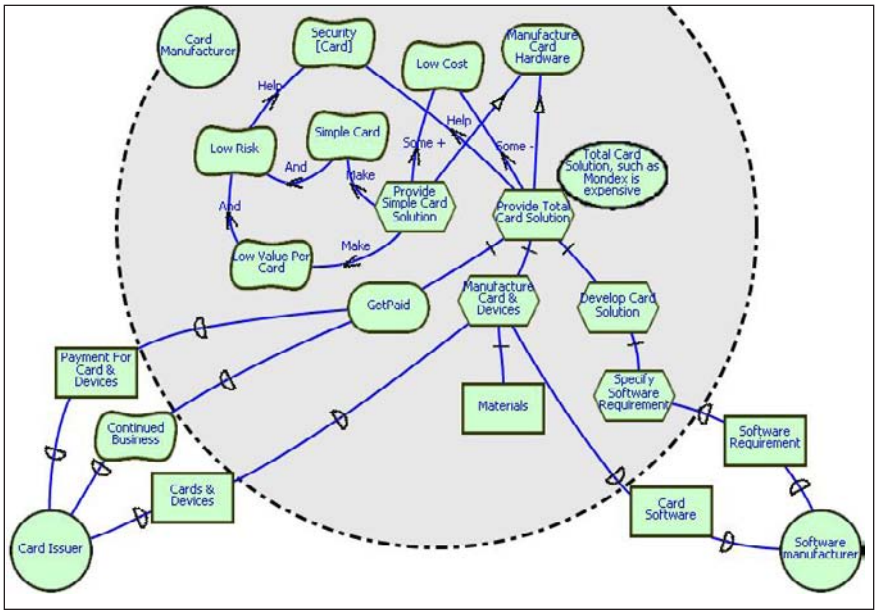
ments arranged into a predominantly hierarchical structure of means-ends, task-decompositions and contribution relationships.

The SR model in Figure 2 elaborates on the rationale of a Card Manufacturer. The Card Manufacturer's business objective Manufacture Card Hardware is modeled as a "hard" functional goal (top right corner). Quality requirements such as Security and Low Cost are represented as softgoals. The different means for accomplishing the goal are modeled as tasks. The task Provide Total Card Solution can be further decomposed into three sub-components (connected with task-decomposition links): sub-goal of Get Paid, sub-task Develop Card Solution, and sub-task Manufacture Card & Devices. To perform the task Manufacture Card & Devices, the availability of Materials need to be taken into consideration, which is modeled as a resource.

In the model, task node Provide Simple Card Solution (such as the Millicent solution), and Provide Total Card Solution (such as the Mondex solution) are connected to the goal with means-ends links. This goal will be satisfied if any of these tasks is satisfied. Provide Total Card Solution will help the Security of the system (represented with a *Help* contribution link to *Security*), while Provide Simple Card Solution is considered to have no significant impact on security if it is applied to cards with small monetary value. The Simple Card Solution is good for the goal of Low Cost whereas the Total Card Solution is bad. This is supported by the belief that "Total Card Solution, such as Mondex, is expensive." Beliefs are usually used to represent such domain properties, or design assumption or environmental condition, so that traceability of evidence of design decision could be explicitly maintained with the model.

During system analysis and design, softgoals such as Low Cost and Security [card] are systematically refined until they can be operationalized and implemented. Unlike functional goals, nonfunctional qualities represented as softgoals frequently interact or interfere with each other, so the graph of contributions is usually not a strict tree structure (Chung et al., 2000).

Figure 2. Strategic rationale model of card manufacturer



Agents, Roles, and Positions

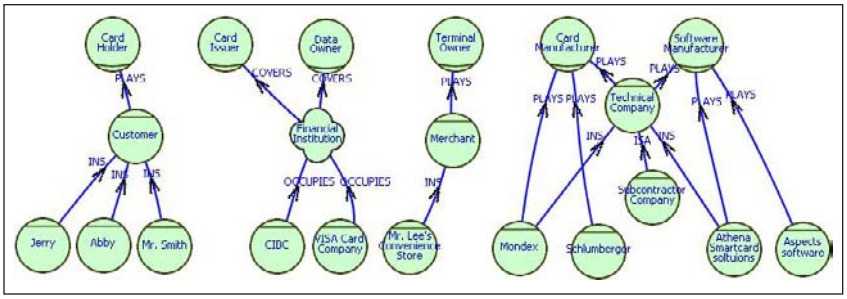
To model complex relationships among social actors, we further define the concepts of agents, roles, and positions, each of which is an actor, but in a more specialized sense.

A *role* ( ) is an abstract actor embodying expectations and responsibilities. It is an abstract characterization of the behavior of a social actor within some specialized context or domain of endeavor. An *agent* ( ) is a concrete actor with physical manifestations, human or machine, with specific capabilities and functionalities. A set of roles packaged together to be assigned to an agent is called a position. A *position* ( ) is intermediate in abstraction between a role and an agent, which often has an organisational flavor. Positions can COVER roles. Agents can OCCUPY positions. An agent can PLAY one or more roles directly. The INS construct is used to represent the instance-and-class relation. The ISA construct is used to express conceptual generalization/specialization. Initially, human actors representing stakeholders in the domain are identified together with existing machine actors. As the analysis proceeds, more actors are identified, including new system agents, when certain design choices have been made, and new functional entities are added.

Figure 3 shows some actors in the domain. At the top, six generic abstract roles are identified, including the Card Holder, the Terminal Owner, the Data Owner, the Card Issuer, the Card Manufacturer, and the Software Manufacturer. These actors are modeled as roles since they represent abstractions of responsibilities and functional units of the business model. Then concrete agents in smart card systems are identified. For instance, actors in a Digital Stored Value Card system include Customer, Merchant, Subcontractor Company, and their instances. These agents can play one or more roles in different smart card systems. Here, Financial Institution is modeled as a position that bridges the multiple abstract roles it covers, and the real world agents occupying it. Initially, human/organisational actors are identified together with existing machine actors. As the requirements analysis proceeds, more actors could be added in, including new system agents such as security monitoring system, counter-forgery system, etc., when certain design choices have been made, and new functional entities are added.

An *agent* is an actor with concrete, physical manifestations, such as a human individual. An agent has dependencies that apply regardless of what role he/she/it happens to be playing. For example, in Figure 3, if Jerry, a Card Holder desires a good credit record, he wants the credit record to go towards his personal self, not to the positions and abstract roles that Jerry might occupy or play. We use the term agent instead of person for generality, so that it can be used to refer to human as well as artificial (hardware, software,

Figure 3. Actor hierarchy (roles, positions, and agents) in a smart card system



or organisational) agents. Customer and Merchant are represented as agent classes and groups. Dependencies are associated with a role when these dependencies apply regardless of who plays the role. For example, we consider Card Holder an abstract role that agents can play. The objective of obtaining possession of the card, and deciding when and whether to use it, are associated with the role, no matter who plays the role.

The INS construct represents the instance-and-class relation. For example, Mr. Lee's Convenience Store is an instance of Merchant, and Jerry is an instance of Customer. The ISA construct expresses conceptual generalization/ specialization. For example, a Subcontractor Company is a kind of Technical Company. These constructs are used to simplify the presentation of strategic models with roles, positions, and agents. There can be dependencies from an agent to the role it plays. For example, a Merchant who plays the role of Terminal owner may depend on that role to attract more customers. Otherwise, he may choose not to play that role.

Roles, positions, and agents can each have subparts. In general, aggregate actors are not compositional with respect to intentional properties. Each actor, regardless of whether it has parts, or is part of a larger whole, is taken to be intentional. Each actor has inherent freedom and is therefore ultimately unpredictable. There can be intentional dependencies between the whole and its parts (e.g., a dependency by the whole on its parts to maintain unity).

DOMAIN REQUIREMENTS ANALYSIS WITH *i**

We now illustrate how the social ontology of ***i**** allows security issues to be identified and addressed early in the requirements process. We continue with the example of smart card systems design. Security in smart card systems is a challenging task due to the fact that different aspects of the system are not under a single trust boundary. Responsibilities are split among multiple parties. The processor, I/O, data, programs, and network may be controlled by different, and potentially hostile, parties. By discussing the security ramifications of different ways of splitting responsibilities, we aim to show how the proposed modelling framework can help produce a proper understanding of the security systems that employ smart cards. Figure 4 shows the basic steps to take during the process of domain requirements analysis with ***i****, before we consider security. The process can be organised into the following iterative steps.

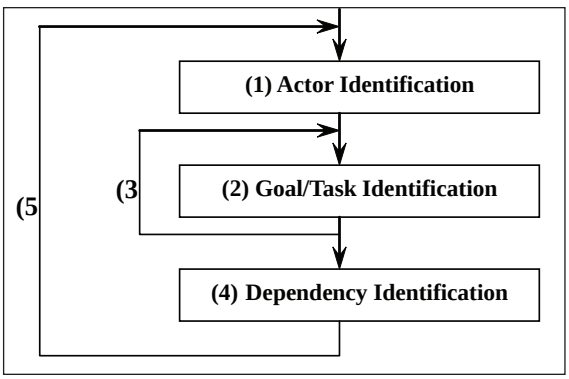
Actor Identification

In step (1), the question "who is involved in the system?" will be answered. According to the definition given above, we know that all intentional units may be represented as actors. For example, in any smart card based systems, there are many parties involved. An actor hierarchy composed of roles, positions, and agents such as the ones in Figure 3 is created.

Goal/Task Identification

In the step (2) of the requirements analysis process, the question "what does the actor want to achieve?"

*Figure 4. Requirements elicitation process with i**



will be answered. As shown in the strategic rationale (SR) model of Figure 2, answers to this question can be represented as goals capturing the high-level objectives of agents. During system analysis and design, softgoals such as low cost and security are systematically refined until they can be operationalized and implemented. Using the SR model, we can reason about each alternative's contributions to high-level non-functional quality requirements including security, and possible tradeoffs.

The refinements of goals, tasks and softgoals (step (3) in Figure 4) are considered to have reached an adequate level once all the necessary design decisions can be made based on the existing information in the model. The SR model in Figure 3 was created by running through steps (1), (2), (3) in Figure 4 iteratively.

Strategic Dependency Identification

In the step (4) of the requirements analysis process, the question "how do the actors relate to each other?" will be answered. Figure 1 shows the SD model for a generic smart card-based payment system. By analyzing the dependency network in a Strategic Dependency model, we can reason about opportunities and vulnerabilities. A Strategic Dependency model can be obtained by hiding the internal rationales of actors in a Strategic Rationale model. Thus, the goal, task, resource, softgoal dependencies in a Strategic Dependency model can be seen as originating from SR models.

The kinds of analysis shown above answers questions such as "who is involved in the system? What do they want? How can their expectations be fulfilled? And what are the inter-dependencies between them?" These answers initially provide a sketch of the social setting of the future system, and eventually result in a fairly elaborate behavioral model where certain design choices have already been made. However, another set of very important questions has yet to be answered (i.e., what if things go wrong)? What if some party involved in the smart card system does not behave as expected? How bad can things get? What prevention tactics can be considered?" These are exactly the questions we want to answer in the security requirements analysis.

SECURITY REQUIREMENTS ANALYSIS WITH *i**

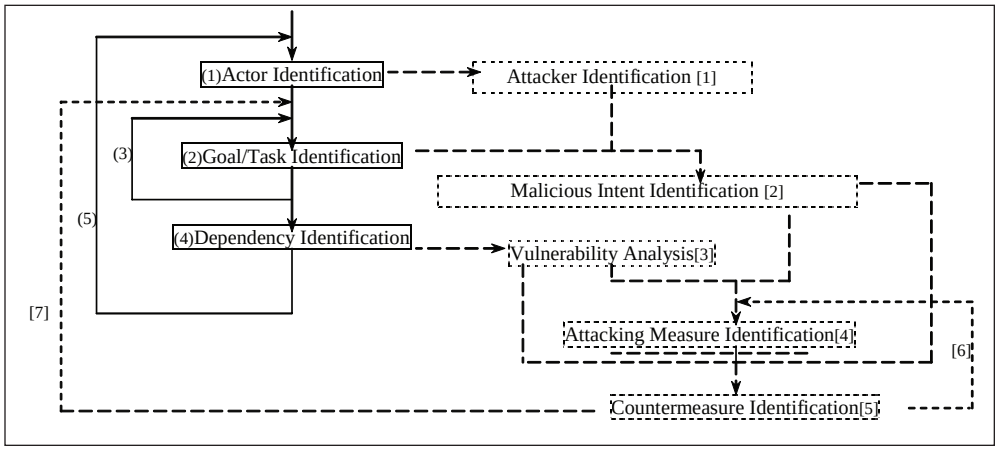
We now extend the process to include attacker analysis, vulnerability analysis, and countermeasure analysis. The dashed lines and boxes on the right hand side of Figure 5 indicate a series of analysis steps to deal with security. These steps are integrated into the basic domain requirements engineering process, such that threats from potential attackers are anticipated and countermeasures for system protection are sought and equipped wherever necessary. Each of the security related analysis steps (step [1] to [7]) will be discussed in detail in the following subsections.

Attacker Analysis

The attacker analysis steps aim to identify potential system abusers and their malicious intents. The basic premise here is that all the actors are assumed "guilty until proven innocent." In other words, given the result of the basic ***i**** requirements modelling process, we now consider any one of the actors (roles, positions, or agents) identified so far can be a potential attacker to the system or to other actors. For example, we want to ask, "In what ways can a terminal owner attack the system? How will he benefit from inappropriate manipulation of the card reader, or transaction data?"

In this analysis, each actor is considered in turn as an attacker. This attacker inherits the intentions, capabilities, and social relationships of the corresponding legitimate actor (i.e., the internal goal hierarchy and external dependency relationships

*Figure 5. Security requirements elicitation process with **i****



in the model). This may serve as a starting point of a forward direction security analysis (step [1] in Figure 5). A backward analysis starting from identifying possible malicious intents and valuable business assets can also be done.

Proceeding to step [2] of the process, for each attacker identified, we combine the capabilities and interests of the attacker with those of the legitimate actor. For simplicity, we assume that an attacker may be modeled as a role or an agent. To perform the attacker analysis, we consider that each role may be played by an attacker agent, each position may be occupied by an attacker agent, and that each agent may play an attacker role (Figure 6). The analysis would then reveal the commandeering of legitimate resources and capabilities for illicit use. The intents and strategies of the attackers are explicitly represented and reasoned about in the models.

This approach treats all attackers as insider attackers, as attacks are via associations with normal actors. We set a system boundary, then exhaustively search for possible attackers. Random attackers such as Internet hackers/crackers, or attackers breaking into a building can also be dealt with by being represented as sharing the same territory with their victim. By conducting analysis on the infrastructure of the Internet, we may identify attackers by treating Internet resources as resources in the ***i**** model. By conducting building security analysis, break-in attackers, or attackers sharing the same workspace can be identified. Alternatively, we could adopt an opposite assumption, i.e., assume there is a trusted perimeter for each agent, all the potential threat sources within this trusted perimeter are ignored, measures will only be taken to deal with threats from outside of the perimeter.

As shown in the Strategic Rationale model in Figure 7, the motives of Attacker in the smart card

Figure 6. Modelling attackers in strategic actors model

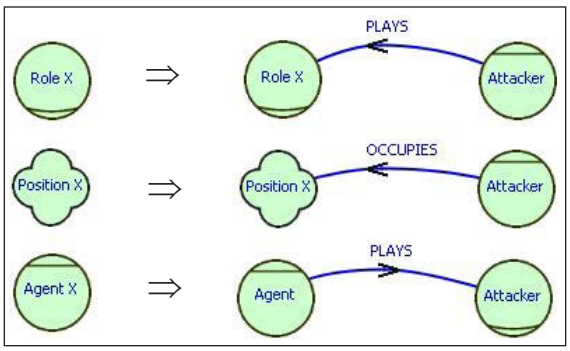


Figure 7. Motives of attacker in a smart card system

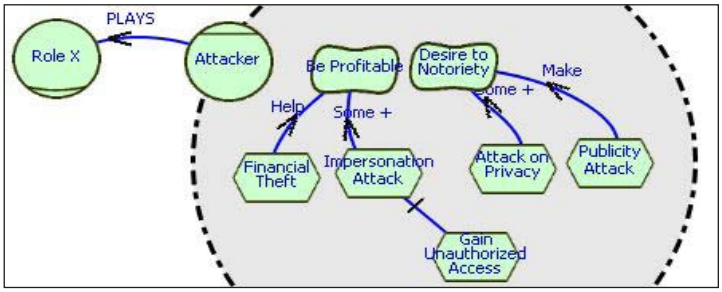

system may be modeled as intentional elements in an i* model. An attacker may be motivated by financial incentives (softgoal Be Profitable), or by non-financial ones (e.g., Desire for Notoriety). These malicious intents may lead to various attack strategies, such as Financial Theft, Impersonation Attack, Gain Unauthorized Access, Attack on Privacy, and Publicity Attack.

Dependency Vulnerability Analysis

Dependency vulnerability analysis aims at identifying the vulnerable points in the dependency network (step [3] in Figure 5). A dependency relationship makes the depender inherently vulnerable. Potential attackers may exploit these vulnerabilities to actually attack the system, so that their malicious intents can be served. ***i**** dependency modelling allows a more specific vulnerability analysis because the potential failure of each dependency can be traced to a depender and to *its* dependers. The questions we want to answer here are "which dependency relationships are vulnerable to attack?", "What are the chain effects if one dependency link is compromised?" The analysis of dependency vulnerabilities does not end with the identification of potential vulnerable points. We need to trace upstream in the dependency network, and see whether the attacked dependency relationship impacts other actors in the network.

Figure 8 is a simplified version of the SD model of Figure 4, showing only the softgoal dependencies. We assume that each of the actors in the SD model can be a potential attacker. And as an attacker, an actor will fail to deliver the expected dependencies directed to it, of whom it is the dependee.

For instance, the Card Holder depends on the Terminal Owner to Read/Write Card Correctly. To analyze the vulnerability arising from this dependency, we consider the case where the terminal owner is not trustworthy. And we try to identify the potential attacks by answering question of "In what possible ways could the attacker break this dependency relationship?" To do this, we elaborate on the agent Attacker Playing Terminal Owner. Starting from attacker's potential motivations, we refine the high-level goals of the attackers (and possible attack routes) based on analysis of the SD and SR models of the normal operations of the smart card (e.g., what resources an actor accesses, what types of interactions exist, etc.). In this way, we may identify a number of potential attacks that are sufficient to make this dependency not viable (*Break*).

Proceeding to step [4], we now focus on how an attacker may attack the vulnerable points identified above by exploring the attacker's capacities. We model potential attacks (including fraud) as negative contributions from the attackers (from their specific methods of attack) toward the de-

Figure 8. Dependencies (in other words, vulnerable points) in a smart card system

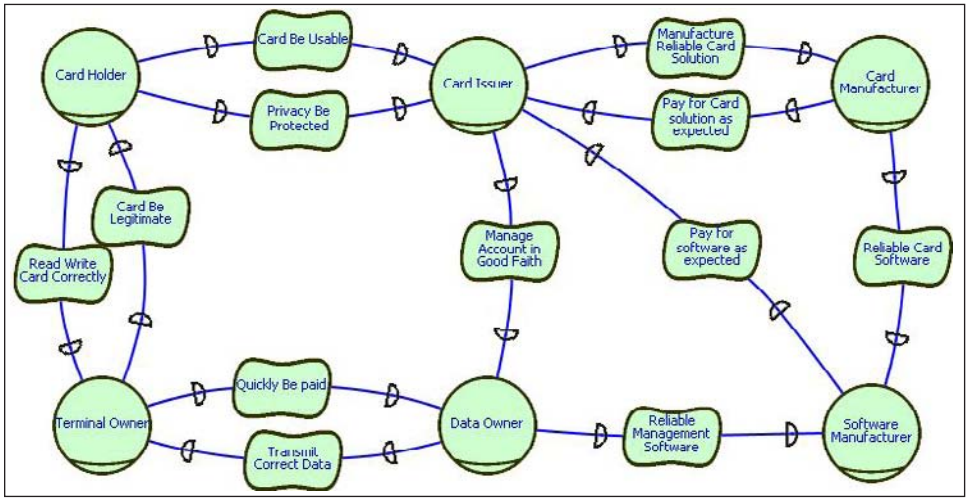

Figure 9. Attacks directed to vulnerable dependencies in a smart card system

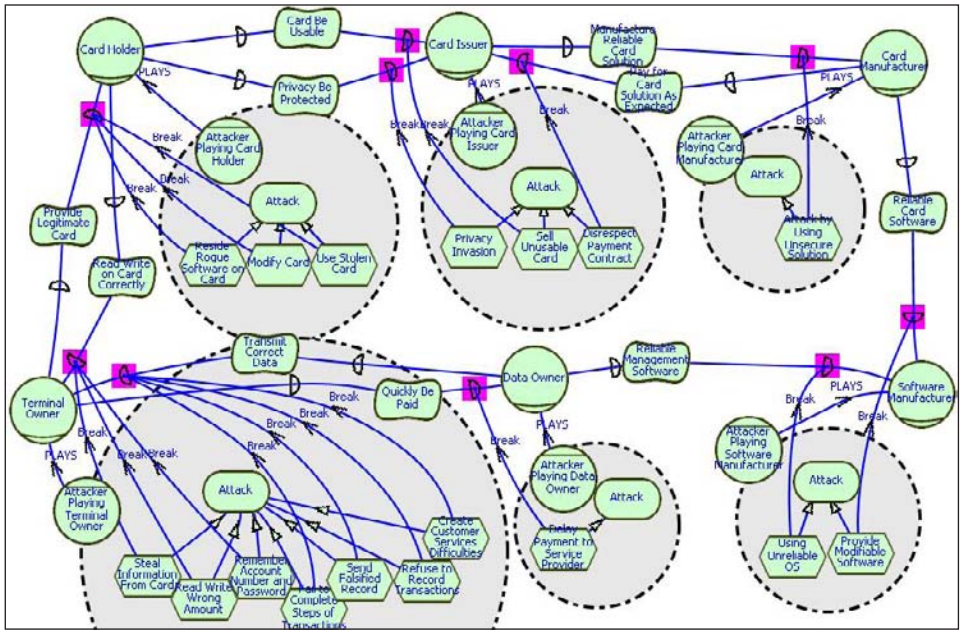


pendee-side dependency link. A *Break* contribution indicates that the attack is sufficient to make the softgoal unviable. For clarity of analysis, we place the attack-related intentional elements into agents called "Attacker Playing Role X." Details of the attack methods (e.g., Steal Card Information, Send Falsified Records) can be elaborated by further means-ends and decomposition analysis. Thus, the steps and methods of the attack can be modeled and analyzed. Other internal details of the Terminal Owner are not relevant and are thus not included in the model. Negative contribution

links are used to show attacks on more specific vulnerabilities of the depender (e.g., refinements of Transact with Card).

The dependencies that could be broken are highlighted with a small square in Figure 9. When a dependency is compromised, the effect could propagate through the dependency network upstream along the dependency links. For example, if the Terminal Owner is not Quickly Be Paid, he may stop accepting card as a payment option.

Countermeasure Analysis

During countermeasure analysis, system designers make decisions on how to mitigate vulnerabilities and set up defenses against potential attackers. This type of analysis covers general types of attacks, and formulates solutions by selectively applying, combining, or instantiating prototypical solutions to address the specific needs of various stakeholders. The general types of attacks and the prototypical solutions can be retrieved from a taxonomy or knowledge repository.

Necessary factors for the success of an attack are attacker's motivations, vulnerabilities of the system, and attacker's capabilities to carry out the attack. Thus, to counteract a hypothetical attack, we seek measures that will sufficiently negate these factors. Based on the above analysis, we already understand the attackers' possible malicious intents and system vulnerabilities. As shown in Figure 5, countermeasure analysis is an iterative process. Adding protective measures may bring new vulnerabilities to the system, so a new round of vulnerability analysis and countermeasure analysis will be triggered (step [6]).

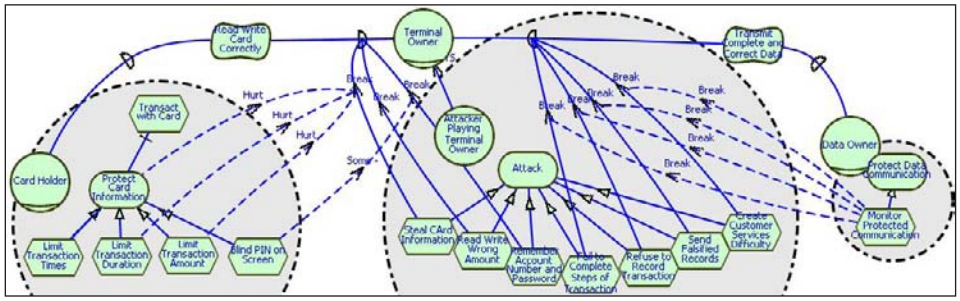
With the knowledge of some potential attacks and frauds, the depender may first look for trustworthy partners, or change their methods of operation, or add control mechanisms (countermeasures) to protect their interests. A countermeasure may prevent the attack from happening by either making it technically impossible, or by eliminating the attacker's intent of attack.

Figure 10 shows a SR model with defensive actions as well as attacks. Protection mechanisms are adopted to counteract specific attacks. In some cases, the protections are sufficient to defeat a strong attack (defense *Break* link (dotted arrow) pointing to an attack *Break* link). In other cases, countermeasures are only partially effective in defending against their respective attacks (through the *Hurt* or *Some*- contribution types).

Qualitative Goal-Reasoning Mechanism

A qualitative goal-reasoning process is used to propagates a series of labels through the models. A label (or satisficing status) on a node is used to indicate whether that intentional element (goal, task, resource, or softgoal) is viable or not (e.g.,

Figure 10. Resistance models defeating hypothetical attacks



whether a softgoal is sufficiently met). Labels can have values such as Satisfied "✓," Denied "✗," Weakly Satisfied "✓ " and Weakly Denied "✗," Undecided "?," etc. (Liu et al., 2003). Leaf nodes (those with no incoming contributions) are given labels by the analyst based on judgment of their independent viability. These values are then propagated "upwards" through the contribution network (following the direction of the contribution links, and from dependee to depender). The viability of the overall system appears in the high level nodes of the various stakeholders. The process is an interactive one, requiring the analyst to make judgments whenever the outcome is inconclusive given the combination of potentially conflicting contributions.

To begin, the analyst labels all the attack leaf nodes as Satisficed since they are all judged to be possible (Figure 11). Similarly, all the defense leaf nodes are judged to be viable, thus labelled Satisfied. The values are then propagated along contribution links. Before adding defense nodes, the Card Holder's dependency on the Terminal Owner for Read Write Card Correctly softgoal was labelled as Denied, because of the potentially strong attacks from Terminal Owner. However, as countermeasures are added, the influences of the attacks will be correspondingly weakened.

Regarding Read Write Card Correctly, three possible attacks are identified. One of them Steal Card Info is counteracted by three defense measures, though each one is partial (Hurt). Another attack Remember Account Number & Password has a defense of unknown strength (*Some-*). The third attack has no defensive measure. The softgoal dependency Read Write Card Correctly is thus judged to be weakly unviable (✗). On the other side, as the Data Owner's protection mechanism could sufficiently defeat the four possible attacks, the Transmit Complete and Correct Data softgoal dependency is thus judged to be viable (✓). Potential attacks lead to the erosion of viability of the smart card system. Incorporating sufficient countermeasures restores viability.

A prototype knowledge-based tool is being constructed to support this framework for analyzing information systems security.

Trust Analysis Based on System Configuration

In the models previously given, the various participants in a smart card system were modelled as abstract roles and analyzed generally. However, in real world smart card systems, various concrete physical or organisational parties play or occupy these roles. These are shown in Table 1. Thus, to actually understand their trust and security situations, we have to apply the generic model to the real world configurations. We consider

Figure 11. Countermeasure effectiveness evaluation model

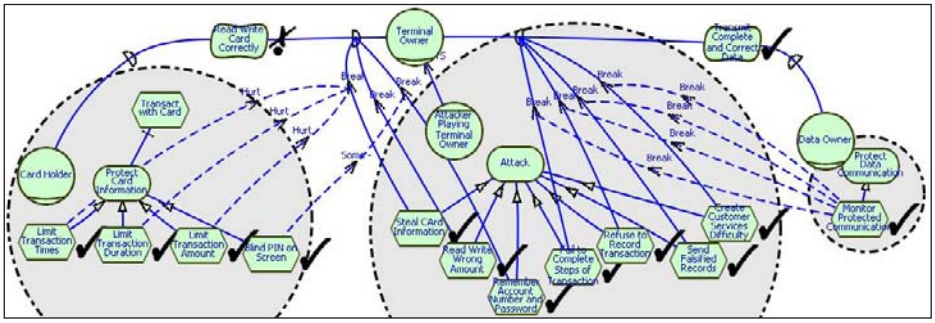


Table 1. Actors (roles, positions, and agents) in various smart card system configurations

Generic Smart Card Model	Card Holder	Terminal Owner	Card Issuer	Data Owner	Card Manufacturer	Software Manufacturer
Digital Stored Value card	Customer	Merchant	Financial Institution		Technology Company	
Digital Check Card	Customer	Merchant	Financial Institution	Customer	Technology Company	
Prepaid Phone Card	Customer	Phone Company				
Account-based Phone Card	Customer	Phone Company		Customer	Technology Company	
Key store card	User		Technology Company			
Employee Access Token	Employee	Employer				
Web browsing card	Customer		Financial Institution		Technology Company	

two representative kinds of smart card based systems. One is the Digital Stored Value Card, the other is the Prepaid Phone Card (Schneier & Shostack, 1998).

Digital Stored Value Card System

These are payment cards intended to be substitutes for cash. Both Mondex and VisaCash are examples of this type of system. The Customer is the Card Holder. The Merchant is the Terminal Owner. The Financial Institution that supports the system is both the Data Owner and the Card Issuer. The Smart Card Technology Company, such as Mondex, is both the Card Manufacturer and the Software Manufacturer.

In such a configuration, the previously separated roles of Data Owner and Card Issuer are Played by the same physical agent, namely, Financial Institution. Similarly, Card Manufacturer and Software Manufacturer are combined into one physical agent — the Smart Card Technology Company. Figure 12 describes the threat model of a digital stored value card. Here the Software Manufacturer's attack on Card Manufacturer can be ignored since they belong to the same agent — the Smart Card Technology Company. Also the attack from Data Owner to Card Issuer can be ignored since they both played by the Financial Institution. These two attacking-defending relationships are highlighted in Figure 11 with little squares.

Prepaid Phone Card System

These are special-use stored value cards. The Customer is the Card Holder. The Phone Company plays all the four roles of Terminal Owner, Data Owner, Manufacturer, and Card Issuer. Figure 13 shows the threat model of a prepaid card system. Under such a system configuration, more attack-defense pairs disappear. Only four possible attacks need to be considered now. Three of them are from the phone company, which includes violat-

Figure 12. A threat model of digital stored value card system

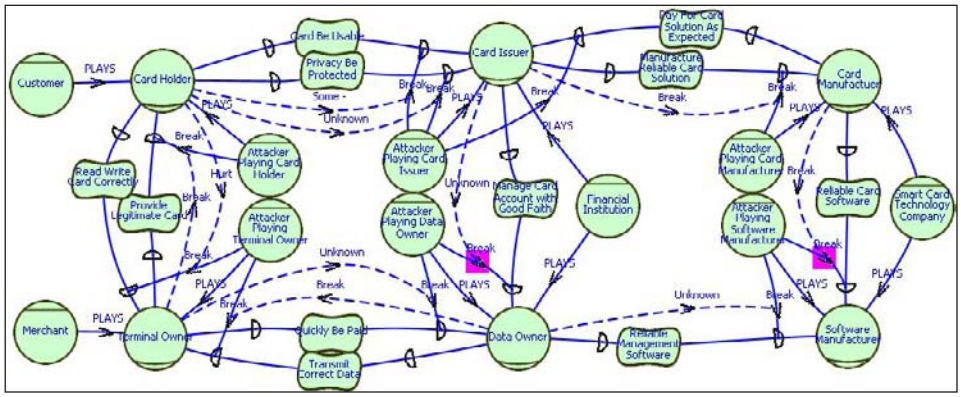

Figure 13. A threat model of prepaid phone card system

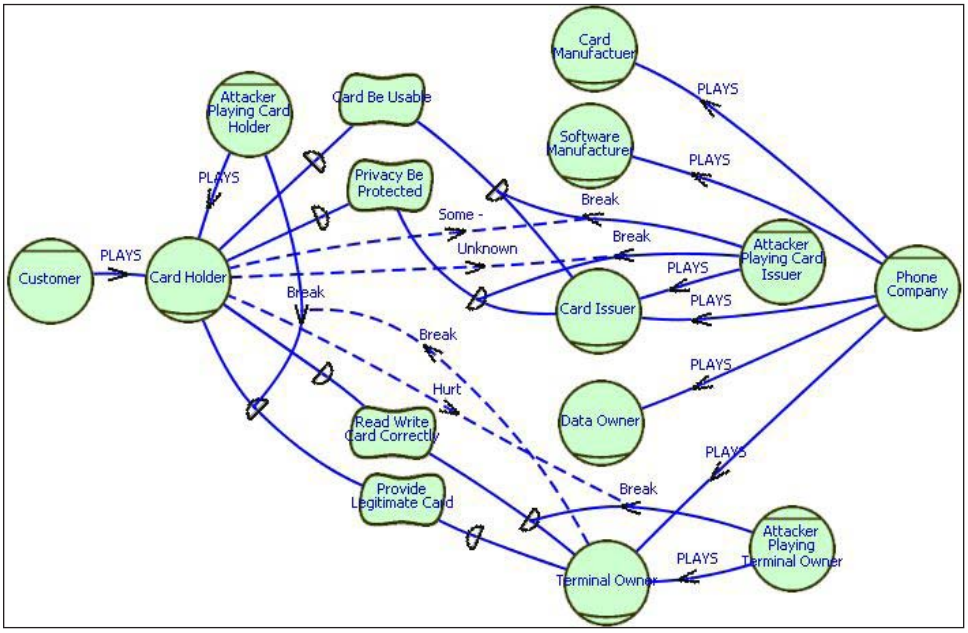

ing privacy, to issue unusable card, to read write card incorrectly. The other attack is from the Card Holder, who might use an illegitimate card.

Note that each time new roles are created, the possibility of new attacks arises. These models reflect Schneier's observation that the fewer splits we make, the more trustworthy the target system is likely to be (Schneier & Shostack, 1998).

RELATED WORK

This section is complementary to the review presented in Chapter I. Each approach to security and software engineering has an ontology, whether explicitly defined or implied. We expect that a social ontology can be complementary and beneficial to various approaches to integrating

security and software engineering. We begin with work from the security community, followed by software engineering approaches that have paid special attention to security.

Security Models

Formal models have been an important part of computer security since mainframe computing (Samarati & Vimercati, 2001). Security policies originate from laws, regulations, or organisational practices, and are typically written in natural language. Security models using mathematical formalisms can provide a precise formulation of the policies for implementation. More importantly, formally specified policy models can be mathematically verified to guarantee security properties. As mathematical abstractions, they provide unambiguous specifications that are independent of implementation mechanisms. Some concepts in security models include: subject, object, action, clearance level, user, group, role, task, principal, owner, etc.

Since security models are idealized abstractions, their application in real life requires a series of translations, involving interpretation and decision making at each stage. Organisational structures must be analyzed so as to select the appropriate models, or a combination of models. Policies need to be interpreted and codified properly to achieve the desired results. Real world entities and relationships are mapped to the model abstractions. Finally, the security model is mapped to security implementation mechanisms. The levels of abstractions used in security requirements, design, and implementation therefore mirror those in software system development and provide a basis for integration.

The social ontology outlined in this chapter can facilitate and augment an integrated security development process by enriching the reasoning support needed to arrive at decisions at each stage in the process. The ontology in existing security models are intended for the automated enforcement of specified security rules (e.g., to decide whether to give access). They do not support reasoning about why particular models or policies are appropriate for the target environment, especially when there are conflicting objectives and interpretations. Furthermore, many of the simplifying assumptions that formal models rely on do not hold in real life (Denning, 1999). The social ontology of strategic actors provides a framework for reasoning about the use of such models from a pragmatic, broader perspective.

In the development of new security models, there is a trend towards ontologies that are more closely aligned with the ontology of organisational work. For example, role based access control (RBAC) (Ferraiolo, Sandhu, Gavrila, Kuhn, & Chandramouli, 2001; Sandhu, Coyne, Feinstein, & Youman, 1996) allows privileges to be organised according to organisational roles such as loan officer or branch manager. These trends are consistent with the proposed social ontology approach, though RBAC models, like other access control models, are meant for enforcement, not strategic organisational reasoning.

Security Management Frameworks

While formal computer security models focus on policies built into the automated system, the overall security of information and software systems depends very much on organisational practices. Security practices have existed long before the computer age. Many of the principles continue to apply and have been adapted to software systems. Standards have been defined to promote best practices (e.g., ISO 17799, 1999).

OCTAVE (Alberts & Dorofee, 2002), CRAMM, and FRAP (Peltier, 2001), are oriented toward decision making from a business perspective, leading to management, operational, and technical requirements and procedures. Although few frameworks have explicit information models, they do have implicit ontologies revolving around key concepts such as asset, attack, threat, vulner-

ability, countermeasure, and risk.

The main focus of these frameworks is on prescriptive guidelines. Tables and charts are used to enumerate and cross-list vulnerabilities and threats. Potential countermeasures are suggested. Risks are computed from potential losses arising from estimated likelihood of threats. Since quantitative estimates are hard to come by, most assessments rely on ratings such as low, medium, high.

While formal computer security models attempt to guarantee security (requiring simplifying assumptions that may depart from reality), security management frameworks acknowledge that security breaches will occur, and suggest countermeasures to reduce risk. This pragmatic stance is very much in the spirit of the social ontology proposed in this chapter. Security management frameworks can be augmented by the modelling of strategic actor relationships and reasoning about how their goals may be achieved or hindered.

Another drawback of checklists and guidelines is that they tend to be too generic. Experience and expert judgment are needed to properly apply them to specific systems and organisational settings. Such judgments are hard to trace or maintain over time as the systems evolve.

The explicit modelling of strategic relationships can provide a more specific analysis of sources of vulnerabilities and failures, thus also allowing countermeasures to be targeted appropriately. Using the strategic dependencies and rationales, one can trace the impact of threats along the paths to determine which business goals are affected. The impact on goals other than security can also be determined through the model since they appear in the same model. One can see how security goals might compete with or are synergistic with non-security goals, thus leading to decisions that take the overall set of goals into account. Using an agent-oriented ontology, one can determine which actors are most affected by which security threats, and are therefore likely to be most motivated to take measures. Tradeoffs are done from the viewpoint of each stakeholder. This approach provides a good basis for an ontology of security, which can mediate between business reasoning from an organisational perspective and system design reasoning from a technical perspective.

Some preliminary work have been done to integrate the ***i**** modelling ontology with risk-based security management approaches (Gaunard & Dubois, 2003; Mayer, Rifaut, & Dubois, 2005). Further extensions could incorporate economic theories and reasoning (e.g., Anderson, 2001; Camp & Lewis, 2004). The ontology of ***i**** can provide the structure representation of social relationships on which to do economic reasoning.

Software Systems Design Frameworks

Having considered work originating from the security side, we now turn to contributions from the software engineering and system development perspective.

Extensions to UML (see Chapter I for information of such approaches).The ontology of UML, consisting of objects and classes, activities, states, interactions, and so forth, with its security-oriented extensions, are useful for specifying the technical design of security features and functionalities, but does not support the reasoning that lead up to those requirements and designs. As indicated in the second section of this chapter, technical design notations are useful for recording the results of decisions, but do not offer support for arriving at those decisions. The social ontology proposed in this chapter can therefore complement UML-based approaches, such as the one presented in Chapter IX, by supporting the early-stage requirements modelling and reasoning that can then be propagated to the technical design stage, resulting in design choices expressed in UML-like design notations. Stakeholder deliberations and tradeoffs therefore

are effectively conveyed to technical designers. Conversely, the effect of technical choices can be propagated upstream to enable stakeholders to appreciate the consequences as they appear in the stakeholders' world.

Extensions to information systems modelling and design. In the information systems area, Pernul (1992) proposes secure data schemas (extension of entity-relationship diagrams) and secure function schemas (extension of data flow diagrams). In Herrmann and Pernul (1999) and Röhm and Pernul (1999), these models are extended to include a business process schema, with tasks, data/material, humans, legal bindings and information flow, and an organisational schema with role models and organisation diagrams to describe which activities are done where and by whom. Other information systems security approaches include the automated secure system development method (Booysen & Eloff, 1995) and the logical controls specification approach (Baskerville, 1993; Siponen & Baskerville, 2001).

These approaches illustrate the extension of conventional information systems ontologies to incorporate security-specific ontologies. Different concepts are added to each level of modelling (e.g., database schemas, process or function schemas, workflow schemas, and organisation diagrams). As with UML extensions, these approaches tend to emphasize the notation needed to express security features in the requirements specification or design descriptions and how those features can be analyzed. However, the notations (and the implied ontology) do not provide support for the deliberations that lead up to the security requirements and design. A social ontology that supports explicit reasoning about relationships among strategic actors, as outlined in this chapter, can be a helpful extension to these approaches.

Responsibility modelling. A number of approaches center around the notion of responsibility. In Strens and Dobson (1994), when an agent delegates an obligation, the agent becomes a responsibility principal, and the receiver of the delegation process is a responsibility holder. An obligation is a high-level mission that the agent can fulfill by carrying out activities. Agents cannot transfer their responsibilities, only their obligations. Three kinds of requirements are derived from responsibilities: need-to-do, need-to-know and need-for-audit. The need-to-know requirements relate to security policies — which subjects (e.g., users) should be allowed to access which objects (e.g., files, etc.) so that they are able to fulfill their responsibilities.

Backhouse and Dhillon (1996) also adopt a responsibilities analysis approach, incorporating speech acts theory. The model for automated profile specification (MAPS) approach (Pottas & Solms, 1995) uses responsibilities and role models to generate information security profiles (such as access control) from job descriptions and organisational policies.

This group of work has a more explicit ontology of social organisation. The emphasis is on the mappings between organisational actors and the tasks or activities they have to perform. While actors or agents have responsibilities, they are not viewed as having strategic interests, and do not seek alternate configurations of social relationships that favor those interests. The focus of attention is on functional behaviors and responsibilities. Security is treated as additional functions to be incorporated, and there are no attempts to deal with interactions and tradeoffs between security and other non-functional objectives such as usability or maintainability. The social ontology of ***i**** can therefore be quite complementary to these approaches. Other socio-organisational approaches are reviewed in Dhillon and Backhouse (2001).

Requirements Engineering Approaches to Security

While security needs to be integrated into all stages of software engineering, there is general agreement that integration starting from the

earliest stages is essential. It is well known that mistakes early in the software process can have far reaching consequences in subsequent stages that are difficult and costly to remedy. Fred Brooks (1995) had noted that the requirements stage is the most difficult, and suggested that software engineering should focus more on "building the right system," and not just on "building the system right."

In requirements engineering research, a large part of the effort has been devoted to verifying that the requirements statements are precise, unambiguous, consistent, and complete. Recently, more attention has been given to the challenge of understanding the environment and context of the intended system so that the requirements will truly reflect what stakeholders want.

Goal-oriented requirements engineering. Traditional requirements languages for software specification focus on structure and behavior, with ontologies that center around entities, activities, states, constraints, and their variants. A goal-oriented ontology allows systems to be placed within the intentional setting of the usage environment. Typically, goal-oriented requirements engineering frameworks employ AND/OR tree structures (or variants) to analyze and explore alternate system definitions that will contribute to stakeholder goals in different ways. Security can be readily integrated into such a framework since attacks and threats interfere with the normal achievement of stakeholder goals. Security controls and countermeasures can be derived from defensive goals to counteract malicious actions and intents.

The NFR framework: Security as softgoal. The NFR framework (Chung, 1993; Chung et al., 2000) is distinctive from most of the above cited approaches to security in that it does not start with vulnerabilities and risks, nor from security features and functions. It starts by treating security as one among many non-functional requirements. As with many other non-functional requirements such as usability, performance, or information accuracy, security is viewed as a goal whose operational meaning needs to be interpreted according to the needs of the specific application setting. This interpretation is done by a series of refinements in a goal graph until the point (called operationalization) where subgoals are sufficiently concrete as to be accomplishable by implementable actions and mechanisms, such as access control mechanisms or protocols. At each stage in the refinement, subgoals are judged to be contributing qualitatively to the parent goals in different ways. Because the nature and extent of the contribution requires judgement from experience and possibly domain expertise, the term softgoal is used, drawing on Simon's notion of satisficing (Simon, 1996).

The NFR framework thus offers a systematic approach for achieving "good enough" security — a practical objective in real life (Sandhu, 2003; Schneier, 2003) that have been hard to achieve in conventional mathematical formalisms. A formal treatment of the satisficing semantics of softgoals is offered in Chung et al. (2000).

The NFR framework is also distinctive in that it allows security goals to be analyzed and understood at the same time as other potentially competing requirements, for example, usability, performance, maintainability, and evolvability. In the past, it has been difficult to deal with these non-functional requirements early in the development life cycle. Typically functional requirements dominate the design process. Experienced and expert designers take non-functional requirement into account intuitively and implicitly, but without support from systematic frameworks, languages, or tools. The softgoal graph approach acknowledges that security needs to compete with other goals during requirements analysis and during design. Different aspects of security may also compete with each other. The NFR goal-oriented approach supports reasoning about tradeoffs among these competing goals and how they can be achieved.

Beyond clarifying requirements, the NFR softgoals are used to drive subsequent stages in

system design and implementation, thus offering a deep integration of security into the software engineering process.

A related body of work is in quality attributes of software architecture, for example, the ATAM approach (Kazman, Klein, & Clements, 2000) for architectural evaluation. Many of the basic elements are similar to the NFR framework. The classification of quality attributes and mechanisms (for security and other attributes), however, are viewed from an evaluation viewpoint. The taxonomy structure of quality attribute is not seen as goals to be elaborated based on tradeoffs encountered in the particular system. Quality attributes are concretized in terms of metrics, which are different for each quality, so trade-offs are difficult across different metrics.

The KAOS framework: Goals, obstacles, and anti-goals. KAOS (Dardenne, van Lamsweerde, & Fickas, 1993; van Lamsweerde, 2001, 2004; van Lamsweerde, Brohez, Landtsheer, & Janssens, 2003) is a goal-oriented requirements engineering framework that focuses on systematic derivation of requirements from goals. It includes an outer layer of informally specified goals, and an inner layer of formalized goal representation and operations using temporal logic. It is therefore especially suitable for real-time and safety critical systems. Refinement patterns are developed making use of temporal logic relationships.

The KAOS ontology includes obstacles, which impede goal achievement. The methodology provides techniques for identifying and resolving obstacles. To incorporate security analysis, attackers present obstacles to security goals. New security requirements are derived from attack generation and resolution.

Tree structures have been used in the security community for analyzing the structure of threats (Schneier, 1999), and in the safety community for the analysis of faults and hazards (Helmer et al., 2002). Experiences from these approaches can be incorporated into goal-oriented frameworks.

Agent-Oriented Requirements Engineering

The agent-oriented approach adopts goal-oriented concepts and techniques, but treats goals as originating from different actors. The ***i**** modelling framework views actors as having strategic interests. Each actor aims to further its own interests in exploring alternative conceptions of the future system and how the system will affect its relationships to other actors. This may be contrasted with other frameworks which may include some notion of actor which are non-intentional (e.g., in use case diagrams in UML) or non-strategic (e.g., in KAOS, where agents are passive recipients of responsibility assignments at the end of a goal refinement process).

i* adopts the notion of softgoal from the NFR framework, but makes further distinctions with goal, task, and resource. Softgoals are operationalized into tasks, which may in turn contain decompositions that include softgoals.

Security issues are traced to antagonistic goals and dependencies among attackers and defenders. As in the NFR framework, security is treated as much as possible within the same notational and reasoning framework as for other non-functional requirements (as softgoals), but extended to include functional elements (as goals, tasks, and resources). Security is therefore not treated in isolation, but interacts with other concerns at all steps throughout the process. The illustration of ***i**** in this chapter is based on the example in Yu and Liu (2000, 2001). Further illustrations are in Liu et al. (2002), Yu and Cysneiros (2001), Liu et al. (2003), Liu and Yu (2003, 2004).

The ***i**** approach has been adopted and extended in a number of directions. The Tropos framework (Bresciani, Perini, Giorgini, Giunchiglia, & Mylopoulos, 2004; Castro, Kolp, & Mylopoulos, 2002) further develops the ***i**** approach into a full-fledged software engineering methodology, using the agent-oriented social ontology originating from

requirements modelling to drive architectural design, detailed design, and eventual implementation on agent-based software platforms. Formal Tropos incorporates formalization techniques similar to KAOS, so that automated tools such as model checking can be applied to verify security properties (Liu et al., 2003).

A number of extensions to ***i**** have been developed to address specific needs of security modelling and analysis. Mouratidis et al. (2003a, 2003b, 2004, 2005, also Chapter VIII) introduced the concepts of security reference diagram and security constraints. Common security concepts such as secure entities, secure dependencies, and secure capabilities are reinterpreted within the ***i**** ontology. The security constraint concept attaches a security-related strategic dependency to the dependency that it applies to. An intuitive benefit of this concept is that the association between the two is indicated without having to refer to the internal rationale structures of actors. An attack scenarios representation structure that aims to support the analysis of specific attacking and protecting situations at a more detailed design stage is developed. New language structures developed include secure capability, and attacking link.

Giorgini et al. (2003, 2005; also Chapter VIII) introduced four new primitive relationships related to security requirements: trust, delegation, offer and owner relation. These new primitives offer an explicit treatment of security concepts such as permission, ownership, and authority, which allows a more detailed analysis.

In Crook, Ince, and Nuseibeh (2005), the problem of modelling access policies is addressed by extending the Tropos approach (Liu et al., 2003), to ensure that security goals can be achieved and that operational requirements are consistent with access policies.

Misuse/Abuse Cases

Misuse and abuse cases techniques (Alexander, 2001; Sindre & Opdahl, 2000, 2001; see also Review in Chapter I) are complementary to goal-oriented techniques as they offer different ways of structuring requirements knowledge (Rolland, Grosz, & Kla, 1999). Use cases are action-oriented and include sequence and conditionals. Goal refinements are (mostly) hierarchical covering multiple levels of abstraction. In addressing security requirements, the development of misuse/abuse cases can be assisted by using goal analysis. Conversely, goal analysis can be made concrete by considering positive and negative use cases and scenarios. Note that use cases are better suited to later stages in requirements analysis since they assume that the system boundary is already defined. Unlike the strategic actors in ***i****, actors in use cases are non-intentional and serve to delineate the boundary of the automated system.

CONCLUSION

In this chapter, we have argued that a social ontology can provide the basis for integrating security and software engineering. We presented the social ontology of ***i**** and illustrated how it can be used to include security goals when designing a smart card system. We have outlined how a social ontology is complementary to a number of techniques in security engineering and in software engineering, thus building common ground between the two areas.

Chapter 2.15
Social Structure Based Design Patterns for Agent-Oriented Software Engineering

Manuel Kolp

Yves Wautelet
Université catholique de Louvain, Belgium

ABSTRACT

Multi-agent systems (MAS) architectures are gaining popularity over traditional ones for building open, distributed, and evolving software required by today's corporate IT applications such as e-business systems, Web services, or enterprise knowledge bases. Since the fundamental concepts of multi-agent systems are social and intentional rather than object, functional, or implementation-oriented, the design of MAS architectures can be eased by using social patterns. They are detailed agent-oriented design idioms to describe MAS architectures composed of autonomous agents that interact and coordinate to achieve their intentions, like actors in human organizations. This article presents social patterns and focuses on a framework aimed to gain insight into these patterns. The framework can be integrated into agent-oriented software engineering methodologies used to build MAS. We consider the Broker social pattern to illustrate the framework. An overview of the mapping from system architectural design (through organizational architectural styles), to system detailed design (through social patterns), is presented with a data integration case study. The automation of creating design patterns is also discussed.

INTRODUCTION

This section introduces and motivates the research. In Section 1.1, we describe the advantages of using multi-agent systems over traditional systems. Section 1.2 presents the importance of *patterns* for designing information systems. We formulate our research proposal in Section 1.3. The section 1.4 introduces elements for work validation. The context of the research and an overview of the state of the art are given in Section 1.5. Finally, Section 1.6 presents the organization of the article.

Advantages of Multi-Agent Systems

The meteoric rise of Internet and World Wide Web technologies has created new application areas for enterprise software, including e-business, Web services, ubiquitous computing, knowledge management and peer-to-peer networks. These areas demand software that is robust, can operate within a wide range of environments, and evolve over time to cope with changing requirements. Moreover, such software has to be highly customizable to meet the needs of a wide range of users, and sufficiently secure to protect personal data and other assets on behalf of its stakeholders.

Not surprisingly, researchers are looking for new software designs that can cope with such requirements. One promising source for designing such business software is the area of multi-agent systems. Multi-agent system architectures appear to be more flexible, modular, and robust than traditional architectures including object-oriented ones. They tend to be open and dynamic in the sense they exist in a changing organizational and operational environment where new components can be added, modified or removed at any time.

Multi-agent systems are based on the concept of agent which is defined as "a software component situated in some environment that is capable of flexible autonomous action in order to meet its design objective" (Aridor & Lange, 1998). An agent exhibits the following characteristics:

- **Autonomy:** an agent has its own internal thread of execution, typically oriented to the achievement of a specific task, and it decides for itself what actions it should perform at what time.
- **Situateness:** agents perform their actions in the context of being situated in a particular environment. This environment may be a computational one (e.g., a Web site) or a physical one (e.g., a manufacturing pipeline). The agent can sense and affect some portion of that environment.
- **Flexibility:** in order to accomplish its design objectives in a dynamic and unpredictable environment, the agent may need to act to ensure that its goals are achieved (by realizing alternative plan). This property is enabled by the fact that the agent is autonomous in its problem solving.

An agent can be useful as a stand-alone entity that delegates particular tasks on behalf of a user (e.g., a personal digital assistant and e-mail filter (Bauer, Muller & Odell, 2001), or a goal-driven office delivery mobile device (Castro, Kolp & Mylopoulos, 2002)). However, in the overwhelming majority of cases, agents exist in an environment that contains other agents. Such environment is a multi-agent system (MAS).

In MAS, the global behavior derives from the interaction among the constituent agents: they cooperate, coordinate or negotiate with one another. A multi-agent system is then conceived as a society of autonomous, collaborative, and goal-driven software components (agents), much like a social organization. Each role an agent can play has a well defined set of responsibilities (goals) achieved by means of an agent's own abilities, as well as its interaction capabilities.

This *sociality* of an MAS is well suited to tackling the complexity of today's organization software systems for a number of reasons:

- It permits a better match between system architectures and its organizational operational environment for example a public organization, a corporation, a non-profit association, a local community, and so forth.
- The autonomy of an agent (i.e., the ability an agent has to decide what actions it should take at what time (Aridor & Lange, 1998)) reflects the social and decentralized nature of modern enterprise systems (Bauer et al., 2001) that are operated by different stakeholders (Parunak, 1997).
- The flexible way in which agents operate to accomplish its goals is suited to the dynamic and unpredictable situations in which business software is now expected to run (see Zambonelli, Jennings, Omicini & Wooldridge, 2000; Zambonelli, Jennings & Wooldridge, 2000).

MAS architectures become rapidly complicated due to the ever-increasing complexity of these new business domains and their human or organizational actors. As the expectations of the stakeholders change every, the complexity of the systems and the communication technologies of organizations continually increases in today's dynamic environments. Developers are expected to produce architectures that must handle more difficult and intricate requirements that were not taken into account 10 years ago, making thus architectural design a central engineering issue in modern enterprise information system life-cycle (Aridor & Lange, 1998).

Patterns for Designing Systems

An important technique that helps to manage this complexity when constructing and documenting such architectures is the reuse of development experience and know how. Over the past few years, *design patterns* have significantly contributed to the reuse of design expertise, improvement application documentation and more flexible and adaptable designs (Bosch, 1998; Buschmann, Meunier, Rohnert, Sommerlad & Stal, 1996; Gamma, Helm, Johnson & Vlissides, 1995). The idea behind a pattern is to record the essence of a solution to a design problem so as to facilitate its reuse when similar problems are encountered (Cockburn, 1996; Pree 1994; Riehle & Züllighoven, 1996).

Considerable work has been done in software engineering on defining design patterns (Gamma et al., 1995; Buschmann et al., 1996; Bosch, 1998). Unfortunately, they focus on object-oriented (Fernandez & Pan, 2001) rather than agent-oriented systems. In the area of multi-agent systems, little emphasis has been put on social and intentional aspects. Moreover, the proposals of agent patterns that could address those aspects (see e.g., Aridor & Lange, 1998; Deugo, Oppacher, Kuester & Otte, 1999; Hayden, Carrick & Yang, 1999) are not aimed at the design level, but rather at the implementation of lower-level issues like agent communication, information gathering, or connection setup. For instance, the Foundation for Intelligent Physical Agents (FIPA, 2007) identified and defined a set of agent's interaction protocols that are only restricted to communication. This research fills this gap by propping a series of social patterns for the detailed design phase of Tropos so that pattern-oriented development can be fully integrated at higher level development stages.

A Framework for MAS Detailed Design

Since there is a fundamental mismatch between the concepts used by the object-oriented paradigm (and other traditional mainstream software engineering approaches) and the agent-oriented approach (Jennings & Wooldridge, 2001), there

is a need to develop high level patterns that are specifically tailored to the development of (multi-)agent systems using agent-oriented primitives.

Research objective is to take the principles of a social organization-based approach that contributes to reduce the distance between the system and the real world together with the important role of design patterns to help to reuse design experience. This research proposes a design framework and develops a catalogue of social patterns for making MAS design more efficient. Research contributions include:

- A framework composed of a set of complementary dimension for designing MAS. The concepts and notions used for each dimension are introduced and illustrated;
- A catalogue of social patterns to help the designer's tasks so that development time is reduced. Each social pattern in the catalogue will be designed in detail through this framework; and
- A tool for designing MAS. It allows the designer to: (i) design the components of a MAS-to-be constructed in a graphical way, (ii) reuse the catalogue of patterns to construct the MAS, and (iii) generate the code for automating the programmer task.

The research also brings secondary contributions:

- A set of predefined predicates integrated into an extended version of formal Tropos for formalizing each pattern; and
- The illustration of concepts introduced in our framework through a case study.

Validation

The social patterns for developing a business data integration application have been applied to multiple case studies. The reusability of these patterns and the code generation help to reduce the development tasks of the application on both designer and programmer sides.

Furthermore, an empirical experience to evaluate the benefits of pattern-oriented development should be to achieve similar case studies with and without the use of patterns and to evaluate the results on the basis of software metrics. To focus on the contribution of the design-patterns we point to structural complexity evaluation. Indeed, structural complexity focuses on MAS architecture and agent relationships, features that should be enriched using patterns.

Due to the lack of literature concerning agent-oriented software metrics evaluating structural complexity, we point to the use of existing object-oriented ones. As a preliminary tests suite, we claim for the use of the metrics proposed by Chidamber and Kemerer (1994). Those include:

- The depth of inheritance tree (DIT). This metric measures the maximum level of the inheritance hierarchy of a class. The root of the inheritance tree inherits from no class and has a DIT count of zero. Chidamber and Kemerer suggest that DIT can be used to indicate the complexity of the design, potential for reuse;
- The number of children (NOC). This metric counts the number of immediate subclasses belonging to a class. NOC was intended to indicate the level of reuse in a system and a possible indicator of the level of testing required;
- The lack of cohesion in methods (LCOM). This metric is intended to measure the lack of cohesion in the methods of a class. It is based on the principle that different attributes occurring in different methods of a class causes that class to be less cohesive than one where the same attribute is used in few methods of the class. It is viewed that a lack of cohesiveness as undesirable as it

is against encapsulation. Lack of cohesion could imply that the class should probably be split into two or more subclasses;
- The weighted methods per class (WMC). The sum of the complexities of the methods in a class;
- The coupling between objects (CBO). The number of other classes whose methods or instance attribute(s) are used by methods of this class;
- The response for a class (RFC). The sum of the number of methods in the class and the number of methods called by each of these methods, where each called method is counted once.

Context of the Research and Limitations

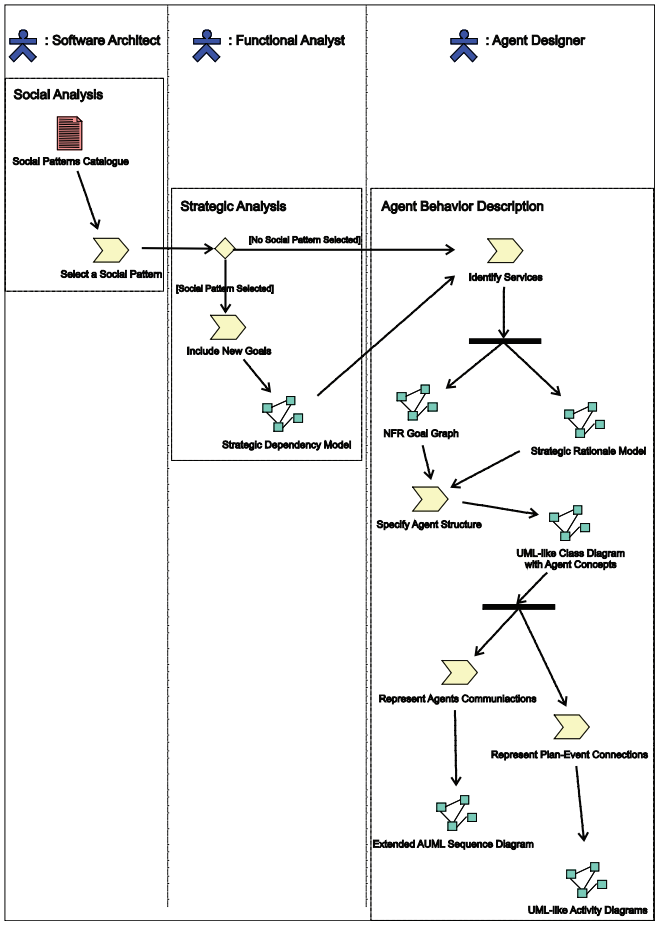
Design patterns are generally used during the *detailed design* phase of software methodologies. Agent-oriented methodologies such as TROPOS (Castro et al., 2002), GAIA (Woodridge, Jennings & Kinny, 2000), MASE (Wood, DeLoach & Sparkman, 2001) and MESSAGE (Caire et al., 2002) span the following steps of software engineering:

- Early requirements, concerned with the understanding of a problem by studying an organizational setting; the output is an organizational model which includes relevant actors, their goals and their interdependencies.
- Late requirements, where the system-to-be is described within its operational environment, along with relevant functions and qualities.
- Architectural design, where the system architecture is defined in terms of subsystems, interconnected through data, control, and dependencies.
- Detailed design, where the behavior of each architectural components is defined in detail.

The catalogue of social patterns proposed in (Kolp, Giorgini, & Mylopoulos, 2002) constitutes a contribution to the definition of agent-oriented design patterns. This article focuses on these patterns, conceptualizes a framework to explore them and facilitate the building of MAS during detailed design as well as the generation of code for agent implementation. It models and introspects the patterns along different complementary dimensions.

As pointed out, the patterns proposed into this article take place at Tropos' detailed design step. The process described hereafter is part of a broader methodology called I-Tropos (Wautelet, Kolp & Achbany, 2006) based on Tropos, driven by i* diagrams and organized following an iterative software development life cycle. This methodology is conceived to bring agent-oriented development to be adopted into real life development of huge enterprise information systems. Due to lack of space we only present the detailed design discipline in the form of a workflow, more details can be found in (Kolp, Faulkner & Wautelet, 2007). Figure 1 describes the workflow of the detailed design discipline using the *software process engineering metamodel* (*SPEM*) notation (see OMG, 2005). The software architect selects the most appropriate social patterns for the components under development from the catalogue overviewed in the article. New goals are included to the strategic dependency model (social dimension) according to the semantics of the pattern. The agent designer identifies services provided by each agent to achieve the goal dependencies. Each service belongs to an agent and is represented with an NFR goal analysis to refine the strategic rationale diagram (intentional dimension). The structure of each agent and its components such

Figure 1. The detailed design workflow



as plans, events, and beliefs are then specified with an agent UML class diagram (structural dimension). Agents communicate through events exchanged in the system and modeled in a temporal manner with extended agent UML sequence diagrams (communicational dimension). The synchronization and the relationships between plans and events are designed through agent oriented activity diagrams (dynamic dimension).

We nevertheless point out some important limitations of our research:

- We only consider the design of cooperative MASs. Indeed, MAS may be either cooperative or competitive. In a cooperative MAS, the agents cooperate together in order to achieve common goals. Inversely, a competitive MAS is composed of agents that pursue personal goals and defend their own interests. The design of competitive MAS is left for future developments;
- The patterns need to gain experience with their use. In this article, we have applied them on a case study. By doing so, we have explored the applicability of patterns and shown how our framework can help the design of MAS. However, it should be tested on more case studies;

- The dissertation only considers an MAS composed of more than one pattern as an "addition" of them. However, the combination of multiple patterns in an MAS is more complicated than that, and the emergence of conflicts remains possible. This issue needs further investigation.

Paper Organization

The article is organized as follows. In section 2, we describe the patterns. Section 3 proposes the framework and illustrates its different modeling dimensions through the broker pattern. A *data integrator* case study that illustrates the mapping from organizational styles (architectural design phase) to social patterns (detailed design phase), is presented in section 4. The automation of social patterns is overviewed in section 5, while section 6 overviews related work on software patterns. Finally, section 7 points to some conclusions.

SOCIAL PATTERNS

Social patterns can be classified in two categories. The *pair* patterns describe direct interactions between negotiating agents. The *mediation* patterns feature intermediate agents that help other agents to reach agreement about an exchange of services.

In the following, we briefly model patterns using i* (Do, Kolp, Hang Hoang, & Pirotte, 2003) and AUML (Bauer et al., 2001) sequence diagrams respectively to represent the social and communicational dimensions of each pattern. In i*, agents are drawn as circles and their intentional dependencies as ovals. An agent (the *depender*) depends upon another agent (the *dependee*) for an intention to be fulfilled (the *dependum*). Dependencies have the form *depender* → *dependum* → *dependee*. Note that i* also allows to model other kind of dependencies such as resource, task or strategic ones respectively represented as rectangles,

Figure 2. Social and communicational diagrams for the booking pattern

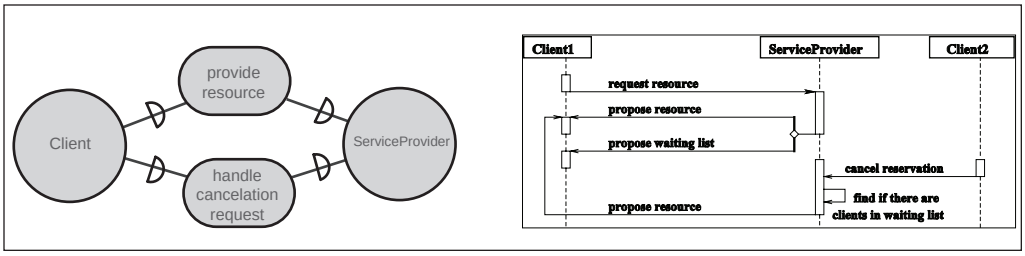


Figure 3. Social and communicational diagrams for the bidding pattern

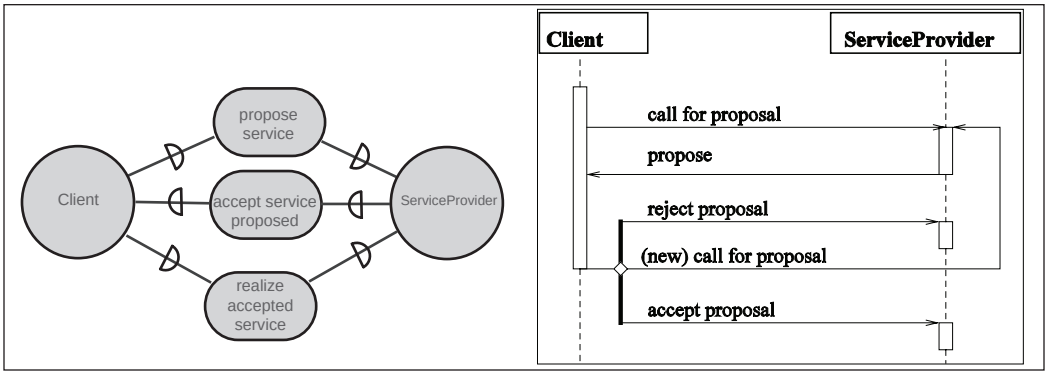

hexagons and clouds as we will see in Figure 13. AUML extends classical sequence diagrams for agent oriented modeling. For instance, the diamond symbol indicates alternative events.

The broker, as well as the subscription and call-for-proposal patterns that are both part of the broker pattern, will be modeled in detail to explain the framework in section 3.

Pair Patterns

The **booking** pattern (Figure 2) involves a client and a number of service providers. The client issues a request to book some resource from a service provider. The provider can accept the request, deny it, or propose to place the client on a waiting list, until the requested resource becomes available when some other client cancels a reservation.

The **subscription** pattern involves a yellow-page agent and a number of service providers. The providers advertise their services by subscribing to the yellow pages. A provider that no longer wishes to be advertised can request to be unsubscribed.

The **call-for-proposals** pattern involves an initiator and a number of participants. The initiator issues a call for proposals for a service to all participants and then accepts proposals that offer the service for a specified cost. The initiator selects one participant to supply the service.

The **bidding** (Figure 3) pattern involves a client and a number of service providers. The client organizes and leads the bidding process, and receives proposals. At each iteration, the client publishes the current bid; it can accept an offer, raise the bid, or cancel the process.

Mediation Patterns

In the **monitor** pattern (Figure 4), subscribers register for receiving, from a monitor agent, notifications of changes of state in some subjects of their interest. The monitor accepts subscriptions, requests information from the subjects of interest, and alerts subscribers accordingly.

In the **broker** pattern, the broker agent is an arbiter and intermediary that requests services from providers to satisfy the request of clients.

In the **matchmaker** pattern (Figure 5), a matchmaker agent locates a provider for a given service requested by a client, and then lets the client interact directly with the provider, unlike brokers, who handle all interactions between clients and providers.

In the **mediator** pattern (Figure 6), a mediator agent coordinates the cooperation of service provider agents to satisfy the request of a client agent.

Figure 4. Social and communicational diagrams for the monitor pattern

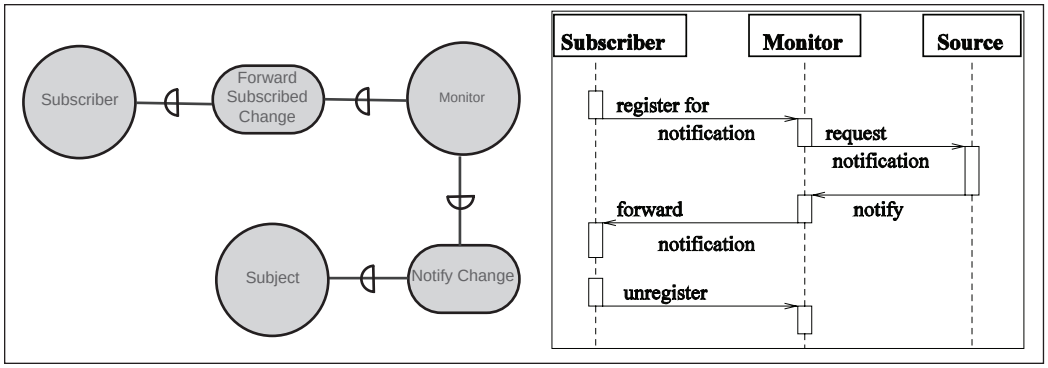

Figure 5. Social and communicational diagrams for the matchmaker pattern

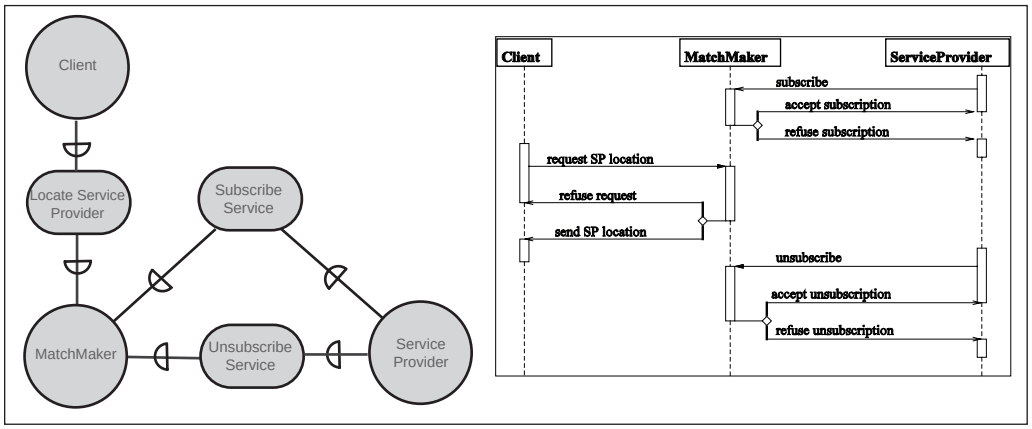

Figure 6. Social and communicational diagrams for the mediator pattern

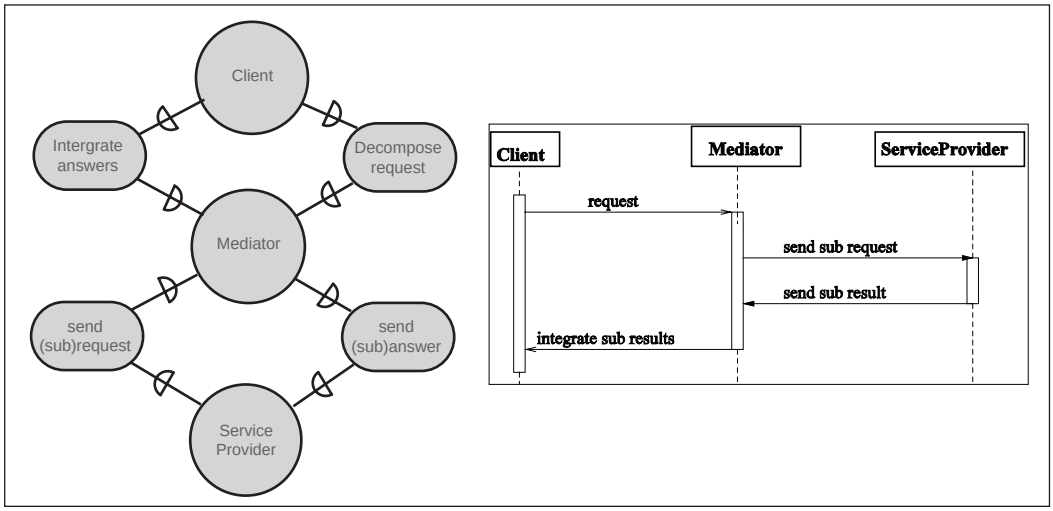

Figure 7. Social and communicational diagrams for the wrapper pattern

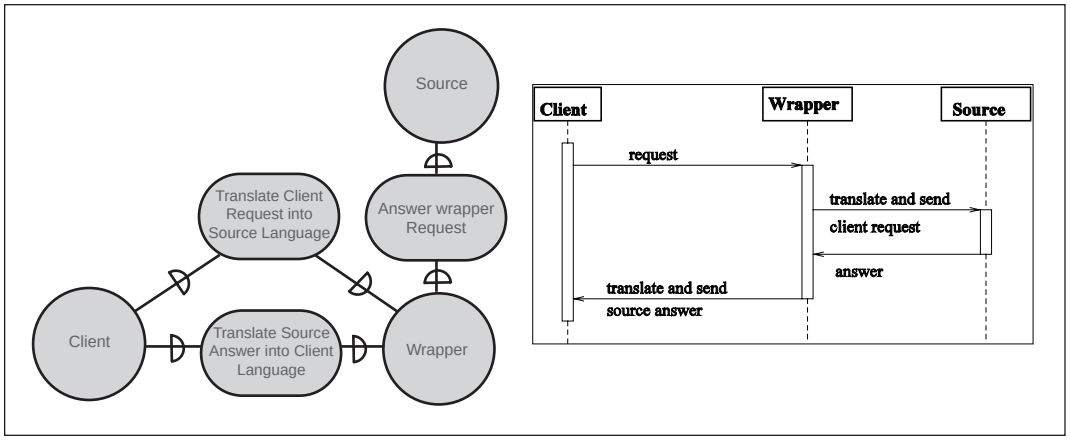


While a matchmaker simply matches providers with clients, a mediator encapsulates interactions and maintains models of the capabilities of clients and providers over time.

In the **embassy** pattern, an embassy agent routes a service requested by an external agent to a local agent. If the request is granted, the external agent can submit messages to the embassy for translation in accordance with a standard ontology. Translated messages are forwarded to the requested local agent and the result of the query is passed back out through the embassy to the external agent.

The **wrapper** pattern (Figure 7) incorporates a legacy system into a multi-agent system. A wrapper agent interfaces system agents with the legacy system by acting as a translator. This ensures that communication protocols are respected and the legacy system remains decoupled from the rest of the agent system.

A SOCIAL PATTERNS FRAMEWORK

This section describes a conceptual framework based on five complementary modeling dimensions, to investigate social patterns. The framework has been applied in the context of the Tropos development methodology (Castro et al., 2002). Each dimension reflects a particular aspect of a MAS architecture, as follows.:

- The *social dimension* identifies the relevant agents in the system and their intentional interdependencies.
- The *intentional dimension* identifies and formalizes services provided by agents to realize the intentions identified by the social dimension, independently of the plans that implement those services. This dimension answers the question: "What does each service do?"
- The *structural dimension* operationalizes the services identified by the intentional dimension in terms of agent-oriented concepts like beliefs, events, plans, and their relationships. This dimension answers the question: "How is each service operationalized?"
- The *communicational dimension* models the temporal exchange of events between agents.
- The *dynamic dimension* models the synchronization mechanisms between events and plans.

The social and the intentional dimensions are specific to MAS. The last three dimensions (structural, communicational, and dynamic) of the architecture are also relevant for traditional (non-agent) systems, but we have adapted and extended them with agent-oriented concepts. They are for instance the modeling dimensions used in object-oriented visual modeling languages such as UML.

The rest of this section details the five dimensions of the framework and illustrates them through the broker pattern (Yu, 1995).

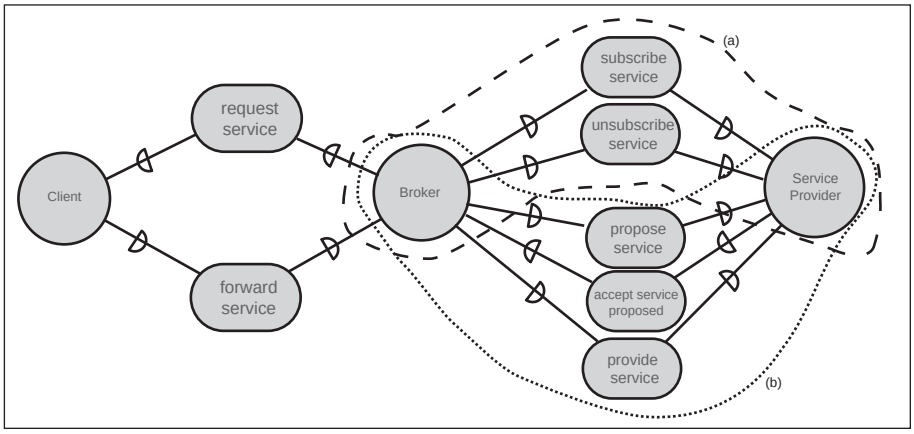
This pattern involves an arbiter intermediary that requests services from providers to satisfy the request of clients. It is designed through the framework as follows.

Social Dimension

The social dimension specifies a number of agents and their intentional interdependencies using the i* model (Do et al., 2003). Figure 8 shows a social diagram for the broker pattern.

The broker pattern can be considered as a combination of (1) a subscription pattern (shown enclosed within dashed boundary (a)), that allows service providers to subscribe their services to the broker agent and where the broker agent plays the role of a yellow-page agent, (2) one of the other pair patterns—booking, call-for-proposals,

Figure 8. Social diagram for the broker pattern



or bidding—whereby the broker agent requests and receives services from service providers (in Figure 13, it is a call-for-proposals pattern, shown enclosed within dotted boundary (b)), and (3) interaction between the broker and the client: the broker agent depends on the client for sending a service request and the client depends on the broker agent to forward the service.

To formalize intentional interdependencies, we use formal Tropos (Fuxman, Pistore, Mylopoulos, & Traverso, 2001), a first-order temporal-logic language that provides a textual notation for i* models and allows to describe dynamic constraints. A *forward service* dependency can be defined in formal Tropos as follows:

Dependum Forward Service
Mode: Achieve
Depender: Client *cl*
Dependee: Broker *br*
Fulfillment:
($\forall$ *sr*: ServiceRequest, *st*: ServiceType)
request(*cl, br, sr*) $\wedge$ provide(*br, st*) $\wedge$ ofType(*sr, st*)
$\rightarrow \Diamond$ received(*cl, br, st*)
[Broker *br* successfully provides its service to client *cl* if all requests *sr* from *cl* to *br*, that are of a type *st* that *br* can handle, are eventually satisfied]

Intentional Dimension

While the social dimension focuses on interdependencies between agents, the intentional dimension aims at modeling agent rationale. It is concerned with the identification of *services* provided by agents and made available to achieve the intentions identified in the social dimension. Each service belongs to one agent. Service definitions can be formalized by its fulfillment condition.

Table 1 lists several services of the broker pattern with an informal definition. With the `FindBroker` service, a client finds a broker that can handle a given service request. The request is then sent to the broker through the `SendServiceRequest` service. The broker can query its belief knowledge with the `QuerySPAvailability` service and answer the client through the `SendServiceRequestDecision` service. If the answer is negative, the client records it with its `RecordBRRefusal` service. If the answer is positive, the broker records the request (`RecordClientServiceRequest` service) and then broadcasts a call (`CallForProposals` service) to potential service providers. The client records

Table 1. Some services of the broker pattern

Service Name	Informal Definition	Agent
FindBroker	Find a broker that can provide a service	Client
SendServiceRequest	Send a service request to a broker	Client
QuerySPAvailability	Query the knowledge for information about the availability of the requested service	Broker
SendService RequestDecision	Send an answer to the client	Broker
RecordBRRefusal	Record a negative answer from a broker	Client
RecordBRAcceptance	Record a positive answer from a broker	Client
RecordClient ServiceRequest	Record a service request received from a Client	Broker
CallForProposals	Send a call for proposals to service providers	Broker
RecordAndSend SPInformDone	Record a service received from a service provider	Broker

acceptance by the broker with the `RecordBRAcceptance` service.

The call-for-proposals pattern could be used here, but this presentation omits it for brevity.

The broker then selects one of the service providers among those that offer the requested service. If the selected provider successfully returns the requested service, it informs the broker, which records the information and forwards it to the client (`RecordAndSendSPInformDone` service).

Services can be formalized in formal Tropos as illustrated below for the FindBroker service.

Service FindBroker (*sr*: ServiceRequest)
Mode: Achieve
Agent: Client *cl*
Fulfillment:
($\exists$ *br* : Broker, *st*: ServiceType)
provide(*br, st*) $\wedge$ ofType (*sr, st*)
$\rightarrow \Diamond$ known(*cl, br*)
[*FindBroker* is fulfilled when client *cl* has found (*known* predicate) *Broker br* that is able to perform (*provide* predicate) the service requested.]

Structural Dimension

While the intentional dimension answers the question "What does each service do?", the structural dimension answers the question "How is each service operationalized?" Services are operationalized as *plans*, that is, sequences of actions.

The knowledge that an agent has (about itself or its environment) is stored in its *beliefs*. An agent can act in response to the *events* that it handles through its plans. A plan, in turn, is used by the agent to read or modify its beliefs, and send events to other agents or post events to itself.

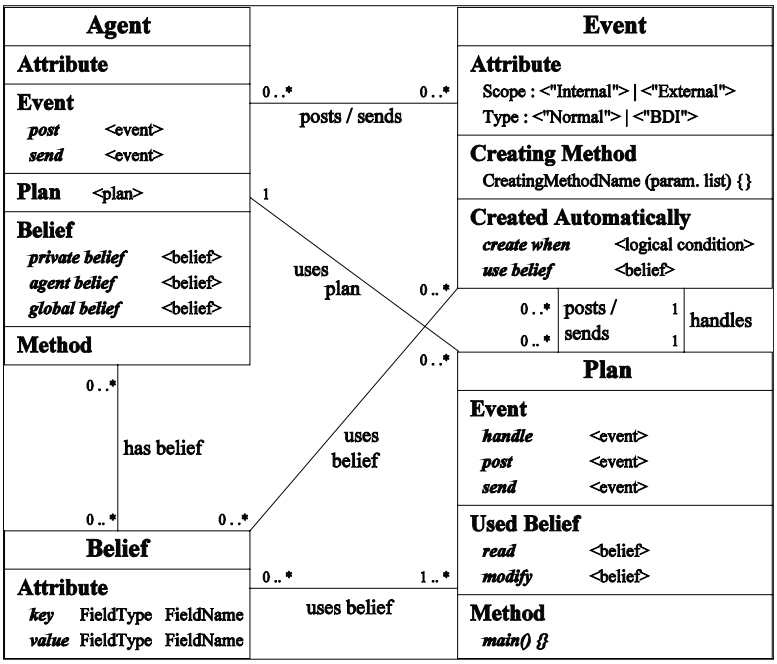
The structural dimension is modeled using a UML style class diagram extended for MAS engineering.

The required agent concepts extending the class diagram model are defined in the following.

Structural Concepts

Figure 9 depicts the concepts and their relationships needed to build the structural dimension.

Figure 9. Structural diagram template



Each concept defines a common template for classes of concrete MAS (for example, agent in Figure 9 is a template for the broker agent class of Figure 10).

A **belief** describes a piece of the knowledge that an agent has about itself and its environment. Beliefs are represented as tuples composed of a key and value fields.

Events describe stimuli, emitted by agents or automatically generated, in response to which the agents must take action. As shown in Figure 9, the structure of an event is composed of three parts: declaration of the attributes of the event, declaration of the methods to create the event, declaration of the beliefs and the condition used for an automatic event. The third part only appears for automatic events. Events can be described along three dimensions:

- *External or internal* event: external events are sent to other agents while internal events are posted by an agent to itself. This property is captured by the *scope* attribute.
- *Normal or BDI* event: an agent has a number of alternative plans to respond to a BDI (belief-desire-event) event and only one plan in response to a normal event. Whenever an event occurs, the agent initiates a plan to handle it. If the plan execution fails and if the event is a normal event, then the event is said to have failed. If the event is a BDI event, a set of plans can be selected for execution and these are attempted in turn. If all selected plans fail, the event is also said to have failed. The event type is captured by the *type* attribute.
- *Automatic or nonautomatic* event: an automatic event is automatically created when certain belief states arise. The *create when* statement specifies the logical condition which must arise for the event to be automatically created. The states of the beliefs

that are defined by *use belief* are monitored to determine when to automatically create events.

A **plan** describes a sequence of actions that an agent can take when an event occurs. As shown by Figure 9, plans are structured in three parts: the event part, the belief part, and the method part. The Event part declares events that the plan `handles` (i.e., events that trigger the execution of the plan) and events that the plan produces. The latter can be either `posted` (i.e., sent by an agent only to itself) or `sent` (i.e., sent to other agents). The belief part declares beliefs that the plan `reads` and those that it `modifies`. The method part describes the plan itself, that is, the actions performed when the plan is executed.

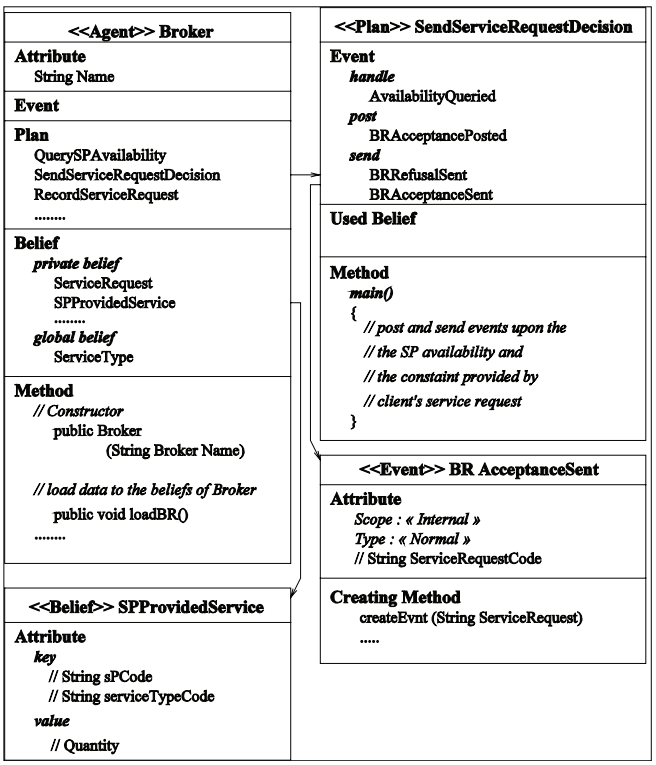
The **agent** concept defines the behavior of an agent, as composed of five parts: the declaration of its attributes, of the events that it can post or send explicitly (i.e., without using its plans), of the plans that it uses to respond to events, of the beliefs that make up its knowledge, and of its methods.

The beliefs of an agent can be of type *private*, *agent*, or *global*. A *private* access is restricted to the agent to which the belief belongs. *Agent* access is shared with other agents of the same class, while *global* access is unrestricted.

Structural Model for the Broker Pattern

Figure 10 depicts the broker pattern components. For brevity, each construct described earlier is illustrated only through one component. Each component can be considered as an instantiation of the (corresponding) template in Figure 9.

Figure 10. Structural diagram—some components of the broker pattern



`Broker` is one of the three agents composing the broker pattern. It has plans such as `QuerySPAvailability`, `SendServiceRequestDecision`, and so forth. When there is no ambiguity, by convention, the plan name is the same as the as the name of the service that it operationalizes. The private belief `SPProvidedService` stores the service type that each service provider can provide. This belief is declared as private since the broker is the only agent that can manipulate it. The `ServiceType` belief stores the information about types of service provided by service providers and is declared as global since its must be known both by the service provider and the broker agent.

The constructor *method* allows a name to be given to a broker agent when created. This method may call other methods, for example `loadBR()`, to initialize agent beliefs.

`SendServiceRequestDecision` is one of the plans that the broker uses to answer the client: the `BRRefusalSent` event is sent when the answer is negative, `BRAcceptanceSent` when the broker has found service provider(s) that may provide the requested service. In the latter case, the plan also posts the `BRAcceptancePosted` event to invoke the process of recording the service request and the 'call for proposals' process between the broker and services providers. The `SendServiceRequestDecision` plan is executed when the `AvailabilityQueried` event (containing the information about the availability of the service provider to realize the client's request) occurs.

`SPProvidedService` is one of the broker's beliefs used to store the services provided by the service providers. The service provider code `sPCode` and the service type code `serviceTypeCode` form the belief key. The corresponding `quantity` attribute is declared as value field.

`BRAcceptanceSent` is an event that is sent to inform the client that its request is accepted.

At a lower level, each plan could also be modeled by an activity diagram for further detail if necessary.

Communication Dimension

Agents interact with each other by exchanging events. The communicational dimension models, in a temporal manner, events exchanged in the system. We adopt the sequence diagram model proposed in AUML (Bauer et al., 2001) and extend it: *agent_name/role:pattern_name* expresses the role (*role*) of the agent (*agent_name*) in the pattern; the arrows are labeled with the name of the exchanged events.

Figure 11 shows a sequence diagram for the broker pattern. The client (`customer1`) sends a service request (`ServiceRequestSent`) containing the characteristics of the service it wishes to obtain from the broker. The broker may alternatively answer with a denial (`BRRefusalSent`) or an acceptance (`BRAcceptanceSent`).

In the case of an acceptance, the broker sends a call for proposal to the registered service providers (`CallForProposalSent`). The call for proposal (CFP) pattern is then applied to model the interaction between the broker and the service providers. The service provider either fails or achieves the requested service. The broker then informs the client about this result by sending an `InformFailureServiceRequestSent` or a `ServiceForwarded`, respectively.

The communication dimension of the subscription pattern (SB) is given at the top-right and the communication dimension of the call-for- proposals pattern (CFP) is given at the bottom-right part of Figure 11. The communication specific for the broker pattern is given in the left part of the figure.

Dynamic Dimension

As described earlier, a plan can be invoked by an event that it handles and it can create new events. Relationships between plans and events can become complex rapidly. To cope with this problem, we propose to model the synchronization and the relationships between plans and events

Figure 11. Communication diagram—broker

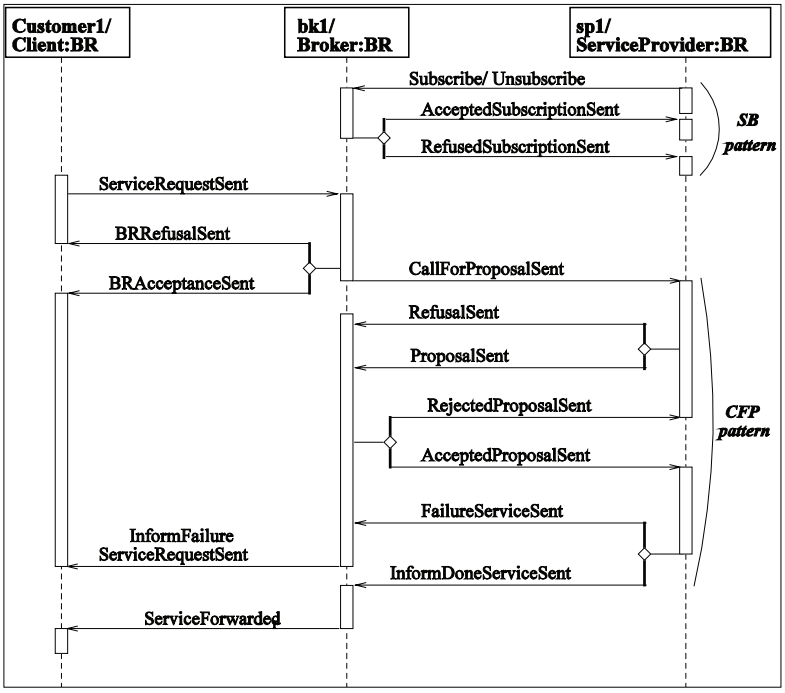


Figure 12. Dynamic diagram—broker

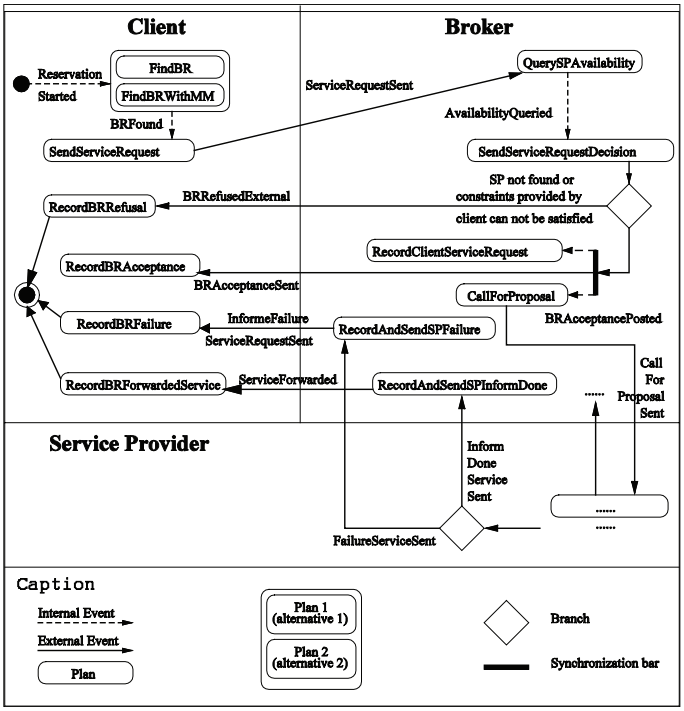


with activity diagrams extended for agent-oriented systems. These diagrams specify the events that are created in parallel, the conditions under which events are created, which plans handle which events, and so on.

An internal event is represented by a dashed arrow and an external event by a solid arrow. As mentioned earlier, a BDI event may be handled by alternative plans. They are enclosed in a round-corner box. Synchronization and branching are represented as usual.

We omit the dynamic dimension of the subscription and the CFP patterns, and only present in Figure 12 the activity diagram specific to the broker pattern. It models the flow of control from the emission of a service request sent by the client to the reception by the same client of the realized service result sent by the broker. Three swimlanes, one for each agent of the broker pattern, compose the diagram. In this pattern, the `FindBroker` service described in Section 3.2.2, is either operationalized by the `FindBR` or the `FindBRWithMM` plans (the client finds a broker based on its own knowledge or via a matchmaker).

FROM ORGANIZATIONAL ARCHITECTURAL STYLES TO SOCIAL DESIGN PATTERNS

A key aspect to conduct MAS architectural design is the specification and use of *organizational styles* (Castro et al., 2002; Do, Faulkner, & Kolp, 2003; Kolp et al., 2002) that are socially-based architectural designs inspired from models and concepts from organization theory (e.g., Mintzberg, 1992; Scott, 1998; Yoshino & Srinivasa Rangan, 1995) and strategic alliances (e.g., Dussauge & Garrette, 1999; Morabito, Sack & Bhate, 1999; Segil, 1996) that analyze the structure and design of real-world human organization. These are for instance the structure-in-fives, the matrix, the joint-venture, the hierarchical contracting, and so forth.

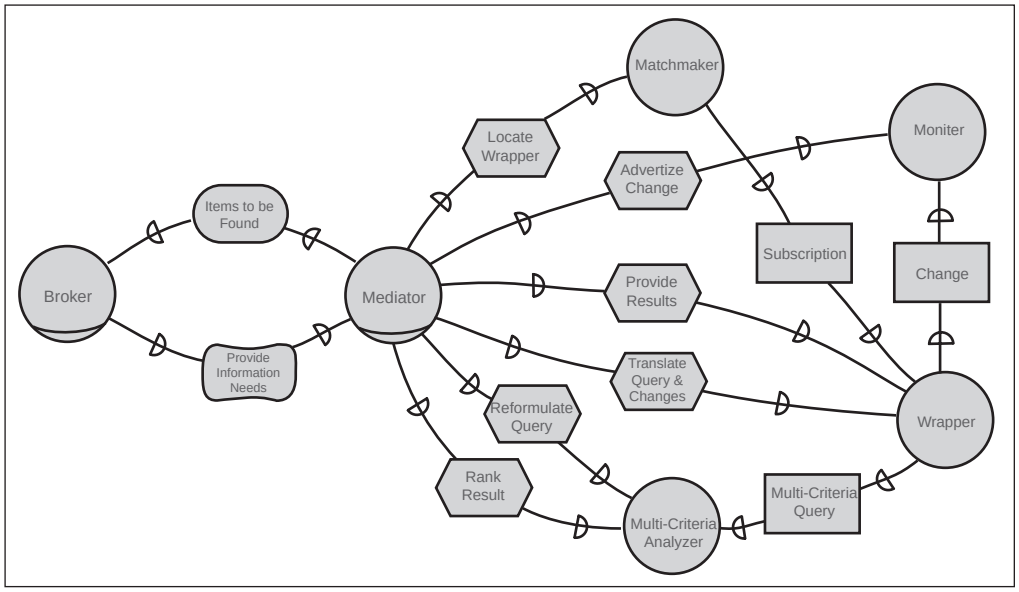
As described in (Castro et al., 2002; Zambonelli et al., 2000), in MAS architectural design, organizational styles are used to give information about the system architecture to be: every time an organizational style is applied, it allows to easily point up, to the designer, the required organizational actors and roles. Then the next step needs to detail and relate such (organizational) actors and roles to more specific agents in order to proceed with the agent behavior characterization. Namely, each actor in an organization-based architecture is much closer to the real world system actor behavior that we consequently aim to have in software agents. As a consequence, once the organizational architectural reflection has figured out the MAS global structure in terms of actors, roles, and their intentional relationships, a deepener analysis is required to detail the agent behaviors and their interdependencies necessary to accomplish their roles in the software organization. To effectively deal with such a purpose, developers can be guided by social patterns proposed in this article.

Social patterns offer a microscopic view of the MAS at the *detailed design* phase to express in deeper detail organizational styles during the architectural design. To explain the necessary relationship between *styles* and *patterns* we consider an original *data integrator* case study and overview how a MAS designed from some style at the architectural level is decomposed into social patterns at the detailed design level.

The **data integrator** allows users to obtain information that come from different heterogeneous and distributed sources. Sources range from text file systems agent knowledge bases. Information from each source that may be of interest is extracted, translated and filtered as appropriate, merged with relevant information from other sources to provide the answer to the users' queries (Widom, 1995).

Figure 13 shows an MAS architecture in i* for the data integrator that applies the *joint-venture* style (Castro et al., 2002; Do et al., 2003) at the

Figure 13. A joint-venture MAS architecture expressed in terms of social patterns—A data integration example



architectural design level. In a few words, the joint venture organizational style is a meta-structure that defines an organizational system that involves agreement between two or more independent partners to obtain the benefits of larger scale, shared investment and lower maintenance costs. A specific joint management actor coordinates tasks and manages the sharing of resources between partner actors. Each partner can manage and control itself on a local dimension and may interact directly with other partners to exchange resources, such as data and knowledge. However, the strategic operation and coordination of such a system, and its actors on a global dimension, are the only responsibility of the joint management actor in which the original actors possess equity participations.

Joint-venture's roles at the architectural design level are expressed in the detailed design level in terms of patterns, namely the broker, the matchmaker, the monitor, the mediator, and the wrapper. The *joint management private interface* is assumed by a mediator, the joint-venture partners are the *wrapper*, the *monitor*, the *multi-criteria analyzer* and the *matchmaker*. The *public interface* is assumed by the *broker*.

The system works as follows. When a user wishes to send a request, she contacts the *broker* agent which is an intermediary to select one or many *mediator(s)* that can satisfy the user information needs. Then, the selected mediator(s) decomposes the user's query into one or more subqueries to the sources, synthesizes the source answers and return the answers to the broker.

If the mediator identifies a recurrent user information request, the information that may be of interest is extracted from each source, merged with relevant information from other sources, and stored as knowledge by the mediator. This stored information constitutes a materialized view that the mediator will have to maintain up-to-date.

A *wrapper* and a *monitor* agent are connected to each information source. The *wrapper* is responsible for translating the subquery issued by

the mediator into the native format of the source and translating the source response in the data model used by the mediator.

The *monitor* is responsible for detecting changes of interest (e.g., change which affects a materialized view) in the information source and reporting them to the mediator. Changes are then translated by the wrapper and sent to the mediator.

It may be also necessary for the mediator to obtain the information concerning the localization of a source and its connected wrapper that are able to provide current or future relevant information. This kind of information is provided by the *matchmaker* agent which then lets the mediator interacts directly with the correspondent wrapper.

Finally, the *multi-criteria analyzer* can reformulate a subquery (sent by a mediator to a wrapper) through a set of criteria in order to express the user preferences in a more detailed way, and refine the possible domain of results.

AUTOMATION

The main motivation behind design patterns is the possibility of reusing them during system detailed design and implementation. Numerous CASE tools such as Rational Rose (IBM Rational Rose, 2007) and Together (Borland Together, 2007) include code generators for object-oriented design patterns. Programmers identify and parameterize, during system detailed design, the patterns that they use in their applications. The code skeleton for the patterns is then automatically generated and programming is thus made easier.

For agent-oriented programming, SKwyRL (Do et al., 2003), for instance, proposes a code generator to automate the use of social patterns introduced in section 2. Figure 13 shows the main window of the tool. It has been developed in Java and produces code for JACK (JACK Intelligent Agents, 2006), an agent-oriented development environment built on top of Java. JACK extends

Figure 14. JACK code generation

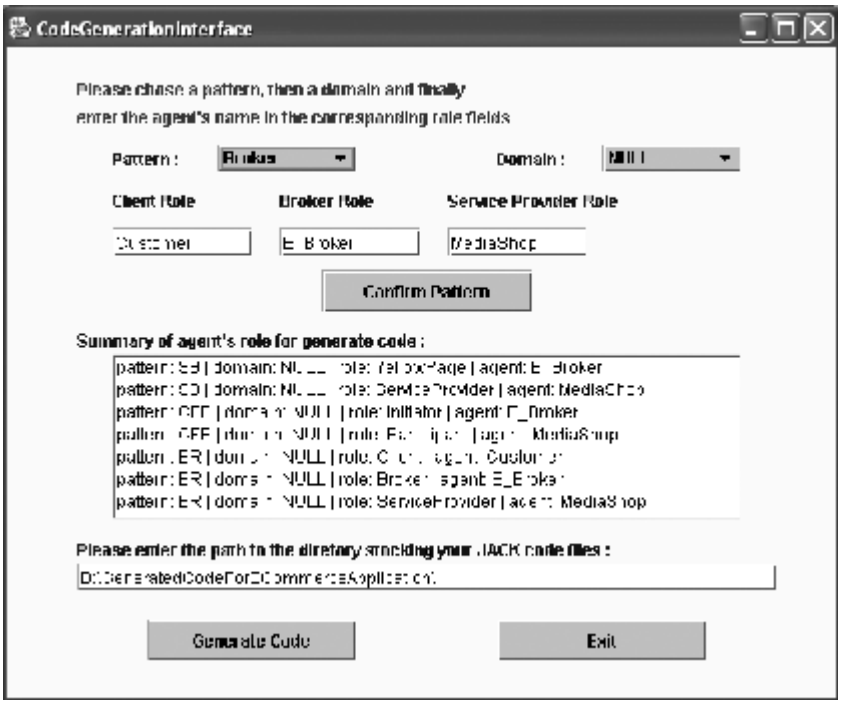


Figure 15. An e-business broker

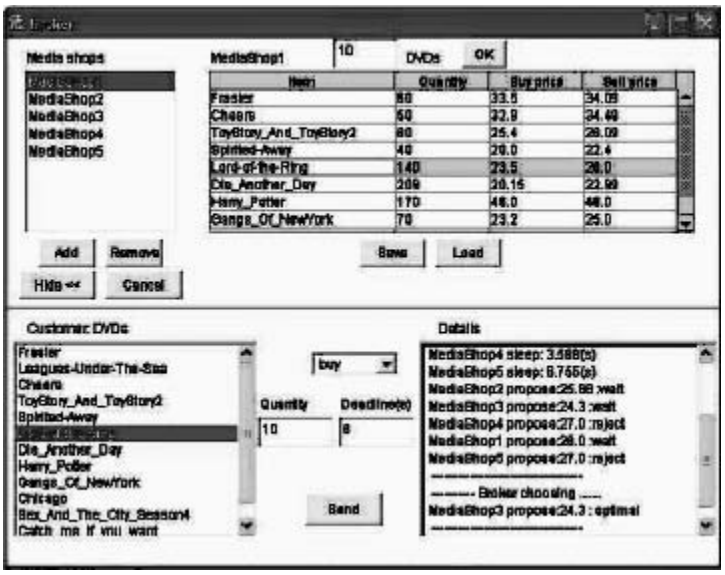

Java with specific capabilities to implement agent behaviors. On a conceptual point of view, the relationship of JACK to Java is analogous to that between C++ and C. On a technical point of view, JACK source code is first compiled into regular Java code before being executed.

In SKwyRL's code generator, the programmer first chooses which social pattern to use, then the roles for each agent in the selected pattern (e.g., the `E_Broker` agent plays the *broker* role for the Broker pattern but can also play the *initiator* role for the CallForProposals pattern and the *yellow page* role for the subscription pattern in the same application). The process is repeated until all relevant patterns have been identified. The code generator then produces the generic code for the patterns (.agent, .event, .plan, .bel JACK files).

The programmer has to add the particular JACK code for each generated files and implement the graphical interface if necessary.

Figure 15 shows an example of the (e-business) broker for the data integrator presented in section 4. It was developed with JACK and the code skeleton was generated with SKwyRL's code generator using the broker pattern explained in the article. The bottom half of the figure shows the interface between the customer and the broker. The customer sends a service request to the broker asking for buying or sending DVDs. He chooses which DVDs to sell or buy, selects the corresponding DVD titles, the quantity and the deadline (the time-out before which the broker has to realizes the requested service). When receiving the customer's request, the broker interacts with the media shops to obtain the DVDs. The interactions between the broker and the media shops are shown on the bottom-right corner of this figure. The top half of the figure shows the items that are provided by each media shop.

RELATED WORK

As already said, a lot of work has been devoted to software patterns these last 15years. Patterns for software development are one of software engineering problem-solving discipline that has its roots in a design movement in contemporary

architecture and the documentation of best practices and lessons learned in all vocations. The goal of patterns is to create a body of literature to help software developers resolve recurring problems encountered throughout all of software development. Patterns help create a shared language for communicating insight and experience about these problems and their solutions.

Ward Cunningham and Kent Beck developed a small set of five patterns (Beck & Cunningham, 1987), for guiding Smalltalk programmers to design user interface. Jim Coplien introduced a catalog of for C++ patterns, called *idioms* (Coplien, 1991). Software patterns then became popular with the wide acceptance of the Gang of Four or GoF (Erich Gamma, Richard Helm, Ralph Johnson, and John Vlissides) book (Gamma et al., 1995).

However, the patterns in the GoF book are only one kind of pattern—the object-oriented *design patterns*. There are many other kinds of patterns. For example, Martin Fowler's "*Analysis Patterns*" (Fowler, 1997) describe the models of business processes that occur repeatedly in the analysis phase of software development; *organizational patterns* (Coplien & Schmidt, 1995) are about software-development organizations and about people who work in such organizations. *Process patterns* (Ambler, 1998) relate to the strategies that software professionals employ to solve problems that recur across organizations. Frank Buschmann, Regine Meunier, Hans Rohnert, Peter Sommerlad, and Michael Stal, helped popularize these kinds of patterns (organizational and process patterns) (Buschmann et al., 1996).

Contrary to pattern, that represents a "best practice," an *anti-pattern* represents a "lesson learned." There are two kinds of "anti-patterns:" those that describe a bad solution to a problem which resulted in a bad situation and those that describe how to get out of a bad situation and how to proceed from there to a good solution. Anti-pattern is initially proposed by Andrew Koenig. Anti-patterns extend the field of software patterns research into exciting new areas and issues, including: refactoring, reengineering, system extension, and system migration (Brown, Malveau, Hays, et al., 1998; Love, 1997; Opdyke, 1992; Webster, 1995).

Recent popularity of autonomous agents and agent-oriented software engineering has led to the discovery of agent patterns (Aridor & Lange, 1998;, Deugo et al., 1999; Do et al., 2003; Hayden et al., 1999; Mouratidis, Giorgini & Manson, 2003), that capture good solutions to common problems in agent design in many aspect such as security, architecture, organization, and so forth. However, as pointed out earlier, little focus has been put on social and intentional considerations and these agent patterns rather aim at the implementation level. The framework presented in the chapter should add more detail to the design process of agent oriented software engineering (Do et al., 2003, Do et al., 2003).

CONCLUSION

Nowadays, software engineering for new enterprise application domains such as e-business, knowledge management, peer-to-peer computing, or Web services is forced to build up open systems able to cope with distributed, heterogeneous, and dynamic information issues. Most of these software systems exist in a changing organizational and operational environment where new components can be added, modified or removed at any time. For these reasons and more, multi-agent systems (MAS) architectures are gaining popularity in that they do allow dynamic and evolving structures which can change at run-time.

An important technique that helps to manage the complexity of such architectures is the reuse of development experience and know-how. Like any architect, software architects use patterns to guide system development. Over the years, patterns have become an attractive approach to reusing architectural design knowledge in software engineering. Patterns describe a problem com-

monly found in software designs and prescribe a flexible solution for the problem, so as to ease the reuse of that solution.

As explored in this article, MAS architectures can be considered social structures composed of autonomous and proactive agents that interact and cooperate with each other to achieve common or private goals. Since the fundamental concepts of multi-agent systems are intentional and social, rather than implementation-oriented, social abstractions could provide inspiration and insights to define patterns for designing MAS architectures.

This article has focused on social patterns. With real-world social behaviors as a metaphor, social patterns are agent-oriented design patterns that describe MAS as composed of autonomous agents that interact and coordinate to achieve their intentions, like actors in human organizations.

The article has described such patterns, a design framework to introspect them and formalize their "code of ethics," answering the question: what can one expect from a broker, mediator, embassy, and so forth. It aims to be used during the detail design phase of any agent-oriented methodology detailing the patterns following different point of views.

Chapter 2.16
Women in the Free/Libre Open Source Software Development

Yuwei Lin
Vrije Universiteit Amsterdam, The Netherlands

INTRODUCTION

Free/libre open source software (FLOSS) has become a prominent phenomenon in the ICT field and the wider public domain for the past years. However, according to a FLOSS survey on FLOSS developers in 2002, "women do not play a role in the [FLOSS] development; only 1.1% of the FLOSS sample is female." (Ghosh, Glott, Krieger, & Robles, 2002). In the mainstream research on FLOSS communities, many researchers also overlook different processes of community-building and diverse experiences of members, and presume a stereotyped male-dominated "hacker community" (e.g., Levy, 1984; Raymond, 2001; Himanen, 2001; Thomas, 2002). Moreover, issues around gender inequality are often ignored and/or muted in the pile of FLOSS studies. Female programmers often are rejected ex/implicitly from the software labour market (Levesque & Wilson 2004). The requirements of female users are not respected and consulted either (European Commission, 2001). This feature is opposite to the FLOSS ideal world where users should be equally treated and embraced (op. cit.). While many researchers endeavour to understand the FLOSS development, few found a gender-biased situation problematic. In short, women are almost invisible in current FLOSS-related literature. Most policies targeting at advocating FLOSS are also gender blind.

Thus, this essay highlights the need for increased action to address imbalances between women's and men's access to and participation in the FLOSS development in cultural (e.g., chauvinistic and/or gender-biased languages in discussions on mailing lists or in documentations), economic (e.g., unequal salary levels for women and men), political (e.g., male-dominated advocacy environment) and technical (e.g., unbalanced students gender in technical tutorials) spheres. On the other hand, it also emphasises the powerful potential of FLOSS as a vehicle for advancing gender equality in software expertise. FLOSS helps transport knowledge and experience of software engineering through distributing

source code together with the binary code almost without any limit. Many FLOSS licences such as the General Public Licence (GPL) also facilitates the flow of information and knowledge. In other words, if appropriately harnessed, FLOSS stands to meaningfully contribute to and mutually reinforce the advancement of effective, more expedited solutions to bridging the gender digital divide.

In the end, this article points out that while women in more advanced countries have a better chance of upgrading their ICT skills and knowledge through participating in the FLOSS development, the opportunity is less available for women in the developing world. It is worth noting that although the gender issues raised in this article are widespread, they should not be considered as universally indifferent. Regional specificities in gender agenda in software engineering should be addressed distinctly (UNDP/UNIFEM, 2004).

TOWARD A FEMINIST ANALYTICS[1] ON THE GENDER ISSUES IN THE FLOSS DEVELOPMENT

To a degree, the gender problems in the FLOSS development can be seen as an extension of the ongoing gender issues in new-tech service industries and/or software industry (e.g., Mitter & Rowbotham, 1995). These long-term problems mainly include low-level work content, unequal payment, emotional distress from discrimination and prejudice, physical ache from the long working hour in front of the computer, division of labour within the home (child-rearing), essentialist notions of women's roles, sexism, informal networks, prejudice, lack of role models and support, and "glass ceilings." Generally speaking, women within the software industry have to work harder than men in order to get the same respect and conquer the glass-ceiling problem in this patriarchy world (DeBare, 1996).

Although FLOSS has dramatically changed the way software is produced, distributed, supported, and used, and has a visible social impact enabling a richer digital inclusion, most of the gender problems existing in the software industry have been duplicated in the FLOSS field.

A FLOSS *social world* (Lin, 2004) is different from what Turkle (1984) argues: "computer systems [mainly proprietary] represent a closed, controllable microworld—which appeals to more men than women" (Turkle, 1984). It requires a holistic perspective to capture the complexity and dynamics within and across the social world. While the heterogeneity and the contingency in this social world are not yet fully explored, analysis from a feminist perspective is almost absent. Little attention has been paid to the internal differences and to the private arena linked with the FLOSS innovation system. However, this methodological lack has not stopped us from observing the gender problems within the field. Instead, by means of the FLOSS development, some gender problems in ICT become even more apparent.

Additionally, in a world of volunteers, we clearly see that men and a competitive worldview are more present in all forms of media. Many women participating in the FLOSS development are invisible: their labour in fields such as NGOs that help implement and promote FLOSS, documentation translation, book editing, teaching and tutoring (e.g., E-Riders[2]) are less visible than male-dominated coding work. Indeed, FLOSS advocates have not adequately addressed this critique of gender equality. They tend to treat the FLOSS community as a monolithic culture—to pay more attention to differences between and among groups than to differences within them. They are so eager uniting the voices on freedom of information that they give little or no recognition to the fact that FLOSS groups, "like the societies in which they exist (though to a greater or lesser extent), are themselves *gendered*, with substantial differences of power and advantage between men and women" (Okin, 1999).

A number of key dilemmas that hinder women's participation in the FLOSS development can be summarised:

1. **A Lack of "Mentors" and Role Models:** It is true that there is a very low percentage of female participants in the FLOSS social world. However, we should not overlook the importance and possible future of outstanding female figures in the FLOSS field. It is difficult to make the majority of male peers respect these female figures. I am not suggesting that men all look down on women, but it is more difficult for women to be assertive in front of male-dominated audience. The whole way the world is constructed means there are just men at every level, which makes it really hard for women to get their feet in the door. A way of overcoming this is to establish more female figures in the world. While few in the computer world actually know that Ms. Ada Byron is the first programmer in the world, how could we expect people to recognise women's ability?
2. **Discriminated Languages Online and/or Offline (e.g., Phrases in Documentaries):** Many female FLOSS developers have complained the highly unfriendly atmosphere within the social world, online (e.g., mailing lists, IRC) and/or offline (e.g., documentation). For instance, referred to prospective readers, existed FLOSS documentation usually use single sex term, he, rather than she or they. This kind of gender-biased words subtly exclude women from participating in the FLOSS development. While the online languages are in a direct way full of men's jargon, reading the documentation offline does not make a female developer/user feel more included in the field. If women need to be encouraged to participate in FLOSS-related discussions, a sexist or discriminative surrounding is definitely not attractive.
3. **A Lack of Women-Centred View in the FLOSS Development:** The consequence of the lack of female FLOSS developers is that there is a greater amount of female-unfriendly software in the FLOSS system. Some scholars in science and technology studies (STS) have pointed out that technologies are gendered both in their design and use (e.g., Edwards, 1993; Wajcman, 2004).The social relations of gender within and across the FLOSS social world are reflected in and shaped by the design of FLOSS. And such a lack of women's perspective on software design and use restricts women's participation in the FLOSS development and, in turn, forms the stereotyped fact that women are almost absent in the FLOSS development because they are less adequate in programming or less likely to be advanced computer users. This absence of female developers would also be a loss of the FLOSS development, and result in inequalities in an ICT-based society as a threat to social cohesion and social order.
4. **A Male-Dominated Competitive Worldview:**
"[The FLOSS market] is literally a war for the best and brightest. If we don't get there, somebody else will" (Andrew Clark, director of strategy and market intelligence for the venture capital group at IBM—interviewed with C|Net.com on February 14, 2005).
As Arun and Arun (2001) point out, "The project-based, competitive nature of software development reproduces a masculine culture, which further interacts with the different career patterns of women and social norms and tends to disadvantage women." While languages in a similar tone with Clark's words above repeatedly turn up in the mass media such as advertisements from big computer companies, the male-led competitive worldview is continuously represented and reinforced in the society. Since there

are fairly clear disparities of power between the sexes within the FLOSS social world, a gender-imbalanced world is ensued. The more powerful male members are those who are generally in a position to determine and articulate the group's beliefs, practices, and interests. Although not all proposals associated with FLOSS are potentially antifeminist under such conditions, but they somehow duplicate and forward the view that might limit the capacities of women and girls to freely choose lives that they would like to live. It is very alarming that a large amount of perspectives and purposes regarding the FLOSS development is determined by white men. This imbalance might give a distorted world view; it is much better to have views from all people from different social worlds.

5. **No Sympathy from Women Peers:** There are many more spoken or unspoken problems for women to take part in the FLOSS development (e.g., Henson, 2002; Spertus, 1991). However, facing these gender inequalities, many women remain remote and feel no need of tackling these problems. While some women-centred online groups have networked together to address the gender issue in the FLOSS movement, many female programmers still do not share the same view on an ongoing and enlarging gap between men and women software developers. While gender issue in FLOSS is not addressed in most of the literature and also not recognised by female peers, it is difficult to network women to tackle the coherent patriarchal hegemony in the computer world.

HOW CAN FLOSS EMPOWER WOMEN?

Like many other ICTs, FLOSS carries the powerful potential as a vehicle for advancing social equality. It opens up an opportunity for women to learn how to communicate and interact with software designers and speak out what kind of software they want (e.g., file bug report, join the user group and online forum etc.), to have access to source code and fork the software (e.g., to have a female-friendly version of the software), if they are interested and competent.

There are three main ends in current "women movement in the FLOSS community": (1) providing women-friendly software and services; (2) creating a women-friendly environment for developing and using FLOSS; and (3) fostering a gender-balanced ICT innovation system for both competition and collaboration. These three points have close connections with one another. In order to create software that engage and build on women's ideas and visions, we need to create a more women-friendly environment for the purpose of attracting more women to participate in the FLOSS development. Encompassing such a women-centred view of design, which usually resembles a more sympathetic and inclusive way of doing, will possibly foster a gender-balanced ICT innovation system that is not only friendly to women but also to various minorities in our society. This system, unlike the current one based on a highly competition-oriented approach, will draw on aptitudes and competences of diverse actors in the FLOSS social world so as to develop a holistic environment which is based on a collaboration-oriented approach.

Networking is important in democratising the access and dissemination of knowledge and establishing a base for a citizenship defined by gender equity. In order to encourage women's participation and also to explain the operation of FLOSS to women, some female developers/users have started to network and form online groups such as, LinuxChix[3], KDE Women[4], Gnurias[5], GenderChangers[6], and Debian-women[7]. They act to dispel the unfriendly wording in documents and in online peer groups, to report this kind of sexist bug reports to other developers, to give

online tutorials. These networking and gathering, online or offline, would serve as a base for gender inclusion.

CONCLUSION AND FUTURE RESEARCH

The essay aims to identify the current challenges of gender politics and help formulate strategies and recommendations in order to advance and to empower women in FLOSS. It is anticipated that through conceptualising and documenting the current gender issues in the FLOSS development, it will help enlarge the knowledge base for gender-sensitive policies on ICTs, and propose a women-centred policy towards developing and implementing FLOSS. While FLOSS denotes a new milestone for software development and knowledge making in a broad sense that might alter the social relations of gender, "in this technoscientific advanced era, feminist politics make wider differences in women-machine relationship than the technologies themselves" (Wajcman, 2004). As such, a gender-sensitive agenda for developing FLOSS is urgently needed.

In terms of future research, in order to get a comprehensive overview of the current gender digital divide in the FLOSS social world, more research, both qualitative and quantitative, needs to be conducted. The former would allow us to understand women's experiences and needs better through ethnographical observation, interviews, and focus groups, while the latter would give a fuller picture of general gender problems. Researchers across disciplines are encouraged to analyse FLOSS activities more critically with regard to gender, and to develop conceptual frameworks and methodologies for better understanding and analysing the relationship between FLOSS and gender. Additionally, in encouraging the FLOSS development, governments and organisations should pay extra attention to gender-related issues as well, and take initiatives to include women in the FLOSS development. Holding training workshops for female developers might be a feasible way of bridging the gender digital divide in the FLOSS social world. Other efforts such as design of products and Web sites for women and girls, supporting networks for female professions in FLOSS shall be encouraged.

However, in speaking of implementing and developing FLOSS, most of the cases are centralised or situated in more developed countries. One should bear in mind that there are many undocumented activities that have happened in the developing world. When strengthening the advantages of FLOSS, we should not overlook many problems emerging from implementing FLOSS in developing countries, such as a lack of sufficient training and support. The digital divide shall be considered as a symptom of inequality, not the cause of it. There is a need of understanding what local people really need: water, food, jobs, decent healthcare and sanitation, or software and ICT infrastructure. The gender issue of ICT might be more complex than we thought as well. Female participants very often suffer from hybrid discriminations, both from the male-dominated FLOSS world and the socio-cultural patriarchy in the society. Although virtual groups such Linuxchix Brazil[8] and Linuxchix Africa[9] have started providing women with help on solving problems in implementing Linux, more efforts need to be spent on documenting, analysing and deconstructing the patriarchal hegemony embedded in the whole ICT infrastructure. As such, like many other fields concerned with gendering, this essay is a mere beginning of a feminist accounts about the FLOSS development—an analytic stage on which "we need to place the details contributed by ethnographic research, cultural critiques, sociological surveys, legal scholarship on men and women in their many specific conditions and subjectivities" (Sassen, 1999, p. 2).

KEY TERMS

Debian GNU/Linux and Debian-Women: Created by the *Debian Project*, is a widely used free software distribution developed through the collaboration of volunteers from around the world. Since its inception, the released system, The Debian Women project, founded in May 2004, seeks to balance and diversify the Debian Project by actively engaging with interested women and encouraging them to become more involved with Debian.

Ethnography: Refers to the qualitative description of human social phenomena, based on months or years of fieldwork. Ethnography may be "holistic," describing a society as a whole, or it may focus on specific problems or situations within a larger social scene.

FLOSS: Free/libre open source software (FLOSS), generically indicates non-proprietary software that allows users to have freedom to run, copy, distribute, study, change and improve the software.

Focus Group: A focus group is a form of qualitative research in which a group of people are asked about their attitude towards a product, concept, advertisement, idea, or packaging. Questions are asked in an interactive group setting where participants are free to talk with other group members.

GPL: General Public License (GPL) is a free software licence that guarantees the freedom of users to share and change free software. It has been the most popular free software license since its creation in 1991 by Richard Stallman.

Hegemony: Is the dominance of one group over other groups, with or without the threat of force, to the extent that, for instance, the dominant party can dictate the terms of trade to its advantage; or more broadly, that cultural perspectives become skewed to favor the dominant group.

KDE(K Desktop Environment): A free desktop environment and development platform built with Trolltech's Qt toolkit. It runs on most Unix® and Unix®-like systems, such as Linux, BSD, and Solaris.

ENDNOTES

1 By "feminism" I mean the belief that women should not be disadvantaged by their sex, that the moral equality of men and women should be endorsed, and that all forms of oppression should be demolished.

Chapter 2.17
Managing Intellectual Capital and Intellectual Property within Software Development Communities of Practice

Andy Williamson
Wairua Consulting Limited, New Zealand

David M. Kennedy
Hong Kong Institute of Education, Hong Kong

Ruth DeSouza
Wairua Consulting Limited, New Zealand

Carmel McNaught
Chinese University of Hong Kong, Hong Kong

INTRODUCTION

In this article, we will develop a framework for educational software development teams that recognizes the conflicts and tensions that exist between the different professional groups and will assist software teams to recognize the intellectual capital created by individuals and teams. We will do so by recognizing the inherent relationship between the tangible elements of intellectual property and the intangible organizational assets that form the basis of intellectual capital and by discussing how knowledge generated by a project team can become an explicit asset.

BACKGROUND

Universities are increasingly becoming developers of complex software-based applications. In-house development ranges from teaching aids and online learning resources to large information systems

products that could ultimately become successful commercial ventures. Increased product complexity is easily recognized, yet research shows that the organizational aspects of a software development project are more likely to affect performance and outcomes than technical issues (Xia & Lee, 2004). Successful development and deployment of today's complex educational systems and environments comes with an imperative for an array of different and unique skill sets for the various stages of each project. One can view a software development team as a microcosm of the wider community of practice of software development professionals who work in information and knowledge management in higher education. As Wenger (1998) observes, such communities of practice are not random but constructed around required skills and through a process of negotiation based on mutuality and accountability.

Workforce mobility has increased: academic staff members regularly and easily move between institutions; development and design staff have many opportunities for contract-based work, move to other academic institutions or into the private sector. The ideas that lie behind a successful process or product are increasingly drawn from a wider pool of talent and, as people move around, these ideas are being taken with them and disseminated through informal and new work practices into a wider community of practice. How then does a team, formed to design and develop a technology-rich educational or systems environment, manage and control issues of intellectual capital and intellectual property such that all of those who contribute throughout the life of a project are acknowledged and rewarded fairly and appropriately for that contribution, even after they have left the project?

Team Formation and Relationships

Additional complexity leads to specialization (Jacobson, Booch & Rumbaugh, 1998). New ways of working bring with them a shift in power, where the academic expert will often lack the technical skills, time or resources to turn ideas into reality. Instead, they must rely on a team of experts from other disciplines to interpret their ideas, evolve them, and deliver the finished product. As complexity increases, communication between team members becomes paramount; specialist educational designers are required to translate pedagogy into functional specifications that can be understood by software developers and graphic designers. Modern software teams are project-based, where resources come and go as required.

Software development communities of practice exist within a larger organizational context. Roles and responsibilities will vary and are negotiated depending on the toolset and architecture used, the size of the project, and the culture of the organization (Phillips, 1997; Williamson et al., 2003). Project team members can be full- or part-time employees (academic or non-academic) or contractors retained specifically for the project. As such, these roles exhibit complex relationships and interfaces between each other and the project. In Figure 1, a range of typical roles and relationships found in a tertiary education software development project are shown.

During the various stages of the development process, various players move into prominent roles. One way to illustrate this shifting set of work responsibilities is to list the main players at each stage of the process. We will do this using the classic instructional systems design (ISD) model (Dick & Carey, 1990) as it is so well known. (There are many other models, many of which are discussed in Bannan-Ritland, 2003.) The key players at each stage of the ISD model are listed in Table 1. In reality, each team parcels out the work depending on the skill set of individuals in the team.

It is important to be aware of the different communities of practice that exist in this field and ensure that the role of individual team members is able to be promoted appropriately. Professional

Figure 1. Intra-project relationships in software development teams (Williamson et al., 2003, p. 345)

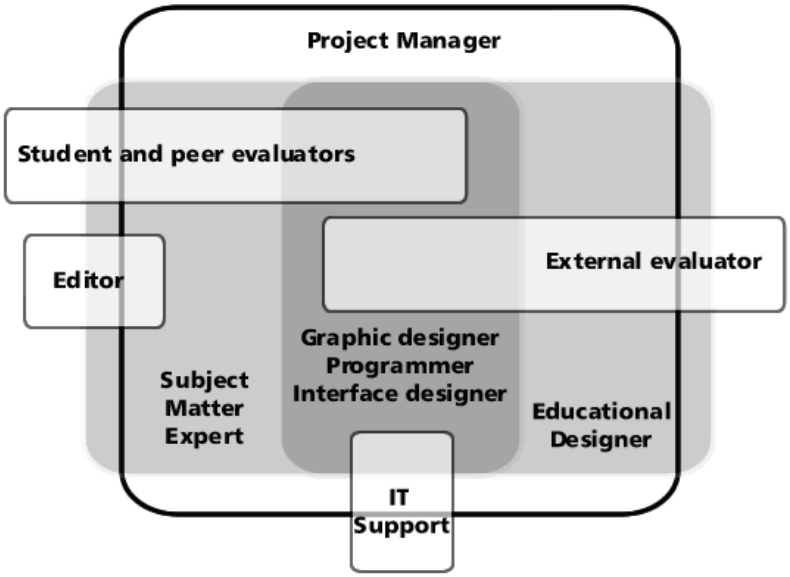

Table 1. Key players at each stage of the ISD model

Stage of the ISD model	Key players
Needs assessment	Subject matter expert
Analysis	Subject matter expert, Educational designer
Design	Subject matter expert, Educational designer, Project manager
Development	Project manager, Graphic designer, Programmer, Interface designer, Editor
Formative evaluation	Student and peer evaluators, Subject matter expert, Educational designer
Revision	Project manager, Graphic designer, Programmer, Interface designer, Editor
Implementation	Subject matter expert, IT support
Summative evaluation	External evaluator
Maintenance	IT support, Subject matter expert (Interface designer)

recognition can come through either publication, a portfolio of work or through the finished product, and the importance of a successful project to the career development of individuals should not be underestimated. It is important to ensure that academic dissemination of successful projects through publication recognizes the contribution made by all team members, including the non-academic members. Many myths persist in relation to acknowledging the veracity of contribution with regard to educational software, and these often have the potential to leave team members feeling their effort and ideas have gone unrecognized and, at worst, feeling they have been exploited (Williamson et al., 2003). In the second half of this article, we will develop a framework that ensures appropriate outlets for reward and recognition of individual contributions within academic software development teams. Before doing this, we will define what is meant by intellectual capital and intellectual property.

Defining Intellectual Capital and Intellectual Property

Florida (2002) argues that the principal factors for successful software development are talent, knowledge, and intellectual capital (IC). The connection of new ideas and existing knowledge within an organizational context leads to the creation of IC. Stewart (1999) defines IC as the sum of everything everybody in a company, organization, or team knows and which provides some advantage over their competitors. Davidson and Voss (2001) agree, describing individual IC as "the sum of individual imagination, intelligence and ideas" (p. 60). They then extend this definition to encapsulate a model for organizational IC that is based on the talent of individuals (human capital), the knowledge that is captured within systems and processes (structural capital), and the characteristics of relationships with customers and suppliers (customer/supplier capital). Organizational IC comes from the "interplay of all three (structural capital augments the value of human capital, leading to an increase in customer/supplier capital)" (p. 61). In terms of this discussion as it relates to the appropriate recognition and acknowledgement of individual contributions within software development teams, human capital is our primary focus. Human capital is "what walks out of the door at the end of the day" (p. 68); it is a vital intangible.

If IC is the intangible but invaluable contribution of human talent to a project, then Intellectual Property (IP) is a formal measurable subset. It is the tangible product that results from the idea. The UK Patent Office (United Kingdom Patent Office, n.d.) defines four formal types of IP:

- patents for inventions
- trademarks for brands
- designs for product appearance
- copyright for material (including software and multimedia).

This definition is then extended to cover a much broader and often more intangible grouping that extends to trade secrets, plant varieties, geographical indications, and performers rights. While many see copyright as a way of protecting IP, it is only a subset. Copyright provides recognition of their invention to the creators of software or multimedia products in order for them to be able to obtain economic rewards for their efforts (Macmillan, 2000). Historically, comparisons have been drawn between software development and the traditional arts, such comparisons reinforcing an argument that IP law is focused on the protection of software such that others are not able to modify the source product (White, 1997). It is important to note that copyright extends only to a tangible product, it does not lend protection to the more intangible areas of IC such as ideas and individual contribution. Since copyright has a primarily commercial imperative, it is a limited and perhaps inappropriate mechanism for acknowledging contribution. This is of greater importance in higher educational settings since copyright of educational materials can reside with the institution (particularly with off-campus courses), rather than the individual, and very few educational software products developed for specific content domains in higher education are ever commercialized (Alexander, McKenzie & Geissinger, 1998).

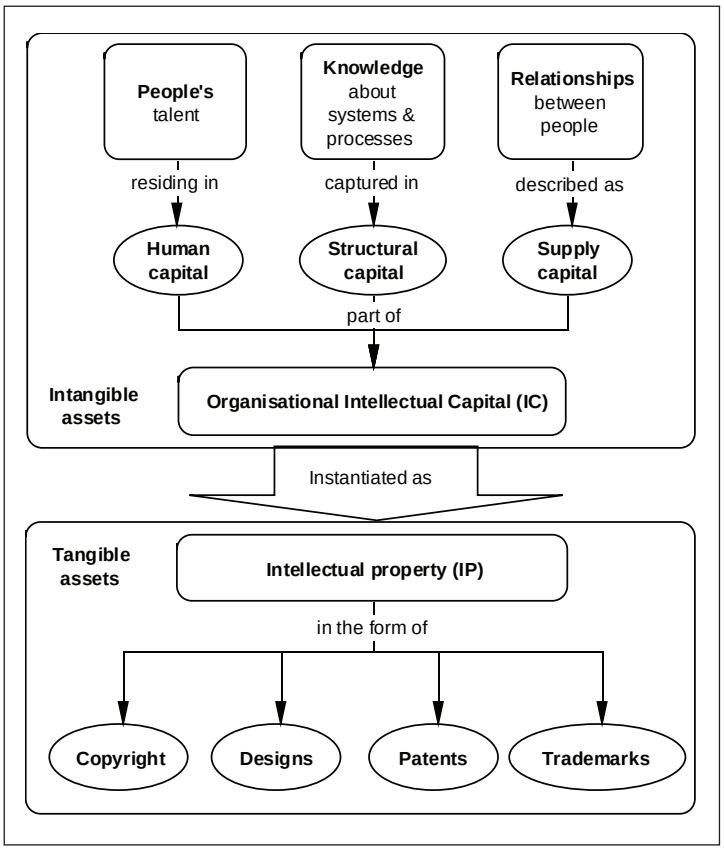
The Relationship between IC and IP

A relationship exists between the tangible elements of intellectual property and the three forms of intellectual capital (the intangible organizational assets) discussed in the preceding section. These are shown in Figure 2.

IC/IP Management Framework

Having addressed the complexity of educational software development teams and defined IC and IP within an educational software context, we will

Figure 2. Intellectual capital and intellectual property (Williamson et al., 2002, p. 342)



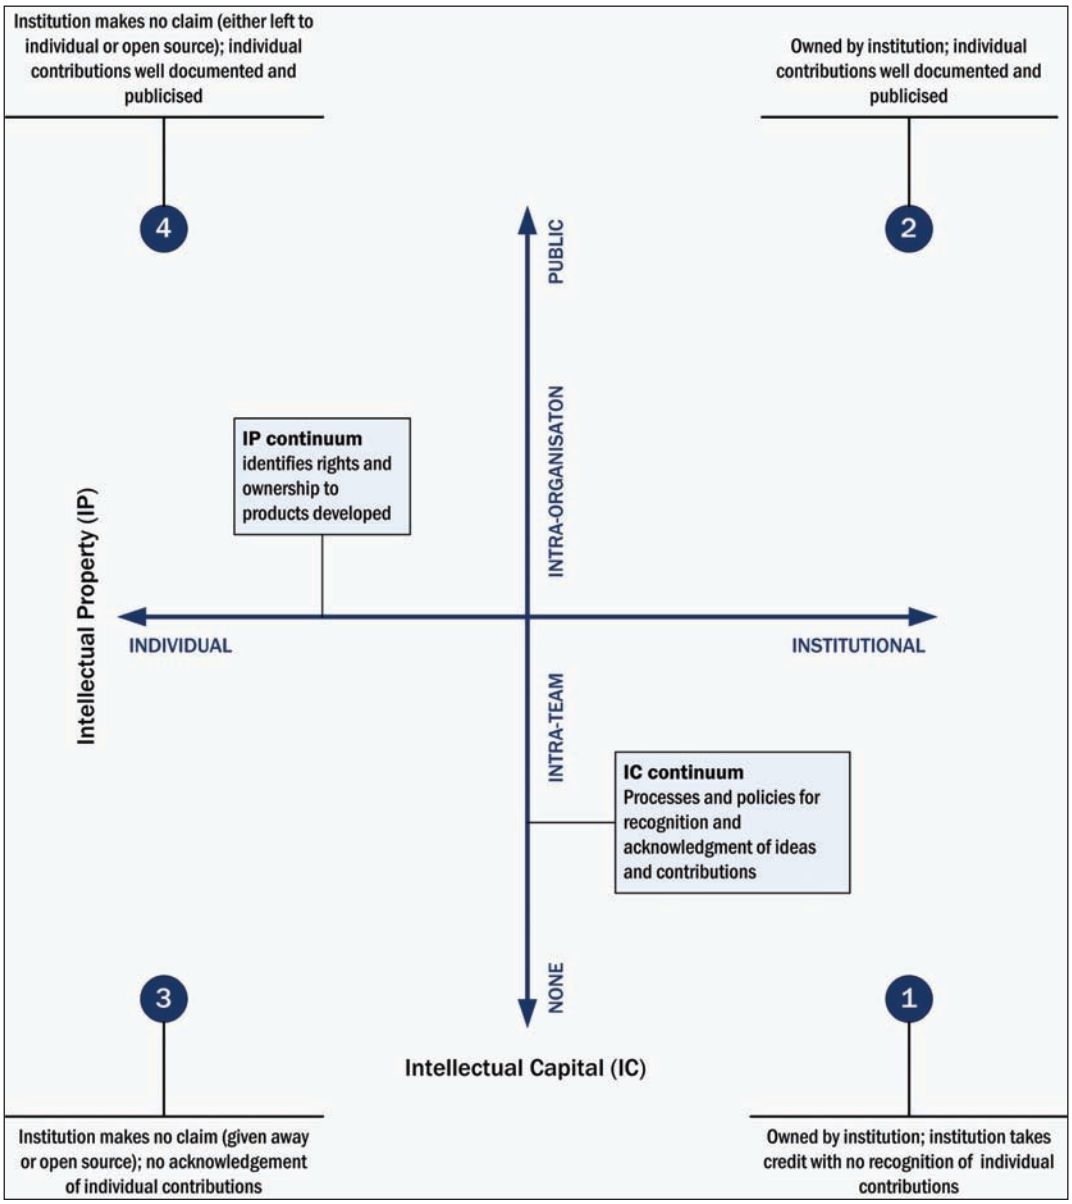
now develop a framework that can be used to ensure proper recognition and reward for individual and collective ideas in such a setting.

Given the critical value of IC in software development (Florida, 2002), it is important that the processes used within educational software development are strengthened and formalized through the adoption of a strong project management framework. Project management is a key role in any project involving information and communication technologies and interactive multimedia software, and it requires specific skills and attributes. These include both the hard skills of contract negotiation, budgeting, scheduling, project definition, and scoping as well as the soft skills of human relations, team building, and facilitation (Burdman, 2000; Schwalbe, 2000). Successful teams work well together because they have clear roles and relationships and because the terms of engagement within the team and with external parties are well defined, understood, and agreed by all. This provides a solid platform for the explicit incorporation of IC and IP policies into project documentation so that such issues can be considered early on, preferably during the project scoping phase.

A process and framework are required to recognize knowledge as it is created so that it becomes explicit. Without doing so, knowledge remains tacit and cannot be rewarded or acknowledged, that is, credited to the appropriate team members in the future. Extending this concept, knowledge

that is explicit within the team can remain tacit beyond team boundaries if no process is in place to ensure appropriate recognition of contribution. It is, therefore, necessary for teams to negotiate clear, up-front delineation of roles, responsibility, and ownership of both tangible and intangible outputs from the project. This does not prejudge what that ownership might be, merely that the agreement takes place before the project commences. It is important to consider how IC/IP generated during the project's life will be disseminated, in what form, and by whom. Such a clear articulation of roles and responsibilities has the benefit of helping to make the process of dissemination more

Figure 3. IP/IC management framework



visible. By doing so, it is hopefully the case that team members will recognize the significance of the different sources of acknowledgment. This in turn will result in up-front agreement on potential opportunities for dissemination of original ideas among the team.

A seldom discussed aspect of the manner in which ideas might be disseminated (and credit obtained) is the potential synergy between individual team members. For example, among academic staff involved in the project, there is a possibility for cross-disciplinary publications.

This framework, shown in Figure 3, maps out two axes: the horizontal axis representing formal ownership of the tangible IP, the vertical axis representing a continuum of recognition for the IC generated during a project, ranging from no acknowledgment of individual effort and contribution to a full public acknowledgment. Intermediate steps include recognition at the team and institutional level.

Enacting the IC/IP Framework

Our discussion so far has shown that, regardless of the nature of the IP ownership, academics and professionals working in software development teams need appropriate recognition for their contributions, but certain factors can prevent this from happening. The challenge, therefore, is to identify a set of project attributes that can be used to inform project management practices such that institutions are cognizant of the need for appropriate recognition. In the following section, we identify seven key attributes of, or processes within, a successful project. The model is developed from a review of the authors' own experiences of software development teams where problems had occurred. This review led to the identification of which weaknesses in the process had resulted in these problems (Williamson et al., 2003). By ensuring that these seven attributes are recognized and actively negotiated by newly forming teams and enacted throughout the life of the team, this model can assist projects in identifying and filling gaps in the structure of development teams, hence future risk can be mitigated.

In essence, the IC embedded in the members of the project team is articulated in terms of the various IP contributions made by these team members. However, if the focus is exclusively on the tangible products of the process (e.g., software and papers) through only considering the IP, then the worth of ideas (IC) can be underplayed, and their potential may not be realized. We are suggesting that explicit application of these seven guidelines can ensure more successful project outcomes and positive professional outcomes for all members of the team.

The nature of an effective community of practice for software development teams is discussed in terms of Figure 3. The two major axes and the four examples in Figure 3 are used to frame the seven attributes.

Intellectual Property: Individual Affirmation to Institutional Affirmation

Have an IP Acknowledgement Strategy

Highly successful projects exhibit a strong team dynamic which arises when the expertise and knowledge of individual team members can be communicated and shared with others. Part of this process involves ensuring that ideas are fairly acknowledged within and outside the team, whether by portfolio (graphic artists), publication (academics), or product (project managers and programmers).

Have an IP Review Strategy

It does not matter for the purposes of academic critical review whether the subject of study is a written paper, a software product, or a portfolio. Contribution from individual team members needs to be acknowledged through an inclusive authorship policy which is regularly revisited in

team meetings. This process can strengthen collegiality and reinforce mutual valuing between team members.

Have a Strategy to Separate IP from IC

The IP might be owned by an organization or institution, but the IC remains with the individuals in the team. Formal acknowledgment of where the ownership of IP lies is important and needs to be negotiated ahead of the commencement of the project. In many higher education institutions, this has become standard practice and involves retaining a competitive advantage and protecting the resources produced by employees of the organization. There are risks associated with key project contributors leaving (for example, a lead programmer) and either taking intellectual property with them or holding a software development team or institution to ransom by withholding access to code or other resources. In some organizations, the IC also remains with the organization via means of a nondisclosure agreement. Communities of practice might consider using a confidentiality agreement as part of a contract or offer of employment in order to keep this issue open and transparent.

Longevity Strategy: Ideas Remain

When a person leaves a team, they cede their IC to the project team or institution, and that contribution should continue to be recognized and acknowledged in project documentation, appropriate publications, and authorship in any finished product. In some projects, this may also involve ceding formal IP to the project (e.g., in the case of commercialization).

Intellectual Capital: No Formal Acknowledgment to Public Acknowledgment

Recognize the Emergent Nature of the Software Development Process and Its Impact on IC/IP for all Team Members

As software becomes more complex, it becomes less and less likely that the original academic imperative that led to the idea for the product will be instantiated in a form initially envisaged by the academic or the organizational unit that initiated the project. The development process and the end result will be strongly influenced by a wide range of individual and group contributions to the process and the product.

Ideas are Perishable

Software has a shelf-life, hence the IC that led to that product is also of limited use. The idea will become superseded and outdated as new ideas and new technologies emerge. For example, there are any number of commercial or free customizable online survey instruments (such as Survey Monkey, http://www.surveymonkey.com) that now exist. Learning Evaluation Online (LEO) was an early system that explored how customizable educational surveys could be developed online using an entirely Web-based interface (Kennedy & Ip, 1998). At the time this was an innovative approach, but it has since been superseded by more robust software. Thus, the IC for LEO has long since expired. The idea behind LEO has been taken up by others and reproduced using different software code. The code is the instantiation of the idea and is the only part of the project subject to IP rights.

Table 2. Implications for IP and IC

#	Scenario	Implications for IP and IC
1	IC and IP is owned by institution; institution takes credit with no contribution of individual creativity and effort.	This is a very poor scenario for developing the IC of an institution. Without affirmation, individuals will seek employment elsewhere and take their IC with them.
2	IP and IC are owned by the institution; individual contributions are well documented and publicized.	This is the scenario in a number of institutions worldwide, particularly those involved in distance education. This scenario is problematic when commercial aspects enter the situation as in the case of patents.
3	Institution makes no claim (software is given away or open source); no acknowledgment of individual contributions.	This is often the result of small student projects (although many institutions claim the IP of all undergraduate student work, not postgraduate) undertaken during a course of study). Most software of this type has a very limited life although there are some exceptions (Gunn, 1995).
4	Institution makes no claim (either left to the individual or open source community); individual contributions are well documented and publicized.	This applies to postgraduate work in universities. In many institutions, postgraduate (especially doctoral) students own their IP, and it is up to the student and supervisor to disseminate the details of the project. This aspect is changing as universities try to gain a competitive advantage, and many postgraduate students working in a large research department would do well to consider how the results of their studies might be retained, negotiating with the university in the early phases of the project. For example, some student projects (see **moodle.org** and moodle.com) have become very high profile products (Dougiamas & Taylor, 2003).

Public Acknowledgment of IP/IC Requires the Source Material to be in the Public Domain

Acknowledgment of unpublished work or work not publicly available is not sufficient to acknowledge IC and IP issues in a publication. In the case of academics where affirmation and professional career progress is at least partially a result of publication in accredited arenas such as books and journals, this is clearly not sustainable. Graphic artists, on the other hand, have their portfolios of work with iterations of visual designs that they take with them to the next project or job; and programmers have compilations of code: for these professionals, the publication is less important or substantive in career development. A key issue for an institution is providing the process by which academic publications can be developed without compromising the IP of the individual or trade advantages in the marketplace.

In summary, the implications for the four scenarios in Figure 3 are shown in Table 2.

THE FUTURE: APPLICATION OF THE SEVEN ATTRIBUTES OF THE IC/IP FRAMEWORK

In order to see how these attributes can be enacted in practice, the example of a major Australian multimedia project, *An@tomedia*, will be used. *An@tomedia* was designed to support problem-based learning (PBL) of anatomy in the Faculty of Medicine at the University of Melbourne (http://www.anatomedia.com). A number of academic evaluations on the role of *An@tomedia* in this PBL learning environment have been published (e.g.,

Table 3. Example of the application of the seven attributes of the IP/IP framework

#	Attribute	Enactment
1	Have an IP acknowledgment strategy	The acknowledgment of IP was never an issue within the project group. Individual contributions were always acknowledged by the core development team, becoming part of the documentation of the project. The extensive documentation ensured that no one was left off the credits on the *An@tomedia* Web site.
2	Have an IP review strategy	The existence of "prior art" was established in the early phases of the project. While the final product did not resemble the initial designs, it was always clear in the project meetings that the team was involved in the instantiation of the educational vision of the project leader (one of the core SMEs).
3	Have a strategy to separate IP from IC	The strategy to separate IP from IC was undertaken by the four principal authors as *An@atomedia* was moved from an interesting project to a commercial product. The documentation resulting from meetings included discussions of commercialization of *An@atomedia* and the associated need to separate IP from IC. The strategy adopted involved consultations with the university's legal advisors and the project team. The IP for the sale and commercial rights to *An@tomedia* were ceded to the four key authors by the other team members; however, the IC remained with members of the project team to use as they required.
4	Longevity strategy: Ideas remain	The credits list contains a list of all members who contributed to the project over a period of many years, including those individuals who either retired (in one case) or moved to other institutions (a number of people). It is possible for all members of the project team to include evidence of contributions to *An@atomedia* by reference to either the Web site or the CD-Roms (the form in which *An@tomedia* is published and sold).
5	Recognize the emergent nature of the software development process and its impact on IC/IP for all team members	The development of *An@tomedia* occurred over a considerable period of time. The genesis of some the clinical approaches adopted in the project were developed by the project leader and occurred well before *An@tomedia* commenced (Eizenberg, 1988, 1991). The use of technology followed as a consequence of the need to develop more effective and engaging approaches to the teaching of anatomy (Driver & Eizenberg, 1995). As the final design of the software emerged, it was always clear in meetings and associated documentation that other members of the project team were involved in the instantiation of prior concepts and developments in new and innovative ways, but the underlying concept derived from the earlier work in paper-based media.
6	Ideas are perishable	*An@atomedia* received a number of awards for innovation and excellence after the first release (see **http://www.anatomedia.com/credits.shtml**). However, as people come and go from the project, the initial ideas will be superseded or altered to reflect teaching evaluations, changes in the medical curriculum, and improvements in technology. Solutions developed in 1999 or 2000 may not be suitable in 2005. What was once a good idea may not be appropriate in the future, but the three major methods of affirmation remain—publication, portfolio, and vitae for all contributions.
7	Public acknowledgment of IP/IC requires the source material to be in the public domain	The *An@atomedia* Web site provides definitive acknowledgment of the specific contributions of individuals, including the evaluators, programmers, educational consultants, photographers, medical consultants, project managers, dissectors, illustrators, interface and graphic designers, and research assistants, to name a few.

Kennedy, Eizenberg & Kennedy, 2000; Kennedy, Kennedy & Eizenberg, 2001).

The software has been successfully commercialized by the four subject matter experts (core SMEs or core authors) after other members of the development team ceded any personal commercial claims to the group by means of a legal document to that effect.

Affirmation and acknowledgment involving publishing for academic members (Kennedy et al., 2000; Kennedy et al., 2001), contributions to portfolios for non-academic members, and public acknowledgments in the *An@tomedia* Web site for every person who contributed in any significant way to the project were not affected by this written agreement. The public affirmation (particularly important for non-academic members of the project team) is illustrated by the observation made by a reviewer of *An@tomedia* in *The Lancet* (Marušić, 2004) where she mentions the extensive list of credits for all the members of the team (over 60) involved with the project. This process was accomplished quite simply because matters of IP had been previously discussed in the course of project meetings, and the "prior art" that existed and underpinned the educational approach was well known to all project members. Table 3 summarizes the way in which the seven attributes worked in this project.

CONCLUSION

While formalized tools exist for capturing IP generated during a project, most software development teams lack formal explicit processes for ensuring that the IC generated is accurately and adequately apportioned. This article has raised issues relating to how software development project teams are recognized for their contribution and a simple framework for measuring recognition of contribution has been presented. Seven key project attributes or processes have been identified to assist project teams develop an awareness of how project roles and structures can be negotiated so that tacit ideas and knowledge generated can become explicit. Such a model must recognize that the requirements for, and process of, recognition will differ within different multiskilled teams. The application of the framework to one major multimedia project has been discussed.

KEY TERMS

Educational Software Development Teams: Software development teams in university settings are multifaceted and multiskilled, requiring the skills of project managers, subject matter experts, educational designers, programmers, graphic designers, interface designers, IT support staff, editors, and evaluators. In many cases, one person can assume more than one role.

Intangible Assets: Higher education institutions are traditionally based upon ideas, one form of intangible assets. However, the modern university frequently seeks to differentiate itself from its competition. In this article, intangible assets include an investment or outcome enjoyed by the institution in knowledge-based resources and processes. Typically, these intangible assets are termed soft assets because they are not either infrastructure or equipment. Some examples are training programs, improvements to organizational communication flows, or new quality assurance systems.

Intellectual Capital (IC): IC is the sum of the individual imagination that, when aggregated, becomes everything everybody in an organization or team knows and which provides them with some advantage over their competitors. Organizational IC comes from the interplay of structural capital, which augments the value of human capital, leading to an increase in customer/supplier capital.

Intellectual Property (IP): IP is a formal measurable subset if IC; the tangible product that results from the idea and is represented and recognized through patents, trademarks, designs, and copyright (which includes software and multimedia). IP can also be extended to cover a much broader and often more intangible grouping that extends to trade secrets, plant varieties, geographical indications, and performers' rights.

Prior Art: In this article, the concept of "prior art" is used in a similar manner to that adopted by the patent office. However, higher education has a long tradition of valuing ideas, not just economic value (as in patent laws). The "prior art" in this instance refers to the intangible ideas (instantiated in the earlier publications) prior to the commencement of a project, such as the An@tomedia project. It was the basis of these earlier ideas that formed the nucleus of the design philosophy and influenced the manner in which the developers reached agreement on design decisions.

Project Framework: Negotiation of a model within the project to ensure that the contributions of all individuals (and their IC) are able to be appropriately recognized.

Recognition: Different professional groups look for and require different forms of recognition for their professional development. Where academic staff focus on publication, designers need to develop a portfolio of work, and software developers receive kudos and build a reputation based on a product that has been developed and the code therein.

This work was previously published in Encyclopedia of Communities of Practice in Information and Knowledge Management, edited by E. Coakes; S. Clarke, pp. 364-374, copyright 2006 by Idea Group Reference (an imprint of IGI Global).

Chapter 2.18
Developing Knowledge Management Systems from a Knowledge-Based and Multi-Agent Approach

ABSTRACT

Developing knowledge management systems is a complicated task since it is necessary to take into account how the knowledge is generated, how it can be distributed in order to reuse it, and other aspects related to the knowledge flows. On the other hand, many technical aspects should also be considered such as what knowledge representation or retrieval technique is going to be used. To find a balance between both aspects is important if we want to develop a successful system. However, developers often focus on technical aspects, giving less importance to knowledge issues. In order to avoid this, we have developed a model to help computer science engineers to develop these kinds of systems. In our proposal we first define a knowledge life cycle model that, according to literature and our experience, ponders all the stages that a knowledge management system should give support to. Later, we describe the technology (software agents) that we recommend

to support the activities of each stage. The article explains why we consider that software agents are suitable for this end and how they can work in order to reach their goals. Moreover, a prototype that uses these agents is also described.

INTRODUCTION

In the last decades, knowledge management (KM) has captured enterprises' attention as one of the most promising ways to reach success in this information era (Malone, 2002). A shorter life cycle of products, globalization, and strategic alliances between companies demand a deeper and more systematic organizational knowledge management. Consequently, one way to assess an organization's performance is to determine how well it manages its critical knowledge.

In order to assist organizations to manage their knowledge, systems have been designed. These are called knowledge management systems (KMS), defined by Alavi and Leidner (2001) as IT-based systems developed to support/enhance the processes of knowledge creation, storage/retrieval, transfer, and application.

However, developing KMS is a difficult task; since knowledge *per se* is intensively domain dependent whereas KMS often are context specific applications. Thus, reusability is a complex issue. On the other hand, the lack of sophisticated methodologies or theories for the extraction of reusable knowledge and reusable knowledge patterns has proven to be extremely costly, time consuming, and error prone (Gkotsis, Evangelou, Karacapilidis & Tzagarakis, 2006). Moreover, there are several approaches towards KMS developing. For instance, the process/task based approach focuses on the use of knowledge by participants in a project, or the infrastructure/generic system based approach focuses on building a base system to capture and distribute knowledge for use throughout the organization (Jennex, 2005). On the other hand, before developing this kind of system it is advisable to study and understand how the transfer of knowledge is carried out by people in real life. However, when developing KMS, developers often focus on the technology without taking into account the fundamental knowledge problems that KMS are likely to support (Hahn & Subramani, 2000).

Different techniques have been used to implement KMS. One of them, which is proving to be quite useful, is that of intelligent agents (van Elst, Dignum & Abecker, 2003). Software agent technology can monitor and coordinate events or meetings and disseminate information (Wooldridge & Jennings, 1995). Furthermore, agents are proactive in the sense that they can take the initiative and achieve their own goals. The autonomous behavior of the agents is critical to the goal of this research since it can reduce the amount of work that employees have to perform when using a KM system. Another important issue is that agents can learn from their own experience. Consequently, agent systems are expected to become more efficient with time since the agents learn from their previous mistakes and successes (Maes, 1994).

Because of these advantages, different agent-based architectures have been proposed to support activities related to KM (Gandon, 2000). Some architectures have even been designed to help in the development of KMS. However, most of them focus on a particular domain and can only be used under specific circumstances. What is more, they do not take into account the cycles of knowledge in order to use knowledge management in the system itself. For these reasons, in this article we propose a generic model for developing KMS. Therefore, in the next section we describe the model and the software agents that we propose to support it. In the following section, we explain how the agents are structured and how they have been modeled using the INGENIAS methodology. Later, the next section describes a prototype that we are implementing by using the agents proposed in the model. The following section summarizes

related works carried out with agents. Finally, conclusions and future work are outlined in the last section.

A MULTI-AGENT MODEL TO DEVELOP KNOWLEDGE MANAGEMENT SYSTEMS

A successful KMS should perform the functions of knowledge creation, storage/retrieval, transfer, and application (Jennex & Olfman, 2006). Taking this fact into account and after reviewing several knowledge life cycles and models (see Table 1) and seeing what stages most authors considered, we decided to define a knowledge life cycle that indicates what process a KMS should support (see Figure 1). This is a focus different to the previous one based on describing the knowledge cycle in human beings and/or in companies.

The stages of our proposal are acquisition, storage, use, transfer, and evaluation. The first three stages are considered in most knowledge life cycles (see Table 1). We have added transfer (also considered in several cycles) and evolution. Transfer is added because a KMS should disseminate knowledge to those people that can need it. Evolution is added because knowledge should always be updated otherwise it would not be used.

Figure 1. Knowledge life cycle model proposed

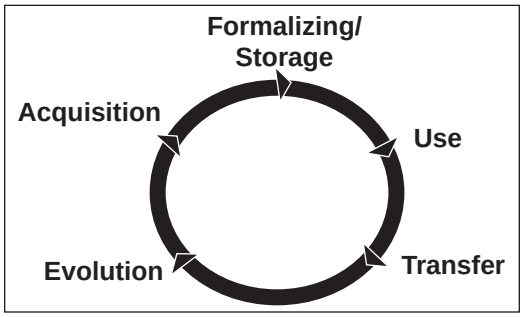

Table 1. Knowledge life cycle

Model	Stage1	Stage2	Stage3	Stage4	Stage5	Stage6	Stage7
Nonaka and Takeuchi (Nonaka & Takeychi, 1995)	Socialization	Externalization	Combination	Internalization			
Wiig (Wiig, 1997)	Creation	Storing/ gathering	Use	Leverage	Sharing		
Davenport and Prusak (Davenport & Prusak, 1998)	Generation	Codify/ Coordinate	Transfer	Roles and Skills			
Tiwana (Tiwana, 2000)	Acquire	Sharing	Use				
Alavi and Leidner (Alavi & Leidner, 2001)	Creation	Storage/ Retrieval	Transfer	Application			
Rus and Lindvall (Rus & Lindvall, 2002)	Creation/ Acquisition	Organization/ Storage	Distribution	Application			
Nissen (Davenport, 1998)	Creation	Organization	Formalize	Distribute	Application	Evolve	
Ward and Aurum (Ward & Aurum, 2004)	Creation	Distribution	Organization	Adaptation	Identification	distribution	Application
Dickinson (Dickinson, 2000)	Identification	Acquisition	Development	Distribution	Use	Preservation	

In the following paragraphs each stage of the model is described. At the same time and with the goal of illustrating that it is possible to support each stage by using current technology, we are going to explain how a software agent could be implemented for a KMS.

a. *Knowledge acquisition* is a key component of a KMS architecture. This stage includes the elicitation, collection, and analysis of knowledge (Rhem, 2006). During this process, it is vital to determine where in the organization the knowledge exists and how to capture it. The definition of the knowledge to be acquired can be assisted by classifying types of knowledge and knowledge sources (Dickinson, 2000). To support this stage we propose to use an agent called a *Captor Agent*. The Captor Agent is responsible for collecting the information (data, models, experience, etc.) from the different knowledge sources. It executes a proactive monitoring process to identify the information and experiences generated during the interaction between the user and the system or groupware tools (e-mail, consulted Web pages, chats, etc.). In order to accomplish this, the Captor Agent can use different techniques to acquire knowledge since there are several tools and techniques that consolidate and transform corporate data into information (Houari & Homayoun Far, 2004). They contain:
    - Front-end system (i.e., decision support system [DSS], executive information system [EIS], and online analytical processing [OLAP]).
    - Back-end system: data warehouse, data mart, and data mining (Giannella, Bhargava et al., 2004).

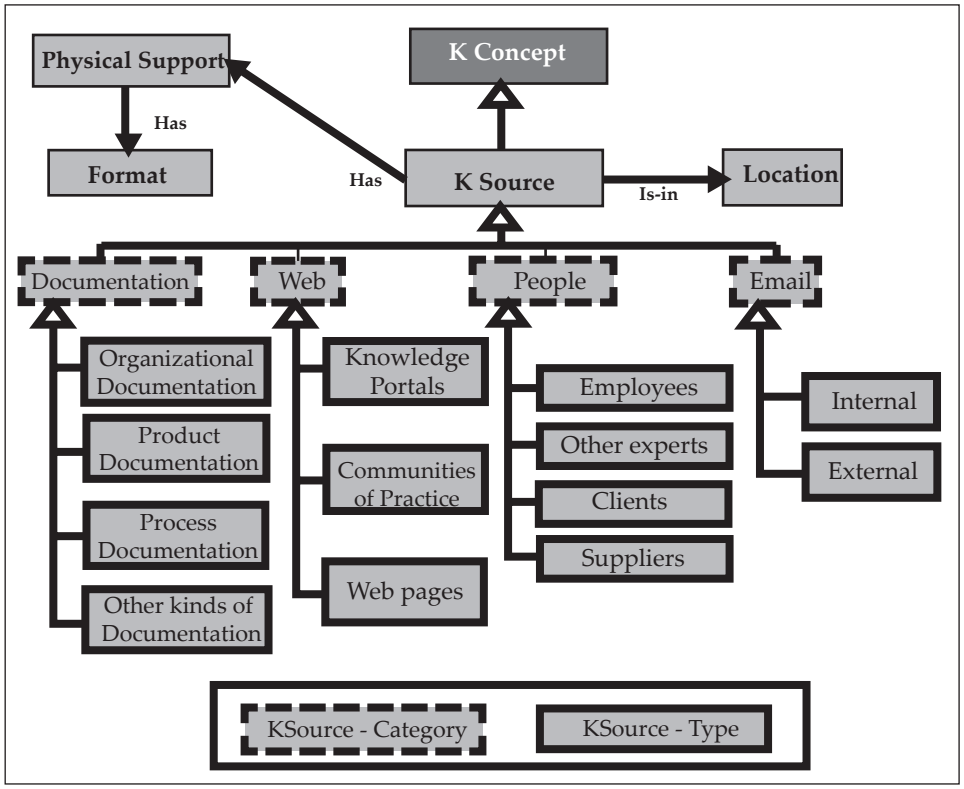
Agents can also apply classical techniques used by experts to acquire knowledge such as structured interviews, questionnaires, goal trees, decision networks, repertory grids, or conceptual maps (Rhem, 2006). More sophisticated techniques such as WebParser (Camacho, Aler & Cuadrado, 2004) to obtain information from the Web, document classification (Novak, Wurst, Fleschmann & Strauss, 2003), mailing list management (Moreale & Watt, 2003), or data mining and neuronal nets can be also used.

Once the knowledge has been obtained, the Captor Agent can classify it by using ontologies according to its type and the knowledge source from it was obtained (see Figure 2). This ontology is based on Rodriguez's ontologies for representing knowledge topics and knowledge sources (Rodríguez, Martínez, Favela, Vizcaíno & Piattini, 2004).

The ontology has four knowledge source categories: Documentation, which can be subdivided into documentation related to the organization's philosophy, documentation which describes the product/s which the company works with, documentation that describes the process that the company carries out, and other types of documentation that an organization has but that cannot be classified into any of the previous subgroups. Another important source where the Captor Agent finds information is the Web, which can also be divided into other subcategories such as portals, communities of practice, and so forth. The main knowledge source in a company is, without any doubt, people. Depending on the type of company, people may be classified as clients, employees, and so forth. The last knowledge source that the Captor Agent can use is e-mail that can be classified as internal mail (mail sent between employees), and external mail (e-mails sent to other people outside the organization).

One advantage of this approach is that the Captor Agent can work in any domain since by changing these ontologies the Captor knows what key knowledge should be found and where it might be.

Figure 2. Knowledge source ontology



b. *Knowledge formalizing/storing* is the stage that groups all the activities that focus on organizing, structuring, representing, and codifying the knowledge with the purpose of facilitating its use (Davenport & Prusak, 1998). To help carry out these tasks we propose a *Constructor Agent*. This agent is in charge of giving an appropriate electronic format to the experiences obtained so that they can be stored in a knowledge base to aid retrieval. Storing knowledge helps to reduce dependency on key employees because at least some of their expert knowledge has been retained or made explicit. In addition, when knowledge is stored, it is made available to all employees, providing them with a reference as to how processes must be performed, and how they have been performed in the past. Moreover, the Constructor Agent compares the new information with old knowledge that has been stored previously and decides whether to delete it and add new knowledge or to combine both of them. In this way, the combination process of the SECI (Nonaka, 1994) model is carried out, producing new knowledge resulting in the merging of explicit knowledge plus new explicit knowledge.

Different techniques exist to store knowledge and frequently the technique used is narrowly related to the retrieval method used. Therefore, if a case-based reasoning is going to be used, the knowledge will be stored as "cases." Other techniques are knowledge objects, frames, predicate logic, or fuzzy logic. In the case of using ontolo-

gies to classify the knowledge, methodologies to represent the knowledge can be used. Examples of these methodologies are Ontolingua (Gruber, 1993) or Representation Formalism for Software Engineering Ontologies (REFSENO) (Tautz & Von Wangenheim, 1998).

c. *Knowledge Use* is one of the main stages, since knowledge is helpful when it is used and/or reused. The main enemy of knowledge reuse is ignorance. Employers often complain because employees do not consult knowledge sources and do not take advantage of the knowledge capital that the company has. KMS should offer the possibility of searching for information; they can even give recommendations or suggestions with the goal of helping users to perform their tasks by reusing lessons already learnt, as well as previous experiences. In our model the agent in charge of this activity is the Searcher Agent, which searches in the knowledge base for the needed knowledge. Different techniques are currently used to search for knowledge. Many of them are based on the use of the position and frequency of keywords (Mohammadian & Jentzsch, 2004) or on information retrieval techniques (Frakes & Baeza-Yates, 1992; Liang & Huang, 2000). Other authors such as Sung Kim (2004) mix several techniques, data mining, and case-based reasoning to develop a recommender system.

d. *Knowledge Transfer* is the most investigated stage in knowledge management (Peachey, Hall & Cegielski, 2005). This stage is in charge of transferring tacit and explicit knowledge. Tacit knowledge can be transferred if it has been previously stored in shared means, for example, repositories, organizational memories, databases, and so forth. The transfer stage can be carried out by using mechanisms to inform people about the new knowledge that has been added. For this stage we propose a *Disseminator Agent*, which must detect the group of people or communities who generate and use similar information; for example, in the software domain, the people who maintain the same product or those who use the same programming language. Therefore, this agent fosters the idea of a community of practice in which each person shares knowledge and learns thanks to the knowledge of the other community members (Wenger, 1998). An appropriate knowledge management linked to communities of practice helps to improve the organization's performance (Lesser & Storck, 2001). Disseminated information may be of different types; it may be information linked to the company's philosophy or specific information about a determined process. Finally, the Disseminator Agent needs to know exactly what kind of work each member of the organization is in charge of and the knowledge flows linked to their jobs. In order to do this, the disseminator agent contacts with a new type of agent called the *personal agent* which is in charge of determining the users' profiles (it will be described in next section). Comparing this stage with the SECI model we can say that the disseminator agent fosters the socialization process since it puts people who demand similar knowledge in touch and once in contact they can share their experience, thus increasing their tacit knowledge.

e. *Knowledge Evolution*. This stage is responsible for monitoring the knowledge that evolves daily. To carry out this activity we propose a *Maintenance Agent.* The main purpose of this agent is to keep the knowledge stored in the knowledge base updated. Therefore, information that is not often used is considered by the Maintenance Agent as information to be possibly eliminated.

MULTI-AGENTS AGENCIES

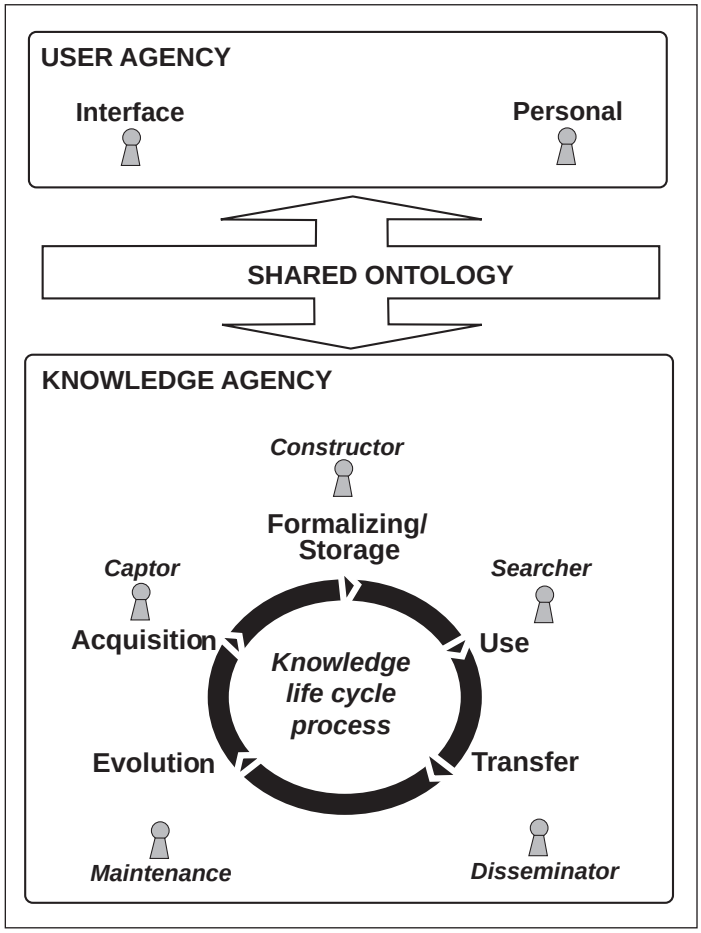
Once the model and the agents that we propose to give support to the different stages have been described, we are going to explain how the agents are structured into two agencies. Therefore, we group all the agents closely in charge of managing knowledge and supporting the different stages of the model proposed in one agency. Auxiliary agents are in another agency (see Figure 3).

Therefore, the *Knowledge Agency* is in charge of giving support to the KM process. It consists of the Constructor Agent, the Captor Agent, the Searcher Agent, the Disseminator Agent, and the Maintenance Agent.

On the other hand, the *User Agency* is formed of the Personal Agent and the Interface Agent. The Personal Agent monitors users' tasks to obtain their preferences and needs. In order to implement the Personal Agent, user modeling techniques can be used. User modeling implies obtaining certain knowledge about the user. This knowledge describes what the user "likes" or what the user "knows" (Chin, 1986).

The *Interface Agent* is the mediator between the users and the agents. Thus, when an agent

Figure 3. Agents distribution



wants to communicate a message to the user, the agent sends the message to the Interface Agent which shows it to the user.

Another component is the *Shared Ontology* which provides a conceptualization of the knowledge domain. The Shared Ontology is used for the consistent communication of the agencies.

In order to carry out the analysis and design of the agents involved we have followed a methodology called INGENIAS (Pavón & Gómez-Sanz, 2003) which provides metamodels to define multi-agent systems, and support tools to generate them. Using metamodels facilitates the development of systems enormously, since they are oriented towards visual representations of concrete aspects of the system.

Below, we are going to show the different agent meta-model diagrams which describe the roles and tasks of each agent.

Figure 4 shows that the goal of the Captor Agent is to obtain information that should be stored. Its role is "filter" since it must decide what information should be transformed into knowledge, the purpose being to use this in future projects. In the following lines, we describe each of the tasks carried out by this agent.

- **IdentifyIS:** This task consists of identifying available knowledge sources in the system.
- **CaptureInfo:** The agent must also capture information.
- **SendToConstructor:** Once the suitability of storing the information has been analyzed, the Captor sends it to the Constructor Agent (described in Figure 5) whose roles are sculptor and treasurer since it is in charge of giving an appropriate electronic format to the information (sculptor) and of storing it in the knowledge base (treasurer). The tasks developed by Constructor Agent are:
  - **CompareInfo:** The agent is in charge of comparing the new information with the previously stored knowledge.
  - **CombineInfo:** The agent is also in charge of combining the new information with the previously stored knowledge.
  - **ClassifyInformation:** Another task is to classify the information received by the Captor Agent (for instance: models, structures, files, diagrams, etc.).
  - **SendToDisseminator:** This is a critical task which consists of sending knowledge to the Disseminator Agent.
  - **SaveKnowledge:** One of the most important tasks is to store the new knowledge into the knowledge base.

The Disseminator Agent, whose role is PostOfficeEmplee, as it behaves the "postman" of

Figure 4. Captor agent diagram

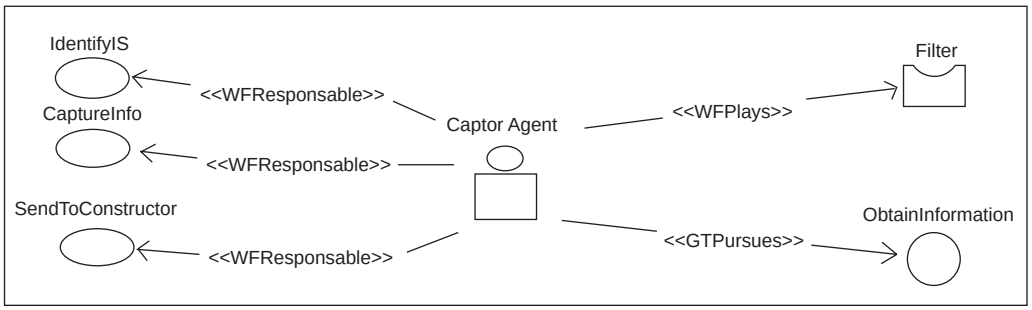


Figure 5. Constructor agent diagram

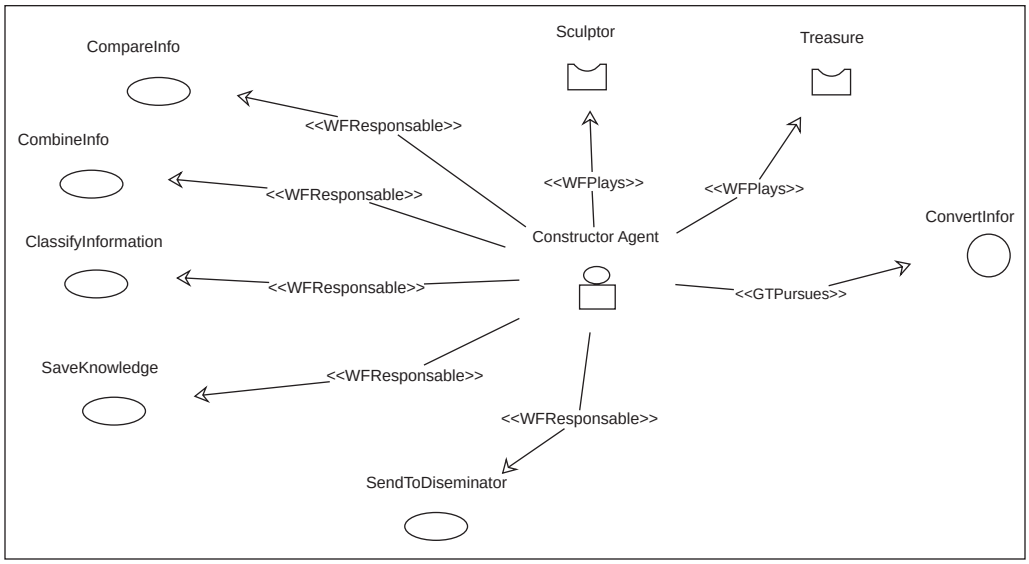

Figure 6. Disseminator agent diagram

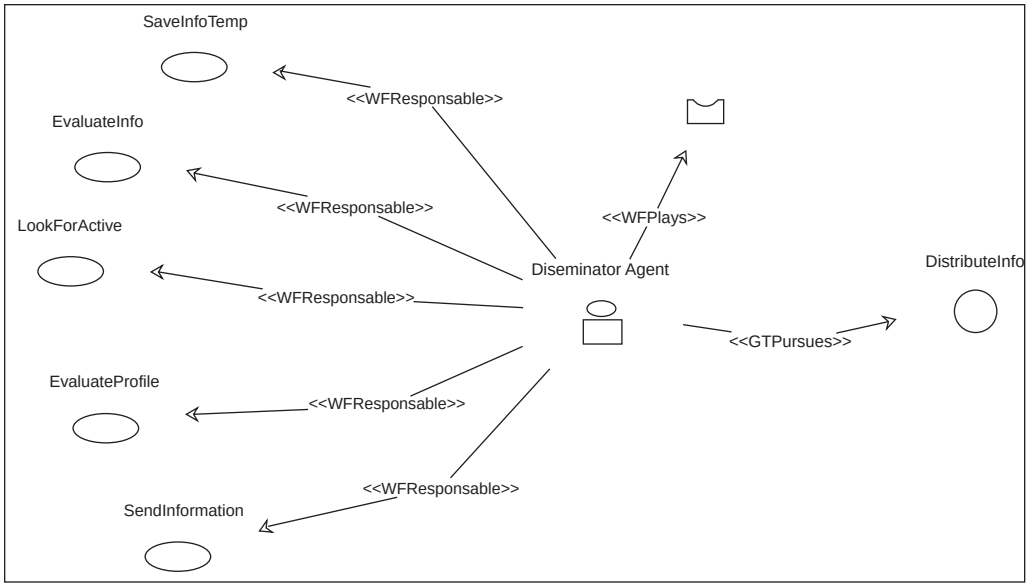

the architecture, (see Figure 6) is composed of the next tasks:

- **SaveInfoTemp:** The Disseminator Agent stores temporally the new knowledge received by the Constructor Agent.
- **EvaluateProfiles:** Once identified one user profile, the Disseminator Agent evaluates it in order to determine user's needs.
- **LookForActivePersonalAgents:** Personal Agents can be distributed into different nodes, so it must identify all active Personal Agents available in the system.

- **SendInformation:** This is a critical task which consists of distributing the information to those people that can need it (really, the information is sent to their interface agents).
- **EvaluateInfo:** This task is focused on evaluating received information to be able to relate it with different user's profiles.

Another agent that supports the knowledge life cycle is the Searcher Agent. The goal of this agent is to foster the internalization process of the SECI model, since the employees have the opportunity of acquiring new knowledge by using the information that this agent suggests. The Searcher Agent diagram (Figure 7) is composed of the next tasks:

- **LookForInfo:** This agent is in charge of searching the information required by the users.
- **ClassifyInfo:** This agent also classifies the information found in the knowledge base.
- **SendInfoToI:** Finally, the agent sends the knowledge found in the knowledgebase to an Interface Agent.

Figure 7. Searcher agent diagram

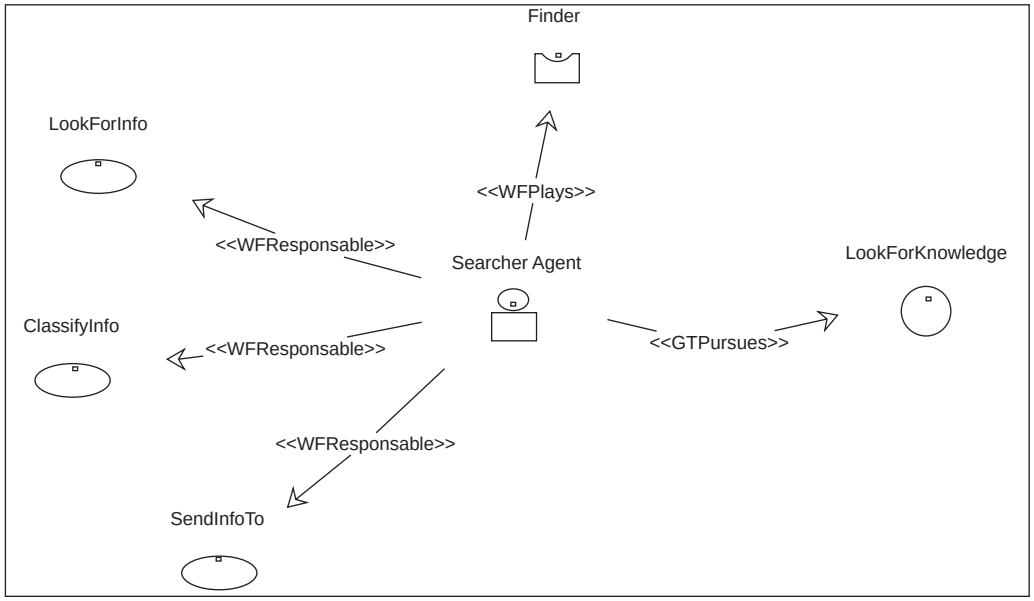

Figure 8. Maintenance agent diagram

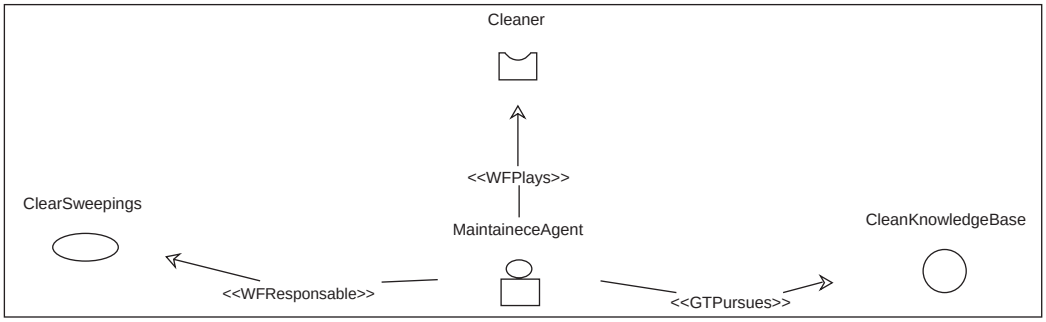

Figure 9. Personal agent diagram

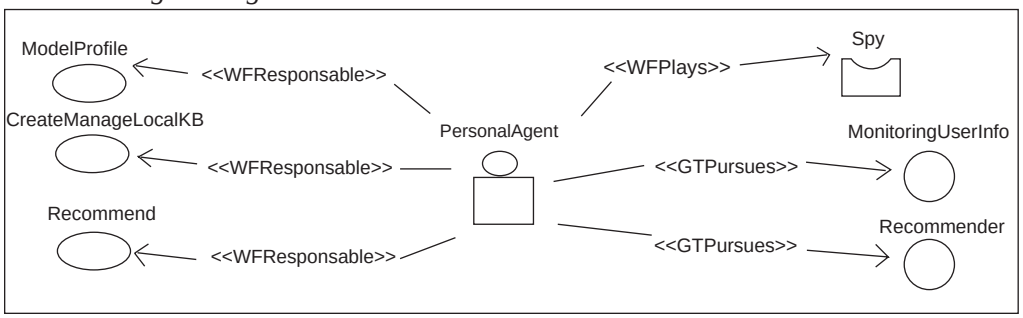

Figure 10. Interface agent diagram

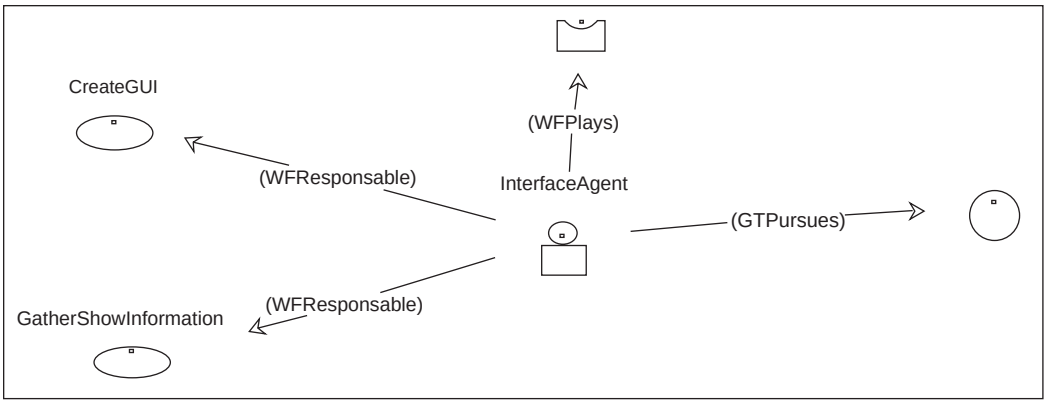

The last type of agent of the Knowledge Agency is the Maintenance Agent (Figure 8). The main purpose of this agent is to keep the knowledge stored in the knowledge base updated. Therefore, its task dealt mainly with deleting obsolete information.

Now, the two types of agents of the User agency are described. Figure 9 shows the Personal Agent diagram whose role is called "spy" since the agent must monitor users' activities in order to obtain their profiles. Therefore, its goals are monitoring users' tasks and recommending information.

In order to attain these goals it should carry out the following tasks:

- **Modeling the users' profiles:** By observing the users' preferences, activities, information consulted, and so forth.
- **CreateManageLocalKnowledgeBase:** Creating and managing a "local knowledge base" where the relevant information for the user can be stored.
- **Recommending knowledge or knowledge sources:** This agent tries to guess what knowledge would be relevant for the user. To accomplish this, this agent communicates with the Searcher Agent and with the Interface agent.

On the other hand, the Interface Agent is an intermediary between the users and the rest of agents. Figure 10 shows that its main tasks are creating GUI and showing information to the users

These tasks are defined in order to attain the goal of showing important information to the

user, named in the diagram ShowInformation, so we have to create an user interface and put the received information from others agents in a nice way to the user.

A PROTOTYPE SYSTEM

In order to test our model we are developing a KMS to be used in software maintenance companies. So far, the prototype recommends what information sources maintainers should consult to solve a particular problem. Before constructing the prototype, the knowledge flows that take place in software maintenance companies were studied (Rodríguez, Martínez, Vizcaíno, Favela & Piattini, 2005). To illustrate how the prototype works let us describe a scenario.

Scenario

A software maintenance engineer selects the project to be work on. Then, the employee starts to work on an activity (for instance a maintenance request). At the same time, the Personal Agent is monitoring the engineer's movements and is logging in what project and activity the engineer is working on. So, the Personal Agent sends the Searcher Agent a message asking for knowledge related to the activity that the employee is carrying out. Depending on the activity, the Searcher Agent can use two retrieval techniques, position and frequency of keywords in the case of needing to give information about a topic, or case-based reasoning in the case of having to propose a solution to a problem. When the Searcher Agent finds suitable information, the agent sends it to the Interface Agent, which is in charge of communicating to the employee that certain information exists which can be useful for the employee's work. The employee will decide if to consult this information. Figure 11 despites the diagram of this part.

Once the employee finishes the work, the Captor Agent checks whether a new case can be constructed (in case the employee had found a solution to a problem) or whether a new knowledge source has been used. In both cases the Captor sends the new knowledge to the Constructor Agent which is in charge of storing this in the knowledge base or adding new concepts to the knowledge source ontology according to the circumstance that have taken place.

The collaboration between the Captor and the Constructor Agent is depicts in Figure 12, which is an interaction model diagram that the INGENIAS methodology utilizes. These diagrams are very useful to see, at first glance, as agents interact.

Some Implementation Aspects

The platform that we are using to develop the architecture is java agent development framework (JADE) since it is FIPA compliant and is currently one of the most widely used. Moreover, JADE has been successfully used in the development of other systems in the domain of knowledge management (Bergenti, Poggi & Rimassa, 2000; Gandon, 2000).

RELATED WORK

Traditional KM systems have received certain criticism, since employees are often overloaded with extra work as they have to introduce information into the KMS and worry about updating this information. One proposal to avoid this extra burden was to add software agents to perform this task in place of the employees. Later, intelligent agent technology was also applied to other different activities, bringing several benefits to the knowledge management process.

The benefits of applying agent technology to knowledge management include distributed system architecture, easy interaction, resource

Figure 11. Scenario diagram

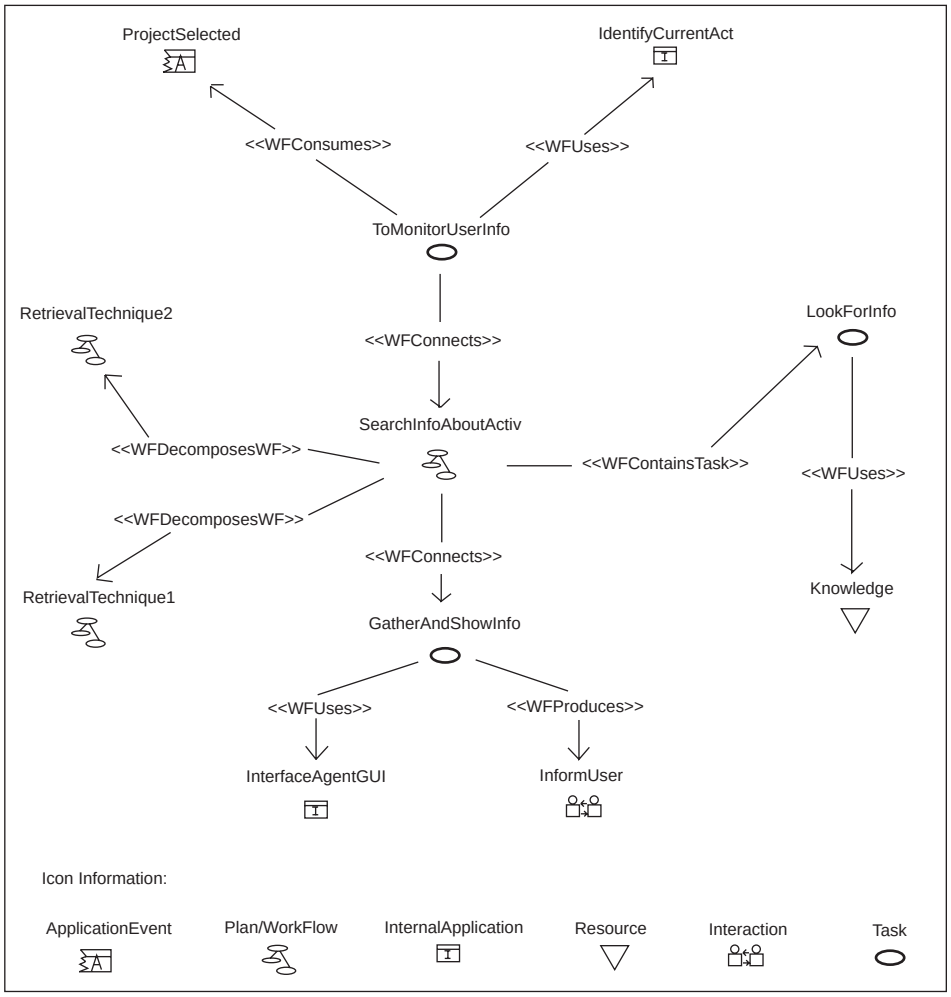

Figure 12. Cooperation between captor and constructor agent

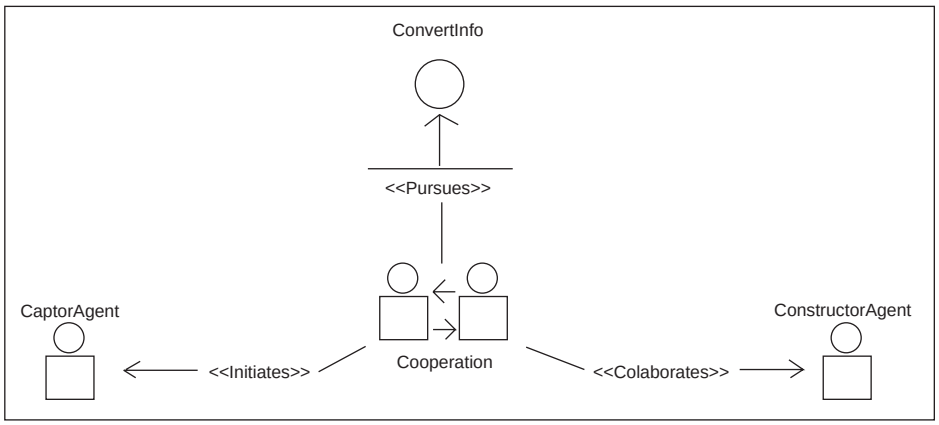

management, reactivity to changes, interoperation between heterogeneous systems, and intelligent decision making. The set of knowledge management tasks or applications in which an agent can assist is very wide, for instance:

- To manage organizational memory, an example being the CoMMA project, (Gandon, 2000) (Corporate Memory Management through Agents), which combines emergent technologies, allowing users to exploit an organizational memory.
- To support cooperative activities. For instance Wang, Reidar, and Chunnian (1999) propose a multi-agent architecture to provide support to cooperative activities.
- To recommend. For instance Sung Kim (2004) describes a system to customize recommendations.
- To find experts. Some systems are used to help people find experts who can assist them in their daily work.
- To share knowledge. For instance Mercer and Greenberg (2001) propose a multi-agent system for knowledge sharing in a system designed to advise good programming practice.
- To manage mailing lists, or document classification (Moreale & Watt, 2003).

These and other existing systems were often developed without considering how knowledge flows and what stages may foster these flows. Because of this, they often support only one knowledge task, without taking into account that knowledge management implies giving support to different process and activities. On the other hand, KM systems often focus on the technology, without taking into account fundamental problems that these kinds of systems are likely to support (Hahn & Subramani, 2000).

CONCLUSION

The main contributions of this article are the design of knowledge cycle for developing KMS where the main functions that this kind of systems must support are described. Moreover, a multi-agent architecture is outlined to help KMS developers to implement these kinds of systems. The advantages of these contributions are:

- The model provides support to different activities: knowledge creation, storage/retrieval, transfer, and application. All are activities which, according to the authors who specialize in evaluating KMS, should support this kind of system.
- The architecture is based on a KM life cycle that we have proposed for this end. Therefore, we try to avoid the lack of other architectures that are focused on the technology and forget the knowledge aspects.
- The architecture makes use of intelligent agents. This is a technique that have proved to be very convenient in knowledge management activities since it avoids one of the problems of some KMS such as overloading the employees with extra work instead of helping them during their daily work. Agents can carry out many tasks on behalf of users. Moreover, they act when they consider that it is necessary to do so without needing users' instructions. Another advantage of using agents is that they can collaborate with other agents already implemented to carry out concrete knowledge tasks; for instance, obtaining information from the Internet or from e-mail. Thus, the development of KMS would be easier since only the basic agents of our model would have to be implemented and these could collaborate with other agents that have already been tested.

On the other hand, we are modeling the agents in a systematic way by using INGENIAS methodology whose metamodels help future developers to understand how the different agents work.

As future work we aim to compare the implementation of a KMS based on our proposal with developments using other architectures. Without any doubt this evaluation will help us to improve our proposal. On the other hand, we are also working on extending the model documentation with a more wide and detailed description of the possible techniques that could be used to implement each type of agent according to the main needs that organizations usually demand.

From a technological point of view, we are also studying JADEx in order to see how easy it would be to migrate to this new platform.

ACKNOWLEDGMENT

Chapter 2.19
Human-Centered Design of a Semantically Enabled Knowledge Management System for Agile Software Engineering

Christian Höcht
Technical University of Kaiserslautern, Germany

Jörg Rech
Fraunhofer Institute for Experimental Software Engineering (IESE), Germany

ABSTRACT

Developing human-engineered systems is considered as a challenge that addresses a wide area of expertise; computer scientists as well as social scientists. These experts have to work together closely in teams in order to build intelligent systems to support agile software development. The methodology developed in the RISE project enables and supports the design of human-centered knowledge-sharing platforms, such as Wikis based on standards in the field of education science. The project "RISE" (Reuse In Software Engineering) is part of the research program "Software Engineering 2006" funded by the German Federal Ministry for Education and Research (BMBF). The goal was to improve the reuse of artifacts in software engineering, and brought together researchers from education science (The Department of Educational Sciences and Professional Development at the Technical University of Kaiserslautern) and computer science (Fraunhofer Institute for Experimental Software Engineering (IESE) and the German Research Center for Artificial Intelligence (DFKI)) with industrial partners (Empolis GmbH and brainbot technologies AG). This chapter gives an overview about the human-centered design of Wiki-based

knowledge and learning management systems in software engineering projects, and raises several requirements one should keep in mind when building human-centered systems to support knowledge and learning management.

INTRODUCTION

The development of complex software systems is based on company- and domain- specific knowledge that has to be constantly cultivated among the employees, because the resulting quality of manufactured software systems depends on what degree the needed knowledge is actually available (Decker, Ras, Rech, Klein, Reuschling, Höcht, & Kilian, 2005). It is not only that the technical platform should release software engineers as much as possible from time-consuming retrieval-processes. At the same time the platform acquires valuable pieces of information from users, who publish their problems and experiences during work. Out of this process, company-based knowledge may be built and refined.

However, it is just because of the various possibilities of searching and browsing through artifacts that users feel overwhelmed by the flood of information. Therefore, the increasing amount of information itself is not the problem, but an unfiltered and unrated access to it. In fact, the main goal is to ensure that software engineers can deal with their daily tasks without burdening them with additional work. A systematic selection and presentation of content helps to avoid the feeling of being swamped with artifacts and so keeps, and even improves, the employees' motivation. For example, on the one hand, it is a good idea to offer plugins that provide visual representations of concepts, but on the other hand, offering totally unrestricted overviews is often too complex to be processed by the users (Tonkin, 2005).

Ballstaedt (1997) mentions four main types of artifacts considering textual content. As Wikis mainly consist of text, this typology is helpful to

Figure 1. Different types of content

	Description	Example	Challenges in Knowledge Management related to Software Engineering
expository text	Expository text describes facts, explains the context, and thus provides conceptual knowledge.	dictionary entry	Information related to software products, solutions, or methods might expire very quickly, and would thus require much effort to maintain it.
narrative text	Narrative text reports actions or plots and events. It informs about specific situations, motives, decisions, acts, and their consequences.	blog entry	Narrative text might be rather helpful for some employees, but probably just a waste of time for others, because the individual usefulness of a specific narrative text is hard to evaluate.
instructional text	Instructional text provides procedural knowledge and enables people to do or not to do something.	help on Installation or maintenance	Providing useful instructional text assumes that the author respects different levels of knowledge and writes adequate content, keeping a specific target group in mind.
additional didactic text	Additional text that supports specific learning activities.	advance organizer	Additional didactic content requires deeper knowledge about reading and learning strategies and depends on rather static content like printed material.

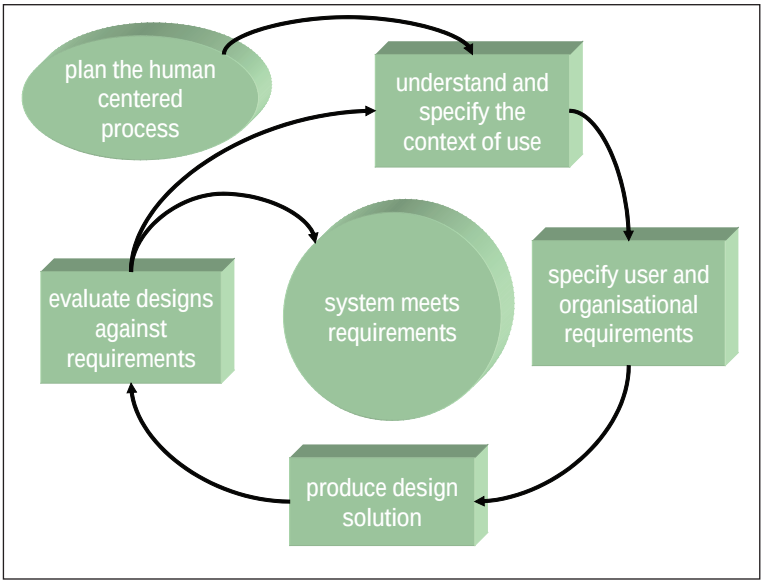
distinguish between different textual instances, as seen in Figure 1.

From the pedagogical point of view, artifacts in a knowledge management (KM) system are considered as not more than a faint representation of knowledge. In order to communicate knowledge to others, its complexity has to be reduced. This can be done, on the one hand, by picking out only those aspects that are necessary to deal with the artifact. The main idea of that principle is that these selected aspects allow one to indicate the underlying complexity. This can be done by letting the users assign adequate metadata to the given concept. Several methods to support the users by means of an intelligent application are discussed later in the chapter. But it has to be critically remarked that the validity of this assumption depends on the type of knowledge that has to be communicated and the given types of content.

This approach itself, which concentrates on essential aspects concerning a concept, does not yet allow other users to adopt the given artifact. It is rather necessary to restructure the chosen aspects in a different way. This method considers the previous knowledge as well as the interests of the targeted users, provided by semantics based on metadata, concept structures, and user profiles. These requirements can be addressed by means of a semantically enabled Wiki that, for example, arranges artifacts in a flexible way depending on the users' needs (e.g., artifacts written/read by the user and given interests or tasks of the user). Besides that, searching the whole system for certain artifacts should present results in a nested or context-based way (e.g., the artifact describing "Pair Programming" should be arranged under the parent concept "Extreme Programming"). This solution is based on underlying ontologies, as discussed later in the chapter. After the whole process of selecting certain aspects and restructuring them, users may be provided with complete, self-contained and motivating knowledge.

Based on the principles of a human-centered design process according to ISO 13407, expected users take an active part in the development process in order to get a clear idea of what might be specific requirements (ISO 13407, 1999). The early

Figure 2. Human-centered design processes for interactive systems (Source: ISO 13407, 1999)



phase of the German research project, "RISE," therefore was dominated by context-analyses within the participating companies. Qualitative-centered studies delivered deep insight into organizational aspects and users' special needs. Two focus groups dealt with the drawbacks and opportunities of using conventional Wiki systems that were formerly introduced by the associated companies. Not only the focus groups, but also further analyses of existing artifacts allowed the allocation of functions among the technical system and respectively, the users themselves.

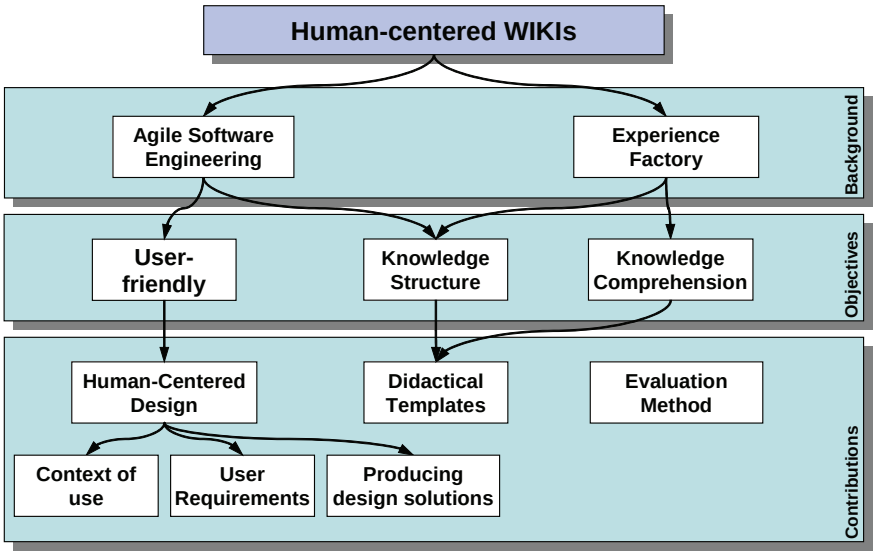
For example, the analysis of individually built file structures showed that an automatically enabled structuring of existing artifacts might be critical because people tend to use structures in different ways (hierarchical, time-based, priority-based, people-based, etc.) and with different granularity. This includes accessing existing artifacts as well as creating new ones. Teevan et al. discovered in a comparable study, for example, that people even use hierarchical organized structures if they do not maintain their individual structures hierarchically (Teevan, Alvarado, Ackerman, & Karger, 2004). This example shows, rather clearly, how important it is to allocate functions between users and intelligent systems. But it also gets clear that definite answers could not be found until final tests of the application.

As depicted in Figure 3, we elaborate in the next section on the background regarding this chapter. This includes information on agile software engineering and software reuse based on the experience factory approach. Thereafter, in "Human-Centered Design in Software Developing SMEs," we describe the relevant objectives of the RISE project, as well as our contribution to human-centered design of Wikis in software engineering. Finally, we describe our evaluation method and results from the project evaluation.

BACKGROUND

Centering the user during the software development process is especially important in engineering knowledge and learning management (KLM) as well as social software systems (e.g., Web 2.0)

Figure 3. Outline and structure of the following chapter



where users freely publish and consume information. Their efficient as well as effective interaction with the technical system gets more and more crucial for the overall success of the software product. The integration of users and users groups into the software systems is steadily increasing. This is also true in development methods such as extreme programming (i.e., an agile method), where the team members and the customer of a software system are deeply integrated to develop the envisioned software system. This section gives an overview about agile software engineering, as well as existing knowledge management approaches (i.e., the experience factory) that build the basis for collaborative human-centered software development.

Software Engineering and Reuse

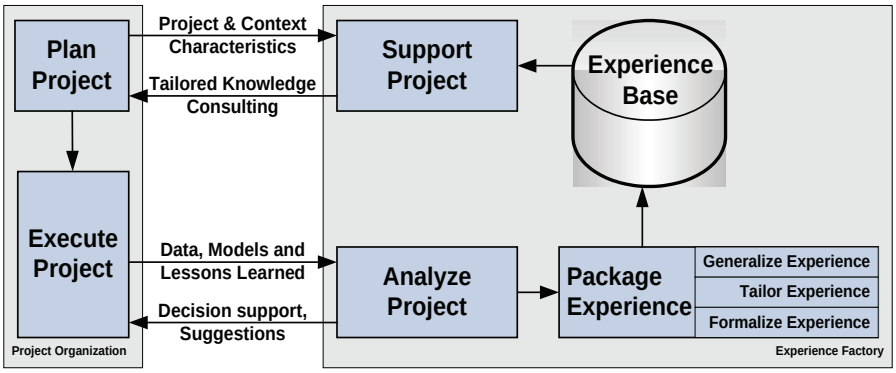
Software engineering (SE) as a field in computer science is concerned with the systematic development of high-quality software systems. During the planning, definition, development, and maintenance of software systems, the people involved generate and require any information and knowledge to support them in their work or to back up their decisions.

This reuse of existing knowledge and experience is one of the fundamental parts in many sciences. Engineers often use existing components and apply established processes to construct complex systems. Without the reuse of well-proven components, methods, or tools we had to rebuild and relearn them again and again.

In the last thirty years, the fields software reuse and experience management (EM) are increasingly gaining importance. The roots of EM lie in experimental software engineering ("Experience Factory"), in artificial intelligence ("Case-Based Reasoning") and in knowledge management. EM is comprised of the dimensions methodology, technical realization, organization, and management. It includes technologies, methods, and tools for identifying, collecting, documenting, packaging, storing, generalizing, reusing, adapting, and evaluating experience knowledge, as well as for development, improvement, and execution of all knowledge-related processes.

The Experience Factory (EF) is an infrastructure designed to support experience management (i.e., the reuse of products, processes, and experiences from projects) in software organizations (Basili, Caldiera, & Rombach, 1994). It supports the collection, pre-processing, and dissemination of experiences of organizational learning, and represents the physical or at least logical separation of the project and experience organization, as shown in Figure 4. This separation is meant

Figure 4. The Experience Factory



to relieve the project teams from the burden to find, adapt, and reuse knowledge from previous projects, as well as to support them to collect, analyze, and package valuable new experiences that might be reused in later projects.

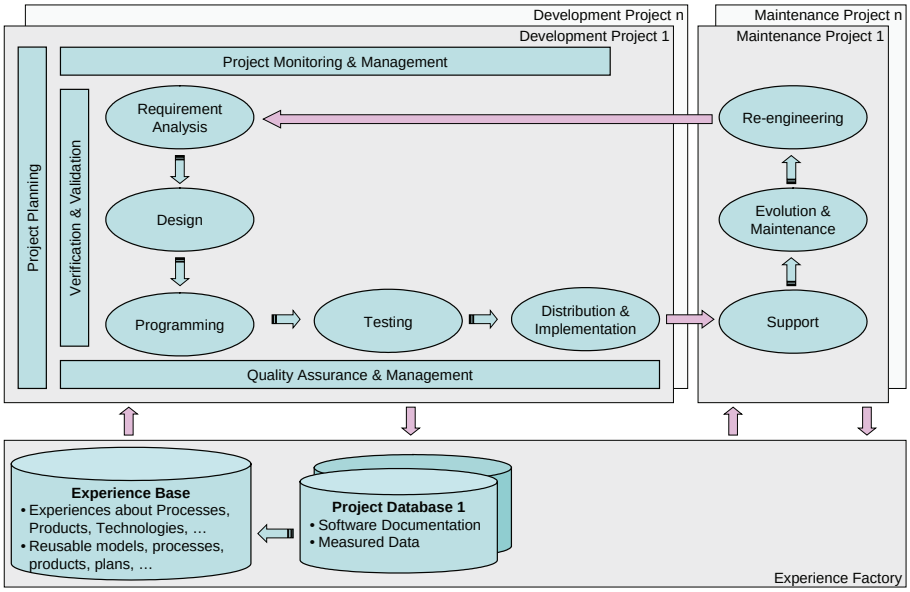
For example, if we begin a project ("Plan project"), we might use the experience factory to search for reusable knowledge in the form of architectures, design patterns, or process models based upon our project context. In the execution phase ("Execute project"), the EF is used to retrieve knowledge "on demand" (e.g., to support decisions or reuse source code) and at the projects end, it is analyzed (i.e., a post-mortem analysis) in order to extract reusable knowledge, for example, in form of project data, architectures, quality models, or other experiences that might be useful in other projects.

Traditional, Process-Oriented Software Development and Reuse

Since its beginning, several research directions developed and matured in field SE. Figure 5 shows the software development reference model integrating important phases in a software lifecycle.

- *Project engineering* is concerned with the acquisition, definition, management, monitoring, and controlling of software development projects, as well as the management of risks emerging during project execution.
- Methods from *requirements engineering* are developed to support the formal and unambiguous elicitation of software requirements from the customers, to improve the usability of the systems, and to establish a binding and unambiguous definition of the resulting systems during and after software project definition.
- The research for *software design and architecture* advances techniques for the development, management, and analysis of (formal) descriptions of abstract representations of the software system, as well as required tools and notations (e.g., UML).
- Techniques to support the professional *programming* of software are advanced to

Figure 5. Software development reference model



develop highly maintainable, efficient, and effective source code.
- *Verification and validation* is concerned with the planning, development, and execution of (automated) tests and inspections (formal and informal) in order to discover defects or estimate the quality of parts of the software.

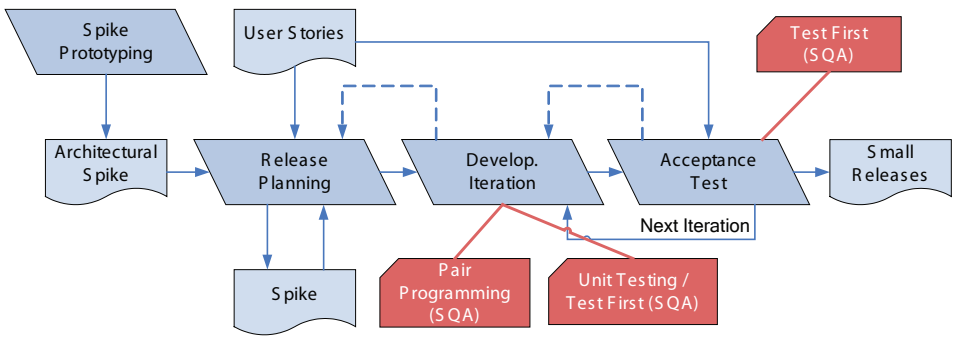
Research for implementation and distribution is responsible for the development of methods for the introduction at the customer's site, support during operation, and integration in existing IT infrastructure. After delivery to the customer, software systems typically switch into one of the following phases:

- In the *software evolution* phase, the focus of research lies on methods in order to add new and perfect existing functions of the system.
- Similarly, in the parallel phase, *software maintenance* techniques are developed for the adaptation to environmental changes, prevention of foreseeable problems, and correction of noticed defects.
- If the environment changes dramatically or further enhancements are impossible, the system either dies or enters a *reengineering* phase. Here, techniques for software understanding and reverse engineering of software design are used to port or migrate a system to a new technology (e.g., from Ada to Java or from a monolithic to a client/server architecture) and obtain a maintainable system.

Agile Software Development and Reuse

Beside the traditional or process-oriented software development another trend arose during the last years. *Agile software development* methods impose as little overhead as possible in order to develop software as fast as possible and with continuous feedback from the customers. Agile methods have in common that small releases of the software system are developed in short iteration in order to give the customer a running system with a subset of the functionality needed. Therefore, the development phase is split into several activities that are followed by small maintenance phases. In contrast to traditional, process-oriented SE where all requirements and use cases are elicited, the agile methods focuses on few essential requirements and incrementally develops a functional system in several short development iterations.

Figure 6. Agile software development (here the XP-Process)



Today, Extreme Programming (XP) (Beck, 2003) is the best-known agile software development approach. Figure 6 shows the general process model of XP that is closely connected to refactoring and basically its cradle (Beck & Fowler, 1999).

These agile methods (and especially extreme programming (XP)) are based upon twelve principles (Beck, 2003). We mention four of these principles, as they are relevant to our work. *The planning game* is the collective planning of releases and iterations in the agile development process and necessary to quickly determine the scope of the next release. Knowledge about the existence of existing code elements or subsystems relevant to the project can be used to plan the scope of the next release. *Small releases* are used to develop a large system by first putting a simple system into production and then releasing new versions in short cycles. The more an engineer can reuse, the faster his work is done and the quicker the customer gets feedback. *Simple design* means that systems are built as simply as possible, and complexity in the software system is removed, if at all possible. The more libraries are used and identified (via code retrieval), the less functionality has to be implemented in the real system. *Refactoring,* or the restructuring of the system without changing its behaviour, is necessary to remove qualitative defects that are introduced by quick and often unsystematic development. Decision support during refactoring helps the software engineer to improve the system.

Traditional software reuse initiatives and approaches that were developed for process-driven software development are inadequate for highly dynamic and agile processes where software cannot be developed for reuse and reuse cannot be planned in advance. Teams and organizations developing with agile methods need automated tools and techniques that support their work without consuming much time. Therefore, *agile software reuse* is a fairly new area where minimally invasive techniques are researched to support software engineers (Cinneide, Kushmerick, & Veale, 2004).

Typically, people in SME do not exactly know what additional knowledge and learning objects they need to support their work. The individual requirements of an employee in an SME will grow as they are working with a KLM system. Therefore, the agile approach to develop a software system; that is, incrementally developing the system with intense interaction with the user, is very important. The traditional approach of developing the system based on a final set of elicited requirements will probably result in an out-dated KLM system that does not fit the users needs.

HUMAN-CENTERED DESIGN IN SOFTWARE DEVELOPING SMES

Software engineering, in general, aims at engineering-like development, maintenance, adjustment, and advancement of complex software systems. One characteristic of software engineering compared with classical engineering lies in the prevalent immateriality and the complexity and abstractness of software resulting from it. For this reason Broy and Rombach (2002), for example, point out the difficulty to gain vital working experiences, and point at deficits in the field of further training. Although many companies apply (agile) methods of software engineering, the transfer of the underlying complex knowledge is still a crucial problem.

Challenges in Software Development

The development of complex software systems requires specific knowledge about technologies, tools, processes, standards, and so forth. The quality of the outcome depends strongly on how successful existing knowledge and expertise of the employees can be provided and actually applied.

Considering that challenging situation, the German research project, "RISE" (http://www.rise-it.info), aims at a holistic support of software engineering tasks. Software engineers should be enabled to deal with their tasks and thus act more professionally. Furthermore, the transfer of existing knowledge within software-related companies has to be optimized. This should be accomplished by systematic reuse of experiences, methods, and models in different application contexts.

The project "RISE" is part of the research program "Software Engineering 2006," funded by the German Federal Ministry for Education and Research (BMBF). Project partners are Dept. of Educational Sciences and Professional Development at the Technical University of Kaiserslautern, Empolis Arvato GmbH, brainbot technologies AG, Fraunhofer Institute for Experimental Software Engineering (IESE), and the German Research Center for Artificial Intelligence (DFKI).

The vision of "RISE" is to develop a usable knowledge-management application for software developers that makes fun and requires minimum effort. Software developers are gently supported during teamwork and their reuse of working experiences and knowledge. Consequently, the organization itself should profit from improved productivity increases.

Based on the already stated special problems and situations, research also focuses on how high the impact of an intranet-based platform could be, in order to ensure the individual capacity to do successful work through reuse of experiences, methods, and models. Thus RISE tries to find answers to the question, *what are the main requirements for a knowledge-management platform from the view of employees?* Inorder to keep complex knowledge manageable so that it can be used individually and updated during work.

It has to be clarified in what respect a technical platform may allow an individually focused view of the information needed (knowledge management) and might facilitate (usability) use of it.

The participating companies already used Wiki systems as our project started. They provided initial data for the empirical study in the early project phase. In our case, we had to deal with technically and functionally rather different Wiki systems, which can all be summarized under the wide term "social software." Such Web-based content-management systems allow users not only to access content, but also to add their own pieces of information or to edit already available artifacts with as little effort as possible.

The underlying rationale is based on a strongly decentralized way of editing content. Early results of the evaluation, however, showed that a sophisticated methodology is required to successfully implement semantic based "social software" at the intranets of software-firms, in order to ensure a broad acceptance. In summary, we observed that our industrial partners had the following problems with KLM systems:

- The organizations used Wiki systems that few people used due to missing structure, participation, and documentation guidelines.
- The people stored their information in their own data repositories, network drives, group directories, and so forth, with individual structures. This made the discovery and goal-oriented retrieval of important knowledge nearly impossible.
- The organizations used several other tools such as content management systems (CMS), e-mail, versioning systems, and chat tools (i.e., ICQ) that comprised valuable information, all unconnected and without a common structure or template support.

As observed, acceptance might decrease rapidly if the application system no longer represents a source of information that is usable, as described within the international standard ISO 9241-11: "*extend to which a product can be used by specified users to achieve specified goals*

with effectiveness, efficiency and satisfaction in a specified context of use" (ISO 9241-11, 1998). So, if the systems fail to be usable, neither contents are published or edited nor even read in the worst case. The communication amongst software engineers will not be intensified, as intended, but stagnates to a total deadlock.

Understanding Context-of-Use and Defining User Requirements

It seems to be obvious that employees are responsible for an individual development of a vital knowledge basis. Not only that, this requires special abilities, resources, and strategies. Moreover, employees increasingly have to gather information and subsequently learn new things besides their working day, which is dominated by different peaks.

One kind of peak is, of course, caused by strict deadlines that temporarily raise the working load to a maximum. Besides those hard and rather ordinary kinds of peaks, there exists even a more elementary one: the problem-orientation that many software engineers cling to. One main hypothesis of the project "RISE" is that this kind of peak not only may provoke benefits, but also causes huge problems that eagerly demand a solution. The term "problem-orientation" refers to the assumption that software development predominantly is a rather trivial process: developers are provided with certain requirements and try to consider them while realizing software systems. But from time to time, that trivial process gets disturbed by rather tricky problems developers get stuck in.

Those more or less hard problems represent a kind of peak that has fatal consequences for knowledge management in software companies: developers that run into that peak are highly motivated to solve the problem and often try to solve it on their own. Probably, they spend hours and hours with their problem and do not bother about existing and proved solutions, concepts, or methods. In that case, reuse might not exceed accidental or sporadic access to available knowledge. Considering that the knowledge collected by means of a content management system, it seems to be almost impossible to build a shared repository. The result would be a collection of various problems (hopefully including a solution) that might resemble each other more or less. The so called "Experience Factory" approach has to be mentioned, which is considered as one answer to that challenge: "the Experience Factory approach was initially designed for software organizations and takes into account the software discipline's experimental, evolutionary and nonrepetitive characteristics" (Basili, Lindvall, & Costa, 2001, p. 1).

In addition to that, existing knowledge does not only grow rapidly, but can be accessed ever more easily. However, the technical feasibility itself does not actually pay off: employees might be overwhelmed by the huge amount of information they can access which suggests to them, despite (and just because of) various and omnipresent search possibilities, the feeling of just being swamped with artifacts.

Basili et al. (2001) see that problem too, and demand that the company has to *unload* its experts: "Experts in the organization have useful experience, but sharing experience consumes experts' time. The organization needs to systematically elicit and store experts' experience and make it available in order to unload the experts" (Basili et al., 2001, p. 2).

One-sided approaches to knowledge management often focus on gathering as much information as possible from experienced employees in order to preserve it. From an educational point of view, however, it neither seems to be reasonable nor possible to store that potentially relevant knowledge with its unreduced complexity if knowledge has to enable the individual capacity to act professionally as a software developer (Renzl, 2004, p. 36).

In fact, it is rather important to support the individual capacity to act professionally of each

developer systematically. It is assumed that this individual ability will get more important in future. Employees will be faced with even more complex working conditions. Customized approaches to knowledge management for different kinds of enterprises should start just from the special abilities and needs of the employees, and thus help to prepare for that situation.

It is assumed that, by means of an adequate selection and presentation of content, the feeling of being swamped with artifacts can be reduced, and the software developers' motivation can be ensured or even be raised. This form of knowledge management centers the affected subjects. Thus, employees with huge expertise are no longer considered like a means to an end but, in fact, the technical knowledge management system.

- *First*, this application system acts as a flexible and customizable view (like a window) on the information needed during working-time. This system strongly relieves software engineers from time-consuming retrieval activities.
- *Second*, the system supports the collection and storage of vital working experience, which has to be subsequently formed and refined.

These are the two main factors of the RISE methodology, which were optimized during project time.

Producing Design Solutions and Evaluating Them Against Requirements

The survey that was dominated by qualitative social research methods revealed valuable insights about requirements of users and organizations. Two focus groups were dedicated to explore usage problems with the knowledge management platforms already introduced.

Especially, the collection of user requirements, related to Wikis as experience management systems for software engineering, important problem areas could be identified.

The gathered qualitative data is characterized by a very high validity, which means (given the background of user-centered design) that a common understanding of user requirements was developed and involved users agreed to high extent which user requirements should be realized in favor.

In order to classify the collected data, the Munich knowledge-management model has been used with its four categories: knowledge-representation, knowledge-usage, knowledge-communication, and knowledge-creation (Reinmann-Rothmeier, 2001):

- **Knowledge-representation:** Some employees tend to write down a minimum of information. It was observed that some of them document just as little as possible, so that they will be able to find out later what was meant by the given artifact. The main disadvantage of that behavior is that the saved data becomes hard or even almost impossible to understand for other employees accessing that content because they do not have the necessary knowledge to »decode« and to classify it. However, it seems to be a kind of game those developers are playing when doing some documentation: they rather puzzle together pieces of information than writing down supposedly redundant or superfluous information.
- **Knowledge-usage:** Crucial information about projects, products, or customers are distributed across various databases. This means that useful knowledge is hard to find and thus hard to be transferred in other contexts like new projects for example.
- **Knowledge-communication:** Employees who browse or search through Wiki con-

tent in order to find some special piece of information have to spend a lot of time. Moreover, editing content in most Wikis is rather uncomfortable: for example, adding a chart, a table or even a picture to Wiki pages requires special handling if it is even possible. As a consequence, information is being transferred by mail under pressure of time and not added to the Wiki site.

- **Knowledge-creation:** With increasing activity in a Wiki, it becomes harder for authors to integrate their piece of information into the existing structure. So, it becomes more and more likely that no new content is being added and already saved content gets orphaned.

Basically, using metadata is a good idea to keep heterogeneous and complex structures describable and thus technically manageable. But the problem is that users often fail to provide useful metadata, or simply do not bother about complex sets of metadata.

One very important hypothesis of the RISE project is that software-development teams that use a Wiki collaboratively to build knowledge repositories are actually about to **create a kind of semantic structure**, which users may not necessarily be aware of. This more or less refined structure, called "Wikitology," can be considered as a weakly formalized ontology. This has three main advantages:

- The *maintenance of metadata* is not considered as extra activity.
- *Ontologies* may always grow behind the content.
- Maintenance of ontologies is an expensive and time-consuming process. But, based on our assumptions, this work can be *automated more efficiently,* and thus releases employees from that job.

Another crucial approach of the RISE project is the **use of tags** as a very minimalistic but rather effective way of providing metadata. Any tags may be assigned individually to WIKI pages. So, each user is able to create his own view on any artifact by using his own depiction. Since in our approach all users are able to see the tags provided by the others, it is, of course, very probable that team members manage to create a shared set of tags as well.

Furthermore, **templates** for special types of content (bug report, use case, user story, etc.) help to provide a minimum of required information. Readers as "consumers" of the artifact can be satisfied, too. For example, the given structure helps them to browse faster through the content in order to find only some piece of information being of interest. Finally, this results in a higher acceptance of the system, which might also motivate employees to add their content to the repository.

Additionally, a **blog component** is added to the system. The blog contains not only news. In fact, the blog can be considered as a human-based *filter* on the Wiki content. For example, users might link to certain Wiki pages and provide some extra information along with the link. So, other users get useful assistance with the evaluation of artifacts.

EVALUATION OF SEMANTICALLY ENABLED KM SYSTEMS

The objective of the evaluation of a KM system, such as the Riki, is to show its effectiveness in a specific application context. The tailored instances of the system at different organizations are evaluated to identify the usefulness to the users, the examined applicability, the evolvability, as well as economic factors. The evaluation was split into two phases. The first phase, called *baseline*

evaluation, at the start of the project was used to elicit the context and current state of knowledge transfer. From the information we gathered in this phase, we designed and developed the Riki system considering people, processes, and available technologies. The second phase, called *delta evaluation,* at the end of the project helped to evaluate the change on the socio-technical knowledge management system. In both phases, we used the following three techniques to elicit valuable information from the organizations and potential end users:

- Goal-oriented, questionnaire-based *interviews* were used to query the previously listed questions with three to ten persons in two to four sessions. The collected answers were summarized and validated by the participants via e-mail.
- *Group discussions* were done at every company to collect any additional information, opinions, ideas, and so forth, that were not covered by the interviews. The discussion was started with a specific topic (e.g., Why did the old Wiki not work for you as a KM system?), and every person could state what they expected from an improved knowledge-management infrastructure.
- *Artifact analyses* were conducted to identify knowledge sources, the type of knowledge within, as well as how employees structure their documents and knowledge in existing storage systems (e.g., the hierarchy of directories in personal file systems or in pre-existing WIKI systems).

These evaluation techniques helped to cover the following three topics:

- **Technology:** Elicitation of the existence and characteristics of the technical infrastructure, existing KM systems, and other software systems that might be integrated into or used as the KM system (i.e., the Riki system). Furthermore, these technological systems potentially have valuable information that can be utilized in a KM system.
- **Methodology:** Elicitation of the applied methodology for production (e.g., software development) and knowledge management (esp. knowledge transfer processes). This gives further information about how the KM system should be integrated into the social system of the organization and where, when, and by whom knowledge is produced or consumed.
- **Knowledge:** Elicitation of the existing knowledge components available in the organization, as well as their characteristics and interrelation (e.g., for the development of an ontology). Furthermore, the typical structure of documents that might be didactically enriched.

A more detailed description, as well as some results of the two evaluation phases, is described in the following sections. They address persons who want to evaluate a KM system, such as the RIKI in an organization.

Baseline Evaluation

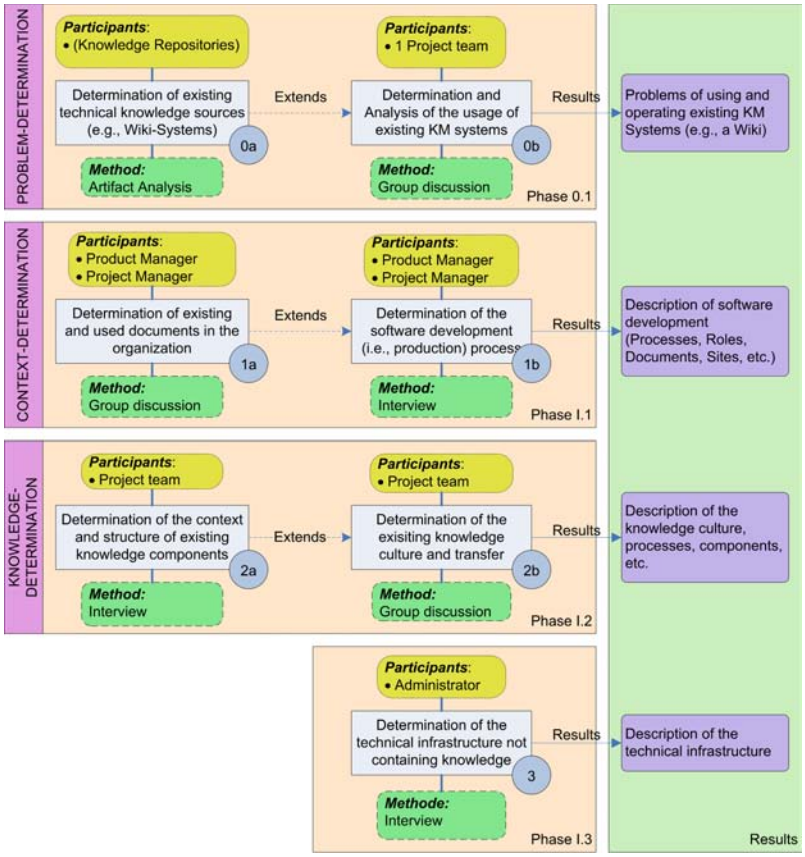
The baseline evaluation is concerned with the determination of the organizational context a social-technical knowledge management should be embedded in. The core goal of the baseline evaluation is to measure and analyze the current status of the implicitly or explicitly performed KM processes, the used knowledge carrying or KM systems, as well as the knowledge culture itself. Baseline evaluations are typically applied only once to get a consistent view of the KM in the organization before larger changes. This section describes the basic process for the evaluation of a KM system as well as a summary of our baseline evaluation.

Baseline Evaluation Process

The baseline evaluation process (and similarly the delta evaluation) is structured into the three subphases: problem-determination, context-determination and knowledge-determination. As depicted in Figure 7, the steps in these subphases define a process that results in several documents (e.g., a problem description) usable for the specification of a socio-technical KM system integrated into the surrounding organizational context:

- **Problem-determination:** The problem determination serves to identify existing knowledge sources (e.g., in case of our partner, "empolis," a Wiki system named MASE) as well as emerged problems and challenges with it. Step 0a is used to determine existing information systems and technical knowledge sources using a systematic analysis method. By means of a group discussion in step 0b, the exchange of knowledge via existing technical (KM) systems in a typical project team is illuminated.
- **Context-determination:** This subphase is concerned with the determination of the context the socio-technical KM system is embedded in. The context determination produces information about the production processes, roles, documents, or sites that might be used in the KM system. The three steps in this subphase are concerned with

Figure 7. Plan for baseline and delta evaluation



the development processes that are to be supported by the KM initiative. Step 1a uses a group discussion technique to determine existing documents, templates, and other potentially reusable elements. To elicit or update the development process in use, we applied an interview with several product and project managers in step 1b.

- **Knowledge-determination:** The knowledge determination subphase targets the core information that should be made reusable via the KM system. The content, context, and structure of reusable elements is determined in step 2a using an interview. Based on this information, the knowledge transfer processes and the knowledge culture itself is analyzed in step 2b using a group discussion with several members of project teams.

Finally, step 3 is used to identify the technical infrastructure of tools and systems that are not used for knowledge management, but might be integrated and connected with the new or improved KM system (i.e., a new or improved Riki).

Results from the Baseline Evaluation

In the context of the RISE project, we applied step 0a to step 3 of the evaluation plan, as depicted in Figure 7. For the execution of the baseline evaluation one period, we required a time span of approximately 3 months, taking into account that not all employees are continuously available. Based on different vacation planning, holidays in summer, autumn, and Christmas, as well as other projects, one should take into account the time-consuming characteristics of such an evaluation.

During the group discussion concerning the usage of existing KM systems (cf. Figure 7, 0b) as well as the knowledge culture and transfer (cf. Figure 7, 2b), we determined the following status in the organization:

- The organization used a Wiki ("MoinMoin") that few people used, and contained partially documented concepts, ideas, comments, and larger documentations about planned as well as already developed software systems. Other information in the WIKI included customer information, dates, ToDo-lists, addresses, and absent lists.
- Important information about the software system itself is documented in the source code (in this case, Python and ePyDoc). To extract this information, one has to check out the whole software system from the versioning system and search for relevant information on file level.
- Important information about changes to the software system is documented in the used versioning system (in this case: Subversion). Changes at the software system are sent to all interested users by e-mail. To extract this information without the e-mails, one has to analyze every check-in into the system and appropriate comments.
- Internal information sources (i.e., repositories) with other project-relevant information are change tracking system, project folders, universal and private network drives, e-mails, and chat tools (e.g., ICQ), with information in files such as plain text or MS Word documents. Furthermore, task cards at a physical blackboard.
- External information sources are distributed over the whole Internet, but the employees had a focus on MSDN and Google if they required further information.

Positive characteristics: What goes well?

- The cooperation between two people closely working together, but who were distributed physically over two cities, worked very well using the old Wiki.
- The local teams worked on one floor and

had only short distances to their colleagues. The face-to-face communication was very good (i.e., everybody was in "shouting" distance).

Negative characteristics: What runs badly?

- The Wiki was not used anymore at the beginning of the evaluation and the feedback indicated that most people were not pleased with the structure of the knowledge base.
- Neither the old Wiki nor the documentation language for Python (ePyDoc) permitted the integration of pictures or graphics.
- The search for information in the Wiki and file system is term based (i.e., no stemming or Boolean operators). This was perceived as insufficient and demotivating by the users. Furthermore, the search within the Wiki was impeded by the use of camel case (e.g., "MyProjectDescription") in the page names.
- The discovery of relevant information is perceived as complicated as they are distributed over multiple repositories that all use different (or nonexistent) search mechanisms.
- Access to the Wiki from a text editor (e.g., emacs under Linux/Unix) or a shell (i.e., command line interface) is impossible and/or uncomfortable. Nevertheless, some developers are biased or required to use these, and are not willing to install or use other operating systems (or Web browsers such as Internet Explorer™).
- Neither were the authors (resp. other observers) informed about changes done to the content in the Wiki, nor were they informed about changes to the navigational or divisional structures (i.e., chapters and sections) of the content.
- It was not clear where to store information as they could be spread or duplicated in multiple repositories, for example, in the versioning system, change tracking system, or the code itself.

In summary, the knowledge transfer and management processes, as they were lived in the organization previously to the introduction of the Riki system, were determined by the baseline evaluation as follows:

- *Storage* of information is limited to few people in the organization and the documented information is only partially complete, consistent, or valid.
- *Reuse* of content is minimal, as the information is distributed over several sources with different search interfaces and techniques. Furthermore, the content of the documents have inconsistent structures, incomplete descriptions, or are simply outdated.
- *Workflow* for reuse of content and getting an *overview* is slow and typically demotivating, as multiple sources have to be searched manually and documents belonging together are not grouped or linked.
- *Sharing knowledge* is cumbersome, there are no templates, guidelines, or checklists to validate if the recorded information has some quality and might be easily reused by the colleagues.
- *Confidence* in the knowledge transfer system and *motivation* to share is low, as only few people are creating shareable documents and they are mostly not accurate or up-to-date. Nevertheless, the people would like to share their knowledge in a more persistent way.
- *Face-to-face communication* is strong, especially as most employees have short distances to their colleagues, are roughly of the same age, and see no need to hide their information (i.e., egghead's syndrome).

Delta Evaluation

The core goal of a delta evaluation is to measure and analyse the changes a KM system has inflicted on the affected organization. Delta evaluations can be applied multiple times during the lifecycle of a KM system (e.g., every year) to evaluate the effect on the organization.

Delta Evaluation Types

Since KM systems are usually used only irregularly in the beginning and not yet a firm part of the working process, the delta evaluation phase can be applied in three different types:

1. **Applicability:** The first type serves to examine how frequently the system is used, if it integrates into the socio-technical infrastructure, and if it helps the users during their daily work. In order to keep the effort of the evaluation down to a minimum, a lightweight evaluation is planned by reusing existing plans and other technology assessment or acceptance models.
2. **Usefulness:** In the second type, the results and experiences from the first type serve to sharpen requirements and improvement goals. The system has already demonstrated that it is applicable in the organization, and represents an integral component of the regular work routine. By means of structured evaluation processes, a formal evaluation plan is constructed to examine, in particular, the aspects usefulness, and ease-of-use for developers as well as management staff.
3. **Economy:** Finally, the third type serves to examine the economical aspects of the KM system. The system is already integrated into the regular work routine, and users share and reuse the knowledge within. An adaptive evaluation, reaction, and risk plan are developed to continuously monitor and improve the system. The focus of this type is the evaluation of the system and a forecast of the usefulness regarding the return on investment (ROI) and total cost of ownership (TCO).

To identify existing or potential problems, the entire system is continuously monitored during start-up phase. Logfiles help to drill-down into specific problems if the users observe a problem while using the system.

Results of the Delta Evaluation

In the context of the RISE project, we could only apply the first subphase and evaluate the applicability of the Riki system. Due to the short amount of time the system was used (two months) we could only get little insight into the usefulness of the system for the users in their daily routine. During the group discussion concerning the usage of the Riki (cf. Figure 7, 0b) as well as knowledge culture and transfer (cf. Figure 7, 2b), we noted the following characteristics the users liked very much about the Riki:

- Metadata elements that can be placed by every user (such as keywords in form of tags) can be very helpful in indexing the content of a Riki, and the users reacted very positively that they were able to *index every page* with their own metadata.
- The usage of metadata enabled the users to build up and use their own *individual ontology* (in form of individual tags) that is not bound to compromises or constraints from universal ontologies that might have been constructed in advance. Furthermore, metadata from the universal ontology (i.e., specified beforehand or as defined by other users) was partially used in their own ontology.
- *Searching* the information stored in the Riki is more accepted by the users when the metadata might be integrated into the search process. In the Riki, the results are *clustered*

by this metadata and the metadata might be used to *refine* the search query. The search technology exploits co-occurring metadata from multiple users and applies "collaborative filtering" techniques (i.e., "metadata x you search for is also called y").

- Annotated pages that were listed in search results reminded the users that they already read them or were highly valuable and should be read again. Similar to the Memex concept by Vannevar Bush (Bush, 1945) (cf. http://en.wikipedia.org/wiki/Vannevar_Bush), the metadata might even be used to record a reading sequence for oneself.
- The integrated view of the Riki system, including various artefacts as well as repositories, enables the user to send links that are not subject to change as, for example, mounted devices in the Windows file system.

In comparison to the status, as determined by the baseline evaluation, the usage of the Riki system had the following subjective effect on the organization:

- *More storage* of information into the Riki than before as barriers (technological and social) are reduced.
- *More reuse* of content from the Riki as users are more likely to share and search for content.
- *Faster workflow* for reuse of content and an *improved overview* due to the integrative view over multiple systems (e.g., file system, e-mail, etc.) in a central integrated repository.
- *Less barriers for sharing knowledge*, as it is easier and faster to enter information, but this typically results in a *low quality* of the content. Most users embrace the Wiki idea and record even preliminary information that is revised by oneself or others over time.
- *Higher confidence* in the system and *increased motivation* as content is easier to find and more people are participating in the sharing process.
- *Consistent face-to-face communication* even as more information is reused from the technical system.

Further and more quantitative results about the usefulness and economical aspects, especially of the more SE specific features of a Riki such as ontology-based templates for requirements, will be elicited in later evaluations.

CONCLUSION

Although the importance of usability is broadly and increasingly accepted, user-centered design processes can hardly be found in software companies in general. Small- and medium-sized companies often fail to apply user-centered design methods due to poorly established role models. Even if user-requirements are (more or less) specified, the problem that remains is to guarantee that they are strictly followed during production.

The whole research process during the project "RISE" was strongly dominated by qualitative evaluation activities. They have been preferred because they helped to specify the context of use as well as user and organizational requirements. In general, empirical data, gathered by means of qualitative research methods, is characterized by its high validity. Unfortunately, it is rather difficult to extract requirements out of this data or to check to what extent those "implicit" requirements have been considered during the development process of the software system.

Strictly following the model of a user-centered design of an interactive software system, that problem could not be bypassed. It is rather necessary to provide prototypes, as soon as possible, that contain as much functionality as necessary in order to check current implementation states against more or less "implicit" requirements.

In terms of a rather comprehensive meaning of *usability*, it was not only about developing user interfaces and improving them. In fact, usability engineering is considered as a vital concept in software development. So, it is not only about describing, designing, or producing design solutions for user interfaces. It is rather about understanding and facilitating human-engineered socio-technical systems.

ACKNOWLEDGMENT

ABSTRACT

Many software organizations have a reputation for producing expensive, low-quality software systems. This results from the inherent complexity of software itself as well as the chaotic organization of developers building these systems. Therefore, we set a stage for software development based on social software for knowledge and learning management to support reuse in software engineering as well as knowledge sharing in and between projects. In the RISE (Reuse in Software Engineering) project, we worked with several German SMEs to develop a system for the reuse of software engineering products such as requirement documents. The methodology and technology developed in the RISE project makes it possible to share knowledge in the form of software artifacts, experiences, or best practices based on pedagogic approaches. This chapter gives an overview of the reuse of knowledge and so-called Learning Components in software engineering projects and raises several requirements one should keep in mind when building such systems to support knowledge transfer and reuse.

INTRODUCTION

The software industry develops complex systems that often have a reputation of being expensive and of low quality. One approach for coping with the increasing complexity of these systems is software reuse—the sharing of knowledge about software products, processes, people, and projects in an organization.

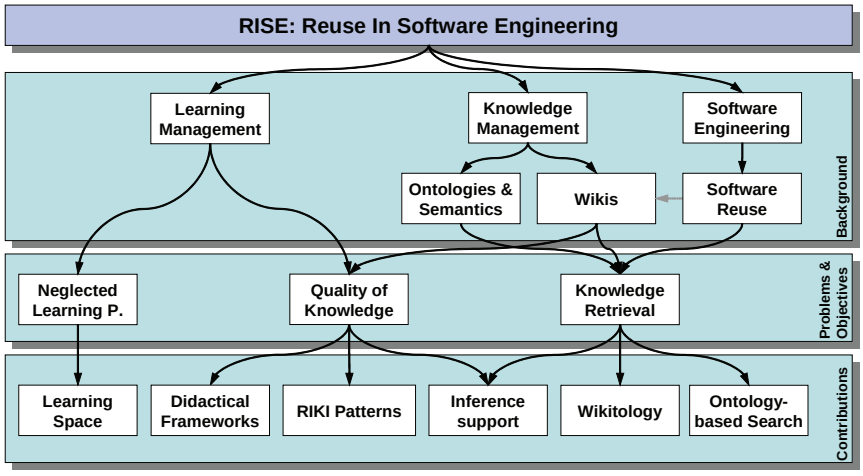
But the poor and often nonexistent documentation of this knowledge inhibits easy recording, collection, management, comprehension, and transfer. The knowledge, for example, in the form of requirement descriptions, architectural information, design decisions, or debugging experiences, needs a systematic, minimally invasive, methodological, and technological basis to strengthen its reuse and transfer in software organizations.

Knowledge management (KM) and *learning management* (LM) seem to have the potential for building this basis if they are used in synergy. However, the relationships between these two promising fields have not been fully understood and harnessed yet. On the one hand, learning as the comprehension of knowledge is considered to be a fundamental part of KM, as employees must internalize shared knowledge before they can use it to perform a specific task. So far, research within KM has addressed learning mostly as part of knowledge sharing processes, and focused on specific forms of informal learning (e.g., learning in a community of practice) or on providing access to learning resources or experts. On the other hand, LM includes techniques to preprocess and formalize knowledge, and might also benefit from other KM approaches. Especially, those approaches that support technical and organizational aspects in an organization can be used in addition to professional e-learning systems.

In this intersection between KM and LM, the Wiki technology (cf. http://en.wikipedia.org/wiki/Wiki) promises to be a lightweight basis to capture, organize, and distribute knowledge that is produced and used in organizations. Wikis are Web-based knowledge repositories where every user can freely submit or retrieve knowledge.

The *RISE* (*Reuse In Software Engineering*) project was started to support software engineers via the reuse of didactically enriched software artifacts from all software development phases in SMEs (small and medium enterprises). As the basis for knowledge transfer, we have developed a reuse-oriented Wiki (Riki) with fast and liberal access to deposit, mature, and reuse experiences made in software projects. Our Riki was extended by search technologies using case-based reasoning technology and ontologies to provide a formal and consistent framework for the description of knowledge and experiences. Ontologies and templates enrich the Riki content with semantics that

Figure 1. Outline and structure of the following chapter



enable us to didactically augment the knowledge within the Riki with additional information and documented experiences.

The RISE system sketches our approach for software reuse and tackles several problems of traditional KM and LM in learning software organizations. We use *semiautomatic indexing of pages* to improve retrieval and enable the semi-automatic creation and evolution of ontologies from Wikis (i.e., Wikitologies). The *cooperative adaptation* of knowledge to community needs and the *didactic augmentation* of content and interface are targeted to improve the usability of lightweight KM applications in agile environments.

In this chapter, we give an overview of the methodology and technology developed in the RISE project to build the reuse-oriented Wiki framework named Riki. As depicted in Figure 1, we describe in the *Background* the relevant background about knowledge and learning management, as well as software engineering and Wikis. This is followed by *Problems and Challenges* containing the targeted problems and objectives examined in the RISE project.

Our main contribution for knowledge transfer and reuse in software engineering is summarized in *Semantic-Based Reuse in SE: The RISE Approach*, which contains both the methodology in *RIME: The RISE Methodology for Knowledge Transfer and Reuse* and the technology in *Riki: The Reuse-Oriented Wiki*. Furthermore, several best practices, Wiki patterns, and lessons learned gathered during the project are listed in *RISE in Retrospective*. Finally, we finish this chapter with our conclusions.

BACKGROUND

This section is concerned with the background and related work in knowledge management with Wikis, problem-based and experiential e-learning in Wiki systems, and reuse for software development artifacts. It gives an overview of related Wikis for SE, for example TRAC, Snip Snap, and MASE.

Software Engineering and Reusable Knowledge

The discipline of *software engineering* (SE) was born in 1968 at the NATO conference in Garmisch-Partenkirchen, Germany (Naur & Randell, 1968; Simons, Parmee, & Coward, 2003). At the same conference, the methodical reuse of software components was motivated by Dough McIllroy (McIllroy, 1968) to improve the quality of large software systems by reusing small, high-quality components. The main concern of software engineering is the efficient and effective development of high-qualitative and very large software systems. The objective is to support software engineers to develop better software faster with tools and methods.

Software Reuse

The reuse of existing knowledge and experience is a fundamental practice in many sciences. Engineers often use existing components and apply established processes to construct complex systems. Without the reuse of well-proven components, methods, or tools, engineers have to rebuild and relearn these components, methods, or tools again and again.

Today, *reuse-oriented software engineering* covers the process of development and evolution of software systems by reusing existing software artifacts. The goal is to develop complex software systems in shorter periods of time or with higher quality by reusing proven, verified, and tested components from internal or external sources. Trough systematic reuse of these components and feedback about their application, their internal quality (e.g., reliability) is continuously improved. But reuse of components is only appropriate if the

cost of retrieving and adapting the component is either less costly or results in higher quality than a redeveloped component.

Since the 1980s, the systematic reuse and management of experiences, knowledge, products, and processes was refined and named *Experience Factory* (EF) (Basili, Caldiera, & Rombach, 1994). This field, also known as *Experience Management* (Jedlitschka, Althoff, Decker, Hartkopf, Nick, & Rech, 2002), or *Learning Software Organization* (LSO) (Ruhe & Bomarius, 1999), researches methods and techniques for the management, elicitation, and adaptation of reusable artifacts from SE projects. The *Component Factory* (CF) as a specialization of the EF is concerned with the reuse of software artifacts (Basili, Caldiera, & Cantone, 1992) and builds the framework in which further analysis and retrieval techniques are embedded.

In the beginning, only the reuse of source code was the focus of reuse-oriented software engineering. Today, the comprehensive reuse of all software artifacts and experiences from the software development process is increasing in popularity (Basili & Rombach, 1991). Besides source code artifacts such as requirements, design document, test cases, process models, quality models, and best practices (e.g., design patterns) are used to support the development and evolution of software systems. These artifacts are collected during development or reengineering processes and typically stored in special artifact-specific repositories.

Software Engineering Experience and Knowledge

The terms knowledge, information, and experience are defined in multiple, more or less formal, and often contradictory ways. Models that define these terms and the processes that transit from one to another differentiate between tacit and implicit knowledge (Nonaka & Takeuchi, 1995) or between data, information, knowledge, ability, capability, and competence (North, 2002). There are positions such as by Stenmark (Stenmark, 2001) that consider the usage of the term "knowledge," for information stored in a computer, inappropriate. In this model, tacit knowledge can, in fact, exist only in the heads of people, and explicit knowledge is actually information. However, the terminology used in the theory and practice of knowledge-based systems (KBS) and knowledge-discovery in databases (KDD) considers knowledge to be information stored together with its context, and we follow this convention throughout this paper.

Types of Knowledge

More specifically, we base our view of knowledge on the model of the architecture of human knowledge developed by Anderson. He classified knowledge not according to its content, but according to its state in the person's long-term memory. Two types of knowledge were defined (Anderson, 1993; Gagné, Briggs, & Wager, 1988):

- **Declarative knowledge** consists of 'knowing about'—e.g., facts, impressions, lists, objects and procedures, and 'knowing that' certain principles hold. Declarative knowledge is based on concepts that are connected by a set of relations forming a network that models the memory of a person. For instance, declarative knowledge items in the domain of software engineering might be: a definition of 'test case,' a listing of defect types, a detailed explanation of key testing principles.
- **Procedural knowledge** consists of 'knowing how' to do something, that is, skills to construct, connect and use declarative knowledge. It contains the discrete steps or actions to be taken, and the available alternatives to perform a given task. For instance, procedural knowledge items in the domain of software engineering might be: a method

for deriving test cases from requirements, a method for classifying defects choosing the right reading technique to perform an inspection.

Both declarative and procedural knowledge can be abstract or concrete. The knowledge can be connected to more or less concrete information that can be described technically, for example, by semantic networks. Nevertheless, knowledge about situations experienced or about evaluating facts or determining circumstances in given situations cannot be classified as declarative or procedural knowledge. Therefore, a third form of knowledge has extended the spectrum of knowledge in cognitive science (Enns, 1993) when Tennyson and Rasch (Tennyson & Rasch, 1988) defined contextual knowledge as another type of knowledge:

- **Contextual knowledge** consists of 'knowing when, where and why' to use or apply declarative or procedural knowledge. Contextual knowledge is created by reflecting on the usage of declarative and procedural knowledge in practice in different contexts. Contextual knowledge enables the individual to be aware of commonalities between situations, and of the appropriateness or applicability of principles or procedures in a new context.

In summary, three types of knowledge have been presented. Documented and stored experiences consist mainly of contextual knowledge. They originate, in most cases, from expert memories, and lack declarative basis background knowledge and detailed procedural knowledge, resulting in them being ineligible for learning purposes.

Furthermore, we identified the following *general artifacts* that are based on the six knowledge types from knowledge management (Mason, 2005):

- **Know-how:** Recorded information about how to do something. This can range from general *guidelines* about how to design a system to more specific and personal experiences about using a tool or software library.
- **Know-who:** Recorded information about a *person* (i.e., developer or maintainer). This can range from who designed a specific subsystem to who has knowledge about a customer.
- **Know-why:** Recorded *rationales* why something was done or decided. For example, why a design technique was applied or a defect had not been removed from the system.
- **Know-what:** Recorded information about the *status* of something (e.g., the current situation). This includes information about the current status of a project or system that was elicited from the project manager.
- **Know-where:** Recorded information about the *location* of something (esp. knowledge). This includes where an algorithm is implemented in the source code as well as information about where to find the project plan or a process description.
- **Know-when:** Recorded information about the *situation* (e.g., time or version) when something happens or a process is applied. This can range from when defects are introduced into the system to when the quality assurance process should be applied.
- **Know-if:** Recorded information about the *consequences* of an action. This can range from what happens if a defect is removed to the effects of applying a specific quality assurance technique.
- **Know-that:** Recorded information about the *facts* of something. This can range from information about the characteristics of a quality defect to a model of the development process.

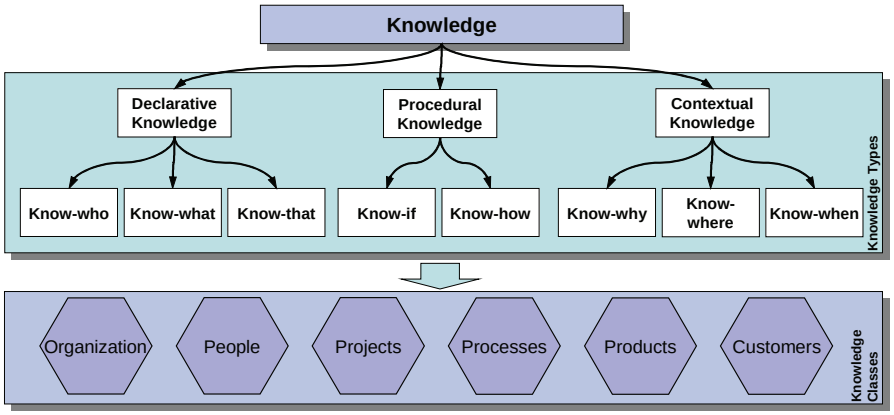
The interconnections between these knowledge types are depicted in Figure 2. The organizational elements at the bottom of the picture are classes of information that are typically existent in (software) organizations. In a KM system, knowledge, or more specifically the know-how, know-who, and so forth, about the organization, products, projects, people, processes, customers, as well as further knowledge (e.g., about a technology such as Java or EJB) is stored. We refer to this group as the OP4C model (Organization, People, Processes, Projects, Products, and Customers).

Software Engineering Artifacts

Software engineering is concerned with the planning, management, design, development, and implementation of large-scale, complex software systems. During these processes, several documents, architectures, ideas, and experiences are created or made. In software reuse, the umbrella term *artifact* is used to describe explicit knowledge objects that are considered for reuse, such as:

- **Methods and techniques** from phases such as project planning, requirements analysis, or programming that describe the know-how.
- **Patterns** about the analysis and structure of software systems (i.e., analysis and design patterns) or the management of processes (i.e., process patterns). In general, these represent knowledge that was created by the aggregation of single experiences, either by human expert judgement or by methodological approaches (Basili, Costa, Lindvall, Mendonca, Seaman, Tesoriero, et al., 2002).
- **Products** used in software projects such as project plans, product descriptions, demonstration installations, or presentation slides, as well as products produced and consumed in these projects, such as requirement documentations, architectures, software libraries, or source code.
- **Models** about the software quality (i.e., quality models) or the execution of processes (i.e., process or lifecycle models) that were used in projects and adapted to the organization and the individual needs of the project and its team.
- **Defects** found in a software system or in a project that reduce its functionality, maintainability, or other aspects like performance. Associated information of this artifact is, for example, their location,

Figure 2. Types and characteristics of knowledge



characteristics, and reactive or preventive measures. If a specific type of defect is recorded over and over again, it might be summarized in a so-called antipattern.

- **Descriptions** of the organization, people, projects, processes, products, and customers (O4PC) as well as technologies (e.g., EJB and JBoss), development rules, interface style guides, corporate quality assurance guidelines, or the corporate identity style.

Knowledge Management and Learning Management

Knowledge as the fourth factor of production is one of the most important assets for any kind of organization, and for all areas of science. Unfortunately, today few experts who have acquired valuable experience through their day-to-day work share this knowledge with other people in the organization. For example, experiences about how to solve complex problems in software development, such as installation or optimization issues, are typically not shared with colleagues.

Knowledge Management

Knowledge management is concerned with methods and technologies to enable an organization to record, inspect, adapt, and share knowledge cooperatively on a large scale. Recording, elicitation, and adaptation of knowledge are the most critical tasks in knowledge management with respect to further reuse of knowledge. The lower the quality of the knowledge is that is recorded (e.g., due to missing context information), the more complex it gets to understand and apply the knowledge in a new context. The participation of colleagues such as managers, employees, or external experts helps to record knowledge from multiple points of view.

In the domain of software engineering, software development can be considered as a human-based, knowledge-intensive activity. Together with sound methods, techniques, and tools, the success of a software project and the software quality itself strongly depends on the knowledge and experience brought to the project by its developers. This fact led to the development and use of experience-based information systems (EbIS) for capturing, storing, and transferring experience (Nick, 2005). Experience management (EM) can be seen as a subfield of KM that aims at supporting the management and transfer of relevant experiences (Bergmann, 2002; Tautz, 2001). The software system used for managing, storing, retrieving, and disseminating these experiences is called an experience-based information system (EbIS) (Jedlitschka & Nick, 2003), which is based on the experience factory concept. Another type of system that is not based on the EF concept is lessons learned systems (LLS) (Weber, Aha, & Becerra-Fernandez, 2001). Amongst the definitions for lessons learned, the most complete definition, is:

A lesson learned is knowledge or understanding gained by experience. The experience may be positive, as in a successful test or mission, or negative, as in a mishap or failure. Successes are also considered sources of lessons learned. A lesson must be significant in that it has a real or assumed impact on operations; valid in that it is factually and technically correct; and applicable in that it identifies a specific design, process, or decision that reduces or eliminates the potential for failures and mishaps, or reinforces a positive result. (Secchi, Ciaschi, & Spence, 1999)

Learning Management

KM and learning management (LM) both serve the same purpose: facilitating learning and competence development of individuals, in projects, and in organizations. However, they follow two different perspectives. KM is related to an organizational perspective, because it addresses the lack of sharing knowledge among members of the

organizations by encouraging individuals to make their knowledge explicit by creating knowledge elements, which can be stored in knowledge bases for later reuse or for participating in communities of practice. In contrast, e-learning emphasizes an individual perspective, as it focuses on the individual acquisition of new knowledge and the socio-technical means to support this internalization process. In the following two sections, expectations on learning content and related specifications and standards that address these expectations are presented.

Expectations on Today's Learning Content

Especially in industrial training settings, learning objectives mostly correspond to concrete, well-defined job-related skills, specific tasks to be done, or problems to be solved. Hence, the delivered learning material and learning approach must suit the current situation that the learner finds himself in. The situation changes over time while the learner is performing his work. Nevertheless, conventional learning systems leave no space for dynamic selection and sequencing of learning material. In addition, the expectations on e-learning content are high (cf. SCORM 2004 2nd Edition Overview page 1-22, http://www.adlnet.org/scorm/index.cfm):

- **Accessibility:** "the ability to locate and access instructional components from one remote location and deliver them to many other locations".
- **Adaptability:** "the ability to tailor instruction to individual and organizational needs".
- **Affordability:** "the ability to increase efficiency and productivity by reducing the time and costs involved in delivering instruction".
- **Durability:** "the ability to withstand technology evolution and changes without costly redesign, reconfiguration or recoding".
- **Interoperability:** "the ability to take instructional components developed in one location with one set of tools or platform and use them in another location with a different set of tools or platform".
- **Reusability:** "the flexibility to incorporate instructional components in multiple applications and contexts".

It is impossible to improve all aspects together. For example, in order to support high adaptability of learning content, more effort has to be spent on realizing adaptation mechanisms and preparing learning content so that it can be adapted to specific learning situations. This will decrease the reusability of the content and its interoperability with other learning management systems. Therefore, tradeoffs have to be made by focusing on the most important aspects for a given purpose. *Semantic-Based Reuse in SE: the RISE Approach* will elaborate on which aspects Riki will focus on. The requirement for content that fulfills these aims leads to the concept of cutting learning material into so-called learning objects with associated metadata. Since then, many standards and specifications have been developed to offer a strong fundament for learning content with the previously listed characteristics.

E-Learning Standards and Specifications

Numerous initiatives like AICC (the Aviation Industry CBT Committee), ADL (Advanced Distributed Learning), IEEE LTSC (the Learning Technology Standards Committee of the IEEE) and IMS Global Learning Consortium have made efforts to establish standards. For several years, a number of initiatives have agreed to cooperate in the field of standards. Among the many available standards and specifications, the ones most relevant for Riki are described in the following.

The LTSC has developed the Learning Object Metadata Standard (LOM). This standard will specify the syntax and semantics of learning

object metadata, defined as the attributes required to fully/adequately describe a learning object. Learning objects are defined here as "any entity, digital or non-digital, which can be used, re-used or referenced during technology supported learning." A huge amount of specifications is being developed by the IMS consortium. Several of these specifications have been incorporated and, in some cases, been adapted by ADL to define the SCORM reference model. SCORM describes that technical framework by providing a harmonized set of guidelines, specifications, and standards based on the work of several distinct e-learning specifications and standards bodies. These specifications have one aspect in common: by separating the content from the structure and layout, they enable the author to develop different variants of learning material very efficiently, while relying on the same set of learning objects. *SCORM sequencing and navigation* provides techniques to sequence learning objects by means of learning activity trees, and the IMS Learning Design specification allows expressing more sophisticated pedagogical concepts by means of a more extensive role concept. However, they prescribe structures for expressing more or less generic instructional designs, and do not provide possibilities for adapting instructional design during run-time. Nevertheless, despite their limitations, Riki will especially make use of specific concepts within SCORM (such as *sharable content object*, *organization*, *manifest*, *learning activity tree*, etc.) and parts of sequencing and navigation. Especially the contextualization of knowledge and experience (i.e., embedding the information in a context) plays a crucial role in Riki. Part of the context description could be done, for example, according to the IMS Learner Information Package specification in order to describe the content owner, or other content related roles. The Dublin Core Metadata Initiative (DCMI) has developed the *Dublin Core Metadata Element Set* outside of the e-learning domain. DC defines a very simple set of metadata attributes that can be used for describing general resources. Since the content of a Riki should be annotated as unintrusively as possible, DC will be a starting point for describing RISE content.

Wikis and Semantics in Software Engineering

The Semantic Web initiative is concerned with the enrichment of information on the Internet through the use of exchangeable and machine-readable metadata. To structure the knowledge in a "mini"-Internet, as represented by a KM system such as a Wiki, we also planned to enrich the knowledge encoded on the Wiki pages with additional metadata. In the remainder of this section, we describe Wikis in general, followed by two overviews of Wikis for SE organizations and Wikis with integrated metadata support, which form the basis of our Riki system (i.e., semantic Wikis).

Wikis facilitate communication through a basic set of features, which allows the project team to coordinate their work in a flexible way. From the authors' point of view, these basic features are: *one place publishing*, meaning that there is only one version of a document available that is regarded as the current version; *simple and safe collaboration*, which refers to versioning and locking mechanisms that most Wikis provide; *easy linking*, meaning that documents within a Wiki can be linked by their title using a simple markup; *description on demand*, which means that links can be defined to pages that have not been created yet, but might be filled with content in the future. Furthermore, the simple mechanism of URL allows easy reference and thus, traceability of Wiki content into other software documents like code. For a further discussion on Wiki features, refer to Cunningham (2005).

Besides those technical aspects, Wikis foster a mindset of a fit-for-use, evolutional approach to requirements documentation and management. The approach of Wikis—in particular, Wikipedia

as the most prominent representative (Wikipedia, 2006)—demands that an initially created document is adequate for its intended usage (fit-for-use). This initial version is then extended, based on the demand of the people using this document.

Software Engineering-Oriented Wikis

Wikis were initially used in a software engineering setting, namely the Portland Pattern Repository (Leuf & Cunningham, 2001). Furthermore, they are often used to support software development, in particular in the area of open source software. The Wikis of the Apache Foundation are a prominent example of this application scenario. Some examples of Wikis offer specific functionality for software engineering:

- **Trac** (Alrubaie, 2006) is a Wiki, written in python, that integrates an issue tracker, allowing it to relate Wiki pages to issues, and vice versa. Furthermore, the python code of a project can be integrated as read-only documents.
- **MASE** (Maurer, 2002) is an extension to the JSP Wiki that offers plugins for agile software development, in particular for iteration planning and integration of automated measurement results.
- **SnipSnap** (John, Jugel, & Schmidt, 2005) is implemented in Java and allows read-only integration of code documentation. Furthermore, it offers support for the integration of Wiki entries into the integrated development environment eclipse.
- **Subwiki** (SubWiki, 2005) is a Wiki implementation that uses the versioning system subversion as a data repository. Since subversion allows attaching metadata to files, the resulting Wiki is supposed to have the same features. However, this project has not released a stable version yet.
- **EclipseWiki** (EclipseWiki, 2005) is a plugin for the eclipse software development platform. It uses the workspace of a project as (local) data storage. By using a versioning system, the Wiki files can be shared and edited by a project team.
- **WikiDoc** (Oezbek, 2005) is a conceptual work that supports adding java code documentation via a Wiki interface. This allows nonprogrammers to participate in the creation of code documentation.

All those examples show that Wikis are increasingly being used as a platform for software development. However, "regular" Wikis (see (WikiEngines, 2005) for an overview of most of the Wikis currently available and WikiMatrix, (2006) for a configurable overview), as well as software engineering-oriented Wikis, build upon the fact that the relations between documents and further metadata are maintained by the users of those Wikis. This lack of explicit semantic information is addressed by an extension to the regular Wiki functionality that is developed in the RISE project. These so-called *semantic Wikis* are elaborated in the next section.

Semantic Wikis

In this section, we present further examples of semantic Wikis. Most of these examples are taken from the overviews presented in Dahl and Eisenbach (2005) and Semantic Wikis (2005). Those examples show that a) even "regular" Wikis offer some support for structuring their content and b) that semantic, RDF-based Wikis can be implemented. Most of those examples are general purpose Wikis that do not focus on software engineering in particular. A general overview of semantic Wikis can be found in Völkel, Schaffert, Kiesel, Oren, and Decker (2005):

- The most common way to categorize within Wikis is the usage of the backlink function of a Wiki (Aumüller, 2005). Basically, a page is created that represents a certain category.

Pages belonging to this category have a reference to this page. The backlink function lists all of these references. However, this approach has one major drawback: pages that are used to navigate to the category entry (and thus do not semantically belong to this category) are also included in the backlink list.

- Some Wikis offer additional support for structuring content. For example, *TikiWiki*, (TikiWiki, 2005) allows assigning pages to structures (table of contents) and categories (taxonomy style classification). XWiki (2005) offers forms (templates) that contain metadata that are instantiated in documents derived from this form.
- From the area of SE-specific Wikis, TRAC offers a labeling feature for pages (smart tags) that could be used for a facetted presentation of the pages annotated with those tags. SnipSnap allows determining the template of a document and offers RDF export.
- *Platypus* (Platypus, 2005) and *SHAWN* (Aumüller, 2005) allow adding RDF annotations for each page. Pages within Platypus represent a concept. While viewing a page, the RDF triples are displayed that have the current page as object (in particular, pages that reference this page) and as subject (in particular, metadata about a page). SHAWN also offers navigation support based on the ontology information added to a page. Wiki. Ont is still in a preliminary version.
- *Rhizome* (Rhizome, 2005; Souzis, 2001) and *RDF-Wiki* (Palmer, 2005) are Wikis that provide their content in RDF, thus allowing to reason about their context.

Only the Wikis mentioned in the last two bullets can be seen as "real" semantic Wikis, since they allow relating their content to an RDF-based ontology. However, all of them—at least in their current state—do not integrate their ontology into the Wiki, for example, they neither provide metadata templates to be filled in based on an ontology nor do they check whether metadata entered is consistent with an ontology. Therefore, when related to the Semantic Web layer cake (Berners-Lee, 2005), all of these semantic Wikis implement the RDF and RDFS layer. The vocabulary layer of these applications is not domain specific and thus, does not allow inferring about domain specific relations.

Ontology Development

The development of ontologies to classify and structure knowledge—often called knowledge engineering—is a rather mature field that has its origins in artificial intelligence. Several methodologies, approaches, and standards have been developed that focus on ontology development in general, or resulted in an ontology for software engineering knowledge. This work is implicitly included in the RODent method presented later, and developers of Riki-specific ontologies might find these works helpful as a source of inspiration for their own ontology development. Furthermore, by adhering to the following standards, the tools and framework based on (some of) these standards can be employed for reasoning-specific tasks in RISE:

- **Ontology development:** CommonKADS (Schreiber, Wielinga, Hoog, Akkermans, & Velde, 1994) is a methodology for developing knowledge-based systems and contains guidelines for developing ontologies.
- **Ontology description standards:** The language set of RDF (Manola & Miller, 2004), RDF-Schema (Brickley & Guha, 2004) and OWL (Smith, Welty, & McGuinness, 2004) defines language constructs that can be used to define ontology in a way suitable for machine reasoning.
- **General ontology standards:** Ontology standards make use of those ontology description standards. In RISE, we referred to

the Super Upper Merged Ontology (Legrand, Tyrväinen, & Saarikoski, 2003; SUMO Ontology), describing general relations (such as part-of) and the Dublin Core metadata to have a general set of document metadata (such as author, creation date) (2005).

- **Software-engineering-specific ontologies:** These ontologies define a general set of concepts and their relations in the field of software engineering. This allows the entries within Riki to be annotated with domain-specific meaning. Examples of such ontologies are the software engineering body of knowledge (Software Engineering Body of Knowledge, Iron Man Version, 2004) and the classification of the Association for Computing Machinery (2005).

This background section illuminated the background of our work and gave a short overview of the application field of software engineering and software reuse, as well as the Wiki technology that was used in the RISE project. These fields represent the context in which several problems were encountered that are described in the following section.

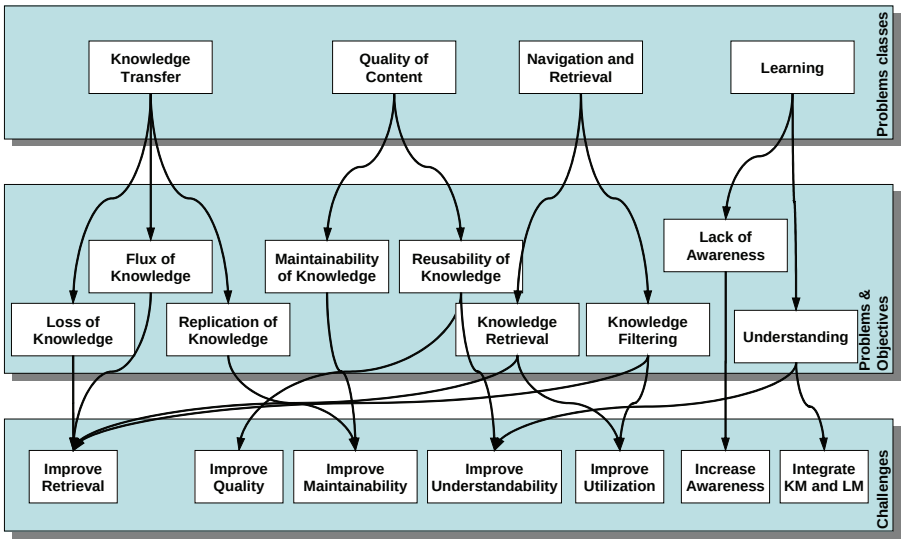
PROBLEMS AND CHALLENGES

After the description of the background of software engineering and the application of techniques from knowledge management and learning management, we look at the specific problems addressed within the RISE project. As depicted in Figure 3, we identified several problems of knowledge and learning management in software engineering.

Problems of Knowledge Transfer and Reuse in Software Engineering

As motivated in *Software Engineering and Reusable Knowledge*, the development of software is a highly knowledge-intensive activity that produces many reusable documents, ideas, and experiences. The productivity as well as the quality of the products developed heavily depends on

Figure 3. Problem overview



the efficient and effective storage and retrieval of knowledge in a socio-technical system. A knowledge management system should at least reduce or prevent the occurrence of the following basic problems in KM:

- **Loss of knowledge:** Key personnel with valuable or even critical knowledge about products, processes, or customers leave the organization and leave a knowledge gap. In a software organization, this might be a senior software developer who is the only person with critical information about the inner structure or function of a software system.
- **Replication of knowledge:** Products, intellectual property, or experiences are developed over and over again in slightly different versions. In a software organization, an algorithm might be developed twice because one project does not always know what other projects are doing. This might also apply to defects that are introduced to different parts of the software system and removed by different testers doing the same work (i.e., solving the same problem) twice.
- **Flux of knowledge:** The knowledge about new technologies, projects, processes, products, people, or standards is continuously subject to change. In order not to fall behind the innovations, competitors who are using these gaps have to be discovered and handled. For example, software organizations have to cope with many new open source projects, competitive systems, development standards, or frameworks that are developed or changed every year.

In the following sections, we have grouped specific problems into classes regarding quality aspects, the integration of KM and LM, the learning processes, as well as retrieval and reasoning about the content.

Problems Related to the Quality of Content

A knowledge base (KB) serves as an asynchronous communication medium or intermediary between people such as managers, developers, or even customers. The whole process is one of mediated communication (i.e., people are leaving messages to other people). Furthermore, there is the danger that relevant content from the outside is not considered, especially from outside the knowledge base (i.e., on the Intranet), from the Internet, and from the social system at large (i.e., the people). Until today, there are several problems related to the quality of the content in a knowledge base that still represent a barrier in knowledge management:

- **Problem of reusability of knowledge:** The quality of the reported and recorded knowledge and experience highly depends on the individual skills of the contributor, for example, the ability to structure the content, to formulate the artifacts with accuracy, and to describe it properly according to the needs of the target audience. Without assistance, this leads to quality discrepancies and gaps in the knowledge base. To be included in the knowledge base, the new content must meet minimal quality requirements, such as described in a correct, complete, consistent, concise, and nonambiguous way, including information on the context of the specific content.
- **Problem of maintainability of the knowledge base:** A regular evaluation of all content and removal of outdated entries is required. Storing several contradictory solutions for a sole problem, originating from different persons at different points in time, is a source of confusion and mistrust. The capacity to retrieve previous related experiences exists in most KB approaches, but it requires time and effort to review them. The risk of

applying outdated content is high if content does not have an attached expiry date, and on many occasions, these repositories become a sort of graveyards: some content is added, but nothing is ever thrown away. With the continually growing size of KBs, it is difficult to keep an overview in order to connect related packages and avoid inconsistencies.

While the use of Wiki systems, as applied in our project, facilitate and improve several of the previously mentioned problems due to the increased flexibility, agility, and simplicity, they also bring along their own new problems, such as the *motivation to contribute* or the *sustainability* of the Wiki system. Furthermore, the flexible and easy creation of links between Wiki pages (i.e., knowledge elements) leads to high cross-linking and hence, to the *deterioration and loss of structure*.

Problems Related to the Navigation and Retrieval

A long running KM system that is accepted by the users and continuously increases the amount of knowledge stored within it typically amasses a plethora of knowledge that is unstructured, not connected, or outdated. The retrieval of a specific knowledge component, either by navigation or search mechanisms, typically leads to an information flood. In order to enable and improve the elicitation, organization, retrieval, and usage of knowledge in software organizations, several problems have to be addressed:

- **Problem of knowledge retrieval:** Software development in general has to cope with the overwhelming amount of new processes, technologies, and tools that periodically appears. As a consequence, the fast retrieval of up-to-date information about new technologies, corporate software systems, or available experts becomes more and more important. Furthermore, there are many knowledge components that become outdated within a few years (e.g., information about Java frameworks).
- **Problem of knowledge filtering:** Searching for crucial information in a large knowledge base, especially if it is focused on a single topic such as software engineering, leads to a flood of results. The more similar the components are in a knowledge base, the more precise a search or navigational structure has to be in order to find the relevant information.

Problems Related to Learning

KM systems focus mainly on organizational learning, that is, where learning leads to collecting knowledge for the organization in order to be used by its employees or for the modifications of the software organization's processes, internal standards, objectives, or strategies. However, Rus and Lindvall stated that individual learning is considered to be a fundamental part of KM because employees must internalize (learn) shared knowledge before they can use it to perform specific tasks (2002). KM systems make the assumption that the problem of continuous competence development can be partially solved by using intelligent retrieval mechanisms and benefitting from innovative presentations of retrieval results. As a result, knowledge-based systems (KBSs) focus mainly on knowledge acquisition, storage, and retrieval, and less on the learning processes themselves, the integration with the work process, and the personal learning needs of the software developers. More specific problems related to experiential learning (i.e., learning from experience) are listed below:

- **Problem of understanding and applying of documented experience:** Experience is often documented by domain experts. A

problem that occurs when expert knowledge is used for teaching novices is that there is a quantitative difference between expert and novice knowledge bases, and also a qualitative difference, for example, the way in which knowledge is organized (Ericsson, Krampe, & Tesch-Romer, 1993). Novices lack SE background knowledge and are not able to connect the experience to their knowledge base. Hence, they often misinterpret other people's documented experience. The organization of knowledge at the experienced provider's level and at the consumer's level makes the transfer of knowledge between different levels of expertise extremely difficult. Expert knowledge is somehow "routine." This makes it challenging for experts to document experiences appropriately and to make them reusable for others. A more detailed summary of problems related to learning from documented experience can be found in Ras and Weibelzahl (2004).

- **Problem of overview and lack of awareness:** Systemic thinking is the conceptual cornerstone of the "Fifth Discipline" (Senge, 1990). It addresses the problem that we tend to focus on the parts rather than seeing the whole, and fail to see organizations as a dynamic process. Unfortunately, learning by documented experience is limited to a very focused view of SE, and does not relate the experience to the whole SE context and related domains. Another problem is that systems do not point explicitly to other available SE methods, techniques, and tools that could be useful for the work at hand, which leads to a lack of awareness.

Objectives, Challenges and Research Issues

Most of the previously mentioned problems were tackled by several researchers in projects around the world, but a solution to them is still far in the future. We tried to improve the situation by using the open Wiki technology and integrated aspects of LM and KM to support reuse in software engineering. This system, which we call reuse-oriented Wiki (Riki), has to support the comprehensive reuse of the artifacts as described in Background, and has to help the users to collect, record, retrieve, reuse, and learn from them. Furthermore, the administrative staff needs to be supported in the packaging, formalization, aggregation, and generalization of artifacts in this knowledge base.

The overall goal of the RISE project was to integrate lightweight experience management with agile software development. RISE pursued the following specific objectives:

- **Improvement of the retrieval of knowledge and orientation** in a body of knowledge to optimize the amount of knowledge and accelerate the time to access relevant knowledge.
- **Improvement of the quality of transferred knowledge** by assisting software engineers in creating optimized artifacts (i.e., with optimized content and structure) based on didactical principles and by delivering didactically augmented experiences. These artifacts should easily be adopted and internalized by users of different expertise levels to support them in their daily work and performance.
- **Improvement of utilization and usability of the KM systems** to allow the user the goal-oriented search for suitable solutions to his problem in minimal time, and to support him in the adaptation of the solution to his specific problems.
- **Integration of knowledge management and experience management** with e-learning and work itself in order to improve the reuse of documented experience and to bring learning to the work place.

- **Improving the understandability** of documented expert experience by explicitly offering additional SE learning components, and by explicitly stimulating learning activities through didactical principles.
- **Increasing the awareness of available but unknown SE topics** in order to increase the software quality based on the application of new software development approaches that have not been applied before.
- **Improve the maintenance of knowledge in KM systems**, and especially Wikis, in order to optimize the amount of potentially relevant knowledge.

SEMANTIC-BASED REUSE IN SE: THE RISE APPROACH

As we have argued, neither the technology nor the methodology currently available is sufficient to challenge the problems listed in *Problems and Challenges*. After introducing the basic concepts of Riki, we describe the methodology and technology that was developed and used in the RISE project.

Basic Concepts in RISE

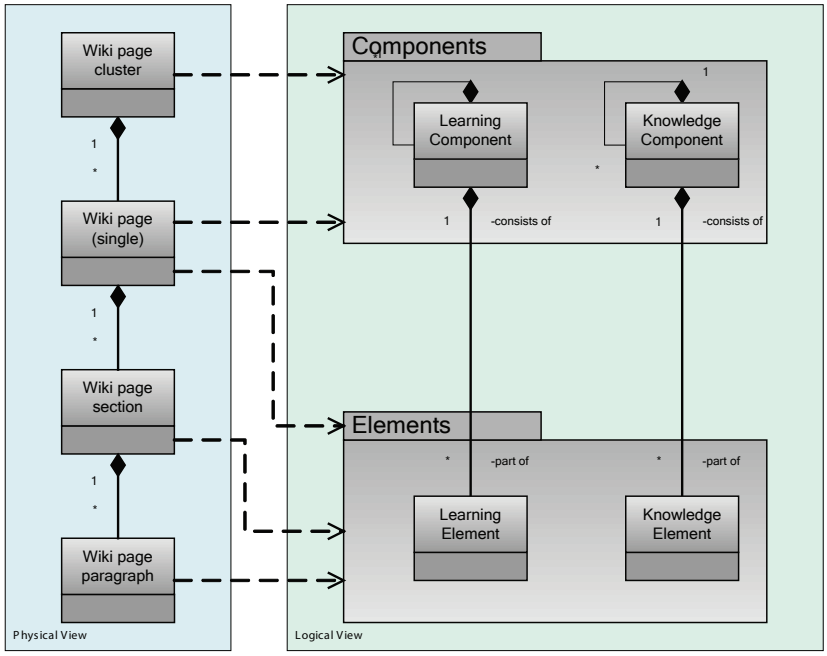
In general, we use the model defined by Tautz: "*knowledge* is the range of learned information or understanding of a human or intelligent information system, experience is considered to be knowledge or practical wisdom gained through human senses, from directly observing, encountering, or undergoing things during the participation in events or in a particular activity" (Tautz, 2001).

Representation of Knowledge in Wiki Systems

After describing Wiki systems and the types of knowledge that might be stored in those systems (see *Wikis and Semantics in Software Engineering*), we shed some light on the storage of knowledge artifacts in a Wiki system. We use the following concepts:

- **Knowledge elements:** are the most basic containers for knowledge and cannot be further divided without destroying the ability to understand them using other knowledge elements.
- **Knowledge components:** are complete and self-sufficient (i.e., independent of other knowledge elements) descriptions of knowledge (e.g., a SE artifact). A knowledge component consists of one or more knowledge elements.
- **Learning elements:** are the most basic learning resources. They are the electronic representation of media, such as images, text, sound, or any other piece of data that could serve as a learning resource when aggregated with other learning elements to form a learning component (Note: Learning elements can be compared with assets of the SCORM content aggregation model).
- **Learning components:** are units of instruction that contain at least one learning element. A learning component represents the lowest granularity of a learning resource that can be reused by the system for learning purposes. The difference between a learning component and a learning element is that a learning component is related to a learning activity and a learning objective. In addition, it can be referenced as a learning resource by the system (e.g., by using hyperlinks). Another difference is that a learning component could possess contractually specified interfaces and explicit context dependencies when these are used within a so-called learning space (Note: Learning components are similar to sharable content objects of the SCORM content aggregation model).

Figure 4. Knowledge in Wiki systems



- **Learning space:** consists of a hyperspace that contains at least one or more learning components that are presented, for example, by linked Wiki pages. A learning space follows a specific global learning goal, and is created based on context information of the current situation (e.g., learner needs, working tasks the learner is currently performing, or attributes of software artifacts). The goal of a learning space is to provide a learning environment for self-directed situated learning (see *Learning Space Analysis* for more details).

As depicted in Figure 4, knowledge elements are the typical content of a Wiki page, while a short knowledge component might equally fit. Furthermore, a knowledge element might have to be split into multiple Wiki pages if the content is too large or structured, as a training course.

Classes of Knowledge in a Riki System

The entrance of a Riki system consists of the six general classes of knowledge: projects, products, processes, people, customers, and (further) knowledge. Around these classes, several knowledge leaves are developed, based on the knowledge types from *Software Engineering Experience and Knowledge* (i.e., know-how, know-where, etc.). Therefore, a specific project page (e.g., about the RISE project) includes information about the requirements and designs of the changes planned for the products involved in the RISE project, but the product page (e.g., about the Riki) will include all requirements relevant for this specific product. However, a single knowledge leaf is not always purely classifiable as a single knowledge type (e.g., know-how), but might include other types of knowledge (e.g., source code developed in a project might include know-where, (i.e., location) as well as know-when, (i.e., version) knowledge.

Figure 5. Knowledge component classes in an SE organization based upon O4PKC

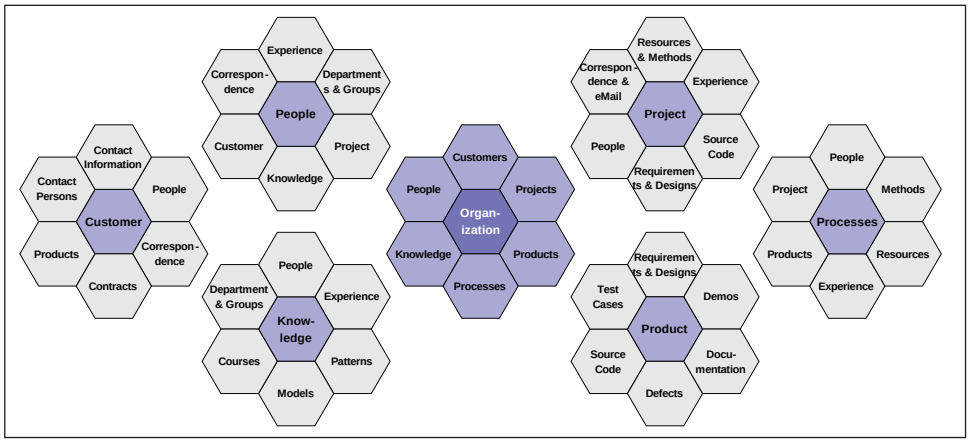


Figure 6. The RIME components (ontology, learning space, and Riki system development)

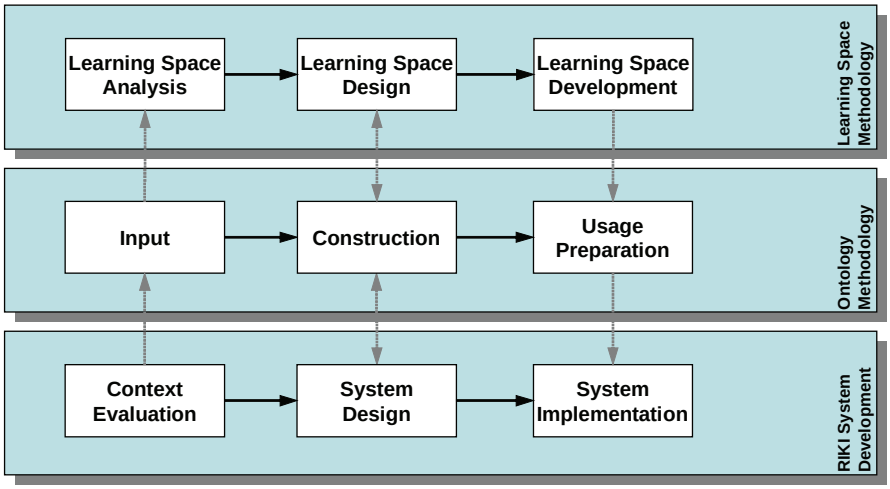


As depicted in Figure 5, the artifacts from *Types of Knowledge* might be grouped around several core artifacts, such as projects or products, and represent connection points usable for further inference. For example, in the configuration shown, one could easily infer employees who have worked in a project that was initiated by a specific customer and therefore might have valuable knowledge for further acquisition activities.

The more often these or similar artifacts are generated, the more probable it is that they might be reused in a new project.

RIME: The RISE Methodology for Knowledge Transfer and Reuse

In this section, we describe three parts of RIME, including the design and development methodol-

ogy for Riki systems, ontologies in a Riki, and learning spaces in a Riki. As depicted in Figure 6, all three are based on a detailed context evaluation in software organizations whose results were used for deriving the requirements for a Riki in the context to be addressed.

The RISE methodology represents a concept for the structuring, implementation, and operation of the Riki system.

Riki System Development

To develop a KM system such as Riki, we first analyzed and evaluated the context in two SMEs, which both develop search technologies systems. From the information we gathered in these context evaluations, we designed and developed the Riki system, considering the people, processes, and available technologies. Finally we developed, tailored, and implemented these systems in the organizations.

Context Evaluation: Analyzing the Existing Socio-Technical Infrastructure

The goal of our context evaluation step was to elicit the existing socio-technical infrastructure of the companies. Therefore, we developed a catalog of questions to elicit information about concrete topics that we wanted to know about (e.g., what technical systems are in use). In order to answer the following questions, and therefore elicit knowledge about the context the RISE system will be embedded in, we conducted an interview using a refined questionnaire based on the know questions from *Software Engineering Expereince and Knowledge*. The basic topics of the questions were:

- Where and what are technical systems with potentially valuable knowledge?
- Who are the experts for specific topics, such as products or technologies?
- How is knowledge transferred from tools to persons? What technical systems for knowledge transfer are available?
- How is knowledge transferred from person to person (interpersonal)? What social knowledge transfer techniques are used?
- How is knowledge collected from persons to tools?
- How is knowledge collected or transformed from tools to tools?
- Who needs and who produces new knowledge?
- What processes and tools are used to develop the software? Where can knowledge be collected and injected?
- When is knowledge collected, transferred, reused, needed, or produced?
- Why is knowledge currently being collected, transferred, or reused?
- What knowledge is (seemed to be) valuable for collection, transfer, or reuse? Which artifacts (as in *Types of Knowledge*) are used and should be reused?

Beside the use of questionnaires to query the employees of the companies, and elicit knowledge about the context a social-technical system has to be embedded in, we also conducted open group discussions and analyzed the existing artifacts and storage system ourselves. Overall, we used the following techniques to gather the knowledge:

- Goal-oriented, questionnaire-based *interviews* were used to put the previously listed questions to three to ten persons in two to four sessions. The collected answers were summarized and validated by the participants via e-mail.
- *Group discussions* were done at every company to collect any additional information, opinions, ideas, and so forth, that were not covered by the interviews. The discussion was started with a specific topic (e.g., why

had the old Wiki not worked for you as a KM system?) ,and every person could state what they expected from an improved knowledge management infrastructure.
- *Artifact analyses* were conducted to identify knowledge sources, the type of knowledge within, as well as how people structure their documents and knowledge in existing storage systems (e.g., the hierarchy of directories in personal file systems or in pre-existing Wiki systems).

Using the information extracted with these techniques, we derived and created tailored versions for each company of:

- **Ontology** with metadata for all pages in the KM system (i.e., the Riki) and relations between them. This metadata is used for inference, search and presentation purposes. The ontology is based upon information from the existing artifacts of the company, the knowledge lifecycle, and standards of knowledge description such as LOM.
- **Templates** for every artifact type with a special focus on requirement documents. These help to record new knowledge of that type and are used in inference, for example, to find similar documents of the same type. The templates represent the inner structure of artifacts and esp. Knowledge Elements on a Wiki page. Information to define the templates came from the identified knowledge artifacts, the knowledge lifecycle (i.e., how would a user read the document in a specific activity of the process?), and industrial best practices such as the Volere requirement template (Robertson & Robertson, 2005a) or the ReadySET requirements-engineering template.
- **Navigational structures** within the KM system (Riki) were created to support the goal-oriented and artifact-centric access to the knowledge. The structures are based upon information from the existing structures used by the employees of the company and the processes, products, and groups of the company.
- **Riki software system** with plugins to support the users with additional information from inference via the currently viewed knowledge as well as connectors to the technical infrastructure. The system design is based upon information from available software systems in the organization, established knowledge transfer techniques, and usability aspects.

System Design: Tailoring a Riki for a Learning Software Organization

After we elicited the information about the context our socio-technical system should be embedded in, we started the design of the system. Beside the information about the context, we needed further information about the technical features and the extensibility of the available systems. The following information was found to be useful for the design of the system:

- **Survey** of systems (e.g., open source), extensible without too much work, and flexible enough to realize the planned systems.
- **Selection** of an appropriate system that fulfills the optimal set of requirements by the specific customer based on the use cases and scenarios as defined by the customer's business or development processes.
- **Design of plugins and portlets** that give specific views on related articles, similar pages (of the same document type) as well as the plugin interface. In general, every know question from *Software Engineering Experience and Knowledge* represents one plugin that shows information related to the currently viewed knowledge element,

for example, the persons who have further knowledge (i.e., know-who) or methods for post-processing (know-how).

- **Design of templates and interface masks** for every specific knowledge type [e.g., templates and masks for use cases (requirements)].

Furthermore, based on the features already existent in Wikis and extensions planned for the Riki, as well as on the features of the search and inference technology, we shaped the ontology and vice versa.

System Implementation: Introducing a Riki into a Software Organization

Based upon the information from the design, the system and required plugins are built using the chosen Wiki systems. During operation, the experiences acquired from the daily work (e.g., projects) are seized and didactically augmented to support users in current or future projects.

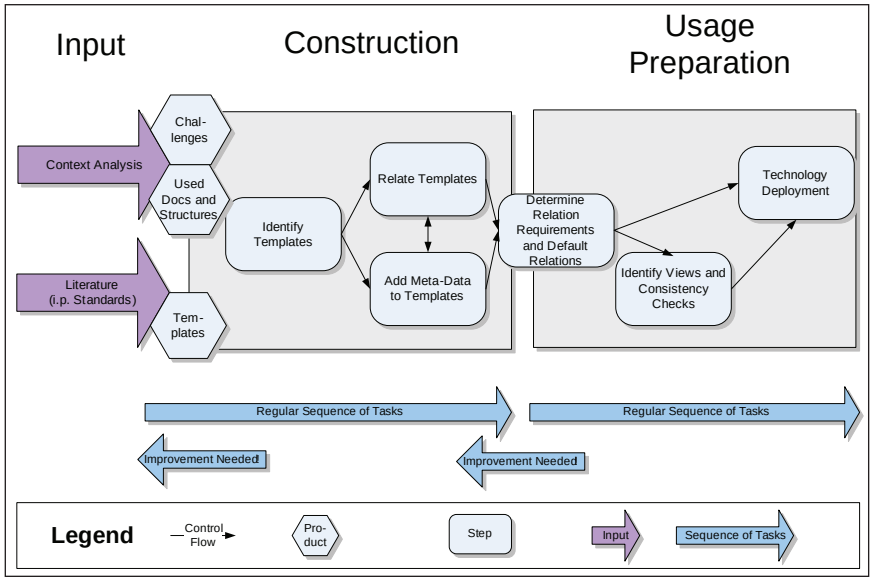
The operation and maintenance of the Riki system, its underlying ontology, and the knowledge stored within it is currently being done by the software organizations themselves.

RODent: Riki Ontology Development

This section explains the RODent method for the design and development of Riki ontologies. In parallel with systems building, we need to develop an ontology to be used by the Riki. In general, an ontology is defined as "an explicit and formal specification of a conceptualization" (Gruber, 1995).

In RISE, we instantiate this definition: An ontology is a set of templates, their metadata,and the relations among those templates. The role of the resulting ontology is to structure and relate the information captured inside the Riki. Therefore, the ontology can be seen as a link between the implementation of a Riki and the content of a Riki. The guiding idea is *Wikitology*, that is, that the Wiki is the physical representation of

Figure 7. Overview of RODent



the ontology with pages as concepts and links as relations (Decker, Ras, Rech, Klein, Reuschling, Höcht, et al., 2005; Decker, Rech, Althoff, Klotz, Leopold, & Voss, 2005).

Besides the ontology itself, the result of this method is an initial set of document templates and content to seed a Riki. In the following sections, an overview of RODent is presented, using requirements engineering as an example application.

Outline of RODent

As depicted in Figure 7, RODent is divided into two groups of subtasks: *ontology construction*, where the concepts and their relations are identified, and *usage preparation*, where the usage of the ontology is defined. A more detailed description of the following tasks is presented in the subsequent sections:

- **Input** to RODent comes from two sources: The first source is the result of the context analysis, with the prioritized challenges of the organization and the currently used structures and documents defining the "asIs" status of the organization. The second source is an analysis of domain-specific literature relevant for the domain where the ontology should be built (in the example, from the area of requirements engineering). This literature will provide an initial set of templates.
- **Construction** as the first group of tasks uses this input as follows: First, the actual templates used in Riki are identified. Second, those templates are related with each other and "equipped" with metadata.
- **Usage Preparation** as the second group is about setting up a Riki to use the ontology defined in the subsequent phase. The task "Determine Relation Requirements and Default Relation" is a link between those phases since it refines ontology relations, but also covers aspects of ontology usage in the Riki. "Identify views and consistency checks" takes care of using the ontology for navigational and editing support as well as to define inconsistencies within the knowledge captured in Riki. In "Technology Deployment," it is defined where the ontology, the views, and consistency checks are put in the Riki.

The application of RODent—provided that no increments or iterations occur—is depicted from left to right in Figure 7.

The challenges, as well as the feedback when developing and using the systems, guide the execution of the method:

- In the first execution of the method, one has to concentrate on solving the most relevant challenges most of the people using the Riki are interested in. In particular, one should try to identify multipliers, that is, people in the organization who have a special stake in the Riki usage and support their daily work. For example, if inconsistent and outdated documentation is a challenge, then the resulting ontology should support the documentation author.
- During development and usage of the systems, increments and iterations are likely to occur. Since those terms are sometimes used with interchangeable meaning, we define their meaning within RODent and their impact on ontology development: Increments are additions to the current ontology without the need to change further parts. Iterations also include a change within the existing ontology.

Within the RISE project, we encountered several increments (e.g., adding an architectural description) and some iterations (e.g., rearranging use cases), but no severe change of the ontology occurred. This experience supports the demand-oriented approach that is the basis of RODent.

However, this stability of the resulting ontology might be a result of the comprehensive context analysis and literature survey.

The following sections describe the task of RODent in detail and provide an example of the usage of this method for requirements engineering.

Identify Templates

The main objective of this task is to identify the templates capturing knowledge inside a Riki, and to create prototypes of the templates needed. As outlined in the method's overview, this task has the following two inputs:

- The result of the context analysis, with its overview of the currently used documents and the challenges of the organization.
- The literature survey identifying standards and other useful information to be used in template development.

During identification and development of those templates, we found the following guidelines to be helpful:

- **Split and link self-contained documents:** Resources found in the literature (e,g., standards) are normally part of a self-contained document written in a linear way. Since Riki is a hypertext-system, one needs split and link coherent information chunks found in those documents. Potential candidates are the different sections within these documents. For example, in the Volere Requirement Specification Template (Robertson & Robertson, 2005b), we identified the different user descriptions based on this approach.
- **Refactor documents covering multiple aspects:** The resulting templates should cover one aspect of information. Given a readable font, this guideline boils down to the following operational rules: (1) When a template is completed, it should not be shorter than one and not longer than five screens. (2) Each (main) section of the template should fit on one screen. Adherence to this guideline is the basis for the reuse of knowledge, since it allows referring to specific information.

When all templates concerning the current challenges are addressed in the first execution of RODent, further templates demanding too much additional effort should be left out. To find out about those templates, one should ask the user whether the information is relevant and whether the template would be completed.

As a preparation to the following steps, "Relate Templates" and "Add Metadata to Templates," the templates should be arranged into main categories according to their purpose. In RISE, we found the following categories helpful:

- **Context templates** like project and homepage of employees (people) based on O4PKC.
- **Navigation templates** like overviews about certain types of documents for specific reader groups.
- **Core templates** that define the structure of SE artifacts (cf. 0) directly related to software engineering activities (in the example, requirements engineering documents).

Finally, in order to test the templates, one should try to map some of the available information in the organization to the developed templates. This test might indicate hints that some of the information required by the templates is not available within the organization.

Add Metadata to Templates

After the templates and their contents are identified, they are annotated with metadata to support filtering and finding of relevant documents. To test

which set of metadata is suitable, one should test it with a template. To identify relevant metadata, the following sources should be considered:

- **General standards:** Domain-independent, standardized metadata-sets like Dublin Core and Learning Object Standards (e.g., LOM) provide general-purpose metadata. This allows other applications that rely on these standards to reuse the content of a Riki.
- **Template-specific metadata:** Some templates derived from existing standards and documents might already contain a set of specific metadata to classify their content. Furthermore, similar templates that are on different sections of the outline of the document are candidates for identifing metadata. One example is the description of stakeholders and users in the Volere Requirement Template (Robertson & Robertson, 2005b), which has a similar structure.
- **Method-specific metadata:** Some metadata might not be directly related to a template, but to the underlying method. Using this metadata allows providing method-specific support in the form of know-how documents. An example from RISE is the TORE method (Paech & Kohler, 2003), which classifies requirements engineering documents (e.g., as description of the current state "As Is" and the system to be developed "to Be").

For adding metadata in general, remember the following guidelines: *Automatically derivable metadata* (like the author's name) can be added without further consideration. *Manually entered metadata* should only be considered if it is of direct benefit to the person who will enter it. In our experience, it is no sufficient benefit that the author is able to find this document based on the metadata entered: This search will be performed in later stages of the project. Therefore, improving the searchability of the document does not provide any direct benefit. An example of metadata with direct use is the use case classification, which can be used to generate overviews. Whether this direct use is actually taking place should be checked in the task "Identify view and consistency checks."

Relate Templates

The tasks before focused on identifying and creating single documents that have a high internal coherence. In this task, these templates are linked in order to define their semantical relations, which are later used by a Riki to identify relevant documents.

In the work, several general types of relations are identified that form the foundation for defining the relations within RISE:

- **Inheritance/Subclass:** This relation denotes that one subconcept (template) inherits the properties (in RODent, the metadata) of a super-concept (a generalized template).
- **Instantiation:** This relation denotes that an object (in Riki: a document) belongs to a certain class (in Riki: a template) and thus, inherits the properties of this class.
- **Part-of/composition:** This relation denotes that an object derived from a concept is supposed to be part of another object.
- **Temporal:** This relation denotes that there is a relation within time between one concept to another concept. For example, it is a temporal relation that one object is created before another one.

Within RODent, those general relations are refined further according to their interrelations between templates and their documents. The actual use of these relations for reasoning is described in the task "identify views and relations":

- **Hierarchy** among documents of the same templates (part-of type): Instances of templates might have a hierarchical relation. For

example, one use case might have several subuse cases. It might be necessary to distinguish between different types of hierarchies for documents derived from one template: However, in RISE, we found one hierarchy to be sufficient.

- **Used in** (part-of type): This relation describes a "strong" relation between documents of different templates: If the content of a document is needed to understand another document. For example, the description of an Actor is part of the description of a use case. Without knowing the description of the Actor, the use case is not sufficiently understandable.
- **Refined in** (temporal): Refined in defines a temporal relation between documents. For example, a user story (a prose text of a certain requirement) is refined in a use case (a more structured representation).
- **Of Interest** (part-of type): This relation is used for weak relations between documents of different templates, that is, where information relevant to one document can be found in another one.
- **Context definition** (inheritance type, relation between context documents and other documents): This relation is used when additional context of a document is defined in another document. For example, the project context (like size, programming language) of a use case is defined in the project homepage. Simplified, when such a relation is established, the referencing document "inherits" the metadata of the document (in this case, the metadata about the project).
- **IsA** (inheritance type, between templates and documents): The IsA relation is reserved for denoting the relation between a template and an instance of this template.

Determine Relation Requirements and Default Relations

In the previous task, (relevant) potential relations between documents have been identified. In this task, those relations are annotated to define requirements concerning the relation itself. These relation requirements are used in the subsequent task to derive views and consistency checks. In addition to these additional relation requirements, a default relation between documents derived from a certain template is defined.

The additional requirements define the nature of a relation between templates and thus, the nature of the link between documents derived from those templates that have this relation. In other words, they define the nature of a link between the source document (i.e., where the link is defined) and the target document (where the links points to). In RISE, the following additional requirements concerning relations were identified:

- "*Required*," "*recommended*," "*optional*," and "*not allowed*" denotes the degree to which a link is supposed to be established between documents.
- "*Unique*" and "*multiple*" denotes the cardinality of the relation, that is, the source document can have only one relation to a target document, or it may have multiple relations.

Based on this overview of relations between these templates, the default relation —that is, the one used most often—is determined. For example, the default relation between use cases and actors is Used In. As long as no other relation is stated, a Riki assumes that the link between those documents is the default relation. Therefore, a Riki must state less explicit information about

Table 1. Ontology elements

Ontology element / structure	Views	Consistency Check
Metadata	Present metadata annotations	n/a
Inheritance	n/a	Is there a cyclic relation among subclasses?
Instantiation (IsA)	Show all documents belonging to a template	Does a template have documents? Does each document belong to a template?
Part-of	Show documents that are the target of a part-of relation	Are there cyclic relations among documents derived from templates that have a part-of relation (i.e., is the "higher" document part-of of a "lower" document")?
Temporal relationship	Show timeline of creation of documents	Does the document derived from the source template have an earlier editing date than the target document?
Quality of relation (i.e., required and not allowed)	Show documents derived from templates that are the target of the required relation.	Are all required or not allowed relations satisfied?
Cardinality of relations	n/a	Are cardinality constraints violated?

the type of the link. In addition, a user not aware of the additional Riki features can use a Riki like any other Wiki system.

Identify Views and Consistency Checks

In the previous steps, the templates, their metadata, and relations were defined. In the task "Identify views and consistency checks," the actual use of these results is determined. In particular, the definition of views and consistency checks is based on the general types of relations and the additional requirements presented in the previous two tasks. For metadata, relation type and additional potential requirement views and consistency checks are presented in Table 1.

Technology Deployment

The task "technology deployment" covers how the templates, metadata, and their relations are implemented within Riki. The task itself is subdivided into two sequentially performed subtasks: 1) Deployment of templates, metadata, and ontology upon distinct Wikis (if any) and 2) the deployment of ontology concepts on native Wiki syntax, that is, how parts of the metadata and relations are expressed by using naming conventions.

The *deployment on different Wikis* is trivial if only one Wiki is used. However, based on the experience from RISE, it is sensible to use, at least in larger organizations, one Wiki for each group (in particular, projects) and one main Wiki for the whole organization. This separation between different Wikis has several advantages independent of whether or not Riki is used: First, it reduces the complexity of access right administration by dividing it into several sub-Wikis. Second, the possibility of name collision is lowered. An example of such a naming collision would be if two projects using the same Wiki have a meeting on the same day. If both want to use "meeting<date>" as the name for the document containing the meeting minutes, a name collision occurs. Furthermore,

if there is no syntactical collision (i.e., the same name), a semantic collision might happen: Members of one project might link to the entry of the other project because they cannot differentiate between the two documents (e.g., "meeting<date>" and "<date>meeting"). Second, it is more likely that the group responsible for a Wiki accepts it as "their" Wiki. The separation into several Wikis also has an advantage for Riki: Since each group owns "their" Wiki, contextual information about this group can be derived. An example is project Wikis, where context information about the project could be derived from the metadata defined on the project homepage.

The *deployment on native Wiki syntax* is partially based on the deployment on several Wikis. By using the interwiki feature, the context of a document can be derived even if referred from a different Wiki. Another example for deployment of parts of the ontology into native Wiki concepts is the instantiation (IsA) relation. Within Riki, we had the following naming convention to denote this relation without the need to explicitly create a link: The instances of a template have the name of the template as prefix. For instance, documents of the type "Actor" are named "Actor_<NameOfActor>."

When an ontology developed using RODent is finished, it should contain the relevant information to execute the software engineering activities it is intended for. How it is actually used and gradually enriched with experience and further information on how to perform software engineering tasks is covered by the learning spaces described in the following section. These are an unintrusive approach for providing the procedural knowledge needed to perform a certain task.

Riki Learning Space Development

In many publications about learning objects, terminological issues are discussed, because there is a lack of solid theoretical foundation in the field of e-learning (Self, 1992), especially concerning learning objects. It seems that the main reason why learning objects have been invented is reuse and the desire for more flexible, adaptive learning systems. Current development efforts with learning objects are mainly concerned with metadata and content packaging aspects. Current object metadata says little about how to combine learning objects with others, and this will limit the success of the numerous repositories of learning objects that are being developed. Nevertheless, a model such as the SCORM *Sequencing and Navigation* is a first step towards a more systematic way for defining the sequencing of learning content and navigating through it.

Sometimes, learning objects are put into relation to object-oriented programming objects. The term "object" is somehow misleading. Some authors toss around theoretical connections to object-oriented theory that stem from computer science. One reason why many of us attempt to connect learning objects to code objects is that there is a grammatical affinity between "object" as used in "learning object" and object-oriented programming theory. It is not wrong to refer to concepts from object-oriented theory in order to increase our understanding of learning objects and our belief in successful reuse. Friesen states that there is not only a conceptual confusion in the literature between software objects and learning objects, it also seems that object-orientated programming objects and learning objects do not fit together at all (Friesen, 2001).

Therefore, we will use the term *learning component* instead of learning object. They should be considered as components instead of objects because their characteristics are similar to software components. A software component is a "unit of composition with contractually specified interfaces and explicit context dependencies only. A software component can be deployed independently and is subject to composition of third parties" (Szyperski & Pfister, 1997). Component-based software development is based on the principles of "separation of concerns" in order to

Figure 8. Development Dimension of Learning Space Engineering

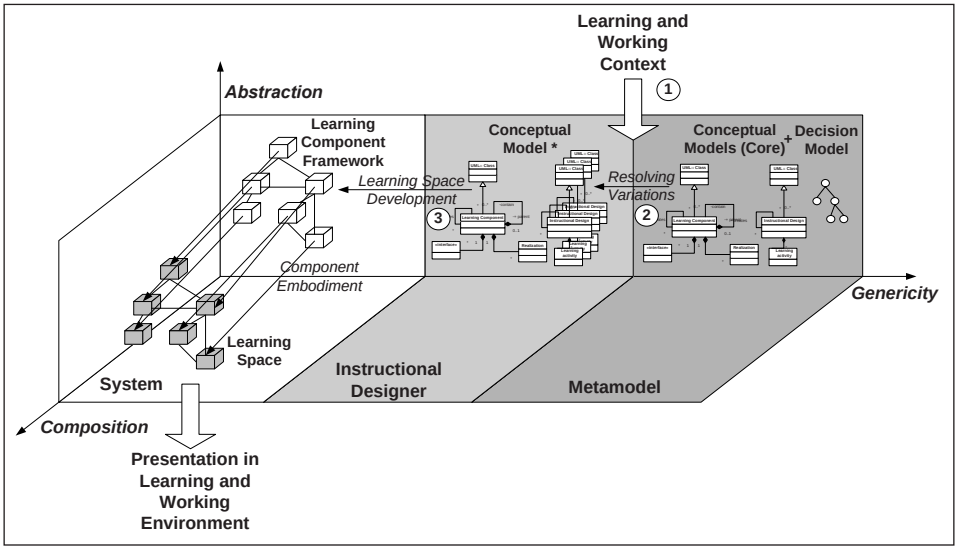


Figure 9. Details of an embodied learning space

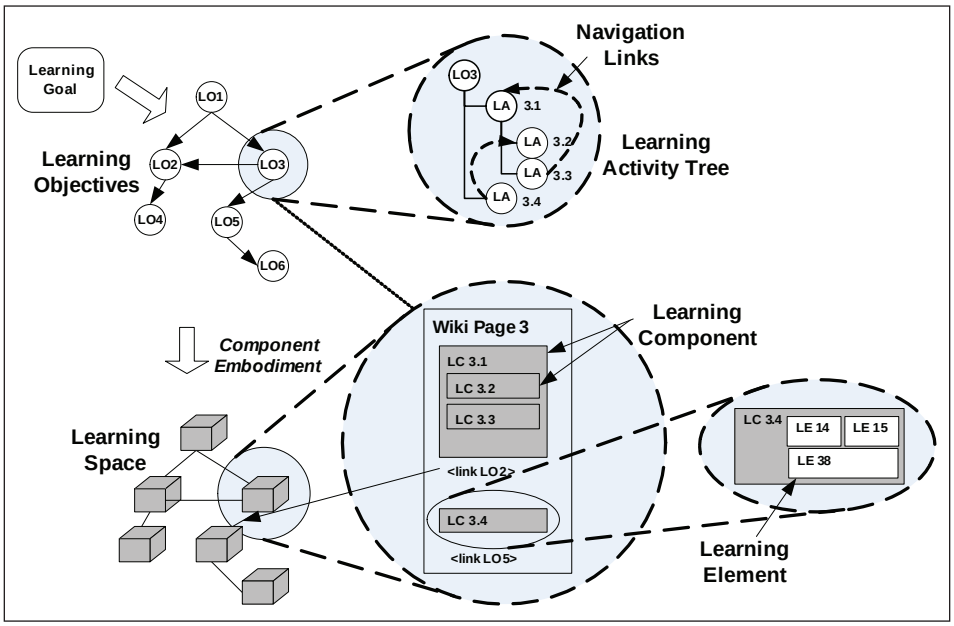

decrease the complexity of system design and its latter embodiment with components. Therefore, a set of formal description models for components, their interfaces, and context dependencies are defined in a metamodel in order to develop components from an abstract, generic, and coarse-grained view of a conceptual component model into concrete, specific, and fine-grained learning material. This material is composed of learning components that can be integrated into a learning space (see Figure 9).

In order to develop learning spaces (see *Representation of Knowledge in Wiki Systems* for the definition of concepts used in these sections), the following three phases can be identified (see numbering in Figure 8):

- During the *learning space analysis* phase, the results of the context evaluation are analyzed. The main goals are to find out what types of content are available and useful for developing appropriate learning spaces, how learning needs can be identified based on analyzing the produced software artifacts, and in which way learning spaces can be connected to the working environment.
- During the *learning space design* phase, the analysis results are used to describe the learning space from a conceptual point of view. This means that appropriate learning methods, learning goals, and a content classification have to be chosen. Based on this information, the metamodels of the learning components and the instructional design are adapted to the current learning context.
- During the *learning space development* phase, the physical learning space is created to be explored by the learner by transforming, in a first step, the metamodels into a framework with "empty" placeholders for learning components and learning elements (see *Representation of Knowledge in Wiki Systems* for the definition of these concepts). The automatic embodiment replaces the placeholders within the framework with concrete learning components and elements, that is, Wiki pages with appropriate links and navigation structures are created during run-time.

The subsequent sections explain the three phases, which have to be performed for setting up a learning space, in more detail. Each phase is described with a few main questions that cover the goal of that phase and end with a concrete example.

Learning Space Analysis

This phase can be motivated around the following four questions:

- What is the most relevant domain for improving task performance and competence development, and which target group do we address?
- What type of knowledge that is suitable for learning is available or created by the software engineers during work?
- Where are the triggers for learning space creation and how can a learning space be related to the working context?
- Which software artifacts could be used to identify (e.g., automatically) competence and skill gaps to be solved by a learning space/learning arrangement?

In general, learning spaces can have two different purposes. First, a learning space can improve short-term task performance, that is, by providing solutions in order to solve problems more efficiently, or by offering different methods or tools that enhance a specific well-known task. The domain under consideration is very narrow. Second, long-term competence development involves an analysis of a much broader domain software engineers are working in. Here, we would like to find our competence gaps that cover perhaps more than one software development phase, such as general software engineering principles or completely new technologies or development approaches.

Usually, a software project covers the whole development cycle from requirements elicitation to programming, testing, and delivery of the software to the customer. The aim of the Riki methodology is not only to address the whole development

Table 2. Overview of educational goals and associated learning element types

Knowledge Type	**Knowledge Dimension**	The Cognitive Process Dimension (Learning Objectives)						Learning Element Types

process, but to focus on very specific tasks first and to extend the scope of the Riki later. This has the advantage that early successes on important and difficult tasks, in terms of better task performance and competence development, can be used to extend the system's scope. This step is called *domain scoping*, and will also influence the development of the domain ontology. We found out that, especially during the requirements and programming phase, suitable tasks can be found to get the system started. The information that is necessary to choose such tasks was gathered through personal interviews, by analyzing content available in knowledge repositories, and by looking at artifacts produced, such as code or software documentation. In addition, a rough process model and a role model are derived in order to relate the learning space to the well-known processes and roles. It is essential to ask software engineers what kind of problems bother them the most, and which tools, methods, and techniques they apply to create software artifacts.

During the context evaluation, available content was already analyzed and software engineering challenges were identified. In this phase, we check especially if this knowledge could be used for learning components and learning elements. The content is classified according to the knowledge dimensions and types (see Table 2 for details). Furthermore, metadata and granularity (i.e., size) are investigated in order to make first decisions about metadata extensions, respectively adaptations, to the metamodel of learning content. The idea is not to change existing policies and rules for content authoring. Learning spaces, and hence the learning components, should be adapted to the existing situation and content within the organization.

Another important issue is to find out which situations trigger a learning need. The generation of a leaning space is demand-driven, that is, learning spaces are created based on a trigger. We distinguish between two types of triggers. The human-based trigger is created by the software engineer himself, for example, by searching for specific information, documented experience, or solutions. These search results could be embedded in a learning space. The system-based trigger is

related to an internal system event, for example, the technical software development environment analyzes a code artifact and finds a defect, which leads to a learning space where the engineer could learn how to remove this defect. Human triggers can be found by interviewing the engineers. System triggers have to be defined by Riki experts. Those triggers strongly depend on the capability of analyzing produced software artifacts such as code or other formally described documents. Based on those findings, appropriate learning spaces could be created in order to improve the quality of those artifacts or their development process.

The last aspect in this phase is to relate learning spaces directly to the working context. Since the learning space should be delivered as close to the work place as possible, connection points have to be found. In the domain where Riki can be implemented, those points are usually located within the technical development environment (e.g., Eclipse IDE) or within the knowledge management environment.

Learning Space Design

After finding out what domains are the most promising for learning (i.e., both long-term as well as short-term learning), and what kind of artifacts could be used to identify skill and competence gaps, this phase defines learning goals and appropriate methods to be applied for the learning space development in the last phase. This phase can be motivated around the following four questions:

- What kind of learning goals could be defined and how are they related to the knowledge dimensions/types and learning content?
- What are appropriate learning methods for the identified learning needs, triggers, and competence levels?
- How is the domain ontology used or adapted to meet the domain context and requirements for creating learning spaces?
- How is the instructional designer supported in adapting the core metamodels to the requirements for creating learning spaces?

Our learning spaces follow the constructivist learning theory and are related to the current working situation as closely as possible. Before we provide answers to these questions, we would like to say some words about learning theories and learning approaches that are suitable for the software engineering context.

First, following the constructivist learning theory, learning can be seen as a self-directed process where the focus lies on opening up information and on constructing individual knowledge, for example, (Bruner, 1973). Constructive learning theories criticize former learning methods for ignoring almost completely the transfer of lessons learned to new situations in practice, that is, knowledge remained in a latent condition and was not applicable.

Second, situated learning approaches developed mainly at the end of the 1980s emphasize that a human's tasks always depend on the situation they are performed in, that is, they are influenced by the characteristics and relationships of the context (Brown, Collins, & Duguid, 1989). Because of the relation between cognition and context, knowledge and the cognitive activities meant to create, adapt, and restructure the knowledge cannot be seen as isolated psychological products: they all depend on the situation in which they take place. Learning involves interpreting individual situations in the world based on one's own subjective experience structures. Learners have an active role and derive most of the knowledge from real situations by themselves, and this knowledge is afterwards integrated into their own knowledge structures. Learning and applying the lessons taught should happen in a situated context, that is, during the development of software artifacts.

Third, research in cognitive psychology has shown that students learn better when in-

volved in solving problems. Collins' Cognitive Apprenticeship (Collins, Brown, & Newman, 1989), Schank's Goal Based Scenarios (Schank, Bermann, & Macperson, 1999), and the 4 Component Instructional Design (4C/ID) Model of Merriënboer (Merriënboer, 1997) are just three of the instructional models that address problem-based learning. Merrill proposed the *First Principles of Instruction*: Learning is facilitated when previous experience is *activated*, when the lessons learned are *demonstrated* to the learners instead of just being presented to them, when the learners are required to *apply* their knowledge or skill to solve a problem, and when the learners are motivated to *integrate* the new knowledge or skill into their daily work (Merrill, 2000).

In fact, instructional design could be handled in two obvious places: embedded within a learning component or as a separate object (e.g., by using specifications such as SCORM Sequencing and Navigation or IMS Learning Design). Riki handles the pedagogical rules of instructional design *outside* of the learning components in a metamodel for instructional design. By applying those didactical rules to this metadata, adequate learning spaces can be created that fit the current situation of the user.

Based on the identified triggers, appropriate learning methods are chosen. In the domain of software engineering, problem-based learning methods, as listed previously, and experiential learning (i.e., compared to experience-based learning, experiential learning integrates elements of reflection, support, and transfer) methods are a good starting set for creating learning spaces. The utilization of a knowledge management system is usually problem-driven, that is, a problem arising during the completion of a software engineering task motivates the software developer to search for suitable information or even complete solutions in the repository. When reusing an experience, a developer is usually engaged in active problem solving while reading, understanding, abstracting, or instantiating the experience, and trying to apply the gathered knowledge to the real problem situation. Ideally, software engineers could learn effectively from experiences when all four phases of Kolb's Experiential Learning Circle (Kolb, 1984) are passed: making a concrete experience, observing and reflecting about the occurrence, forming abstract concepts, and testing these concepts in new situations. When a software engineer documents an experience for later reuse (i.e., this is usually done by creating abstractions), he or she profits from being involved in the situation that leads to the experience, and his or her own observation and reflection about the happening. When a software engineer other than the experience's provider wants to reuse this documented experience, he or she will lack specific knowledge about the event that led to the experience, and the knowledge that results from observation and reflection. Hence, the learning space should focus on the delivery of appropriate content, in addition to the experience, in order to support knowledge construction as described in Kolb's learning cycle.

In addition to the triggers, the role and the competence level of the software developer plays a crucial role in how learning methods are implemented in a learning space. We follow a self-directed learning approach with a specific amount of guidance based on the capabilities of the learners, that is, learners proceed through the learning space at their own pace, and decide by themselves which learning components they want to access in which order. Nevertheless, when learning spaces are created, a certain amount of guidance and suitable content is provided to learners, depending on their competence level. Riki distinguishes between three competence levels: novice (knowledge dimension: declarative knowledge), practitioner (declarative and procedural knowledge), and expert (all kinds of knowledge).

Content for learning has been identified in the first phase, and domain-related basic software-engineering content that is not available has to

be added to the repository. This content is now classified according to learning element types. A basic set, as listed in Table 2, is used to categorize the learning content. The set is a mixture of different instructional designs as well as software engineering specific types. This set could be extended if necessary. Learning elements could not be related directly to the cognitive processes categories, respectively learning objectives, because many learning elements could be used in different cognitive processes such as "Example."

We refer to Bloom's taxonomy of educational goals (Bloom, Engelhart, Furst, Hill, & Krathwohl, 1956), which is widely accepted and applied in various topic areas including software engineering (Dupuis, Bourque, & Abran, 2003). In addition, we refer especially to the revision of the original taxonomy by Anderson and Krathwohl (2001), which is briefly explained next. The new taxonomy can be explained by two dimensions: the knowledge and the cognitive processes dimension. Our work is based on a similar knowledge dimension as the one in this taxonomy. Regarding the cognitive process dimension, Anderson and Krathwohl distinguish between six different categories:

- **Remembering** is to promote the retention of the presented material, that is, the learner is able to retrieve relevant knowledge from long-term memory. The associated cognitive processes are *recognizing* and *recalling.*
- **Understanding** is the first level to promote transfer, that is, the learner is able to construct meaning from instructional messages. He/she builds a connection between the "new" knowledge to be gained and prior knowledge. Conceptual knowledge provides the basis for understanding. The associated cognitive processes are *interpreting, exemplifying, classifying, summarizing, inferring, comparing,* and *explaining.*
- **Applying** also promotes transfer and means carrying out or using a procedure in a given situation to perform exercises or solve problems. An exercise can be done by using a well-known procedure that the learner has developed a fairly routinized approach to. A problem is a task for which the learner must locate a procedure to solve the problem. Applying is closely related to procedural knowledge. The associated cognitive processes are *executing* and *implementing.*
- **Analyzing** also promotes transfer, and means breaking material into its constituent parts and determining how the parts are related to one another, as well as to an overall structure or purpose. Analyzing could be considered as an extension of Understanding and a prelude to Evaluating and Creating. The associated cognitive processes are *differentiating, organizing,* and *attributing.*
- **Evaluating** also promotes transfer and means making judgments based on criteria and/or standards. The criteria used are mostly quality, effectiveness, efficiency, and consistency. The associated cognitive processes are *checking* and *critiquing.*
- **Creating** also promotes transfer and is putting elements together to form a coherent whole or to make a product. Learners are involved in making a new product by mentally reorganizing some elements or parts into a pattern or structure not clearly presented before. The associated cognitive processes are *generating, planning,* and *producing.*

Riki addresses all the categories of these dimensions, with the focus being on the first three categories, because these are important for reaching the upper levels and can be taught directly, while the fourth to sixth levels require a longer term and deeper understanding of a subject matter.

Common instructional design theories often speak of the following elements in the design of instruction: generalities, examples, explanations,

practice items, test items, overviews, advance organizers, and analogies, among others (Yacci, 1999). Table 2 shows the educational goals and the related learning component types that were selected as a first set for a Riki in the domain of software engineering.

Although a lot of effort has been put into the definition of standards, and although the LOM standard seems to be widely accepted by now, "key issues related to global content classification such as a common schema, ontology, granularity, taxonomy and semantics of learning objects which are critical to the design and implementation of learning objects remain unsolved" (Mohan & Daniel, 2004). Hence, one of the key issues of this phase is to adapt the domain ontology in order to describe the semantics of learning components/elements and their relations, and to find a common vocabulary for describing learning components/elements.

The resulting ontology created by RODent covers the domain that was identified in the analysis phase. Learning spaces tie into this ontology. After defining the types of learning components, each learning component/element has to be related to the concepts of this ontology. This means that the ontology concepts are used for describing the learning components/elements with metadata. Riki will use LOM as metadata description. The suggested LOM vocabularies are adapted to the types of Table 2 (right column) in order to specify the value range of the LOM attributes.

The most complex task in this phase is the adaptation of both metamodels to the working and learning context where the Riki should be implemented. There exists one learning component core metamodel for defining the learning component and its composition of learning elements on a conceptual level, and one core metamodel for instructional design applied to this domain. The adapted metamodels are used to produce a learning space framework (i.e., a concrete implementation framework to create learning spaces). The types and relations between learning components (i.e., according to the relations defined by RODent) are explicitly modeled in the metamodels. The conceptual model covers aspects, such as the specification of metadata (i.e., by using LOM), containment rules that specify the parent-child relationships between learning components/elements within a containment tree (e.g., for modeling the location of learning components), specialization rules that define the types of learning components and their specialization (e.g., definitions-, examples-, table of content-, overview-, and summary-components). Furthermore, this model could contain elements that specify the kind of interaction between the system and the user, and adaptation rules for adapting the learning components to learner types or context aspects. These rules are very similar to the contracts used as specifications for interfaces. Beside the conceptual core model for instructional design that is based on learning objectives with related learning activities (see Table 2 right section), a decision model exists that enables the instructional designer to adapt the model. The decision model contains so-called variation points, their resolution space, and their effects on the conceptual model. The variation points mark variable parts of the model that are resolved by questions. The instructional designer uses these questions in order to change the conceptual model in a systematic way. The questions refer to the categorization of learning components (i.e., the instructional designer adapts the categories or the specialization structure), instructional design strategies (i.e., the instructional designer adapts the containment rules, for example, to an *experiential learning* strategy), or the questions consider adaptation aspects (i.e., the instructional designer changes the variable parts of the logical learning component such as their composition of learning elements, see Table 2, middle section). The answers to the questions include solution packages, so that the instructional designer gets support on how to adapt the model. One possibility for defining such solution packages is to use design patterns. They are very useful

for describing instructional design strategies in a comprehensive manner. A design pattern can be understood as a transformation process from one conceptual model state to a new state. Each transformation step relates to specific parts of the model and tells the instructional designer how to change those parts.

Based on these models, frameworks can be derived that can be used for creating learning spaces. The next section describes how a pedagogical agent creates learning spaces.

Learning Space Development

After the selecting of learning goals and appropriate methods as well as the generation of the metamodels, this section explains how a learning space could be created based on a framework from the metamodels.

This last phase can be motivated around the following four questions:

- How can a framework be built from the adapted metamodels in order to develop learning spaces?
- How can this framework be embodied with learning components and elements?
- How can the learning space be presented by means of Wiki pages?
- How can sequencing of learning activities and navigation through a learning space be realized?

Before we answer those questions, a small excursus about pedagogical agents is given. A learning space is created automatically by a so-called pedagogical information agent. Information agents are a special kind of intelligent software agents (Wooldridge & Jennings, 1995). Software agent technology itself originates from distributed artificial intelligence. Software agents have access to multiple, heterogeneous, and geographically distributed information sources. Klusch provides an overview of information agents and describes their main tasks as performing proactive searches, as well as maintaining and communicating relevant information on behalf of their users or other agents. This includes skills such as retrieving, analyzing, manipulating, and fusing heterogeneous information, as well as visualizing and guiding the user through the available individual space (Klusch, 2001).

The pedagogical agent is a special type of information agent: it puts its emphasis especially on the mediation of information by taking into account learner profiles' learning preferences, such as preferred learning styles, presentation modes, and so forth, and creates their learning space based on the metamodel. The difference, as compared to instructional tutoring systems (ITS), lies in the fact that agents react proactively and take into account the current environment the learner is working in, instead of simply analyzing the current status of the learner's knowledge as ITS do. In our approach, a task agent observes specific software engineering tasks that are suitable for monitoring. For example, the activity of programming in an integrated development environment, such as the *Eclipse IDE,* can be monitored. Once a trigger condition, as specified in the design phase, has been observed, the task agent sends a notification message to the pedagogical information agent that has registered interest in the occurrence of particular triggers during the monitored task.

For each instructional design metamodel, a framework is derived that is consistent with the metamodel for learning components, which was developed in the previous phase. An instructional design refines a learning goal into several objectives (see values in the cells of Table 2). Each learning objective refers to a cognitive process (e.g., remember the task of refactoring). As illustrated in Figure 9, arrows between the learning objectives show how the learning objectives should be sequenced in a learning space. The difference between a learning goal and a learning objective is that usually, learning goals are broad, often im-

precise statements of what learners will be able to do when they have completed the learning space. Learning objectives are more specific, have a finer granularity, and are measurable by performing assessments (i.e., through tests, questionnaires). The learning objective network is transformed into the learning component framework. The next step is the embodiment of this framework by learning components and elements.

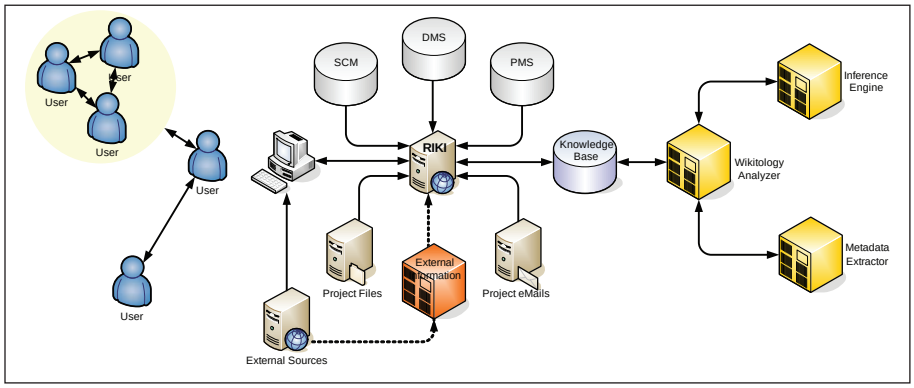
Before the embodiment can take place, each learning object is refined in a learning activity tree (i.e., similar to the SCORM activity tree that could be derived from the SCORM content packages). The tree serves as a help structure for navigation. Each activity tree consists of learning activities that enable the learner to reach the related learning objective (e.g., reading, thinking about a question posed, removing a real code defect). In contrast to the learning objective network, this structure can only be created during run-time, that is, after a notification message has been sent to the pedagogical agent. This structure depends on the following factors: the learning objective, the addressed domain and topic, the available content, and the context. A default structure for each learning objective/topic category pair is defined in the instructional design metamodel. The two latter factors influence the adaptation of these structures during run-time, for example, learning activities have to be abandoned if suitable content is not available, or if the context allows transferring learning activities directly into the working environment instead of keeping it within the learning space environment. The embodiment creates learning components from learning elements by using the domain ontology. Afterwards, each learning activity of the activity tree is extended with a reference to learning components created.

The learning components are presented to the learner by means of Wiki pages. Wiki pages are used within Riki because of their advantages of relating pages; other technologies could also be used instead of Wiki pages. Each learning objective represents one Wiki page, respectively one learning activity tree. They are shown by sections and paragraphs using the Wiki syntax. The difference to a standard Wiki page is that only parts of the Wiki page can be changed by the learner. These parts usually consist of specific knowledge, such as project, customer, people, or product knowledge (see Figure 2 for the knowledge types), or assessment parts (e.g., answering questions etc.). General learning content cannot be changed (e.g., the definition of "Software Quality" or explanation of "Polymorphism"). Only one Wiki page is generated by the agent at a time. The activity tree sometimes offers alternative navigation options to proceed to the next learning objective, respectively to another Wiki page (see link of *LO3* Figure 9). When such a link is chosen, the agent creates the corresponding Wiki page by first resolving the references to learning components and second, by generating navigation options by means of links within the Wiki page or external navigation portlets on the Web site.

By default, sequencing of learning activities on a Wiki page is done hierarchically (see top of Figure 9). Beside the navigation options between learning objectives, additional navigation options could also be offered within the same Wiki page, that is, between learning components. Within the SCORM Sequencing and Navigation model, navigation requests are processed based on a kind of learner model, that is, data about, for example, answered multiple-choice questions that are stored. This data influences which navigation options are available, or whether they are not. In the Riki context, assessments play a minor role. Only data from the software development task and changing learner preferences will be used to adapt the navigation options.

In summary, a learning space consists of several Wiki pages with links forming a hypermedia network. Agent technology allows us to adapt the learning space dynamically during run-time, for example, while the user is browsing through the space and working on his task. Important triggers

Figure 10. Infrastructure around a Riki system



are forwarded by the task agent to the pedagogical information agent, who adapts the content selecting, sequencing, and navigation of the learning space. Observing certain tasks performed by a software engineer and the demand-driven creation of learning spaces ensures close integration of the learning process and the working task, and enables the provision of a situated learning environment for the user where he/she can construct his/her individual knowledge.

Riki: The Reuse-Oriented Wiki

In RISE, we developed a platform and a methodology for the management of experiences in SE organizations, which is integrated smoothly into the infrastructure. In this section, we will elaborate the architecture and technology of a plugin-based, reuse-oriented Wiki (Riki). This technical system sets the stage for the knowledge-based development of software systems strengthened via the support of social relationships, as well as competence development, and knowledge sharing in and between projects. As depicted in Figure 10, three domains or spaces are connected to the core system.

The social-technical system of RISE into which the Riki is embedded consists of the *social space* on the left side, the *technical space* symbolized in the middle, and the *logical space* on the right. The social space encompasses all users of the Riki from the target group(s). They are all accessible via the personal pages and references such as (co-) author or inspector (i.e., know-who entries). In the technical space, all hard- and software systems are collected. The Riki is statically or dynamically (i.e., online) integrated into the existing infrastructure and previously collected information. The integration of information includes internal sources such as software configuration management (SCM) systems, defect management systems (DMS), project management systems (PMS), as well as project files and e-mail messages. For example, SCM systems can be used to extract information about persons who have changed the source code over the different configurations. If a newbie (at least for this part of the system) needs more information about this subsystem, the newbie can directly access these persons and knowledge about it. Furthermore, information from external sources, such as technology specific mailing groups or search engines such as Google, are dynamically integrated.

The Riki Architecture

The general plugin concept of the RISE system is a service that is invoked via the Web service interface. The Web service approach was chosen to provide the added functionality independent of the actual implementation. The result of the Web service request is delivered text or simple html. The result is then integrated into the GUI via a content plugin, the templating mechanism of the Wiki, or as a pop-up window.

The RISE system has three different types of plugins that are differentiated based on their integration: Plugins that change the workflow of the underlying Wiki, plugins whose results are integrated into a single point on the GUI, and plugins whose results are integrated into the content.

This integration is supported by plugin interfaces that are already provided by some Wikis: First, Wikis might offer a plugin interface to add dynamic content to pages. The RISE system uses this interface by implementing a general plugin to request Web services and to present the result. Second, Wikis might provide an XML-RPC interface to read and write content of a page. The RISE system uses this interface to standardize the access to Wiki content independent of the actual Wiki used.

The basic knowledge flow of the Riki is shown in Figure 11. It depicts the *elicitation subsystem*, where information from the community of users (or experts) is injected into the system as a first pool of knowledge in the knowledge base. This knowledge as well as the created ontology and approach for creating learning space are used in the *augmentation subsystem* to construct the learning spaces and augmented knowledge (e.g., a knowledge component about a project with context-specific information such as similar projects) that are presented to the user. The *integration subsystem* provides additional knowledge and information from the existing infrastructure.

RISE IN RETROSPECTIVE

In this section, we will raise requirements and lessons learned from the development and application of a Riki in the context of two SMEs that one should keep in mind when building such a system.

Lessons Learned and Implications for Developing a Riki

During the RISE project, while building two KM systems for SMEs in the software industry, we developed the Riki technology and RIME methodology. From the development and evaluation, we extracted several lessons learned that are stated in the following:

- The KM system should be *tailored* to the characteristics and needs of the organization, its projects, and the target group(s). The process where knowledge is generated, how it is recorded, and who reuses it should be considered. In a medium to large organization (i.e., more than 100 persons), the knowledge should be far more general and self-sufficient than in a small organization (e.g., with five persons). The larger the organization, the more probable it is that the knowledge is used by persons with a totally different context, from another culture, or without the opportunity to ask the author.
- The KM system should be *integrated* into the existing tool landscape and socio-technical infrastructure of the organization. It should represent either integrated relevant information from other systems as a single point of consistent knowledge (SPOCK) or offer links to these other systems. Yet, another system that is used to store information will only be used at the start and then vanish over time as nobody cares to store information in multiple systems.
- The knowledge within the knowledge base should be *goal-oriented*. The author should have a clear organizational, project-specific, or personal goal in mind and identify the problem, potential solutions, and side effects. A simple observational experience that does not inform the reader about a specific problem or solution is of low interest and use in a KM system.
- The knowledge within the knowledge base should allow *individual structuring* by the users. Everybody structures his knowledge individually based on his personal worldview (in German, *weltbild*), which needs to be mapped to the general ontology as implemented in the KM system. This can be realized either by giving all the rights to insert personal links or by mapping between personal, project-specific, departmental, organizational, or community-specific ontologies.
- The knowledge in a knowledge base should be versioned and managed using *authorized groups*. For example, knowledge about marketing processes should only be modifiable by marketing personnel, while knowledge about the interface of two departments (e.g., travel application) should be modifiable by all those involved.
- The plugin-based design and development of a KM system allows defining development tasks for separate subgroups of the project. This enables the independent implementation of functionality and improves the further extension of the system. In contrast to a monolithic system architecture, this furthermore allows the independent testing of plugins, thereby reducing development risks.
- By abstracting from the actual implementation and by implementing plugins independently from other plugins, this architecture allows using different configurations of

plugins for tailored KM systems. This is particularly important when functionality is provided by different partners that should work independently even after the project.

Patterns and Anti-Patterns in Knowledge Management

In the 1990s, a new concept was transferred from architecture to computer science, which helped to represent typical and reoccurring patterns of good and bad software architectures. These design patterns (Gamma, Richard, Johnson, & Vlissides, 1994) and anti-patterns (Brown, Malveau, McCormick, & Mowbray, 1998) were the beginning of the description of many patterns in diverse software phases and products. Today, we have thousands of patterns (Rising, 2000) for topics such as agile software projects (Andrea, Meszaros, & Smith, 2002) or pedagogies (http://www.pedagogicalpatterns.org/) (Abreu, 1997; Fincher & Utting, 2002). Many other patterns are stored in pattern repositories such as the Portland pattern repository (PPR, 2005) or the Hillside pattern library (HPL, 2005), and are being continuously expanded via conferences such as PLOP (Pattern Languages of Programming; see http://hillside.net/conferences/).

While there are similar concepts such as barriers (Riege, 2005; Sun & Scott, 2005) and incentives (Ravindran & Sarkar, 2000) in KM and software reuse (Judicibus, 1996), the identification of patterns seems to be underdeveloped and informal.

We will use the concept of patterns and antipatterns to describe the experience and knowledge we acquired during RISE and several other projects, such as indiGo (Rech, Decker, althoff, Voss, Klotz, & Leopold, 2005), V(I)SEK (Feldmann & Pizka, 2003), or ESERNET (Jedlitschka & Ciolkowski, 2004). In software engineering, design patterns are defined as follows:

- **Design pattern:** A design pattern is a general, proven, and beneficial solution to a common, reoccurring problem in software design. Built upon similar experiences, they represent "best-practices" about how to structure or build a software architecture. An example is the façade pattern that recommends encapsulating a complex subsystem and only allows the connection via a single interface (or "façade") class. This enables the easy exchange and modification of the subsystem.

By transferring the concept of patterns to knowledge management, we therefore define knowledge and knowledge management patterns as follows:

- **Knowledge pattern:** A knowledge pattern is a general, proven, and beneficial solution to a common, reoccurring problem in knowledge design, that is, the structuring and composition of the knowledge (e.g., on or via Wiki pages) or the ontology defining metadata and potential relationships between knowledge components.
- **Knowledge management pattern:** A knowledge management pattern is a general, proven, and beneficial solution to a common, reoccurring problem in knowledge management, that is, the implementation, interconnection, or interface of technical knowledge management systems (e.g., a Wiki system), as well as social methods or systems to foster knowledge elicitation, exchange, or comprehension.

Furthermore, we cluster the patterns into six groups ranging from KM system (Wiki) patterns via content patterns to KM maintenance patterns. We describe several patterns and anti-patterns from three of these groups. In the following, the

Table 3. Knowledge Content Patterns and Anti-Patterns

Name	***Knowledge Blob Anti-Pattern***
Problem	The description of an experience or knowledge component get's larger and larger over time and subsumes more and more information. The search for an arbitrary knowledge component will often include the knowledge blob. The knowledge blob can be used for different problems, has multiple solutions or contact data.
Solution/Countermeasures	• **Compact knowledge:** Summarize and rewrite the knowledge in a shorter form on one page. • **Extract elements:** Apply divide & conquer to create several mutually exclusive pages with parts of the original page. • **Extract commonalities:** Find elements on other pages with overlapping knowledge and extract this overlapping element from both (or all) pages to a new page.
Causes/Consequences	The KM system makes it easy to find and change (extend) a knowledge component; the users are not sensitized to create individual experiences; or there is no maintenance of the knowledge in the KM system.

Name	***Redundant Information Anti-Pattern***
Problem	The description of an experience or knowledge component is too long and has information that is either not relevant to the topic, already stored elsewhere, or outdated. The reader has to read more to get little relevant information, which might lead to an abandoned system. Furthermore, the description is longer than one page in the KM system and requires that the user scrolls (and has to interrupt his learning mode).
Solution/Countermeasures	• **Compact knowledge:** Summarize and rewrite the knowledge in a shorter form on one page • **Offer templates:** Find all knowledge components of a specific type and offer a distinct template for every type.
Causes/Consequences	The writer does not really know what to describe in order to produce a simple, short and comprehensive knowledge component.

Name	***Unnecessary Breakdown Anti-Pattern***
Problem	Multiple pages are used to describe one topic that is not reusable for other knowledge descriptions, and all have to be read to understand the knowledge. The reader has to read several pages in order to understand the knowledge; he/she interrupts his/her learning mode and might interrupt the learning activity altogether. Furthermore, a search on the knowledge base might return only a page within this knowledge chain.
Solution/Countermeasures	• **Compact knowledge:** Summarize and rewrite the knowledge in a shorter form on one page. • See Explicit Start Pattern
Causes/Consequences	The writer does not really know what to describe in order to produce a simple, short and comprehensive knowledge component.

Table 4. Knowledge Maintenance Patterns and Anti-Patterns

Name	***Duplicated Knowledge Anti-Pattern***
Problem	Multiple versions of the same information reside in different locations in the knowledge base. The change of one piece of information causes changes to be made on several pages of different knowledge components. If not all replications are changed as well, multiple, slightly different versions might exist in the knowledge base.
Solution/Countermeasures	• **Compact knowledge:** Summarize and rewrite the knowledge in a shorter form on one page • **Extract commonalities:** Find elements on other pages with overlapping knowledge and extract this overlapping element from both (or all) pages to a new page.
Causes/Consequences	Writers are not aware of or do not care about similar knowledge. Furthermore, either the knowledge base is not cleaned up from time to time, or similar knowledge components are not aggregated.

Name	***Dead Knowledge Antipattern***
Problem	Knowledge is considered useless, is not reused anymore by the users, and wastes space in the knowledge base or computational power (e.g., in search algorithms).
Solution/Countermeasures	• **Fuse knowledge:** Find a similar and "nondead" knowledge component and integrate the remaining useful information (i.e., combine, compact, or rewrite their descriptions). • **Forget knowledge:** Remove the knowledge from the knowledge base (maybe after an inspection by possibly interested parties).
Causes/Consequences	The knowledge is outdated, too specific, or too general.

Name	***Undead Knowledge Antipattern***
Problem	Knowledge is not used anymore by the system and undiscoverable by the users. While it might be useful to the users it, cannot be reused anymore and wastes space or computational power (e.g., in search algorithms).
Solution/Countermeasures	• **Reintegrate knowledge:** Reintegrate the component in the search index or an applicable navigational structure. • **Fuse knowledge:** Find a similar and "non-dead" knowledge component and fuse them together (i.e., combine, compact, or rewrite their descriptions). • **Forget knowledge:** Remove the knowledge from the knowledge base (maybe after an inspection by possibly interested parties).
Causes/Consequences	The knowledge is not linked anymore and does not show up in any navigational structures or search results.

format to describe these patterns consists of the pattern name, the description of the problem, the solutions or countermeasures, and causes or consequences. While patterns typically state and emphasize a single solution to multiple problems, antipatterns typically state and emphasize a single problem to multiple solutions.

Knowledge Content Patterns and Anti-Patterns

These patterns and anti-patterns apply to the content of knowledge components or elements and are typically used from the viewpoint of the reader or writer.

See Table 3.

Knowledge Maintenance Patterns and Anti-Patterns

These patterns and anti-patterns apply to the maintenance of knowledge components or elements and are typically used by the knowledge maintainer or gardener.

See Table 4.

CONCLUSION

We have shown that reuse in software engineering needs support in order to work in agile software organizations. Poor documentation and management of knowledge, experiences, decisions, or architectural information accompanies the development of software with agile methods in distributed software organizations. The Wiki technology promises a lightweight solution to capture, organize, and distribute knowledge that emerges and is needed fast in agile software organizations.

The RISE framework sketches our approach for agile reuse and tackles several problems in traditional KM and agile software organizations. Semi-automatic indexing of pages improves the retrieval and enables the semi-automatic creation and evolution of ontologies from Wikis (i.e., Wikitologies). The cooperative adaptation of knowledge to community needs, and the didactic augmentation of the content and interface are targeted to improve the usability of lightweight KM applications in agile environments.

As a basis, we are using Wikis as repositories with fast and liberal access to deposit, mature, and reuse experiences made in agile projects. Our next step is the design and implementation of additional functionality to Wikis with a first version targeted for 2006. In the context of our project, we pursue the following research questions:

- **Are free structures of knowledge and hierarchies more accepted by the users than fixed structures?** A long-term goal would be the development of dynamic or individual structures based on personal arrangement of documents.
- **Does the extraction of information from existing sources (e.g., versioning, defect tracking, etc.) improve the integration and interrelation of knowledge?** This will improve the access to experts and knowledge carriers and will facilitate the build-up of goal-oriented face-to-face communication.
- **Does the didactical augmentation of knowledge improve the understandability and applicability of the knowledge, compared to conventional, non-enriched knowledge descriptions?** A long-term goal is to improve the mechanism for creating learning spaces by considering different instructional designs tailored to software engineers.
- **Is Wiki-based management of knowledge better accepted by the users than classical knowledge management applications in agile processes?** Classical knowledge management applications need a well-defined process to be integrated. Wikis—in particular, if enhanced by ontologies—might provide a solution for agile and hence, less-structured processes.

By using a plugin-based architecture, the Riki system represents a flexible and expandable infrastructure to support reuse in software organizations of different shapes and sizes. The main variability mechanism in this infrastructure is realized by using the plugins as independent services. Currently, this includes only functional aspects of the developed system, but we plan to adapt this idea to knowledge inside the Riki system to improve the reusability of knowledge across software development organizations. By bundling content and functionality, additional complexity is introduced concerning the variability mecha-

nisms needed to establish this product line. This interrelation between content and functionality is subject of the research area of knowledge product lines. The RISE project will provide a first step into this research area.

FUTURE TRENDS

This section discusses future and emerging trends and provides insights about the future of knowledge transfer and reuse in software engineering. A system for knowledge reuse and transfer, such as the Riki, might not only be used in software engineering but also in other domains.

- **OSS reuse—from code to content:** Currently, most of the reuse within OSS is focused on software code. However, with Wikipedia and WikiCommons, there is a growing amount of content (such as music, videos, or research results) available under an open-source-style license. This content will help to overcome the initial seeding problem observed in current reuse systems.
- **Bi-directional openness:** Through open standards and APIs (Web 2.0, Semantic Web), future reuse systems can rely on content and functionality already available to the public. For example, code search engines like Koders.com or Krugle.com can be integrated in reuse systems to provide reusable (code) artifacts from outside the organization.
- **Proactive suggesting instead of searching:** Future reuse systems will make even more use of the context of a user than depicted in Riki. Based on the metadata and their underlying ontologies, inference is done to support the user in generating more high-quality knowledge. In particular, showing similar and relevant content reduces redundancy because people are aware of available content and do not create the content from scratch. Hence, the content is subject to continuous evolution.
- **Amount of guidance during learning:** Riki provides a first significant step towards the integration of e-learning and knowledge management. Nevertheless, several problems remain to be solved and addressed. Riki intends for users to learn at their own pace, and decide which content is suitable. Self-directed learning requires that the system provides a certain amount of guidance and support during learning. For example, experts need a different kind and amount of guidance than novice people.
- **Support for situated learning:** These approaches, developed mainly at the end of the 1980s, emphasize that a human's tasks always depend on the situation they are performed in, that is, they are influenced by the characteristics and relationships of the context (Brown et al., 1989). Because of the relation between cognition and context, knowledge and the cognitive activities meant to create, adapt, and restructure the knowledge cannot be seen as isolated psychological products; they all depend on the situation in which they take place. This means that the Riki has to gather more context information in order to tailor the learning space for situated learning.

Further barriers to integrating learning management and knowledge management were identified during the LOKMOL2005 workshop (Ras, Memmel, & Weibelzahl, 2005). Examples are the lack of interactivity, lack of dynamic adaptation of content, or adequate presentation of content.

To cope with these problems, we see the need for further research and development in the following directions:

- **Ontology usage and development:** The content of reuse systems needs to be indexed according to currently available ontologies

such as SWEBOK, Dublin Core, and FOAF, in order to make it available to inference support. This indexing should be done automatically wherever possible. Based on the experience gained during this indexing, the need for further software ontologies can be derived (e.g., an ontology of software engineering artifacts).

- **Integrated context models:** Besides indexing content according to ontologies, models for describing content information are another issue to be addressed further in the future. Based on context information, knowledge, and learning space can be tailored to the current situation. Different approaches in software engineering exist for describing domains and context. However, they mostly focus on one context dimension (e.g., organizational context, group context, activity context, project context, product context, individual or process context). Context models have to be developed that integrate the different dimensions in order to tailor the content delivery (e.g., by learning space) to the current situation and needs of the software engineer. Standards such as AttentionXML will play a bigger role in context description in the future (see http://developers.technorati.com/wiki/attentionxml).
- **Integrated user models:** In order to provide user tailored content, we need to know about the users' activities, their competence profiles, their learning and working preferences, their roles, and their relationships to other people and teams. The first challenge is to integrate this information in a standardized user model, and the second one is to investigate how this information can be gathered automatically during daily work.

ACKNOWLEDGMENT

Our work is part of the project RISE (Reuse in Software Engineering), funded by the German Ministry of Education and Science (BMBF) grant number 01ISC13D. We thank our colleagues Bertin Klein, Christian Höcht, Lars Kilian, Volker Haas, and Ralph Trapphöner as well as Prof. Klaus-Dieter Althoff, Dr. Markus Nick, Ludger van Elst, Heiko Maus, and Dr. Ingeborg Schüssler for their ideas during the first phases of the project.

APPENDIX I: INTERNET SESSION: KNOWLEDGE AND SOFTWARE REUSE

http://www.sei.cmu.edu/productlines/index.html
Software product lines are a way to describe commonalities and variabilities in a software system that are used in different contexts by different groups of people such as embedded software systems on mobile phones (each with different hardware characteristics and software features).

Interaction

Survey the information presented at the websites on product-line software engineering (PLSE) and software reuse methods and theory. Prepare a brief presentation on the core concepts and history of software reuse with a focus on PLSE. Alternatively, transfer the ideas behind PLSE to knowledge or learning management and assume that "software = knowledge" or "software = course". How would a "knowledge product line" or "course product line" look like? Are there commonalities or variabilites in KM/LM systems or the knowledge/courses itself?

Chapter 2.21
Constructivist Learning During Software Development

Václav Rajlich
Wayne State University, USA

Shaochun Xu
Laurentian University, Canada

ABSTRACT

This article explores the non-monotonic nature of the programmer learning that takes place during incremental program development. It uses a constructivist learning model that consists of four fundamental cognitive activities: absorption that adds new facts to the knowledge, denial that rejects facts that do not fit in, reorganization that reorganizes the knowledge, and expulsion that rejects obsolete knowledge. A case study of an incremental program development illustrates the application of the model and demonstrates that it can explain the learning process with episodes of both increase and decrease in the knowledge. Implications for the documentation systems are discussed in the conclusions.

INTRODUCTION

One of the puzzling issues of software engineering is the nature of the knowledge that is needed in order to develop and evolve a program. The program itself is a repository of knowledge about the program domain and may contain knowledge that is not available elsewhere, as documented by Kozaczynski and Wilde (1992). It also contains knowledge of all design decisions that were made during the program development and consequent program evolution (Rugaber, Ornburn, & LeBlanc, 1990). When evolving or maintaining the program, it is necessary to recover this knowledge; otherwise, maintenance or evolution will be impossible. It is also necessary to communicate this knowledge to all new programmers who are joining an existing software project. The loss of the programming knowledge can be a serious

problem and was identified as a leading cause of the code decay (Rajlich & Bennett, 2000).

Although the knowledge is embedded in the program, it cannot be easily recovered since it is encoded in programming structures and delocalized into different components of the program. Moreover, the consequences of the decisions, rather than the decisions themselves, appear in the code. In many ways, the recovery of knowledge from the code is similar to solving a puzzle and is laborious and error prone.

One of the most basic questions that concerns the nature of the programmer knowledge is the issue of its monotonicity. According to a naïve view, the knowledge steadily increases, as the new facts emerge and are absorbed by the programming team; many current documentation systems are geared towards that (Ye, 2006). However, in this article we show that there are also episodes of the knowledge retraction, and the documentation systems should provide an adequate support for that also.

Our approach in the article is based on cognitive informatics (CI). CI is a multidisciplinary study of cognition and information sciences, which investigates human information processing mechanisms and processes and their applications in computing (Wang & Kinsner, 2006); studying the knowledge and cognitive process involved in software development is one of the goals of cognitive informatics.

In order to understand the nature of programming knowledge and its acquisition, we adopted and further developed a constructivist model of programmer learning that is based on four basic cognitive activities: absorption, denial, reorganization, and expulsion of the knowledge. We validated this model in a case study of the pair programming that is a part of eXtreme Programming (Martin, 2002). In pair programming, two programmers work side-by-side at one machine as they collaborate in program design, implementation, and testing. The programming pair has to communicate and share the knowledge, and this gives an opportunity to analyze unobtrusively their dialog for the indications of the programmer knowledge and learning.

The first section of this article describes our theory of constructivist learning. The second section describes the case study. The third section contains the discussion of the results of the case study and the fourth section has an overview of the related literature. The fifth section contains general conclusions and future work.

THEORY OF CONSTRUCTIVIST LEARNING

The constructivist learning model is based on the work of Piaget (Piaget, 1954). The original aim of Piaget was to explain learning in children, but the constructivist theory extends to adult learning and to epistemology (von Glasersfeld, 1995). The theory assumes that the learners actively and incrementally construct their knowledge. They start from some preliminary knowledge, and they extend it by adding new facts to it; they may go through stages in which they may accept ideas that they will later discard as wrong. The two main activities are assimilation and accommodation, where assimilation describes how learners deal with new knowledge, and accommodation describes how learners reorganize their existing knowledge.

We modified this theory by dividing assimilation into two separate activities. Absorption means that the learners add new facts to their knowledge. However, if the new facts do not fit in, the learners may reject them; we call this second activity a denial. We also divided accommodation into two separate activities. Reorganization means that the learners reorganize their knowledge to aid future absorption of new facts. Expulsion is the process where part of the knowledge becomes obsolete or provably incorrect and the learners reject it. Of course, there are also mixed activities: learners may absorb a modified fact, rather than make an

Table 1. Learning activities

Activity	Symbol	Characterization of the activity
Absorption	a	The learners add new facts to their knowledge.
Denial	d	The learners reject the new facts that do not fit in.
Reorganization	r	The learners reorganize their knowledge to aid future absorption.
Expulsion	e	A part of the knowledge becomes obsolete and the learners reject it.

outright denial; learners may reorganize their knowledge while absorbing new facts, and so forth. Table 1 lists the four basic learning activities.

In order for learning to occur, the learners must possess *preliminary knowledge*. Preliminary knowledge makes learning possible; the more the learners know, the more they can learn. Sometimes this preliminary knowledge turned out to be inaccurate or even completely wrong, and the learners employed the four cognitive activities to build more accurate knowledge. The theory is particularly suitable to the situations where learners must discover the facts of the knowledge on their own, without a teacher, which is a common situation in software engineering.

The assertion of this theory is the following: When the process of learning is recorded and divided into episodes, every episode can be classified in terms of the categories of the constructivist learning model. The model would be falsified (Popper, 2003) if there were episodes that laid outside of our classification scheme, or if independent observers frequently arrived at different conclusions about the same observed episode, indicating that the classifications are arbitrary.

Each episode deals with specific concepts that are part of the knowledge. In the context of program development, the concepts can be classified as either domain concepts or programming concepts. Domain concepts belong to a specific domain that the program addresses (Biggerstaff, Mitbander, & Webster, 1994), while programming concepts belong to the knowledge of programming, such as the programming language, program development process, design decisions, and so forth. Design decisions involve program architecture, selection of the program classes, methods, or attributes, and so forth (Ran & Kuusela, 1996).

The leaning process can be explained in terms of analogy with incremental program development. The knowledge that is constructed by the programmers is analogous to the program they

Table 2. Analogy between programming activities and cognitive activities

Programming Activities	Cognitive Activities
Incremental change	Absorption
Rejection of change request	Denial
Refactoring	Reorganization
Retraction	Expulsion

incrementally develop, and the activities of their learning are analogous to the activities of incremental development. The analogy is summarized in Table 2 where analogous terms are in the same row. The case study of the next section examines an application of this model.

THE CASE STUDY

For our case study, we utilized the eXtreme Programming process (Beck, 2000), where pair programming is one of the recommended practices. Pair programming offers a unique opportunity to study the parallel construction of both the program and the programmer knowledge. In pair programming, the programmers communicate with each other about the evolving program. By recording and analyzing their dialog, we study how both the knowledge and program grow.

The program developed during this case study records bowling scores (Martin, 2002). The programming was done by two experts who have been working in the industry for more than 25 years (Martin, 2002).

The programming pair started the process with the preliminary knowledge of the domain (bowling rules), represented by the concept map

Figure 1. Domain concepts

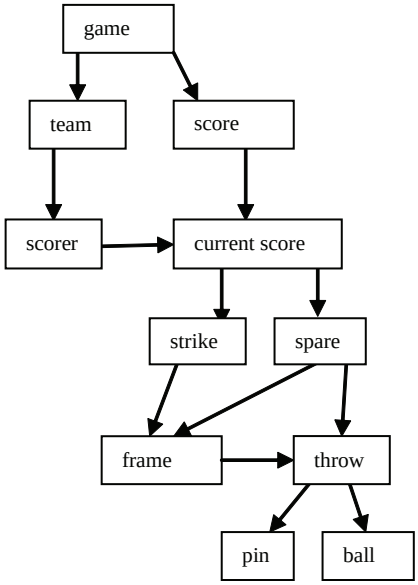

Figure 2. UML diagram of the first version

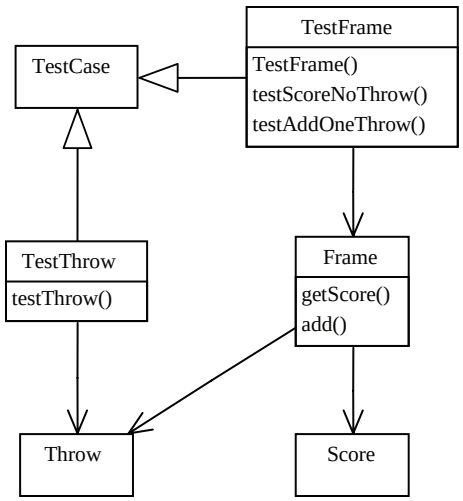

Figure 3. Design decisions for the first version

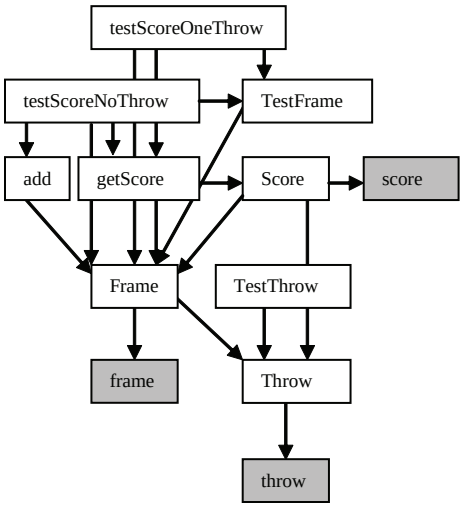

in Figure 1 (Novak, 1998), where concepts are represented by rectangles and the arrows represent the dependencies. The dependencies stand for the order in which the concepts have to be explained to somebody who is not familiar with the domain; a concept can be explained only if all previous concepts on which it is dependent have been explained and understood. Preliminary programming knowledge includes knowledge of the programming language, algorithms, eXtreme Programming practices, and so forth.

Equipped with this knowledge, the programmers implemented a sequence of the program versions and recorded their dialog. The UML class diagram (Fowler, 1999) of the first version is in Figure 2. The design decisions that led to this diagram were extracted from the recorded dialog and appear in Figure 3. The rectangles represent design decisions, while arrows represent the order in which the design decisions were made. Dark rectangles represent domain concepts that serve as the basis of some of the design decisions. Please

Figure 4. Design decisions after episode 87

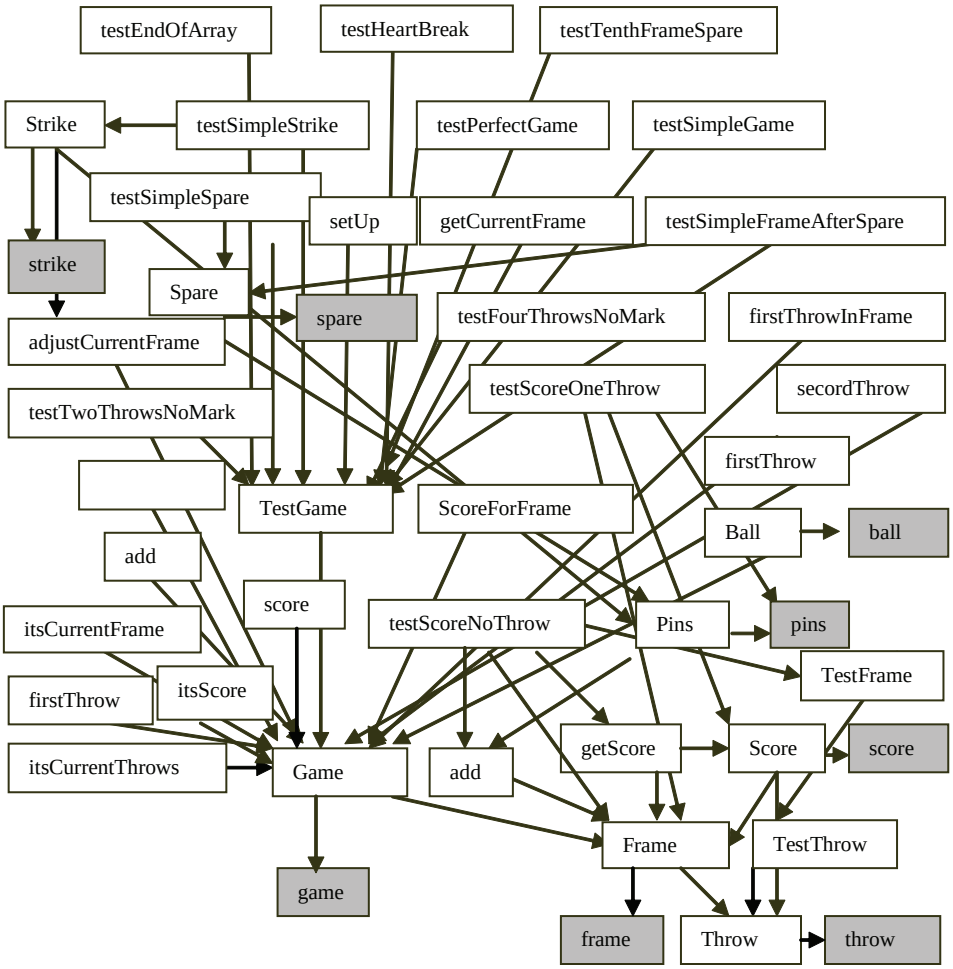

Figure 5. Final program

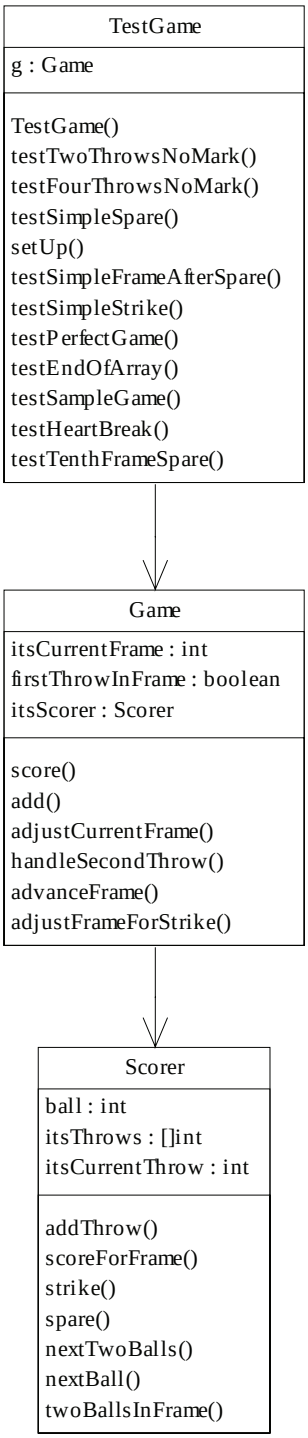


note that the order of the design decisions does not correspond to the order of the dependencies in the UML diagram. If the two orders were identical, that would mean that all design decisions were done in bottom-up order.

The development continued through several steps; see the progress of the learning in Figure 4 that shows the situation toward the end of the dialog. Programmers realized that the class "Frame" and the related classes do not contribute toward the functionality of the program and deleted them. The resulting UML class diagram of the program is in Figure 5.

We divided this dialog into 94 small episodes, and then three independent observers classified each episode as one of the four cognitive activities, using the characterization of the activities in Table 1. Out of 94 episodes, only 5 episodes were classified differently by each of the observers; in 30 episodes there was a partial disagreement where one observer differed from the other two; in these cases we discussed the cases and chose the majority opinion as the final classification. While acknowledging these differences, we found the classification in general was acceptable and reliable. The sample dialog and its resulting classification are shown in Table 3.

THE RESULT OF THE CASE STUDY

In the case study, we observed that the knowledge required by even a small program is quite extensive, as demonstrated in Figure 4. It should be remembered that these figures are only the "tip of the iceberg," as there is a large preliminary knowledge of the domain and programming that these figures do not capture. Yet all that knowledge is necessary to evolve the program.

During the incremental program development, the most common cognitive activity was absorption (about 71.3%) as shown in Table 4,

Table 3. Fragment of the dialog and the classification

No	Programmers' actions	Activity	Concepts updated
35	**K**: Why the magic number 21? **M**: That's the maximum possible number of throws in a game. **K**: **scoreForFrame** needs to be refactored to be more communicative.	r	
36	**K**: But before we consider refactoring, let me ask another question: Is **Game** the best place for this method? In my mind, **Game** is violating Bertrand Meyer's SRP (Single Responsibility Principle). It is accepting throws *and* it knows how to score for each frame. What would you think about a **Scorer** object?	a	Game, Scorer
37	**M**: But there are side-effects in the **score+=** expression. They don't matter here because it doesn't matter which order the two **addend** expressions are evaluated in. **K**: I suppose we could do an experiment to verify that there aren't any side-effects, but that function isn't going to work with spares and strikes. Should we keep trying to make it more readable or should we push further on its functionality?	d	
38	**M**: The experiment would only have meaning on certain compilers. Other compilers might use different evaluation orders. Let's get rid of the order dependency and then push on with more test cases.	r	
39	**M**: Next test case. Let's try a spare. **K**: Let's refactor the test and put the creation of the game in a **setUp** function.	r	
40	**M**: That's better now. Let's write the spare test case. I think the increment of ball in the **frameScore==10** case shouldn't be there. Here's a test case that proves my point.	a	Spare
41	**M**: See, that fails. Now if we just take out that pesky extra increment. It still fails.... Could it be that the **score** method is wrong?	d	Score
42	**M**: I'll test that by changing the test case to use **scoreForFrame (2).**	a	
43	**M**: That passes. The **score** method must be messed up.	a	
44	**M**: That's wrong. The **score** method is just returning the sum of the pins, not the proper score. What we need **score** to do is call **scoreForFrame** with the current frame.	a	Score
45	**K**: We don't know what the current frame is. Let's add that message to each of our current tests, one at a time.	a	
46	**M**: OK, that works. But it's stupid. Let's do the next test case.	a	
47	**M**: Let's try the next. This one fails. Now let's make it pass.	a	
48	**K**: I think the algorithm is trivial. Just divide the number of throws by two, since there are two throws per frame. Unless we have a strike ... but we don't have strikes yet, so let's ignore them here too. What if we don't calculate it each time? What if we adjust a **currentFrame** member variable after each throw?	a	Frame

and it dominated the programming process from the beginning to the end. This coincides with the intuition that the knowledge increases during the program implementation.

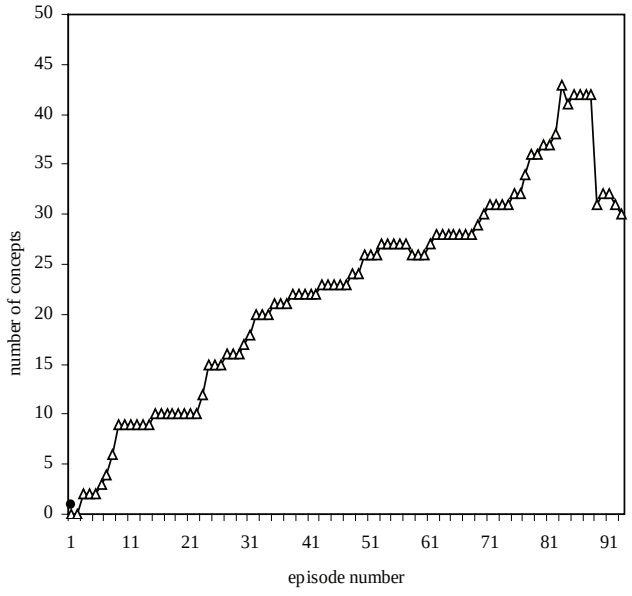
While absorption was the driving force of the learning, there was one large episode of knowledge expulsion in the last part of the dialog. Class "Frame" of Figure 4 and six related design decisions out of the total of 39 were retracted as a part of code "cleaning," resulting in a substantial knowledge change. This episode illustrates the non-monotonic nature of constructivist learning. The changing number of concepts are presented in Figure 6.

There were also episodes of reorganization, which amounts to 17% of all episodes. The rejection of concepts "Score Card" and "Team" in the first part of the dialog are examples of denial.

Table 4. The distribution of the cognitive activities in the case study

Activities	**beginning**	**middle**	**end**	**total**	**percentage**
Absorption	27	18	22	67	71.3%
Denial	1	4	0	5	5.3%
Reorganization	0	7	9	16	17%
Expulsion	2	1	3	6	6.4%
Total	30	30	34	94	100%

Figure 6. Changing numbers of the concepts and their dependencies



We observed that the absorption occurred mostly at the beginning and middle of the dialog, while the expulsion happened most often in the last part. Reorganization appeared mostly in the middle and last parts, and denial appeared only in the first and middle parts of the dialog.

Programmers discussed nine domain concepts in three episodes before the coding started, but during the rest of the development almost all the domain concepts were revisited, and their comprehension was updated. The domain concept "Frame" was updated as many as nine times, with each update resulting in more accurate knowledge. Many design decisions were also updated, but less frequently than domain concepts. As a result of the case study, we conclude that the constructivist learning model explains the learning that takes place in incremental software development and that the learning is significantly non-monotonic.

RELATED WORK

CI is a multidisciplinary research area that is at the intersection of cognitive science, neural psychology, philosophy, software engineering, and other disciplines (Wang, 2002). Wang (2004) previously investigated the relationship between software engineering and cognitive informatics.

There have been numerous publications on constructivist learning, including the classical work of Piaget (Piaget, 1954). von Glasersfeld (1995) described constructivism as a theory of knowledge and defined radical constructivism as a theory of learning. Novak (1998) addressed theories of learning, knowledge, and instruction and used concept maps as tools to describe the knowledge. The knowledge graphs of this article follow Novak's approach.

Other notable learning theories include Vygotsky (1978), who proposed the social cognition learning that emphasizes social interaction in the development of cognition. Although social interaction is an important element during software engineering processes, we believe that our emphasis must be on the individual programmers and their autonomous construction of their knowledge, and hence we found this theory less applicable.

Observational learning theory states that learning occurs through the simple processes of observing someone else's activity (Biederman, Stepaniuk, Davey, Raven, & Ahn, 1999). However, software engineering processes involve more complicated processes than simple observation; therefore, observational learning is not suitable here. Behaviorism focuses on the objectively observable behaviors at the expense of mental activities; therefore, we do not use it for explanation of software engineering activities.

Brain-based learning is based on the structure and function of the brain and emphasizes the fact that the brain can perform several activities at once, like tasting and smelling. Learning involves both focused attention and peripheral perception and both conscious and unconscious processes (Jensen, 2000). Because brain-based learning deals with the functions of the brain rather than the cognitive activity of learners, we did not use it.

Control theory claims that behavior is not caused by a response to an outside stimulus, but inspired by what a person wants most, such as survival, love, and freedom (Glasser, 1998). Again we did not find that view useful for the study of software engineering learning.

We concluded that although these theories contain valuable insights, they are not directly applicable to our purposes. The most promising theories we found include the constructivist learning, which we adopted as part of our model of constructivist learning.

Incremental software development has been described in numerous publications, for example Beck (2000), Martin (2002), and Williams, Kessler, Cuningham, and Jeffries (2000). Beck (2000) introduced a new approach to software

development, called eXtreme Programming that is based on practices of incremental development, continuous testing, pair programming, and several other practices.

Several researchers have studied knowledge contained in a program. According to Brooks (1983), a programmer understands a program through construction of a mental model that consists of successive knowledge domains. Fischer, McCall, Ostwald, Reeves, and Shipman (1994) proposed a support for the incremental development based on a specific knowledge model, where seeding, evolution, and reseeding are the three stages of knowledge capture and transformation. Henninger (1997) recognized that software development is a process involving various knowledge resources, which keep changing during the process. Robillard (1999) identified two types of knowledge: topical and episodic. Topical knowledge refers to the meaning of words, and episodic knowledge consists of people's experience with knowledge.

In our previous work, Rajlich (2002) presented the program comprehension as a learning process. In a case study of an incremental software development, Rajlich and Xu (2003) described an analogy between incremental software development and constructivist learning. A study of program debugging was based on Bloom's taxonomy (Bloom, 1956; Xu & Rajlich, 2004). Xu and Rajlich (2005) developed a dialog-based protocol, a novel empirical research method that is based on the analysis of the dialogs in a programming pair, and give an insight into the programmer cognitive activities. This approach may reduce Hawthorne and placebo effects that are present in other empirical techniques.

Many existing software documentation tools do not pay sufficient attention to the changes in knowledge and essentially assume that the knowledge is unchanged (Forward & Lethbridge, 2002). Among them, JavaDoc extracts documentation statically from Java source files and produces formatted HTML output (Gosling, Joy, & Guy, 1996), Doc++ (Wunderling & Zцckler, n.d.) is useful for creating hierarchical documentations of class libraries; Doxygen (2004) is used for documentation of Java, C, and C++ programs. Donald Knuth's Literate Programming (Knuth, 1984) places both source code and documentation into the same file. None of these systems directly supports non-monotonicity in the construction of the knowledge. PAS (Rostkowycz, Rajlich, & Marcus,2004) is a hypertext-based documentation system suitable for incremental redocumentation

CONCLUSION AND FUTURE WORK

In this article, we introduced a model of constructivist learning and used it to explain programmer learning during a software engineering process. The model is based on the four cognitive activities: absorption that adds new facts to the knowledge, denial that rejects facts that do not fit in, reorganization that reorganizes the knowledge, and expulsion that rejects obsolete knowledge.

We validated the model in a case study of pair programming during incremental program development. The data of this article are based on the analysis of the dialog in a programming pair. From the data we concluded that the classification of programmers' actions according to the constructivist model of learning reflects well the process of learning.

We noted that the knowledge required for incremental software development is large and changes rapidly. We plan to investigate nature of this knowledge in more detail and see whether there are any particular substructures of this knowledge that require greater programmer attention.

We observed episodes of both knowledge increase and decrease and hence the growth of the knowledge in non-monotone. This fact is important for the program documentation systems.

Future work includes additional studies of pairs of programmers during the development of larger programs, in order to further assess the insights provided by the constructivist learning, and to analyze the differences between novices and experts. We also plan to develop specialized documentation tools that will support the non-monotonic nature of the knowledge growth during the program development.

ACKNOWLEDGMENT

The authors would like to acknowledge Jay Rajnovich for his help with writing this article and Claudia Iacob for being one of the observers who classified the episodes. We also thank the anonymous reviewers for their comments that significantly improved this article. This research was supported in part by grants from the National Science Foundation (CCF-0438970), the National Institute for Health (NHGRI 1R01HG003491), and by 2005 and 2006 IBM Faculty Awards. Any opinions, findings, conclusions, or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the NSF, NIH, or IBM.

Chapter 2.22
Designing for Service-Oriented Computing

Bill Vassiliadis
Hellenic Open University, Greece

EXECUTIVE SUMMARY

This case describes major management and technology issues which arise when designing advanced service-oriented architectures in distributed networked environments used for e-learning. The organization at hand uses a mixed funding model and is preparing for a large expansion of its services and capacity. This case takes place after the initiation of a project and during the design phase where significant decisions have to be taken about what is feasible, what are the risks and how they can be dealt with and finally, what is to be developed and how. The need to address diverse goals set by business, technology and education right from the start of the project requires new methodologies for documenting development plans, feasibility studies, risk, and human resource management policies. The project manager needs to go beyond traditional project management methods in order to cope with the needs of this use case and most importantly, to manage the risk that arises from many directions.

ORGANISATIONAL BACKGROUND

This case is set in the higher education industry involving an Open University which utilizes a mixed business model: its operation is funded by both public and private funds. This institution is supporting a diverse population of students which undertake undergraduate or postgraduate studies. Moreover, it provides postgraduate curricula to graduates who wish to extend or upgrade their studies to subjects related to their profession. The University's curricula correspond to various certificates, Bachelor or Master's degrees. A Bachelor degree is comprised of several research directions. Courses, organized in modules, are designed according to the distance learning methodology: students study using text books, participate in 5 tutorials for each module taking place in 8 towns, communicate with the corresponding tutor by telephone, fax, e-mail and letters, prepare 4 – 6 assignments for each module and finally, take a final examination 10 months later. A student belongs to one student group, called class. A class

is based on a major city in which class sessions take place. A tutor is allocated for each class of a maximum capacity of 32 students who inhabit in a specific geographical region.

The organization's educational services are targeted to a very specific audience:

- students: students are the main clients of the organization. They pay fees for attending courses.
- other Academic Institutions collaborating with the University: academic institutions are possible collaborators in the development and provision of MSc Curricula.

The academic personnel of the institution involve a small number of about 30 permanent personnel (Professors, Associated Professors and Assistant Professors) as well as a large number of tutors (about 1000). Each one of the permanent personnel undertakes, besides tutoring, the coordination of all classes and the overall academic responsibility for a specific course. Tutors cooperate with the University on an annual basis.

This organization is supported by a mixed funded scheme: it allows admission of students without an entry examination but although it is a state University, students pay fees for the cost of their studies. Fees cover the cost of the instructive material and all the expenses related to the studies. The number of annual registrations in each bachelor degree programme is about 500. To date, over 1800 students are registered for various stages of each course. Future plans of the administration foresee a significant increase in the number of new registrations will reach up to 1500 per year. The total number of students attending at all the educational programmes totals to 16000. Table 1 summarizes these figures.

The institution is relative new, with only five years of existence. It monopolizes the open and distance education of the country since it is the first and only higher education institute of its kind with bachelor and MSc. degrees recognized by the state. This fact has given the administration of the University the possibility to expand both its range of services and its capacity without serious competition in the domestic market. The following graph depicts in approximation, the annual increase of the organization's budget for the last 5 years.

It is worth noting that the unique services offered has created a large and ever-increasing client base. As the University is annually increasing its capacity, more and more applications are made for filling new student positions. Figure 2 presents this annual increase in capacity and the corresponding applications for registration for the last five years.

Since the organization is an Open University, new technologies are used for delivering education: electronic material, video lectures, electronic forums and e-mail. Advanced services include high-end communication and collaboration tools for online delivery of content and lectures in real time. It is reported that these tools have several drawbacks and they will be probably replaced in the near future. Asynchronous services are

Table 1. Organization's staff and clients

Administrative Staff	Permanent Academic Staff	Non-permanent Academic Staff	Students (clients)
100	30	1000	16000+

Figure 1. Annual budget increase

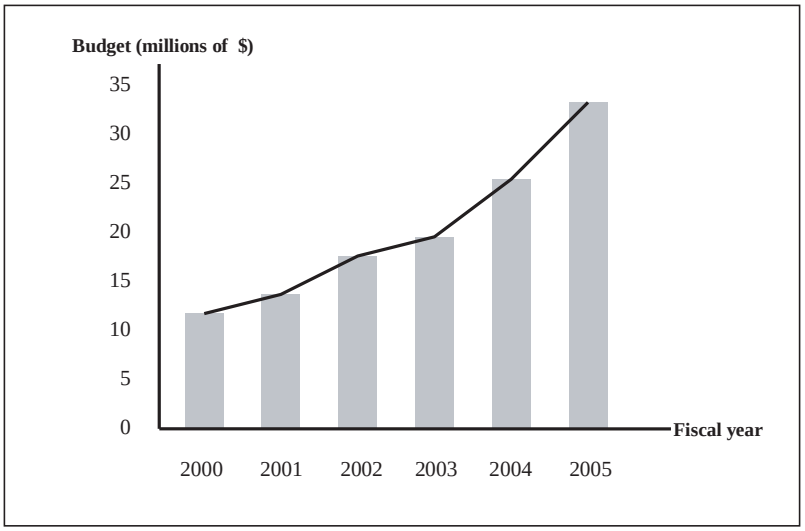

Figure 2. Applications vs. admission of students (clients) for the last five years

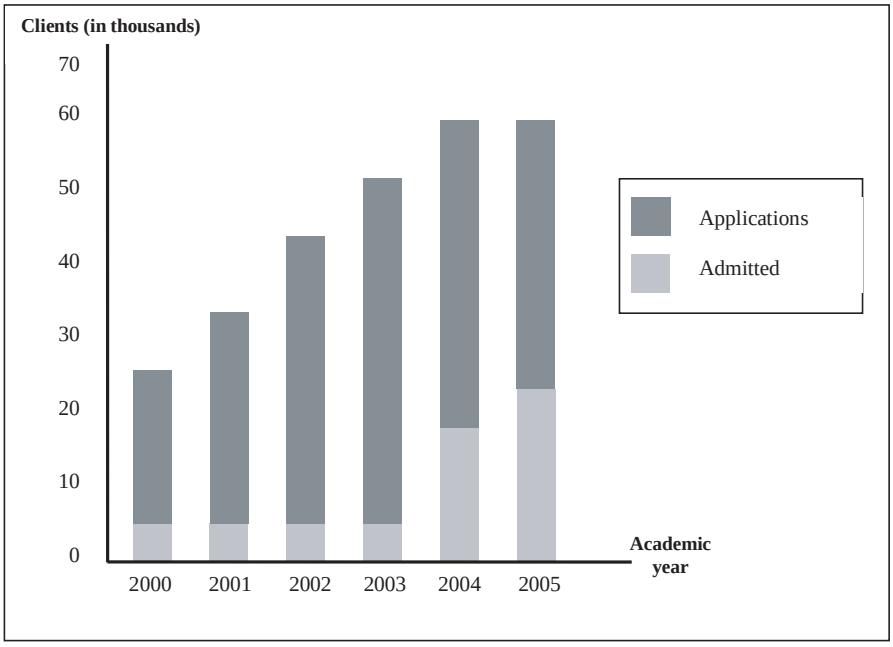


provided through Web sites, forums and e-mail. Frequent meetings between tutors and students take place for presentations, discussing problems or for providing additional information. Since this University covers the whole country, a small number of centres are used in major cities providing support such as lecture rooms and in the near future, video-conferencing facilities. It must be noted that a firm policy of the organization is to keep the tutor/student ratio steadily at 1:30, regardless of the increase in user capacity. This allows the continuing monitoring of student's performance and the establishment of tight relations between the learners and the academic staff.

The organization's culture is characterized by a spirit of innovation both technologically and administratively. Although some initial organizational problems prohibited rapid expansion in the first 4 years of its operation, rapid growth has taken place in the beginning of the fifth year while ambitious plans have been set for the next 5 years: a 50% expansion with regard to current numbers.

The population of students, the actual users of the organization's services, is extremely diverse. A typical student is rather of a mature age, part time student. Many students are already professionals and have different cultural backgrounds and career goals. They are highly geographically dispersed all around the country.

SETTING THE STAGE

In order to support the rapid expansion within the next five years, the organization has decided to use new technologies as a spearhead for increasing quality of service and reducing organizational complexity. The main effort was focused on the main product: e-learning service provision. The effort of upgrading services was of a high risk because the client population was very sensitive to changes in the way learning was delivered. On the other hand, repeated evaluations of current procedures had shown several deficiencies in service delivery and most of all inability to support the ever-increasing client population. In short, services were suffering from the following drawbacks:

- low participation. The participation of students to e-learning sessions and the use of collaboration tools were extremely low. The main reason was that users were not motivated enough. Although basic functionality such as video-conferencing and collaborative support were provided, procedures and tools seemed to lack the interactivity and the efficiency needed for broad acceptance.
- interactivity: The lack of interactivity in current services was largely reducing the interest of users.
- efficiency. Since students had significant time constraints (most of them were employed), services should have been tailored as mush as possible. This means that an upgraded version of the system should provide the means to cut down the costs of learning through adaptation, along with effective task assignment, execution duration control and monitoring.
- cost reduction. The inclusion of new tools or services to the existing system was deemed to be a too costly process. Costs increase when management of the integration of internal and external resources is needed: aspects such as security, heterogeneity and copyright were not dealt with by current approaches.
- ever-increasing number of clients. The number of clients (actually students) that need to be supported by distance learning applications was quite large. Their number is estimated to increase by 50% within the next five years. Normally, this would not be a problem if static Web applications were used for delivering content. A simple Web server would be adequate. Nevertheless, in

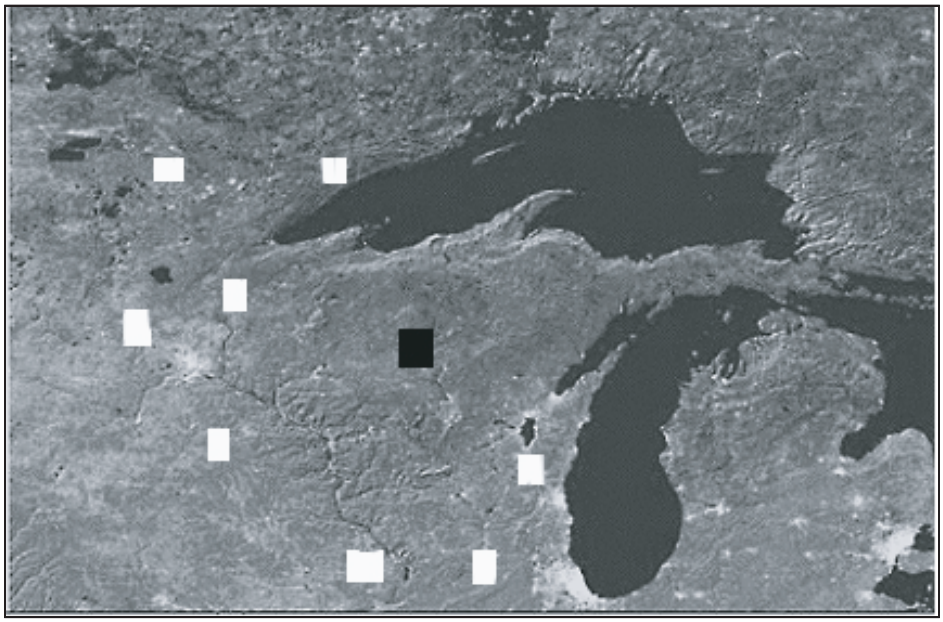
the case of more complex services, there was a problem on how to cope with tens or even hundreds of processes running at the same time by remote users. Furthermore, according to the organisation's rules, there could be no strict rules on when students may access a service or not. Access to services is quite random in terms of number of users, time of access and duration of use. The University's policy to improve the quality and capacity of the e-learning services (number of user supported), required a solution that could handle possibly thousands of users at the same time.

Existing tools used were quite cost-effective to support, relying mainly on Web-based technology. They included:

- asynchronous collaboration tool, which was being used for simple collaboration/ sharing of knowledge and resources and virtual class management.
- Web sites and forums, used for asynchronous delivery of educational material and for off-line collaboration.
- tools and Web browsers were used to access and manipulate information objects:
  - Internet Explorer/Mozilla for Web browsing,
  - Word for creating documents,
  - PowerPoint for creating, organizing and illustrating presentations,
  - WordPad for plain text editing.

Besides the obvious drawbacks of using such simple technology for supporting an extremely

Figure 3. Example of a distributed business model: headquarters (black square) and satellite centers (white squares) of the organization are geographically dispersed



demanding and diverse client population, another disadvantage relating to the philosophy of the organisation was soon discovered: its business model was distributed and current technological solutions were based on a client-server model. The University has its headquarters in a major city of the country while clients are supported by 8 satellite centers based on 8 other cities (Figure 3). This network was already supported by a high speed network backbone guarantying fast delivery of heavy loads. Although electronic services were geographically independent, other services were provided on-site. The latter included mainly facilities for regular face to face sessions, a significant aspect of the University's educational policy. Thus, several of the provided services were geographically-sensitive, but the supporting technology was not.

Such a business model was recognized as an advantage but only in the case were distributed computing would be used as its enabler. Administration as well as user services should be supported by a networked model mapped to the nodes of the existing, underlying business model. Classic practices used so far were minimizing ROI (Return on Investment) and kept quality and user satisfaction at low levels.

The above-mentioned situations required a mixed economic/technological/pedagogical solution that would not address all problems at once, but rather deal with the most important ones. This decision was made after considering several similar cases of organisations that tried to introduce state of the art technologies, although not all of them were based on a high risk/high gain model. Most such efforts involved small scale, single institute adoption of state of the art tools from which the organization's experts have drawn some useful conclusions (Haywood, Anderson, Coyle, Day, Haywood & Macleod, 2000; Jefferies, Thornton, Alltree & Jones, 2004; Saunders & Klemming, 2003). Cross-institution (Van Weert & Pilot, 2003) or nation-wide (Demb, Erickson & Hawkins-Wilding, 2004) efforts were also considered since one of the University's future and most bold goals was to become a nationwide service provider of e-learning services to the commercial sector also.

Before any decision was taken about how to proceed, feelings about changes were mixed. On one hand, most thought that using advanced IT for facilitating better service provision was a must but the economy and benefits of such a solution were under question. The benefits of introducing advanced e-learning services, even in an organization that already uses IT as a backbone, still remains in theory. Services that are considered the most promising are also the most costly: personalization, real-time communication and other advanced functionalities lead to significant costs. So the business problem faced in this situation was focused on how to improve e-learning services by keeping costs to a minimum and maximize ROI in such a diverse and difficult sector as the educational one (Bender, 2003).

CASE DESCRIPTION: GOALS

Before undertaking any large effort to upgrade the current system, it was decided that it would be wiser to test some high risk/high gain technological/educational solutions to a specific curriculum. Three main directions where considered as most important for project execution: economy, pedagogy and technology. Funding was provided by the participation of the University to a large international project with very ambitious goals: to design and develop new educational services using distributed technologies. Although this entailed a high risk, possible benefits were also high. Furthermore, the fact that funding was coming from external sources, did reduced somewhat the economic risk of the University itself.

The pedagogical goal of the project was to improve learning through real time cooperation/

working among individuals, sharing and reuse of information in highly distributed and dynamic environments. The pedagogical goals outlined had highly demanding technical requirements, many of which were also the concerns of distributed systems research (Duffy & Jonassen, 1992). Group working implies shared interactive resources, necessitating both concurrency control and awareness of others activities. Active learning requires interactive resources, many of which will only be engaging if they are suitably responsive – a quality of service (QoS) issue that depends on many components of a distributed system – the low-level infrastructure (hardware, OS, network), the middleware and the interface software. Concurrency control and interactive responsiveness can make conflicting demands on a system. Real world input, such as live student interaction makes a network connection mandatory, and this again raises QoS issues such as fault detection, masking and tolerance for the learning environment. Accessibility, as in anytime/anywhere, requires availability, which may be supported through replication of resources, but this creates further tensions with responsiveness and concurrency control due to the need to maintain state across replicas. Accessibility also means adapting to available capabilities. For example: can the same learning environment be delivered through low-bandwidth mobile devices and high-bandwidth multimedia workstations? Accessibility also means supporting special needs of the individual, such as disabilities. More generally, the individual user should be recognized and catered for, and this personalization requires semantic tagging and profiling that can be difficult to formulate, both conceptually and in terms of machine representation. Standards efforts have been particularly slow in addressing this problem. Finally, contextualization required a move from the traditional view of an online learning environment as a stable long-lived entity (e.g., during the lifetime of a teaching module) – to another where the environment may evolve and change much more frequently, perhaps even several times a year – a dynamicity that is alien to current e-learning products.

The overall goal of the project was set to be the improvement of the efficiency of current e-learning practices by promoting a collaborative/social learning model based on services rather on tools. Furthermore, to use the new services as reinforcements to the foundations laid by the linear structured text books and the online and off-line lectures. As mentioned in a previous section, the goal was not to solve all identified problems, but rather to integrate a new learning methodology that would work as a supplement to existing practices. The aim was to increase:

- student motivation to participate in online sessions,
- student confidence and satisfaction,
- efficiency of the learning process.

In order to reach the main goal, the following subgoals had to be accomplished:

Sub-Goal 1

- provide added value services in the form of highly interactive multi-cooperation sessions and advanced virtual communities support.
- provide advanced, media rich services in the form of multi-step, cooperative working sessions for the a specific course.
- facilitate social learning and collaboration through knowledge sharing and reuse between groups and individuals.

Sub-Goal 2

- support thousands of users while preserving adequate Quality of Service.

- provide the services to a diverse and very large student population.
- provide a single access point with a homogeneous interface.
- preserve quality of service (fault tolerance, response time) at any time.

Sub-Goal 3

- evaluate the didactical approach and the technology infrastructure by contacting a real, large scale experiment in the selected course.
- provide/configure metrics for measuring performance in terms of scalability, quality of service and security.
- test the infrastructure in a real situation.
- assess the results and provide feedback.

Supporting computationally expensive services for thousands of users with minimum costs and maximized ROI was the biggest challenge. A novel, and thus high risk technology was selected for delivering the services: grid computing.

GRID COMPUTING: STATE OF THE ART

Grid computing is a new paradigm that enables the virtualization, management and provision of heterogeneous and geographically dispersed computing resources (Berman, Fox & Hey, 2003). A resource may be CPU power, storage, information/knowledge or even services. The vision of the grid is to provide computing resources in the form of commodities just like as the electric grid provides electricity to consumers. Providing computing as a commodity means that the end-user just plugs into a provision and gets all the resources needed under payment, transparently and with adequate quality of service. Transparency is essential because users should not be worried about how to find and manage computing resources, they just consume them. Quality of service involves not only high availability but increased security as well.

In order for this vision to become a reality, the distributed computing research community defined a set of functions that a grid should perform: resource scheduling, data virtualization, provisioning, and resource management (Li & Baker, 2005). The enabling software of the grid, actually in the form of middleware, should be able to operate on a variety of operating systems and network configurations.

In the past ten years, the grid has matured from a purely scientific instrument that processed vast amount of data to a collaboration enabler (De Roure, Jennings & Shadbol, 2005). Besides standard distributed computing technologies (virtualization, grouping of resources), the

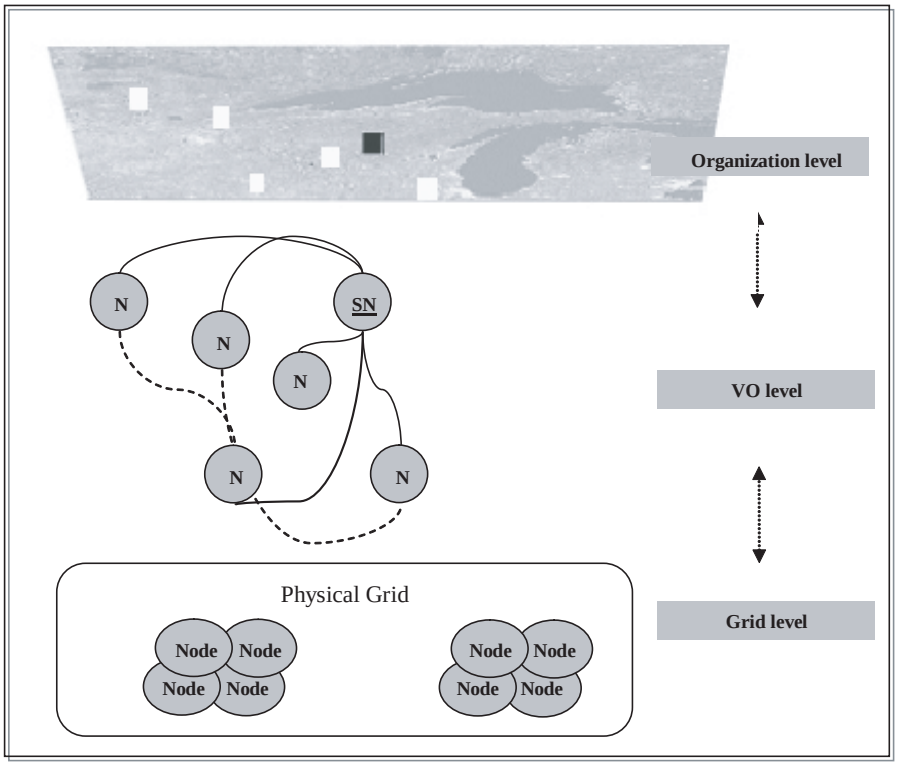
Table 2. Grid characteristics/functionalities vs. other technologies

Characteristic / Functionality	**Other Technologies**	**grid**
Transparency	*WWW*: simple collaboration	Enables advanced collaboration
Sharing	*P2P*: files	resources
Virtualization	*Virtualization tech*: single system	multiple systems
Grouping of computational resources	*Cluster computing*: homogeneous systems with geographical proximity	heterogeneous and geographically dispersed systems

grid now incorporates semantics (De Roure et al., 2005), Peer to Peer (Talia & Trunfio, 2003) and Web Services' (Cannataro & Talia, 2004) characteristics/functionalities. The use of these functionalities in the grid however is slightly different as described in Table 2.

The grid was originally applied in e-science but the framework it engendered to realize effective sharing of distributed heterogeneous resources is now being applied to many other areas, especially enterprise computing, e-commerce and recently higher education (Maldonado, 2004). The first application is extremely interesting since the grid has been proposed as a Virtual Organization (VO) enabler (Foster, Kesselman & Tuecke, 2001). In this model, grid technology is used for coordination, sharing and reuse of services, knowledge and data across the geographically dispersed nodes of the VO. VO nodes are mapped onto the physical grid nodes (computers or clusters of computers) and predefined workflows are used for service execution and data management (Figure 4). The next generation of grid solutions will increasingly adopt the service-oriented model for exploiting commodity technologies. Its goal is to enable as well as facilitate the transformation of Information into Knowledge, by humans as well as – progressively – by software agents, providing the electronic underpinning for a global society in business, government, research, science, educa-

Figure 4. An organization's central and regional centers mapped to a central (SN) and secondary (N) VO nodes, mapped to a grid



tion and entertainment. The most important benefit of this technology is its ability to meet major bursts of CPU demand using existing resources. By decoupling the services from the underlying h/w, resources are automatically allocated/deallocated as loads are increased/decreased. This increases ROI on h/w since idle computers are used instead of buying new ones.

TECHNOLOGY SELECTION

The grid computing paradigm is relatively new although it uses ideas and technologies from other, more mature disciplines. It has been recognized as a high risk technology that may provide significant benefits in special kinds of applications and especially in distributed coordination/cooperation. Although its potential has been recognized by the research and commercial community, the lack of grid-specific standards has been viewed as a serious uncertainty factor, prohibiting currently its wider adoption. Thus, projects that use grid technology bear a significant technological risk but also have a lot of potential.

The use of grid technology was chosen because the services anticipated were computationally expensive since a large number of users would be engaged in processes including massive calculations (e.g., online experiments). Furthermore, the grid had already shown significant advantages in collaboration and knowledge sharing for large teams. The organization's policy to adopt new technologies in order to minimize costs and maximize return on investment in all levels played a significant role in taking this decision. Improvements were anticipated in many levels, from administration to the delivery of education. In the latter case, new e-learning services were supposed to be designed in a way that:

- fully utilizes existing resources,
- could be expanded in order to support a large number of users while minimizing costs,
- would be flexible and able to respond to the rapidly evolving market,
- increases the power of core resources without creating the need for investing in additional hardware or hosting infrastructures,
- supports the University's dynamic policy for expansion.
- In this context, grid technology would play a significant role towards the direction of a compact, scalable and cost-efficient infrastructure for e-learning services. The use of grid technology was also necessary in order to fulfil real business needs:
- to combine resources on-demand for service provision,
- to intelligently allocate finite resources to the appropriate applications,
- to free expensive supercomputing resources for only the most high-end processing needs while still supporting the wide range of compute-intensive applications run by research groups throughout the University,
- to increase ROI on existing resources,
- to be able to support the ever-increasing number of users,
- to provide cross-domain functionality.

A grid infrastructure would permit transparent access to services and resources wherever they are located. Furthermore, special grid functions valuable for the efficient provision of services such as resource reservation, storage of large volumes of data and minimization of data transferred by using a super-node grid structure would be made available. In conclusion, the business value of using grid technology for this project stemmed from the possibility to leverage existing h/w and s/w investments and resources, reducing operational costs and creating a scalable and flexible infrastructure. It has been argued by some of the technical staff that acquiring CPU power and increasing storage capacity by using clusters of computers was both a cheap and efficient solution for supporting large numbers of users. This

was partially true, but the real problem was not purely technological (e.g., about CPU power) but business as well. If contemporary technology would be used then cost would be increased since the management and monitoring of different resources, would be difficult and expensive. Furthermore, expanding usually means buying and dedicating new hardware and software to new services, possible fragmented resources while ROI would not be maximized. It was also recognized that return of value would stem from educational, organizational and external benefits. Educational benefits would include more efficient learning models overcoming limitations problems of current computing infrastructure, provision of ubiquitous e-learning services. Exploiting potentials from the provision of consulting services to other academic institutions in the country concerning new e-learning models, and grid-enabled learning were also identified. Organizational benefits were supposed to include improvements in organizational efficiency (better information flow, savings in staff time, and improvements in service provision), a possibly, enhanced public profile of the institution and high return on investment: support more students, with less effort and reduced costs. Other secondary factors such as strategic partnering with external organizations (e.g., other higher education institutions, commercial, or community organizations), and the opening of new markets by providing new services through the collaboration with other academic organizations were identified.

CASE DESCRIPTION: DESIGN AND INITIAL STEPS

Before the design phase of the project was initialized, a strategic decision was taken concerning the identification of the project's stakeholders: the actors involved and/or affected by its implementation. It was decided to include:

- Students: students of the University. They indirectly provide the requirements for designing a new learning model. This means that their requirements should be assessed though their behaviour throughout the learning process.
- Teaching Staff: academic personnel including professors and tutors. They would provide input on the design and adoption of new learning models and evaluate the project's efficiency.
- Technical and support staff: including network and server administrators, special technical staff for supporting e-learning service provision.
- Laboratories: laboratories include laboratory staff, equipment, e-learning modules, services, knowledge.
- Academic Institutions collaborating with the University.
- Government: a potentially successful deployment of grid service architecture in the University would boost the adoption of new learning models and grid services in other higher education institutions. This would be made possible through the cooperation of the local Ministry of Education. Experts of the Ministry would evaluate the new methods and decide if the return of investment for its adoption in a wider scale would be feasible.

The actual role of the University was to produce specific requirements, test and evaluate solutions developed by the other partners. A proactive approach was adopted for the management of risk in the larger project. Project risks, especially the ones related to technological innovation, but also those related to budget, schedule and coordination were considerable but the Consortium was comprised of selected partners with strong research and development experience. The University's subproject purpose, referred in this communica-

Figure 5. The context of the case study

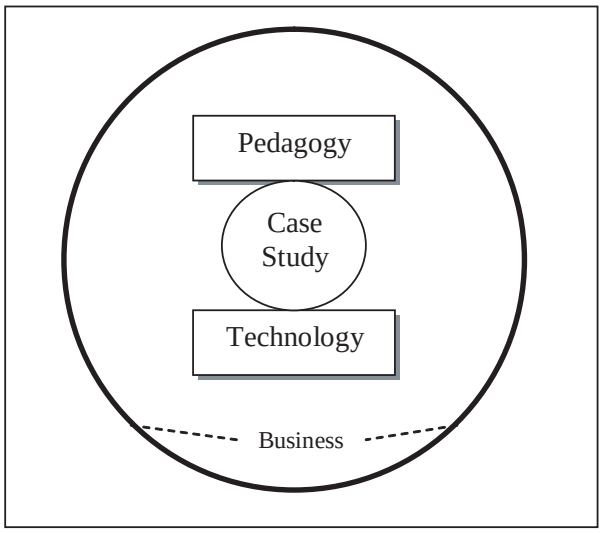


Figure 6. General approach to project completion

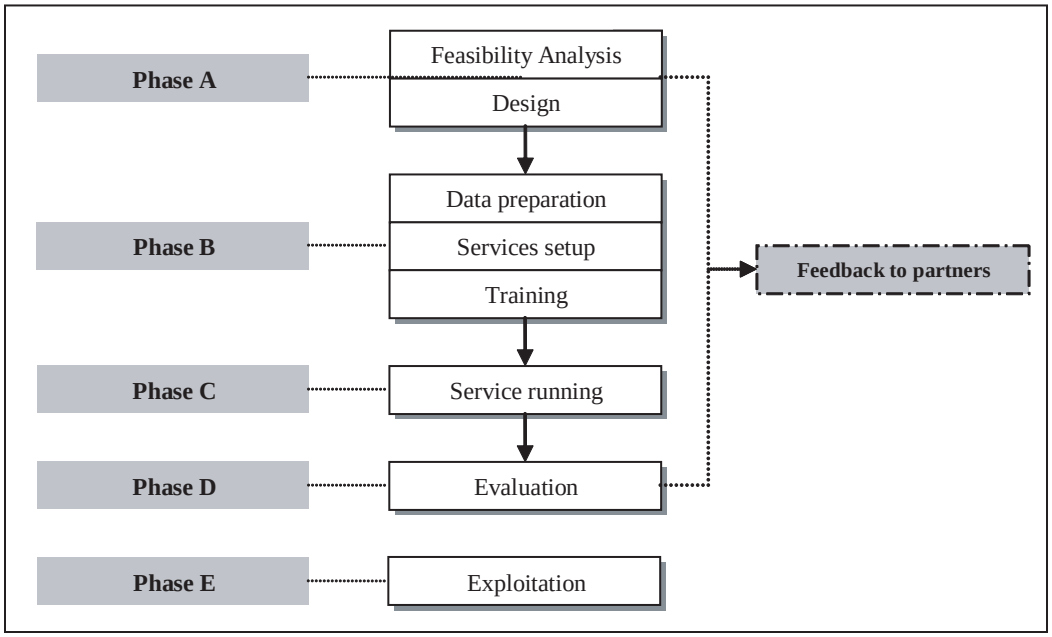


tion as *case study,* was to develop and gain insight into the processes involved from formulating pedagogic requirements to the implementing environments that meet these requirements. The case study and the University's goals were converging, since they were both aimed at a mixed pedagogic/economic/technological solution for advanced service provision (Figure 5).

The case study was anticipated to include five main phases, each of them decomposed in smaller tasks: design, development, deployment, evaluation, and exploitation (Figure 6). The first phase would check the feasibility of reaching the goals with the available funds and technology and define detailed requirements. During the development, phase data preparation, services setup and configuration would take place. Furthermore, tasks such as introduction, motivation and training of staff for operating the service were anticipated. Case study enactment would involve the actual running of the new services in real conditions for a short period of time. These services would be then evaluated by different user groups and conclusions would be communicated to the consortium.

FEASIBILITY ANALYSIS

Although the project is its initial phase, the project team is able to pinpoint the milestones for the upcoming phases. Phases are not necessarily sequential; two phases may be executed in parallel at a given moment. The first phase is relatively easy to decompose into smaller phases and set exact milestones, while for the others it is harder since one phase depends on the results of the previous ones. Assumptions however are possible (and useful) to make (Table 3).

As described previously, in the first phase requirements are defined. A feasibility study that takes into account technological, pedagogical, organisational and economical considerations would be of great help to define concrete and

Table 3. Milestones per project phase

Phase	Milestones
A: Design	• Feasibility study completed • Requirements are identified • Resources (human/financial) needed are committed • Initial plan for the first year has been agreed upon
B: Development	• Services are designed according to user requirements • The architecture of the infrastructure (e.g., exact technologies used) is defined • First prototype is made available • Second prototype is made available
C: Deployment	• Software (first prototype) is installed • Initial feedback is given to the developer team
D: Evaluation	• Evaluation methodology and plan has been agreed upon • Evaluation group formed • Feedback is provided to the developer team
E: Exploitation	• Demonstrators are made available • Licences (e.g., patents) are acquired

realistic objectives (Bates, 2000; Boucher, 1998). Subsequently, a detailed initial plan for the first period (e.g., the first year) can be drafted. Since this plan is based on the feasibility study, it is (theoretically) based on solid ground and it is as close to reality as possible. This study should consider the economic viability of the project. As mentioned previously, major cost savings of ICT introduction still remains in theory while it seems that its greatest pedagogical advantages are the most costly. Other, usually overlooked, costs may include courseware development costs, incremental capital and recurrent equipment costs, costs associated with provision of appropriate resources, infrastructure costs, maintenance, user support costs, costs of adoption, access costs, security costs, replacement costs and institutional overheads. This has lead Rumble (1999) to suggest that the cost of utilising advanced ICT services is nearly the same with face to face teaching. This assumption holds for complete distance learning solutions where traditional methods are completely replaced by ICT but in this blended learning situation it remains to be seen if this is the case.

The project team should be extremely careful in determining the resources needed and technologies used. Since grid technologies and Service-Orientation are relatively new fields, changes in frameworks or standards may have a significant impact on the project. For this reason, a technology-watch team should be formed in order to monitor changes and inform the partners.

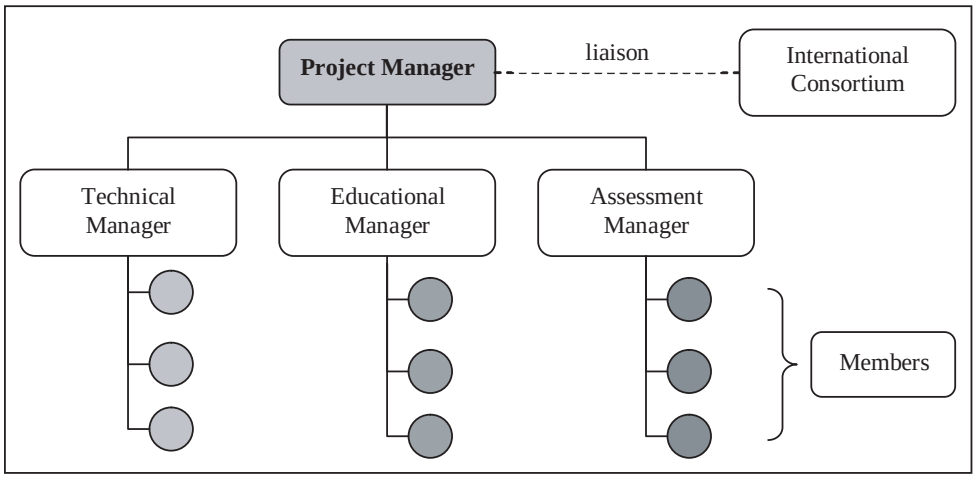
The milestones of the subsequent phases (B-E) can only be generally defined. They include the design and development of services and infrastructure, the availability of prototypes and demonstrators and finally, the evaluation results (performed by a specially selected user group).

Management Structure

A local project team was put together coordinated by an experienced project leader with background in both technology and pedagogy. Achieving a consensus between these two disciplines was important since the failure of addressing the requirements of one was automatically transformed to the failure of the other. The project leader was responsible for managing three sub-teams: the technological, the educational, and the evaluation team. Each of these teams would be managed by a corresponding leader and would have a relatively small number of members (3-4). As depicted in the team chart (Figure 7), there are many different roles that cover managerial, assessment, technological and educational criteria. Many of the actors involved, would work in the project for a specific, short period of time engaged in special duties (e.g., assessment).

The *Project Manager* would be responsible for the overall management of the case study. The project manager would coordinate the staff working in the project and would be responsible for the completion of individual tasks within the appropriate timeline. Project manager's responsibilities also included the final quality check of the work produced by the team. The *Technical Manager* would be responsible for the technical development of the project. This included the provision of technical requirements and guidance to experts during the installation, enactment and evaluation of the services. The *Educational Manager* had the responsibility to put together the requirements analysis, design, and integration of new e-learning models. Furthermore to design and support a concrete e-learning use case that would have an actual educational value for the University. Finally, the *Assessment Manager* was responsible for assessing the services during the installation and enactment phase. For this purpose, three tutors would be cooperating along with a number of students for assessing the final output of the project. Since assessment was going to take place at the final stages of the project, the names of the above mentioned actors were not made available from the beginning. The project team should cooperate smoothly with the much larger

Figure 7. The structure of the local project team



international team responsible for designing and producing the solutions.

The project manager and the members of the local project team interact with other members of the international consortium. This consortium is also organised so as to cope with a range of legal, contractual, ethical, financial and administrative tasks that may occur during the project life-cycle. The management structure of the consortium is divided into four bodies: project management (project manager, Project Coordination Board, Executive Board and Scientific Advisory Board), financial management (financial manager), Operations/Technical management and Quality management. Each of these bodies is comprised of separate roles and/or special boards with distinct authorities. These authorities are defined in a consortium agreement which is agreed upon and signed by each participant organisation before the start of the project. There are a lot of different configurations in these kinds of managerial structures; structure flexibility and the competence of the leading persons are the keys to successful management.

CURRENT CHALLENGES FACING THE ORGANIZATION

The project manager has a draft of a general implementation plan which defines major deliverables and deadlines. The project manager knows that this plan must be detailed and refined in the near future. For the time being, he is concentrated in the first phase of the project. One of the most important phases of project elicitation is feasibility and requirements analysis. The feasibility study to be contacted for the case study has the purpose of instigating cross-project understanding of requirements engineering, identifying and agreeing on common representations and modelling techniques for requirements engineering. The value of this analysis is very important since the adoption of a new technology like the grid in

such a difficult application domain as distance learning, is of high risk. The existence of a gap between technologists, educationists and final users is natural to exist but it should not exceed a certain threshold; otherwise the final solutions would fail to perform successfully in real situations (Xenos, Pierrakeas & Pintelas, 2002).

The University's project team needs to initiate an intense specification process to clarify, on the one hand, for the user groups the specific options in a given learning setting and on the other, to enable technologists to efficient communicate their views about emerging features and services useful for learning. This analysis process is demanding in time and resources since there are different views and a broad spectrum of ambitions and contexts inside the consortium.

The basic idea for the requirement analysis is to analyze the case study with a well experienced tool that provides sophisticated semantics for describing Service-Oriented architectures (SOA). The project leader needs to choose a general framework as a starting point for the requirements specification that also takes into account economic, technological and educational parameters. Furthermore, it should be oriented to the application of innovative technological solutions to traditional contexts.

A challenge that needs to be addressed in the first phase of the project is the methodology that should be followed for putting together the feasibility analysis plan. From his experience, there is no formal template or methodology for SOA cases. Most methodologies are either too technical or business/product oriented. But this project will produce services not products and furthermore, these services will be developed by a third party using an innovative, high risk technology. Services are different from tools; they have to be composed on the fly depending on needs (Rust & Kannan, 2003). They promote the so called "user-centered" approach for the design and development of software. Software as a service (SaS) has emerged as a response to a fundamental shift in enterprise business culture that started at the late 1990s (Foster & Tuecke, 2005). Traditional monolithic architectures are giving way to Service-Oriented Computing, which permits the utilization of large systems comprised of self-containing building blocks: services. Services may be made public, searched, reused, and combined to form complex business processes while in the same time retaining a significant level of flexibility. Since services are a relatively new concept, then the design of a SOA is in itself a challenge (Singh & Huhns, 2005). Again are the questions of what method is appropriate for system design and will classic approaches do the job?

The context also complicates things. Distance learning does not fall into any of the classic product categories, maybe it resembles e-commerce in some aspects, but there are differences: an online user does not behave as an e-learner does (De Bra, Brusilovsky, & Houben, 1999). How is it possible to identify and take into account business, technology and pedagogy requirements at the same time?

Anyway, before deciding on the methodology, the project team made some assumptions about the project, hoping that they would be the correct ones. First, that the design envisaged for the project could be developed in time and it would work within the context of the mission and goals that were set by the consortium and that the characteristics of the envisioned system would be among its high priorities. Secondly, that the organization's educational policy and legislative requirements would not prevent or circumvent key aspects of the system and those tools and technologies used so far can be integrated in the new infrastructure. Other assumptions should also be made on conceptual, legislative, stakeholder-related, and technological matters.

The administration of the institution also puts pressure on the project manager to consider the economic goals of the project, which closely relate to exploitation potential. A plan is needed to identify exploitation results and opportunities

during and after the completion of the project. Furthermore, the project manager needs to consider the quality aspects of both the procedure and the deliverables. The project manager is responsible for producing an output that is efficient and workable. In cooperation with the assessment manager, an expert in software quality and assessment, he is planning on putting together an initial *evaluation plan* to assess both methodology and services. This plan will be used as a guide to insure that quality is maintained at high levels. Priorities for evaluation must also be divided into categories and related to goals. Several indicators must be identified that can supply a measure of the success of the project in achieving the targets set in each of the above mentioned categories.

Expansion, a strategic business objective of the institution is one of the drivers of the project. It would seem thus, that this IT-focused project strengthens the strategic alignment between business and IT: the alignment of business and IT strategy in order for the organisation to stay competitive and gain profit from the use of advanced technology (Boar, 1994). In this case, the added value expected is (1) to provide more quality services to existing clients and (2) the ability to serve more clients efficiently. So the benefits are only connected to client services and not directly to organisational structure, internal infrastructure or processes; these will probably remain stable due to the academic nature of the organisation. One way to ensure strategic alignment is through assessments that is, setting performance goals for the processes affected. This should be dealt with both in the feasibility analysis of the design phase (phase A) and in the evaluation phase; software developed should be evaluated in the light of its impact on business strategy. For this reason cross-discipline metrics need to be defined during the design phase, metrics that measure the impact and relationships between IT and business strategy. These metrics should be evaluated at specific milestones and, if needed, corrective actions should be taken.

A set of assessment criteria must also be clearly identified for several categories of e-learning provision that the deployment of new services will affect. These criteria should then be de-composed, where possible, into smaller metrics that can be quantifiable — that is, a number can be assigned to them. All this "atomic" measurements, combined together using mathematical equations, will finally provide some kind of performance indicator. These criteria should try to establish whether the services create new possibilities compared to present tools and methodology, support the transition from classic educational models to advanced, student-centric methods and finally if they are cost-effective. It is apparent that different complexities (or levels) for these criteria exist and they need to be identified.

The case study's project management should also be based on a concrete *project plan* that anticipates risks stemming from the collaboration with many partners in a multi-cultural, international environment. Specifications are greatly affected by the technological solutions at hand, so strong cooperation with other partners need to exist in order to exchange information on what or what cannot be done. A risk that has been identified by all partners is the possibility that a different visions exists for different institutions in the consortium. Although the goals of each partner participating in the project may be different in an atomic level, the general goals should be the same and most importantly, well understood. The project manager and its colleagues at the institute are a little bit concerned about this but at the beginning of the project there is little thinks they can do. But they have in mind to follow a formal methodology in order to anticipate future misunderstandings or risks relating to these differences in vision, anticipations and business/technology culture between partners.

The formation of the project team is also a challenge. Its basic structure should include experienced sub-team leaders with proven abilities to cope with high risk research and development.

Although the four main members of the team (the managers) will work in the project from the beginning to its completion, other members will participate only in certain phases of the project. The project manager is concerned about the dynamicity of its team so he needs to put together a flexible *human resource management plan*.

After a discussion with the assessment manager, the project manager also decides to anticipate risk by developing a *risk assessment and contingency plan* that will monitor all ongoing management activities. The initial version of this plan should identify only high level, major risks and propose measures to overcome them. The challenge here is to correctly describe the impact of each potential problem on the project. The relevant coordinators and managers will review and apply risk management strategies. Risks will be re-evaluated at the regular consortium meetings. The project manager's opinion is that, in general, the strategy for reducing the risks related to project management is to reduce their probability of occurrence, rather than their impact. This necessitates a proactive style of management, with strong emphasis on planning, control, and corrective action.

Chapter 2.23
A Model-Driven Development Framework for Non-Functional Aspects in Service Oriented Architecture

Hiroshi Wada
University of Massachusetts – Boston, USA

Junichi Suzuki
University of Massachusetts – Boston, USA

Katsuya Oba
OGIS International, Inc., USA

ABSTRACT

Service oriented architecture (SOA) is an emerging style of software architectures to reuse and integrate existing systems for designing new applications. Each application is designed in an implementation independent manner using two major abstract concepts: services and connections between services. In SOA, non-functional aspects (e.g., security and fault tolerance) of services and connections should be described separately from their functional aspects (i.e., business logic) because different applications use services and connections in different non-functional contexts. This paper proposes a model-driven development (MDD) framework for non-functional aspects in SOA. The proposed MDD framework consists of (1) a Unified Modeling Language (UML) profile to model non-functional aspects in SOA, and (2) an MDD tool that transforms a UML model defined with the proposed profile to application code. Empirical evaluation results show that the proposed MDD framework improves the reusability and maintainability of service-oriented applications by hiding low-level implementation technologies in SOA.

INTRODUCTION

A key challenge in large-scale distributed systems is to reuse and integrate existing systems to build new applications in a cost effective manner (Vinoski, 2003; Zhang, 2004). Service Oriented Architecture (SOA) addresses this challenge by improving the reusability and maintainability of distributed systems (Arsanjani, Zhang, Ellis, Allam, & Channabasavaiah, 2007; Bichler & Lin, 2006; Endrei, Ang, Arsanjani, Chua, Comte, Krogdahl, Luo, & Newling, 2004; Foster, 2005; Lewis, Morris, Brien, Smith, & Wrage, 2005; Papazoglou, 2003). It is an emerging style of software architectures to design applications in an implementation independent manner using two major abstract concepts: *services* and *connections* between services. Each service encapsulates the function of a subsystem in an existing system. Each connection defines how services are connected with each other and how messages are exchanged through the connection. SOA hides the implementation details of services and connections (e.g., programming languages and remoting middleware) from application developers. They can reuse and combine services to build their applications without knowing the implementation details of services and connections.

In order to make this vision of SOA a reality, this article focuses on a research issue of increasing the reusability of services and connections and addresses this issue by separating non-functional aspects (e.g., security and fault tolerance) of services and connections from their functional aspects. The separation of functional and non-functional aspects can improve the reusability of services and connections because it allows different applications to use services and connections in different non-functional contexts. For example, an application may unicast messages to a service and another may manycast messages to multiple replicas of the service to improve fault tolerance. Also, an application may send signed and encrypted messages to a service, when the messages travel to the service through third-party intermediaries, in order to prevent the intermediaries from maliciously sniffing or altering the messages. Another application may send plain messages to the service via unsecured connection when the service is hosted in-house. The separation of functional and non-functional aspects can also improve the ease of understanding application design and enable the two different aspects to evolve independently. This results in higher maintainability of applications.

This article describes a model-driven development (MDD) framework for non-functional aspects in SOA. The MDD framework consists of (1) a Unified Modeling Language (UML) profile to model non-functional aspects in SOA, and (2) an MDD tool that accepts a UML model defined with the proposed profile and transforms it to application code (e.g., program code and deployment descriptors). The proposed UML profile allows application developers to graphically describe and maintain non-functional aspects in SOA as UML diagrams (composite structure diagrams and class diagrams). Using the proposed UML profile, non-functional aspects can be modeled without depending on any particular implementation technologies. The proposed MDD tool, called Ark, transforms implementation independent UML models into implementation specific application code.

This article describes design details of the proposed UML profile and demonstrates how Ark transforms an input UML model to application code that runs with certain implementation technologies such as Enterprise Service Buses (ESBs) (Chappell, 2004), secure file transfer protocols and grid computing platforms. Empirical evaluation results show that the proposed MDD framework improves the reusability and maintainability of service-oriented applications by hiding implementation technologies in UML models.

CONTRIBUTIONS

This article offers the following three contributions to the design space of service-oriented applications.

- **Modeling support for non-functional aspects in SOA**: This work is the first attempt to investigate a UML profile to consistently model a wide range of non-functional aspects in SOA, although there exist several UML profiles for specific aspects (e.g., functional aspects and service discovery) in SOA. (See the Related Work section for more details.) The proposed UML profile covers the following four areas of non-functional aspects.
  1. **Service deployment semantics:** Service redundancy.
  2. **Message transmission semantics:** Messaging synchrony, message delivery assurance, message queuing, multicast, manycast, anycast, message routing, message prioritization, messaging timeout, message logging, and message retention.
  3. **Message processing semantics:** Message conversion, message split, message aggregation, message validation, and message filtering.
  4. **Security semantics:** Transport-level encryption, message-level encryption (entire/partial message encryption), message signature, message access control, and service access control.
- **Modeling support for regulatory compliance**: As regulatory compliance has been becoming an important factor in software development and maintenance, regulatory mandates (e.g., the Sarbanes-Oxley Act and HIPPA) dramatically increase the number of non-functional aspects that application developers need to consider (O'Grady, 2004). This work is the first attempt to investigate a visual modeling language to describe non-functional aspects derived from regulatory mandates. The proposed UML profile allows application developers (or compliance management staffs) to graphically specify and verify how their applications meet regulatory mandates. Currently, the proposed UML profile addresses data retention, data/process validation (e.g., consistency validation among an order, invoice, and payment) and security (e.g., access control and data integrity).
- **MDD support for service-oriented applications**: Non-functional requirements change during application lifecycle more often than functional aspects (Bieberstein, Bose, Fiammante, Jones, & Shah, 2005). It can be expensive to manage frequent changes in non-functional requirements. This results in escalating maintenance cost, in turn total cost of owning. When a non-functional requirement (e.g., security policy) changes in an application, the proposed MDD framework allows application developers to make the change in a UML model specifying the application's non-functional aspects and keep its functional part intact. The proposed MDD tool (Ark) generates non-functional code from the updated UML model and combines the generated code with existing functional code. Ark makes application's functional aspects reusable across the changes in non-functional requirements, thereby improving the productivity of application development and maintenance.

BACKGROUND AND A MOTIVATING EXAMPLE

UML is a modeling language to describe application designs as graphical diagrams. It specifies the syntax (or notation) and semantics of every model element that appears in diagrams (e.g.,

class, interface and association). The syntax and semantics are defined in the UML metamodel (Object Management Group, 2004), which is the grammar specification for standard (default) model elements in UML.

In addition to standard model elements, UML provides extension mechanisms (e.g., stereotypes and tagged-values) to specialize them to precisely describe domain or application specific concepts (Fuentes & Vallecillo, 2004). A stereotype is applied to a standard model element and specializes its semantics to a particular domain or application. Each stereotyped model element can have data fields, called tagged-values, specific to the stereotype. Each tagged-value consists of a name and value. A particular set of stereotypes and tagged-values is called a UML profile.

For example, a UML profile for Enterprise Java Beans (EJB) (Java Community Process, 2001) defines the stereotype `<<EJBEntityBean>>`, which extends `Class` in the UML metamodel. This means the stereotype can be applied to classes. Thus, a UML class stereotyped with `<<EJBEntityBean>>` indicates that the class is designed as an EJB entity bean. The stereotype `<<EJBEntityBean>>` has a tagged-value, called `EJBPersisitenceType`, to specify who provides persistence to an entity bean. The tagged-value can have a value `Bean` or `Container`. `Bean` indicates an individual entity bean is responsible for its own persistence, and `Container` indicates an EJB container takes care of persistence.

Figure 1 shows an overview of an example purchasing system across buyers, retailers, sup-

Figure 1. The structural architecture of an example purchasing system

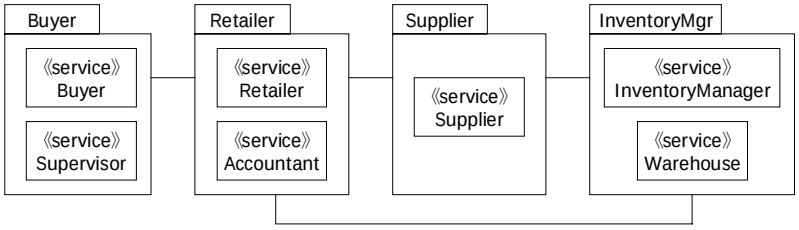

Figure 2. An example UML model

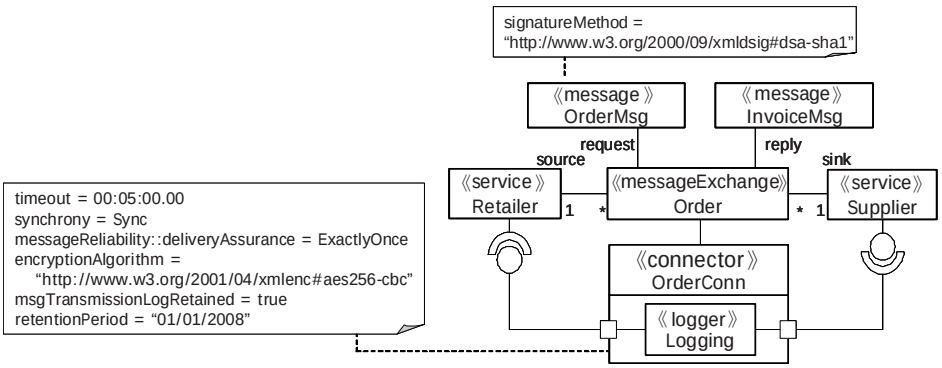


pliers, and inventory managers. All example models in this article focus on and define several particular parts of this system. In this example system, a Buyer purchases a product from a Supplier via Retailer. A Supervisor authorizes each order that a Buyer places. An Accountant performs accounting tasks for a Retailer. An InventoryManager manages a Retailer's inventory.

Figure 2 shows an example model built with the proposed UML profile. This model focuses on an interaction between a Retailer and Supplier in Figure 1, and defines an order processing scenario in which a Retailer places an order and a Supplier issues an invoice. In this example, two services (Retailer and Supplier) exchange messages. Each service is represented by a class stereotyped with <<service>>. These services exchange two types of messages (OrderMsg and InvoiceMsg), each of which is stereotyped with <<message>>. Each message can have multiple tagged-values to specify additional message transmission/processing semantics. In this example, the tagged-value signatureMethod specifies that an OrderMsg carries a digital signature created with DSA (Digital Signature Algorithm). Each pair of a request and reply messages is represented by a class stereotyped with <<messageExchange>>.

<<connector>> represents a connection that transmits messages between services. In this example, messages are delivered through a connector called OrderConn. Every message exchange is bound with a connector in order to specify which connector is used to deliver messages. A connector has a provided interface (represented as a "ball" notation) and a required interface (represented as a "socket" notation) to transmit messages between services. Services use the provided and required interfaces to send and receive messages, respectively. The two interfaces are intended to show how services use (connect with) a connector.

Each connector can have multiple filters inside. They are used to define message transmission/processing semantics in a connector. This example uses a Logger in the OrderConn connector. Logger logs messages that transmitted through the filter (OrderMsg and InvoiceMsg in this example).

Also, each connector can have multiple tagged-values to specify additional message transmission/processing semantics. In this example, OrderConn specifies the timeout of message transmissions (five minutes), the synchrony of message transmissions (synchronous), the assurance level of message delivery (exactly once) and the message encryption algorithm (Advanced Encryption Standard). Also, through the use of tagged-values msgTransmissionLogRetained and retentionPeriod, OrderConn specifies to retain the logs of message transmissions until a certain date.

As shown above, the proposed UML profile provides a visual and intuitive abstraction to model the architectures and non-functional aspects of service-oriented applications.

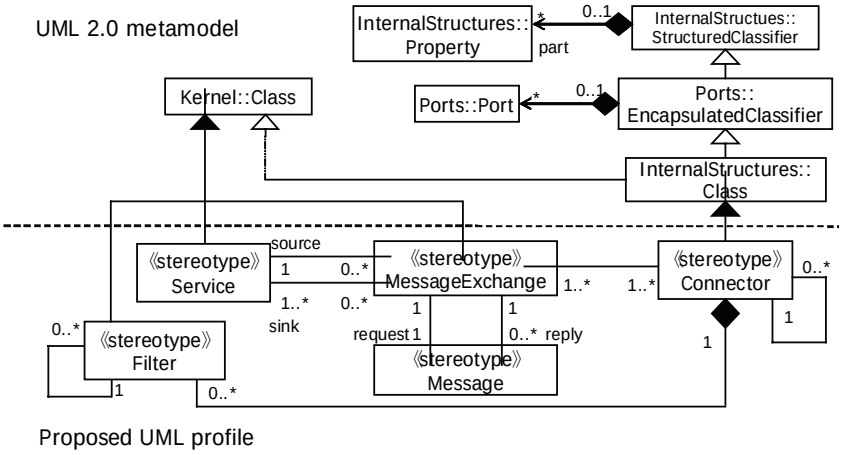
DESIGN OF THE PROPOSED UML PROFILE

The proposed UML profile provides key model elements to specify service-oriented applications: *service*, *message exchange*, *message*, *connector*, and *filter*, each of which is defined as stereotypes (Table 1). Figure 3 shows how the proposed profile defines these stereotypes by extending the UML metamodel. Each stereotype is defined as a metaclass stereotyped with <<stereotype>>[1]. Except Connector, four stereotypes inherit the Class metaclass in the Kernel package of the UML metamodel. Thus, they are applied to classes in user-defined models (see Figure 2). A Service can be a source or sink of each request/reply message. The source and sink are identified with source and sink, roles on two associations between a MessageExchange and Services (Figure 2). Each MessageExchange may have multiple reply messages per request message (Figure 3). Using multiplicity on two associations between a MessageExchange

Table 1. Key model elements (stereotypes) in the proposed UML profile

Stereotype	Description
<<service>>	Represents a service.
<<messageExchange>>	Represents a pair of a request and reply messages. Specifies which services send and receive the messages.
<<message>>	Represents a (request or reply) message.
<<connector>>	Represents a connection between services (i.e., message source and destination). Defines the semantics of message transmission and processing. Specifies which messages (message exchange) to transmit.
<<filter>>	Customizes the semantics of message transmission and message processing in a connector.

Figure 3. Definition of stereotypes



and `Services`, `MessageExchange` can indicate one-to-one (unicast) and one-to-many (multicast or manycast) message exchanges. For example, Figure 2 shows a one-to-one message exchange between a `Retailer` and a `Supplier`.

`Connector` is a stereotype extending the `Class` metaclass in the `InternalStructures` package of the UML metamodel (Figure 3). This metaclass defines a composite class, a special type of class, which can contain other model elements (e.g., inner classes)[2] and have `Ports` to specify how internal model elements interact with external elements. In the proposed UML profile, a `Connector` can contain `Filters` to specify the semantics of message transmission and message processing. The `Ports` connected with a `Connector` identify the `Messages` it receives and sends out, using association roles `input` and `output`. For example,

Figure 2 shows the `OrderConn` connector , which contains a filter (a `Logger`). This filter receives, records message's log, and sends out `OrderMsg` or `InvoiceMsg` messages.

Connector

`Connector` has 10 tagged-values (Figure 4). `timeout` is a mandatory tagged-value to specify the timeout period (in millisecond) in which a connector needs to deliver each message. If a message is not delivered to its destination (sink) within the timeout period, a connector discards the message. In Figure 2, the timeout period of the connector `OrderConn` is specified as five minutes.

`synchrony` is a mandatory tagged-value to specify the synchrony semantics of message transmissions between a message source and destination. Synchronous, asynchronous and oneway non-blocking semantics are defined as an enumeration in `Synchrony` (Figure 4), and each connector chooses one of them. In Figure 2, a `Retailer` and a `Supplier` exchange `OrderMsg` and `InvoiceMsg` messages synchronously.

`priority` is a mandatory tagged-value to specify the priority of each message that a connector delivers. The range of `priority` is from 0 to 255 (0 is the lowest and 255 is the highest), and the default value is 0 (Figure 4).

`inOrder` is a mandatory tagged-value to specify whether the order of messages that a service (message destination) receives is same as the order of messages that the other service (message source) sends out. The default value of `inOrder` is false.

`deliveryAssurance` is an optional tagged-value to specify the assurance level of message delivery. Three different semantics are defined as an enumeration in `DeliveryAssurance` (Figure 4), and each `Connector` chooses one of them at a time. `AtLeastOnce` means that a connector retries delivering a message until its destination receives the message. (A message retransmission is triggered with the `timeout` tagged-value.) However, the message may be delivered to its destination more than once. `AtMostOnce` means that a connector discards a message if the message has already been delivered to its destination; however, there is no guarantee of message delivery. `ExactlyOnce` satisfies the requirements of the above both semantics. It guarantees that a connector delivers a message to its destination without duplications. When `inOrder` is true, `ExactlyOnce` is implicitly (automatically) set to `deliveryAssurance` because duplicated or missing messages violate the `inOrder` semantics.

Figure 5 shows an example model using `inOrder` and `deliveryAssurance`. This example illustrates an extension to an order processing

Figure 4. Tagged-values of connector

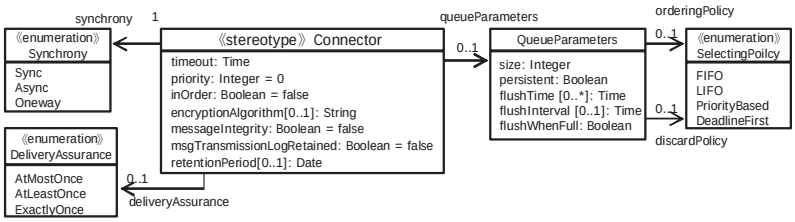


Figure 5. An example of inorder and delivery assurance

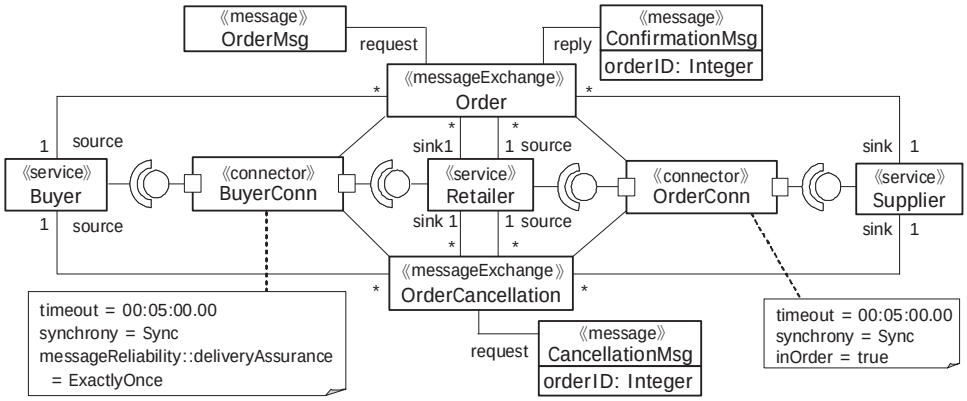

application in Figure 2. In this example, a Buyer transmits an `OrderMsg` to a `Supplier` via `Retailer` (see also Figure 1). After a `Retailer` forwards an `OrderMsg` from a Buyer to a `Supplier`, the `Buyer` can cancel the order by transmitting a `CancellationMsg` to the `Retailer`, and in turn, to the `Supplier`. In this example, the order of message transmissions is important between `Retailer` and `Supplier` because an order must be delivered to a `Supplier` before a corresponding order cancellation. Therefore, the `inOrder` semantics is assigned to the `OrderConn` connector. This semantics implicitly assigns `ExactlyOnce` to the `deliveryAssuarance` semantics in the `OrderConn` connector.

`encryptionAlgorithm` is an optional tagged-value used for transport-level encryption in a connector. This tagged-value defines an algorithm to secure a connection upon which request and response messages are transmitted. (See Figure 2 for an example.) The encryption algorithm is specified as a URI defined in the XML Encryption specification (World Wide Web Consortium, 2002). For example Triple DES is represented with `http://www.w3.org/2001/04/xmlenc#tripledes-cbc`, and AES-256 (Advanced Encryption Standard) is represented with `http://www.w3.org/2001/04/xmlenc#aes256-cbc`.

`queueParameters` is an optional tagged-value to deploy a message queue between services (i.e., message source and destination) and specify the semantics of message queuing between them. `size` specifies the maximum number of queued messages. `flushWhenFull` specifies whether queued messages are flushed from a queue to their destinations when the queue overflows. When `flushWhenFull` is false, the overflowing queue discards a message according to `discardPolicy` (Figure 4); discarding the oldest message (First-In-First-Out), the newest message (Last-In-First-Out), the lowest priority message or the closest deadline message. These four policies are defined as an enumeration in `SelectionPolicy` (Figure 4). `flushTime` and `flushInterval` specify when and how often a queue flushes messages, respectively. `orderingPolicy` specifies how to order messages in a queue: FIFO, LIFO, highest-priority-first or earliest-deadline-first. `persistent` specifies

whether a queue stores messages in a storage (e.g., a file or database) so that the queue can recover them when it crashes unexpectedly.

Figure 6 shows an example using `queueParameters`. It illustrates an inventory management application for retailers (see also Figure 1). Each `Retailer` transmits an `OrderMsg` to an `InventoryManager` when it has no or few products in stock. The `InventoryManager` receives `OrderMsg`s from multiple `Retailers` every two hours in a batch manner. The `OrderConn` connector implements a synchronous queue that stores and forwards

Figure 6. An example of queue

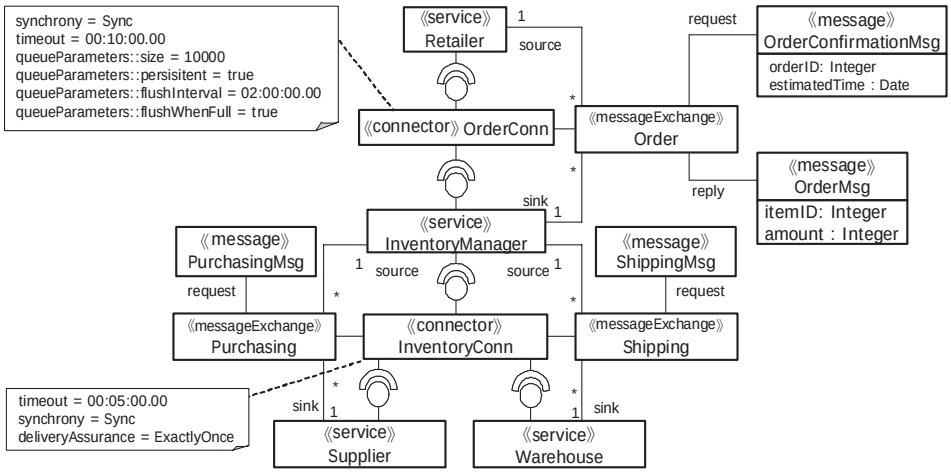

Figure 7. An example model for regulatory compliance

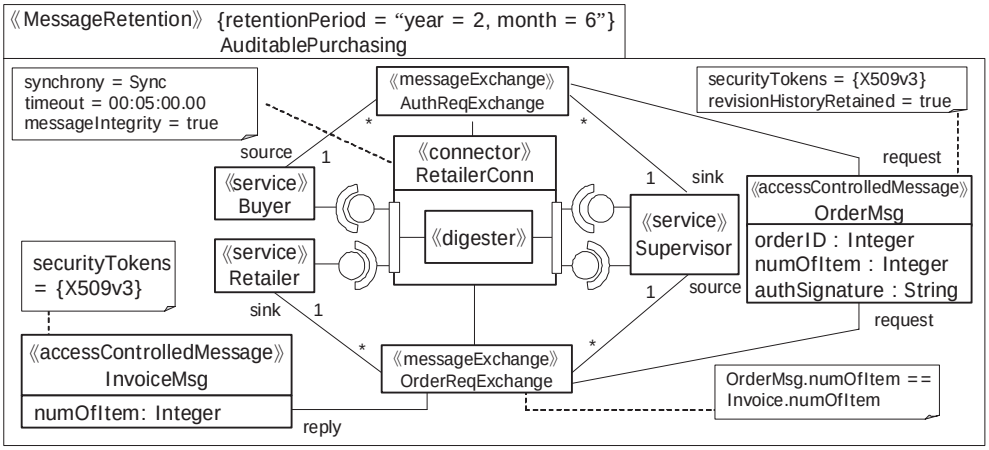

OrderMsgs. The InventoryManager schedules which warehouses deliver which products to which retail stores (every two hours), and based on the shipping schedule, sends ShippingMsgs to Warehouses. If a warehouse has a small inventory of a particular product, the InventoryManager orders the product by sending a PurchasingMsg to a Supplier.

msgTransmissionLogRetained is a mandatory tagged-value to specify whether to retain logs on message transmissions (see Figure 2 for an example). Regulatory mandates require applications to retain the logs and make them auditable for the third party organizations in the future. A connector with this tagged-value records (1) which messages are transmitted, (2) message source and destination (services), and (3) when the messages are transmitted. If msgTransmissionLogRetained is true, retentionPeriod must be specified to define the period to retain each message transmission log. The default value of msgTransmissionLogRetained is false. If it is false, retentionPeriod is ignored.

messageIntegrity is a mandatory tagged-value to specify whether to ensure the message integrity. The default value of messageIntegrity is false. A connector with this tagged-value checks whether messages are changed during their transmission.

Figure 7 illustrates an order processing application in which a Buyer places an order and a Retailer receives it via authorization by a Supervisor. By assigning a signature to the authSignature data field of an OrderMsg, Supervisor authorizes the message (order). Services are connected through a connector with the messageIntegrity semantics. This semantics ensures that OrderMsg messages are not altered during their transmission, and eliminates the possibility of malicious alteration.

A package stereotyped with <<messageRetention>> specifies that contained connectors have the msgTransmissionLogRetained semantics implicitly if the connectors omit it (Figure 7). Each connector follows the retentionPeriod specified in the package. When a connector specifies msgTransmissionLogRetained and retentionPeriod explicitly, they override the retentionPeriod specified in a package. Also, a package stereotyped with <<messageRetention>> enforces contained services and messages to log their message transmissions. Connectors, services, and messages retain their logs independently, and the third party organizations can discover fraud activities by checking the inconsistencies between their logs.

Application developers can specify constraints using the Object Constraint Language (OCL). Constraints are used to ensure the consistency among application data and check whether services work correctly. For example, in Figure 7, OrderReqExchange has a constraint that ensures the number of items in an order (OrderMsg) and a corresponding invoice (InvoiceMsg) are always equal. When this constraint is violated, fraud activities could be committed.

Filter

This article describes eight of the filters that the proposed UML profile defines. Filters are defined as stereotypes extending the Filter stereotype (Figure 8). New filters can be defined as its subclasses. This section shows six filters to specify message transmission semantics and two filters to specify message processing semantics.

The stereotypes Multicast, Manycast, Anycast, Router, Logger, and Digester are used to define the message transmission semantics in a connector. A Multicast filter receives a request message from its source and transmits it to multiple destinations (services) simultaneously (one-to-many message exchange). A group of destinations can contain different types of services. When the Multicast filter receives reply messages from the destinations, it sends them back to the source of the request message. Multicast is used to improve the efficiency of message transmissions.

Figure 9 shows an example that models an application for wholesale price notification using `Multicast`. A `Retailer` subscribes for the price changes of a particular supply, and a `Supplier` notifies (or publishes) any price changes to the `Retailer`. A `Retailer` transmits a `Subscription` message to a `Supplier` in a synchronous and exactly-once manner. A `Supplier` multicasts a `PriceNotificationMsg` message, which contains a supply's GTIN (Global Trade Item Number)[3] and price, to multiple `Retailers` in asynchronous and at-most-once semantics.

`Manycast` is used to improve fault tolerance by forwarding a request message to a group of replicated destinations (i.e., to the same type of services). The tagged-value `groupSize` specifies how many services are deployed as a group. `standby` specifies the operation of replicated services: *hot standby*, *warm standby*, or *cold standby*. In hot standby, all services in a group remain active to receive request messages. A `Manycast` filter sends a message to all services in a group. `Manycast` returns only one reply message to the source of a request message, out of multiple replies from

Figure 8. Tagged-values of filters

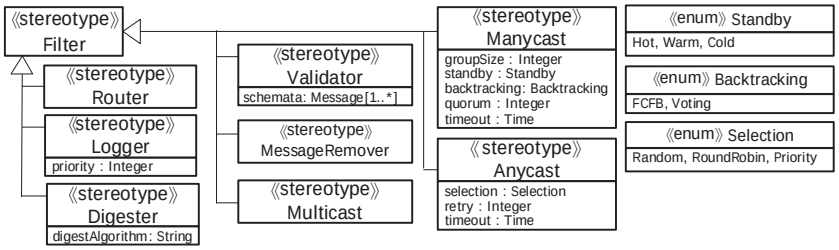

Figure 9. An example of multicast

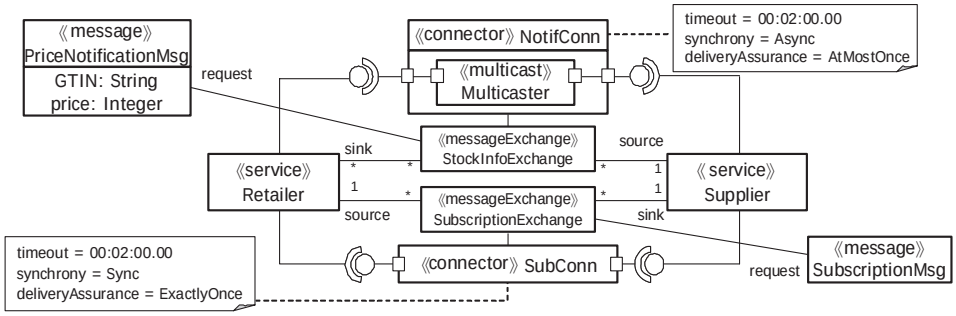

services. `backtracking` defines two policies to decide which reply message to be returned. When `FCFB` (first-come-first-backtracked) is selected, a `Manycast` filter returns the first reply that it receives from destination services. When `Voting` is selected, the `Manycast` filter performs a voting process. It counts the number of reply messages and inspects their contents. If the number of replies that have the same content reaches `quorum`, the `Manycast` filter returns one of the replies. If the number does not reach `quorum` within `timeout`, the `Manycast` filter returns the reply that generates the highest voting count.

In warm standby, all services in a group remain active to receive request messages. A `Manycast` filter sends a message to all services in a group, but only one service returns a reply. In this case, `backtracking` is not used. In cold standby, only one service in a group is active, and a `Manycast` filter sends a message to the service. If the service does not respond within `timeout`, the filter activates another service in the group and sends a message to the service. In cold standby, `backtracking` is not used.

In an example model shown in Figure 10, a supplier sends an inquiry to a cluster of transaction record servers to obtain a transaction record containing a set of orders. A manycast filter, `Replicator`, is used in the connection `RecordConn`. The filter intercepts each `Inquiry` (request) message and sends it to three replicated instances of `TransactionRecServer`, which is maintained with the hot standby policy. `Replicator` returns a `TransactionRecordMsg` (reply message) to a `Supplier` on FCFB basis.

`Anycast` is a variation of the hot standby policy in `Manycast`. It forwards a request message to only one destination in a group of replicated services. This filter is used to balance workload placed on services. `selection` defines how to choose a destination from multiple services; randomly, on round robin or on destination's priority basis (the service with the highest priority in a group is selected). If an `Anycast` filter fails to deliver a request message within `timeout`, it retries to forward the request message. `retry` specifies the maximum number of retries. If the `Anycast` filter fails the maximum number of retries, it returns an error message to the source of the request message.

Figure 11 shows an example model describing a content delivery system, for example, for delivering contents among supplier's online catalogs of their supplies. (For simplicity, tagged-values of the connector `RedirectionConn` and

Figure 10. An example of manycast

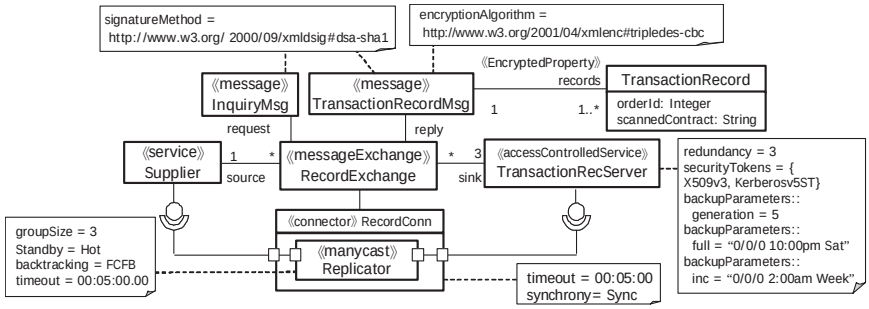

Figure 11. An example of anycast

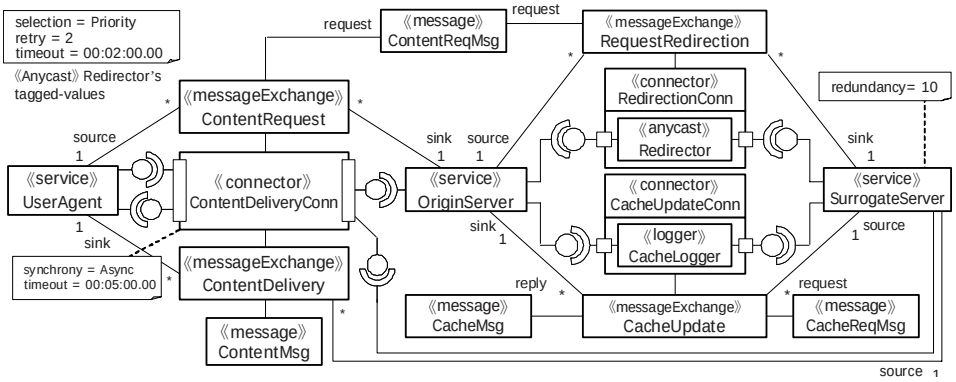


`CacheUpdateConn` are omitted, but both have the synchronous semantics and their timeout is five minutes.) A user agent (`UserAgent`) sends a request (`ContentReqMsg`) to a content server (`OriginServer`) through a connector (`ContentDeliveryConn`). To balance workload, the content server redirects the request to a surrogate server (`SurrogateServer`). This model has a cluster of surrogate servers which consists of 10 replica servers. An `Anycast` filter in the connector `RedirectionConn` selects one of servers on their priority basis and redirects a request to it. (tagged-values of the `Anycast` filter is described on the upper left corner.) If a surrogate server does not have data to process a request, it sends a request (`CacheReqMsg`) to a content server to obtain cache data (`CacheMsg`). After processing a request, a surrogate server returns content (`ContentMsg`) to a user agent.

`Router` routes an incoming message to one or more destinations with certain criteria. Since UML does not provide a means to define rules, the proposed profile has no facility to specify routing rules at design time. Supporting tools transform a `Router` to a skeleton source code (e.g., in Java) or a rule description (e.g., in XPath) that performs message routing. Developers are expected to complete the skeleton code/description.

`Logger` records the transmission of each message whose priority value is higher than `priority`. When `priority` is omitted, all message transmissions are recorded.

`Digester` records digest values of all messages. This filter can be used to check whether a message is altered after its transmission. The digest algorithm is specified as a URI defined in the XML Encryption specification (The World Wide Web Consortium, 2002a). For example, `http://www.w3.org/2000/09/xmldsig#sha1` specifies SHA-1.

In addition to the stereotypes for message transmission semantics, the proposed UML profile provides two other stereotypes to define the message processing semantics in each connector: `Validator` and `MessageRemover` (Figure 8). `Validator` and `MessageRemover` validate incoming messages against the message schema specified in its tagged-value `schemaURI` and a given criteria (e.g., rules specifying valid data ranges) respectively, and transmit only validated messages. Since UML does not provide a means to define rules, the proposed profile has

no facility to specify message filtering rules for `MessageRemover` at design time. Supporting tools transform a `Validator` and `MessageRemover` to a skeleton source code (e.g., in Java) or a rule description (e.g., in XPath) that performs message filtering. Developers are expected to complete the skeleton code/description. When a connector is encrypted with `encryptionParameter`, `Validator` and `MessageRemover` in the connector cannot validate messages (all messages are transmitted to their destinations.)

Service

`Service` has six tagged-values (Figure 12). `timeout` is an optional tagged-value to specify the timeout period (in millisecond) of each message that a service issues. If a message is not delivered to its destination within this time period, a connector discards the message.

`priority` is an optional tagged-value to specify the priority of each message that a service issues. `Anycast` filter uses `priority` to select its destinations. Also, it is used to order messages in a message queue when a connector has `queueParameters`.

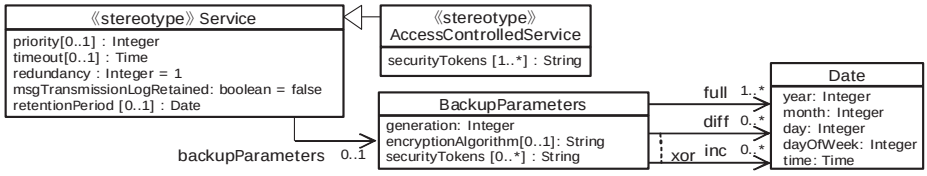
Each service is expected to have data fields corresponding to the `priority` and `timeout` tagged-values. Usually, class instances cannot read and write tagged-values because tagged-values are defined in a metamodel (see Figure 3) and used in a model. The data fields allow different class instances to have different tagged-values, and tagged-values specified in a model behave as default values of corresponding data fields.

`redundancy` is an optional tagged-value to specify the number of runtime instances of a service. This tagged-value must be specified when a service is accessed by `Manycast` or `Anycast` filters. In Figure 10, three instances of `TransactionRecServer` are used for fault tolerance with the manycast filter `Replicator`.

Same as a connector, a service with `msgTransmissionLogRetained` and `retentionPeriod` records information on its message transmissions. A package stereotyped with `<<messageRetention>>` specifies that enclosed services have the `msgTransmissionLogRetained` semantics implicitly if the services omit it (Figure 7). When a service specifies `msgTransmissionLogRetained` and `retentionPeriod` explicitly, they can overrides package's ones.

`backupParameters` is an optional tagged-value to specify service's backup policy. `full`, `diff`, and `inc` specify the time when full, differential, and incremental backups is performed respectively. The class `Calendar` can specify a specific time in point and a repetition time. For example, when `year` is omitted (value zero means omission), the backup is performed every year (the date and time to perform a backup is specified by other data fields in `Calendar`). Full backup stores all

Figure 12. Tagged-value of service



data in a service, differential backup stores all data which have been modified since the last full backup, and incremental backup stores all data which have been modified since the last full or incremental backup. Differential backup requires much amount of storage and longer time to perform than incremental backup, but it can restore data faster. Also, data redundancy in differential backup reduces the risk of data loss. Differential and incremental backups must be used with full backup, and full backup must be performed at least once before differential or incremental backups are performed. One backup policy can have either differential or incremental backup at a time (xor). If `diff` and `inc` are omitted, only full backup is performed. `generation` specifies the number of full backups retained in a storage. `encryptionAlgorithm` specifies an algorithm to secure backup data. `encryptionAlgorithm` specifies an algorithm to secure backup data. `securityTokens` specifies security tokens for the purpose of authentication (see below). In Figure 10, the service `TransactionRecServer` has a backup policy. The backup policy specifies the generation (five), the time when full and incremental backup are performed (10:00pm on every Saturday and 2:00am on week days respectively).

`AccessControlledService` is a stereotype extending the stereotype `Service` (Figure 12). It is a special type of service that enforces an access control policy. The tagged-value `securityTokens` is mandatory to specify security tokens (or certificates). The security tokens are used to authenticate entities (e.g., services) that access a message. This tagged-value can contain multiple values in order of precedence. The values use the names defined in the WS-SecurityPolicy specification (Organization for the Advancement of Structured Information Standards, 2005). In Figure 10, `TransactionRecServers` control accesses from `Supplier`s using X.509 certificates or Kerberos tickets. Since UML does not provide a good means to describe policies (or rules), the proposed UML profile does not define how to specify access control policies. `<<accessControlledService>>` is used only for indicating a service implements a certain access policy. A supporting tool transforms an `AccessControlledService` to a skeleton program code or an access control description in accordance with an implementation technology that an application designer chooses. Application developers are required to complete implementing access control policies.

In addition to the general type of service, the proposed UML profile provides three special types of services, `MessageConverter`, `MessageSplitter`, `MessageAggregator`, to define the message processing semantics. They inherit the `Service` stereotype.

`MessageConverter` converts an incoming message with a given rule. Similar to `Router`, supporting tools transform a `MessageConverter` to a skeleton source code or rule description (e.g., in XSLT) that performs message conversions, and developers complete the skeleton code/description.

`MessageSplitter` divides an incoming message into multiple fragments with a certain rule. Similar to `MessageConverter`, supporting tools transform a `MessageSplitter` to a skeleton code or rule description that performs message split, and developers complete the skeleton. In an example model shown in Figure 13, a `Retailer` sends an order message (`OrderMsg`) to a `MessageSplitter`, and the splitter divides the message into two fragments (`PurchasingMsg` and `AccountingMsg`), and sends them to different destinations (`Supplier` and `Accountant`). The destinations directly returns reply messages (`PurchasingConf` and `AccountingConf`) to the `Retailer`. The connector `OrderConn` encrypts all messages with Triple DES. Also, the message `OrderMsg` retains routing information, which includes source of a message. (i.e., it is auditable which customer sends which message.)

`MessageAggregator` combines multiple incoming messages. Figure 14 shows an example extending the model in Figure 2. In addition to `OrderMsg`, `Retailer` sends a message `AuthReqMsg`

Figure 13. An example of messagesplitter

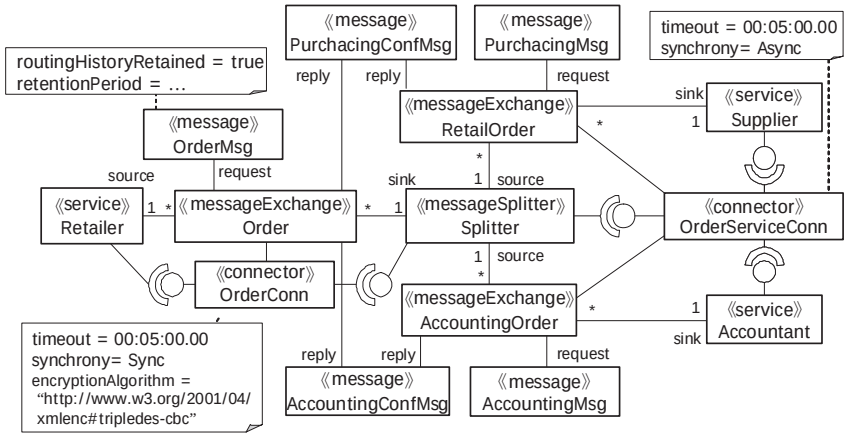


Figure 14. An example of messageaggregator

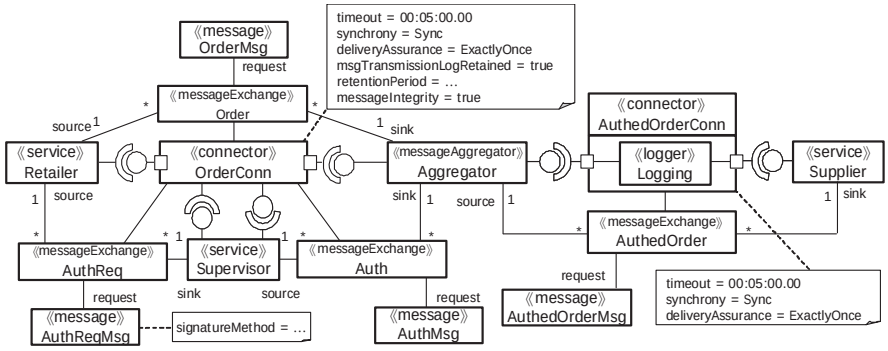


to ask the service `Supervisor` to authorize the order. `Aggregator` synchronizes and combines `OrderMsg` and `AuthMsg` (an authorization message from `Supervisors`), and it sends new message `AuthedOrderMsg` to `Supplier`. The connector `OrderConn` retains logs on message exchanges between `Buyer`, `Supervisor`, and `Aggregator`. It makes logs on order and authorization process auditable. Also, `OrderConn` ensure the integrity of messages.

Message

Message has seven tagged-values (Figure 15). schemaURI is a mandatory tagged-value to identify the schema of a message. The default value of schemaURI is message's qualified name (a combination of a package name and message's name).

priority and timeout are optional tagged-values to specify the priority and timeout period of messages. Connector has timeout, and Service also has those two tagged-values. The precedence is that Message's tagged-values override Service's ones, and Service's tagged-values override Connector's ones. Same as Service, each message is expected to have data fields corresponding to the priority and timeout tagged-values, and different message instance can have different priority and timeout.

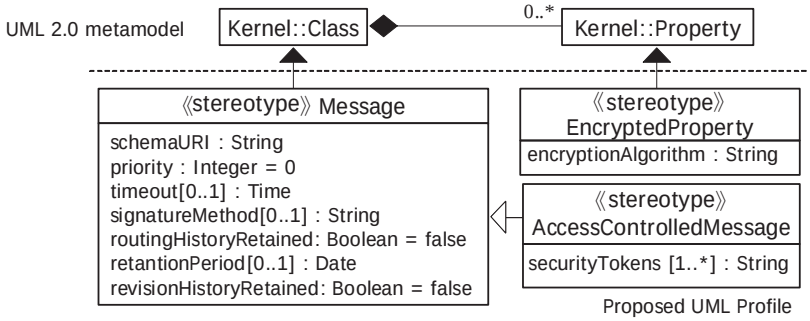
signatureMethod is used an optional tagged-value to ensure the integrity of a message. It specifies an algorithm for generating the message's digital signature. The algorithm is represented with a URI defined in the XML Signature specification (The World Wide Web Consortium, 2002b). For example, DSA (Digital Signature Algorithm) is represented with http://www.w3.org/2000/09/xmldsig#dsa-sha1. In Figure 10, each Inquiry and TransactionRecord message is signed with DSA. When signatureMethod is specified, each message is expected to maintain its signature in a data field called signature.

Same as a connector, a message with routingHistoryRetained and retentionPeriod records information on its message transmissions. A package stereotyped with <<messageRetention>> specifies that enclosed messages have the routingHistoryRetained semantics implicitly if the services omit it (Figure 7). When a message specifies routingHistoryRetained and retentionPeriod explicitly, they can overrides package ones.

revisionHistoryRetained is an optional tagged-value to specify whether to retain message's revision history (Figure 7). It makes the revision history to auditable in the future. A message with this semantics records 1) which data fields are revised, 2) how they revised (i.e., newly created, replaced, or deleted), 3) when they revised, and 4) who revised them. The tagged-value retentionPeriod is used to specify the period to retain the history. A package stereotyped with <<messageRetention>> specifies that enclosed messages have the revisionHistoryRetained semantics implicitly

The stereotype EncryptedProperty is used for message-level (end-to-end) encryption. It is

Figure 15. Tagged-values of message



defined as a stereotype extending `Property` in the UML metamodel (Figure 15). This stereotype is attached to data fields to be encrypted in a message. `EncryptedProperty` has a tagged-value, `encryptionAlgorithm`, to specify an algorithm used to encrypt a message. The semantics of this tagged-value is same as that of `encryptionAlgorithm` in `Connector`. An encryption algorithm is specified as a URI that the XML Encryption specification defines (World Wide Web Consortium, 2002a). Different data fields in a message can be encrypted with different encryption algorithms. In Figure 10, `orders` in `TransactionRecordMsg` are encrypted with Triple DES, which is represented with `http://www.w3.org/2001/04/xmlenc#tripledes-cbc`.

`AccessControlledMessage` is a stereotype extending `Message` (Figure 15). Similar to `AccessControlledService` it is a special type of message that enforces an access control policy. It removes the possibility of unauthorized accesses (i.e., altering messages by unauthorized users) and accidental altering (i.e. altering messages mistakenly by authorized users). The tagged-value `securityTokens` must be specified in `AccessControlledMessage` for the purpose of authentication. Since UML does not provide a good means to describe policies (or rules), the proposed UML profile does not define how to specify access control policies. `AccessControlledMessage` is used to indicate a message implements a certain access policy. A supporting tool transforms an `AccessControlledMessage` to a skeleton program code or an access control description in accordance with an implementation technology that an application developer chooses. Application developers are required to complete implementing access control policies.

APPLICATION DEVELOPMENT WITH THE PROPOSED MDD FRAMEWORK

This section describes a model-driven development (MDD) tool, called Ark, which accepts a UML model designed with the proposed UML profile and transforms the model into a skeleton of application code (program code and deployment descriptor). Currently, Ark implements transformations between the proposed UML profile and three middleware technologies: Mule ESB[4], ServiceMix ESB[5] and GridFTP[6] (Figure 16). UML models in this work are maintained with the metameta model of the Eclipse Modeling Framework (EMF; http://www.eclipse.org/emf/). The proposed UML profile is defined as an extension to the UML metamodel. Each application designer gives his/her UML model to Ark, and instructs Ark which transformation to use for generating skeleton application code.

Figure 17 shows the development process using Ark. (This figure assumes that generated application code uses Mule ESB.) Application designers define application models using the proposed UML profile (e.g., an example model in Figures 2). Ark Transformer, one of the components in Ark, takes the application models in the format of XML Metadata Interchange (XMI) and transforms the input models into application code compliant with Mule ESB.

Ark has been tested with MagicDraw[7], a visual UML modeling tool that can serialize UML models to XMI (Figure 18). Ark Transformer is implemented based on openArchitectureWare[8], a model transformation engine. Each input UML model (XMI file) is validated against the UML standard metamodel and the proposed profile's metamodel (see Figure 3), and transformed to application code for Mule ESB (Java programs and deployment descriptors in XML). A transformation rule between UML models and application

Figure 16. The Architecture of Ark

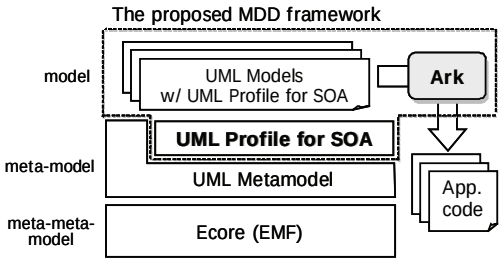


Figure 17. Application development with Ark

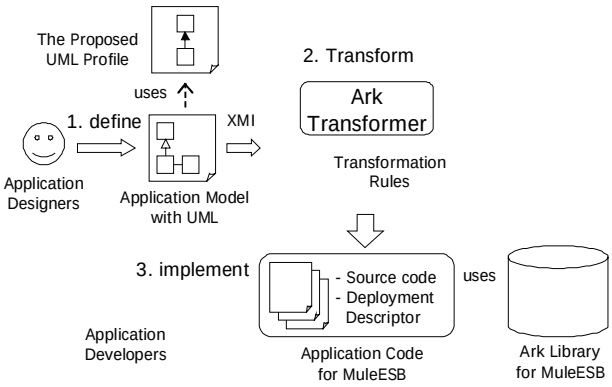

Figure 18. A UML model in magicdraw

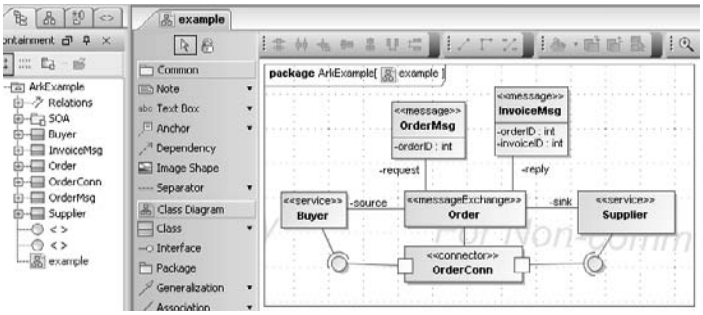


code is implemented as a set of transformation templates, which define how to transform UML model elements to program elements in application code.

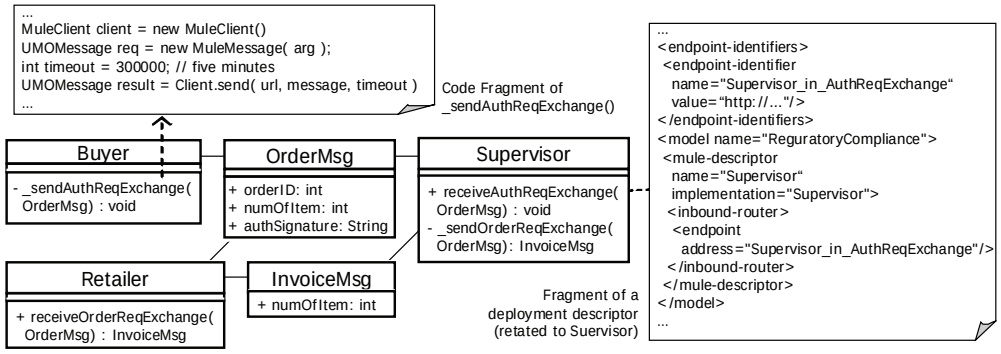
Transformation Rules for ESB Applications

Figure 19 shows some of the Java classes and deployment descriptors that Ark generates from the UML model in Figure 7 when Mule ESB is selected as middleware to operate applications. Table 2 shows the transformation between model elements in the proposed UML profile and program elements in Mule ESB. Ark transforms a UML class stereotyped with `<<message>>` to a Java class that has the same class name and the same data fields. The Java class implements the interface `Serializable`. This is required to implement messages exchanged with Mule ESB.

A UML class stereotyped with `<<service>>` is transformed to a Java class that has the same class name and the same data fields. Ark inserts several operations to the Java class, depending on whether its association role is `source` or `sink` against a message exchange. The operations are used to send and receive messages: `_sendX()` to send messages where X references the name of a message exchange, and `receiveX()` to receive messages. For example, in Figure 19, `Supervisor` has `_sendOrderReqExchange()` and `receiveAuthReqExchange()` to send and receive `OrderMsg` messages to `Supplier` and from `Retailer` respectively. `_sendX()` is supposed to be invoked by methods in the same service class. (This is why its visibility is private.) `receiveX()` is called by source services that have messages to deliver. A fragment of a deployment descriptor in Figure 19 specifies the URL of `Supervisor`. `<endpoint-identifier>` specifies a name of an end point (`name`) and its URL (`value`), e.g., when a service is deployed to be accessed via HTTP, `value` is `http://...`. `<mule-descriptor>` specifies the implementation (`implementation`) of a service (`name`), and `<inbound-router>` specifies the URL of a service by referencing an end point.

A template fragment of this transformation rule is shown below. `<<service.name>>` in the template represents the name of a UML class stereotyped with `<<service>>`. (Note that the variables and keywords in a transformation rule are embraced with << and >>.) `<<messageExchange.name>>` references the name of an UML class stereotyped with `<<messageExchange>>`. `<<requestMessage.name>>` and `<<replyMessage.`

Figure 19. Generated code for mule ESB



name>> represent the names a request and reply messages, respectively. Ark replaces each variable in a transformation template with the name of a UML model element (e.g., class name), and generates Java code. When a service transmits multiple pairs of request and reply messages, Ark generates corresponding sets of _ sendX( ) and receiveX( ). <<sinkID>> represents the logical name of a destination service. Each pair of a logical service name and its access point is specified in a deployment descriptor. For example, if a service is deployed to be accessed via HTTP, its access point starts with http://.

Table 2. Transformation between the proposed UML profile and mule ESB

Model Element in the Proposed UML Profile	Program Element in Mule ESB
<<service>> <<accessControlledService>>	A Java class with the same name.
securityTokens	A security filter implemented in Ark library
<<message>>	A Java class implementing Serializable interface
signatureMethod	A security filter implemented in Ark library
<<encryptedProperty>>	A property in a corresponding Java class
encryptionAlgorithm	A message transformer implemented in Ark library
<<messageExchange>>	Methods to send/receive messages
sink (Service's role)	Service's operations sending messages.
source (Service's role)	Service's operations receiving messages.
<<connector>>	A set of entities in a deployment descriptor
timeout	An operation's parameter to specify message's timeout period
synchrony	Different types of Mule ESB's operation used to send a message.
deliveryAssurance	A filter implemented in Ark library
queueParameters	JMS parameters specified in a deployment descriptor
encryptionAlgorithm	A message transformer implemented in Ark library
msgTransmissionLogRetained	A message transformer implemented in Ark library
routingHistoryRetained	A message transformer implemented in Ark library
messageIntegrity	A message transformer implemented in Ark library
<<messageAggregator>>	A class implementing AbstractEventAggregator in Mule ESB
<<messageConverter>>	A class implementing DefaultTransformer in Mule ESB
<<messageSplitter>>	A class implementing AbstractMessageSplitter in Mule ESB
<<logger>> <<messageFilter>> <<router>> <<validator>>	Filters provided by Mule ESB
<<multicast>>	A filter implemented in Ark library
<<manycast>>	A filter implemented in Ark library
<<anycast>>	A filter implemented in Ark library

```
public class <<service.name>> {
    private void
    _ send<<messageExchange.name>>(
  <<requestMessage.name>> request){
   MuleClient muleClient =
       new MuleClient();
    String endpointName =
    <<sinkID>>;
     UMOEndpoint url =
       MuleManager.
        getInstance().
        lookupEndpoint(
            endpointName );
    int timeout =
    <<connector.timeout>>000;
    <<IF connector.synchrony
        == Sync>>
    UMOMessage result =
        muleClient.send(
        url, message, timeout );
  <<ELSEIF connector.synchrony
          == Oneway>>
    // generating code for
    //an oneway call
    <<ELSE>>
    // generating code for
    //an asynchronous call
    <<ENDIF>>
    }

    public void
    receive<<messageExchange.name>>(
        <<replyMessage.name>>reply){
    }
}
```

UML classes stereotyped with `<<messageExchange>>` and `<<connector>>` are not transformed to particular Java classes. The message transmission/processing semantics specified in a UML model is implemented in Java classes of message sender and destination. For example, in Figure 7, a `Buyer` sends an `OrderMsg` message to a `Supervisor` synchronously. Therefore, Ark generates a Java code to send the message synchronously using Mule ESB's API[9], and embeds the code in `_sendAuthReqExchange()` of `Buyer`. `<<connector.synchrony>>` in the above transformation template references the synchrony of a connector, and Ark interprets it to generate Java code to send messages to a destination service. (`<<IF>>`, `<<ELSEIF>>` and `<<ENDIF>>` are the reserved keywords for branching statements.) Ark also generates Java code to handle timeout using Mule ESB's API (`<<connector.timeout>>` references the timeout period specified in a UML model.), and embeds the code in `_sendAuthReqExchange()` of `Buyer` (see also Figure 19).

As Figure 7 shows, a connector has the `messageIntegrity` semantics. To support this semantics, Ark provides a pair of message transformers to generate and verify a message's hash value. (These transformers are implemented as a part of Ark Library; see Figure 19.) In Mule ESB, each service can have an arbitrary number of message transformers as the classes implementing the interface `org.mule.transformer.UMOTransformer`. Message transformers are invoked (or hooked) when a service sends/receives a message. At a message source, a transformer (`edu.umb.cs.MessageIntegrityGenerator`) generates a message's hash value and embeds it into the message's header. At a message sink, a transformer (`edu.umb.cs.MessageIntegrityVerifier`) verifies the message's integrity using the hash value. Ark Library also implements the `msgTrasmissionLogRetained` and `routingHistoryRetained` semantics as message transformers `edu.cs.umb.TransmissionLogger` and `edu.cs.umb.RoutingHistoryLogger`).

When a UML model specifies a connector as a message queue, Ark generates application code that uses Java Message Service (JMS) because Mule ESB supports message queues through the use of JMS. For example, in Figure 6, `OrderConn` is specified as a message queue. Ark generates a corresponding deployment descriptor to configure

and establish JMS connector that exchanges `OrderMsg` and `OrderConfirmationMsg` between `Retailer` and `InventoryManager`.

When a UML model uses the `MessageSplitter` or `MessageAggregator` filter (e.g., Figures 14 and 15), Ark generates application code that uses corresponding class in Ark Library. Corresponding to `MessageSplitter`, Ark generates a class implementing the interface `org.mule.routing.outbound.AbstractMessageSplitter`. In Mule ESB, the implementation class can be attached to arbitrary services in order to split an outgoing message into fragments and route them to different services. When Ark transforms a UML model in Figure 14, the implementation class is attached to a `Retailer` for intercepting an `OrderMsg` message from the `Retailer` and spliting it to a `PurchasingMsg` and `AccountingMsg`.

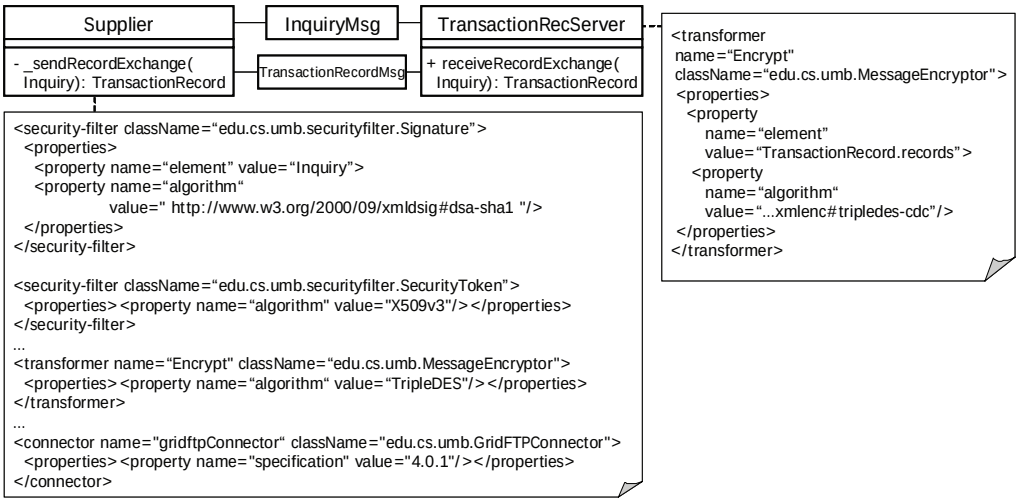
Similarly, corresponding to `MessageAggregator`, Ark generates a class implementing the interface `org.mule.routing.outbound.AbstractEventAggregator`. The implementation class can be attached to arbitrary services to aggregate an incoming message into a single message. In order to transform a UML model in Figure 15, Ark attaches the implementation class to a `Supplier` to aggregate a `OrderMsg` and a `AuthMsg` to a `AuthedOrderMsg` and pass the aggregated message to the `Supplier`.

The `Logger`, `MessageFilter`, `Router`, and `Validator` filters are transformed to and implemented with corresponding classes built in Mule ESB. Those classes are attached to services to perform message loging, filtering, routing, and validation functionalities as specified in an input UML model.

Transformation Rules for Secure and Broadband File Transfer Applications

When an application designer chooses GridFTP to operate his/her application, the application is deployed on Mule ESB and configured to use GridFTP as a message transport. Figure 20 shows some of the Java classes and deployment descriptors that Ark generates from a UML model in Figure 10.

Figure 20. Generated code for mule esb and gridFTP



As Figure 10 shows, the data field `records` is encrypted in `TransactionRecordMsg`. Since Mule ESB does not support message-level encryption, Ark Library provides a pair of message transformers to encrypt and decrypt data fields in messages (`edu.cs.umb.MessageEncryptor` and `edu.cs.umb.MessageDecryptor`). Ark generates a deployment descriptor to configure services so that they use those encryption/decryption transformers when they send/receive messages. Figure 20 shows a fragment of generated deployment descriptor for `TransactionRecServer`. It configures `TransactionRecServer` to use a message encryption transformer (`edu.cs.umb.MessageEncryption`) to encrypt the data field `records` in `TransactionRecordMsg` using Triple DES.

As Figure 10 shows, each `InquiryMsg` and `TransactionRecordMsg` message is signed with DSA, and `TransactionRecServer` performs authentication with X.509 or Kerberos. Since Mule ESB does not support DSA signatures and X.509/Kerberos security tokens, Ark Library provides a set of security filters to write/read signatures and security tokens by implementing the interface `org.mule.umo.security.UMOEndpointSecurityFilter`. Similar to message transformers, security filters are invoked when a service sends/receives a message. Ark generates a deployment descriptor that configures services to use the security filters Ark provides. Figure 20 shows a fragment of generated deployment descriptor for `Supplier`. It configures `Supplier` to include a DSA signature and an X.509 security token in each `Inquiry` message using two filters (`edu.cs.umb.securityfilter.Signature` and `edu.cs.umb.securityfilter.SecurityToken`).

In Figure 10, a `TransactionRecordMsg` is expected to contain a huge amount of data (e.g., scanned contract). When this example application uses GridFTP as a message transport to improve its throughput, Ark generates a deployment descriptor that configures `Supplier` and `TransactionRecordServer` to use GridFTP to transmit `InquiryMsg` and `TransactionRecordMsg` messages (Figure 20). Although Mule ESB does not support GridFTP, it provides a plug-in mechanism to implement arbitrary message transports. Ark Library implements a plug-in for GridFTP (`edu.cs.umb.GridFTPConnector`) so that services can use it in Mule ESB.

Extensibility of the Proposed MDD Framework

The proposed MDD framework (i.e., the proposed UML profile and Ark) is designed and implemented extensible. For example, application developers can change the default transformation rules that Ark provides. They can also integrate arbitrary implementation technologies with Ark in addition to currently-supposed three middleware (e.g., other ESBs and databases). These extensions can be made by changing the default set of transformation templates.

Moreover, the proposed MDD framework allows application developers to introduce arbitrary non-functional aspects that it does not support currently. Since the proposed UML profile is built on the UML standard metamodel with the standard extension mechanism (i.e., stereotypes and tagged-values), application developers can add new stereotypes and tagged-values representing their own non-functional aspects. This extension can be made by defining a set of transformation rules for new stereotypes and tagged-values. These newly-defined stereotypes/tagged-values and transformation rules have no effects on existing UML models and Ark itself (e.g., existing transformation rules, Ark Transformer and Ark Library).

Another type of extensibility of the proposed MDD framework is the ability to support arbitrary UML modeling tools. As described earlier, MagicDraw has been used as the default UML modeling tool; however, Ark can accept UML models from any modeling tools that serialize them in XMI. Choices of modeling tools have no effects on existing models and Ark.

EVALUATION

This section evaluates how the proposed MDD framework (i.e., the proposed UML profile and Ark) improves the reusability and maintainability of service-oriented applications. Given its two properties, the proposed MDD framework allows UML models (i.e., non-functional models built with the proposed profile) to be reusable across different implementation technologies. The first property is that the proposed UML profile allows application developers to model non-functional aspects in their applications in an implementation independent manner by abstracting away low-level details of implementation technologies (e.g., ESBs). As the second property, Ark can map a single UML model to different implementation technologies by switching transformation rules, even if those technologies are very different with each other. For example, Ark currently supports very different ESBs as implementation technologies: Mule ESB and ServiceMix ESB; their APIs and deployment descriptor schemata have no compatibility. The following code fragments are Java classes that Ark generates from the `Supervisor` class in Figure 7 to Mule ESB and ServiceMix ESB. In Mule ESB, a service can be implemented as a simple Java class.

```
public class Supervisor {

public void
receiveAuthReqExchange(
 OrderMsg reply){
  //…
 }

private void
_ sendOrderReqExchange(
OrderMsg request){
MuleClient muleClient =
 new MuleClient();
String endpointName = …
UMOEndpoint url = …
Int timeout = …
FutureMessageResult result =
 muleClient.sendAsync(
     url, request, timeout );
}}
```

On the other hand, in ServiceMix ESB, a service is implemented as a class that extends the `ComponentSupport` class and implements the `MessageExchangeListener` interface. Messages are received through the `onMessageExchange` method.

```
public class Supervisor
extends ComponentSupport
implements MessageExchangeLis
 tener {
public void
onMessageExchange(
 MessageExchange exchange)
     throws MessagingException {
     if (exchange.getRole() ==
     Role.CONSUMER) {
    ServiceEndpoint ep =
 exchange.getEndpoint();
    if (ep.getServiceName()
 .getLocalPart()
 .equals(RETAILER)) {
receiveAuthReqExchange(exchange)}}}
private void
receiveAuthReqExchange(
 MessageExchange exchange)
     throws MessagingException {
  // ...
 }

 private void
_ sendOrderReqExchange(
OrderMsg orderMsg){
InOut inout =
 createInOutExchange(
 SUPPLIER, null, null);
  NormalizedMessage msg =
 inout.createMessage();
```

Table 3. Generated program elements and their LOC

Model Elements in the Proposed UML Profile	Program Elements and their LOC in Mule ESB	Program Elements and their LOC in ServiceMix ESB
<<service>> <<accessControlledService>>	A Java class (8) An endpoint identifier in DD (1) A service entry in DD (7)	A Java class (9) A service entry in DD (6)
securityTokens	An in-bound filter in DD (3)	An in-bound filter in DD (3)
<<message>>	A Java class (2)	A Java class (2)
signatureMethod	In-bound and out-bound filters in DD (6)	In-bound and out-bound filters in DD (6)
<<encryptedProperty>>	An attribute in a Java class (1)	An attribute in a Java class (1)
encryptionAlgorithm	In-bound and out-bound filters in DD (6)	In-bound and out-bound filters in DD (10)
<<messageExchange>>	In-bound and out-bound routers in DD (6)	A routing conf. in DD (14)
sink (Service's role)	A method to send in Java (10)	A method to send in Java (10)
source (Service's role)	A method to receive in Java (2)	A method to receive in Java (12)
<<connector>>	No code generated (0)	No code generated (0)
synchrony	Java code in Mule ESB API (1)	Java code in ServiceMIX API (1)
deliveryAssurance	A configuration entry in DD (3)	A configuration entry in DD (6)
queueParameters	A configuration entry in DD (14) A JMS configuration file (20)	A configuration entry in DD (6) JNDI configuration in DD (7) A JMS configuration File (20)
encryptionAlgorithm	In-bound and out-bound filters in DD (6)	In-bound and out-bound filters in DD (10)
msgTransmissionLogRetained	In-bound and out-bound filters in DD (6)	In-bound and out-bound filters in DD (6)
routingHistoryRetained	In-bound and out-bound filters in DD (6)	In-bound and out-bound filters in DD (6)
messageIntegrity	In-bound and out-bound filters in DD (6)	In-bound and out-bound filters in DD (6)
<<messageAggregator>>	A Java class (4) An In-bound filter in DD (3)	A Java class (4) An endpoint conf. in DD (2)
<<messageConverter>>	A Java class (4) An out-bound filter in DD (3)	A Java class (4) An endpoint conf. in DD (2)
<<messageSplitter>>	A Java class (4) An out-bound filter in DD (3)	A Java class (4) An endpoint conf. in DD (2)
<<logger>>	An out-bound filter in DD (3)	An out-bound filter in DD (3)
<<messageFilter>>	An out-bound filter in DD (3)	A filter conf. in DD (7)
<<router>>	An out-bound filter in DD (3)	A routing conf. in DD (7)
<<validator>>	An out-bound filter in DD (3)	An out-bound filter in DD (3)
<<multicast>>	An out-bound filter in DD (3)	A routing conf. in DD (7)
<<manycast>>	An out-bound filter in DD (3)	A routing conf. in DD (7)
<<anycast>>	An out-bound filter in DD (3)	A routing conf. in DD (7)

```
  // ...
  inout.setInMessage(msg);
  sendSync(inout);
}}
```

By making UML models (i.e., non-functional models) reusable across different implementation technologies, the proposed MDD framework allows application developers to reuse or repurpose services without knowing the details of implementation technologies.

Table 3 shows the program elements (Java code and/or deployment descriptors: DD) that Ark generates for Mule ESB and ServiceMix ESB from a single UML model element. Table 3 also shows the lines of code (LOC) of each generated program element. (LOC is shown in parentheses.) As this figure illustrates, a single model element represents multiple program elements in the proposed MDD framework. For example, `queueParamters` represents 34 LOC in Mule ESB and 33 LOC in ServiceMix ESB. This contributes to improve the maintainability of service-oriented applications by freeing application developers from manually and carefully dealing with many lower-level program elements in a consistent manner.

RELATED WORK

This article is a set of extensions to the authors' prior work (Wada, Suzuki, & Oba, 2006a, 2006b, 2006c). As one of the extensions, this work investigates new non-functional aspects for regulatory compliance, which were beyond of the scope of the prior work. Another extension is that Ark currently supports a wider range of implementation technologies. As a result, the proposed MDD framework now allows application developers to model SOA's non-functional aspects through hiding the implementation differences across two of the most major ESBs (Mule ESB and ServiceMix ESB). Given these extensions, this article fully discusses the updated details in the design and implementation of the proposed MDD framework. Moreover, unlike the prior work, this work empirically evaluates how the proposed MDD framework contributes to the reusability and maintainability of service-oriented applications.

There are several UML profiles proposed for SOA. Marcos, Castro, and Vela (2003) and Amsden, Gardner, Griffin, and Iyengar (2005) propose UML profiles to specify functional aspects in SOA. Both profiles are designed based on the XML schema of Web Service Description Language (WSDL). Each profile provides a set of stereotypes and tagged-values that correspond to the elements in WSDL, such as `Service`, `Port`, `Messages` and `Binding`[10]. Since WSDL is designed to define only functional aspects of web services, non-functional aspects are beyond of the scope of Marcos et al. (2003) and Amsden et al. (2005). Ermagan and Krüger (2007) propose and Object Management Group (2006b) standardizes UML profiles for functional aspects in SOA. Unlike the above profiles, the proposed profile focuses on specifying non-functional aspects in SOA.

Amir and Zeid (2005) propose a UML profile to describe both functional and non-functional aspects in SOA. This profile is generic enough to specify a wide range of non-functional aspects. For example, the stereotypes for non-functional aspects include `<<policy>>` and `<<permission>>`. However, their semantics tend to be ambiguous. This profile does not precisely define what non-functional aspects developers can (or are supposed to) specify and how to represent them with tagged values in accordance with given stereotypes. Ortiz and Hernández (2006) also propose a generic UML profile to describe various non-functional aspects (called extra-functional properties). Arbitrary non-functional aspects can be defined as stereotypes extending the `<<Extra-Functional Property>>` stereotype. However, it is ambiguous how to define particular non-func-

tional aspects with user-defined stereotypes and tagged-values. The World Wide Web Consortium (2006) standardizes the WS-Policy specification, a generic XML format to specify arbitrary non-functional aspects of web services. No explicit principles and guidelines are available on how to define particular non-functional aspects with XML document elements. Unlike the above three schemes, the proposed UML profile carefully and precisely defines a variety of stereotypes and tagged-values for non-functional aspects in SOA so that the proposed MDD tool (Ark) can interpret and transform models to code in an unambiguous manner.

Vokäc (2005) proposes a UML profile for data integration in SOA. It provides data structures to specify messages. Application developers can use the data structures for building dictionaries that maintain message data used in existing systems and new applications. This profile separates data integration as a non-functional aspect from functional aspects, and enables specifying data integration in an implementation independent manner. This UML profile and the proposed profile focus on different issues in SOA. Data integration is beyond of the scope of the proposed profile, and Vokäc (2005) does not consider non-functional aspects in message transmission, message processing, security and service deployment.

Heckel, Lohmann, and Thöne (2003) propose a UML profile for dynamic service discovery in SOA. This profile provides a set of stereotypes (e.g., `<<uses>>`, `<<requires>>` and `<<satisfies>>`) to specify relationships among service interfaces, service implementations and functional requirements. For examples, a relationship can specify that a service *uses* other services, and another relationship can specify that a service *requires* other services that *satisfy* certain functional requirements. These relationships are intended to aid dynamic discovery of services. Rather than service discovery, the proposed UML profile focuses on non-functional semantics in message transmission, message processing, security, and service deployment.

Object Management Group (2007) standardizes a UML profile for Data Distribution Service (DDS). DDS is a standard specification for publish/subscribe middleware, and it supports several non-functional aspects in real-time messaging. OMG's UML profile for DDS allows UML models to specify these non-functional aspects. In contrast, the proposed profile is not limited to real-time messaging, but supports a wider range of non-functional aspects. Moreover, OMG's profile is designed to be mapped into only DDS implementations. In contrast, the proposed profile is designed in an implementation independent manner; it can be mapped to arbitrary implementation technologies.

Gardner (2003), List and Korherr (2005), Johnston (2004) and Object Management Group (2005a) define UML profiles to specify service orchestration and map it to Business Process Execution Language (BPEL) (Organization for the Advancement of Structured Information Standards, 2003). These profiles provide a limited support of non-functional aspects in message transmission, such as messaging synchrony. The proposed profile does not focus on service orchestration, but a comprehensive support of non-functional aspects in message transmission, message processing, security and service deployment.

Lodderstedt, Basin, and Doser (2002) propose a UML profile, called SecureUML, to define role-based access control for network applications. SecureUML provides stereotypes to assign roles (`<<security.role>>`) and access control permissions (`<<security.constraint>>`) to applications (e.g., UML interfaces and classes). SecureUML uses Object Constraint Language (OCL) to define access control. Jürjens (2002) propose another UML profile, called UMLsec, to define data encryption (`<<data security>>`) and secure network links (`<<encrypted>>`). Wang and Lee (2005) and

Nakamura, Tatsubori, Imamura, and Ono (2005) also propose UML profiles to define security aspects. In addition to security aspects, Soler, Villarroel, Trujillo, Medina, and Piattini (2006) propose a UML profile extending the Common Warehouse Metamodel (Object Management Group, 2003) in order to define regulatory audit policies in data warehouses. For example, the profile provides stereotypes to specify whether a data warehouse retains logs to access data sources. Gönczy and Varró (2006) propose a formal definition of reliable messaging mechanisms as a metamodel. These profiles/metamodels are parallel to the proposed UML profile in terms of the ability to describe security aspects, audit policies, and reliable messaging in network applications. However, the proposed UML profile covers not only security, auditing or reliable messaging aspects but also many other non-functional aspects in SOA (e.g., message queuing, message validation/filtering, and message.

Zhu and Gorton (2007) and Zou and Pavlovski (2006) propose UML profiles to visually define non-functional requirements such as desirable response time and throughput. However, they do not consider model transformation to map non-functional requirements to certain implementation technologies. In contrast, the proposed profile is designed to consider model transformation, although non-functional requirements are beyond of the scope of the proposed profile.

There are several specifications and research efforts to investigate implementation techniques for non-functional aspects in SOA (Baligand & Monfort, 2004; Mukhi, Konuru, & Curbera, 2004; Organization for the Advancement of Structured Information Standards, 2003, 2004a, 2004b; Wang, Chen, Wang, Fung, & Uczekaj, 2004). Each specification and technique provides a means to implement non-functional requirements in, for example, performance, reliability, and security and to enforce services to follow the requirements. Rather than investigating specific implementations of non-functional aspects in SOA, the proposed MDD framework is intended to provide a means for application developers to model and maintain non-functional aspects in an implementation independent manner so that they can be mapped on different specifications or implementation technologies.

CONCLUSION

This article proposes a model-driven development (MDD) framework for non-functional aspects in SOA. The proposed MDD framework consists of (1) a UML profile to graphically specify and maintain SOA non-functional aspects in an implementation independent manner and (2) an MDD tool that accepts a UML model defined with the proposed profile and transforms it to application code (program code and deployment descriptors). This article presents design details of the proposed UML profile and describes how the proposed MDD tool uses the profile to develop service-oriented applications that can run with different implementation technologies such as Mule ESB, ServiceMix and GridFTP. Empirical evaluation results show that the proposed MDD framework contributes to improve the reusability and maintainability of service-oriented applications by hiding the details of implementation technologies.

Several extensions to the proposed MDD framework are planned as future work. As described in the Related Work section, there are several other UML profiles for SOA. The proposed profile will be co-used or integrated with some of them (e.g., Oba, Hashimoto, Fujikura, & Munehira, 2005; Object Management Group, 2005b) in order to investigate a more comprehensive development framework for SOA.

Another extension is to integrate the proposed UML profile with a modeling language for business processes such as Business Process

Modeling Notation (Object Management Group, 2006a). The proposed profile is designed to specify applications from a structural point of view; it does not consider a viewpoint of processes or workflows. Therefore, as the size of a model (application) increases, it becomes harder to understand how messages are exchanged among services and define non-functional aspects along with message flows. For example, in order to specify secure messaging for a certain business process (e.g., order processing process), it can be time-consuming and error-prone to find all the services associated with the process and define a security aspect for the connections among those services. The integration with a business process modeling language can make non-functional modeling more intuitive by providing both structural and process viewpoints.

The proposed MDD framework will be evaluated in several different application domains[11]. One of them is service-oriented system integration in a natural gas utility company. The proposed UML profile and Ark are planned to be used in a system integration project, and their design and implementation will be enhanced through the project experience. Another application domain is eco-informatics. The proposed framework has been used to design and maintain ecological observation systems (Wada & Suzuki, 2006d). Ecological observation systems monitor ecosystems, record various observation data (e.g., a niche of a particular species and weather in the niche), and help ecologists understand and predict the observation of ecosystems. Currently, ecological observation systems are often implemented monolithic; their extensibility and customizability are limited. SOA is expected to overcome this issue by decomposing an observation system into multiple services, implementing the system as a combination of services, and extending/customizing it through a recombination of services (Bermudez, Bogden, Bridger, Creager, Forrest, & Graybeal, 2006). The proposed MDD framework has been used to separate functional and non-functional aspects in an ecological observation system and model/implement non-functional aspects in the system. Through this practice, the proposed MDD framework will be enhanced to improve its generality.

ABSTRACT

This chapter presents a methodology used as reference model for a free software factory that is part of the National Centre for Free Technologies in Venezuela. This centre is oriented at promoting free software development for serving mostly the public sector in order to promote endogenous development and technologic autonomy. Under this strategy, strengthening the software small and medium size enterprises and cooperatives, by allowing them to participate in different projects (improving their know-how) and providing them with a methodology for increasing their capabilities and software quality, is necessary and urgent. This methodology plans the development process incrementally, based on a prioritisation of the software functionalities development in accordance to the functionalities risks, development urgency, and dependencies. It combines aspects of the two styles of free software development,

namely cathedral and bazaar. The development process is centralised, in essence collaborative, and continuously allows source code release.

INTRODUCTION

The Free Software Factory (FSF) of CENDITEL (Venezuelan national centre for promoting free technologies) has been conceived and created as part of the efforts of the Venezuelan State aiming at increasing endogenous development and technological sovereignty. In particular, it intends to strengthen the national software sector, especially the small and medium software enterprises (including the cooperatives), by allowing them to access the technology and participate in the software market, on one hand, and to increase their capabilities and software quality, on the other hand.

Two styles exist for developing free software: the cathedral style and the bazaar style. In the cathedral mode, software is developed from a unified *a priori* project that prescribes all the functions and the features to be incorporated in the final product. Programmers' work is centrally coordinated and supervised in order to assure the integration of various components. On the other hand, in the bazaar style, software emerges from an unstructured evolutionary process. Starting from a minimal code, groups of programmers add features and introduce modifications and patches to the code. There is no central allocation of different tasks; developers are free to develop a given program in directions they favor.

This chapter presents an attempt at building a free software development methodology having many characteristics of the cathedral style but keeping certain principle of the bazaar mode. The methodology has been developed at a public organisation which responds to public sector free software necessities and requirements that must be satisfied in a limited time period. Because of this, it is necessary to adopt the cathedral mode of work while taking key advantages of the bazaar style. For instance, it is allowed that developers from outside the organisation contributes with software coding, testing, and so forth; these external developers do not follow a centrally controlled process; and the software code is made public as soon as it is tested.

This methodology assumes an organisational structure oriented towards specific processes. The processes dedicated to software development are:

- *Process # 1*: Free Software Project Management
- *Process # 2*: Specific Project Administration
- *Process # 3*: Free Software Application Development

Actions to be carried out in these processes are classified in steps and activities. In particular, steps and activities in the third process are implemented by the following six phases. This methodology has taken ideas from diverse software development methodologies, methods, and models such as the extreme programming method (Beck, 2004), the rational unified process (Kruchten, 2000; Pollice, 2001; Probasco, 2000), the watch method (Montilva, 2004; Montilva, Hamzan, & Ghatrawi, 2000), and the model of processes for software development (MoProSoft) (Oktaba et al., 2005). Due to the fact that these models and methods, except extreme programming, have been proposed proprietary software development, it has been necessary to adapt the hints, ideas, or procedures taken from them to the free software development needs.

The methodology to be proposed has been validated at the FSF of the Foundation for Science and Technology of the Mérida State in Venezuela (FUNDACITE-Mérida). This factory has permitted us to understand better, empirically, the real needs of a free software development process and has also been a source of interesting ideas. The

proposed structure will allow planning and control activities which are required in the management and administration of software projects. In addition, the free software application development process is iterative and incremental, in terms of the software application functionalities. On the other hand, the design of the application is based on component architecture, which allows software reuse. Each process will be explained in detail in the main body of this chapter. For facilitating each process, some free software tools will be suggested.

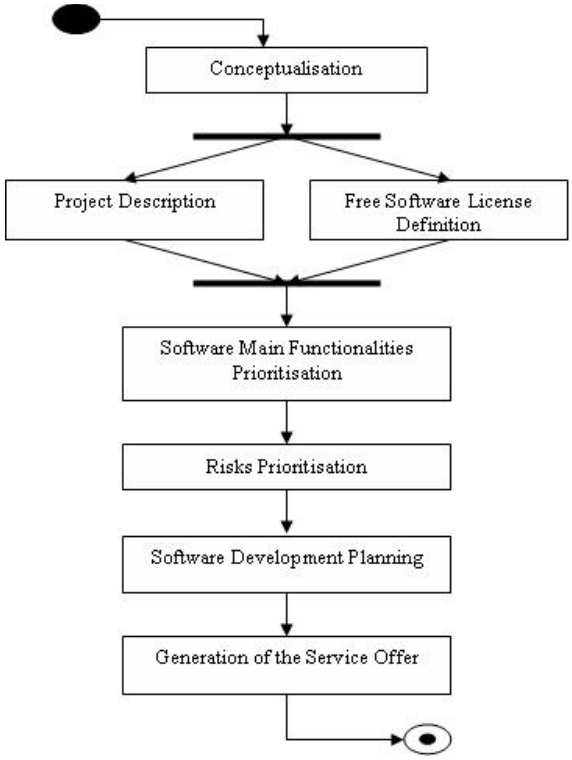
FREE SOFTWARE DEVELOPMENT METHODOLOGY

Process # 1: Free Software Project Management (FSPM)

This process is responsible for managing all projects being carried out by the organisation, that is, both internal projects (projects for the organisation) and external projects (projects for other organisations) are managed. Specifically, in this process, a "service offer" for the project to be developed is generated. This offer must include a conceptualisation, a description, and a (general) development plan for the project, as well as the definition of the free software license. Figure 1 shows the steps as a workflow for the FSMP process. Subsequently, these steps will be described.

a. **Conceptualisation**
   Description: Specific user needs and/or problems must be identified in order to define the scope of the project. In case of a high complexity of the project, for instance, the scope of the problem goes beyond a software need and involves organisational issues, methodologies such as technologic prospective and strategic planning, and/or tools such as fish bone (a technique commonly used in operation research and in quality control) are recommended. In this case, the study would suggest a set of solutions and organisational changes, of which software needs would be only part of the whole answer.
   People Responsible: According to free software philosophy, all people associated with the project (project manager, project administrator, developers, users, and so forth) must be involved from the very early stages of it, even when new actors can be incorporated to any phase of the project.
   Techniques: Prospective analysis, strategic planning, or any other useful technique.
   Products: (1) Client/user's needs and/or problems; (2) scope of the project.

Figure 1. Free software project management process



b. **Project Description**
   The main point in this phase is to achieve a detailed description of the project. Each actor must analyse the client's need and problem,

as well as the project's scope, in order to contribute to the description of the project.
People Responsible: Clients, users, project manager, project administrator, developers, assessors and other people interested in the project participation.
Products: Project description document.

c. **Free Software License Definition**
Description: In this step, the free software license to be adopted for the development is defined. It might be the case that a license from the market satisfies the client requirements and then is chosen or, in case that there is not an existent license matching the user's requirements, a new license is defined.
People Responsible: Clients, users, project manager, project administrator, assessors.
Products: Project license.

d. **Software Main Functionalities Prioritisation**
Description: In this step, the goal is to describe and classify the software functionalities in accordance with the implementation urgency required by the client.
People Responsible: Clients.
Products: Functionalities prioritised.

e. **Risk Prioritisation**
Description: To identify, prioritise, and associate the risks to software application functionalities. The risks are prioritised in accordance to their impact on the application development.
People Responsible: Clients, users, project manager, project administrator, developers, assessors, and other people interested in the project.
Products: Risks prioritised.

f. **Software Development Plan**
Description: To build the development plan, the implementation order of the functionalities of the application must be established, in accordance to the functionality priorities defined by the client, and the risks prioritised associated to the functionalities. This must allow determining the number of cycles or iterations required for the development of the application. A cycle is responsible for developing a certain number of functionalities (taken into account their priority order). A development plan can be modified after an iteration, as a result of work reorganisation, in line with the dynamic of the project.
People Responsible: Project manager, project administrator, and developers.
Products: Development plan.

g. **Generation of the Service Offer**
Description: The service offer is completed in this step. It specifies all important issues of the project, such as the goal, scope, and description of the project; the development plan; the due dates for deliverables; the work team; the project cost; and the operation platform.
People Responsible: Project manager, clients.
Techniques and Tools: Service offer forms.

Note: In accordance to the chosen software license, the products achieved in this process must be published in a collaborative development platform. This will facilitate the interested people access to the software products and their documentation.

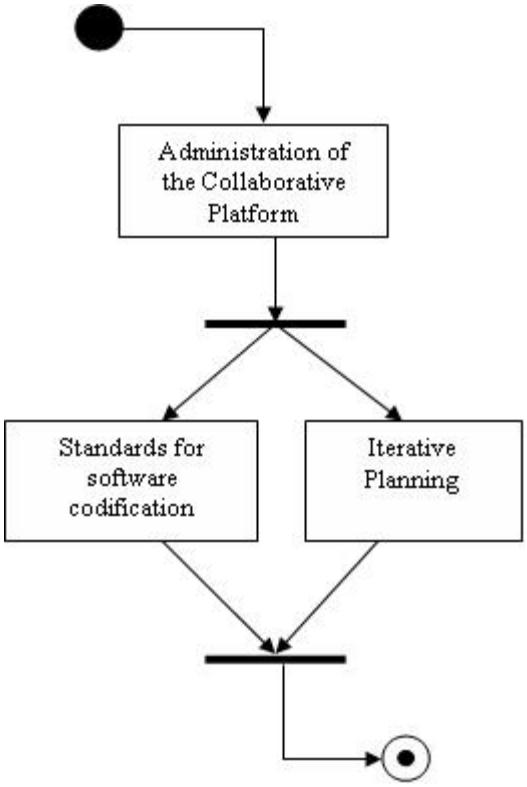
Process #2: Administration of Specific Projects (ASP)

The administration of specific projects leads the developer team of a software application (it is assumed that a software application development corresponds to a software project). In this sense, each software project must have at least one project administrator. The project administrator is responsible for organising and planning the activities corresponding to each iteration defined in the development plan. Additionally, the project administrator must assure the software quality, manage the system configuration, and the collaborative technical platform, as well as supervise

and control the project development and the administration of subcontracts. Figure 2 shows the main steps as a workflow for the ASP process. Subsequently, these steps will be described.

a. **Administration of the Development Collaborative Platform**
Description: The processes related to the ASP phase are facilitated by using a collaborative platform. A software developing team has its own necessities; accordingly it is important to select the correct tool for collaborative software management considering such necessities. In this phase, the collaborative platform is set up. The collaborative platform permits any interested person to collaborate with and share ideas, source code, documentation, testing, and so forth. This is a very important aspect of the free software development. However, as part of the administration of this platform, the project administrator must approve and then publish the software versions and the associated documentation in accordance with the free software license assumed.
People Responsible: Project administrator.
Tools: GFORCE, and so forth.
Products: Collaborative development server.

Figure 2. Process for the Administration of Specific Projects



b. **Standard for Software Codification**
Description: This step establishes the standards for code generation and for the documentation to be used during the software development. These standards allow a quick and simple reading of the code, facilitating the work of the whole group, including the client, the user, and other actors.
People Responsible: Project administrator.
Products: Coding and documentation standards.

c. **Iterative Planning**
Description: The activities of the iteration to be carried out in accordance with the functionalities to be developed are planned. After an iteration is performed, the next iteration is planned and takes into account functionalities that could not be implemented and problems found during the previous iteration.
People Responsible: Project administrator.
Techniques: Gantt, Pert/CPM
Tools: Planner, GFORCE, XPTracker, SourceForge, and so forth.
Products: Plan for the iteration to be developed.

Note: Products accomplished in this process must be placed at the collaborative platform in accordance with the adopted free software license.

Process #3: Free Software Application Development

The software application is constructed by the sequence of iterations or cycles in an incremental and iterative way, allowing that users and clients can check the advances of the work and give feedback useful for improving the development and testing processes. The methodology presents a general reference framework or structure for the activities to be planned at each iteration of this process (see Figure 3). In each cycle, one activity receives the main attention while the others are secondary. The whole set of functionalities is developed during the cycles.

Any person can access and execute the source code stored in the collaborative platform. In this way, everyone can contribute to the project. Experiences show that the more people use and test the software, the more quickly the errors and bugs will be found and solved.

It is important to mention that during the software application construction, not only must the code be published but also all associated documentation. In this manner, new programmers and collaborators can be easily incorporated. As mentioned earlier, the code and associated documentation publication depends on the software license established. Next, in Figure 3, the development phases carried out during this process will be presented.

a. **Application Domain Analysis**
Description: This phase is considered one of the most important in the software development process, since the domain environment and context where the application will operate are analysed and understood. Such analysis is carried out in the first iteration but can be upgraded in the subsequent iterations. The activities workflow for this phase is shown in Figure 4. Following this figure, the main activities will be described.

- ***Domain Description***
Description: Establishes and validates the application domain and its organisational scope.
People Responsible: System analyst internal to the developer organisation, users, clients, programming team. In this chapter, the phrase "*internal to the organization*" means a person who works for the organization that develops the software, as opposed to "external

Figure 3. Free software development process

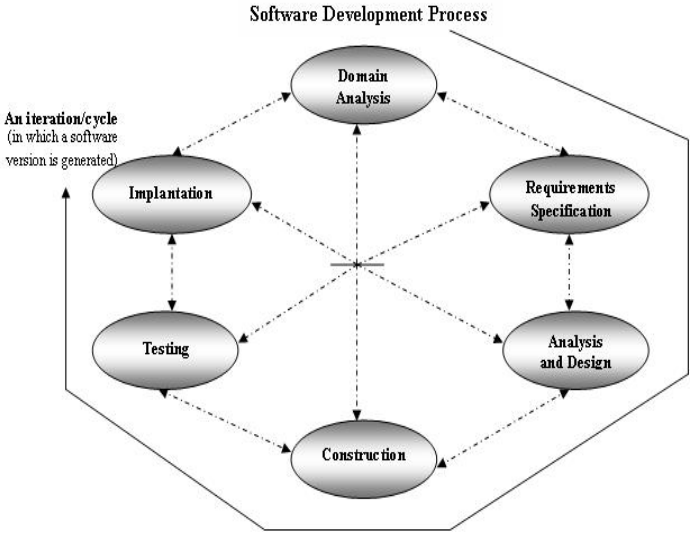


Figure 4. Steps for the application domain analysis phase

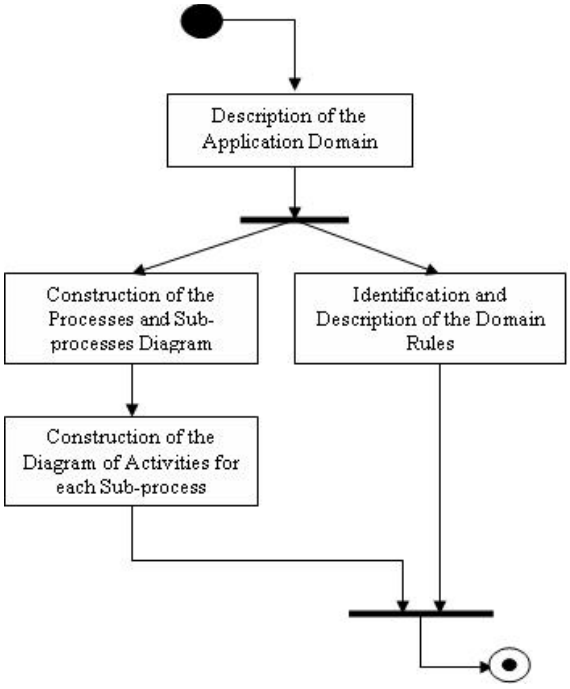


to the organization," which means a person who is not actually working for the developer organization.

Techniques: Domain engineering, interviews, revision of documents, and bibliography.

Products: Domain application definition.

- ***Construction of the Processes and Subprocesses Diagram***

  Description: This activity must identify processes and subprocesses related to the application domain, as well as events associated to all these, in order to generate the domain processes and subprocesses diagram. Finally, this diagram must be validated.

  People Responsible: System analyst (internal to the organisation), users, clients.

  Techniques: The processes diagram given by UML.

  Tools: Umbrello, ArgoUML, caseUML.

  Products: Domain processes and subprocess diagram.

- ***Construction of the Diagram of Activities for Each Subprocess***

  Description: Generates and validates the activities diagram for each subprocess.

  People Responsible: System analyst (internal to the organisation), users, clients.

  Techniques: Activities diagram offered by UML.

  Tools: Umbrello, ArgoUML, caseUML.

  *Products: S*ubprocess activity diagrams.

- ***Identification and Description of the Domain Rules***

  Description: Domain rules regulating the application domain must be identified and studied.

  People Responsible: System analyst (internal to the organisation), users, clients.

  Techniques: the activities diagram offered by UML.

  Tools: Umbrello, ArgoUML, caseUML.

*Products: S*ubprocess activity diagrams.

b. **Requirements Specification**

Description: In this phase, the functionalities to be developed in the planned iteration are specified, and the nonfunctional requirements are defined or upgraded. Generally, the nonfunctional requirements are defined in the early iterations. The requirement specification document will be upgraded from iteration to iteration. It is important to notice that in this phase the user or the client can modify, change, include, or eliminate requirements and risks, which, in turn, might entail updates of the development plan. The activities workflow

for this phase is shown in Figure 5. Following this figure, the main activities for this phase will be described.

- ***Description of Requirements Related to the Actual Iteration***

  Description: A detailed description of the functional requirements for the present iteration is generated, and the nonfunctional requirements are defined or upgraded. These will allow generating and validating the requirements definition document. It is important to mention that only the definition of such requirements related to the present iteration are validated, since those requirements related to previous iterations were validated during the corresponding iterations.

  People Responsible: System analyst (internal to the organisation), users, clients.

- ***Specification of Requirements Related to the Actual Iteration:***

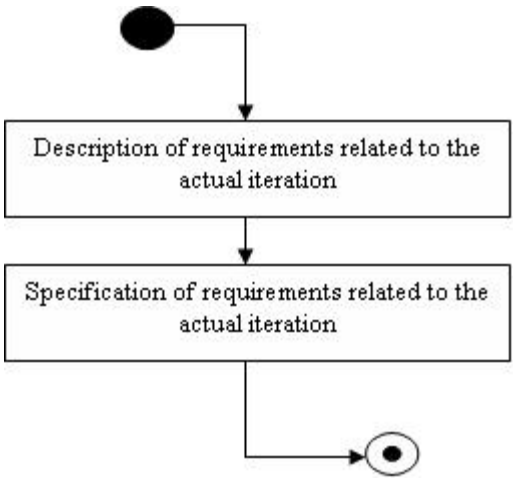
  Description: To create or upgrade the requirements specification document, including the use cases describing the functional requirements associated with the actual iteration. In this methodology, it is understood that the requirements specification is made in terms of diagrams and textual descriptions of the use cases. Only the specification of those requirements associated to the present or actual iteration must be verified and validated in this step.

  People Responsible: System analyst (internal and/or external to the organisation), users, clients.

  Techniques: the use cases diagram offered by UML.

  Tools: Umbrello, ArgoUML, caseUML.

Figure 5. Steps for the requirements specification



c. Analysis and Design

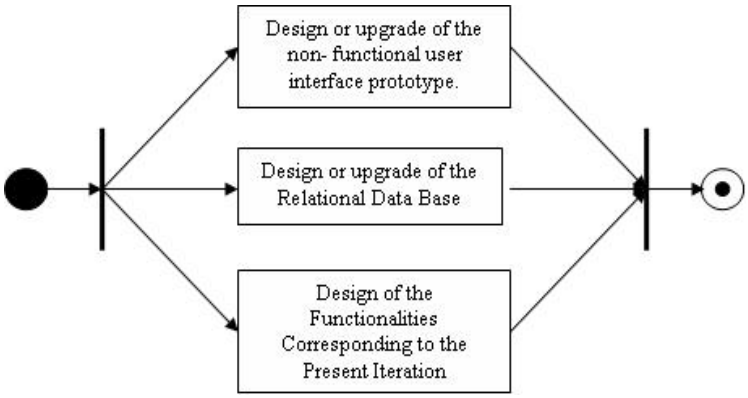
Description: In this phase, the specification of requirements is translated into a design specification, based on a set of architectonic views, which represent the system architecture. In this phase also, the user interfaces and databases are designed. The application architecture, like the requirements, is enriched or upgraded as the subsequent iterations are carried out, since each iteration add functionalities to the software application been developed. All this gives flexibility to the design, permitting that change in the client's viewpoint about desired functionalities be taken into account without great difficulties. The activities workflow for this phase is shown in Figure 6. Afterwards, the main activities are going to be described.

- ***Design or Upgrade of the Nonfunctional User Interface Prototype***

  Description: Create or update the nonfunctional user interface prototype. This design includes the hierarchic diagram of windows, taking into account the user requirements. This design must be validated.

  People Responsible: System analyst (internal or external to the developer organisation), programmers, users, clients.

Figure 6. Steps for the analysis and design phase



Tools: UX, DIA.
Products: Design of the nonfunctional user interface prototype.

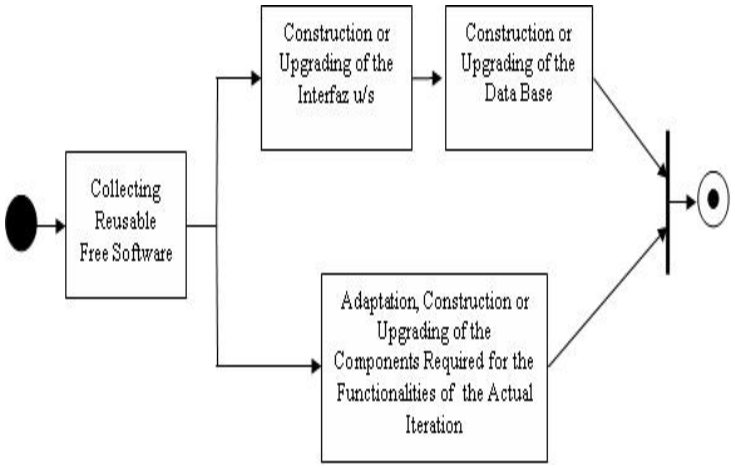
- ***Design or Upgrade of the Relational Database:***
  Description: The database design document is generated or upgraded. This document must contain the diagram entity/relation and the relational scheme, for the actual iteration. For these diagrams, the entities of the database and their attributes, as well as the primary and the foreign keys, must be defined. The entities of the database are identified by using the use cases for the present iteration. Finally, the database administrative procedures (i.e., backup, security, recovery, etc.) must be defined, and the database design document must be validated.
  People Responsible: System analyst (internal and external to the organisation), programmers.
  Techniques: Normalisation formulas.
  Products: Entity relation diagrams.
- ***Design of the Functionalities Corresponding to the Present Iteration***
  Description: The architectonic views must be generated or upgraded. It is constituted by the logic, the implementation, the behaviour, and the conceptual views. The logic view is defined by the class diagrams of the software application. It is created or upgraded by: (a) deriving from the use cases (associated to the actual iteration) the objects of the application, (b) generating the sequence diagrams for the "methods" or functions involved in the realisation of the use cases for the actual iteration. The implementation view is generated or upgraded from the components diagrams. The behaviour view is created or upgraded from the interaction relations among the components. The conceptual view is defined or upgraded from the use case diagrams corresponding to the actual iteration.
  People Responsible: System analyst (internal or external to the organisation).
  Techniques: Class, components, and interaction diagrams
  Tools: Umbrello, ArgoUML, caseUML.
  Products: Architectonic view of the software application.

d. **Construction**
Description: For the actual iteration or cycle, the user interface, the database, and the functionalities of the application are constructed or upgraded in this phase. For that,

the software application source code for the actual version is developed. The activities workflow for this phase is shown in Figure 7. Afterwards, the main activities of this phase will be described.

- ***Collecting Reusable Free Software*:**
  Description: Reusable free software components, abstract data type, classes, functions, and whole systems, useful for the software application, are searched for and collected.
  People Responsible: Programmers (internal and/or external to the organisation). This is the first activity where external programmers participate in the software development.
  Tools: Some are available at Web sites such as www.fsl.funmrd,gov.ve, freshmeat.net, sourceforge.net, and so forth.
- ***Construction or Upgrading of the User Interface U/S***
  Description: The reusable user interface components corresponding to the design of the interface associated to the actual iteration are adapted and, when required, those of the previous iterations are upgraded.
  People Responsible: Programmers (internal and/or external to the organisation).
- ***Construction or Upgrading of the Database***
  Description: Build or upgrade the database using information from the database design document for the actual iteration. Additionally, components of the user interface must be integrated along the database.
  People Responsible: Programmers (internal and/or external to the organisation).
  Techniques and Tools: Web sites like www.fsl.funmrd,gov.ve, freshmeat.net, sourceforge.net, and so forth.
- ***Adaptation, Construction, or Upgrading of the Components Required for the Functionalities of the Actual Iteration***
  Description: For the components, abstract data types, classes, and functions requited for the functionalities of the actual iteration: (a) adapt those reusable already collected, (b) construct those that could not be found, (c) update those useful from previous iterations.

Figure 7. Steps for the construction phase



People Responsible: Programmers (internal and/or external to the organisation).

Tools: Some are available at Web sites such as www.fsl.funmrd,gov.ve, freshmeat.net, sourceforge.net, and so forth.

e. **Testing**

Description: In this phase, the unitary, integration, functional, and nonfunctional tests, for the components corresponding to the functionalities associated to the actual iteration, are designed or upgraded, and applied. The nonfunctional tests are applied only in the last version of the software application, which is obtained in the last iteration. The installation tests are also designed in this phase, but are applied in the implantation phase. It is important to say that code modified by developers external to the developer organisation must also be appropriately tested. Only after these tests are successfully completed can the project administrator publish the code. Figure 8 shows the workflow for this phase. Since this figure sufficiently explains each step, in the text following the figure, only the people responsible, techniques, tools, and products for a test design/upgrade or for a test application will be specified.

- **Test design/upgrade:**

  People Responsible: Tester (internal and/or external to the organisation).

  Techniques: White and black box tests.

  Products: Test plans.

- **Test application:**

  People Responsible: Tester (internal and/or external to the organisation).

  Tools: Test, Check, Junit, Cppunit.

  Products: Test reports.

f. **Implantation**

In this phase, the actual iteration version is released to the client so that the client can validate this version while other functionalities are developed in the next iterations. The migration strategies towards the new application are defined, the user is trained for using the delivered version, the actual version is installed, the installation test is applied, and the software application manuals are generated or upgraded, and verified. Finally, the actual version of the software application is integrated along with the organisation activities. Figure 9 shows the workflow for this phase. Given that the figure sufficiently explains each step of this phase, a detailed description for each step will not be given. However, it is important to mention that: (a) the people responsible for these steps are

Figure 8. Steps for the testing phase

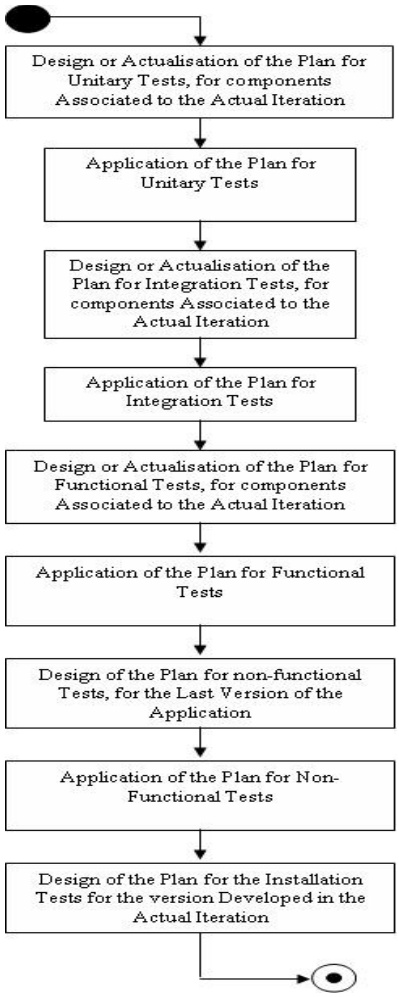


Figure 9. Steps for the installation phase

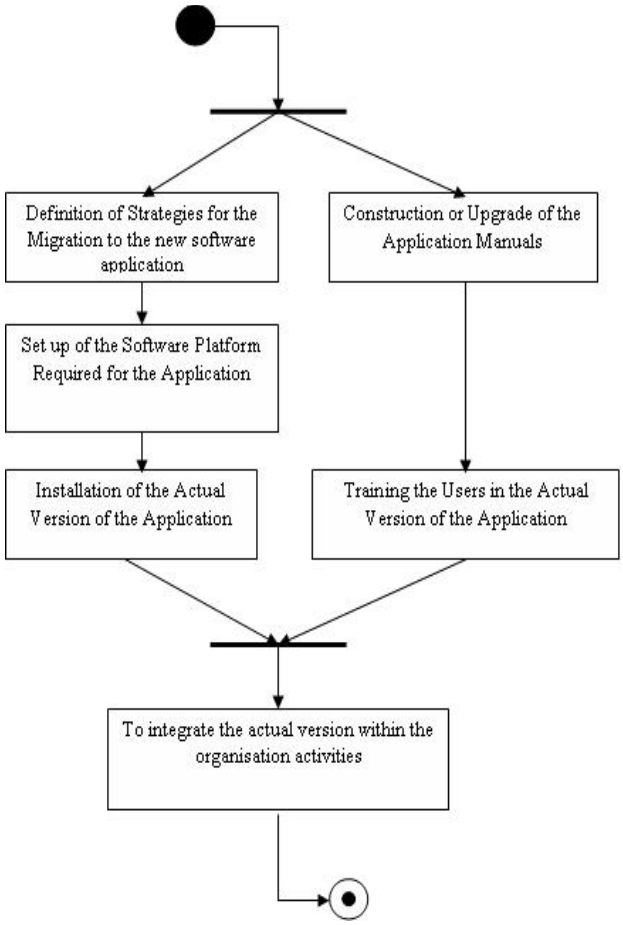

programmers and testers (both internal to the developer organisation) and (b) the main products of this phase are the system manuals, the training material, and the installation test reports for each installed version.

STUDY CASE

The presented methodology has been shaped and updated recently and has been implanted partially only in two projects. The implantation process will continue during the present year (2007) in order to apply the whole methodology to all projects. The two projects involved in the implantation process until now are:

1. The Dis-centralised Administrative System.
2. The Automation of the FSF. This means the automation of the free software project management, administration of specific projects, and software application development processes.

The Dis-centralised Administrative System had already been started and was entering the test phase at the moment the methodology began implantation. Because of this, until now, the methodology has been applied in this project only for part of the software application development process, more specifically, for the unitary tests of the test step. On the other hand, since

the automation of the FSF is still in course, the methodology has been applied up to the point the project has reached at present. However, the methodology has been applied from the beginning of the project. The following processes of the methodology have been implanted: the free software project management**,** administration of specific projects, and some aspects of the software application development process. Next, details about the application of the methodology to both of these projects will be presented.

Case 1: Automation of the Free Software Factory

Process # 1: Free Software Project Management

a. **Conceptualization**
Results of carrying out this step are summarised in a set of filled templates, which are stored in the GForge server (see Alvarez, 2007, sections 1 and 2). These templates show needs and problems, and scope of the project of implementation of the FSF. Those problems and needs include:
- Lack of a database of digitalised templates for documenting the development processes.
- The dynamics of the demand requires urgent development.
- Need of a knowledge base for learned lessons.

The scope of the project delimitates the system to be developed in terms of which processes and which steps will be covered.

b. **Project Description**
This gives an overview of how the automation of the FSF project is being carried out.

c. **Free Software License Definition**
There is not any licence defined for this project. All material developed in this project will be available from the GForge server.

d. **Software Main Functionalities Prioritisation.**
All functionalities to be covered by the automation system of the factory were defined and prioritised. Results of this phase are presented in Alvarez (2007, section 3). Among these functionalities, we have:
- Digitalise the functionalities and the risks prioritisation templates.
- Select analysis and design tools.
- Choose testing tools.
- Automate the project plan template.
- Integrate templates and design tools.
- Integrate design and programming phases (generation of automatic code)
- Develop a knowledge base.

These functionalities received a weight, as the methodology states.

e. **Risk Prioritisation**
At this step, the more important development risks were defined (see Alvarez, 2006, section 4 for more details). Among these risks, we have:
- Scarcity of free automation tools and FSF's development team's lack of knowledge and capacities for building, design, and test tools for free software development.
- Few people dedicated at testing and short experience in testing.
- Low experience in following methodologies.

As above, a weight is associated to these risks.

f. **Development Priorities Definition**
A prioritisation of the functionalities was performed (Alvarez, 2006, section 5), by following this formula:
Total functionality F_1 weight = ($\sum VR_i$ para F_1) * PR + VF_1 * PF , where,
- the VR_i are the risks for the functionality F_1;

- VF_1 is the weight for the functionality F_1;
- PR and PF are the relative weights-of-the-factors, in this case, between the total sum of risk weights, factor 1, and the functionality weight, factor 2.

Following this procedure, one of the most important functionalities resulted to be automated design and testing facilities. Tools for these tasks were selected from those available on the Internet.

g. **Software Development Plan**
This plan presents the development schedule, indicating the functionalities to be developed at each iteration; there were seven defined iterations after considering the functionality dependencies, size of the development team, and the functionalities development prioritisation (for more details, see Alvarez, 2007, section 5).

h. **Generation of the Service Offer**
The service offer indicates (Alvarez, 2007, section 6), for instance:
   - The offer proposal: to develop a system to automate the free software development processes.
   - The project scope: to automate in some degree, by integrating and digitalising (and in some cases completely automating, when the complexity of these tasks allows it) tools for implementing the FSF.
   - The release schedule (to the client).

Process #2: Administration of Specific Projects

a. Administration of the Collaborative Platform.
GForce was installed as the collaborative Platform.

b. Standards for software codification.
The codification standard is being defined at present.

c. Iterative planning.
This step is performed by using a GForce scheduling facility (Alvarez, 2007, section 7).

Process #3: Software Application Development

The software application development process consists basically on programming on top of GForge, in order to adapt it and add functionalities, to permit carrying out the software development activities required by the FSF processes. Some of the adaptations already implemented are:

- Digitalisation of templates, among which we have: client's needs and problems; scope of the project; service offer; test plan; test reports.
- Automation of the project plan.

Case 2: Dis-Centralised Administrative System

Process #3: Software Application Development

As mentioned previously, for this project, the methodology has been implanted to perform the unitary test plan (Alvarez, 2007, section 8).

CONCLUSION

The presented methodology pretends strengthening the software national sector, especially the small and medium software enterprises (including the cooperatives), by allowing them to access the technology and participate in the software market through a collaborative development of software for the public administration (main goal of the FSF), on one hand, and to increase their capabilities and software quality, on the other hand.

In this sense, the development process presents certain specific characteristics and numerous advantages (as it is stated in the methodology). As said before, a fundamental aspect is the collaborative development by iteration: a particular development group may enter or leave to collaborate at any iteration in accordance to the group interests. Additionally, the software developments and upgrades coming from any involved group are open to the community via a collaborative platform. Consequently, the development groups get benefits from a methodological framework, which establishes the ways and moments for participation, forms to recovery versions of the development, development rules and tools, and so forth. All these practices on the bases of the development framework allow any small or medium enterprise to share/communicate with partners in the free software development community, in accordance with the free software development philosophy. The proposed methodology has been partially validated at the FSF of the Foundation for Science and Technology of the Mérida State in Venezuela (FUNDACITE-Mérida). In addition, this factory has permitted to understand better, empirically, the real needs of a free software development process and has also been a source of ideas.

Chapter 2.25
Agile Outsourcing to India:
Structure and Management

Boris Roussev
University of the Virgin Islands, USA

Ram Akella
University of California, USA

ABSTRACT

The combination of low labor costs, technological sophistication, project management skills, and successful software establishment makes India a particularly attractive location for software production outsourcing. Furthermore, in most situations, information and communication technologies render virtual presence practically equivalent to physical presence, thus enabling effective communication and cooperation in a distributed mode. This chapter introduces a project structure creating agile conditions for large outsourcing software projects. The agility advantage is achieved by scaling down a large project into a number of small-sized projects working in agile settings. We divide the work into R&D activities, located onsite, and production activities, located offsite. The proposed approach makes Agile applicable to the stressed condition of outsourcing environments without compromising the quality and the pace of the software development effort. Creating a context congenial to agile methods hinges on maintaining a good balance between the functions and sizes of onsite and offsite teams, on redefining the developers' roles, and on reorganizing the information flow between the different development activities to compensate for the lack of customer onsite, team co-location, and tacit project knowledge.

INTRODUCTION

We live in a digital world, where any activity not requiring a "physical presence" can be outsourced to any place that is connected. Even the term "physical presence" comes with a qualification. Information and communication technologies (ICTs) enable cooperation in a distributed mode. Technologies, such as groupware and video-conferencing, are increasingly becoming feasible for

organizations to use in international projects. In addition, these technologies are changing the way we perceive presence and absence. The largely digital nature of software development allows changing its geography of provision. Advances in ICT have been essential for loosening the spatial constraints on software development.

The combination of low labor costs, technological sophistication, project management skills, and successful software establishment makes India a particularly attractive location for software production outsourcing. From 1996-1997 to 2003-2004, the export software sales of the Indian IT industry had an average annual growth rate of 38.7% to reach a total of US$12.2 billion in 2003-2004 (Nasscom, 2004).

Even though India has had a qualified labor pool and the enabling technologies, along with the great pressure exerted on firms in developed nations to lower costs, the Indian software industry still operates in the low value-added segments, typically in applications development, testing, and maintenance, while the high-end work, such as developing the IT strategy, building the software architecture, designing the system, integrating the project with enterprise packages, and designing custom components are all discharged by firms in developed countries (Dossani & Kenney, 2003).

Agile methods (Beck, 1999) are popular software development processes designed to be used on small- to mid-sized software projects. The Agile movement started in the mid-1990s. The first major project to apply an agile method was the Chrysler Comprehensive Compensation system, a payroll system developed in 1996. This method, called extreme programming, was described in Beck (1999) and became the foundation for the Agile Alliance Manifesto (Agile Alliance, 2001).

Agile methods are based on the notion that object-oriented software development is not a rigidly defined process, but an empirical one that may or may not be repeated with the same success under changed circumstances.

Agile methods are based in four critical values—simplicity, communication, feedback, and courage—informing a set of key practices (Pollice, 2004), which will be considered later on. Boehm and Turner (2004) define agile methods as "very light-weight processes that employ short iterative cycles; actively involve users to establish, prioritize, and verify requirements; and rely on tacit knowledge within a team as opposed to documentation."

Many of the agile practices are incompatible with the context of outsourcing, for example, customer onsite, team co-location, short lifecycle, and embracing change. But above all, agile methods can be applied only to small-sized projects.

In the past, there have been several attempts to reproduce the conditions for agility in large-sized projects. To the best of our knowledge, no such attempt has been made for outsourcing projects. Pollice (2001), Evans (2004), and Boehm and Turner (2004) propose to scale up agile methods by balancing agility and discipline. Pollice and Evans, for instance, look out for common grounds between Agile and RUP (Jacobson, Booch, & Rumbaugh, 1999), while Boehm and Turner try to get the best of both agile and plan-driven (waterfall) worlds. In contrast, Kruchten (2004) proposes to scale down large projects to meet the Agile "sweet spot," based on experience reported in Brownsword and Clements (1996) and Toth, Kruchten, and Paine (1994).

In this chapter we show how to reengineer large-sized (and small-sized) outsourcing projects to benefit from the "sweet spot" of Agile, while avoiding its "bitter spot." The proposed approach makes Agile applicable to the stressed condition of outsourcing environments, without compromising the quality of the software development effort. Creating a context congenial to agile methods hinges on maintaining a good balance between the functions and sizes of onsite and offsite teams, on redefining the developers' roles, and on reorganizing the information flow between the different development activities.

The rest of the chapter is structured as follows. First, we examine the state of the Indian software industry and show the problems experienced by Indian software suppliers. Next, we present the structure of the Agile outsourcing project, customized to the needs of the Indian outsourcing context. We then elaborate the inception and architectural activities, giving enough detail of how large-sized projects can be decomposed to a number of relatively independent agile projects and showing how the resulting builds are integrated. A discussion of many of the issues likely to be faced by Indian suppliers when applying the proposed approach follows, and the final section concludes and outlines plans for future work.

OUTSOURCING TO INDIA

Brief History

The genesis of outsourcing to Indian software firms can be traced back to the 1970s. By the late 1990s, India had become a leading supplier of contract software programming due to its combination of skilled, low-cost labor and project management skills (D'Costa, 2003). Indian software firms such as HCL, Infosys, and Wipro have become globally competitive. Further, their interaction with the global economy has contributed to the development of executive and managerial talent capable of securing overseas contracts, managing the interface with foreign customers, and migrating software development activities across national and firm boundaries.

Multinationals in developed countries and domestic firms quickly understood that there was a significant opportunity to undertake labor-cost arbitrage offshoring to India and moved, beginning in the 1990s, to establish Indian operations. Because the economics were so compelling, Indians living in the U.S. and the UK soon followed suit by establishing outsourcing firms in the U.S. and the UK, respectively, which discharged the work to India.

Drivers

The foremost reason for outsourcing is the potential cost savings, with quality commensurate or even better than that currently provided by the developed nation software developers. India-based outsourcers estimate that, in general, savings on a given activity would have to be at least 40% to make the relocation worthwhile (Dossani & Kenney, 2003). We group the rest of the drivers for outsourcing into technological and economic.

During the last decade, the cost of data transmission has dropped by more than 50%. The lowered telecom costs make it feasible to undertake even communication-intensive tasks outside of the U.S.

Another technological enabler is the ongoing revolution in the world of documents. Today's industrial-strength scanners digitize documents at the rate of 400 pages per minute. The digitized documents can be viewed anywhere in the world on a computer with a high-speed connection.

The last technological development we would like to consider is the widespread use of standard software platforms in corporate information systems, for example, database systems and ERP systems. Standard software platforms facilitate outsourcing since domain knowledge becomes uniform and transferable across industries, or branches thereof. This means that employees ought to acquire only standard, portable skills, thus lessening risks for both suppliers and clients.

Technology is necessary, but not sufficient to convince companies that they should outsource software development to India. Clients need assurance that the process would not be to their detriment and would bring in good return on investment. India has a very successful software establishment, with a proven track record

in satisfying international customers in the area of application programming and maintenance. This creates the necessary comfort levels in the clients. The comfort-building process is assisted by the visible presence of large multinationals like IBM, Dell, Microsoft, General Electric, and British Airways, who have established Indian operations over the past years.

Another very significant factor driving software development outsourcing is the profitability crisis in the developed countries. With revenues largely stagnant for the last four years, firms are under intense pressure to cut costs while retaining quality.

Analysis of the Indian IT Sector

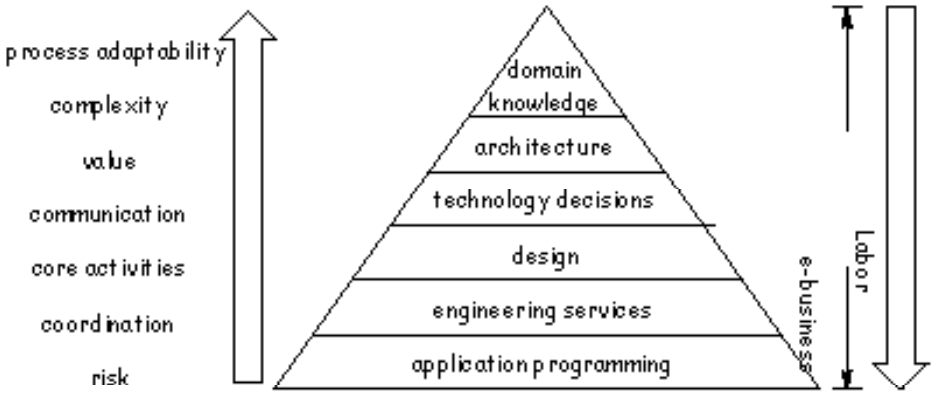
In their analysis, Akella and Dossani (2004) divide the Indian software export into two functional areas: services and products. The authors conclude that, in countries like India, the ability to develop global (but not local) products is more difficult relative to producing services. They observe that, in the Indian software export, services dominate products, and also that services in particular are supplied mostly to non-IT firms in the core, non-critical components of their activities.

A second division is between serving clients from the IT sector and clients outside the IT sector. The ratio between the two sectors offers an insight into the maturity of a software industry: the greater the numbers and the greater the relative weight for the non-IT sector, the more mature the software industry is.

Akella and Dossani classify the Indian software industry output into the following nearly exhaustive list of categories: 1) Web-based support; 2) data processing and management; 3) embedded software; 4) maintenance and legacy systems; and 5) application software development and maintenance. The complexities of the activities involved in all five categories fare low in the complexity pyramid of labor, as shown in Figure 1. Moreover, all five categories predominantly serve clients from the IT sector.

Both IT and non-IT client activities can be divided into core and non-core on the one hand, and critical and non-critical on the other hand. Core activities are manufacturing and engineering services that differentiate a firm from its competi-

Figure 1. Activities and pyramid of labor



tors, and they are key to its continued growth. Non-core activities are the firm's non-competitive services, such as payroll and human resources. The boundary between core and non-core is not clearly cut. Within both core and non-core activities, there are activities crucial to their functioning, termed critical activities.

From Indian suppliers' point of view, non-core and non-critical activities are the easiest to obtain because they tend to be the most standardized across industries, and clients are most willing to outsource them because they do not involve knowledge transfer. Indian suppliers commonly work on applications at the next more difficult level—core, non-critical activities, and rarely on core, critical activities (Akella & Dosssani, 2004).

Strengths of Indian Software Firms

The substantial share of services provided to non-IT clients suggests that Indian firms have expanded their project management capabilities and started to acquire domain knowledge. This could explain the trend of moving away from consultants to direct supplying of end users.

The resource of skilled and motivated people is the most important component of any project. The level of experience and educational qualification of staff at Indian software firms is commensurate to that of most developed countries. The major Indian corporations, for example, are overwhelmingly qualified for ISO 9001, a European standard on quality assurance, and most of them have SEI/CMM certification with a high average score of 4.2 (out of 5) (Nasscom, 2004). SEI/CMM is the Carnegie Mellon University-based Software Engineering Institute's Capability Maturity Model (Paulk, Curtis, Chrissis, & Weber, 1993).

Availability of skilled workers is complemented by a rising supply of CS/EE graduates, which was expected to reach about 99,000 new graduates in 2004-2005 (Nasscom, 2004). Furthermore, Akella and Dossani's study implies that Indian suppliers have the skills to manage projects remotely.

It has been observed that the ratio of onsite/offsite workers increases with firm size. This trend reflects the growing capabilities of larger Indian firms to provide more sophisticated consulting services. The approach proposed in this work relies on an increased onsite presence.

Outsourcing Software Development Activities

What Can Be Outsourced?

When the software development process is considered in its totality, it appears to resist relocation because software production requires face-to-face interactivity with clients (and among co-developers), for example, user requirements elicitation and testing. The development workflow has to be parsed into activities requiring different levels of interactivity, and the less client-communication-intensive activities can be potentially outsourced.

The software complexity chain is frequently described as a series of processes, each of which is less complex than the earlier one. The initial processes are less labor intensive than the later ones. The complexity of a process is roughly inverse-proportional to its labor intensity. The pyramid model in Figure 1 gradates the processes in terms of labor, complexity, risk, and communication intensity.

Theoretically, outsourcing is possible for all the levels of the complexity pyramid, but there are important differences of how outsourcing for each level is likely to be implemented. The processes at or closer to the pyramid's apex, such as domain knowledge acquisition, architecture design, and technology determination, are objectively more difficult to outsource.

Moving up the complexity pyramid entails establishing an intimate client-supplier rapport and acquiring knowledge about the client's core

and critical activities. The higher the pyramid level is, the more communication-intensive the activities become, and the bigger the demand grows for domain, architectural, and design knowledge. Adopting agile methods can help Indian suppliers move up the "value chain" because agile methods address the issues enumerated above.

Developing domain expertise, however, is difficult and risky because the firm becomes dependent on a single industry sector or process. And yet, specialization offers the potential of finding a niche outside the ferocious competition in highly commoditized sectors.

Smaller software firms are at a disadvantage because they lack domain skills and acquiring domain knowledge may be risky. The step transforming the business proposition from simple labor cost arbitrage to significant value addition involves acquiring deep-enough domain expertise.

Interactivity

Interactivity always comes across as a stumbling block for outsourcing. Interactivity has two dimensions—interaction among co-developers and interaction with clients. Requirements elicitation and acceptance testing are the activities requiring the most active involvement on the part of the client, which makes them impossible to offshore.

The greater the need of co-developers to interact across a set of different activities of the software process, the higher the risk threshold of outsourcing a subset of the activities is. Outsourcing the entire set of activities might be considered as a way of retaining interactivity at the new location. But, if some activities cannot be outsourced because that would disrupt the interaction with the client, then outsourcing the others might need rethinking.

Savings from Concentrating Activities in One Location

Often, a number of teams distributed across multiple time zones and reporting to different companies work on a large common project. There might be different reasons for having multiple teams with an inefficient spatial posture cooperating on a project. Most commonly, as companies expand, they outgrow the local labor pools and must establish teams in other regions. It might be too expensive to consolidate these teams in a single location in a developed country, especially for multinationals (e.g., a company with teams in France, Switzerland, Canada, and the Silicon Valley).

The advantages of concentration by relocating to India stem from the larger team size, which relates to economies of scale, such as retaining interactivity at the new location, standardized management practices, and tacit knowledge dissemination. Furthermore, a larger team is likely to have experts with precious domain knowledge in different industry sectors or technologies. In addition, an outsourcing supplier could pool many clients' businesses. A big firm in India can offer guarantees of quality that smaller domestic software firms could not match, owing to the larger labor pool and the division of labor.

For foreign equity participation companies (FEPs)—Indian firms whose foreign equity funding is 100%—the software development process can be reengineered during the act of outsourcing, and inefficient and ineffective practices can be easily abandoned. Very often such practices are legacies of earlier methodologies, such as waterfall lifecycle, iteration planning, and project controlling, that were not eliminated as the development process evolved. As Arthur (1994) has observed, all too often processes evolve in a path-dependent manner, which may not be the most efficient configuration. These inefficiencies can be addressed during the transfer without

disrupting work patterns, since the developers at the new location would not have the outsourcing company culture.

Rethinking of Earlier Cost-Benefit Decisions

The lower cost of more highly skilled personnel calls for rethinking of established cost-benefit decisions. The much lower cost of software engineers in India compared to the U.S. makes it possible to increase the density of software inspections or to dispel managers' doubts about the feasibility of pair programming. Other activities that are candidates for reconsideration are regression and integration testing, iteration planning, and metrics for tracking project progress. In all of the above-mentioned practices, lower labor costs can change the break-even point, and thus create new sources of revenue.

There may also be diseconomies of scale. There are quite naturally risks associated with centralizing the development process at one location. The most significant of these is the danger of losing touch with the national environment(s). In this respect, the effectiveness of the communication process between supplier and outsourcer is critical.

Problems Experienced by Indian Suppliers

The following issues are likely to have an impact on outsourcing. The major challenge faced by Indian software firms is shortage of domain expertise in some function areas. According to the Outsourcing Institute (2004), domain knowledge and expertise are needed in subject areas that are new to India, such as finance, insurance, healthcare, and logistics. However, Indian software firms have acquired sufficient expertise in accounting and banking, which have already been successfully outsourced to India. Maintaining a seamless relationship between the outsourcing supplier and the outsourcing organization back in the developed country is always a challenge.

The problems experienced by Indian suppliers can be "objective" or "subjective." For instance, it is objectively difficult to communicate effectively with a remote client. The lack of expertise in project scheduling is, on the other hand, subjective, particular because it is not universally true. More often than not, a lot more could be done to alleviate the subjective problems rather than the objective ones.

Outsourcing problems fall into three categories: 1) communication—relationship with remote clients; 2) technical know-how—domain expertise, experience in building software architectures, design experience, and inadequate quality thereof; and 3) management—project coordination and project scheduling.

In order to compete successfully on the global market for software products and long-lasting assets (reusable domain solutions), Indian software firms need to resolve the communication, technical know-how, and management issues listed above.

THE AGILE OUTSOURCING PROJECT

In this section, we present an agile method of software development geared toward the context of outsourcing.

Core Agile Practices

Agile methods are iterative and incremental. In an iterative process, the activities that were performed earlier in the process are revisited later. Revisiting activities provides developers in areas such as requirements engineering and software architecture with the opportunity to fix mistakes they have made. The iterative model implies more

interactions among the various management and technical groups. It is a means of carrying out exploratory studies early on in a project when the team develops the requirements and discovers a suitable architecture.

Some important agile practices are the following (Beck, 1999):

- **Embracing Change:** Respond to change quickly to create more value for the customer.
- **Fast Cycle:** Deliver small releases frequently, implement highest priority functions first, speed up requirements elicitation, and integrate daily.
- **Simple Design:** Strive for a lean design, restructure (refactor) the design to improve communication and flexibility or to remove duplication, while at the same time preserve the design's behavior.
- **Pair Programming:** To quote from Beck, "If code reviews are good, we'll review code all the time." With pair programming, two programmers collaborate side by side at one machine. This quality control practice also helps disseminate tacit knowledge among the team members.
- **Test-Driven Development:** Quality control technique, where a developer first writes a test, and then writes the code to pass that test.
- **Tacit Knowledge:** Preference for project knowledge in team members' heads rather than in documents.
- **Customer Onsite:** Continuous access to a customer to resolve ambiguities, set priorities, establish scope and boundary conditions, and provide test scenarios.
- **Co-Location:** Developers and onsite customer work together in a common room to enhance tacit project knowledge and deepen members' expertise.
- **Retrospection:** A post-iteration review of the work done and work planned. This reflective activity facilitates learning and helps improve the estimates for the rest of the project.

The enumerated practices (or disciplines) vary with the method. The disciplines can be divided into three broad categories: 1) communication, such as pair-programming and tacit knowledge; 2) management, such as planning game, scrums (short daily planning sessions, in which the whole team takes part), short cycle, and frequent delivery; and 3) technical, such as test-driven design, simple design, and refactoring. These categories correspond to the three groups of problems experienced by Indian suppliers, as previously discussed.

The fast cycle of agile methods gives business stakeholders multiple and timely feedback opportunities, which makes agile methods explorative (aid in architecture discovery and requirements verification) and adaptive to change. There is a broad consensus that agile methods outperform other software development methods for small projects in dynamic environments, such as in e-commerce.

What we see as a problem with all agile methods (e.g., extreme programming) is that they do not provide guidelines for building high-quality software, which is a natural consequence of their informal nature.

The feasibility-impact grid in Figure 2 shows how the core agile practices can alleviate the Indian suppliers' concerns.

Structuring the Agile Outsourcing Project

The main question we address below is how to reproduce the conditions ideal for agility in an outsourcing project.

Even a quick look at the core agile practices above would reveal that some of them are incompatible, while others are not entirely consistent with the context of outsourcing, for example,

Figure 2. Impact of agile practices on Indian suppliers' concerns

Practices\ Concerns	Domain expertise	Architecture	Design	Scheduling	Communication	Coordination	Quality
Customer onsite	√				√		
Fast cycle		√	√		√		√
Embracing change		√		√			√

Planning game				√		√	
Scrums				√		√	
Pair-programming			√				√
Immediate customer feedback	√	√			√		√

customer onsite, co-location, short lifecycle, and embracing change. Above all, agile methods can be applied only to small projects.

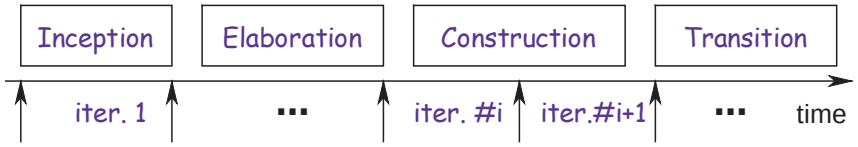
Kruchten (2004) proposes to scale down large projects to meet the Agile "sweet spot." The author describes the organization of a large project as an evolving structure, starting out as one, co-located team, which over time is transformed to a team of teams (with a tree-like structure).

Kruchten suggests organizing the iterative process into four typical RUP phases, as shown in Figure 3. Each phase shifts the focus of the development effort onto a different activity. A phase consists of one or more iterations, where iterations can be thought of as mini waterfalls.

The structure of the agile outsourcing project is based in Kruchten's approach. However, in an agile outsourcing project, the primary goal is not to slice a big project into multiple agile subprojects (which might be required anyway), but to outsource the project to one or more agile teams, which are co-located at a remote site and share common culture and educational background.

The structure of the development process is illustrated in Figure 4. The phases of the lifecycle are separated between "research and development" (R&D) activities and "production" activities, as suggested in Royce (2002). R&D is carried out onsite—close to the client—while production takes place offsite (the supplier's site). Elaboration

Figure 3. Typical RUP phases of the iterative process



is split between R&D and production. The two new phases are called architectural elaboration and production elaboration.

A team comprising requirements engineers and architects starts the development process. Initially, this team focuses on the business case, vision, and requirements. The team works closely with the client in a typical agile setting. The team's objective, however, is not to deliver executable code (a must in agile methods), but to set up an architectural prototype, including prioritized system-level use cases.

When the team has got enough clarity on key architectural choices, it can set about building and testing an architectural prototype.

Towards the end of the architectural elaboration phase, when the architecture stabilizes, additional teams are created offsite. Each new team is seeded preferably with two members of the architecture team. For large projects, the early architectural prototype is used to slice the project into smaller, considerably independent agile projects. Each agile project "owns" part of the system architecture.

The "seed developers" transfer domain expertise from the client to the supplier's site. The "seed developers" take on several roles. They lead the teams, serve as local architects, act as customer surrogates, communicate with the initial architecture team, and if necessary, communicate directly with the client. This organization creates near-perfect conditions for agility in each offsite team.

Each agile offsite team works on a subsystem and develops its detailed subsystem use case model—hence the second elaboration phase, named "production elaboration" in Figure 4.

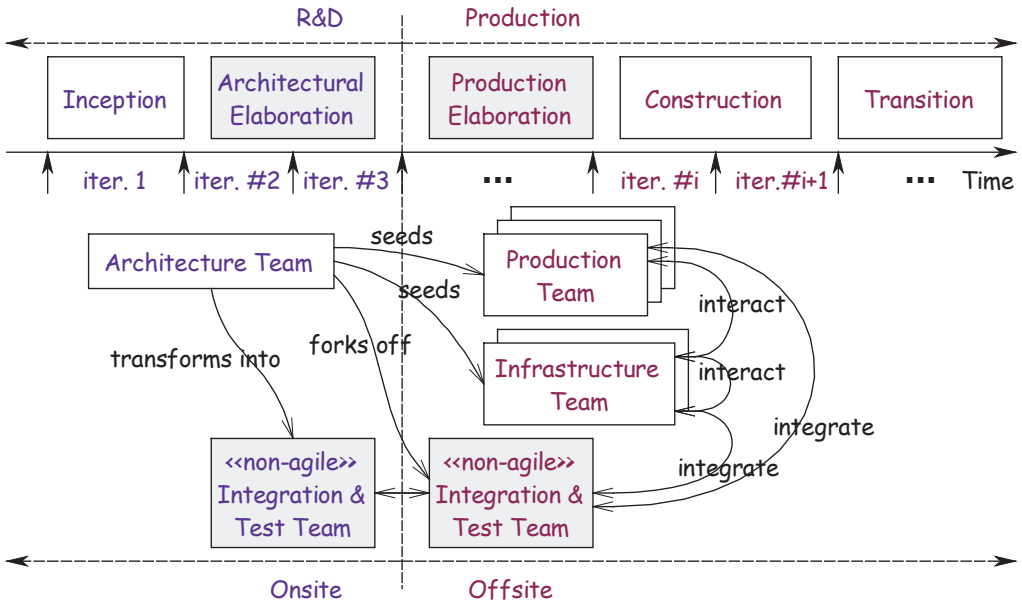
For small projects, one offsite production team will suffice to develop the complete code. For large projects, however, several production teams might be necessary to do the job. In addition, one or more infrastructure teams must be set up to develop common elements such as middleware, services, and any reusable assets. The customers for the infrastructure teams are all other teams. Thus, no matter how many teams are spawned offsite, they all work in agile conditions, even though predominantly with customer surrogates.

It is important to use a common software tool to reduce the risk of miscommunication, to track and communicate project requirements, to identify replicated modules, to map test cases to requirements, and to successfully integrate the outputs from the agile teams' builds.

The context diagrams in Figure 5 model the environments in which the different offsite teams operate. Note the dual nature of "seed developers." On the one hand, a "seed developer" impersonates a customer, and on the other hand, he/she is part of the team.

The interactions of offsite teams with the real customer are supposed to be infrequent, and to

Figure 4. Team structure of agile outsourcing



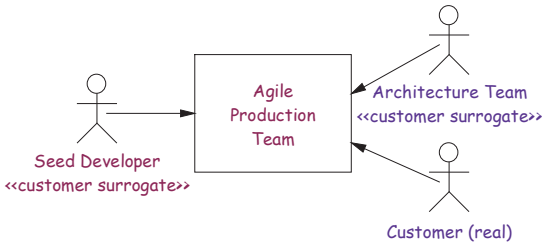
be mediated by the "seed developers" and the architecture team. For large projects, somebody needs to put together the builds delivered by the production and infrastructure teams, and to test the assembled system. This job is assigned to the Integration & Test Team, or integration team for short. The testing engages the client so that the client's feedback situates the project and steers the future effort.

The problem with the integration team is that it gets input from the offsite teams, but receives feedback from the client. Normally, the input and the feedback are coming from the same place—the customer. To account for this anomaly, we split the integration team into two teams, one located onsite and the other offsite (see Figure 4). Both integration teams derive directly from the initial architecture team. This guarantees that the developers in charge of integration and testing thoroughly understand the client's needs.

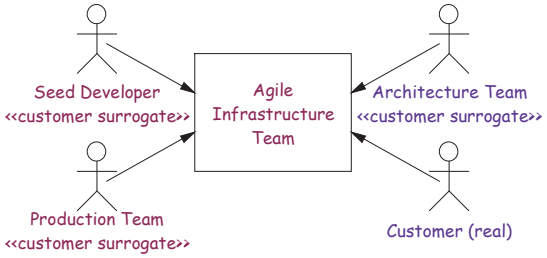
A sore issue stemming from the proposed organization is that of fault propagation. For example, a defect committed by one of the production or infrastructure teams can propagate through the integration process before the client detects it. Owing to the late stage of its detection, isolating and removing such a defect is expensive.

We have provisioned for two floodgates preventing fault propagation: 1) the "seed developers" in each offsite team; and 2) the test engineers in the integration team. Since they all come from the primary architecture team, it is very likely that they would be able to detect many of defects, which are normally revealed with help from customers.

Figure 5. Context diagrams for offsite teams

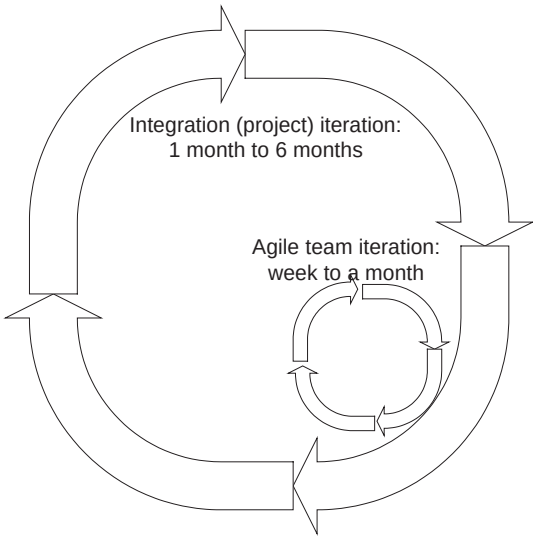


(a) Production team.



(b) Infrastructure team.

Figure 6. Nested iterations



The only two teams operating in non-agile, but still iterative and incremental mode, are the onsite and offsite integration teams.

The iterations (heart beats) of both the agile and integration teams can be best illustrated with the dual beat structure shown in Figure 6. Striking a balance between the lengths of the agile and integration iterations is the underlying objective of the management team.

The management team, composed of all local team managers, is led by the managers of the integration teams. We do not show the management team as a separate box in Figure 4 because management is thinly distributed across all teams.

Since all offsite teams reside in the same country, and most probably in the same city, say Bangalore, there are no cultural differences to overcome, and communications among production, infrastructure, and integration teams are not as ineffective as they are with geographically distributed teams. The management team is in a favorable position because good communication is a prerequisite for effective coordination.

ACTIVITIES AND WORKFLOW

In this section, we give more detail about the activities in an agile outsourcing project, as well as their workflow and information artifacts. We focus on inception, architectural elaboration, and production elaboration because they are critical to creating the agile contexts for the offsite teams.

Inception Phase

During inception, the emphasis is on the user requirements. A user requirement is a specification of what the system must do. As user requirements are elicited, they are organized into use cases. Very briefly, use cases are dialogical descriptions of system usage. By coalescing related transactions and scenarios into identifiable chunks, use case models focus on the dynamic behavior of a system at a macro level.

Use case descriptions can smoothly scale to large and small systems alike. They promote refinement and traceability from system-level usage goals down to low-level (subsystem, component, and instance) usage goals. Use cases are sufficiently flexible to be used in highly iterative and incremental development environments, as the one proposed in this work.

If a system consists of several subsystems, use case analysis can be applied recursively to the subsystems as well. This defines clearly the requirements and responsibilities of each subsystem. Subsystem-level use cases are derived from the system-level use cases and the system architecture (the architectural decomposition of the system into subsystems).

A system is decomposed into subsystems of related use cases, for example, use cases linked by <<include>> and <<extend>> dependency relationships or use cases sharing common actors. The <<include>> relationship is used to extract out a coherent part of a use case, typically for the purpose of reuse. It can also be used to decompose a system-level use case into part use cases to be realized by different subsystems.

The following technique is helpful in mapping a system-level use case to two or more subsystem use cases. The high-level use case is decomposed into a partially ordered set of activities on an activity diagram, where the different subsystems are modeled as swim lanes. Concurrent activities can be mapped to different swim lanes. Each such activity forms a subsystem use case. The actors of the subsystem use cases may be the original actors or other subsystems.

Architectural Elaboration

The onsite team carries out the architectural elaboration. The goals of the architecture team are to partition the system into multiple semantic

domains centered around different subject matters, to define the architectural decomposition of the system into subsystems, and to map system-level use cases to subsystem use cases.

The architecture team defines the model organization of the system being developed, and thus determines the allocation of jobs to teams. Appropriate model organization would allow teams to work effectively on a common project. The two main issues in model organization are how to allow different teams to reuse parts of the projects they do not "own" and how to efficiently implement a build process.

A UML package is a container for modeling elements, and as an organizational unit, it is a natural choice for a configuration item (CI) (a piece of ownership) in a configuration management (CM) tool. A package defines a namespace for the modeling elements it contains. Since UML offers no guidelines as to what constitutes a package, the question is what modeling elements should go into one package versus another.

Domain Modeling

A domain is a subject area with a shared vocabulary (Mellor & Balcer, 2002), for example, user interface (UI) or payment transaction management. Each domain contains many classes organized around a single subject matter. Most domains require specialized expertise, such as experience and knowledge in UI design or in payment transaction management. It makes sense to allocate the modeling of a domain to a developer with domain knowledge in that particular subject area.

Since a domain model captures precisely the conceptual entities of a single subject matter, it can be said that domain models are logical models. Logical models are in sharp contrast to subsystem models, which are pieces of the physical system. Typically, a physical subsystem is constructed from instances of several logical models. For example, a collaboration realizing a system-level use case would involve instances from a UI domain, a business logic domain, a transaction management domain, a persistent storage domain, and a security domain.

At first, it might seem that domains add yet another concern to a software development initiative, but it is all about economic numbers. Constructing domain models reduces production cost by simplifying the development process and by improving product quality.

The underlying philosophy is that a domain-specific model captures precious domain knowledge (e.g., persistence). Domain modeling leverages scarce domain knowledge normally limited to very few team members and shields the rest of the team from the domain implementation detail. For example, to make an object persistent, a developer needs only to mark its class or one of its attributes as persistent, and a persistent software entity is automatically generated at compile time. The result is a simplified development process, where only a few developers need detailed knowledge about domain technicalities.

Henderson-Sellers (1996) and Bettin (2004) observe that software quality degrades faster when software is treated as capital cost (i.e., maintenance only delays the inevitable obsolescence). Treating software as capital cost is incompatible with incrementally building software assets[1] and strategic software[2] assets reused across a large number of enterprise applications, software assets whose value appreciates rather than depreciates. Since domain modeling leverages domain-specific knowledge captured in the form of domain models, strategic software assets are built at no extra cost. Domain models do not degenerate into liabilities[3] over time because they are aligned with the business process architecture of the enterprise and they have the potential to achieve mass customization[4] (Bettin, 2004).

Domains, unlike objects, are not elemental, but just like objects they are cohesive. The classes and components in a domain are tightly coupled

and interdependent, and yet the domain is autonomous—its classes and components are decoupled from entities lying outside the domain boundary. Once constructed, domain models have greater longevity than an application because they evolve independently of other domain models out of which the application is built; that is, they become corporate assets and the biggest units of reuse.

Companies want to be able to adapt their software systems to the constantly changing business environment with minimum effort. It is easy to cope with the intra-domain effect of a change because the domain model naturally fits to the domain's subject matter, and the effect of the change is expressed in the language of the domain (i.e., in familiar domain concepts). The latter taken to the extreme is called end user programming. This scenario works only if no changes are made to the modeling notation. Changing the modeling notation leads to domain engineering and software product line engineering (SEI, 2004).

Domain modeling also alleviates the problem with the inter-domain effect of a change. The semantic autonomy of each domain implies that a domain can be replaced by another one using different conceptual entities or different implementation without affecting the application.

Domain modeling is a pragmatic approach that avoids heavy up-front investment and long-term design degradation (Bettin, 2004). It provides an incremental path of building sustainable domain-specific assets. Software products built out of domain models are not liabilities designed as one-off systems.[5]

Partitioning the project into domains promotes the development of domain models, with externalized interface definitions serving the goal of active dependency management. This is especially true for a domain model that has been developed by domain experts over several years. The market for such software assets has not matured yet, but it is projected to grow up (Booch, 2004; Mellor et al., 2004).

Structured Classes, Subsystems, and Components

In UML2.0, developers represent the containment hierarchy of a system through structured classes. A structured class may contain internal structured classes and instances, each of which may be further decomposed into structured classes and instances, ad infinitum.

The concept of a structured class is based on decomposition and encapsulation. The parts contained in the structured class define the decomposition aspect. Of course, the structured class is more than a simple container for the parts. A structured class has parts connected with connectors, publishes services via provided interfaces, provides runtime connections via ports, and imposes demands on other structured classes (servers) via required interfaces.

Components are structured classes constituting the primary replaceable units of software. In addition, components have an <<artifact>> section used mainly to specify a unit of deployment, such as a .dll file (dynamic library).

In UML 2.0, a subsystem is defined as a subordinate system within a larger system. The subsystems define the large-scale physical architecture of the system. Subsystems are specialized components (i.e., structured classes) used to decompose a system into parts. A subsystem has one compartment for its specification and one compartment for its realization. Either or both of these compartments could be empty or omitted. Developers can use ports and interfaces to show how subsystems relate to other subsystems. The components and objects within a subsystem cooperate to realize a common set of use cases. Ports and interfaces aid in encapsulating the subsystem's internal structure.

Model Organization

Use Case-Based Model Organization for Small-Sized Systems

For small-sized systems, the package structure can be organized by use cases. The system model is divided into packages of related use cases. This model organization is straightforward and allows tracing requirements easily to model elements. The downside of the use-case-based model organization is that it does not scale up well and encumbers reuse. Developers are forced to reinvent similar classes in different use case collaborations.

A quick remedy is to add a framework package for common elements such as usage points (services) and extension points (classes to subclass in use case packages). Regardless of this remedy, the use-case-based model organization still works well only for small-sized systems. Identifying commonalities in large systems leads to an explosive context and inter-team communication growth.

Domain-Based Model Organization—Large-Sized Systems

We propose to derive the package structure and contents for large-sized systems from the requirements model, the architecture model, and the domain model. The top-level packages of the domain-based system model are:

- System use cases and actors package
- Domains package
- Infrastructure package
- Subsystems package
- Builds package

The system use cases package contains system-level use cases and their actors. The domain package has one sub-package for each domain.

The infrastructure domain is a special type of domain. Infrastructure domains contain services and extension points for system communication and infrastructure, and they are dependent on the selected implementation technology (e.g., RMI/J2EE or CORBA). The infrastructure package contains one sub-package for each infrastructure domain. An infrastructure domain evolves into a self-contained subsystem package, which is assigned to an infrastructure team. Several production teams may use the classes and components, realizing the services of the infrastructure package.

Each subsystem package contains the classes and components of a subsystem, the largest-scale pieces of system functionality. If any of the subsystem packages is large enough, it can be recursively divided into sub-packages until the size of the leaf packages becomes manageable. A leaf package is a unit of ownership, such as a CI in a CM tool. A subsystem package normally refers to classes of several domain packages.

The builds package is divided into sub-packages, one per prototype to allow for easy management of incremental builds. This package also includes the system test model, such as test cases, test procedures, and test scripts, along with the drivers, stubs, and collaborations realizing the test model.

The domain-based model organization scales up well to large-sized projects for three main reasons. First, subsystem package decomposition can be applied recursively, resulting in subsystems realizing subsystem use cases. Second, classes from different domains may be reused in different deployment settings of the designed system, and third, domain models are assets that can be reused across projects.

The following are the major problems teams may experience with the domain-based model organization. Developers tend to blur the distinction between domain models and subsystem models. There is an overhead associated with maintaining

two separate types of models: domain models (logical) and subsystem models (physical).

If reuse is not a primary objective or if the system being designed is a small-sized one, a use-case-based model organization might work better because of the lower added overhead associated with model organization.

Production Elaboration

All strategic decisions for the overall organization structure of the system have been made in the architectural elaboration phase. Production elaboration drills down inside the subsystems to specify the semantic objects whose collaborations deliver the system's structure and behavior.

The demarcation line between architectural and production elaborations is the divide between logical and physical models, and between system-level use cases and subsystem use cases.

In production elaboration, the subsystem use cases are detailed and mapped to collaborations of components and objects. The following technique can assist in elaborating a system-level scenario. The developer starts out with the high-level sequence diagram for the scenario, and then adds lifelines for the instances of the identified classes. In this way, the developer can trace the elaborated scenario back to the original one and verify the design. Communication diagrams are extensively used to represent the stabilized semantic object structure. The measure of goodness at this level is benchmarked by whether the architectural design can realize the usage scenarios defined at the system level.

The described approach scales up well to many levels of subsystem decomposition. As mentioned earlier, the seed developers and production teams serve as customer surrogates.

Packages	Team
System use cases package	Architecture team
Domains package	Reused if already developed or assigned to the architecture team
Infrastructure domain packages	Infrastructure teams
Subsystem packages	Production teams
Builds package	integration and test teams

Next we show how packages are assigned to teams, for example, the architecture team is in charge of developing the system use cases, and therefore "owns" the systm use cases package.

DISCUSSION

Challenges to Agile Outsourcing Projects

Managers of agile outsourcing projects ought to be aware of the following challenges looming ahead.

The architecture team is the key to project success. It is of paramount importance that this team be a good mix of requirements analysts and architects. According to Akella and Dossani (2004), the total percent of technical staff in Indian software firms is about 85% and of MBAs about 4.9%. In contrast, in Silicon Valley, 28% of the Indian IT engineers have MBA degrees, which is a significant comparative advantage. According to the same study, Indian suppliers are mostly "pure-IT" firms, that is, they have limited domain knowledge outside the IT sector, and the average percentage share of architecture/technology consulting amounts to about 2.9%.

In this context, we see the formation of a balanced architecture team as a major challenge to agile outsourcing projects, for members of this team elicit requirements, build the primary system architecture, and subsequently take the roles of surrogate customers, local managers, integration and test engineers, and communicate with the customer throughout the entire lifecycle.

Inter-team dependencies reduce teams' abilities (especially affected is the infrastructure team) to test code and deliver builds. Production teams should provide early on the infrastructure team(s) with stubs, so that the work of the infrastructure team(s) proceeds smoothly.

In large projects, it is difficult to balance teams' workloads. Adaptive scheduling algorithms in grid computing have proven superior to static scheduling algorithms (Blumofe & Leiserson, 1999; Rousev & Wu, 2001). We propose employee stealing as an adaptive technique for load balancing. An overloaded team (thief) picks up a victim team at random and tries to steal a developer from the victim. If the victim is under-loaded, the stealing succeeds. Otherwise, a new attempt to steal a developer is made.

The random choice of a victim team and a developer makes the technique dynamic and adaptive. The geographical proximity of the offsite teams and the agile method applied are essential prerequisites for employee stealing because they facilitate fast learning.

Employee stealing is a knowledge dissemination technique, which can be viewed as a generalization of pair programming and developer rotation in extreme programming. Employee stealing may be applied as a routine practice, even with balanced projects, in order to improve inter-team communication and coordination, to arbitrate in problems straddling two teams, and to preclude loss of common goal.

With multiple teams, there is always the danger of replicating functionality across teams. The proximity and common culture of the offsite teams work against the chances of duplicating functionality. The participation of the members of the architecture and later integration teams in design reviews and software inspections helps detect replication early. Employee stealing is another effective mechanism to curb duplication.

Why Agility is the Right Path for Indian Suppliers

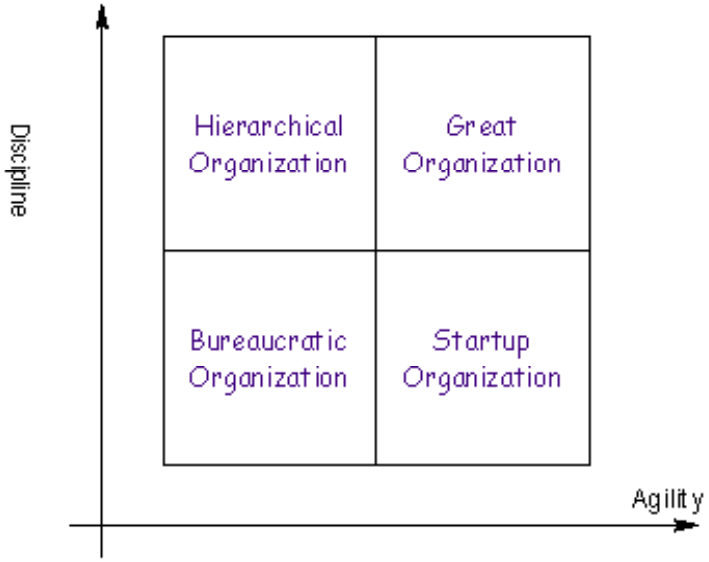
In his book *Good to Great*, Collins (2001) characterizes how self-discipline and entrepreneurial agility contribute to greatness at the corporate level (see Figure 7). Boehm and Turner (2004, p. 156) observe similarity between the patterns of creativity at corporate management and in software development, and apply Collins' method for performing self-assessment to software organizations.

Small Indian firms are mostly startup organizations, and agility improves their chances of survival. Both foreign equity participation companies and major Indian companies aim at the North-East quadrant in Figure 7, and therefore agility will be instrumental in attaining their goals.

The rapid growth of Indian outsourcing suppliers has created a dynamic labor market with a large demand for lead developers for new projects. The average turnover level exceeds 15%. Suffice it to mention that in some cases contracts have placed a liability on the supplier for certain levels of turnover in an attempt to protect the interests of the client. Agile outsourcing could break the impact of high turnover. Several core agile practices (e.g., preference for tacit knowledge, pair programming, and retrospection), along with employee stealing, allow new team members to be brought quickly up to speed.

Agile outsourcing could aid the transfer of domain knowledge to Indian suppliers. With more domain knowledge and the pressing need to communicate directly with customers, agile outsourcing would help organizations move farther away from consultants to directly supply end users.

Figure 7. Good-to-great matrix of creative discipline



The increased revenue per employee, arising from moving up the "value chain," could be partly offset by the increase in the onsite/offsite developers ratio. The small agile team size would allow small and medium enterprises to catch up with foreign equity participation companies and major Indian companies. As a result, small and medium companies could directly participate in complete service and product development.

Executable Domain Models

Below we discuss briefly executable domain models, which are believed to become mainstream in the near future (Booch, 2004; Mellor et al., 2004). Executable models are at the heart of the latest OMG initiative—the Model-Driven Architecture (OMG, 2004).

When working on a model or part of it, a developer must be able to answer the question, "Is this model correct?" Agile methods, through the "prove with code principle" and fast cycle, answer this question almost instantaneously, hence the shorter development times and the better customer satisfaction.

In our view, a problem with agile methods is the level at which the software artifacts are tested. When a system is designed in UML, it has to be tested in UML and not in the underlying source language. While, at times, it is necessary to drill down to the lowest level of detail (e.g., to stress-test the build), the majority of testing ought to be at model level, where the precious business logic and knowledge are captured.

In order for a model to be testable, it has to be executable, which means that the modeling language must have executable semantics. Executable UML (xUML) is a UML profile with precise action semantics (AS, 2001) that allows system developers to build executable system models, and then to map these models using code generators to source code for a target platform (Mellor & Balcer, 2002).

Executable domain models are expected to play an increasing role in software production. Executable domain models fit naturally with

the domain-based model organization of agile outsourcing projects.

CONCLUSION

In the late 1990s and early 2000s, agile methods took the imagination of software developers by storm. This fact clearly indicates that heavyweight methods have not been embraced wholeheartedly by developers and managers alike, and are found either impractical or costly (or both) in many environments. Driven by low labor costs for commensurate quality in India, and also by stagnant revenues in developed countries, firms have been increasingly outsourcing software production to India. In this chapter, we introduced a novel project structure creating agile conditions for large outsourcing software projects. The proposed structure is tailored to the needs of the Indian outsourcing suppliers. Several assumptions make agile outsourcing Indian-unique. First, we assume that there are large pools of qualified developers residing in one geographical area and even in one city. Second, the outsourcing country has grown a sustainable software industry that is supported by advanced information and telecommunication technologies, and led by talented managers, allowing it to secure large software projects.

We showed how to slice a large software project into multiple agile projects. We proposed to separate the development activities to R&D activities, carried out onsite, close to the client, and production activities, carried out offsite in India. The onsite, architecture team starts work on the project. In cooperation with the client, the architecture team develops the high-level use case model of the system and completes an architectural prototype with the strategic decisions for the overall system structure. The agile offsite teams are seeded with members of the architecture team and start functioning toward the end of the architectural elaboration. The "seed developers" transfer domain expertise to the supplier's site and act as customer surrogates to help reproduce agile conditions offsite. Outsourcing the entire set of production activities retains interactivity at the offsite location.

The domain-based package structure of the system model is organized by domains, subsystem use cases, and builds. This model organization scales up well to large-sized projects, because the subsystem packages can be recursively divided into smaller ones. The domain packages facilitate reuse of components and classes from different subject matters. The domain models could become software assets reused across projects.

To balance the teams' workloads and avoid replicating functionality by different teams, we proposed a new adaptive technique called employee stealing. Employee stealing is instrumental in disseminating tacit knowledge about the project and in lifting up the developers' expertise. It also improves the inter-team communication and coordination, and precludes the loss of common goal.

We plan on combining aspects of domain engineering and executable domain models in xUML with agile outsourcing to raise the level of abstraction and reuse, and to automate the repetitive tasks in the software process. We are especially interested in employing techniques preventing architectural degradation in large systems and in building "software factories" that produce families of sustainable software assets using highly automated processes. We would like to support the emerging "supply chains" for software development, which enables mass customization. To fully support domain-driven design, we ought to differentiate clearly between building a product platform and designing an application. Gearing executable domain models to the proposed agile outsourcing methodology will result in making agile outsourcing even more agile.

ENDNOTES

1. In domain modeling, a software asset is anything from models, components, frameworks, generators, to languages and techniques.
2. Strategic assets are the software assets at the heart of a business—assets that grow into an active human- and machine-usable knowledge base about a business and its process.
3. A software liability is software that is cost burden—that is., software that costs more than it is delivering to the business (Bettin, 2004).
4. Mass customization meets the requirements of heterogeneous markets by producing goods and services to match individual customer's needs with near mass production efficiency.
5. One-off systems have a very short lifespan and are too expensive for most practical purposes.

Chapter 2.26
Decision Rule for Investment in Frameworks of Reuse

Roy Gelbard
Bar-Ilan University, Israel

ABSTRACT

Reuse helps to decrease development time, code errors, and code units. Therefore, it serves to improve quality and productivity frameworks in software development. The question is not HOW to make the code reusable, but WHICH amount of software components would be most beneficial, that is, cost-effective in terms of reuse, and WHAT method should be used to decide whether to make a component reusable or not. If we had unlimited time and resources, we could write any code unit in a reusable way. In other words, its reusability would be 100%. However, in real life, resources are limited and there are clear deadlines to be met. Given these constraints, decisions regarding reusability are not always straightforward. The current research focuses on decision-making rules for investing in reuse frameworks. It attempts to determine the parameters, which should be taken into account in decisions relating to degrees of reusability. Two new models are presented for decision-making relating to reusability: (i) a restricted model and (ii) a non-restricted model. Decisions made by using these models are then analyzed and discussed.

INTRODUCTION

Reuse helps decrease development time, code errors, and code units, thereby improving quality and productivity frameworks in software development. Reuse is based on the premise that educing a solution from the statement of a problem involves more effort (labor, computation, etc.) than inducing a solution from a similar problem for which such efforts have already been expended. Therefore, reuse challenges are structural, organizational, and managerial, as well as technical.

Economic considerations and cost-benefit analyses in general, must be at the center of any discussion of software reuse; hence, the cost-benefit issue is not HOW to make the code reusable, but WHICH amount of software components would be most beneficial, that is, cost-effective

for reuse, and WHAT method should be used when deciding whether to make a component reusable or not.

If we had unlimited time and resources, we could write any code unit in a reusable way. In other words, its reusability would be 100% (reusability refers to the degree to which a code unit can be reused). However, in real life, resources are limited and there are clear deadlines to be met. Given these constraints, reusability decisions are not always straightforward.

A review of the relevant literature shows that there are a variety of models used for calculating-evaluating reuse effectiveness, but none apparently focus on the issue of the degree to which a code is reusable. Thus, the real question is how to make reusability pragmatic and efficient, that is, a decision rule for investment in reuse frameworks. The current study focuses on the parameters, which should be taken into account when making reusability degree decisions. Two new models are presented here for reusability decision-making:

- A non-restricted model, which does not take into account time, resources, or investment restrictions.
- A restricted model, which takes the above-mentioned restrictions into account.

The models are compared, using the same data, to test whether they lead to the same conclusions or whether a contingency approach is preferable.

BACKGROUND

Notwithstanding differences between reuse approaches, it is useful to think of software reuse research in terms of attempts to minimize the average cost of a reuse occurrence (Mili, Mili, & Mili, 1995).

[Search* + *(*1-p*) * (ApproxSearch* +q ** Adaptation old **+ *(*1-q*)* Development*** new ***)]***

Where:

- ***Search*** (***ApproxSearch***) is the average cost of formulating a search statement of a library of reusable components and either finding one that matches the requirements exactly (appreciatively), or being convinced that none exists.
- ***Adaptation*** old is the average cost of adapting a component returned by approximate retrieval.
- ***Development*** new is the average cost of developing a component that has no match, exact or approximate, in the library.

For reuse to be cost-effective, the above must be smaller than:

p ****Development* exact **+*(*1-p*)* q * Development*** approx **+*(*1-p*)* (*1-q*)´ Development*** new***)***

Where:

- ***Development*** exact and ***development*** new represent the average cost of developing custom-tailored versions of components in the library that could be used as is, or adapted, respectively. Note that all these averages are time averages, and not averages of individual components, that is, a reusable component is counted as many times as it is used.

Developing reusable software aims at maximizing P (probability of finding an exact match) and Q (probability of finding an approximate match), that is, maximizing the coverage of the application domain and minimizing adaptation for a set of common mismatches, that is, packaging components in such a way that the most common old mismatches are handled easily. Increasing P

and Q does not necessarily mean putting more components in the library; it could also mean adding components that are more frequently needed, because adding components not only has its direct expenses (adaptation costs), but also increases search costs.

There are two main approaches to **code adaptation**: (1) identifying components that are generally useful and (2) covering the same set of needs with fewer components, which involves two paradigms: (i) abstraction and (ii) composition. Composition supports the creation of a virtually unlimited number of aggregates from the same set of components, and reduces the risk of combinatorial explosion that would result from enumerating all the possible configurations. In general, the higher the level of abstraction at which composition takes place, the wider the range of systems (and behaviours) that can be obtained. The combination of abstraction and composition provides a powerful paradigm for constructing systems from reusable components (Mili et al., 1995).

Frakes and Terry describe a wide range of metrics and adaptation models for software reuse. Six types of metrics and models are reviewed: cost-benefit models, maturity assessment models, amount of reuse metrics, failure modes models, reusability assessment models, and reuse library metrics (Frakes & Terry, 1996).

Other studies (Henninger, 1999; Otso, 1995; Virtanen, 2000; Ye, Fischer, & Reeves, 2000; Ye & Fischer, 2002), present additional metrics and methods, evaluate and make comparisons, but as is typical in an emerging discipline such as systematic software reuse, many of these metrics and models still lack formal validation. Despite this, they are used and are found useful in industrial practice (Ferri et al., 1997; Chaki, Clarke, Groce, Jha, & Veith, 2004).

Empirical work (Mens & Tourwé, 2004; Paulson, Succi, & Eberlein, 2004; Tomer, Goldin, Kuflik, Kimchi, & Schach, 2004; Virtanen, 2001; Ye, 2002) has analyzed existing reuse metrics and their industrial applicability. These metrics are then applied to a collection of public domain software products and projects categories to assess the level of correlation between them and other well-known software metrics such as complexity, volume, lines of code, and so forth.

Current research is focused on decision-making rules for investment in reuse frameworks. The well-known "simple model" and "development cost model" deal with these decisions, but do not take into account restrictions and constraints such as time, budget, resources, or other kinds of investment, such as delivery time, that may impact on the decision to reuse.

ANALYZING NEW REUSE MODELS

Assume a software development project contains 3 code components: A, B, and C, and we need to determine two things: Which of these components should be reusable? What criteria should be taken into account?

There are eight combinations—choice alternatives for these 3 components, as shown in Table 1 (+ represents "make reusable," - represents "don't make reusable").

A. The Non-Restricted Model

The model contains the following parameters:

- **Ci—**cost of creating component **i** from scratch (without making it reusable).
- **Ri**—cost of making component **i** reusable (extra costs – not included in **Ci**).
- **ICi**—cost of implementing reusable component **i** into code.
- **NRi**—number of reuses of component i. (C, R, and NR are in man-hours).

Savings resulting from making component **i** reusable are represented as follows:

Table 1. Choice alternatives

Alternative	Component A	Component B	Component C
1	-	-	-
2	+	-	-
3	-	+	-
4	+	+	-
5	-	-	+
6	+	-	+
7	-	+	+
8	+	+	+

SAVi = NRi *(Ci – ICi) – (Ci + Ri)

Therefore: If **SAVi** > 0, it is worthwhile to make component **i** reusable.

Suppose a company that employs two kinds of programmers: **M** and **N**. Programmers of type **M** are permanent employees of the firm. Programmers of type **N** are highly qualified consultants who are employed by the company for specific projects. The company is going to write/create/develop a new project, and has to make a decision regarding which components should be reusable.

The following are additional parameters:

- **Cim**—hours needed for programmer M to create component **i** from scratch.
- **Rim**—hours needed for programmer M to make component **i** reusable.
- **ICim**—hours needed for programmer M to implement reusable component **i** into code.
- **Sm**—costs of programmer M, per 1 hour.

Hence:

Ci= Min(Cim*Sm, Cin*Sn)
Ici= Min(ICim*Sm, ICin*Sn)
Ri= Min(Rim*Sm, Rin*Sn)

Hence:

SAVi = NRi *(Min(Cim*Sm, Cin*Sn) – Min(ICim*Sm, ICin*Sn)) – (Min(Cim*Sm, Cin*Sn) + Min(Rim*Sm, Rin*Sn))

B. The Restricted Model

The non-restricted model has the following limitations:

- It requires absolute values
- It is quite difficult to measure parameters such as: **Ci**, **Ri,** and **Ici**
- It does not take into account the most typical situation where time and budget are restricted as well as in-house investment in reuse, that is, time and resources for reusable code developing.

In order to avoid these limitations, the restricted model is based upon the following parameters:

- **I**—maximal **investment** that can be allocated for writing a reusable code.
- **T**—maximal calendar **time** that can be allocated for writing a reusable code.
- **Ii**—percent of "**I"** needed to make component **i** reusable.
- **Ti**—percent of "**T"** needed to make component **i** reusable.
- **Ci**—relative **complexity** of creating component **i** from scratch.
- **Fi—frequency** (%) of future projects that are likely to reuse component **i.**
- **Pi**—relative **profit** of making component **i** reusable.
- $\mathbf{R_I}$**—r**emainder of "**I"**, after some reusable components have been written.
- $\mathbf{R_T}$**—**remainder of "**T**," after some reusable components have been written.

Assume that: **Pi** = **Ci** * **Fi.**

Hence: component **i** is the next component to be made reusable if:

Pi = Max(P1, P2, ..., Pn-1, Pn)
Ii <= **RI**
Ti <= RT

C. Illustrative Example: Non-Restricted Model

The following example (Example 1) demonstrates the decision made by the non-restricted model. Assume we want to develop 10 projects, each one containing components A, B, and C according to Table 2.

Hence**: NRa** = 10, **NRb** = 1, **NRc** = 4

Table 3 presents illustrative assumptions concerning **Cim** and **Cin** (hours needed for programmer type M and N to create component **i** from scratch).

Moreover, assume programmers' costs to be: **Sm** = 20, **Sn** = 40

Hence:

Table 2. Example 1, number of components for future reuse

Project	1	2	3	4	5	6	7	8	9	10
Component A	+	+	+	+	+	+	+	+	+	+
Component B	+									
Component C	+	+	+	+						

Table 3. Example 1, Ci illustrative assumptions

Programmer type	Component A	Component B	Component C
Type M	*300*	*20*	*150*
Type N	*200*	*10*	*100*

Ca = Min(300*20, 200*40) = 6,000
Cb = Min(20*20, 10*40) = 400
Cc = Min(150*20, 100*40) = 3,000

Table 4 presents illustrative assumptions concerning **Rim** and **Rin** (hours needed for programmers type M and N to make component **i** reusable).

Hence:

Ra = Min(650*20, 300*40) = 12,000
Rb = Min(15*20, 7*40) = 280
Rc = Min(150*20, 80*40) = 3,000

Table 5 presents illustrative assumptions concerning **ICim** and **ICin** (hours needed for programmers type M /N to implement reusable component **i** into code).

Hence:

ICa = Min(60*20, 15*40) = 600
ICb = Min(5*20, 3*40) = 100
ICc = Min(50*20, 10*40) = 400

Hence:

SAVa = 10 *(6,000 – 600) – (6,000 + 12,000) = 36000 > 0
SAVb = 1 *(400 – 100) – (400 + 280) = -380 < 0
SAVc = 4 *(3000– 400) – (3,000+ 3,000) = 4400 > 0

In light of the mentioned, the reuse decision according to the non-restricted model is to make components A and C reusable (i.e., alternative 6).

D. Illustrative Example: Restricted Model

The following example (Example 2) demonstrates the decision made by the restricted model, based on the previous example (Example 1). Assume the following:

1. **I**—10,000.
2. **T**—150. The available remaining time to make the existing code reusable.

Table 4. Example 1, Ri illustrative assumptions

Programmer type	Component A	Component B	Component C
Type M	*650*	*15*	*150*
Type N	*300*	*7*	*80*

Table 5. Example 1, ICi illustrative assumptions

Programmer type	Component A	Component B	Component C
Type M	*60*	*5*	*50*
Type N	*15*	*3*	*10*

Table 6. Parameters used by Example 2

Component	Ci	Fi(%)	Pi	Ii(%)	Ti(100%)
A	*30*	*100*	*30*	*120*	*200*
B	*1*	*10*	*0.1*	*2.8*	*4.7*
C	*15*	*40*	*0.6*	*30*	*100*

3. **Ci**—assume component B is the easiest one to develop, and requires 10 hours. Assume component A requires 300 hours and component C requires 150 hours. Hence, complexities are: C_A=30, C_B=1, C_C =15.
4. **Fi**—component A will be reused by 100% of future projects, B by 10%, and C by 40%.
5. $\mathbf{I_A}$ = 12,000/10,000 = 120%, $\mathbf{I_B}$ = 280/10,000 = 2.8%, $\mathbf{I_C}$ = 3000/10,000 = 30%.
6. $\mathbf{T_A}$ = 300/150 = 200%, $\mathbf{T_B}$ = 7/150 = 4.7%, $\mathbf{T_C}$ = 150/150 = 100%.

Hence Example 2 parameters are shown in Table 6.

Taking time and investment restrictions into account, the reuse decision, according to the restricted model is to make only component C reusable (i.e., alternative 5).

CONCLUSION AND FUTURE TRENDS

The current study presented two new reuse decision making models: a restricted model and a non restricted model, which mainly differ in the way they take into account real-life constraints-restrictions such as time, budget, and resources repetition.

The models produced different results from the same data. The decision made by the restricted model pinpointed fewer software components for reuse. It is worth mentioning that different groups of software components were not the issue, but rather different subgroups of the same group, that is, software components selected by the restricted model were subgroups of components selected by the non-restricted model.

Moreover, the parameters of the restricted model relate to relative value arguments, by contrast to the parameters of non-restricted model, which relate to absolute values. While absolute values are difficult to measure, relative values are simpler to define. There are a variety of formal methods by which relative values may be defined, methods that are used in other areas of software engineering, such as cost estimation, effort estimation, priority decision, and others.

The reusability decision made by the restricted model may be biased by the following parameters: time, resources, component complexity, and number-percent of future projects in which the component would be reused. Further research should be conducted, focusing on decision robustness in light of the mentioned parameters and their possible spectrum.

ACKNOWLEDGMENT

I would like to thank Tami Shapiro for her contribution to this work.

KEY TERMS

Decision Rule: Either a formal or heuristic rule used to determine the final outcome of the decision problem.

Non-Restricted Reuse-Costing Model is a reuse-costing model that does not take into account real-life constraints and restrictions, such as time, budget, resources, or any other kind of investment.

Reuse: Using an item more than once. This includes conventional reuse where the item is used again for the same function and new-life reuse where it is used for a new function (wikipedia).

Reuse-Costing Model: A formal model, which takes into account the expenditure to produce a reusable software product.

Restricted Reuse-Costing Model: A reuse-costing model that takes into account real-life constraints and restrictions such as time, budget, resources, or any other kind of investment.

Software Reuse: Also called code reuse, is the use of existing software components (e.g., routines, functions, classes, objects, up to the entire module) to build new software.

Chapter 2.27
Integrated Product Life Cycle Management for Software: CMMI[1], SPICE, and ISO/IEC 20000

Dirk Malzahn
OrgaTech GmbH, Germany

ABSTRACT

This chapter describes how models for software development and service delivery can be integrated into a common approach to reach an integrated product life cycle for software. The models covered by this chapter are the capability maturity model integration (CMMI), SPICE (software process improvement and capability determination, ISO 15504) and ISO 20000 (service management). Whilst the CMMI constellation approach delivers an integration perspective defined in three models (development, acquisition and services), SPICE and ISO 20000 need additional alignment to be usable in an integrated approach.

INTRODUCTION

The focus of the market for IT solutions has changed. Whilst many companies and organizations followed the latest "hype" several years ago, they now trust in reliable and sustainable solutions.

To ensure this, standardization of quality evaluation becomes more and more important. For supplier selection, make-or-buy decisions and outsourcing strategies, a powerful set of procedures, that can help to assess the capability of internal and external software processes, is required. These procedures have to be based on best practices and must be widely accepted.

On this basis, standards offer the best possibilities: they are usually defined by a wide group of experts, which all contribute their experiences and best practices. Standards are either sponsored by an industry or by national bodies—therefore making these standards de facto mandatory for an industry, nation, or combination of both enforces the acceptance. If a significant group uses a standard, market dynamics have an additional impact. Official certificates, levels, and so forth can be and are used for marketing activities.

In the field of software related standards, lots of different standards have been defined for special topics, but one standard is still missing: a standard that covers a software product from the very beginning—the first idea—up to the very end—the retirement of the software.

On the one hand powerful standards, for example the capability maturity model integration (CMMI) or SPICE (ISO 15504), have been defined for software development. On the other hand, standards for service delivery, for example ITIL or ISO 20000, have been well established; but there is still a wall between the worlds of software development and service delivery. Even though some standards – like SPICE – take a look over the wall, an integrated approach has not been delivered yet.

The need for this integration is obvious. A customer is not interested in having some quality for development and some other quality for service delivery—the customer needs one quality approach that covers the full life cycle of a software product.

BACKGROUND

The Wall Between Software Development and Service Delivery

When IT systems are planned, the focus of the planning is mostly restricted to software development. Topics like operation environment or data management are discussed, but the strategy usually ends with the delivery of the software product.

On the other hand, service-delivering organizations mostly just provide "services" and are not really interested in the software development process.

This behavior leads to multiple difficulties and inefficiencies:

- Software developers and service people do not understand each other. They work in different worlds and have their own "language" and processes.
- The efficiency and effectiveness of service delivery highly depends on the architecture of and assumptions for the software, therefore the service organization has to be integrated early into the software development.
- Service level agreements can be optimized, when both sides reach a common understanding. The development of service level agreements is often based on the "what we need" position of both sides and not on the "what will be best for the customer" position.
- Problem Management is not transparent to the customer. The customer is not interested whether he has a service problem or a software problem—the customer wants a quick and reliable solution. If the software side does not understand the service side, problems often become ping-pong balls.
- Software usually lives longer than the original developer intends. Systems often have to be enhanced just to fulfil the requirements of a new service platform. If this is not taken into account when the software is developed, the effort for updating software may become enormous. Sometimes software has to be retired, just because it is not executable on the new platform!
- New approaches like service oriented architectures (SOA) demand the high integration of software and service elements. Future trends will rather lead to small combined software/service environments than to big software solutions operated by massive computer environments.

Just to ensure that I am not misunderstood: software developing and service delivering orga-

nizations will still deliver and operate solutions with high quality—but the will not do it in the most efficient and effective way. Organizations and companies aiming for the delivery of sustainable and reliable solutions have to ensure, that the solutions are not only developed in the best way but will meet the requirements of the future efficiently, effectively and still with high quality.

Standards for Software Development and Service Delivery

Regarding software development, two standard are widely accepted all over the world: the Capability Maturity Model Integration, published by the Software Engineering Institute (SEI) at the Carnegie Mellon University, and SPICE (Software Process Improvement and Capability Determination), which is published as ISO standard 15504. Both standards define a process framework based on best practices and provide an assessment model to evaluate process capability.

A process reference model (PRM) and a process assessment model (PAM) usually characterize a process framework. The PRM defines processes that have shown evidence to support high quality for the defined domain – in our case software development. The PAM builds the basis for collecting evidence that the PRM is adhered to and to evaluate the capability of the processes defined in the PRM.

In the world of service delivery, ITIL (IT Infrastructure Library) is the most acknowledged standard. To make ITIL assessable, the ISO 20000 standard was developed.

But as it was said before, none of these standards cover the complete software life cycle. This gap is seen by the SEI and discussed by relevant contributors to the ISO standards. In this article two approaches for this integration are discussed—one based on the CMMI and the other based on the connection of SPICE and ISO 20000.

CMMI INTEGRATION PERSPECTIVE

CMMI is one of the best-established process frameworks for software development. Starting with the publication of Watts Humphreys book "Managing the Software Process" in 1989, the CMM and its successor—the CMMI—nearly became a synonym for process improvement in the software world.

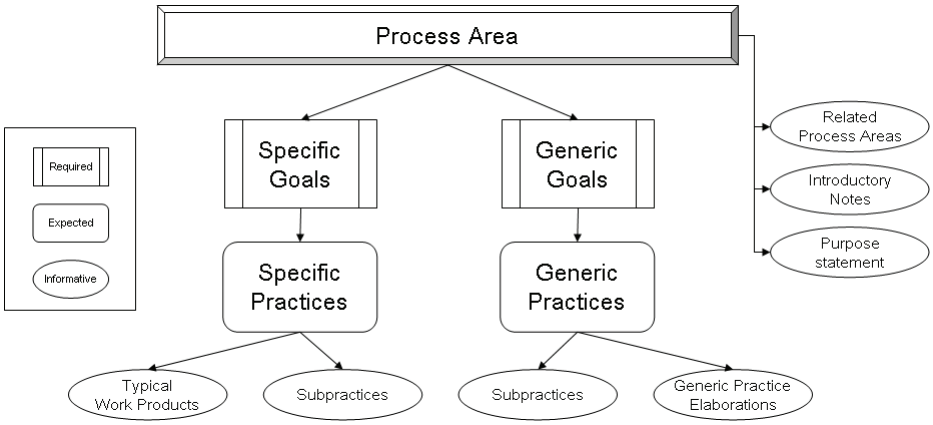
Nevertheless, until 2006, the CMMI was restricted on software and systems development. Since then a new initiative has been started to further develop the CMMI in the direction of acquisition and service processes. If one is talking about "CMMI" mostly the CMMI-DEV (for Development) is meant. This is the classical CMMI stream that covers service development. Other ideas concerning the usage and benefits of the CMMI for organizations that only acquire software, lead to the CMMI-ACQ (for Acquisition), which was published in November 2007. In 2006 and 2007 a CMMI for Services (CMM-SVC) has been developed to close the gap between software development and service delivery. The CMMI-SVC awaits publication in 2008.

CMMI Basics

Independent from the different CMMIs each of these models follows the same structure as shown in Figure 1.

In each CMMI a set of process areas is defined. For each process area the purpose is described, some introductory notes are given and other process areas which have a relation to this process area are listed. To satisfy the process area, goals must be fulfilled. Each process area has specific goals which are unique for this process area. Additional generic goals are defined, which are common for all process areas. For each goal a set of practices is defined, which are considered important for reaching the goal. For each practice

Figure 1. CMMI structure



subpractices, typical work products and elaborations are defined.

From an evaluation perspective, only the goals are required. To reach a so-called "level" an organization has to fulfil the goals of the processes for this level. Nevertheless it is expected, that the defined practices are also fulfilled.

Process Capability vs. Organization Maturity

Talking about the CMMI always means talking about "level". But before the different levels can be explored, the different representations have to be discussed. CMMI knows two different representations, staged and continuous. In the staged representation each process area is assigned to a specified maturity level. To reach a maturity level, all specific goals of the assigned processes and a subset of generic goals have to be fulfilled.

In the continuous representation, each process area is evaluated separately by fulfilling generic goals for this process area. Based on the set of generic goals that are fulfilled, the capability of the process area is measured.

In both representations, the generic goals have high importance. In total 5 generic goals are defined:

- **GG1:** The process supports and enables achievement of the specific goals of the process area by transforming identifiable input work products to produce identifiable output work products[2].
- **GG2:** The process is institutionalized as a managed process.
- **GG3:** The process is institutionalized as a defined process.
- **GG4:** The process is institutionalized as a quantitatively managed process.
- **GG5:** The process is institutionalized as an optimizing process.

In the staged representation 5 levels are defined. The lowest level is level 1, which means that the processes of the organization are still over-

whelmingly chaotic. Goals for process maturity start with the definition of maturity level 2. For this level the specific goals of the assigned process areas and generic goal 2 have to be satisfied. For maturity level 3 the specific goals of the process areas assigned to level 2, the specific goals of the process areas assigned to level 3 and the generic goals 2 and 3 have to be satisfied. For level 4 and 5 specific goals of other process areas are added, but even for these higher levels, only generic goal 2 and 3 have to be satisfied.

In the continuous representation, 6 levels are defined, starting with level 0 and ending with level 5. Remembering, that a capability level is evaluated for each process area, the level is given by the fulfilment of the generic goals. On level 0 no generic goal is satisfied. On level 1, GG1 has to be satisfied, on level 2 GG1 and GG2 have to be satisfied and so on.

As this article is focused on the integration of activities and not mainly on evaluation issues, we will restrict the following chapters to the parts specific to certain process areas. For more information on the generic parts and evaluation procedures the CMMI itself should be used (Software Engineering Institute, 2006a).

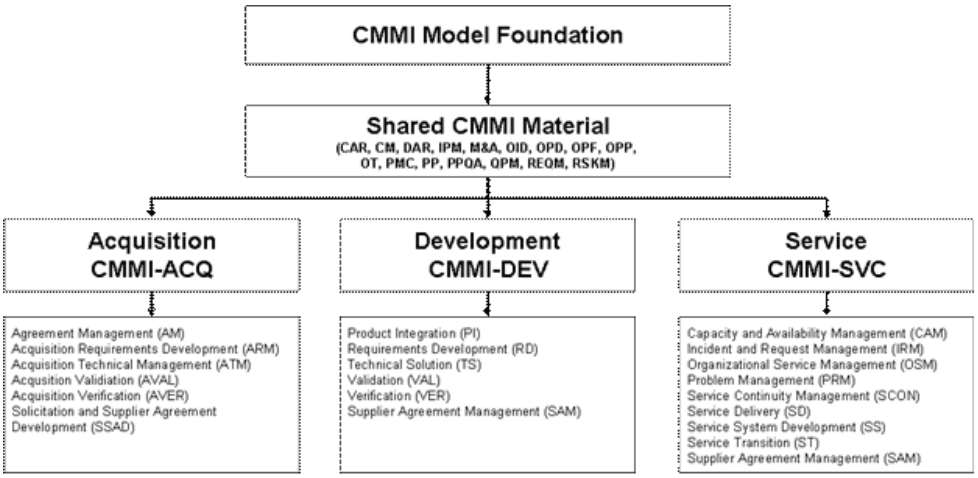
The Constellation Approach

As said before, there is not the "one" CMMI. The idea of the current CMMI version is to have different constellations which share some process areas that are common for all constellations and have additional process areas that are unique for the constellation.

Currently, three constellations are published or planned to be published in 2007:

- **CMMI-DEV:** For development (June 2006) (Software Engineering Institute, 2006-1)
- **CMMI-ACQ:** For acquisition (November 2007) (Software Engineering Institute, 2007)
- **CMMI-SCV:** For services (2008, initial draft September 2006) (Software Engineering Institute, 2006b)

Figure 2. CMMI constellation approach



These constellations only differ in the number and content of process areas. All other contents of the CMMI, for example generic elements, level definitions, typographical conventions, build the model's foundation and are identical for all constellations.

In a first overview the constellation approach can be structured as shown in Figure 2.

The purposes of all process areas are explained in the next chapter.

Shared Process Areas

Causal Analysis and Resolution

The purpose of causal analysis and resolution (CAR) is to identify causes of defects and other problems and take action to prevent them from occurring in the future.

Configuration Management

The purpose of configuration management (CM) is to establish and maintain the integrity of work products using configuration identification, configuration control, configuration status accounting, and configuration audits.

Decision Analysis and Resolution

The purpose of decision analysis and resolution (DAR) is to analyze possible decisions using a formal evaluation process that evaluates identified alternatives against established criteria.

The IPPD Addition (Integrated Product and Process Development)

Before describing the next process area, a new term has to be defined: the "IPPD addition". In CMMI, "additions" are used to include material that may be of interest to particular users. The IPPD group of additions covers an IPPD approach that includes practices that help organizations achieve the timely collaboration of relevant stakeholders throughout the life of the product to satisfy customers' needs, expectations, and requirements (Department of Defense, 1996). If you apply the CMMI, you are free to add the IPPD addition or not.

Integrated Project Management + IPPD

The purpose of integrated project management (IPM) is to establish and manage the project and the involvement of the relevant stakeholders according to an integrated and defined process that is tailored from the organization's set of standard processes.

IPPD Addition: For IPPD, integrated project management +IPPD also cover the establishment of a shared vision for the project and the establishment of integrated teams that will carry out objectives of the project.

Measurement and Analysis

The purpose of measurement and analysis (MA) is to develop and sustain a measurement capability that is used to support management information needs.

Organizational Innovation and Deployment

The purpose of organizational innovation and deployment (OID) is to select and deploy incremental and innovative improvements that measurably improve the organization's processes and technologies. The improvements support the organization's quality and process-performance objectives as derived from the organization's business objectives.

Organizational Process Definition + IPPD

The purpose of organizational process definition (OPD) is to establish and maintain a usable set of organizational process assets and work environment standards.

IPPD Addition: For IPPD, organizational process definition +IPPD also cover the establishment of organizational rules and guidelines that enable conducting work using integrated teams.

Organizational Process Focus

The purpose of organizational process focus (OPF) is to plan, implement, and deploy organizational process improvements based on a thorough understanding of the current strengths and weaknesses of the organization's processes and process assets.

Organizational Process Performance

The purpose of organizational process performance (OPP) is to establish and maintain a quantitative understanding of the performance of the organization's set of standard processes in support of quality and process-performance objectives, and to provide the process-performance data, baselines, and models to quantitatively manage the organization's projects.

Organizational Training

The purpose of organizational training (OT) is to develop the skills and knowledge of people so they can perform their roles effectively and efficiently.

Project Monitoring and Control

The purpose of project monitoring and control (PMC) is to provide an understanding of the project's progress so that appropriate corrective actions can be taken when the project's performance deviates significantly from the plan.

Project Planning

The purpose of project planning (PP) is to establish and maintain plans that define project activities.

Process and Product Quality Assurance

The purpose of process and product quality assurance (PPQA) is to provide staff and management with objective insight into processes and associated work products.

Quantitative Project Management

The purpose of quantitative project management (QPM) is to quantitatively manage the project's defined process to achieve the project's established quality and process-performance objectives.

Requirements Management

The purpose of requirements management (REQM) is to manage the requirements of the project's products and product components and to identify inconsistencies between those requirements and the project's plans and work products.

Risk Management

The purpose of risk management (RSKM) is to identify potential problems before they occur so that risk-handling activities can be planned and invoked as needed across the life of the product or project to mitigate adverse impacts on achieving objectives.

Acquisition Process Areas

Solicitation and Supplier Agreement Development

The purpose of solicitation and supplier agreement development (SSAM) is to prepare a solicitation package and to select one or more suppliers for delivering the product or service and establish and maintain the supplier agreement.

Acquisitions Management

The purpose of agreement management (AM) is to ensure that the supplier and the acquirer perform according to the terms of the supplier agreement

Acquisition Requirements Development

The purpose of the acquisition requirements development (ARD) is to produce and analyze customer and contractual requirements.

Acquisition Technical Management

The purpose of the acquisition technical management (ATM) is to evaluate the supplier's technical solution and to manage selected interfaces of that solution.

Acquisition Validation

The purpose of the acquisition validation (AVAL) is to demonstrate that an acquired product or service fulfils its intended use when placed in its intended environment.

Acquisition Verification

The purpose of acquisition verification (AVER) is to ensure that selected work products meet their specified requirements.

Development Process Areas

Product Integration

The purpose of product integration (PI) is to assemble the product from the product components, ensure that the product, as integrated, functions properly, and deliver the product.

Requirements Development

The purpose of requirements development (RD) is to produce and analyze customer, product, and product component requirements.

Supplier Agreement Management

The purpose of supplier agreement management (SAM) is to manage the acquisition of products from suppliers.

Technical Solution

The purpose of technical solution (TS) is to design, develop, and implement solutions to requirements. Solutions, designs, and implementations encompass products, product components, and product-related lifecycle processes either singly or in combination as appropriate.

Validation

The purpose of validation (VAL) is to demonstrate that a product or product component fulfils its intended use when placed in its intended environment.

Verification

The purpose of verification (VER) is to ensure that selected work products meet their specified requirements.

Service Process Areas

As mentioned before, the CMMI-SVC has not been published yet. Nevertheless, it is available as initial draft (Software Engineering Institute, 2006b) and was already widely discussed on several conferences (Hollenbach & Buteau, 2006).

Capacity and Availability Management

The purpose of capacity and availability management (CAM) is to plan and monitor the effective provision of resources to support service requirements.

Incident and Request Management

The purpose of the incident and request management (IRM) process area is to ensure the timely resolution of requests for service and incidents that occur during service delivery.

Organizational Service Management*

The purpose of the organizational service management (OSM) process area is to establish and maintain standard services that ensure the satisfaction of the organization's customer base.

Problem Management

The purpose of the problem management (PRM) process area is to prevent incidents from recurring by identifying and addressing underlying causes of incidents.

Service Continuity*

The purpose of the service continuity (SCON) is to establish and maintain contingency plans for continuity of agreed services during and following any significant disruption of normal operations.

Service Delivery

The purpose of the service delivery (SD) process area is to deliver services in accordance with service agreements.

Service System Development*

The purpose of the service system development (SSD) process area is to analyze, design, develop, integrate, and test service systems to satisfy existing or anticipated service agreements.

Service Transition

The purpose of the service transition (ST) process area is to deploy new or significantly changed service systems while managing their effect on ongoing service delivery.

Supplier Agreement Management

The purpose of supplier agreement management (SAM) is to manage the acquisition of products from suppliers.

The process areas marked with an asterisk (*) are additions (like IPPD in the CMMI for Development) and therefore optional.

CMMI Process Categories

In order to develop a better understanding for the dependencies between the process areas, the CMMI-DEV defines 4 categories which are applied to the other constellations below, and collect process areas with a similar focus. Therefore, 3 categories are identical for all constellations. These are

- Process management
- Project management
- Support

Table 1. Shared process areas

	Process Management	**Project Management**	**Support**	**Acquisition / Engineering / Service Establishment and Delivery**
Shared process areas	Organizational Innovation and Deployment, Organizational Process Definition +IPPD, Organizational Process Focus, Organizational Process Performance, Organizational Training	Project Monitoring and Control, Project Planning, Quantitative Project Management, Risk Management	Causal Analysis and Resolution, Configuration Management, Decision Analysis and Resolution, Measurement and Analysis, Process and Product Quality Assurance	Requirements Management

Table 2. CMMI-ACQ process areas

	Process Management	**Project Management**	**Support**	**Acquisition / Engineering / Service Establishment and Delivery**
CMMI-ACQ				Solicitation and Supplier Agreement Development, Agreement Management, Acquisition Requirements Development, Acquisition Technical Management, Acquisition Validation, Acquisition Verification

The fourth category is focussed on the field of application of the constellation and is labelled

- Acquisition (in CMMI-ACQ)
- Engineering (in CMMI-DEV)
- Service Establishment and Delivery (in CMMI-SVC)

Based on this categorization the complete set of CMMI process areas can be categorized as follows.

For shared process areas see Table 1; for CMMI-ACQ see Table 2; for CMMI-DEV see Table 3; for CMMI-SVC see Table 4.

Table 3. CMMI-DEV process areas

	Process Management	**Project Management**	**Support**	**Acquisition / Engineering / Service Establishment and Delivery**
CMMI-DEV		Supplier Agreement Management		Product Integration, Requirements Development, Technical Solution, Validation, Verification

Table 4. CMMI-SVC process areas

	Process Management	**Project Management**	**Support**	**Acquisition / Engineering / Service Establishment and Delivery**
CMMI-SVC	Organizational Service Management	Supplier Agreement Management, Capacity and Availability Management	Problem Management	Incident and Request Management, Service Continuity, Service Delivery, Service System Development, Service Transition

Constellation Based Maturity Levels

As described before, each process area is assigned to a defined maturity level. Whilst on level 4 and 5 only shared process areas are assigned, the assignment on level 2 and 3 is dependent on the constellation (see Table 5).

The shared processes assigned to level 4 are

- Organizational process performance
- Quantitative project management

Table 5. Maturity level 2 and 3 for CMMI constellations

	Maturity Level 2	Maturity Level 3
Shared process areas	Requirements Management, Project Planning, Project Monitoring and Control, Measurement and Analysis, Process and Product Quality Assurance, Configuration Management	Decision Analysis and Resolution, Integrated Project Management +IPPD, Organizational Process Definition +IPPD, Organizational Process Focus, Organizational Training, Project Management
CMMI-ACQ	Solicitation and Supplier Agreement Development, Agreement Management, Acquisition Requirements Development	Acquisition Technical Management Acquisition Validation, Acquisition Verification
CMMI-DEV	Supplier Agreement Management	Product Integration, Requirements Development, Technical Solution, Validation, Verification
CMMI-SVC	Supplier Agreement Management, Incident and Request Management	Capacity and Availability Management, Service Continuity Service Delivery, Service System Development, Service Transition, Organizational Service Management, Problem Management

The shared processes assigned to level 5 are

- Causal Analysis and Resolution
- Organizational Innovation and Deployment

A CMMI Based, Integrated Product Life Cycle

Even though the CMMI provides 3 different constellations, these constellations can be used to define 2 different integrated product life cycles:

- Organizations which provide service delivery for acquired software products should use the process areas of the CMMI-ACQ in combination with the process areas of the CMMI-SVC.
- Organizations which develop software and provide service delivery should use the process areas of the CMMI-DEV in combination with the process areas of the CMMI-SVC.

Even the combination of all three constellations is thinkable, when a service delivering organization partially acquires and partially develops the software.

SPICE / ISO 20000 INTEGRATION PERSPECTIVE

Besides the CMMI world, another possibility for an integrated product life cycle is the combination of two ISO standards: the ISO 15504—better known as SPICE—and the ISO 20000.

SPICE Basics

The ISO 15504 (SPICE) is structured in 5 parts. Part 1 defines the basic concept and the vocabulary. In part 2 rules for performing an assessment are defined, and in part 3 guidance for the assessment is given. Part 4 gives additional guidance on the use for process improvement and capability determination.

The interesting part under the integration perspective is part 5. This part defines an exemplar process assessment model.

Whilst the capability determination is widely similar to the approach of the CMMI continuous representation, the process model is different from the CMMI.

SPICE defines 3 categories. These categories are structured in groups and each group has several processes (ISO/IEC, 2006). The categories with their groups are:

- Primary life cycle processes
  - Acquisition process group (ACQ)
  - Supply process group (SPL)
  - Engineering process group (ENG)
  - Operation process group (OPE)
- Organizational life cycle processes
  - Management process group (MAN)
  - Process improvement process group (PIM)
  - Resource and infrastructure process group (RIN)
  - Reuse process group (REU)
- Supporting life cycle processes
  - Supporting process group (SUP)

Comparing the SPICE categories with the CMMI constellations, strong connections can be identified between the process groups of the primary life cycle processes and the CMMI constellations. The acquisition process group and supply process group have the same focus as the CMMI-ACQ as well as the engineering process group and the CMMI-DEV. Only the CMMI-SVC does not have a counterpart in SPICE. The operation processes group and some processes of the supporting process group address service related topics, but a common approach is not delivered.

To better understand the content of the SPICE process groups each group with its processes should be further described—as defined in SPICE (ISO/IEC, 2006):

Primary Life Cycle Processes

The primary life cycle processes consist of processes that serve primary parties during the life cycle of software. A primary party is one that initiates or performs the development, operation, or maintenance of software products. These primary parties are the acquirer, the supplier, the developer, the operator, and the maintainer of software products.

- The acquisition process group (ACQ) consists of processes performed by the customer, in order to acquire a product and/or a service. The processes of this group are:
  - ACQ.1: Acquisition preparation
  - ACQ.2: Supplier selection
  - ACQ.3: Contract agreement
  - ACQ.4: Supplier monitoring
  - ACQ.5: Customer acceptance
- The supply process group (SPL) consists of processes performed by the supplier in order to propose and deliver a product and/or a service. The processes of this group are:
  - SPL.1: Supplier tendering
  - SPL.2: Product release
  - SPL.3: Product acceptance support
- The engineering process group (ENG) consists of processes that directly elicit and manage the customer's requirements, specify, implement, and/or maintain the software product and it's relation to the system. The processes of this group are:
  - ENG.1: Requirements elicitation
  - ENG.2: System requirements analysis
  - ENG.3: System architectural design
  - ENG.4: Software requirements analysis
  - ENG.5: Software design
  - ENG.6: Software construction
  - ENG.7: Software integration
  - ENG.8: Software testing
  - ENG.9: System integration
  - ENG.10: System testing
  - ENG.11: Software installation
  - ENG.12: Software and system maintenance
- The operation process group (OPE) consists of processes performed in order to provide for the correct operation and use of the software product and/or service. The processes of this group are:
  - OPE.1: Operational use
  - OPE.2: Customer support

Organizational Life Cycle Processes

The organizational life cycle processes consist of processes employed by an organization to establish and implement an underlying structure made up of associated life cycle processes and personnel and continuously improve the structure and processes. They are typically employed outside the realm of specific projects and contracts; however, lessons from such projects and contracts contribute to the improvement of the organization.

- The management process group (MAN) consists of processes that contain practices that may be used by anyone who manages any type of project or process within a software life cycle. The processes of this group are:
  - MAN.1: Organizational alignment
  - MAN.2: Organizational management
  - MAN.3: Project management
  - MAN.4: Quality management
  - MAN.5: Risk management
  - MAN.6: Measurement
- The process improvement process group (PIM) consists of processes performed in order to define, deploy, assess and improve the

processes performed in the organizational unit. The processes of this group are:
  - PIM.1: Process establishment
  - PIM.2: Process assessment
  - PIM.3: Process improvement
- The resource and infrastructure process group (RIN) consists of processes performed in order to provide adequate human resources and necessary infrastructure as required by any other process performed by the organizational unit. The processes of this group are:
  - RIN.1: Human resource management
  - RIN.2: Training
  - RIN.3: Knowledge management
  - RIN.4: Infrastructure
- The reuse process group (REU) consists of processes performed in order to systematically exploit reuse opportunities in the organization's reuse programmes. The processes of this group are:
  - REU.1: Asset management
  - REU.2: Reuse program management
  - REU.3: Domain engineering

Supporting Life Cycle Processes

The supporting life cycle processes consist of processes that support another process as an integral part with a distinct purpose and contribute to the success and quality of the software project. A supporting process is employed and executed, as needed, by another process. The processes of this group are:

- SUP.1: Quality assurance
- SUP.2: Verification
- SUP.3: Validation
- SUP.4: Joint review
- SUP.5: Audit
- SUP.6: Product evaluation
- SUP.7: Documentation
- SUP.8: Configuration management
- SUP.9: Problem resolution management
- SUP.10: Change request management

Each SPICE process has a well-defined structure. After the process ID (e.g., SUP.10) and the process name (e.g., change request management), the purpose of the process is described. Then the

Table 6. CMMI and SPICE process structure

CMMI	SPICE
Acronym	Process ID
Process Name	Process Name
Purpose Statement	Process Purpose
Specific Goals	Process Outcomes
Specific Practices	Base Practices
Generic Goals	Process Attributes
Typical Work Products	Work Products

process outcomes are defined. These process outcomes—plus process attributes—have to be achieved to reach a capability level in SPICE. Afterwards base practices for each process are defined and work products of the process are listed.

Comparing the structure of a CMMI process area and a SPICE process, there are lots of similarities (see Table 6).

All in all, SPICE has 48 processes that mainly cover software development and have only small focus on service delivery. For this part, the ISO 20000 seems more applicable.

ISO 20000 Basics

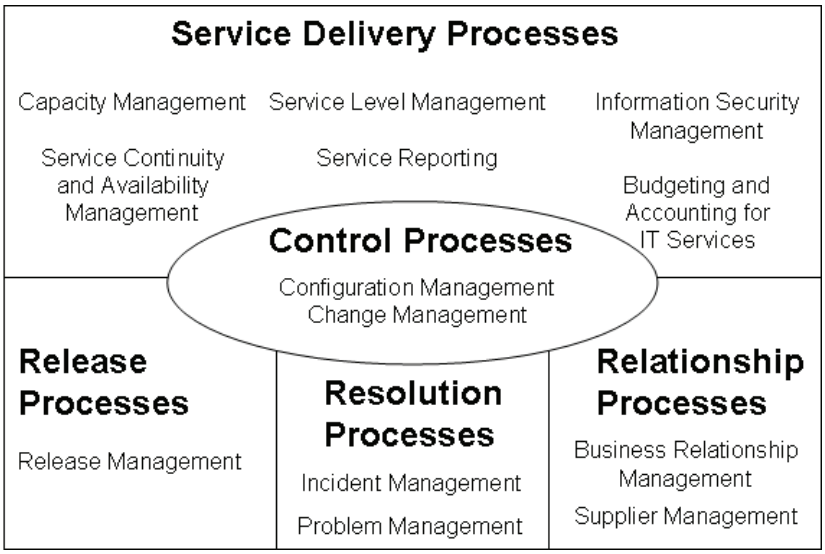
ISO 20000—Service Management covers the classical service delivery processes. Regarding the scope of ISO 20000, this standard represents "an industry consensus on quality standards for IT service management processes. These service management processes deliver the best possible service to meet a customer's business needs within agreed resource levels" (ISO/IEC, 2005b).

ISO 20000 defines 13 processes in 5 process groups.

Regarding each process group,

- The objective of the service delivery process group is to define, agree, record and manage levels of service, and consists of the processes
  - Capacity management
  - Service continuity and availability management
  - Service level management
  - Service reporting
  - Information security management
  - Budgeting and accounting for IT services
- The objective of the relationship process group is to describe the related aspects of

Figure 3. ISO 20000 processes



supplier management and business relationship management, and consists of the processes
    - Business relationship management
    - Supplier management
- The objectives of the resolution process group are to restore agreed service and minimize disruption to the business, and consists of the processes
    - Incident management
    - Problem management
- The objective of the control process group is to define and control the components of service and infrastructure, and consists of the processes
    - Configuration management
    - Change management
- The objective of the release process group is to deliver, distribute and track changes, and consists of the process
    - Release management

Those who know ITIL may have found lots of similarities in the process names and structure of ISO 20000. The ISO 20000 is well aligned with ITIL. Whilst ITIL is a collection of best practices, ISO 20000 defines specifications to support a service provider in delivering high quality services. The other way round, ITIL best practices help to achieve the quality of service management as defined by ISO 20000. It has to be recognized that ISO 20000 and ITIL are developed in strong connection, often impacted by the same persons.

Interfaces Between SPICE and ISO 20000

Trying to integrate SPICE and ISO 20000 it has to be taken into account, that both standards cover similar or identical elements in some processes. If an integrated product life cycle should be defined, these interfaces have to be harmonized.

First of all, the operational process group of SPICE has to be analyzed. This process group consists of two processes, operational use (OPE.1) and customer support (OPE.2).

The operational use process has the purpose to ensure the correct and efficient operation of the product for the duration of its intended usage and in its installed environment. Topics like operational risks, operational testing, criteria for operational use and the monitoring of the operational use are covered by this process.

The customer support process has the purpose of establishing and maintaining an acceptable level of service. Topics of this process are establishing of product support, performance monitoring and customer satisfaction.

Even though these processes address service aspects, they only deliver a high level overview. Nevertheless these topics address similar elements as the ISO 20000 processes service level management and business relationship management.

Other service delivery related processes can be found in the group of the supporting life cycle processes. The processes in focus are:

- SUP.8: Configuration management
- SUP.9: Problem resolution management
- SUP.10: Change request management

With configuration management the integrity of work products is established and maintained and these work products are made available to parties concerned. The problem resolution management process focuses on identification, analysis, management and controlling of discovered problems, while change request management ensures that change requests are managed, tracked and controlled.

Some other useful information for service delivery can be found in the process related to supplier management (acquisition / supply process groups).

Integration of SPICE and ISO 20000

To reach a fully integrated product life cycle, two requirements have to be satisfied:

- A set of processes has to be defined, which covers all stages of the life cycle—a so called process reference model (PRM)
- A model to evaluate the process capability has to be defined and must be applicable to all processes—a so called process assessment model (PAM)

Both requirements are satisfied by the CMMI constellations: the PAM is defined in the model foundation which is mandatory for all constellations and the PRM is given by the defined process areas.

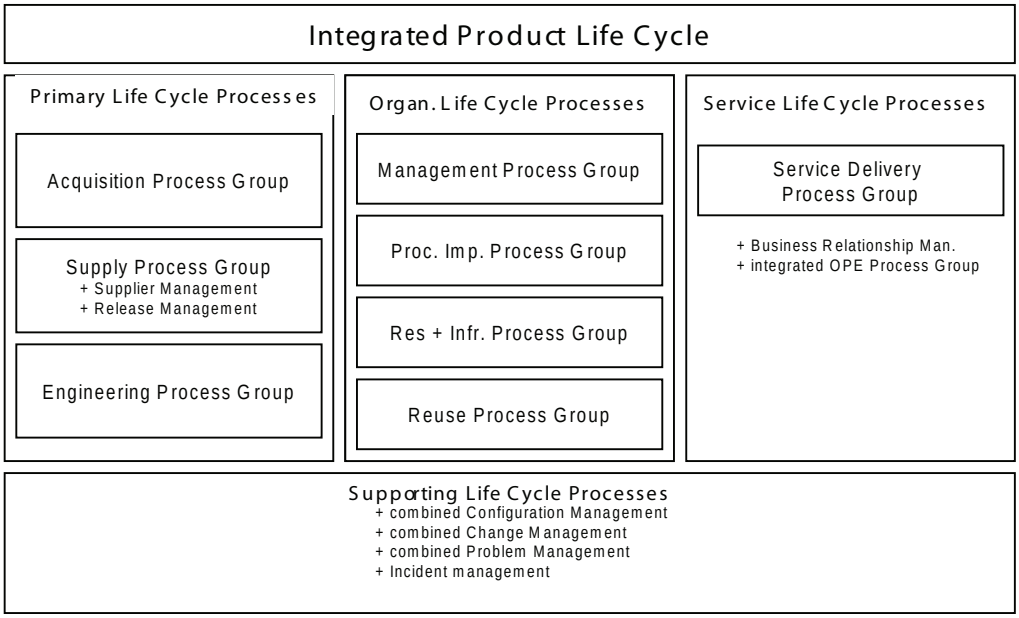
For the SPICE and ISO 20000 integration, this is not that easy. On the one hand SPICE and ISO 20000 address identical topics in different processes, on the other hand, only SPICE has an assessment model. A way to solve this problem was defined in early 2007 (Malzahn, 2007) and should be described in the following chapters.

A Combined PRM for SPICE and ISO 20000

As described before, double definitions in SPICE and ISO 20000 have to be eliminated and all processes need to have an identical structure. Therefore in a first step, the ISO 20000 processes have to be restructured into the SPICE process structure. In a second step, processes with a similar focus must be aligned.

For the first step, the ISO 20000 process groups and processes become process groups and processes of the combined model. For each ISO 20000 process the defined objective becomes the

Figure 4. Integrated Product Life Cycle based on SPICE and ISO 20000



process purpose. For the rest of the text it has to be decided, which text passage becomes an outcome, a base practice, or a work product.

In the second step, all processes with a similar focus have to be aligned. Concerning SPICE and ISO 20000 it is proposed to

- Integrate the SPICE OPE process group into the service level management, service reporting and business relationship management processes of ISO 20000,
- Combine configuration management
- Combine problem resolution management and problem management,
- Combine change request management and change management.

Other possibilities for further alignment are e.g., given by the combination of the ISO 20000 release management process and the SPICE product release process, and by integrating the relationship processes into the acquisition / supply process group.

After this integration and combination, the process groups may be restructured as follows:

- The ISO 20000 control processes become part of the support process group,
- The ISO 20000 release management process becomes part of the Supply process group,
- ISO 20000 problem management and incident management become part of the support process group,
- Business relationship management may become part of the service delivery process group.

In the very end, a combined PRM for SPICE and ISO 20000 may consist of the SPICE process categories and a new service life cycle category with the following amendments:

A Combined PAM for ISO 20000 and SPICE

The definition of a process assessment model for the integration of SPICE and ISO 20000 is easy to define—it is the approach defined for SPICE. Regarding ISO 20000, no measurement framework is defined. The requirements concerning measurement are given in part one of the ISO 20000 as follows:

"The service provider shall apply suitable methods for monitoring and, where applicable, measurement of the service management processes" (ISO/IEC, 2005a). Therefore no inconsistencies in the measurement and rating can occur. The SPICE definitions are applicable because each ISO 20000 process was restructured in the PRM and therefore all contextual and structural requirements are satisfied.

COMPARISON OF BOTH APPROACHES

Regarding both approaches—the CMMI constellations and the integration of SPICE and ISO 20000—there are pros and cons for each approach:

- The CMMI constellations are highly integrated by using the same model foundation, but CMMI-SVC will not see the light of day before 2008
- SPICE and ISO 20000 require additional effort to be integrated, but both are ISO standards and therefore widely accepted—especially if legal matters have to be taken into account.

Other impacts may be the region or industry of the organization. The CMMI is very strong in the United States; SPICE is heavily used in Europe.

Most defence industry companies are interested in CMMI, whilst major parts of the automotive industry prefer SPICE.

FUTURE TRENDS

This article covers two possible integration approaches. Nowadays more and more approaches see the light of day. Especially the integration of ITIL and CMMI or SPICE is widely discussed (Barafort, Di Renzo, Lejeune, Prime & Simon, 2005; Foegen & Graumann, 2007). Nevertheless ITIL is a best practice collection and not a measurement framework and therefore we still see some problems in the ITIL integration.

Hopefully the CMMI-SVC proves that it is a powerful tool for this intended integration and maybe at some point in time the ISO will find a way to publish an assessment model that covers the complete product life cycle for software.

Another promising approach will be the Enterprise SPICE initiative. The goal of this initiative is to "integrate and harmonize existing standards [...] to provide a single process reference model and process assessment model that addresses broad enterprise processes. Enterprise SPICE will provide an efficient and effective mechanism for assessing and improving processes deployed across an enterprise" (SPICE User Group, 2007).

Using Integrated Models

Defining an integration approach is only a short part on the way to software development and service delivery integration. Even though it builds the indispensable basis, integration only works, if it is accepted by organizations, teams, and people. To reach this, some simple rules of the thumb should be followed:

- Integrate the working level of development and service delivery at least in the review of an integrated model – preferably in the development. If the working level understands the need for integration and is part of the integration process, the integrated model is better accepted.
- Provide translation between the development, service delivery and integration approach. Only if software development and service delivery people reach a common understanding, an integrated approach can be established.
- Provide training on the approach. Training must not be focused on "we combine standard A with standard B" but on "we define an approach for the complete life cycle". There is no longer "their work" and "our work" but a common responsibility from first idea to retirement.

If and only if the need for integration is understood and accepted by people on working level, integration can be established – otherwise there will still be two worlds with all their differences and borders.

CONCLUSION

The decision, which approach may deliver the best benefit, must be taken by the organization itself. But one thing is inevitable: if the capability of the processes of an organization is not evaluated against accepted standards and for the complete life cycle, the organization keeps the back door open for chaotic elements in their process suite and therefore has an open door for abusing strategies, processes, and procedures.

BROOD:
Business Rules–Driven Object Oriented Design

Pericles Loucopoulos
Loughborough University, UK

Wan M. N. Wan Kadir
Universiti Teknologi Malaysia, Malaysia

ABSTRACT

A critical success factor for information systems is their ability to evolve as their environment changes. There is compelling evidence that the management of change in business policy can have a profound effect on an information system's ability to evolve effectively and efficiently. For this to be successful, there is a need to represent business rules from the early requirements stage, expressed in user-understandable terms, to down-stream system design components and maintain these throughout the lifecycle of the system. Any user-oriented changes could then be traced and if necessary propagated from requirements to design specifications and evaluated by both end-users and developers about their impact on the system. The BROOD approach, discussed in this article, aims to provide seamless traceability between requirements and system designs through the modelling of business rules and the successive transformations, using UML as the modelling framework.

INTRODUCTION

The ubiquitous nature of information systems and the increasing dependency of organizations, government and society on such systems highlight the importance of ensuring robustness in their operation. At the same time rapid changes in the environment of information systems places an increasing emphasis on the ability of these systems to evolve according to emerging requirements. A large proportion of a total systems' lifecycle cost is devoted to introducing new requirements, and removing or changing existing system functional-

ity (Grubb & Takang, 2003). Software evolution therefore is considered as a key challenge in the development and maintenance of information systems (Erlikh, 2000).

In recent years there has been an increasing interest of the IS community in business rules, which has resulted in dedicated rule-centric modeling frameworks and methodologies (Ross & Lam, 1999; Zaniolo et al., 1997), international initiatives for the investigation of business rules' role in the context of knowledge management (Hay & Healy, 1997), conferences, workshops and tutorials (Mens, Wuyts, Bontridder, & Grijseels, 1998), and rule-centric rule management tools and application development support environments (e.g., Blaze Advisor Builder, BRS RuleTrack, Business Rule Studio, Haley Technologies, ILOG Rules, Platinum Aion, Usoft Developer and Visual Rule Studio). Whilst these efforts make significant contributions in their own right, a key challenge remains unanswered namely the *linking of business rules specifications to software designs*.

The aim of the BROOD (business rules-driven object oriented design) approach is to address the issue of software evolution from both *requirements* and *design* perspectives. This confluence should provide a seamless and traceable facility that arguably should bring about a more effective way of dealing with software evolution, by aligning changes of the information system to changes in its environment. BROOD adopts as its methodological paradigm that of object orientation with UML as its underlying graphical language. It augments UML by explicitly considering business rules as an integral part of an object-oriented development effort. To this end BROOD aims:

i. To explicitly model business rules in a manner understandable to end-user stakeholders.
ii. To map these to formal descriptions amenable to automation and analysis.
iii. To provide guidelines on the deployment of business rules in the development process.
iv. To provide guidelines on the evolution of requirements and related design specifications.

The article is organized as follows. Section 2 discusses the background to business rules modeling. Section 3 introduces the motivation for BROOD. Section 4 introduces the BROOD metamodel as the foundation for modeling business rules. Section 5 discusses the manner in which business rules are linked to design components via the concept of 'rule phrase.' The BROOD process is detailed in section 6. The BROOD approach is supported by an automated tool and this is briefly discussed in Section 7. The article concludes with an overview of BROOD, observations on its use on a large application and comparisons with traditional approaches.

The language details for business rules definition are given in appendix A. The BROOD approach is demonstrated through an industrial application which is described in appendix B. This application had originally been developed using a traditional approach. Therefore, it proved useful not only as a means of providing a practical grounding on BROOD but also on comparing and contrasting the use of BROOD with a traditional development effort.

BUSINESS RULES MODELLING

The motivation of BROOD is to provide a development environment whereby the business analysis and system design domains are supported by business rules modeling with the specific aim to facilitating more effective software evolution.

The term "business rule" has been used by different authors in different ways. For example, in (Rosca, Greenspan, Feblowitz, & Wild, 1997), business rules are:

statements of goals, policies, or constraints on an enterprise's way of doing business.

In (Herbst, 1996a), they are defined as:

statements about how the business is done, i.e. about guidelines and restrictions with respect to states and processes in an organization.

Krammer considers them as "programmatic implementations of the policies and practices of a business organization" (Krammer, 1997) whilst Halle states that:

depending on whom you ask, business rules may encompass some or all relationship verbs, mathematical calculations, inference rules, step-by-step instructions, database constraints, business goals and policies, and business definitions. (Halle, 1994).

In general, business rules in the information systems field may be viewed in terms of two perspectives: (a) business rules as applied to conceptual modeling and (b) business rules as applied to evolvable software systems development.

Business Rules in Conceptual Modeling

1. Business rules as part of requirements gathering and systems analysis have not been ignored by structured analysis, information engineering or object-oriented analysis approaches (Moriarty, 1993) which, to varying degrees, subsume or represent business rules as part of notation schemes used to specify application requirements (Gottesdiener, 1997) Ross (1997) comments that traditional IS methodologies have addressed rules poorly, and only relatively late in the system development lifecycle. (Hay & Healy, 1997) mention that rules dealing with information structure may be represented by any of several flavors of entity—relationship or object class diagrams, and responses to events may be shown via essential data flow diagrams (McMenamin & Palmer, 1984) or as entity life history diagrams (Robinson & Berrisford, 1994).

From a conceptual perspective there are approaches that consider business rules as an integral part of the modeling and analysis of systems' requirements. An early effort in this direction was the *RUBRIC* project (Loucopoulos & Layzell, 1986; van Assche, Layzell, Loucopoulos, & Speltinex, 1988) parts of which were integrated into the information engineering (Martin, 1989) method.

In *BROCOM* (Herbst, 1996b, 1997), the rule language is a type of structured English, and therefore it is highly expressive. Moreover, rules are organized according to a rich meta-model, and can be retrieved based on a number of different criteria. As far as methodological guidance is concerned, Herbst proposes the development of various models which are helpful during the analysis phase, but the process of creating and using them is not clearly defined. The transition from analysis to design and implementation has not been addressed by this approach.

The *DSS* approach (Rosca, Greenspan, & Wild, 2002; Rosca et al., 1995) focuses on the analysis phase of IS development by supporting the rationale behind the establishment of rules. DSS adopts the ECA (event-condition-action) paradigm for structuring rule expressions and also links these expressions to the entities of an underlying enterprise model. The absence of a formal rule language confines the use of DSS on modeling tasks.

The Business Rules Group (*BRG*), formerly known as the GUIDE Business Rule Project (Hay & Healy, 1997), investigated an appropriate formalization for the analysis and expression of business rules (Hay & Healy, 2000). This approach identifies terms and facts in natural language rule statements, and consequently, it offers a high level

of expressiveness. The meta-model it provides for describing the relations between these terms and facts is very detailed. Therefore, rule models are (a) highly manageable and (b) formal and fully consistent with the information models of a specific organization.

The *IDEA* method (Zaniolo et al., 1997) focuses on the maintenance of formality and consistency with underlying business models. The method offers guidance for every activity being involved in the development of a rule-centric information system. The IDEA method is directed towards the use of specific active and deductive databases, and of the corresponding rule languages. As a result of this, (a) IDEA rules are rather difficult to be expressed or even understood by business people;

Table 1. Comparative evaluation of business rule in conceptual modeling

Criteria \ BR Approach	BRG	BRO-COM	BRS
Concepts			
Business Rule Definition	IS	IS	Business
Business Rule Taxonomy			
- Structural Rules	High (10)	Low (0)	Medium (1)
- Behavioural Rules	Medium (8)	High (>30)	Medium (8)

Resources availability	Low	Medium	High
Openness	High	Medium	High

Lifecycle coverage: A-Analysis, D-Design, I-Implementation, M-Maintenance

and (b) the choice of technologies to be employed for the development of an information system is rather limited.

The *BRS* approach (Ross, 1997) is formal, in accordance with the underlying data models of an organization, offers sufficient methodological guidance, and allows management of rule expressions based on a very detailed meta-model. It is also one of the few methods that adopts a graphical notation for expressing rules. Regarding the development process, BRS introduces a business rule methodology called BRS Proteus™ methodology that defines a number of steps for both business and system modeling (Ross, & Lam, 2003). BRS also provides the BRS RuleTrack™, an automated tool for recording and organizing business rules.

The object constraint language (*OCL*) of UML (Eriksson & Penker, 2000) is tightly bound with the widely accepted UML but lacks methodological guidance for the collection of rules. Rule structures are implied by the allocation of rules to classes, attributes, associations and operations.

A comparative evaluation of the treatment of business rules for conceptual modeling by three widely used approaches is shown in Table 1.

Business Rules in Evolvable Software Evolution

The majority of approaches in this category aim to improve the understanding and evolution of a software system by logically and physically separating business rule components from other software components.

The adaptive object model (*AOM*), which is also known as the dynamic object model (Riehle, Tilman, & Johnson, 2000), is *"a system that represents classes, attributes, and relationships as metadata"* (Yoder, Balaguer, & Johnson, 2001). Unlike traditional object-oriented design, AOM is based on objects rather than classes. It provides descriptions (metadata) of objects that exist in the system. In other words, AOM provides a meta-architecture that allows users to manipulate the concrete architectural components of the model such as business objects and business rules. These components are stored as an object model in a database instead of in code. The code is only used to interpret the stored objects. Thus, a user only needs to change the metadata instead of changing the code to reflect domain changes.

The *coordination contract* method aims to separate coordination from computation aspects (or core components) of a software system (Andrade, Fiadeiro, Gouveia, & Koutsoukos, 2002). It is motivated by the fact that there should be two different kinds of entities in a rapidly changing business environment—core business entities which are relatively stable and volatile business products which keep changing for the business to remain competitive (Andrade & Fiadeiro, 2000). Volatile business products are implemented as contracts. A contract aims to externalize the interactions between objects (core entities) by explicitly define them in the conceptual model. It extends the concept of association class by adding a coordination role similar to other components in architecture-based software evolution such as architectural connectors (Oreizy, Medvidovic, & Taylor, 1998), glue (Schneider, 1999), actor (Astley & Agha, 1998) or change absorbers (Evans & Dickman, 1999).

Business Rule Beans (*BRBeans*), formerly known as accessible business rules (Rouvellou, Degenaro, Rasmus et al., 1999; Rouvellou, Degenaro, Rasmus et al., 2000), is a framework that provides guidelines and infrastructures for the externalization of business rules in a distributed business application (IBM, 2003). Business rules are externally developed, implemented and managed to minimize the impact of their changes on other components such as core business, application, and user interface objects. They are implemented as server objects, which are fired by embedded trigger points in application objects. A rule management facility is provided to help us-

Table 2. Comparative evaluation of business rules in evolvable software systems

Criteria \ BR Approach	Adaptive Object Model (AOM)	Coordination Contract	Business Rule Beans (BRBeans)
Concepts			
Business Rule Definition	Implicit	Implicit	Explicit
Business Rule Taxonomy	primitive, composite, workflow	ECA	derivation, constraint, invariant, script, classifier
Business Rule Management Elements	Nil	Nil	Yes
Modelling Language			
Understandability	High	Medium	Medium
Expressiveness (business rules)	Low	Medium	Medium
Formality	Low	High	Medium
Evolvability	High	High	High
Process			
Lifecycle coverage	(Evolutionary)	D + I + T + M	A + D + I + T + M
Process description	Low	Medium	High

Support for evolution	Low	Medium	High
Pragmatics			
Communicability	High	Medium	Medium
Usability	Low	Medium	Medium
Resources availability	Medium	Medium	High
Openness	Medium	Medium	Low

ers to understand the existing rules and to locate the rules when changes are required. BRBeans is implemented as a part of WebSphere Application Server by IBM *"to support business applications that externalize their business rules"* (Kovari, Diaz, Fernandes et al., 2003).

A comparative evaluation of the treatment of business rules evolvable software systems development by the three approaches is shown in Table 2.

MOTIVATION FOR THE BROOD APPROACH

According to Lehman's laws (Lehman & Belady, 1985), a software system that is used in a real-world environment inevitably must change or become progressively less useful in that environment. Lehman's laws also state that the software structure tends to become more complex due to the implemented changes and its size must continue to grow to accommodate new user requirements. Therefore, there is a need to introduce a method

that facilitates the management of the increasingly complex and larger size software system due to its evolution.

The position put forward in this article is that developers need to identify the sources of changes for software evolution in the system's environment and that some of the most volatile of these components tend to be business rules. In section 0 many contemporary approaches were reviewed all of which aim to externalize business rules from software components.

At the conceptual modeling level, there are approaches that separate syntax and semantics for modeling business rules. This effort localizes the changes to business rule components, and also increases the understanding and maintainability of business rules specification. This category of approaches provides a great deal of help in dealing with the concepts related to business rules, but they provide relatively little description on the design and implementation aspect of business rules.

At the implementation level, approaches create separate software components that implement business rules. As a result, the business rule changes will only localize to such components, and reduce the impact of changes to the overall software structure. This group of approaches provides very good facilities for developing evolvable software components but is less helpful in representing business rules at the conceptual business level.

The BROOD approach addresses both business modeling and the linking of business model components to software architecture components. By focusing on the conceptual level, BROOD attempts to externalizing changes from software components. This user-oriented view enhances understandability and maintainability since it encourages the direct involvement of business stakeholders in the maintenance of their business rules.

By introducing a linking component between the conceptual model of business rules and software design, BROOD attempts to increase business rule traceability. Traceability is highly desirable since one can keep 'forward' and 'backward' tracks of changes between business and software.

BROOD considers both *product* and *process* perspectives of the development and evolution of a software system. The *product* is defined using the BROOD metamodel, which specifies the structure for business rule specification, software design, and their linking elements. The *process* refers to a set of systematic and well-defined steps that should be followed during software development and evolution. The BROOD process emphasizes several important activities in a software lifecycle that contribute to a more resilient software system.

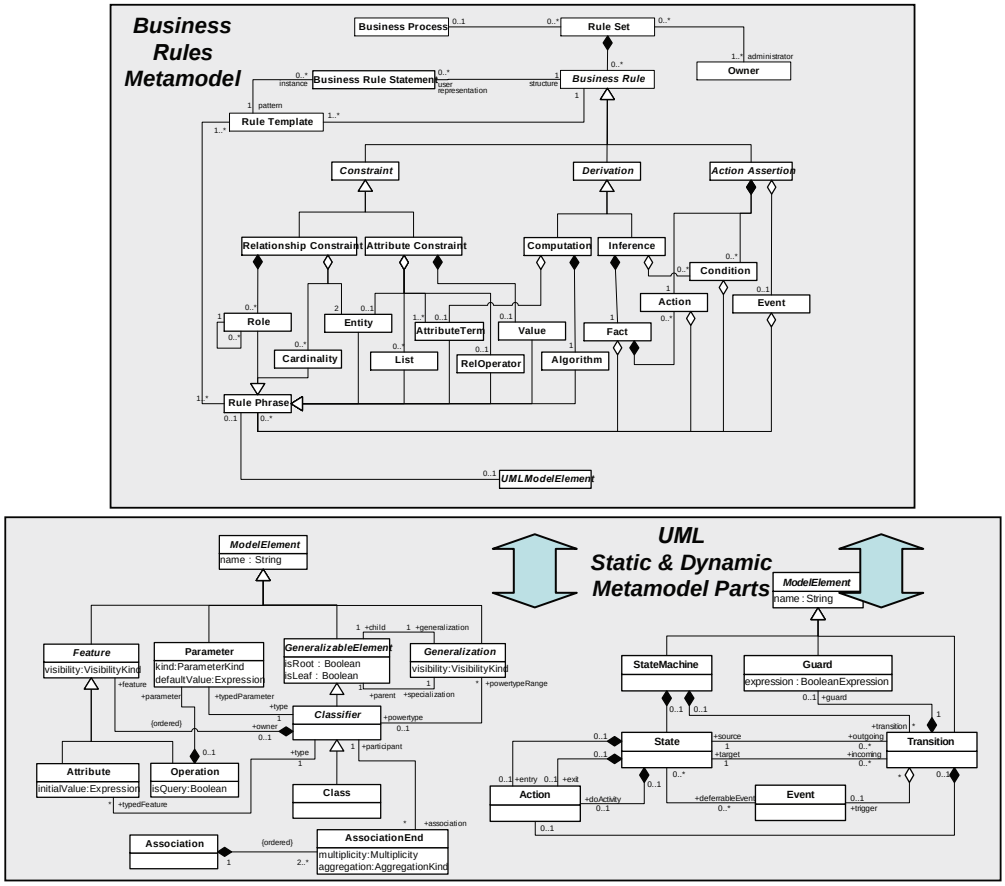
THE BROOD METAMODEL

The initial concept of the metamodel was introduced in (Wan Kadir & Loucopoulos, 2003; Wan Kadir & Loucopoulos, 2004). The metamodel is complemented by a language definition based on the context-free grammar EBNF, which is included in appendix A. The language definition defines the allowable sentence patterns for business rule statements and describes the linking elements between business rules and the related software design elements.

At the outset, three main desirable characteristics were set for developing an appropriate business rule metamodel, which would be consistent with the aims of BROOD:

- It should have an exhaustive and mutually exclusive typology to capture different types of business rules.
- It should have the structured forms of expressions for linking the business rules to software design.
- It should include rule management elements to improve business rule traceability in a business domain.

Figure 1. The BROOD business rule metamodel



These three characteristics form the basis for the development of the business rule metamodel, which is shown in Figure 1. This figure shows the business rules metamodel together with parts of the UML metamodel that deal with static (classes) and dynamic (actions and events) aspects. The key requirement of BROOD for tracing changes from business to software through the use of business rules is achieved by integrating these three metamodels.

Business Rules Typology

The metamodel classifies business rules into three main types, which are constraint, action assertion, and derivation.

Constraints

Constraint rules specify the static characteristics of business entities, their attributes, and their relationships. They can be further divided into

attribute and relationship constraints. The former specifies the uniqueness, optionality (null), and value check of an entity attribute. The latter asserts the relationship types as well as the cardinality and roles of each entity participating in a particular relationship.

Examples of attribute constraints from the MediNet application expressed according to the BROOD syntax (see `attribute constraint` definition in appendix A) are the following:

Patient must have a unique patient registration number.
Patient may have a passport number.
Bill must have a unique bill number.
The amount of Bill must be less than the maximum bill amount set by the paymaster.
An employee level of a Panel Patient must be in {employer, executive, production operator}.

Examples of relationship constraints for MediNET (see `relationship constraint` definition in appendix A) are:

Clinic item is a/an item type of bill item.
Bill must have zero or more bill item.
HCP Service Invoice is a/an Invoice.

Actions

Action assertion concerns a behavioral aspect of the business. Action assertion specifies the *action* that should be activated on the occurrence of a certain *event* and possibly on the satisfaction of certain *conditions*. An event can be either a simple or a complex event where the latter is constructed by one or more simple events using the logical connectives AND/OR. A condition may be a simple or complex condition. A simple condition is a Boolean expression which compares a value of an entity attribute with any literal value or the value of another entity attribute using a relational operator. It can also be an inspection of the existence of a value of an entity attribute in a list of values.

An action is performed by a system in response to the occurrence of an event and the satisfaction of the relevant condition. The execution of action may change the state of the system. An action may be a simple action or a sequence of simple actions. Simple actions can be further categorized into three different types, trigger actions, object manipulation actions, and user actions. Trigger action invokes an operation, a process, a procedure, or another rule under certain circumstances. Object manipulation action sets the value of the attribute or create/delete an instance of an entity. User action is a manual task that is done by system users. During implementation, user action is often implemented as a message displayed to the user.

Examples of action assertion for MediNET (see `action assertion` definition in appendix A) are:

When new invoice created then calculate invoice end date.
When patient consultation completed then removed the patient from consultation queue and create bill for the patient.
When invoice entry updated if stock of drug smaller than re-order threshold then reorder the drug.

Derivation

A derivation rule derives a new fact based on existing facts. It can be of one of two types, *computation*, which uses a mathematical calculation or algorithm to derive a new arithmetic value, or *inference*, which uses logical deduction or induction to derive a new fact. Typically, an inference rule may be used to represent permission such as user policy for data security. An example of a computation derivation rule such as "The amount HCP MediNET usage invoice is computed as the amount of transaction fees, which are calculated as the transaction

fee multiply by the total number of transactions, plus the monthly fee" would be expressed as:

```
let a = transaction_fee;
let b = number_of_treated_patient;
transaction_fees = a * b;
invoice_amount = transaction_fees + monthly_fee;
```

Examples of inference rules are given below:

Table 3. Business rule templates

Types	Templates
Attribute Constraint	<entity> must have | may have [a unique] <attributeTerm>. <attributeTerm1> must be | may be <relationalOperator> <value> | <attributeTerm2>. <attributeTerm> must be in <list>.
Relationship Constraint	[<cardinality>] <entity1> is a/an <role> of [<cardinality>]<entity2>. [<cardinality>] <entity1> is associated with [<cardinality>]<entity2>. <entity1> must have | may have [<cardinality>] <entity2>. <entity1> is a/an <entity2>.
Action Assertion	When <event> [if <condition>] then <action>. *The templates of <event> :* <attributeTerm> is updated <entity> is deleted | is created <operation>|<rule> is triggered the current date/time is <dateTime> <number> <timeUnit> time interval from <dateTime> is reached <number> <timeUnit> after <dateTime> <userEvent> *The templates of <condition> :* <attributeTerm1> <relationalOperator> <value | attributeTerm2> <attributeTerm> [not] in <list> *The templates of <action> :* trigger <process> | <operation> | <rule> set <attributeTerm> to <value> create | delete <entity> <userAction>
Computation	<attributeTerm> is computed as <algorithm>
Derivation	if <condition> then <fact>. *The templates of <fact> :* <entity> | <attributeTerm> is [not] a <value> <entity> may [not] <action>

If the paymaster's last quarter transaction is more than RM12,000.00 and the paymaster has no past due invoices then the paymaster is a preferred customer.

If the user type is equal to HR Officer and the user company is equal to patient paymaster then the user may view the patient's medical certificate.

The Rule Template

Rule templates are the formal sentence patterns by which business rules can be expressed. They are provided as a guideline to capture and specify business rules as well as a way to structure the business rule statements. Each rule template consists of one or more well-defined rule phrases, which are discussed in section 0.

By using the available templates, an inexperienced user may easily produce a consistent business rule statement. Rule templates help users to avoid tedious and repeated editing when creating many similar rules; and ensure uniformity by restricting the type of rules that can be written by business users. The use of templates also allows the precise linking of business rules to software design elements. The templates can be directly derived from the rules definition in Appendix A. Business rules templates are shown in Table 3.

The Rule Management Elements

Management elements are also included in the BROOD metamodel for facilitating the organization and management of business rules. These elements include the *rule set*, *business process*, and *owner*.

Rule set is used to group business rules into a set of closely interrelated rules. Each business rule model must have a single rule set, which is considered as the root rule set. This rule set must have at least one rule statement or another rule set.

One of the popular ways to identify a rule set is through its related business process. For example, the rules 'The bill amount is calculated as the sum of amounts of all bill items' and 'If a patient is a panel patient and his paymaster pays the bill in full, the balance is set to 0 and the bill status is set to paid' can be grouped in a rule set which is related to 'bill preparation' process. By properly organizing rules, the complexity of managing a large set of rules can be reduced.

Each business rule model must have an owner. An owner may also be defined for a rule set. The owner of a parent rule set is assumed to be the owner of its child rule set if the child does not define its owner. It is important to define the owner information in a business rule model to determine the access rights and responsibility to a business rules repository, especially for software systems with multiple user groups that possess different business rules. An owner may be an organizational unit, an individual user, a user group or role that is responsible for the management of the respective business rules. During business rule implementation, each rule set, business process, and owner is given a unique identifier.

THE RULE PHRASE

A rule phrase in BROOD links a user-oriented business rule definition to a software design component. There are alternative ways in which this may be achieved. For example, using a rule object or rule engine, or making use of OCL. The use of rule object or rule engine increases the semantic distance between analysis and design and imposes implementation considerations. The use of constraints expressed using OCL may provide a link between business rule specifications and software design but OCL is still hard to understand by business users although OMG claims that no mathematical background is required in using OCL.

Rule phrases are considered as the building blocks for rule statements. They can be maintained independently during implementation, in other words, they are not deleted when a business rule is deleted. However, the modification and deleting of a rule phrase is not recommended since a careful effort is needed in reviewing its aggregated business rules. In addition to playing a role as the building blocks for business rule statements, rule phrases are also important in linking business rules to software design elements.

The mappings between rule phrase types and UML model elements are summarized in Table 4. Most of the rule phrases are directly linked to class diagram model elements. Entity and attribute term are directly connected to the respective class and attribute in the class diagram. Cardinality and role are correspondingly linked to multiplicity and role of an association end of a relationship. Algorithm is linked to operation specification.

Rule phrases for event, condition, and action, which are the building blocks for action assertion rules, are naturally linked to statechart diagram. Event, condition, and action are respectively linked to event, guard, and action of a state transition in a statechart diagram. Consequently, event and action may be linked to a class operation, and guard may be linked to an operation specification, in a class diagram. List and relational operator contain enumerated values whilst value contains a literal value. However, value and list can be linked to an operation that return a single and multiple values respectively.

THE BROOD PROCESS

The BROOD process is described using the process model based on the syntax and semantics of the OMG software process engineering

Table 4. Association between rule phrases and design elements

Rule Phrase Type	Software Design Elements
Entity	Class
Attribute Term	Attribute
Operation Term	Operation
Attribute Constraints	Attribute.isUnique, Attribute. notNull
Cardinality	AssociationEnd.multiplicity
Role	AssociationEnd.role
Event	Transition.event □ Class.operation
Condition	Transition.guard, Operation.specification
Action	Transition.action □ Class.operation
Algorithm	Operation.specification
Value	- (literal value), Operation.
List	- (enumeration), Operation
Relational Operator	- (enumeration)

Figure 2. An excerpt from OMG software process engineering metamodel (OMG, 2002)

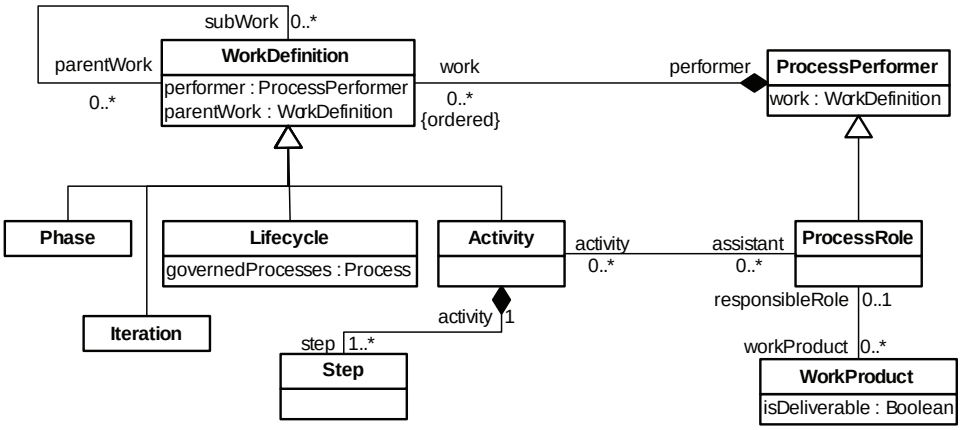


Figure 3. The flow of activities in the BROOD process

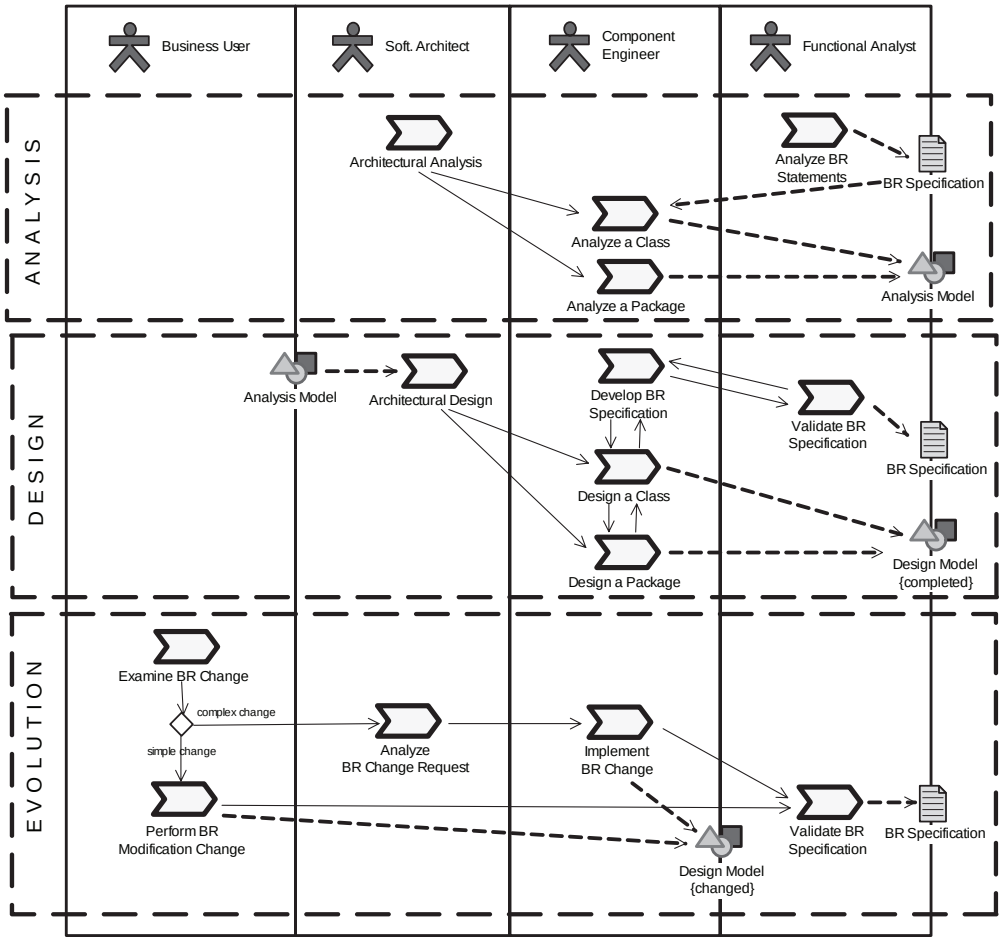


metamodel (SPEM). SPEM was developed by the Object Management Group to provide a metamodel and notations for specifying software processes and their components (OMG, 2002). SPEM extends the unified modeling language (UML) (OMG, 2001) metamodel with process specific stereotypes. A part of SPEM that shows most of the important components of a process structure is shown in Figure 2.

In SPEM, a *work product* is an artifact produced, consumed, or modified by a process. It may be a piece of information, a document, model, or source code. It is either used as an input by workers to perform an activity, or a result or an output of such activities. A work product is called a deliverable if it is needed to be formally delivered by a process. The examples of work products in BROOD are class diagram, statechart diagram, and business rule specification. Each work product is associated with a process role that is formally responsible for its production.

A *process role* defines the responsibilities of an individual, or a group of individuals working together as a team. Each process role performs or assists with specific activities.

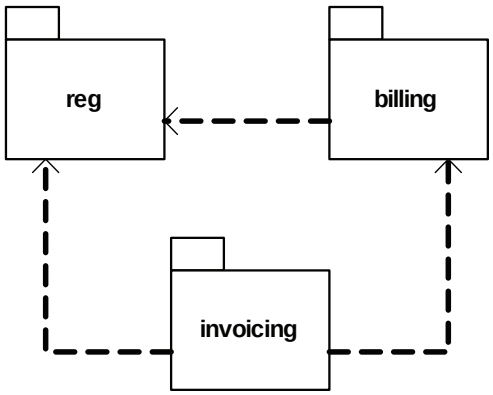
The core activities of the BROOD process are situated in the analysis, design, and evolution phases. Analysis phase produces analysis model that contains two main work products: the initial business rule specification and preliminary software design models. Both work products are refined and linked during the design phase to produce a more traceable and consequently evolvable software system. The flow of activities in each BROOD phase is shown in Figure 3.

The Analysis Phase

As shown in Figure 4, the analysis phase starts with an architectural analysis activity that considers the work products from requirements phase such as use-case model, business model, initial architecture descriptions, and supplementary requirements. A software architect performs architectural analysis by identifying the analysis packages based on the functional requirements and knowledge of the application domain. Each package realizes a set of closely related use cases and business processes to minimize the coupling between packages, which in turn localizes business changes. This activity identifies analysis classes and outlines their name, responsibilities, attributes, and relationships. In order to extract more information about the behavior of the classes, collaboration or interaction diagrams can be developed based on the process flows (scenario) in the use case models. The main work products produced by this activity are analysis class diagrams and packages in their outline version.

Considering the MediNet application, architectural analysis resulted in three packages *business processes* i.e. *registration*, *billing*, and *invoicing*. The registration package groups all classes related to patient registration such as `Patient`, `Paymaster`, `HCProvider`, `Clinic`, `User`, and `RegLocation`. Billing package contains classes related to billing and drugs inventory such as `Bill`, `BillPayment`, `Bill _ Item`, `TransType`, `TransItem`, and `ExpenseItem`. Invoicing package includes classes related to invoicing and invoice payment

Figure 4. Packages for the MediNet application



for example `Invoice`, `InvoiceItem`, `Payment`, and `PaymentAllocation`.

The outline of analysis class diagrams and packages are further refined by class analysis and package analysis activities, respectively. A component engineer identifies more detailed information about responsibilities and attributes of each class. Different types of relationships between classes such as association, aggregation, and inheritance are also identified. The possible states and their transitions can be identified to understand the behavior of objects from certain classes. These steps are repeated until a complete analysis class diagram, statechart diagram and package are achieved.

The activity of business rule modeling considers the informal statements captured during initial requirements and identifies the types for each business rule statement based on the BROOD typology. Business rule statements are transformed into more structured business rule specifications according to the templates' definition.

Table 5. Business rule statements for the MediNET application

Business Process	Business Rule Example	Rule Type
Registration	A patient must have a unique registration number.	Att. Constraint
	A patient may have more than one paymaster.	Rel. Constraint
	If a patient has an outstanding balance, then the patient should be banned from consultation registration	Action Assertion
	When consultation registration is successfully completed, then put the patient into the consultation queue.	Action Assertion
	If a patient's condition is critical then the patient is an emergency patient.	Inference
Billing	The amount of a panel patient's bill must not exceed the maximum bill amount set by the paymaster.	Att. Constraint
	Each bill item is associated with an item from the clinic transaction items	Rel. Constraint
	When consultation is completed then create bill.	Action Assertion
	If the bill is a panel patient's bill then create panel transaction item.	Action Assertion
	The amount of a bill is computed as the sum of all amounts of bill items.	Computation
	The amount of bill item is computed as the unit amount multiply by the quantity.	Computation
	A bill can be modified only if the user role is Chief Clinic Assistant.	Inference
Invoicing	One invoice must have zero or more payments.	Rel. Constraint
	When a payment is not received within 30 days from the invoice date, then the first reminder will be sent.	Action Assertion
	The amount of HCP MediNET usage invoice is computed as the sum of monthly subscription fee plus transaction fees.	Computation
	A paymaster (panel company) is under probation if the paymaster has an invoice with category 1 past due and the current balance is more than RM 5,000.00.	Inference

Table 5 shows a set of structured rules for the MediNet application. This template provides the means of managing rules as they get discovered and analyzed and acts as a 'repository' of rules for their entire lifecycle.

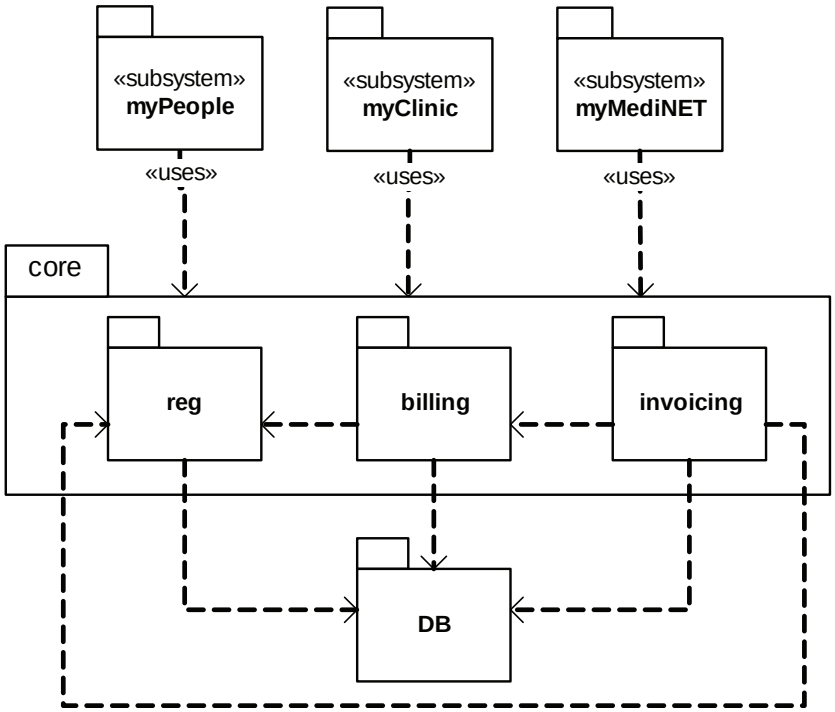
The Design Phase

The design phase involves the identification of application-specific and application-general subsystems. The application-specific subsystems are related to packages that group a set of closely related services in an application domain. The application-general subsystems are related to implementation technology decisions such as the introduction of user interface and database connectivity layers. The MediNet subsystems definition is shown in Figure 5.

The class design activity elaborates further the static and dynamic information of classes that were defined during the analysis phase. Additional information on the operations, attributes, and relationships can be added to each class. The specification of operations and attributes is made using the syntax of the chosen programming language. If necessary, the methods that specify the algorithm for the implementation of operations are specified.

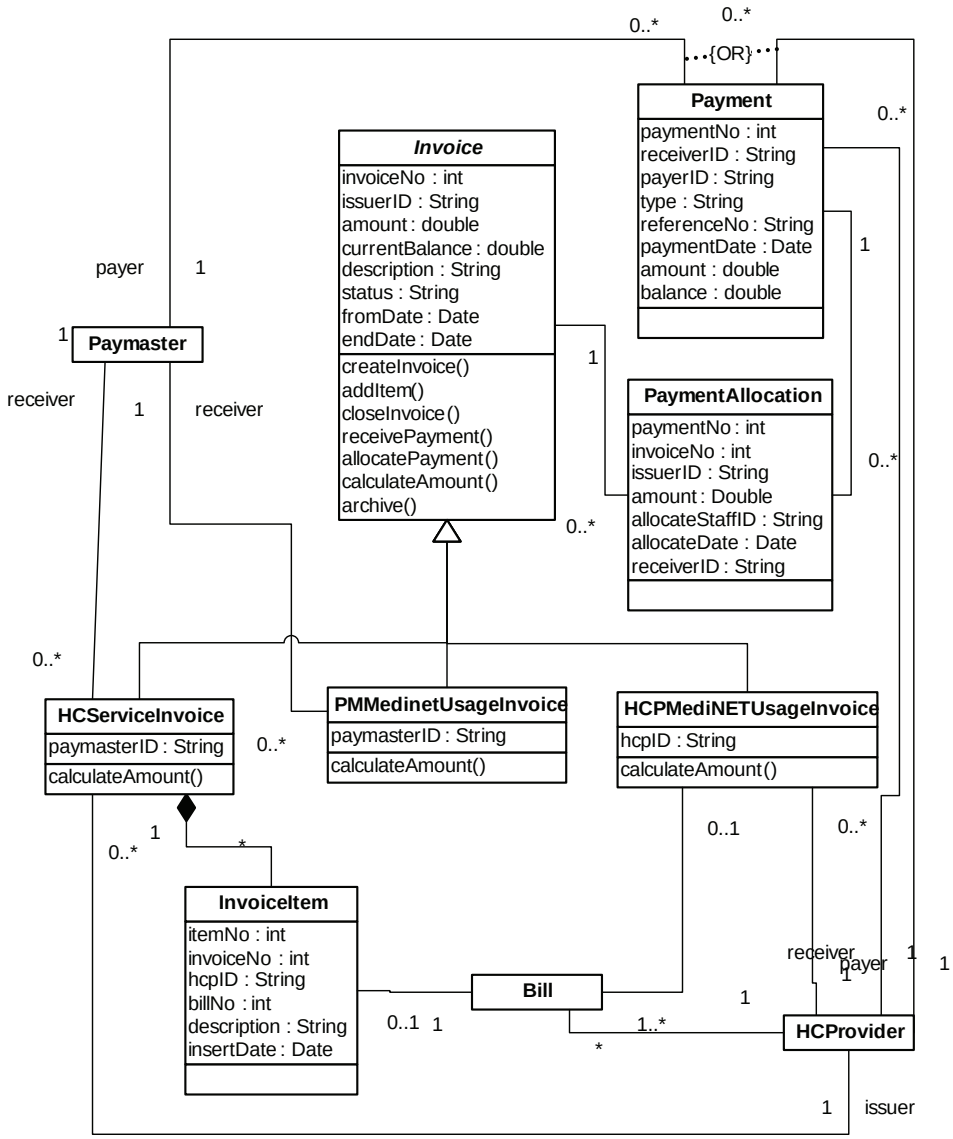
The class design activity for the MediNet application resulted in detailed specification of for the three packages of registration, billing and invoicing. The class association diagram of Figure 6 shows the class details for invoicing. In order to reduce diagrammatic complexity all parameters and return values are hidden in the class operations.

Figure 5. Software architecture for the MediNet application



The calculation of invoice amount is different for different types of invoice. The amount for healthcare service invoice is calculated as the total of its item amounts after applying additional computation rules such as bill limit, invoice limit and discount. MediNET uses the open item invoicing method that allows an invoice issuer to track each unpaid invoice as an individual item for aging purposes. Panel patient bills are considered as the items for HCP MediNET usage and HCP service usage invoices. For HCP MediNET usage invoice, the number of bills issued by a particular HCP is counted as the number of transactions, which is later used in the invoice amount calculation.

Figure 6. Class association diagram for invoicing for the MediNet application



In terms of payment, MediNET allows balance forward invoicing method in addition to open item method.

Within the design process classes are further elaborated in terms of the events and conditions that trigger their transition from one state to another. These are shown as statechart diagrams. For example, a statechart diagram for the `HCServiceInvoice` object is shown in Figure 7.

Within the BROOD design phase, rule phrase specifications are developed. Each rule phrase definition is stored in the repository called rule phrase entries. The possible values for rule phrase may be a set of enumerated values or the values of the linked software design element. A component engineer may define certain attributes for each business rule specification such as rule priority, owner, and business process. Each business rule

Figure 7. The STD `HCServiceInvoice` *object for the MediNet application*

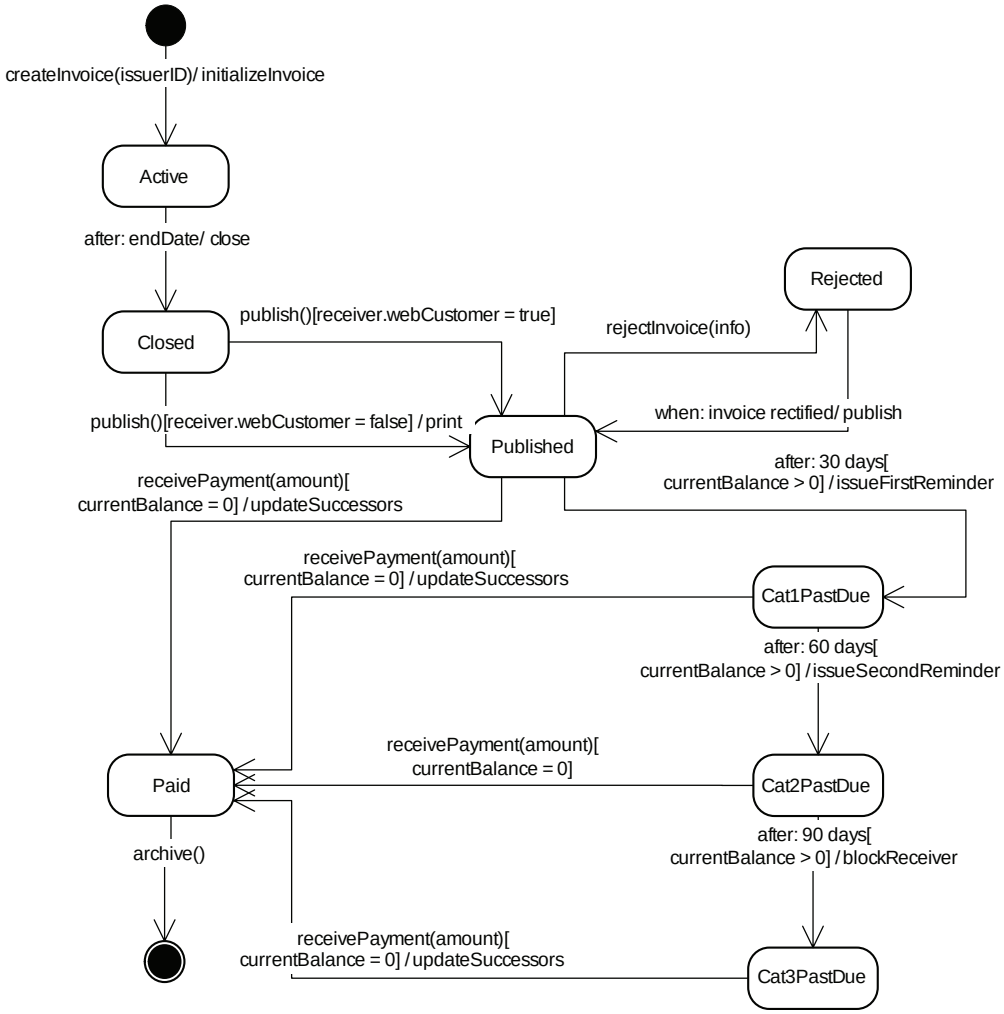


Table 6. Rule phrases and linked software design elements for the MediNet application

B Rule Category	Business Rule Phrases	Software Design Elements
Attribute Constraint	<entity> = 'a patient'	Patient (class)
	'must have'	- (patRegNo.optionality)
	'a unique'	- (patRegNo.uniqueness)
	<attributeTerm> = 'registration number'	Patient.patRegNo (attribute)
Relationship Constraint	<cardinality> = 'one and only one'	- (AssociationEnd.multiplicity)
	<entity> = 'transaction item'	TransItem (class)
	<role> = 'item type'	- (AssociationEnd.name)
	<entity> = 'bill item'	Bill_Item (class)
Action Assertion	<event> = '30 day after the creation date of the invoice'	- (Trans1.event.spec)
	<condition> = 'current balance of the invoice is greater than 0'	- (Trans1.guard.body)
	<action> = 'trigger issue the first reminder'	- (Trans1.action.initialiseInvoice(). spec)
Computation	<attributeTerm> = 'the amount of HCP MediNET Usage invoice'	HCPMediNETUsageInvoice.amount
	<algorithm> = 'the sum of monthly subscription fee plus transaction fee'	HCPMediNETUsageInvoice. calculateAmount().specification
Inference	<attributeTerm> = 'a paymaster status'	Paymaster.status
	<value> = 'under probation'	- (literal value)
	<condition> = 'the paymaster has an invoice with category 1 past due' AND 'the current balance is greater than RM 5,000.00'	Paymaster.getStatus().specification

statement can also be arranged in an appropriate rule set to assist the future management of the business rules.

For the MediNet application, the rules shown in Table 5 are specified according to rule phrases syntax as shown in Table 6.

The first rule in Table 6 shows the rule phrase derived from the attribute constraint rule, informally defined in the analysis phase as "A patient must have a unique registration number." The rule phrases '`a patient`' and '`registration number`' are respectively linked to `Patient` class and `patRegNo` attribute. The keywords '`must have`' and '`a unique`' are not statically linked to any design element. Instead, they are used to dynamically toggle the optionality and uniqueness values of `patRegNo` attribute during the creation or modification of the business rule statement. In other words, they are used to enable the automated change propagation to software design.

The second rule in Table 6 shows a relationship constraint., The rule phrases '`clinic item`'

and '`bill item`' are respectively linked to `TransItem` class and `Bill_Item` class. The rule phrases '`one and only one`' and '`clinic item`' play a similar role to keywords as in the attribute constraint rule, that is their purpose is to propagate business changes to design elements. The former specifies the multiplicity of an association end whilst the latter specifies the role of an association end.

In the *action assertion* rule "When a payment is not received within 30 days from the invoice date, then the first reminder will be sent," the rule phrases that represent the event, condition, and action are not directly linked to any design element but they are respectively used to generate the specifications of the transition's event, guard, and action in the HCP service usage invoice STD. Since event, condition, and action rule phrases are themselves composed by other rule phrases, they may be indirectly linked to the related design components via these rule phrases.

The *computation* and *inference* rules are linked to the operation specification —the computation rule is linked to the specification of `calculateAmount()` operation in `HCPMediNETUsageInvoice` class and the inference rule is linked to `getStatus()` operation from `Paymaster` class. During the development of an inference rule, a new operation is often needed to be added in its associated class to perform the derivation and return the inferred value.

The Evolution Phase

In general, business rule changes may be classified into simple and complex changes. A simple change is concerned with the modification, addition, or deletion of business rules that do not need to in-

Table 7. Simple change scenarios for the MediNet application

Change Scenarios	Changed Business Rules
1. HCP allows patients to make 'more than one payment for their bills' instead of the previously set 'single payment for each bill'.	One patient bill is associated with zero or more payments.
2. HCP makes small changes on the conditions to issue the reminder and block paymaster.	WHEN *15 days* from the invoice date IF a payment is not received THEN issue the first reminder. WHEN *30 days* from the invoice date IF the payment is not received THEN issue the second reminder. WHEN *45 days* from the invoice date IF the payment is not received THEN block the paymaster.
3. The MediNET supplier offers a more attractive usage charge to HCPs. They are charged based on the number of treated patients regardless the number of patient visits.	The amount of HCP usage invoice IS CALCULATED AS if (opt new package) then the transaction fee multiply by the number of registered patients, else, the transaction fee multiply by the number of treated patients, plus the monthly fee.
4. HCP introduces 5% discount to its internet customer.	If the paymaster is an internet customer, then give 5% discount to their invoices.
5. The HCP decides that each expense item must belong to one of the pre-defined types.	Zero or more expense item is associated with one and only one transaction item.

troduce new rule phrases or design elements. A complex change involves the addition or deletion of rule phrases or design elements.

Ordinarily, *simple business rules changes* could be performed by business users. The examples of five change scenarios that require simple business changes in MediNET system are shown in Table 7.

The implementation of a *complex* business rule change requires more effort than that of simple change. It involves the introduction of new rule phrases or design elements, which is needed to be performed by an individual with the knowledge of software design. In addition to technical skills, it often requires creative skills in making a design decision. Three examples of complex rules changes are shown in Table 8.

The first scenario initiates the modification of two existing business rule statements, the calculation of bill and the calculation of invoice amount. These business rule changes consequently lead to a minor change in software design, that is the introduction of `hasMaxBill` attribute in the `Paymaster` class.

Table 8. Complex change scenarios for the MediNet application

Change Scenarios	Changed Business Rules

1. HCP introduces new package for paymaster. In this package, the paymaster may limit the maximum amount of each patient bill to RM 20.00, and the excessive cost is absorbed by HCP. However, the paymaster must pay a monthly fee of RM5.00 for each patient.	The amount of a bill is computed as
	let amount = the sum of all amounts of bill items
	if (patient is a panel patient) AND (paymaster has maximum bill amount) AND (amount > RM 20.00)
	amount = 20
	The amount of HCP service invoice is computed as
	let amount = the total of the invoice items
	if (paymaster has maximum bill amount)
	amount = amount + 5 * the number of paymaster's patients

2. Paymaster wishes to provide different healthcare benefit coverage for different groups of its payees.	If (the patient is a panel patient) AND (the patient is an executive staff) then the patient is entitled to any type of treatments and medical procedures. If (the patient is a panel patient) AND (the patient is a production staff) then the patient is entitled for an outpatient treatment.

3. HCP would like to introduce a 5% discount on the invoices to preferred paymasters as a way to express gratitude to the loyal, potential, and good paying paymasters.	If (a paymaster has been a paymaster panel for more than 5 years) then (the customer is a 'loyal' customer).
	If (a paymaster has an average of at least RM24000.00 for the invoices over the last five years) then (the paymaster is considered as a 'potential' customer).
	If (a paymaster never has a past due invoice for the last two years) then (the paymaster is considered as a good paying paymaster).
	When (the invoice in created) if (the paymaster is a loyal, potential and good paying customer) then (set the discount of the invoice to 5%)

In the second scenario, the paymaster decided to introduce different healthcare benefit coverage to different levels of their payees. For example, executive staff is entitled to any medical treatment and medical procedures whilst production staff is only paid for outpatient treatments. It is obvious that simply implementing this new requirement into the existing `Paymaster` or `PanelPatient` class may increase the complexity of these classes. Therefore, additional classes that are responsible to manage the healthcare benefit coverage are required to be added to the existing software design. The possible candidates for these classes include `BenefitCoverage`, `SelectedClinic`, `MedicalProcedure`, and `Entitlement`.

The third scenario requires the intervention of a software developer. This scenario requires a number of new inference rules to be added to define a loyal, potential, and good paying customer. In addition to these business rules, an action assertion rule that initializes the value of the invoice discount during invoice creation should also be added. The introduction of the new inference rules consequently requires `isLoyal()`, `isPotential()`, and `isGoodPaying()` operations to be added to the `Paymaster` class. Similarly, the newly introduced action assertion rule requires component engineers to modify the action component of the transition from the initial state to '`Active`' state in the STD for `HCServiceInvoice` object.

THE BROOD SUPPORT TOOL

The BROOD process introduces several additional activities to the traditional object-oriented software design process. These additional activities include the documentation of business rules and their linking to software design components. To assist a developer with these BROOD-specific activities, a tool has been developed that supports the activities of business rule specification and management, software design editing, and business rule change propagation.

The BROOD tool was developed on top of the generic modeling environment (GME) (Ledeczi et al., 2001; VU, 2003), which is a configurable modeling environment.

The metamodel and templates, which are discussed in section 0, were used to implement the BROOD tool environment.

GME was used to visually edit the software design models, business rule specification, and rule phrase entries. Three main modules (known as interpreters in GME) were developed to simplify the rule phrase management, business rule composition, and business rule modification. These modules also perform the *automated propagation* of business rule changes to the respective software design elements, since a manual undertaking of such propagation would be impractical for most applications.

The BROOD tool has been designed to be used by both software developers and business users. A user-friendly interface is provided to ease the management and traceability of business rules by non-IT users. An overview of the BROOD support tool is shown in Figure 8.

The metamodel, the graphical model editor, the rule phrase management, the business rules composition and the business rules modification functions are part of the core component and user application layer in the BROOD tool architecture. The rule phrase entries, business rule specification, and software design models are stored in the storage layer.

The BROOD tool maintains the consistencies between business rule and the linked software design each time a business rule is created or modified. It provides full automated support in performing simple changes and partial support for complex changes since these require creative skills of software engineers in making a design decision.

There are four main types of model that can be managed using the BROOD tool: rule phrase entries, business rule, class diagram, and statechart diagram. Users may select the type of model to

Figure 8. Overview of the BROOD tool

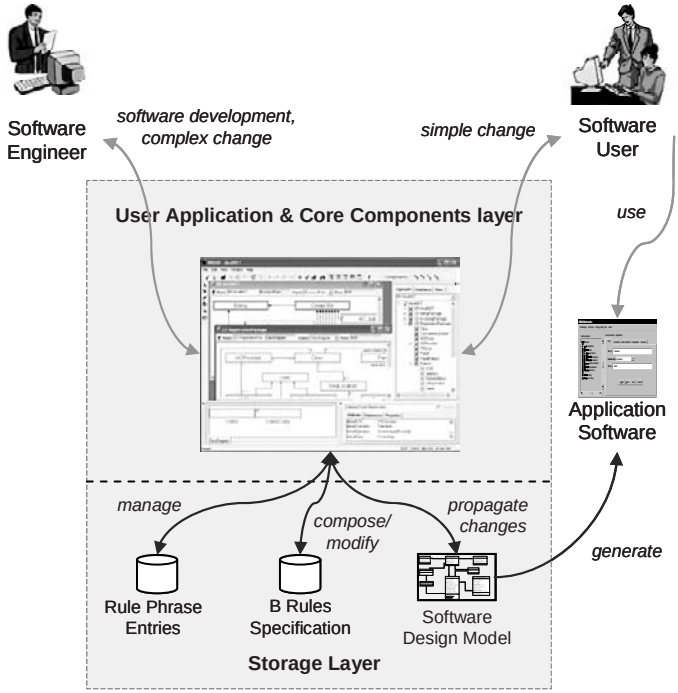

Figure 9. Example of the BROOD model editor

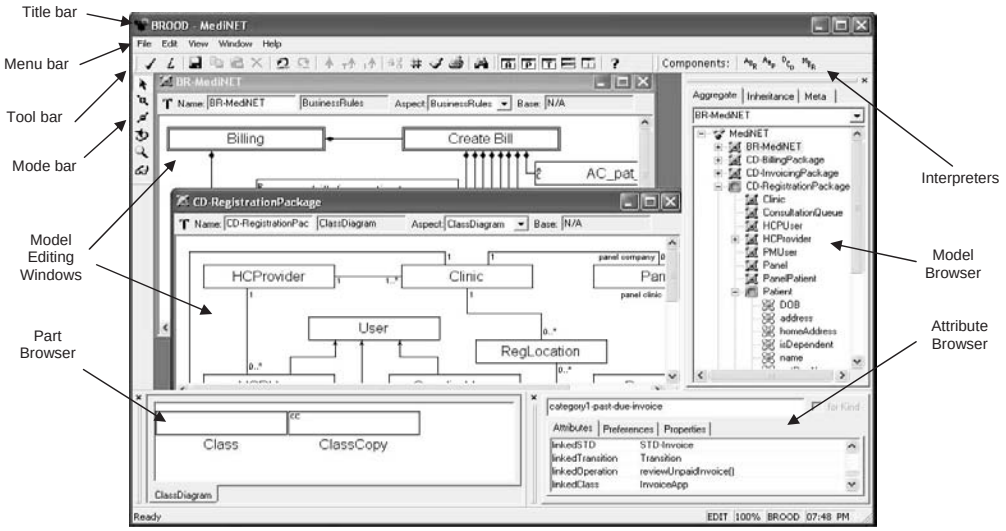


be created from a set of choices. An example of the BROOD model editor is shown in Figure 9. The model editor provides a convenient way to create a model and also to connect it or parts of it to other models.

While graphical model editing is convenient for visual models such as those of class and statechart diagrams, it is less helpful for business rules specification.

The graphical model editor can be used for some simple business rules definition such as cardinality, relational operator, list, and optionality but for more complex rules the BROOD tool offers a dedicated rule editor, the add business rule (ABR) module. This module performs two main tasks: business rule composition and software design updating. In business rule composition mode, rule phrases are used to construct a business rule statement. In software design updating mode the module updates the software design model that corresponds to the composed rule.

The BROOD tool also helps with the implementation of business rule changes. The modify business rule (MBR) module was developed to assist tool users in performing this task, an example of which is shown in Figure 9.

A full description of the tool is beyond the scope of this article. It should be stressed however, that the tool plays an important part in the effective application of the BROOD approach by simplifying a sometimes tedious, error-prone, and time-consuming task of linking and propagating business rule changes to software design components.

DISCUSSION

The main aim of BROOD has been to facilitate the process of software evolution through: (a) externalization of business rules and their explicit modeling and (b) the linking of each modeled business rule with a corresponding software component. This approach provides full traceability between end-user concepts and software designs. By combining BROOD to design traceability in source code (Alves-Foss, Conte de Leon, & Oman, 2002), it is possible to achieve effective traceability in a software system.

The BROOD metamodel offers a complete foundation and infrastructure for the development of a software system that is resilient to business rule changes.

With regard to business rule typology, BROOD introduces three main business rule types: constraints, action assertion, and derivations. These types are further divided into an adequate number of sub-types and templates. In contrast to BRG, BROCOM, and BRS approaches, BROOD attempts to remove the redundancy by reducing the unnecessary business rule types. At the same time, it improves the incompleteness of business rule types in AOM, coordination contract, and BRBeans approaches. In terms of business rule management elements, BROOD provides the concept of *ruleset* to organize the groups and hierarchy of the closely related business rules.

In terms of its modeling language, BROOD offers a high level of expressiveness. The keywords in the language definition and a sufficient number of sentence templates should provide adequate representation constructs. In general, achieving total expressiveness of the modeling language business rules is relatively hard to achieve due to the large number of ways of expressing business rules in a natural language. The usability of BROOD in this context will be proved in due course once the approach has been applied on different domains and applications. BROOD was found to have a high level of un-ambiguity by the introduction of the appropriate typology and templates. BROOD provides a mutually exclusive set of business rule types and removes the superfluous templates in order to avoid conflict and redundancy in representing the meaning of business rules.

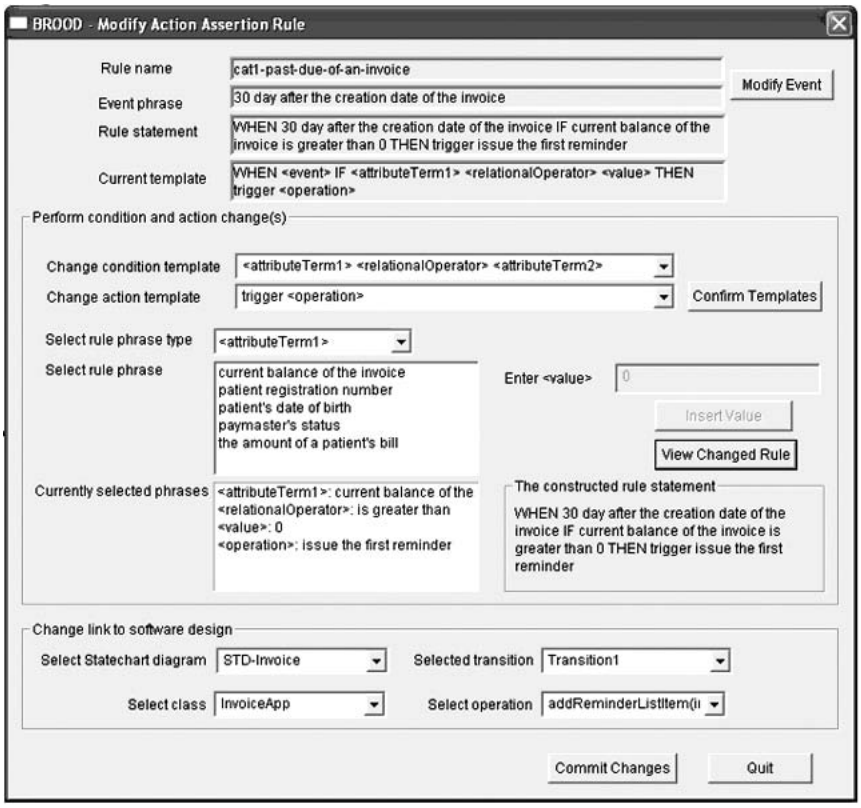
In practical terms, BROOD can be applied using the UML-based SPEM metamodel, which provides a set of concepts and notations to de-

scribe various software process components such as lifecycle phases, activities, process roles, and work products. The use of business rule templates and UML improves the usability of the BROOD approach. The templates allow users to create a business rule statement by simply composing the existing rule phrases whilst UML provides abstractions for users to naturally design a software system. Moreover, the detailed process description is provided to guide users especially in performing complex tasks such linking business rules to software design and handling different types of changes.

The utility of BROOD was demonstrated in this paper through the use of the MediNet industrial application. This application had originally been developed using a standard object-oriented approach. It was therefore possible (and indeed desirable) to use the case study not only as a way of demonstrating BROOD but also for comparing and contrasting BROOD to a traditional development approach.

By considering UML for software design, BROOD maintains the well-known object-oriented design quality attributes such as modularity, high cohesion, low coupling, efficiency, and portability. BROOD however provides additional quality attributes such as *requirements traceability*, *software evolvability*, and *approach usability*.

Figure 10. Example of the BROOD business rules modifier



The traditional approach deployed for MediNet did not provide explicit traceability of business policy defined during the requirements specification phase. Instead, it provides a so-called 'seamless transition' from the use case models that document the user requirements to the analysis and design models. This resulted in business rules being embedded in both requirements specification and software design models. In contrast, with BROOD there was a natural transformation of the MediNET requirements into the structured business rules specification and in turn this specification was directly related to software design components.

Concerning software evolution, the implementation of changes using the traditional approach required the use of expertise with specific knowledge of the MediNET software design. Since software engineers do not normally initiate business changes, they had to repeat all phases in MediNET development lifecycle especially requirements and analysis phases. Locating the related software design components was hard since there was no explicit link between the MediNET design models and its user requirements.

In relation to approach usability, the traditional approach was easier to apply during development since it did not have to deal with additional steps that were added to explicitly specify, document, and link business rules specification to software design. These steps were found to increase the complexity and duration of software development process. However, the availability of the business rule typology and templates, which provide the guidelines for the analysis of business rule statements and the identification of rule phrases, were found useful in minimizing these problems. The business rule templates have improved the MediNET system understandability and increased the involvement of business users in the MediNET development. During evolution, BROOD was found easier to be used than the traditional approach. Using BROOD, business users could perform the simple business rule changes as demonstrated in the MediNET application. Rapid change implementation is important especially in business critical applications with intolerable downtime. The detailed process description facilitated the implementation of complex changes in MediNET.

In summary, BROOD contributes to three critical areas namely business rules specification, object-oriented design, and software evolution process. The proposed business rule specification extends the state-of-the-art approaches to business rule representation by reducing redundancy and avoiding conflict among business rule types in its typology. The structures of rule templates have been defined so as to make them suitable for linking to software designs in support of future software evolution. A specification is aligned to changing user requirements via the linking of business rules to software designs through a detailed transformation of business rule into the specification of related software design components. Thus, the externalization of frequently changing aspects of a system into detailed business rules and the maintenance of associations between these and corresponding software components should provide a strong framework for effective software evolution.

ACKNOWLEDGMENT

The authors would like to thank the human resource department of Universiti Teknologi Malaysia (UTM) for partially sponsoring this research, and Penawar Medical Group, Malaysia for the permission to use its MediNET healthcare information system requirements specification as the case study. The authors wish to also express their gratitude to the three anonymous reviewers and to the editor of the special issue, Professor Dinesh Batra, whose insightful and detailed comments have contributed to the production of a much improved version of this article.

APPENDIX A. SPECIFICATION OF BROOD

Part I: The BROOD Metamodel

Business Rule Organisation and Typology

business_rule_model = rule_set, owner;
rule_set = (rule_set | rule_statement), {rule_set | rule_statement}, [owner], [business_process];
business_rule = (constraint | action_assertion | derivation), name, [is_mandatory], [priority], [is_propagatable];
Contraint
constraint = att_constraint | rel_constraint;
Attribute Constraint
att_constraint = entity, ('must have' | 'may have'), ['a unique'], att_term | att_term, ('must be' | 'may be'), relational_op, (value | att_term) | att_term, 'must be in', list;
att_term = attribute, 'of', entity;
Relationship Constraint
rel_constraint = ([cardinality], entity, 'is a/an', role, 'of', [cardinality], entity | [cardinality], entity, 'is associated with', [cardinality], entity | entity, ('must have' | 'may have'), [cardinality], entity | entity, 'is a/an' entity), *{Association}*;

Action Assertion

action_assertion = 'WHEN', event, ['IF', condition], 'THEN', action, {StatechartDiagram, Transition};
Event
event = simple_event | complex_event;
simple_event = (change_event | time_event | user_event), {Class, Operation};
change_event = att_term ('is updated' |) | entity ('is deleted' | 'is created') (operation | business_rule), 'is triggered';
time_event = date_time | n, time_unit, 'time interval from', date_time , 'is reached' | number, time_unit, 'after', date_time;
user_event = string;
complex_event = simple_event, {('Or' | 'And'), simple_event {('Or' | 'And'), simple_event}
Condition
condition = simple_condition | complex_condition;

simple_condition = [‘Not’], attribute_term, relational_op, (value | attribute_term) | attribute_term, (‘in’ | ‘not in’), list;
complex_condition = simple_condition, (‘Or’ | ‘And’), simple_condition, {(‘Or’ | ‘And’), simple_condition};
Action
action = simple_action | action_sequence;
simple_action = trigger_action | object_ manipulation_action | user_action, {Class, Operation};
trigger_action = ‘trigger’, (process | operation | business_rule);
object_manipulation_action = ‘set’, att_term, ‘to’, value | (‘create’ | ‘delete’), object;
action_sequence = simple_action, {simple_action};

Derivation

derivation = computation | inference;
Computation
computation = attribute_term, ‘is computed as’, algorithm, {Class, Operation};
algorithm = string;
(* i.e. any specification language for specifying the algorithm e.g., OCL, pseudo-code, etc. *)
Inference
inference = ‘If’, condition, ‘then’, fact;

Part II: The BROOD Process

The following specification is based on OMG Software Process Engineering Metamodel.

Process: Business Rule-based Object-Oriented Design (BROOD)

Phase: **Analysis**
Activity: **Analyze Business Rule Statements**
ProcessRole: **Functional Analyst**
ActivityParameters {kind: input}
WorkProduct: **Use-Case Model** {state: **revised**}
WorkProduct: **Business Rule Statements** {state: **revised**}
ActivityParameters {kind: output}
WorkProduct: **Business Rule Specification** {state: **initial draft**}
Steps
Step: **Identify business rule type**
Step: **Rewrite business rules according to sentence templates**
Step: **Resolve rule conflicts and redundancy**

Activity: **Architectural Analysis**
ProcessRole: **Software Architect**
ActivityParameters {kind: input}
WorkProduct: **Use-Case Model** {state: **revised**}
WorkProduct: **Business Model** {state: **completed**}
WorkProduct: **Architecture Description** {state: **initial draft**}
WorkProduct: **Supplementary Requirements** {state: **revised**}
ActivityParameters {kind: output}
WorkProduct: **Analysis Class Diagram** {state: **outline**}
WorkProduct: **Analysis Package** {state: **outline**}
WorkProduct: **Architecture Description** {state: **revised draft**}
Steps
Step: **Identify analysis packages**
Step: **Identify analysis classes**
Step: **Describe analysis object interactions**

Activity: **Analyze a Class**
ProcessRole: **Component Engineer**

ActivityParameters {kind: input}
WorkProduct: **Analysis Class Diagram** {state: **outlined**}
ActivityParameters {kind: output}
WorkProduct: **Analysis Class Diagram** {state: **completed**}
Steps
Step: **Identify class responsibilities**
Step: **Identify class attributes**
Step: **Identify class relationships**

Activity: **Analyze a Package**
ProcessRole: **Component Engineer**
ActivityParameters {kind: input}
WorkProduct: **Analysis Package** {state: **outlined**}
WorkProduct: **Architecture Description** {state: **revised draft**}
ActivityParameters {kind: output}
WorkProduct: **Analysis Package** {state: **completed**}
Steps
Step: **Analyze the cohesiveness of each package**
Step: **Analyze the dependencies between packages**
Phase: **Design**
Activity: **Architectural Design**
ProcessRole: **Software Architect**
ActivityParameters {kind: input}
WorkProduct: **Use-Case Model** {state: **revised**}
WorkProduct: **Analysis Model** {state: **completed**}

APENDIX B. THE MEDINET APPLICATION

MediNET is a suite of internet applications that addresses the administrative and back-end processing requirements of the healthcare business community. It acts as a secondary layer to the existing administrative and information systems. MediNET allows various components of the healthcare industry to exchange business data instantaneously and automate their routine administrative tasks. Therefore, facilitated businesses are able to reduce their administrative burdens, become more efficient and make better informed business decisions. In contrast to the traditional applications, MediNET does not require its users to maintain separately installed software. It allows its users to leverage the power of technology without having to bear massive development, acquisition, infrastructure or maintenance costs.

MediNET users only need to pay as and when they use the application. In general, MediNET users can be divided into three categories: paymasters, healthcare providers (HCPs), and supplier. Paymasters are those who pay for medical or healthcare services, for examples employers, insurers and managed care organizations. They use MediNET to maintain the basic parts of the patient records such as performing their payee registration and defining the healthcare benefit coverage of their payees. HCPs are the professionals who dispense medical treatment, for examples general practitioners (GPs), hospitals and dentists. HCPs use MediNET to manage patient records, patient billing and paymaster invoicing.

The current implementation of MediNET is only limited to employers as the paymasters and GPs as the HCPs. The supplier is the company who owns, provides and maintains the MediNET application. It rents MediNET to HCPs and paymasters as and when the applications are needed and charges them based on the number of performed transactions.

MediNET was chosen as a case study due to the various frequently changing business rules introduced by its different users. For example, HCPs provide different packages to the paymasters that constrain the way they perform the patient billing and paymasters invoicing. Paymasters may also want to introduce different healthcare benefit coverage to different staff levels that control the eligibility of the staff's treatments. The business rules related to the packages and benefit coverage are frequently changed by the HCPs and paymasters. Other common changes to business rules include the introduction of invoice discounts, the rule to block non-paying paymasters, and the conditions to issue reminder for past due invoices. These frequent changes indicate the need for an approach to simplify the implementation of changes in MediNET software system.

Chapter 2.29
Bug Fixing Practices within Free/Libre Open Source Software Development Teams[1]

Kevin Crowston
Syracuse University, USA

Barbara Scozzi
Politecnico di Bari, Italy

ABSTRACT

Free/Libre open source software (FLOSS, e.g., Linux or Apache) is primarily developed by distributed teams. Developers contribute from around the world and coordinate their activity almost exclusively by means of email and bulletin boards, yet some how profit from the advantages and evade the challenges of distributed software development. In this article we investigate the structure and the coordination practices adopted by development teams during the bug-fixing process, which is considered one of main areas of FLOSS project success. In particular, based on a codification of the messages recorded in the bug tracking system of four projects, we identify the accomplished tasks, the adopted coordination mechanisms, and the role undertaken by both the FLOSS development team and the FLOSS community. We conclude with suggestions for further research.

INTRODUCTION

In this article, we investigate the coordination practices for software bug fixing in Free/Libre open source software (FLOSS) development teams. Key to our interest is that most FLOSS software is developed by distributed teams, that is, geographically dispersed groups of individuals working together over time towards a common goal (Ahuja et al., 1997, p. 165; Weisband, 2002). FLOSS developers contribute from around the world, meet face to face infrequently, if at all, and coordinate their activity primarily by means of computer mediated communications (Raymond, 1998; Wayner, 2000). As a result, distributed teams

employ processes that span traditional boundaries of place and ownership. Since such teams are increasingly commonly used in a diversity of settings, it is important to understand how team members can effectively coordinate their work.

The research literature on distributed work and on software development specifically emphasizes the difficulties of distributed software development, but the case of FLOSS development presents an intriguing counter-example, at least in part: a number of projects have been outstandingly successful. What is perhaps most surprising is that FLOSS development teams seem not to use many traditional coordination mechanisms such as formal planning, system level design, schedules and defined development processes (Mockus et al., 2002, p. 310). As well, many (though by no means all) programmers contribute to projects as volunteers, without working for a common organization and/or being paid.

The contribution of this article is to document the process of coordination in effective FLOSS teams for a particularly important process, namely bug fixing. These practices are analyzed by adopting a process theory, that is, we investigate which tasks are accomplished, how and by whom they are assigned, coordinated, and performed. In particular, we selected four FLOSS projects, inductively coded the steps involved in fixing various bugs as recorded in the projects' bug tracking systems and applied coordination theory to identify tasks and coordination mechanisms carried out within the bug-fixing process.

Studying coordination of FLOSS processes is important for several reasons. First, FLOSS development is an important phenomenon deserving of study for itself. FLOSS is an increasingly important commercial issue involving all kind of software firms. Million of users depend on systems such as Linux and the Internet (heavily dependent on FLOSS software tools) but as Scacchi notes "little is known about how people in these communities coordinate software development across different settings, or about what software processes, work practices, and organizational contexts are necessary to their success" (Scacchi, 2002, p. 1; Scacchi, 2005). Understanding the reasons that some projects are effective while others are not is a further motivation for studying the FLOSS development processes. Second, studying how distributed software developers coordinate their efforts to ensure, at least in some cases, high-performance outcomes has both theoretical and managerial implications. It can help understanding coordination practices adopted in social collectives that are not governed, at least apparently, by a formal organizational structure and are characterized by many other discontinuities that is, lack of coherence in some aspects of the work setting: organization, function, membership, language, culture, etc. (Watson-Manheim et al., 2002). As to the managerial implications, distributed teams of all sorts are increasingly used in many organizations. The study could be useful to managers that are considering the adoption of this organizational form not only in the field of software development.

The remainder of the article is organized as follows. In Section 2 we discuss the theoretical background of the study. In Section 3 we stress the relevance of process theory so explaining why we adopted such a theoretical approach. We then describe coordination theory and use it to describe the bug-fixing process as carried out in traditional organizations. The research methodology adopted to study the bug-fixing process is described in Section 4. In Section 5 and 6 we describe and discuss the study's results. Finally, in Section 7 we draw some conclusions and propose future research directions.

BACKGROUND

In this section we provide an overview of the literature on software development in distributed environment and the FLOSS phenomenon.

Distributed Software Development

Distributed teams offer numerous potential benefits, such as the possibility to perform different projects all over the world without paying the costs associated with travel or relocation, or ease of reconfiguring teams to quickly respond to changing business needs (DeSanctis & Jackson, 1994; Drucker, 1988) or to exploit available competences and distributed expertise (Grinter et al., 1999; Orlikowski, 2002). Distributed teams seem particularly attractive for software development, because software, as an information product, can be easily transferred via the same systems used to support the teams (Nejmeh, 1994; Scacchi, 1991). Furthermore, while many developed countries face a shortage of talented software developers, some developing countries have a pool of skilled professionals available, at lower cost (Metiu & Kogut, 2001, p. 4; Taylor, 1998). As well, the need to have local developers in each country for marketing and localization have made distributed teams a business need for many global software corporations (Herbsleb & Grinter, 1999b, p. 85).

While distributed teams have many potential benefits, distributed workers face many real challenges. The specific challenges vary from team to team, as there is a great diversity in their composition and in the setting of distributed work. As mentioned, distributed work is characterized by numerous discontinuities that generate difficulties for members in making sense of the task and of communications from others, or produce unintended information filtering (de Souza, 1993). These interpretative difficulties make it hard for team members to develop a shared mental model of the developing project (Curtis et al., 1990, p. 52). A lack of common knowledge about the status, authority and competencies of participants brought together for the first time can be an obstacle to the creation of a social structure and the development of team norms (Bandow, 1997, p. 88) and conventions (Weisband, 2002), thus frustrating the potential benefits of increased flexibility.

Numerous studies have investigated social aspects of software development teams (e.g., Curtis et al., 1988; Humphrey, 2000; Sawyer & Guinan, 1998; Walz et al., 1993). These studies conclude that large system development requires knowledge from many domains, which is thinly spread among different developers (Curtis et al., 1988). As a result, large projects require a high degree of knowledge integration and the coordinated efforts of multiple developers (Brooks, 1975). However, coordination is difficult to achieve as software projects are non-routine, hard to decompose perfectly and face requirements that are often changing and conflicting, making development activities uncertain.

Unfortunately, the problems of software development seem to be exacerbated when development teams work in a distributed environment with a reduced possibility for informal communication (Bélanger, 1998; Carmel & Agarwal, 2001; Herbsleb & Grinter, 1999a). In response to the problems created by discontinuities, studies of distributed teams stress the need for a significant amount of time spent in "community building" (Butler et al., 2002). In particular, members of distributed teams need to learn how to communicate, interact and socialize using CMC. Successful distributed cross-functional teams share knowledge and information and create new practices to meet the task-oriented and social needs of the members (Robey et al., 2000). Research has shown the importance of formal and informal adopted coordination mechanisms, information sharing for coordination and communications, and conflict management for project's performance and quality (Walz et al., 1993). However, the processes of coordination suitable for distributed teams are still open topics for research (e.g., Orlikowski, 2002).

The FLOSS Phenomenon: A Literature Overview

The growing literature on FLOSS has addressed a variety of questions. Some researchers have examined the implications of free software from economic and policy perspectives (e.g., Di Bona et al., 1999; Kogut & Metiu, 2001; Lerner & Tirole, 2001) as well as social perspective (e.g., Bessen, 2002; Franck & Jungwirth, 2002; Hann et al., 2002; Hertel et al., 2003; Markus et al., 2000). Other studies examine factors for the success of FLOSS projects (Hallen et al., 1999; Leibovitch, 1999; Pfaff, 1998; Prasad, n.d.; Valloppillil, 1998; Valloppillil & Cohen, 1998, Crowston and Scozzi, 2003). Among them, an open research question deals with the analysis of how the contributions of multiple developers can be brought into a single working product (Herbsleb & Grinter, 1999b). To answer such a question, a few authors have investigated the processes of FLOSS development (e.g., Jensen & Scacchi, 2005; Stewart & Ammeter, 2002). The most well-known model developed to describe FLOSS organization structure is the bazaar metaphor proposed by Raymond (1998). As in a bazaar, FLOSS developers autonomously decide the schedule and contribution modes for software development, making a central coordination action superfluous. While still popular, the bazaar metaphor has been broadly criticized (e.g., Cubranic, 1999). According to its detractors, the bazaar metaphor disregards some aspects of the FLOSS development process, such as the importance of the project leader control, the existence of de-facto hierarchies, the danger of information overloads and burnout, the possibility of conflicts that cause a loss of interest in a project or forking, and the only apparent openness of these communities (Bezroukov, 1999a, 1999b).

Nevertheless, many features of the bazaar model do seem to apply. First, many teams are largely self-organizing, often without formally appointed leaders or formal indications of rank or role. Individual developers may play different roles in different projects or move from role to role as their involvement with a project changes. For example, a common route is for an active user to become a co-developer by contributing a bug fix or code for a new feature, and for active and able co-developers to be invited to become members of the core. Second, coordination of project development happens largely (though not exclusively) in a distributed mode. Members of a few of the largest and most well-established projects do have the opportunity to meet face-to-face at conferences (e.g., Apache developers at *ApacheCon*), but such an opportunity is rare for most project members. Third, non-member involvement plays an important role in the success of the teams. Non-core developers contribute bug fixes, new features or documentation, provide support for new users and fill a variety of other roles in the teams. Furthermore, even though the core group provides a form of leadership for a project, they do not exercise hierarchical control. A recent study documented that self-assignment is a typical coordination mechanism in FLOSS projects and direct assignment are nearly non-existent (Crowston et al., 2005). In comparison to traditional organizations then, more people can share power and be involved in FLOSS project activities. However, how these diverse contributions can be harnessed to create a coherent product is still an important question for research. Our article addresses this question by examining in detail a particular case, namely, coordination of bug-fixing processes.

CONCEPTUAL DEVELOPMENT

In this section, we describe the theoretical perspectives we adopted to examine the coordination of bug fixing, namely, a process-oriented perspective and the coordination theory. We also introduce the topic of coordination and discuss

the literature on coordination in software development and the (small) literature on coordination in FLOSS teams.

Processes as Theories

Most theories in organizational and information system research are variance theories, comprising constructs or variables and propositions or hypotheses linking them. By adopting a statistical approach, such theories predict the levels of dependent or outcome variables from the levels of independent or predictor variables, where the predictors are seen as necessary and sufficient for the outcomes. In other words, the logical structure of such theories is that if concept *a* implies concept *b*, then more of *a* means more (or less) of *b*. For example, the hypothesis that the adoption of ICT makes organization more centralized, examined as a variance theory, is that the level of organization centralization increases with the number of new ICTs adopted.

An alternative to a variance theory is a process theory (Markus & Robey, 1988). Rather than relating levels of variables, process theories explain how outcomes of interest develop through a sequence of events. In that case, antecedents are considered as necessary but not sufficient for the outcomes (Mohr, 1982). For example, a process model of ICT and centralization might posit several steps each of which must occur for the organization to become centralized, such as development and implementation of an ICT system and use of the system to control decision premises and program jobs, resulting in centralization of decision making as an outcome (Pfeffer, 1978). However, if any of the intervening steps does not happen, a different outcome may occur. For example, if the system is used to provide information directly to lower-level workers, decision making may become decentralized rather centralized (Zuboff, 1988). Of course, theories may contain some aspects of both variance and process theories (e.g., a variance theory with a set of contingencies), but for this discussion, we describe the pure case. Typically, process theories are of some transient process leading to exceptional outcomes, for example, events leading up to an organizational change or to acceptance of a system. However, we will focus instead on what might be called "everyday" processes: those performed regularly to create an organization's products or services. For example, Sabherwal and Robey (1995) described and compared the processes of information systems development for 50 projects to develop five clusters of similar processes.

Kaplan (1991, p. 593) states that process theories can be "valuable aids in understanding issues pertaining to designing and implementing information systems, assessing their impacts, and anticipating and managing the processes of change associated with them". The main advantage of process theories is that they can deal with more complex causal relationships than variance theories. Also they embody a fuller description of the steps by which inputs and outputs are related, rather than noting the relationship between the levels of input and output variables. Specifically, representing a process as a sequence of activities provides insight into the linkage between individual work and processes, since individuals perform the various activities that comprise the process. As individuals change what they do, they change how they perform these activities and thus their participation in the process. Conversely, process changes demand different performances from individuals. ICT use might simply make individuals more efficient or effective at the activities they have always performed. However, an interesting class of impacts involves changing which individuals perform which activities and how activities are coordinated. Such an analysis is the aim of this article.

Coordination of Processes

In this subsection, we introduce the topic of coordination and present the fundamentals of coordination theory. Studying coordination means analyzing how dependences that emerge among the components of a system are managed. That stands for any kind of system, for example, social, economics, organic, or information system. Hence, the coordination of the components of a system is a phenomenon with a universal relevance (Boulding, 1956). The above definition of coordination is consistent with the large body of literature developed in the field of organization theory (e.g., Galbraith, 1973; Lawrence & Lorsch, 1967; Mintzberg, 1979; Pfeffer & Salancik, 1978; Thompson, 1967) that emphasizes the importance of interdependence.

For example, according to Thompson (1967), organizational action consists of the coordination of the interdependences and the reduction of the costs associated to their management. Two components/systems are said to be interdependent if the action carried out by one of them affect the other one's output or performance (McCann & Ferry, 1979; Mohr, 1971; Victor & Blackburn, 1987). For space reason, it is not possible to present all the contributions on coordination in the literature, but because of its relevance, we here briefly report on Thompson's seminal work. Thompson (1967) identified three main kinds of interdependence, namely *pooled*, *sequential* and *reciprocal interdependence*. Pooled interdependence occurs among organization units that have the same goal but do not directly collaborate to achieve it. Sequential dependence emerges among serial systems. A reciprocal dependence occurs when the output of a system is the input for a second system and vice versa. The three kinds of interdependence require coordination mechanisms whose cost increases going from the first to the last one. The coordination by standardization, that is, routine and rules, is sufficient to manage pooled-dependant systems. Coordination by plan implies the definition of operational schemes and plans. It can be used to manage pooled and sequential dependences. Finally, coordination by mutual adjustment is suitable for the management of reciprocal dependences.

The interest devoted by scholars and practitioners to the study of coordination problems has recently increased due to the augmented complexity of products, production processes and to the rapid advancement in science and technology. To address these issues scholars have developed coordination theory, a systemic approach to the study of coordination (Malone & Crowston, 1994). Coordination theory synthesizes the contributions proposed in different disciplines to develop a systemic approach to the study of coordination. Studies on coordination have been developed based on two level of analysis, a micro and a macro level. In particular, most organization studies adopt a macro perspective, so considering dependencies emerging among organizational units. Other studies adopt a micro perspective, so considering dependencies emerging among single activities/actors. Coordination theory adopts the latter perspective and, in particular, focuses on the analysis of dependencies among activities (rather that actors). Hence, it is particularly useful to the description and analysis of organizational processes, which can be defined as a set of interdependent activities aimed to the achievement of a goal (Crowston, 1997; Crowston & Osborn, 2003). In particular, this approach has the advantage of making it easier to model the effects of reassignments of activities to different actors, which is common in process redesign efforts. We adopted this perspective because the study focuses on analyzing coordination mechanisms within processes.

Consistent with the definition proposed above, Malone and Crowston (1994) analyzed group action in terms of *actors* performing *interdependent tasks.* These tasks might require or create

resources of various types. For example, in the case of software development, actors include the customers and various employees of the software company. Tasks include translating aspects of a customer's problem into system requirements and code, or bug reports into bug fixes. Finally, resources include information about the customer's problem and analysts' time and effort. In this view, actors in organizations face *coordination problems* arising from dependencies that constrain how tasks can be performed.

It should be noted that in developing this framework, Malone and Crowston (1994) describe coordination mechanisms as relying on other necessary group functions, such as decision making, communications, and development of shared understandings and collective sensemaking (Britton et al., 2000; Crowston & Kammerer, 1998). To develop a complete model of a process would involve modeling all of these aspects: coordination, decision making, and communications. In this article though, we will focus on the coordination aspects, bracketing the other phenomenon.

Coordination theory classifies dependencies as occurring between a task and a resource, among multiple tasks and a resource, and among a task and multiple resources. Dependencies between a task and a resource are due to the fact that a task uses or creates a resource. Shared use of resources can in turn lead to dependencies between the tasks that use or create the resource. These dependencies come in three kinds. First, the flow dependence resembles the Thompson's sequential dependency. Second, the fit dependence occurs when two activities collaborate in the creation of an output (though in the case where the output is identical, this might better be called synergy, since the benefit is that duplicate work can be avoided). Finally, the share dependency emerges among activities that share the use of a resource. Dependencies between a task and multiple resources are due to the fact that a task uses, creates or produces multiple resources or a task uses a resource and create another resource. For example, in the case of software development, a design document might be created by a design task and used by programming tasks, creating a fit dependency, while two development tasks might both require a programmer (a share dependency) and create outputs that must work together (a fit dependency).

The key point in this analysis is that dependencies can create problems that require additional work to manage (or provide the opportunity to avoid duplicate work). To overcome the coordination problems created by dependences, actors must perform additional work, which Malone and Crowston (1994) called *coordination mechanisms.* For example, if particular expertise is necessary to perform a particular task (a task-actor dependency), then an actor with that expertise must be identified and the task assigned to him or her. There are often several coordination mechanisms that can be used to manage a dependency. For example, mechanisms to manage the dependency between an activity and an actor include (among others): (1) having a manager pick a subordinate to perform the task; (2) assigning the task to the first available actor; and (3) having a labour market in which actors bid on jobs. To manage a usability subdependency, the resource might be tailored to the needs of the consumer (meaning that the consumer has to provide that information to the producer) or a producer might follow a standard so the consumer knows what to expect. Mechanisms may be useful in a wide variety of organizational settings. Conversely, organizations with similar goals achieved using more or less the same set of activities will have to manage the same dependencies, but may choose different coordination mechanisms, thus resulting in different processes. Of course, the mechanisms are themselves activities that must be performed by some actors, and so adding coordination mechanisms to a process may create additional dependences that must themselves be managed.

Coordination in Software Development

Coordination has long been a key issue in software development (e.g., Brooks, 1975; Conway, 1968; Curtis et al., 1988; Faraj & Sproull, 2000; Kraut & Streeter, 1995; Parnas, 1972). For example, Conway (1968) observed that the structure of a software system mirrors the structure of the organization that develops it. Both Conway (1968) and Parnas (1972) studied coordination as a crucial part of software development. Curtis et al. (1988) found that in large-scale software project, coordination and communication are among the most crucial and hard-to-manage problems. To address such problems, software development researchers have proposed different coordination mechanisms such a planning, defining and following a process, managing requirements and design specifications, measuring process characteristics, organizing regular meetings to track progress, implementing workflow systems, among the others.

Herbsleb and Grinter (1999b), in a study of geographically-distributed software development within a large firm, showed that some of the previously mentioned coordination mechanisms—namely integration plans, component-interface specifications, software processes and documentation—failed to support coordination if not properly managed. The mechanisms needed to be modified or augmented (allowing for the filling in of details, handling exceptions, coping with unforeseen events and recovering from errors) to allow the work to proceed. They also showed that the primary barriers to coordination breakdowns were the lack of unplanned contact, knowing whom to contact about what, cost of initiating a contact, ability to communicate effectively and lack of trust or willingness to communicate openly.

Kraut and Streeter (1995), in studying the coordination practices that influence the sharing of information and success of software development, identified the following coordination techniques: formal-impersonal procedures (projects documents and memos, project milestones and delivery schedules, modification request and error-tracking procedures, data dictionaries), formal-interpersonal procedures (status-review meetings, design-review meetings, code inspections), informal-interpersonal (group meetings and co-location of requirements and development staff, electronic communication such as e-mail and electronics bulletin boards, and interpersonal network). Their results showed the value of both informal and formal interpersonal communication for sharing information and achieving coordination in software development. Note though that this analysis focuses more the media for exchanging information rather than particular dependencies or coordination mechanisms that might be executed via these media. That is, once you have called a group meeting, what should you talk about?

Coordination in FLOSS Development

A few studies have examined the work practices and coordination modes adopted by FLOSS teams in more detail, which is the focus of this article (Iannacci, 2005; Scacchi, 2002; Weber, 2004). Cubranic (1999) observed that the main media used for coordination in FLOSS development teams were mailing lists. Such a low-tech approach is adopted to facilitate the participation of would-be contributors, who may not have access to or experience with more sophisticated technology. The geographical distribution of contributors and the variability in time of contributors precluded the use of other systems (e.g., systems that support synchronous communication or prescriptive coordination technology, such as workflow systems). Mailing lists supported low-level coordination needs. Also, Cubranic (1999) found no evidence of the use of higher-level coordination, such as group decision making, knowledge management, task scheduling and progress tracking. As they are the main coordination mechanisms, the volume

of information within mailing lists can be huge. Mailing lists are therefore often unique repositories of source information on design choices and evolution of the system. However, dealing with this volume of information in large open source software projects can require a large amount of manual and mental effort from developers, who have to rely on their memory to compensate for the lack of adequate tools and automation.

In a well-known case study of two important FLOSS projects, namely Apache and Mozilla, Mockus et al. (2002) distinguished explicit (e.g., interface specification processes, plans, etc.) and implicit coordination mechanisms adopted for software development. They argued that, because of its software structure, the Apache development team had primarily adopted implicit coordination mechanisms. The basic server was kept small. Core developers worked on what interested them and their opinion was fundamental when adding new functionality. The functionality beyond the basic server was added by means of various ancillary projects, developed by a larger community that interacted with Apache only through defined interfaces. Such interfaces coordinate the effort of the Apache developers: as they had to be designed based on what Apache provided, the effort of the Apache core group was limited. As a result, coordination relied on the knowledge of who had expertise in a given area and general communication on who is doing what and when. On the other hand, in the Mozilla project, because of the interdependence among modules, considerable effort is spent in coordination. In this case, more formal and explicit coordination mechanisms were adopted (e.g., module owners were appointed who had to approve all changes in their module).

Jensen & Scacchi (2005) modelled the software-release process in three projects, namely Mozilla, Apache and NetBeans. They identified tasks, their dependencies and the actors performing them. However, they did not analyze the coordination issues in depth and did not focus specifically on the bug-fixing process, which is the aim of this article. Rather, their final goal was to study the relationships among the three communities that form a Web Information Infrastructure.

Iannacci (2005) adopted an organizational perspective to study coordination processes within a single large-scale and well-known FLOSS development project, Linux. He identified three main (traditional) coordination mechanisms, namely standardization, loose coupling and partisan mutual adjustment. Standardization is a coordination mechanism to manage pooled dependencies emerging among different contributors. It implies the definition of well-defined procedures, such as in the case of patch submission or bug-fixing procedures. Loose coupling is used to manage sequential dependencies among the different subgroups of contributors. It is the coordination mechanisms used to, for example, incorporating new patches. Finally, partisan mutual adjustment is a mechanism used to manage what Iannacci (2005) called networked interdependencies, an extension of the reciprocal dependencies as proposed by Thompson (1967). Networked interdependencies are those emerging among contributors to specific part of the software. Partisan mutual adjustment produces a sort of structuring process so creating an informal (sub-)organization. However, these findings are based on a single exceptional case, the Linux project, making it unclear how much can be generalized to smaller projects. Indeed, most of the existing studies are of large and well-known projects and focused on the development process. To our knowledge, no studies have analyzed the bug-fixing process in depth within small FLOSS development teams.

A Coordination Theory Application: The Bug-Fixing Process

To ground our discussion of coordination theory, we will briefly introduce the bug-fixing process, which consists of the tasks needed to correct

software bugs. We decided to focus on the bug-fixing process for three reasons. First, bug fixing provides "a microcosm of coordination problems" (Crowston, 1997). Second, a quick response to bugs has been mentioned as a particular strength of the FLOSS process: as Raymond (1998) puts it, "given enough eyeballs, all bugs are shallow". Finally, it is a process that involves the entire developer community and thus poses particular coordination problems. While there have been several studies of FLOSS bug fixing, few have analyzed coordination issues within bug-fixing process by adopting a process view. For example, Sandusky et al. (2004) analyzed the bug-fixing process. They focus their attention on the identification of the relationships existing among bug reports, but they do not examine in details the process itself. In contrast to the prior work, our article provides empirical evidence about coordination practices within FLOSS teams. Specifically, we describe the way the work of bug fixing is coordinated in these teams, how these practices differ from those of conventional software development and thus suggest what might be learned from FLOSS and applied in other settings.

We base our description on the work of Crowston (1997), who described the bug-fixing process observed at a commercial software company. Such a process is below defined as traditional because 1) it is carried out within a traditional kind of organization (i.e., the boundary are well defined, the environment is not distributed, the organization structure is defined) and 2) refers to the production of commercial rather than FLOSS software. The process is started by a customer who finds a problem when using a software system. The problem is reported (sometimes automatically or by the customer) to the company's response center. In the attempt to solve the problem, personnel in the center look in a database of known bugs. If a match is found, the fix is returned to the customer; otherwise, after identifying the affected product, the bug report is forwarded to an engineer in the marketing center. The assigned engineer tries to reproduce the problem and identify the cause (possibly requesting additional information from the reporter to do so). If the bug is real, the bug report is forwarded to the manager responsible for the module affected by the bug. The manager then assigns the bug to the software engineer responsible for that module. The software engineering diagnoses the problem (if she finds that the problem is in a different module, the report is forwarded to the right engineer) and designs a fix. The proposed fix is shared with other engineers responsible for modules that might be affected. When the feedback from those engineers is positive, the proposed design is transformed into lines of code. If changes in other module are needed, the software engineer also asks the responsible engineers for changes. The proposed fix is then tested, the eventual changed modules are sent to the integration manager. After approving, the integration manager recompiles the system, tests the entire system and releases the new software in the form of a patch. To summarize then, in the traditional bug-fixing process, the following tasks have been identified (Crowston, 1997):

Report, Try to solve the problem, Search database for solution, Forward to the marketing manager, Try to solve the problem/Diagnose the problem, Forward to the Software Engineering Group, Assign the bug, Diagnose the problem, Design the fix, Verify affected modules and ask for approval, Write the code for the fix, Test it, Integrate changes, Recompile the module and link it to the system.

After describing the above process, Crowston (1997) went on to analyze the coordination mechanisms employed. A number of the tasks listed can be seen as coordination mechanisms. For example, the search for duplicate bugs as well as the numerous forward and verify tasks manage some dependency. Searching for duplicate outputs is the coordination mechanism to manage a dependency between two tasks that might have the same output. In this case, the tasks are to respond

to bug reports from customers. These tasks can be performed by diagnosing and repairing the bug, but if the solution to the bug report can be found in the database, then the effort taken to solve it a second time can be avoided. Thus, searching the database for a solution is a way to manage a potential dependency between the two bug-fixing tasks. Forwarding and verifying tasks are coordination mechanisms used to manage dependency between a task and the actor appropriate to perform that task. These steps are needed because many actors are involved in the process and each of them carry out a very specialized task, requiring additional work to find an appropriate person to perform each task.

RESEARCH METHODOLOGY

To address our research question, how are bug fixes coordinated in FLOSS projects, we carried out a multiple case study of different FLOSS projects, using the theoretical approach developed in the previous section. In this section, we discuss sample selection and data sources, data collection and data analysis, deferring a discussion of our findings to the following section.

Sample Section

In this sub-section we describe the basis for selecting projects for analysis. Projects to be studied were selected from those hosted on SourceForge, (http://sourceforge.net/), a Web-based system that currently supports the development of more than 100,000 FLOSS projects (although only a small proportion of these are actually active). We chose to examine projects from a single source to control for differences in available tools and project visibility. Because the process of manually reading, rereading, coding and recoding messages is extremely labor-intensive, we had to focus our attention on a small number of projects. We selected projects to study in-depth by employing a theoretical sampling strategy based on several practical and theoretical dimensions.

First, we chose projects for which data we need for our analysis are publicly available, meaning a large number of bug reports. (Not all projects use or allow public access to the bug-tracking system.) Second, we chose teams with more than 8 developers (i.e., those with write access to the source code control system), since smaller projects seemed less likely to experience significant coordination problems. The threshold of eight members was chosen based on our expectation that coordinating tasks within a team would become more complicated as the number of members increases. We assumed that each member of the team could manage 4 or 5 relationship, but with eight members, we expected some difficulty in coordination to arise. Only 140 projects of SourceForge met the first two requirements in 2002 when we drew our sample. Third, projects were chosen so as to provide some comparison in the target audience and addressed topic, as discussed below. Finally, because we wanted to link coordination practices to project effectiveness, we tried to select more and less effective development teams. To this aim we used the definitions of effectiveness proposed by Crowston et al. (2006a), who suggest that a project is effective if it is active, the resulting software is downloaded and used and the team continues in operation. We selected 4 FLOSS projects to satisfy the mentioned criteria. Specifically, from the 140 large active projects, we selected two desktop chat clients that are aimed at end users (KICQ and Gaim) and two projects aimed primarily at developers (DynAPI, an HTML library and phpMyAdmin, a web-based database administration tool). A brief description of the projects is reported in Table 1, including the project goal, age at the time of the study, volume of communication and team membership. A consequence of the requirement of a significant number of bug reports is that all four projects are relatively advanced, making them representative of mature FLOSS projects. Based on the definition

proposed by Crowston et al. (2006a), Kicq, Gaim and phpMyAdmin were chosen as examples of effective projects because they were active, the resulting software was being downloaded and the group had been active for a while. DynAPI was chosen as an example of a less effective project because the number of downloads and programming activity had rapidly decreased in the months leading up to the study.

Table 1. Four examined projects

	KICQ	**DynAPI**	**Gaim**	**phpMyAdmin**
Goal	ICQ client for the KDE project (a chat client)	Dynamic HTML library	Multi-platform AIM client (a chat client)	Web-based database administration
Registration date	1999-11-19	2000-05-15	1999-11-13	2001-03-18
Development Status	4 Beta, 5 Production Stable	5 Production Stable	5 Production Stable	5 Production Stable
License	GPL	LGPL, GPL	GPL	GPL
Intended Audience	Developers, End Users/Desktop	Developers	Advanced End Users, Developers, End Users/Desktop	Developers, End Users/Desktop, System Administrators
Topic	ICQ, K Desktop Environment (KDE)	Dynamic Content	AOL Instant Messenger, ICQ, Internet Relay Chat, MSN Messenger	Front-Ends, Dynamic Content, Systems Administration
Open bugs/ Total # of bugs	26 /88	45/220	269 /1499	29 /639
Open Support Requests/Total # of requests	12/18		20/107	3/125
Open Patches/ Total # of Patches	1/8	14/144	75/556	7/131
Open Features requests/Total # of requests	9/9	5/12	214/447	214/447
Mailing lists	813 messages in 3 mailing lists	9595 in 5 mailing lists	304 in 1 mailing list (developers)	5456 in 5 mailing lists
# of team members	9	11	9	9
Team member roles (# in role)	Admin/project manager (2); packager (1); developers (3); advisor/ mentor/ consultant(1); not specified (2)	Admin/project manager (1); developers (4); admin (3); not specified (3)	Project manager (1); admin/ developer (1); support manager (1); web designer (1); developers (3) not specified (2)	Project manager/ admin (1); admin/ developer (2); developers (6)

Data Collection

In this sub-section we describe how data were selected and collected. As mentioned above, all of these projects are hosted on SourceForge, making certain kinds of data about them easily accessible for analysis. However, analysis of these data poses some ethical concerns that we had to address in gaining human subjects approval for our study. On the one hand, the interactions recorded are all public and developers have no expectations of privacy for their statements (indeed, the expectation is the opposite, that their comments will be widely broadcast). Consent is generally not required for studies of public behaviour. On the other hand, the data were not made available for research purposes but rather to support the work of the teams. We have gone ahead with our research after concluding that our analysis does not pose any likelihood of additional harm to the poster above the availability of the post to the group and in the archive available on the Internet.

We collected several kinds of data about each of the cases. First, we obtained data indicative of the effectiveness of each project, such as its level of activity, number of downloads and development status. Unfortunately, no documentation on the organization structure, task assignment procedures and coordination practices adopted was available on the projects' web sites (further supporting the position that these teams do not employ formal coordination methods). To get at the bug-fixing process, we considered alternative sources of data. Interviewing the developers might have provided information about their perceptions of the process, but would have required finding their identities, which was considered problematic given privacy concerns. Furthermore, reliance on self-reported data raises concerns about reliability of the data, the response rate and the likelihood that different developers would have different perceptions. While these issues are quite interesting to study (e.g., to understand how a team develops shared mental models of a project, for example, Crowston & Kammerer, 1998), they seemed like distractions from our main research question. Because of these concerns, we elected to use objective data about the bug-fixing process. Hence, the main source of data about the bug-fixing process was obtained from the archives of the bug tracking system, which is the tool used to support the bug-fixing process (Herbsleb et al., 2001, p. 13). These data are particularly useful because they are unobtrusive measures of the team's behaviors (Webb & Weick, 1979) and thus provide an objective description of the work that is actually undertaken, rather than perceptions of the work.

In the bug tracking system, each bug has a request ID, a summary (what the bug is about),

Figure 1. Example bug report and followup messages

[206585] crash with icq chat

Email: Monitor (?)
Date: 2000-05-28 12:56
Priority: 5
Submitted By: hub (khub)
Assigned To: Bill Soudan (bills)
Category: system
Status: Closed
Summary: crash with icq chat
each time I try an icq chat session the whole program closes itself immediately

Followups:

Message

Date: 2000-07-29 08:56
Sender: denis
Ok, since khub reported it works for him, I am closing this bug.

To robvnl I repeat:
"please try latest sources from CVS"...

Date: 2000-06-29 13:02
Sender: robvnl
Module Name: kicq
Latest release is 19991212.
is written here, or did I probably install a Beta version 19991212?
It would be great to can chat again!

Date: 2000-06-18 01:10
Sender: khub
I've try the latest version, it seems to work perfectly
That's marvellous...

Date: 2000-06-17 06:50
Sender: denis
Ok, lets try it one more time - WHAT VERSION OF KICQ do you use?
There was dramatic improvements in chat code since 19991212 beta,
so please try latest sources from CVS and report your comments
back.

Date: 2000-06-08 12:32
Sender: robvnl
Hi, I have the exact same problem. It doesn't make difference
wether I initiate or the other party initiates the chat. I use
RedHat 6.2 and compiled kicq with the export QTDIR=/usr/lib/qt-1.45
(the previous libs) because it needed it. Also it doesn't make
difference to run with the old or new QTDIR set. Sometimes the
chat request results in an user ABORTed at the other side and
I get USER HAS LEFT the chat. In case kicq realy crashes I have
a core dump.

Date: 2000-05-29 05:03
Sender: denis
What version do you try?

a category (the kind of bug, e.g., system, interface), the name of the team member (or user) who submitted it, and the name of the team member it was assigned to. An example bug report in shown in Figure 1 (the example is fictitious). As well, individuals can post messages regarding the bug, such as further symptoms, requests for more information, etc. From this system, we extracted data about who submitted the bugs, who fixed them and the sequence of messages involved in the fix. By examining the name of the message senders, we can identify the project and community members who are involved in the bug-fixing process. Demographic information for the projects and developers and data from the bug tracking system were collected in the period 17–24 November 2002. We examined 31 closed bugs for Kicq, 95 closed bugs for DynAPI, 51 bugs for Gaim and 51 for PhPMyAdmin. The detailed text of the bug reports is not reported because of space restriction but is available on request.

Data Analysis

In this section we present our data analysis approach. For each of the bug reports, we carefully examined the text of the exchanged messages to identify the task carried out by each sender. We first applied the framework developed by Checkland & Scholes (1990), who suggested identifying the owners, customers and environment of the process, the actors who perform it, the transformation of inputs into outputs, the environment and the worldview that makes the process meaningful. We then followed the method described by Crowston & Osborn (2003), who suggested expanding the analysis of the transformation by identifying in more detail the activities carried out in the transformation. We identified the activities by inductively coding the text of the messages in the bug tracking systems of the four projects. We started by developing a coding scheme based on prior work on bug fixing (Crowston, 1997), which provided a template of expected activities needed for task assignment (those listed above). The coding system was then evolved through examination of the applicability of codes to particular examples. For example the message:

I've been getting this same error every FIRST time I load the dynapi in NS (win32). After reloading, it will work… loading/init problem?

represents a report submitted by another user (someone other than the person who initially identified and submitted the bug). This message was coded as "report similar problems". Table 2 shows the list of task types that were developed for the coding. The lowest level elementary task types were successively grouped into 6 main types of tasks, namely *Submit, Assign, Analyze, Fix, Test & Post,* and *Close*. A complete example of the coded version of a bug report (the one from Figure 1) is shown in Figure 2.

Once we had identified the process tasks, we studied in depth the bug-fixing process as carried out in the four cases. Specifically, we compared the sequence of tasks across different bugs to assess which sequences were most common and the role of coordination mechanisms in these sequences. We also examined which actors performed which tasks as well as looked for ways to more succinctly present the pattern of tasks, for example, by presenting them as Markov processes. Because of the shortness and relative simplicity of our task sequences, we could exactly match task sequences, rather than having to statistically assess the closeness of matches to be able to form clusters (Sabherwal & Robey, 1995). Therefore, we were able to analyze the sequences by simple tabulation and counting, though more sophisticated techniques would be useful for larger scale data analysis. In the next Section we present the results of our analysis.

Table 2. Coded tasks in the bug-fixing process

1.0.0 **Submit (S)**
1.1.0 Submit bug (code errors)
1.1.1 Submit symptoms
1.1.2 Provide code back trace (BT)
1.2.0 Submit problems
1.2.1 Submit incompatibility problems (NC)
2.0.0. **Assign (As)**
2.1.0 Bug self-assignment (A*)
2.2.0 Bug assignment (A)
3.0.0 **Analyze (An)**
3.1.0 Contribute to bug identification
3.1.1Report similar problems (R)
3.1.2 Share opinions about the bug (T)
3.2.0 Verify impossibility to fix the bug
3.2.1 Verify bug already fixed (AF)
3.2.2.Verify bug irreproducibility (NR)
3.2.3 Verify need for a not yet supported function (NS)
3.2.4 Verify identified bug as intentionally introduced (NCP)
3.3.0 Ask for more details
3.3.1 Ask for Code version/command line (V)
3.3.2 Ask for code back trace/examples (RBT/E)
3.4.0 Identify bug causes (G)
3.4.1 Identify and explain error (EE)
3.4.2 Identify and explain bug causes different from code (PNC)
4.0.0 Fix (F)
4.1.0 Propose temporary solutions (AC)
4.2.0 Provide problem solution (SP)
4.3.0 Provide debugging code (F)
5.0.0 **Test & Post (TP)**
5.1.0 Test/approve bug solution
5.1.1 Verify application correctness (W)
5.2.0 Post patches (PP)
5.3.0 Identify further problems with proposed patch (FNW)
6.0.0 **Close**
6.1.0 Close fixed bug/problem
6.2.0 Closed not fixed bug/problems
6.2.1 Close irreproducible bug (CNR) and close it
6.2.2 Close bug that asks for not yet supported function (CNS)
6.2.3 Close bug identified as intentionally introduced (CNCP)

Figure 2. Coded version of bug report in Figure 1

Bug ID	**Summary**	**Assigned to**	**Submitter**
0000000	crash with *alfa* chat	gills	kkhub

Task	**Person**	**Comments**
(S)	kkhub	
(V)	cenis	asks what version kkhub is running
(R)	cobvnl	reports the same problem as kkhub. submits information about the operating systems and the libraries
(V)	cenis	asks again what version both users are running
(W)	kkhub	reports the most recent version of cicq works
(TP&C)	cobvnl	reports version information and close the bug
(C)		bug closed

FINDINGS

In this section we present the findings from our analysis of the bug-fixing process in the four projects and the coordination mechanisms employed. Data about the percentage of submitted, assigned and fixed bugs both by team members and individuals external to the team for each project are reported in Table 3. Table 4 summarizes our findings regarding the nature of the bugs fixing process in the four projects.

We now present our overall analysis of the bug-fixing process. Each instance of a bug-fixing process starts (by definition) with a bug submission (S) and finishes with bug closing (C). Submitters may submit problems/symptoms associated with bugs (Ss), incompatibility problems (NC) or/and also provide information about code back trace (BT). After submission, the team's project managers or administrators may assign the bug to someone to be fixed ((A); (A*) if they self-assign the bug). Other members of the community may report similar problems they encountered (R), discuss bug causes (T), identify bug causes (G) and/or verify the impossibility of fixing the bug. Participants often ask for more information to better understand the bug's causes (An). In most cases, but not always, after some discussion, a team member spontaneously decides to fix (F) the bug. Bug fixing may be followed by a test and the submission of a patch (TP). Testing is a coordination mechanism that manages usability between producing and using a patch, by ensuring that the patch is usable. However, as later explained, in the examined projects this type of activity is not often found. The bug is then closed (C). Bugs may also be closed because they cannot be fixed, for example, if they are not reproducible (CNR), involve functions not supported yet (CNS) and/or are intentionally introduced to add new functionality in the future (CNCP). Notice that the closing activity is usually attributed to a particular user.

For our analysis, we consider *Submission*, *Analysis*, *Fix* and *Close* to be operative activities, while *Assignment*, *Test* and *Posting* are coordination mechanisms. As already discussed, *Assignment* is the coordination mechanisms used

to manage the dependency between a task and the actor appropriate to perform it. *Posting* is the mechanisms used to manage the dependency between a task and its customers (it makes the fix available to the persons that need it).

The tasks identified above are linked by sequential dependencies as shown in Figure 3. These dependencies were identified by considering the logical connection between tasks based on the flow of resources. For example, a patch

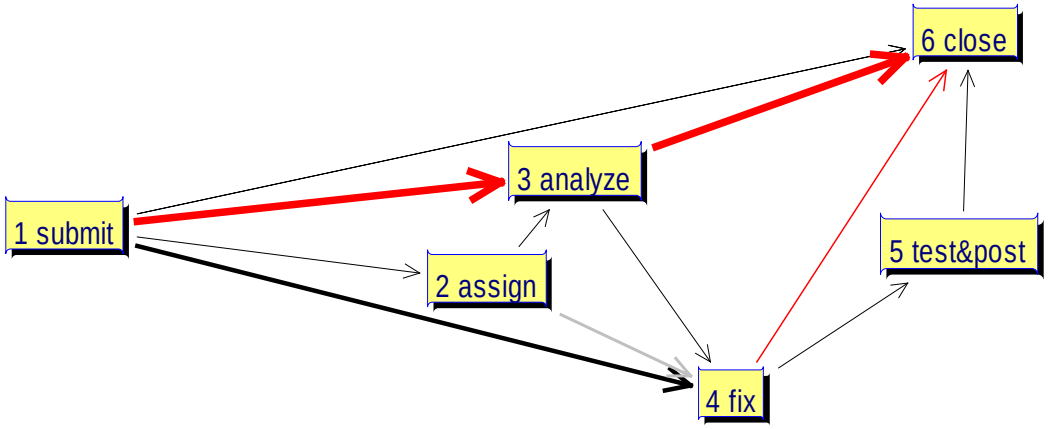
Table 3. The bug-fixing process: Main results

	Kicq	**DynAPI**	**Gaim**	**phpMyAdmin**
Bugs submitted by team members	9.7%	21%	0%	21.6%
Bugs submitted by members external to the team	90.3%	78.9%	100%	78.4%
Bug assigned/self-assigned of which:	9.7%	0%	2%	1%
Assigned to team members	0%	-	100%	100%
Self assigned	66%			0%
Assigned to members external to the team	33%	-	-	0%
Bug fixed	51,6%	42,1%	51%	80%
Fixed by team members	81,3%	50%	84%	90,2%
Bug fixed by members external to the team	18,7%	50%	16%	9.8%

Table 4. Observed characteristics of the bug-fixing processes in the four projects

	Kicq	**DynAPI**	**Gaim**	**phpMyAdmin**
Min task sequence	3	2	2	2
Max task sequence	8	12	9	13
Uncommon tasks (count)	Bug assignment (3)	Bug assignment (0)	Bug assignment (0)	Bug assignment (1)
Community members	18	53	23	20
Team members' participation	2 of 9	6 of 11	3 of 9	4 of 10
Most active team members Role/ name	Project mgr: denis; Developer: davidvh	Admin: rainwater; Ext member: dcpascal	Admin-developer: warmenhoven; Developer: robflynn	Admin-developer: loic1; Admin-developer lem9.
Max posting by single community member	2	6	4	3
Not fixable bug closed	8	5	5	-

Figure 3. Task dependencies in the bug-fixing process



can not be tested before it is created. Because the dependencies can be satisfied in different orders, different sequences of the activities are possible. The tasks and their sequence change from bug to bug. Figure 3 shows the most frequent sequences observed, as identified by tabulating and counting the sequences.

Table 5 shows the portion of processes that follow each possible paths, based on the collected ways the bug-fixing process is observed to be performed within the FLOSS teams. For example, row 1 of Table 5 is read as follows. In the Dynapi project, submission always occurs as the first task (as it does for all of the groups, by definition), while the second task is S in 26% of cases, An in 39% of cases, F in 19% of cases, TP in 1% of cases and C in 15% of cases, and so on.

In Table 6, we describe the occurrences per task for the four projects and the average number of tasks to fix bugs. A χ^2 test shows a significant difference in the distribution of task types across projects ($p<0.001$). On all projects, *submit* is the task that always appears first, while *analyze* is the most common second task and *fix*, third. The first three most frequent task sequences are reported in Table 7. As noted above, given the limited number of examined sequences, the sequences were manually identified. Finally, in Table 8 we show which tasks are carried out by which roles. Please notice that differences in percentage shown in Table 3 and Table 8 are due to the fact that results reported in Table 8 are calculated based on the total number of tasks carried out per bug. For example, in Table 3 the considered submissions are those carried out only as first task. In Table 8 all submissions tasks (i.e., also those carried out as second, third etc. task) are considered. As reported in Table 2, submissions tasks can be more than one per bug because submissions can occur also in the form of a *submit* sub-task. The same stands for the fixing tasks. In Table 3 only the final fixing tasks are considered.

A detailed description of the process as performed in the four cases is provided below considering both the sequence of tasks and the participation in the bug-fixing process.

Table 5. Portion of processes for each possible path

i	task i-1	task i	Kicq	Dynapi	Gaim	PhPmyadmin
2	S	S	42%	26%	4%	2%
		As	6%	-	2%	2%
		An	39%	39%	61%	41%
		F	13%	19%	24%	45%
		TP	-	1%	2%	8%
		C	-	15%	8%	2%
3	S	An	38%	36%	50%	100%
		F	62%	40%	50%	-

Kicq

The minimal sequence is composed of three tasks, the longest by eight. Bug fixing is usually the second task in the sequence, meaning that it is most common for bugs to be fixed immediately after they are submitted, which is different from the overall picture in which analysis was most common. *Bug assignment* is a quite rare task, as only three bugs are formally assigned. Eight bugs were closed because they were considered to be not fixable.

There are 18 identified users, but many (anonymous) users submitted bugs and contributed to analysis and fixing. Team members are not very active in bug fixing, except for one of the two project managers (denis), who is involved in all the tasks and, in particular, in bug analysis and fixing. Out of 23 fixed bugs, 16 are fixed by denis. Apart from a developer (davidvh), the other project members seem not take part in the bug-fixing process at all. However, it is noteworthy that the bug tracking system register three bugs as submitted and assigned to the administrator (bill), although he does not otherwise take part in the process. Most of the community members have posted just one bug, and only two of them posted 2 bugs each.

Dynapi

The minimal sequence is composed of two tasks, the longest by 12. Again, *bug assignment* is not explicitly carried out; apparently community or team members decide autonomously to take part to the bug-fixing process. However, the system reports that six bugs (out of 95) are assigned to an administrator and the rest to a member external to the team. Five bugs are closed because they are said to be not fixable. Bug fixing is usually the second or the third task in the sequence.

Team members are not very active except for an administrator (rainwater), who is involved in all the tasks and, in particular, in bug *analysis* and *fixing.* The other five team members (two without a specific role, one administrator/developer, one developer and one administrator) are mostly involved in bug *fixing*. The community members involved in the process are 47 persons plus some anonymous posts. Most of them submitted just one bug, but some submitted more (e.g., one submitted six bugs). Community members are mostly involved in bug *submission* but some also carry out

other tasks. In particular, one of them (dcpascal) is very active in all the process tasks. Out of 57 fixed bugs, 20 are fixed by a team member (the project manager).

Gaim

The minimal sequence is composed of two tasks, the longest by nine. *Bug assignment* is not explicitly carried out, as community or team members decide autonomously to take part to the bug-fixing process. However, the system reports that 24 bugs (out of 51) are assigned to an administrator (and the rest to member external to the team). Five bugs are directly closed because they are said to be not fixable.

Team members are not very active in bug fixing except for the administer/developer (warmenhoven) and a developer (robflynn), who are involved in many tasks and, in particular, in bug analysis and fixing. Apart from them, just another member of the project team, a developer (lschiere), is also involved in the bug fixing. The community members involved in the process are 21 persons plus some anonymous users. Most of them posted just one bug (2 of them posted five bugs, one 4 bugs). Some of them are also involved in bug analysis and fixing. Out of 29 fixed bugs, 23 are fixed by a team member (the project manager).

Phpmyadmin

The minimal sequence is composed of two tasks, the longest by thirteen. *Bug assignment* is a quite rare task, as only one bug is formally assigned. The assignment is carried out by an administrator/developer (lem9) and directed to a team member (loic1). However, the system reports that all 51 are assigned, of which 40 to team members. Bug fixing is usually the second or the third task.

Team members are not very active in the process, except for two administer/developers (loic1 and lem9), who are involved in all the tasks and, in particular, in bug analysis and fixing (but also submission). Apart from them, two team members take part to the process, a project manager/adminster (swix) and a developer (robbat2), that are involved (not heavily) in bug submission and analysis. The community is composed of 16 members plus some anonymous users. Most of them have just posted one bug (two of them posted 3 bugs), but some are also involved in bug analysis and fixing. Out of 49 fixed bugs, 44 are fixed by team member (administrator/developers).

DISCUSSION

In this section, we discuss the implications of our findings for understanding the coordination of bug fixing in FLOSS teams. Our findings provide some interesting insights on the bug-fixing process for FLOSS development in these teams. First, process sequences are on average quite short (four tasks) and they seem to be quite similar: submit, (analyze), fix and close. As shown in Table 3, formal task assignments are quite uncommon: only few bugs are formally assigned. Coordination seems rather to spontaneously emerge. From bug description and initial analysis, those who have the competencies autonomously decide to fix the bug and simply go ahead and do so. That activity is facilitated by the supplied bug report and analysis, which is often undertaken by several contributors. Apart from the procedure to submit bugs (we analyzed only bugs submitted through the bug tracking system), we do not observe any other formal process: roles are not predefined, delivery dates are not assigned nor are formal-interpersonal, formal-impersonal or informal-interpersonal procedures adopted. The lack of assignment is one of main aspects differentiating the process as it occurs in FLOSS development team from the traditional commercial bug-fixing process described above.

Testing is also quite an uncommon task in the data. Most of the proposed fixes are directly

posted, though presumably after personal testing that is not documented. If no one describes the emergence of new problems with these fixes, they are automatically posted and the relevant bug closed without a formal test process. It is important also to note that many of the posted problems do not represent real bugs (i.e., they have been already fixed, are not reproducible, have been intentionally produced, are associated to functions not yet supported or are associated to related programs), so they are directly closed with that explanation.

Another striking finding is that the bug-fixing process is apparently carried out without any explicit discussion about where knowledge is located in the team, contrary to the findings of Faraj and Sproull (2000), who stress the importance of expertise coordination for team effectiveness (they distinguish expertise coordination from what they call administrative coordination, which is the focus of this article). They define expertise coordination as the management of knowledge and skill dependencies. To manage knowledge it is necessary to know where it is located within development team, where it is needed and how to access it. However, in our observations, the knowledge needs seem to emerge by "(informal and asynchronous) electronic meetings".

The bug tracking system represents a sort of organizational memory, storing bug reports and solutions found to submitted problems (which not always are real bugs). However, as discussed in Cubranic (1999), the large number of emails stored makes it difficult for contributors to easily identify the solutions to their own problems, so making different users repeat the same (already fixed or addressed) submission more times. In those cases (i.e., for bugs closed without being fixed or the attended patches posted), it is usually the team members that act as "memory".

A further difference is that in these projects, the process is performed by few team members (usually not more that two or three) working with a member of the larger community. Team members (usually project managers, administrators or developers) are most involved in bug fixing, testing and posting. Surprisingly, only a few members of the team are involved in the process. The other participants are active users who submit bugs or contribute to their analysis. We also noted striking differences in the level of contribution to the process. The most active users in the projects carried out most of the tasks while most others contributed only once or twice. Most community members submit only one bug; only two or three members of the involved community are involved in fixing tasks and can be referred to as co-developers. As expected, the most widely dispersed type of action was submitting a bug, while diagnosis and bug-fixing activities were concentrated among a few individuals.

As we have few members of the team and few members of the community (co-developers) mostly involved in bug fixing and many users/members of the community (active users) mostly involved in bug submission, the organizational models proposed in the literature (Cox, 1998) seem to be valid for the bug-fixing process. It would be interesting to further investigate if those, among the active users also involved in bug fixing also contribute to software coding, for example, by analysis of contributions of source code independent of bug fixes.

As an apparently less effective project, we expected to find that DynAPI had a smaller active user base than the other projects. However, as noted above, our data shows the opposite. However, our estimation of the effectiveness of the projects is based on activity levels. It appears that DynAPI somehow does not benefit from its larger community in increased activity. One striking difference is the proportion of bugs fixed by the team members, shown in Table 3, which is much lower in DynAPI than in the other projects. This finding suggests that the contribution of core members may be particularly important in the effectiveness of the team. The case studies presented here are not sufficient to test this

hypothesis, so it is one that should be followed up in future studies.

CONCLUSION

In this article, we investigated the coordination practices adopted within four FLOSS development teams. In particular, we analyzed the bug-fixing process, which is considered central to the effectiveness of the FLOSS process. The article provided some interesting results. The task sequences we observed were mostly sequential and composed of few steps, namely *submit, fix and close*. Second, our data supports the observation that FLOSS processes seem to lack traditional coordination mechanisms such as task assignment. Third, effort is not equally distributed among process actors. A few contribute heavily to all tasks, while the majority just submit one or two bugs. As a result, the organization structure reflected in the process resembles the one proposed in the literature for the FLOSS development process. Few actors (core developers), usually team project managers or administrators, are mostly involved in bug fixing. Most of the involved actors are active users instead of developers, who just submit bug reports. In between are few actors, external to the team, who submit bugs and contribute to fixing them. Finally, while we did not find obvious associations between coordination practices and project effectiveness, we did notice a link to participation: our least effective team also had the lowest level of participation from core developers, suggesting their importance, even given the more widely distributed participation possible.

The article contributes to fill a gap in the literature by providing a picture of the coordination practices adopted within FLOSS development team. Besides, the article proposes an innovative research methodology (for the analysis of coordination practices of FLOSS development teams) based on the collection of process data by electronic archives, the codification of message texts, and the analysis of codified information supported by the coordination theory.

Based on the analysis of the tasks carried out and the attendant coordination mechanisms, we argue that the bazaar metaphor proposed by (Raymond, 1998) to describe the FLOSS organization structure is still valid for the bug-fixing process. As in a bazaar, the actors involved in the process autonomously decide the schedule and contribution modes for bug fixing, making a central coordination actor superfluous.

As with all research, the current article has some limitations that limit the scope of our current conclusions and suggests directions for further research. First, although the selected projects are quite different in terms of target audience and topic, other characteristics (not examined because they are not explicitly present on the project web sites) could be shared among projects so affecting the obtained results. In the future, we would like to deepen our knowledge about the coordination practices adopted by the four projects by directly interviewing some of the involved actors. Second, due to the limited number of examined bugs, the process sequences have been manually examined. In the future, we intend to enlarge the number of examined bugs and adopt automatic techniques (e.g., the optimal matching technique) to analyze and classify the task sequences. In particular, we plan to further explore the hypothesis about the importance of core group members by examining a larger number of projects (e.g., to examine the change in the population over time). Finally, in the article we only examined administrative coordination. In the future, we intend to examine also expertise coordination in more detail. A particular interesting consideration here is the development of shared mental models that might support the coordination of the teams' processes.

Chapter 2.30
Evaluating Performance of Software Architecture Models with the Palladio Component Model

ABSTRACT

Techniques from model-driven software development are useful to analyse the performance of a software architecture during early development stages. Design models of software models can be transformed into analytical or simulation models, which enable analyzing the response times, throughput, and resource utilization of a system before starting the implementation. This chapter provides an overview of the Palladio Component Model (PCM), a special modeling language targeted at model-driven performance predictions. The PCM is accompanied by several model transformations, which derive stochastic process algebra, queuing network models, or Java source code from a software design model. Software architects can use the results of the analytical models to evaluate the feasibility of performance requirements, identify performance bottlenecks, and support architectural design decisions quantitatively. The chapter provides

a case study with a component-based software architecture to illustrate the performance prediction process.

INTRODUCTION

To ensure the quality of a software model, developers need not only to check its functional properties, but also assure that extra-functional requirements of the system can be fulfilled in an implementation of the model. Extra-functional properties include performance, reliability, availability, security, safety, maintainability, portability, etc. Like functional correctness, these properties need to be addressed already during early development stages at the model level to avoid possible later costs for redesign and reimplementation.

Performance (i.e., response time, throughput, and resource utilization) is an extra-functional property critical for many business information systems. Web-based information systems rely on fast response times and must be capable of serving thousands of users in a short time span due to the competitive nature of internet businesses. Furthermore, the responsiveness of software used within companies is important to ensure efficient business processes.

Performance problems in large distributed systems can sometimes not be solved by adding more servers with improved hardware ("kill it with iron"). Large software architectures often do not scale linearly with the available resources, but instead include performance bottlenecks that limit the impact of additional hardware.

Therefore, it is necessary to design a software architecture carefully and analyse performance issues as early as possible. However, in the software industry, performance investigations of software systems are often deferred until an implementation of the system has been build and measurements can be conducted ("fix it later"). To avoid this approach, which might lead to expensive redesigns, software architects can use performance models for early, pre-implementation performance analysis of their architectures.

This chapter provides an overview of the Palladio Component Model (PCM), a domain specific modelling language for component-based software architectures, which is specifically tuned to enable early life-cycle performance predictions. Different developer roles can use the PCM to model the software design and its targeted resource environment. The models can be fed into performance analysis tools to derive the performance of different usage scenarios. Software architects can use this information to revise their architectures and quantitatively support their design decisions at the architectural level.

The chapter is structured as follows: Section 2 provides background and describes related work in the area of model-driven performance prediction. Section 3 introduces different developer roles and a process model for model-driven performance predictions. Section 4 gives an overview of the PCM with several artificial model examples, before Section 5 briefly surveys different model transformations to analysis models and source code. Section 6 describes the performance prediction for an example component-based software architecture and discusses the value of the results for a software architect. For researchers interested working in the area of model-driven performance prediction, Section 7 highlights some directions for future research. Section 8 concludes the chapter.

BACKGROUND AND RELATED WORK

Model-driven performance predictions aim at improving the quality of software architectures during early development stages (Smith et al., (2002)). Software architects use models of such prediction approaches to evaluate the response time, throughput, or resource utilization to be expected after implementing their envisioned

design. The prediction model's evaluation results enable analysing different architectural designs and validate performance-related requirements (such as maximum response times or minimum throughput) of software systems. The advantage of using prediction models instead of testing implementations is the lowered risk to find performance problems in already implemented systems, which require cost-intensive redesigns.

Researchers have put much effort into creating accurate performance prediction models for the last 30 years. Queuing networks, stochastic process algebras, and stochastic Petri nets are the most prominent prediction models from the research community. However, practitioners seldom apply these models due to their complexity and high learning curve. Therefore, focus of the research community has shifted to create more developer-friendly models and use model transformations to bridge the semantic gap to the above mentioned analytical models.

From the more than 20 approaches in this direction during the last decade (Balsamo et al., (2004)), most use annotated UML models as a design model and ad-hoc transformations to create (layered) queuing networks as analytical models. Tools encapsulate the transformation to the analytical models and their solution algorithms to limit the necessary additional skills for designers. For these approaches, the Object Management Group (OMG) has published multiple UML profiles (SPT profile cf. OMG, (2005); QoS/FT profile; MARTE profile) to add performance-related annotations to UML models. However, these profiles remain under revision, are still immature, and are still not known to have been used in practise in a broader scope.

Component-based software engineering (CBSE) adds a new dimension to model-driven performance prediction approaches. CBSE originally targeted at improved reusability, more flexibility, cost-saving, and shorter time-to-market of software systems (Szyperski et al. (2002)). Besides these advantages, CBSE might also ease prediction of extra-functional properties. Software developers may test components for reuse more thoroughly and provide them with more detailed specifications. These specifications may contain performance-related information.

Hence, several research approaches have tackled the challenge of specifying the performance of a software component (cf. survey by Becker et al., (2006)). This is a difficult task, as the performance of a component depends on environmental factors, which can and should not be known by component developers in advance. These factors include:

- **Execution environment:** The platform a component is deployed on including component container, application server, virtual machine, operating system, software resources, hardware resources
- **Usage profile:** User inputs to component services and the overall number of user requests directed at the components
- **Required services:** Execution times of additionally required, external services, which add up to the execution of the component itself

Component developer can only fix the component's implementation, but have to provide a performance specification, which is parameterisable for the execution environment, the usage profile, and the performance of required services. The following paragraph summarises some of the approaches into this direction.

Sitaraman et. al (2001) model the performance of components with an extension to the O-calculus, but do not include calls to required services. Hissam et. al (2002) aim at providing methods to certify component for their performance properties. Bertolino et. al (2003) use the UML SPT profile to model component-based systems including dependencies to the execution environment, but neglecting influences by the usage profile. Hamlet et al. (2003) investigate

the influence of the usage profile on component performance. Wu et al. (2004) model components with an XML-based language and transform this notation into layered queueing networks. The APPEAR method by Eskenazi et al. (2004) aims at predicting performance for changes on already built systems, and thus does neglect the influence of the execution environment. Bondarev et al. (2005) target components in embedded systems with the ROBOCOP component model. Grassi et al. (2005) develop an intermediate modelling language for component-based systems called KLAPER, which shall bridge the gap between different design and analytical models.

The Palladio Component Model (Becker et al., (2007)) described in this chapter is in line with these research approaches and tries to reflect all influences on component performance. Unlike some of the above listed approaches, the PCM does not use annotated UML as design model, but defines its own metamodel. This reduces the model to concepts necessary for performance prediction and does not introduce the high complexity of arbitrary UML models with a variety of concepts and views.

DEVELOPER ROLES AND PROCESS MODEL

The PCM metamodel is divided into several domain-specific modelling languages, which are aligned with developer roles in CBSE. This section introduces these roles and provides an overview of the process model for using the PCM.

An advantage of CBSE is the division of work between different developer roles, such as component developers and software architects. *Component developers* specify and implement components. They also have to provide a description of the component's extra-functional properties to enable software architects to predict their performance without deploying and testing them. *Software architects* compose components from different component developers to application architectures. They are supported by tools to predict the architecture's performance based on the performance specifications of the component developers. With the predicted performance metrics, they can support their design decisions for different architectural styles or components.

For performance predictions, the software architect needs additional information about the execution environment and the usage profile. The role of the *system deployer* provides performance-related information about the hardware/software environment of the architecture (such as processing rate of a CPU, throughput of a network link, scheduling policies of the operating system, configuration of the application server, etc.). Business *domain experts* provide knowledge about the anticipated user behavior (in terms of input parameters and call frequencies), and must assist software architects in specifying a usage model of the architecture.

Figure 1 depicts the overall development process of a component-based system including performance prediction (Koziolek et al. (2006)): Boxes model workflows, thick and grey arrows indicate a change of activity, and thin and black arrows illustrate the flow of artefacts. The workflows do not have to be traversed linearly; backward steps for revision are likely. After collecting and analysing requirements for the system to develop (Requirements), the software architect specifies components and the architecture based on input by component developers (Specification). With a fully specified architecture, performance predictions can be carried out by tools (QoS-analysis). The software architect can use the results to alter the specification or decide to implement the architecture. This is done either by obtaining existing components from third-party vendors or by implementing them according to their specification (Provisioning). Afterwards, the software architect can compose the component implementations (Assembly), test the full application in a restricted environment (Test), and then install and

operate it in the customer's actual environment (Deployment).

During "Specification", the above introduced roles interact as follows (cf. Figure 2): The PCM provides a domain-specific modelling language for each developer role, which is restricted to its known concepts. Component developers model performance-related component behaviour, software architects add an assembly model. System deployers model hardware/software resources and the components' allocation to these resources. Finally, domain experts provide a usage model.

Figure 1. Component-based development process (©2007 Heiko Koziolek. Used with permission)

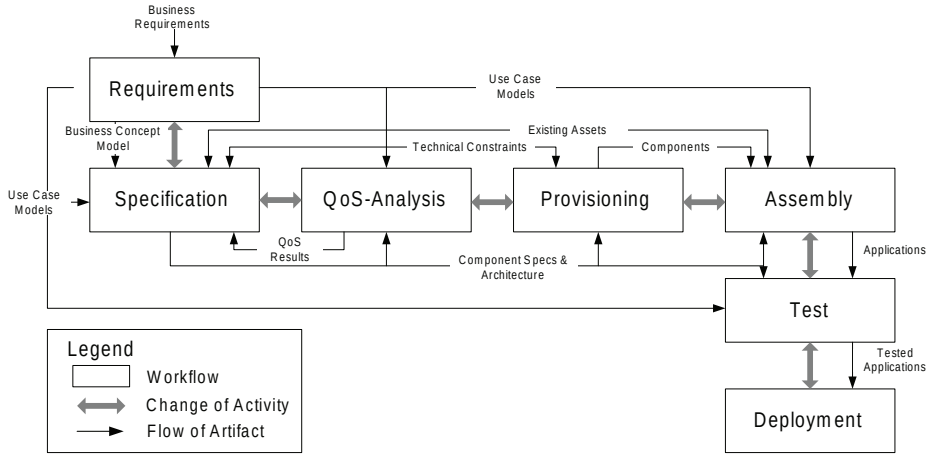

Figure 2. Specification and QoS analysis with the PCM (©2007 Heiko Koziolek. Used with permission)

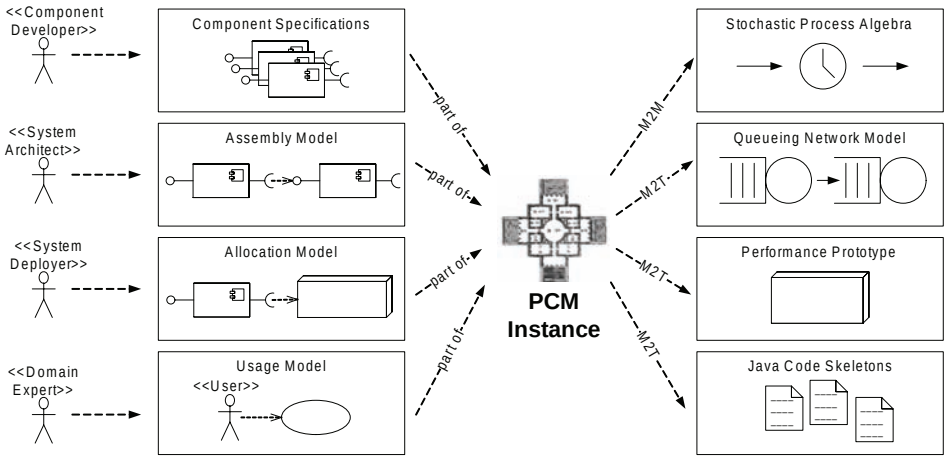


All specifications can be combined to derive a full PCM instance. Section 4 will elaborate on the PCM's specification languages.

During "QoS-Analysis", this model can be transformed into different analysis models, such as a stochastic process algebra or a queueing network. These models provide capabilities to derive performance metrics such as response times, throughputs, or resource utilisations for specific usage scenarios. Additionally, the PCM can be transformed into a performance prototype, which simulates the specified resource demands. This prototype enables pre-implementation performance measurements on the target platform. Finally, the PCM instance can be converted into Java code skeletons via model-2-text transformation, as a starting point for implementing the system's business logic. Section 5 describes the analysis models and code transformations in more detail.

OVERVIEW PALLADIO COMPONENT MODEL

This section provides an overview of the modeling capabilities of the PCM to describe component-based software architecture. The PCM is a metamodel specified in Ecore from the Eclipse Modelling Framework (EMF). The following section will mainly use examples to introduce the concepts, and does not go into technical details of the metamodel, which are elaborated in (Reussner et al., 2007). The description of the PCM in this section is structured along the developer roles and their domain-specific languages.

Component Developer

Component developers specify the functional and extra-functional properties of their components. They put the specification as well as the implementation in repositories, where software architects can retrieve them. This section will first introduce all entities, which can be stored in repositories and then focus on service effect specifications, which model the abstract behavior and performance properties of component services.

Component Repositories

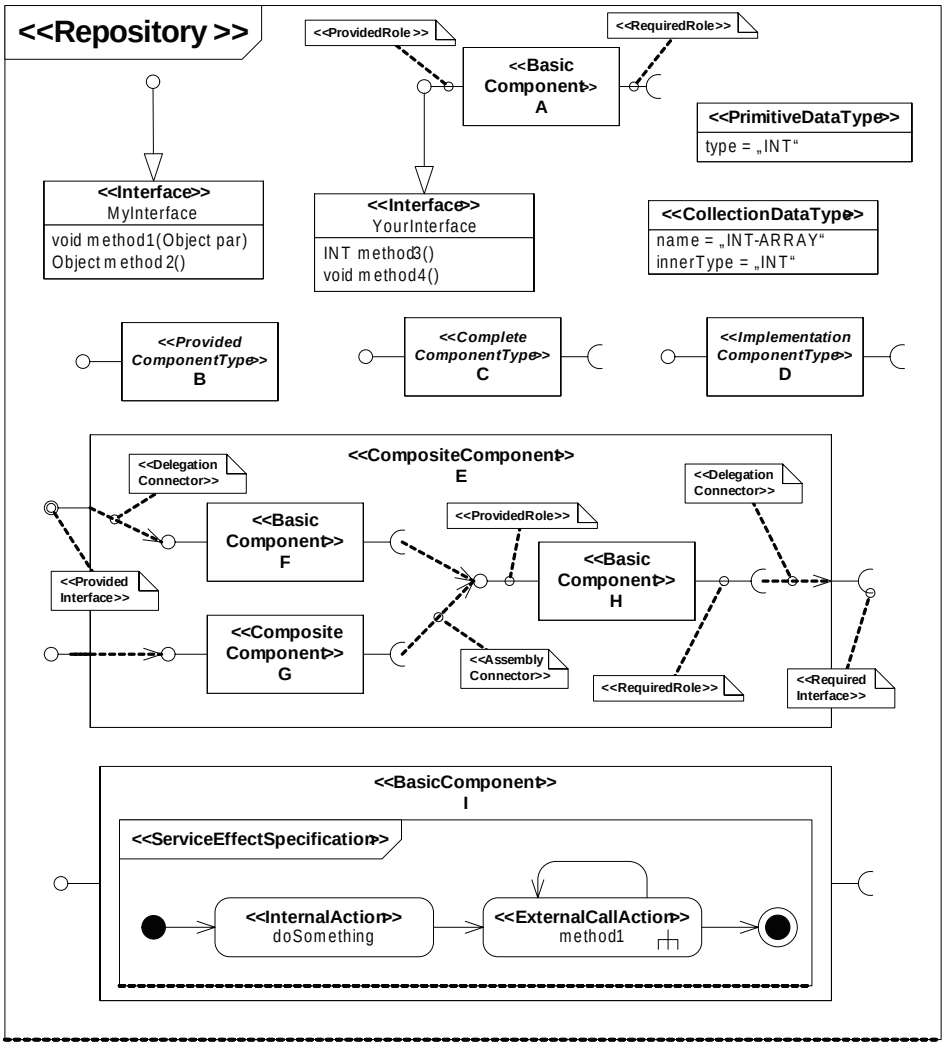
Figure 3 shows an example PCM repository, which includes all types of entities that can be specified. First class entities in PCM repositories are interfaces, data types, and components. They may exist on their own and do not depend on other entities.

The *interface* `MyInterface` is depicted on the upper left in Figure 3. It is not yet bound to a component, but can be associated as a provided or required interface to components. An example of interfaces existing without clients and an implementation in practice was the Java Security API, which had been specified by Sun before an implementation was available. Interfaces in the PCM contain a list of service signatures, whose syntax is based on CORBA IDL. Additionally, component developers may supplement an interface with protocols, which restrict the order of calling its services. For example, an I/O interface might force clients to first open a file (call service open()) before reading from it (call service read()).

Components may provide or require interfaces. The binding between a component and an interface is called "provided role" or "required role" in the PCM. For example, component `A` in Figure 3 is bound to `YourInterface` in a provided role. This means that the component includes an implementation for each of the services declared in the interface. Other components, which are bound to a compliant interface in a required role can use component `A` to execute these services.

Repositories need common data types, so that the service signatures refer to standardized types (e.g., INT, FLOAT, CHAR, BOOL, STRING, etc.). In the PCM, data types are either primitive types, collection types, or composite types

Figure 3. Example component repository (©2007 Heiko Koziolek. Used with permission)



(composed out of inner types). Figure 3 contains a primitive data type `INT` and a collection data type `INT-Array`, which contains `INT`s as inner elements.

The PCM supports modeling different types of components to a) reflect different development stages, and b) to differentiate between basic (atomic) components and composite components.

Different development stages are reflected by *provided, complete, and implementation component type*. Component developers can refine components during design from provided to implementation component types.

Provided component types (component `B` in Figure 3) only provide one or more interfaces, but include no mandatory required interfaces. Compo-

nent developers can use these type of components early during the development, when they know that a certain functionality has to be provided, but do not know whether other components are needed to provide this functionality.

Complete component types (component C in Figure 3) are provided component types, but additionally may contain mandatory required interfaces. However, the inner dependencies between provided and required interfaces are not fixed in complete component types, as different implementations can lead to different dependencies. Within a component architecture, a software architect may easily replace one component with another component, which conforms (i.e., implements the same provided and required interfaces) to the same complete component type, without affecting the system's functionality.

Implementation component types (component D in Figure 3) are complete component types, but additionally contain fixed inner dependencies between provided and required interfaces. Replacing implementation component types in an architecture ensures not only signature but also protocol compatibility at the required interface.

Implementation component types are either basic (i.e., implemented from scratch) or composite components (i.e., implemented by composing other components). Component E in Figure 3 is a *composite component.* It contains several inner components (F, G, H). Inner component may again be composite components (G) to build up arbitrary hierarchies. Assembly connectors bind the roles of inner components. Delegation connectors connect provided roles of composite components with provided roles of inner components, or required roles of composite components with required roles of inner components. From the outside, composite components look like basic components, as they provide and require services. The inner structure of a composite component should only be known to the component developer, but not to the software architect, who shall use the component as a unit and treat it the same as other components.

Finally, basic components are atomic and therefore cannot be further decomposed. They may contain a mapping for each provided service to required services, which is called resource demanding service effect specification.

Service Effect Specification

Resource demanding service effect specifications (RDSEFF) provide means to describe resource demands and calls to required services by a provided component service. Component developers use RDSEFFs to specify the performance of their components.

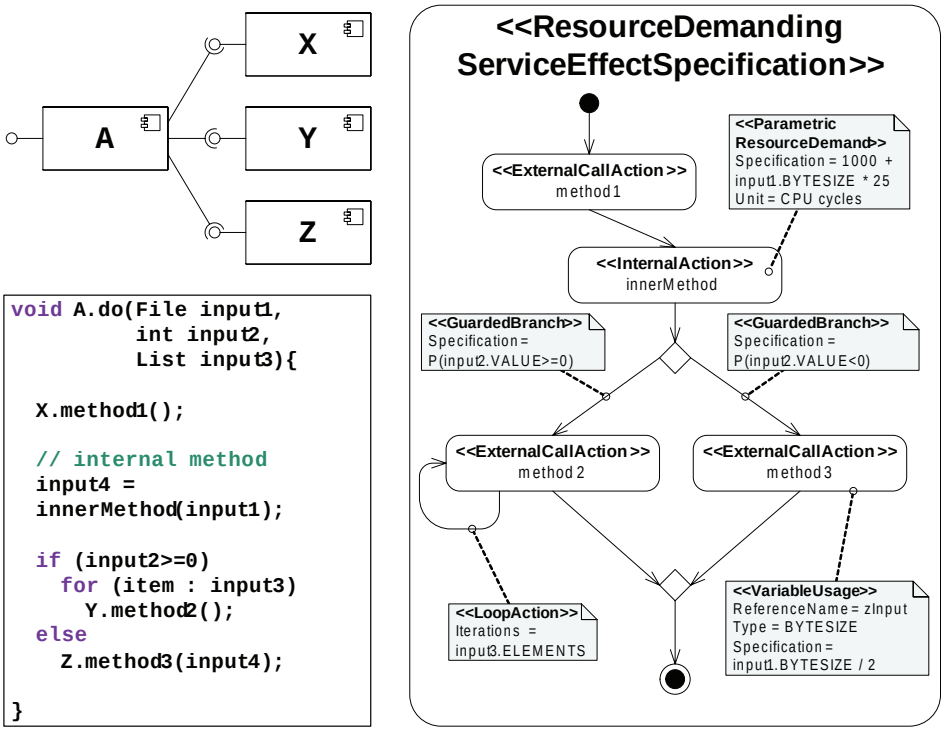
RDSEFFs reflect the environmental factors on component performance introduced in Section 2. These are external services, execution environment, usage profile, and component implementation as described in the following subsection.

RDSEFFs abstractly model the externally observable behavior of a component service. They only refer to method signatures and parameters that are declared in the interfaces and not to local, private variables. They abstractly model control flow between calls to required services, parametric dependencies, and resource usage. These specifications do not reveal any additional knowledge about the algorithms used to implement the service's functionality and thus retain the black-box principle.

Consider the artificial example in Figure 4 for a brief introduction into RDSEFFs. Component A invokes required functionality via its required X,Y, and Z. It provides a service called "`do`", whose source code is sketched in Figure 4. The service first calls a service from interface X, and then executes some internal code processing parameter "`input1`". Afterwards, depending on "`input2`", either services from interface Y or Z are called. "`method2`" from interface Y is located within a loop, whose number of iterations depends on the array length of "`input3`".

The corresponding RDSEFF for service "`do`" is located on the right hand side in Figure 4. As a

Figure 4. Resource demanding service effect specification (©2007 Heiko Koziolek. Used with permission)



graphical, concrete syntax, the illustration uses the UML activity diagram notation. However, in this case, the metamodel underlying the modeling constructs is not the UML metamodel, but the PCM, which is indicated by enclosing the PCM class names in brackets. In the following, the underlying concepts for control flow, resource demands, and parametric dependencies will be described.

Control Flow: Actions in RDSEFFs can either be internal actions (i.e., the component executes some internal code) or external call actions (i.e., the component calls a service declared in its required interface). RDSEFF offer as basic control flow constructs sequences, alternatives, loops, and parallel executions (forks). The order of these actions may influence performance properties of the service, because different services may concurrently use the same resources or synchronize each other, which induces delays for waiting.

Alternatives or branches split the control flow with an XOR semantic (with guards covering the whole input domain of parameters), while forks (not depicted in Figure 4) split the control flow with an AND semantic, i.e., all following actions are executed concurrently. Loops have to specify

the number of iterations, so that the execution times for actions within the loop can be added up a limited number of times.

Notice that the control flow in RDSEFFs is an abstraction from the actual inner control flow of the service. Internal actions potentially summarize a large number of inner computations and control flow constructs, which do not contain calls to required services.

Resource Demands: Besides external services, a component service accesses the resources of the execution environment it is deployed in. Ideally, component developers would provide measured execution times for these resource accesses in the RDSEFF. However, these measured times would be useless for software architects, who want to use the component, because their hardware/software environment can be vastly different from the component developer ones. The execution times of the service could be much faster or slower in the software architect's environment.

Therefore, component developers specify resource demands in RDSEFFs against abstract resource types such as a CPU or hard disk. For example they can provide the number of CPU cycles needed for execution or the number of bytes read from or written to a hard disk. The resource environment model supplied by the system deployer (Section 4.3) then contains execution times for executing CPU cycles or reading a byte from hard disk. These values can be used to calculate the actual execution times of the resource demands supplied by the component developers. As an example, the "ParametricResourceDemand" on the internal action "`method1`" in Figure 4 specifies that the service needs 1000 CPU cycles plus the amount of a parametric dependency (described in the next paragraph) to execute.

In addition to active resources, such as processors, storage devices, and network devices, component services may also acquire and release passive resources, such as threads, semaphores, database connections etc. Passive resources are not capable of processing requests and usually exist only a limited number of times. A service can only continue its execution, if the required amount of resources is available. Acquisition/Release of passive resources is not depicted in Figure 4.

Parametric Dependencies: To include the influence of the usage profile into the RDSEFF, component developers can specify parametric dependencies. When specifying an RDSEFF, component developers cannot know how the component will be used by third parties. Thus they cannot fix resource demands, branching probabilities or the number of loop iterations if those values depend on input parameters. Hence, RDSEFFs allow specifying dependencies to input parameters.

There are several forms of these dependencies. For example, in Figure 4, the resource demand of the internal action "`innerMethod`" depends on byte size of input parameter "`input1`" (e.g., because the method processes the file byte-wise). Once the domain expert characterizes the actual size of this parameter (cf. Section 4.4), this value can be used to calculate the internal action's actual resource demand.

Furthermore, branching probabilities are needed for the alternative execution paths in this RDSEFF. These probabilities are however not fixed, but depend on the value of input parameter "`input2`". Therefore, the RDSEFF includes no branching probabilities but guards (i.e., Boolean expressions) on the branches. Once the domain expert characterizes the possible values of "`input2`" and provides probabilities for the input domains "`input2>=0`" and "`input2<0`", these values can be mapped to the branching probabilities.

The RDSEFF in Figure 4 also contains a parametric dependency on the number of loop iterations surrounding the external call to "`method2`" of component `Y`. Loop iterations can be fixed in the code, but sometimes they depend on input

parameters. In this case the service iterates over the list "`input3`" and calls the external service for each of its elements. The RDSEFF specifies this dependency as the component developer cannot know in advance the lengths of the lists.

Finally, the service "`do`" executes the external call to "`method3`" in Figure 4 with an input parameter that in turn depends on an input parameter of the service itself. The service processes "`input1`", assigns it to a local variable "`input4`", and then forwards it to interface `Z` via "`method3`". While processing "`input1`", the service "`do`" reduces its byte size by 50% ("`input1.BYTESIZE / 2`"). The RDSEFF includes the specification of this dependency. Once the domain expert specifies the actual byte size of "`input1`", the byte size of the input parameter of "`method3`" can be calculated.

Software Architect

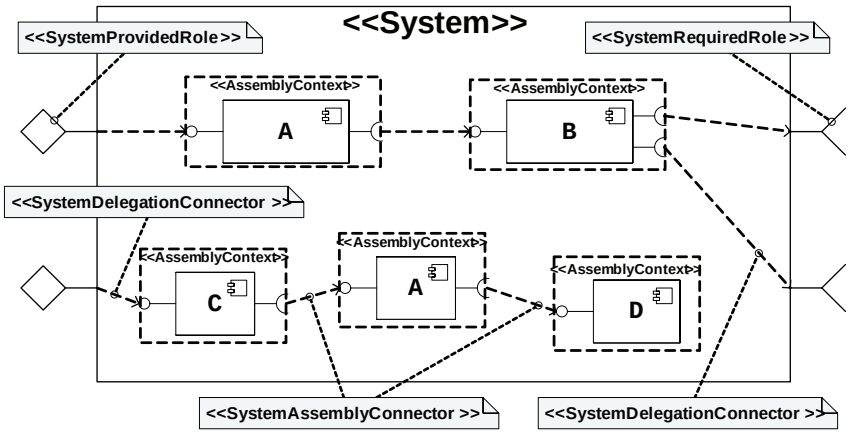
Software architects retrieve components (including their RDSEFFs) from repositories and compose them to architectures. They can use several component instances of the same type in an architecture at different places. Hence, in the PCM, software architects put component instances in so called assembly contexts, which save the connections of a single component instance.

Software architects bind the roles of components in assembly contexts with system assembly connectors, as illustrated in the example in Figure 5. Notice that the component type A is used in two assembly contexts in this example (once connected with component B and once with C and D).

A set of connected assembly contexts is called *assembly*. An assembly is part of a *system*, which additionally exposes system provided roles and system required roles (cf. Figure 5). System delegation connectors bind these system roles with roles of the system's inner components. Domain experts later use system provided roles to model the usage of the system (Section 4.4). System required roles model external services, which the software architect does not consider part of the architecture. For example, the software architect can decide to model a web service or a connected database as system external services.

There is a distinction between composite components and systems. For software architects

Figure 5. System example (©2007 Heiko Koziolek. Used with permission)



and system deployers, composite components hide their inner structure and the fact that they are composed from other components. The inner structure is an implementation detail and its exposure would violate the information hiding principle of components. Opposed to this, the structure of assemblies is visible to software architects and system deployers. Therefore, system deployers can allocate each component in a system to a different resource. However, they cannot allocate inner components of composite components to different resources, because these stay hidden from them at the architectural level.

System Deployer

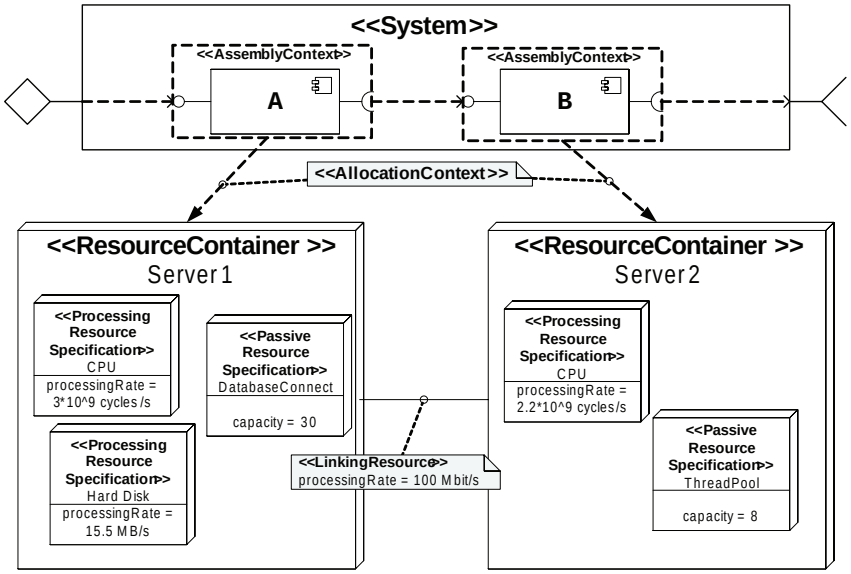
System deployers first specify the system's resource environment and then allocate assembly contexts (i.e., connected component instances) to resources.

In *resource environments*, resource containers group resources. For example, in Figure 6, the resource container "Server1" contains a CPU, a hard disk, and a database connection pool. The PCM differentiates between processing resources, which can execute requests (e.g., CPU, hard disk, memory), and passive resources, which cannot execute requests, but only be acquired and released (e.g., threads, semaphores, database connections).

Processing resources specify a processing rate, which can be used to convert the resource demands in RDSEFFs into timing values. Passive resources specify a capacity. If a component acquires a passive resource, its amount of available units (i.e., its capacity) decreases. Once the capacity reaches zero, further components requesting the passive resource must wait until other services release it again. Linking resources connect resource containers and are themselves special processing resources.

System deployers use *allocation contexts* to specify that a resource container executes an assembly context. In Figure 6, the system deployer

Figure 6. Resource environment and allocation (©2007 Heiko Koziolek. Used with permission)



has allocated component A's assembly context to "Sever1" and component B's assembly context to "Server2".

System deployers can specify different resource environments and different allocation contexts to answer sizing questions. The PCM's resource model is still limited to abstract hardware resources. We will extend it in the future with middleware parameter, operating system settings, and scheduling policies.

Domain Expert

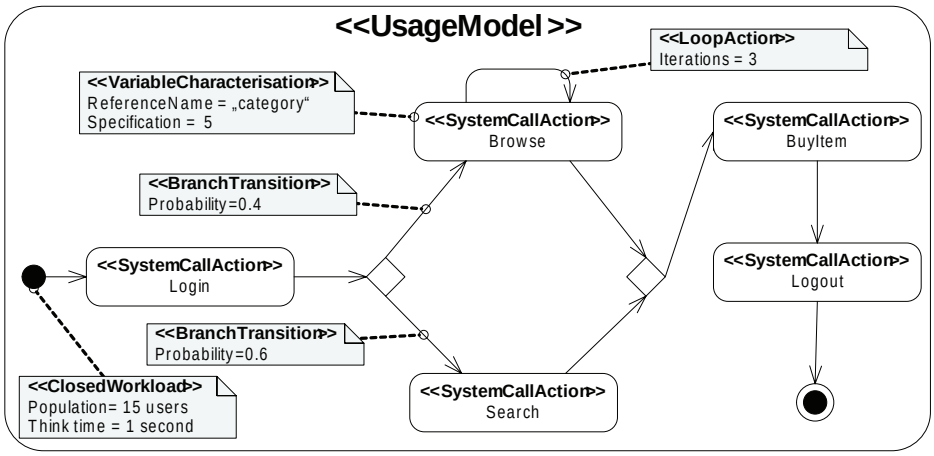
Domain experts create a usage model that characterizes user behavior and connects to system provided roles. In the example in Figure 7, users first log in to the system, then either browse or search, then buy an item, and finally log out. All actions target system provided roles (i.e., services exposed by the system, cf. Section 4.2).

Domain experts can specify user behavior with control flow constructs such as sequence, alternative, and loop. They must specify branching probabilities for alternatives and the number of iterations for loops.

Additionally, domain experts specify the user workload. Workloads are either closed or open. Closed workloads specify a fixed number of users (population) circulating in the system. In Figure 7, the domain expert has specified a closed workload with 15 users, which perform the specified actions and then re-enter the system after a think time of 1 second. Open workloads specify a user arrival rate (e.g., 5 users/second), and do not limit the number of users in the system.

The PCM usage model also enables domain experts to characterize the parameter values of users. In Figure 7, variable "category" of action browse has been characterized with a constant (5) meaning that users always browse in the category with id number 5. Besides constants, the usage model offers specifying probability distribution functions over the input domain of a parameter, so that domain experts can provide a fine-grained stochastic characterization of the user's input parameters. The reader may find details in Reussner et al. (2007).

Figure 7. Usage model example (©2007 Heiko Koziolek. Used with permission)



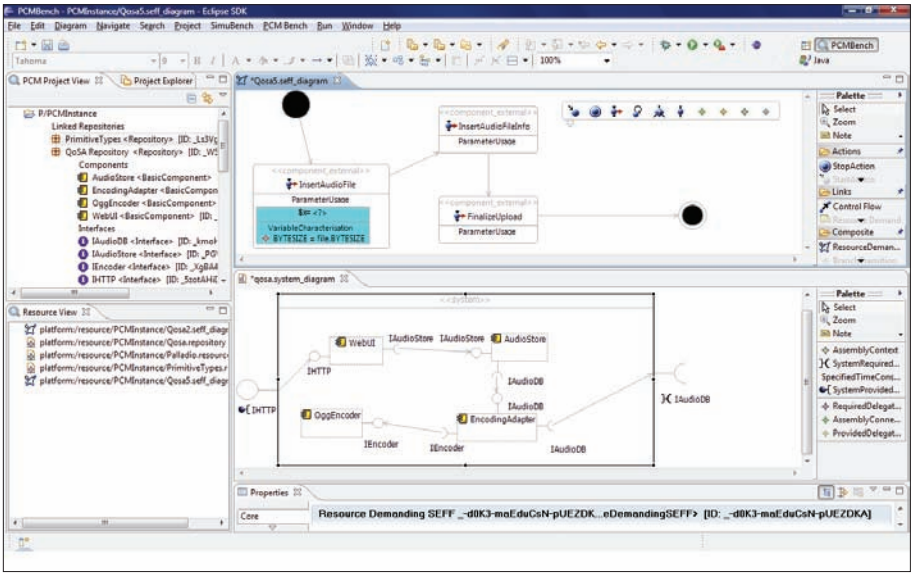
Tool Support

We have implemented an Eclipse-based open-source tool called "PCM-Bench", which enables software developers to create instances of the PCM metamodel and run performance analyses (cf. Figure 8). The tool offers a different view perspective for each of the four developer roles and provides graphical model editors. Models of the different developer roles reference each other in the editor, which enables the creation of a full PCM instance. The PCM-Bench is an Eclipse RCP application and its editors have been partially generated from the PCM Ecore metamodel with support of the Graphical Modelling Framework (GMF).

The graphical editors provide an intuitive way of modeling component-based architectures analogous to UML modeling tools. They offer model validation by checking OCL-constraints (Object Constraint Language). The PCM-Bench visualizes violated constraints directly in the model diagrams. The editors support entering performance annotations with special input masks that offer syntax highlighting and code completion. Model instances can be serialized to XMI-files.

Besides graphical editors, the PCM-Bench is a front-end for the performance analysis techniques described in Section 5. Software architects can configure and run simulations. They can retrieve different performance metrics such as response times for use cases, throughputs, and resource utilizations. The PCM-Bench visualizes probability distribution functions of response times as histograms and provides standard statistical values such as mean, median, standard deviation etc. Furthermore, the PCM-Bench supports Model-to-Text transformations to generate Java code from PCM instances.

Figure 8. Screenshot PCM-bench (©2007 Heiko Koziolek. Used with permission)



MODEL TRANSFORMATION AND PREDICTION METHODS

The PCM offers different performance evaluation techniques, which are still subject to research. For analyzing use cases without concurrency, a PCM instance can be transformed into a stochastic process algebra (SPA), which offers a fast way of predicting response times (Section 5.1). A PCM instance can alternatively be transformed into a queuing network based simulation model (Section 5.2). The simulation model is less restricted than the SPA, but its execution is usually more time consuming than solving the SPA. Finally, there are transformations to derive Java code skeletons from a PCM instance, to provide a starting point for implementing the modeled architecture (Section 5.3).

Stochastic Process Algebra

The PCM-Bench supports a model-2-model transformation of a PCM instance into an SPA called Capra (Happe et. al (2007), Koziolek et. al (2007c)). Capra includes concurrent processes, resources with current operating systems scheduling policies, and is able to efficiently incorporate timing values specified as arbitrary probability distributions into the analysis process. It employs a hybrid approach of analysis and simulation to conduct the performance prediction.

To transform a PCM instance into a Capra expression, a tool first solves the parametric dependencies within the RDSEFFs. They use the parameter characterizations provided by the domain expert in the usage model to transform parametric resource demands to resource demands, guards on branches to probabilities, and parameter dependent loop iteration specifications into iteration numbers. Afterwards, the transformation into Capra is straightforward (Koziolek et. al (2007a)). The remainder of this section gives a brief overview on Capra's syntax, semantics, and analytical capabilities.

The basic entities of a process are actions. In Capra, the set of actions *Act* is divided into a set of event actions *EAct* and demand actions *DAct*. Event actions represent atomic, indivisible behavior which is mainly used for process communication. Demand actions on the other hand represent the usage of resources, like processors and hard disks, for a certain time span. During the execution of a demand action other activities might happen in the system. A random variable $D_{a,r}$ specifies the demand issued by a demand action *a* to a resource *r*. It is characterized by a probability density function (pdf) $f_{a,r}(t)$. To create more complex behavioral structures, Capra offers a set of different operators for sequential and alternative composition as well as for the specification of recursive process behavior. The following describes the available operators.

Process $P \cdot Q$ denotes the *sequential composition* of two processes *P* and *Q*. It first executes *P* and then, after the successful termination of *P*, it executes *Q*.

The *alternative composition* models the execution of only one of the two processes *P* and *Q*. Capra distinguishes two types of alternative composition, depending on where the decision for the next activity is made. If the process itself decides on the next activity, the internal or probabilistic choice is used. Process $P \oplus_p Q$ selects process *P* with probability π and process *Q* with probability $1 - \pi$. On the other hand, the external or non-deterministic choice $P + Q$ models different possible behaviors. Here, the selection is determined by event actions issued by the process' environment, i.e. other processes running in parallel.

A process variable *X* can be used to define *recursive processes*. For example, $Do := a \cdot Do$ specifies a process that executes an infinite number of *a* actions. In real systems, the number of recursive calls is usually bounded. Furthermore, the limit is usually not fixed to a single value, but depends on the system's parameters. To approximate such behavior, Capra models the number

of recursive calls as a discrete random variable specified by a probability mass function (pmf). Process $P^{*(Iter)}$ describes the *bounded loop* of a processes *P*. The random variable $Iter$ characterized by a pmf $P(Iter = n)$ denotes the probability of executing the recursion *n* times (Koziolek et. al., 2007c).

Process $P \mid_A Q$ denotes the *parallel composition* of the processes *P* and *Q*. The processes communicate (and synchronize) over the event actions in the set *A*. Both processes compete for the available resources, which might delay their execution.

To reduce the complexity of the simulation, the total demand of some operations can be determined in advance. If two processes issue only demands to a single resource, their total demand can be computed for the operations sequential composition, probabilistic choice, and finite recursion. The following gives an impression on the possible analyses.

The total demand of a sequence of demand actions is the sum of the single demands. So, the random variable for the sequential demand is given by $D_{P \cdot Q,r} = D_{P,r} + D_{Q,r}$. The sum of two random variables is the convolution of its pdfs. Thus, the pdf of $D_{P \cdot Q,r}$ is $f_{P \cdot Q,r}(t) = (f_{P,r} \otimes f_{Q,r})(t)$, where $\otimes$ denotes the convolution.

For the probabilistic choice $P \oplus_p Q$, the demand is either $D_{P,r}$ with probability π or $D_{Q,r}$ with probability $1 - \pi$. Thus, the pdf of $D_{P \oplus_p Q}$ is the weighted sum of the probability density functions:

$$f_{P \oplus_\pi Q,r}(t) = \pi \cdot f_{P,r}(t) + (1 - \pi) f_{Q,r}(t).$$

Finite recursion can be considered as large probabilistic choices over the n-time sequential composition of processes *P* and *Q*. The pmf $P(I = n)$ defines the probabilities for the probabilistic choice. Thus, function:

$$f_{\langle P[I]Q \rangle,r}(t) = (\sum p_I(i) \otimes^i_{j=1} (f_{P,r} \otimes f_{Q,r}))(t)$$

computes the pdf for demand $D_{\langle P[I]Q \rangle}$.

With such combined resource demands, the number of required simulation steps is reduced significantly. The simulation itself is an event-discrete simulation based on the Desmo-J framework and yields as result the response time of a usage scenario as a probability distribution. Details on Capra and the simulation can be found in Happe et al. (2007).

Queuing Network Simulation

Many performance analysis methods use queuing networks as underlying prediction models because of their capability to analyze concurrent system interactions. Queuing models contain a network of service centers with waiting queues which process jobs moving through the network. When applying queuing networks in performance predictions with the PCM, some of the commonly used assumptions need to be dropped. As the PCM uses arbitrary distribution functions for the random variables, generalized distributed service center service times, arrival rates, etc. occur in the model. Additionally, the requests are routed through the queuing network according to the control flow specified in the RDSEFF. In contrast, common queuing networks assume probabilistic movement of the jobs in the network. As a result, only simulation approaches exist, which solve such models.

Hence, we use a model-to-text transformation to generate Java code realizing a custom queuing network simulation based on the simulation framework Desmo-J. The simulation generates service centers and their queues for each active resource. Passive resources are mapped on semaphores initialized with the resource's capacity. The transformation generates Java classes for the components and their assembly. Service implementations reflect their respective SEFF.

For the usage model workload drivers for open or closed workloads simulating the behavior of

users exist in the generated code. For any call issued to the simulated system, the simulation determines the parameter characterizations of the input parameters and passes them in a so called virtual stackframe to the called service. Originally, the concept of a stackframe comes from compiler construction where they are used to pass parameters to method calls. In the PCM simulation, stackframes pass the parameter characterizations instead.

Utilizing the information in the simulated stackframes, the simulated SEFF issues resource demands to the simulated resources. If the resource is contented, the waiting time increases the processing time of the demand.

The simulation runs until simulation time reaches a predefined upper limit or until the width of the estimation for the confidence interval of the mean of any of the measured response times is smaller than a predefined width. After the end of a simulation run, the simulation result contains different performance indicators (response times, queue lengths, throughputs …) which the software architect can analyze to determine performance bottlenecks in the software architecture.

The computations described here reduce the complexity of Capra expressions allowing a more efficient and more accurate simulation. In the special case, that all demands are issued to the same resource and no concurrency is used, the whole expression can be solved analytically.

Java Code & Performance Prototype

The effort spent into creating a model of a software architecture should be preserved when implementing the system. For this, a model-2-text transformation based on the openArchitectureWare (oAW) framework generates code skeletons from PCM model instances. The implementation uses either Plain Old Java Objects (POJOs) or Enterprise Java Beans (EJBs) ready for deployment on a J2EE application server.

The transformation uses as much model information as possible for the generation of artifacts. Repository models result in components, assembly connectors in distributed method calls, the allocation is used to generate ant scripts to distribute the components to their host environment and finally, the usage model results in test drivers.

A particular challenge is the mapping of concepts available in the PCM to objects used in Java or EJB. Consider for example the mapping of composite components to Java. As there is no direct support of composed structures in Java, a common solution to encapsulate functionality is the application of the session façade design pattern.

Another issue with classes as implementing entities for components is the missing capabilities to explicitly specify required interfaces of classes in object oriented languages. A solution for this is the application of the component context pattern by Völter et al. (2006). This pattern moves the references to required services into a context object. This object is injected into the component either by an explicit method call or by a dependency injection mechanism offered by the application server.

Finally, we can combine the EJB and the simulation transformation. This way, users can generate a prototype implementation which can be readily deployed and tested on the final execution environment. Internal actions of the prototype only simulate resource demands by executing dummy code which offers quality characteristics as specified in the model. By using the prototype, early simulation results can be validated on the real target environment to validate early performance estimates.

EXAMPLE

To illustrate the performance prediction approach with the PCM, this section provides a

case study, in which we predicted the response time of a usage scenario in a component-based software architecture and compared the results with measured response times from executing an implementation.

The system under analysis is the "MediaStore" architecture, a web-based store for purchasing audio and video files, whose functionality is modeled after Apple's iTunes music store. It is a three-tier architecture assembled from a number of independently usable software components (Figure 9). Users interact with the store via web browsers, and may purchase and download different kinds of media files, which are stored in a database connected to the store's application server via Gigabit Ethernet.

We analysed a scenario, in which users purchase a music album (10-14 files, 2-12 MB per file) from the store. As a measure for copy protection, a component "DigitalWatermarking" shall be incorporated into the store. This component unrecognisable attaches the user's ID to the audio files via digital watermarking. In case the audio files would appear illegally in public file sharing services, this enables tracking down the responsible user. However, this copy protection measure has an influence on performance, as it decreases the response time of the store when downloading files. With the model-driven performance prediction, we analysed whether the store is capable of answering 90% of all user download requests in less than 8 seconds.

Each component in the store provides RDSEFFs to enable performance analyses (three examples in Figure 10). The execution time in this use case mainly depends on the number and size of the files selected for download, which influences network traffic as well as CPU utilisation for the watermarking algorithm. The specifications of the the components' RDSEFFs have been calibrated with measurements on the individual components. In this case, we carried out the predictions using Capra.

Besides modelling the store, we also implemented the architecture assisted by the introduced model-to-text transformations to Java code (EJB3). After generating code skeletons from the design, we manually added the implementation of the business logic of forwarding requests and watermarking audio files. The code

Figure 9. MediaStore architecture (©2007 Heiko Koziolek. Used with permission)

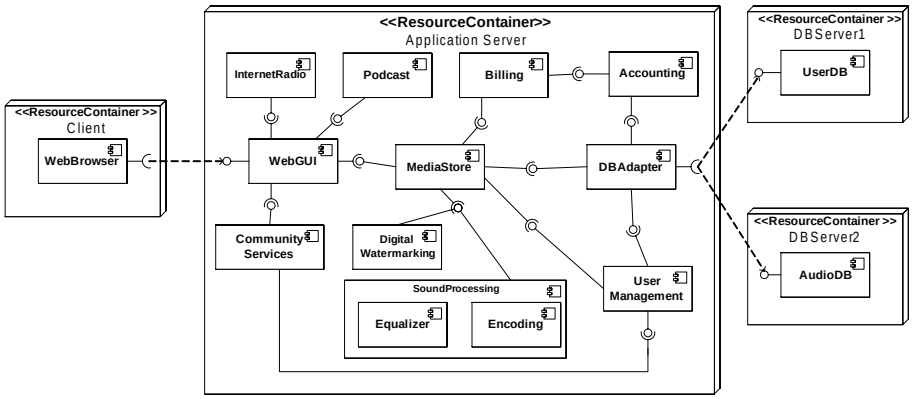


Figure 10. MediaStore service effect specifications (©2007 Heiko Koziolek. Used with permission)

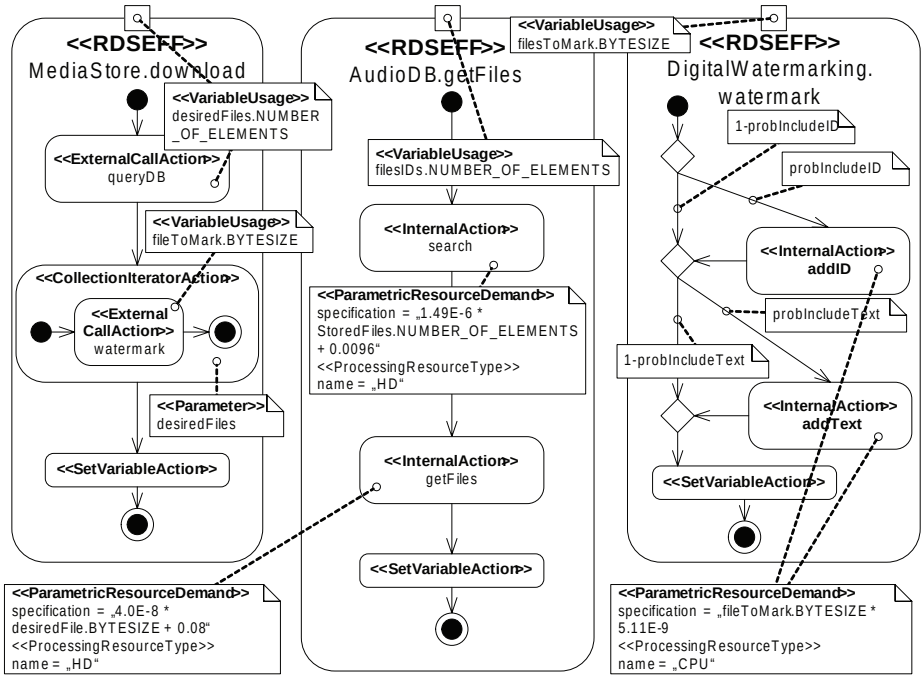

Figure 11. Case study results (©2007 Heiko Koziolek. Used with permission)

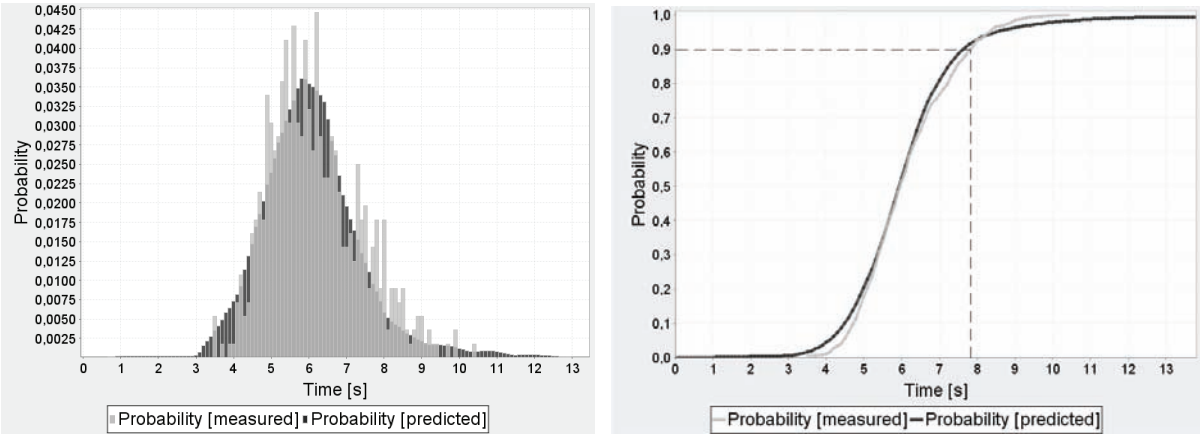

generation also creates build scripts, test drivers, deployment descriptors, and configuration files. We weaved measurement probes into the code using AspectJ.

The results of prediction and measurement are compared in Figure 11. The diagram on the left hand side visualises the histograms of the response times. The dark columns indicate the prediction, while the bright columns on top of the dark columns indicate the measurement. The highest probability of receiving a response from the store with the mentioned parameters is at around 6 second. In this case, the prediction and the measurement widely overlap.

The diagram on the right hand side visualises the cumulative distribution functions of the response time prediction and measurements. This illustration allows to easily check our constraint of at least 90% of all responses in less than 8 seconds. It was predicted that 90% of all requests would be responded in 7.8 seconds even if watermarking was used in the architecture. The measurements confirmed the predictions, because in our tests 90% of the request could be answered less than 7.8 seconds. There is a difference of 0.1 seconds or 1.3 percent.

In this case, the predictions were useful to quantitatively support the software architect's decision to introduce watermarking without violating a service level agreement. Note, that the predictions are not meant to be real-time predictions for safety-critical systems. They are useful at early development stages on the architectural level to support design decisions and lower the risk of performance problems in implementations. Safety-critical systems (e.g., airbag controls) instead need formal verifications of predictions to prevent harming human lives. That requires more fine grain specifications at lower abstraction levels, which developers can only create if most details of the system are known.

FUTURE RESEARCH DIRECTIONS

Model-driven performance prediction and quality assurance of software architecture models is still in its infancy and provides lots of opportunities for future research. Woodside et al. (2007) recently commented on the future of software performance engineering. We provide a list of future research directions from our viewpoint complementing their ideas:

- **Intermediate languages:** To bridge the gap between designer-friendly model notations and analytically-oriented formalisms, many approaches have developed ad-hoc model transformations. Several approaches aim at providing a standard interface, i.e., an intermediate modelling language, to ease the implementation of model transformations (Grassi et al. (2005), Petriu et. al. (2005))
- **Dynamic architectures:** The PCM is only targeted at static architectures, and does not allow the creation/deletion of components during runtime or changing links between components. With the advent of web services and systems with dynamic architectures changing during runtime, researchers pursuit methods to predict the dynamic performance properties of such systems (Caporuscio et al. (2007), Grassi et al. (2007)).
- **Layered resource models:** With OMG's MDA vision of platform independent models and platform specific models, it seems straight forward to follow this approach in performance modelling. For different system layers (e.g., component containers, middleware, virtual machine, operating system, hardware resources), individual models capturing performance-relevant properties could be built. These models could be com-

posed with architectural models to predict the performance (Woodside et. al (2007)).

- **Combination of modeling and measurement:** Developers can only carry out performance measurements if the system or at least parts of it have been implemented. Measurement results could be used to improve models. In component-based performance modelling, measurements are useful to deduce the resource demands of components. A convergence of early-life cycle modelling and late-life cycle measurement can potentially increase the value of performance evaluations (Woodside et. al (2007)).
- **Performance engineering knowledge database:** Information collected by using prediction models or measuring prototypes tends to get lost during system development. However, the information is useful for future maintenance and evolution of systems. Systematic storage of performance-related information in a knowledge database could improve performance engineering (Woodside et. al (2007)).
- **Improved automated feedback:** While today's model-transformations in software performance engineering bridge the semantic gap from the developer-oriented models to the analytical models, the opposite direction of interpreting performance result back from the analytical models to the developer-oriented models has received sparse attention. Analytical performance results tend to be hard to interpret by developers, who lack knowledge about the underlying formalisms. Thus, an intuitive feedback from the analytical models to the developer-oriented models would be appreciated (OMG (2005), Woodside et. al (2007)).

CONCLUSION

This chapter provided an overview of the Palladio Component Model, a modelling language to describe component-based software architectures aiming at early life cycle performance predictions. The PCM is aligned with developer roles in CBSE, namely component developers, software architects, system deployers, and domain experts. Therefore, the PCM provides a domain specific modelling language for each of these developer roles. Combining the models from the roles leads to a full PCM instance specification, which can be transformed to different analysis models or Java code. An hybrid analysis model (SPA) provides a fast way to predict response times. Simulation of PCM instances is potentially more time-consuming, but offers more expressiveness than the hybrid approach. Finally, developers may use generated Java code skeletons from a PCM instance as a starting point for implementation. To illustrate the PCM's capabilities the chapter included a case study predicting the performance for a small component-based architecture.

The PCM is useful both for component developers and software architects. Component developers can specify the performance of their components in a context-independent way, thereby enabling third party performance predictions and improving reusability. Software architects can retrieve component performance specification from repositories and assemble them to architectures. With the specifications they can quickly analyse the expected performance of their designs without writing code. This lowers the risk of performance problems in implemented architectures, which are a result of a poor architectural design. The approach potentially saves large amounts of money because of avoided re-designs and re-implementations.

The chapter provided pointers for future directions of the discipline in Section 7. Future work

for the PCM includes improving the resource model, supporting dynamic architectures and reverse engineering. The resource model needs to be improved to support different scheduling disciplines, concurrency patterns, middleware parameters, operating system features etc. Dynamic architectures complicate the model as they allow changing links between components and allow the creation and deletion of components during runtime. However, this is common in modern service-based systems, and thus should be incorporated into performance predictions. Finally, reverse engineering to semi-automatically deduce performance models from existing legacy code seems an interesting pointer for future research. Reducing the effort for modelling would convince more developers of applying performance predictions. The inclusion of legacy systems enables predicting the impact on performance of planned system changes.

Section III
Tools and Technologies

This section presents extensive coverage of the technology that both derives from and informs software applications. These chapters provide an in-depth analysis of the use and development of innumerable devices and tools, while also providing insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with examples of the tools that facilitate and support software design and engineering. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Chapter 3.1
Knowledge Management Toolkit for SMEs

Kerstin Fink
University of Innsbruck, Austria

Christian Ploder
University of Innsbruck, Austria

ABSTRACT

The discipline of knowledge management is no longer emerging in large organizations, but also small and medium-sized enterprises (SMEs) are focusing on finding the right process that will allow them to make advantages of their intellectual capital. Using survey data from 219 small and medium-sized enterprises in Austria and Switzerland, this chapter illustrates the four key knowledge processes (1) knowledge identification, (2) knowledge acquisition, (3) knowledge distribution, and (4) knowledge preservation for SMEs and also reports the findings of the empirical study designed to allocate cost-efficient software products to each of the four knowledge processes. As a result a knowledge toolkit for SMEs that integrates knowledge processes, methods and software tool for decision support making is given. Finally, the social view of knowledge management to SMEs is discussed, showing that the use of information technology is currently far more important than the integration of a social-cognitive perspective.

INTRODUCTION

The academic literature on knowledge management has become a major research field in different disciplines in the last ten years (Nonaka & Takeuchi, 1995; Ruggels, 1997; Sveiby, 1997; Davenport & Prusak, 1998; Back, Enkel, & Krogh, 2007). Through knowledge management, organizations are enabled to create, identify and renew the company's knowledge base and to deliver innovative products and services to the customer. Knowledge management is a process of systematically managed and leveraged knowledge in an organization. In a global and interconnected society, it is more difficult for companies to know where the best and most valuable knowledge is.

The term knowledge has a wide range of definitions in the knowledge management literature. The authors follow the definition by Davenport and Prusak (1998, p. 5) "knowledge is a fluid mix of framed experiences, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the mind of knowers." For a better understanding of knowledge management Jennex (2007, p. 4) points out that the concepts of organizational learning and memory should be integrated. Therefore, knowledge management can be defined as "the practice of selecting applying knowledge from pervious experiences of decision making to current and future decision-making activities with the express purpose of improving the organization´s effectiveness" (Jennex, 2007, p. 6).

Knowledge management is more than the technological solutions provided to give people access to better and more relevant information (Wang & Plaskoff, 2002, p. 113). It is important that the design of the knowledge management systems reflect the mindset of the knowledge workers and their way of offering highly qualitative knowledge solutions with quick solution processes. An effective knowledge management system must integrate people, processes, technology and the organizational structure.

Historically, knowledge management focused on the domain of larger organizations and issues of culture, networking, organizational structure and technological infrastructure are applied upon the implementation of knowledge management initiatives in large multi-national organizations and seem to give little relevance (Delahaye, 2003) to small and medium-sized enterprises (SMEs). SMEs are playing a key role in European economic performance because they account for a high proportion of the gross domestic product (GDP) and employ some two- thirds of the European workforce. According to the OECD (Organisation for Economic Co-operation and Development) *Small and Medium-sized Enterprise Outlook 2002 and 2005* (OECD, 2005), the role of SMEs in OECD economic is very important for strengthening economic performances. SMEs represent over 95% of enterprises in most OECD countries, and generate over half of private sector development. A similar impact of SMEs to economic value can be found in the report of the Asia-Pacific Economic Cooperation (APEC, 2006), where about 90% of enterprises are SMEs. During their 2006 meeting in Beijing, the members agreed to strengthen the SME`s competitiveness for trade and investment. For example, SMEs account for more than 95% of companies in Australia. Of the 624.010 SMEs in Australia, more than two-thirds employ between one and four people. A further 180,880 SMEs employ between five and 19 people meaning that 93.5% of people employed by SMEs in Australia are employed by what can be described as 'micro-SMEs,' namely companies with less than 20 employees. However, the success and growth of SMEs depends on how well they manage the knowledge of their knowledge workers. In 2000, the European Council set the clear strategic goal for the European Union (EU) of becoming "the most competitive and dynamic economy in the world, capable of sustaining economic growth with more and better jobs and greater social cohesion" by the year 2010 (EC, 2000). Dezouza and Awazu (2006) point out that SMEs have to compete on the know-how in order to gain competitive advantages. Even more, SMEs do not have much money to spend on knowledge management initiatives, so knowledge must be leveraged that goals can be achieved in an effective and efficient manner (Fink & Ploder, 2007c). Ordanini (2006) discusses the issue that the adoption of information technology by SMEs began to be discussed during the 1980s. Furthermore, it has to be stated that the adoption of information technology for SMEs was slower than that of larger organizations, which can be referred to as the so-called digital divide phenomenon.

Looking to the European countries of Austria and Switzerland including Liechtenstein, a similar

landscape of SMEs can be identified. According to the *Austrian Statistical Year Book* (SA, 2006) and the Austrian Institute for SMEs Research (ASME, 2006) for the year 2006, 99.7% which are 297,800 companies are SMEs in Austria. In Switzerland, also 99.7% of the companies are SMEs, looking at the data from CHSME (2006). There are several research articles dealing with knowledge management in SMEs (Sveiby, 1997; Beijerse, 2000; McAdam & Reid, 2001; Salojärvi, Furu, & Sveiby, 2005), but only a few empirical studies are conducted to see the impact of knowledge processes in SMEs. McAdam and Reid (2001) found out that the time is right for knowledge management within the SME-sector. The results of their comparative study of large organizations and SMEs showed that both sectors have much to gain by the development of knowledge management systems. Salojärvi, Furu and Sveiby (2005) have observed that SMEs should be able to enhance their performance and competitive advantages by a more conscious and systematic approach to knowledge management.

In this chapter, the focus lies on the impact of knowledge process modeling for SMEs to help them getting a framework to be more innovative (Donnellan, Conboy, & Hill, 2006). In research methodology, the theoretical framework for the identification of knowledge processes in SMEs will be discussed. The section that follows that covers the use of cost-efficient software products for the implementation of knowledge processes in SME and introduces a SME knowledge toolkit. Discussion and future research gives an outlook of future research and a discussion of social factors influencing knowledge management in SMEs.

RESEARCH METHODOLOGY

Definition of SMEs

There are several quantitative and qualitative definitions of the term small and medium-sized enterprise (SME) depending on regional and national differences. In the United States, the definition of small business is set by a government department called the Small Business Administration (SBA) Size Standards Office. The SBA uses the term "size standards" which is a numerical definition to be considered as a small or medium-sized business. It must also be independently owned and operated. Unlike the European Union, which has simple definitions applied to all industries, the United States has chosen to set size standards for each individual industry. This distinction is intended to better reflect industry differences. SMEs are also of high importance for in the U.S. Economy. Similar to Europe, more than 97% of the firms in the U.S. can be defined as SMEs.

The definition of SMEs of the European Commission 2005 (EC, 2000) is used for this research design. The European Commission analyzes SMEs by using the following three characteristics: (1) number of employees, (2) annual revenue and (3) total assets. Characterized through these three factors, the European Commission differs: (1) middle enterprises (less than 250 employees and less than 50 million euro annual revenue or less than 43 million total assets); (2) small enterprises (less than 50 employees and less than 10 million euro annual revenue or less than 10 million euro total assets); and (3) micro enterprises (less than 10 employees and less than 2 million euro annual revenue or less than 2 million euro total assets).

Since the authors focus on the definition of the European Commission of SMEs, they follow the research view of a quantitative perspective of SMEs. This means that all enterprises with less than 250 employees and less than 50 million euro annual revenue or less than 43 million euro total assets in Austria and Switzerland including Liechtenstein are the target population.

Research Framework

The basic research model is the "building block" approach by Probst, Raub and Romhardt (2002)

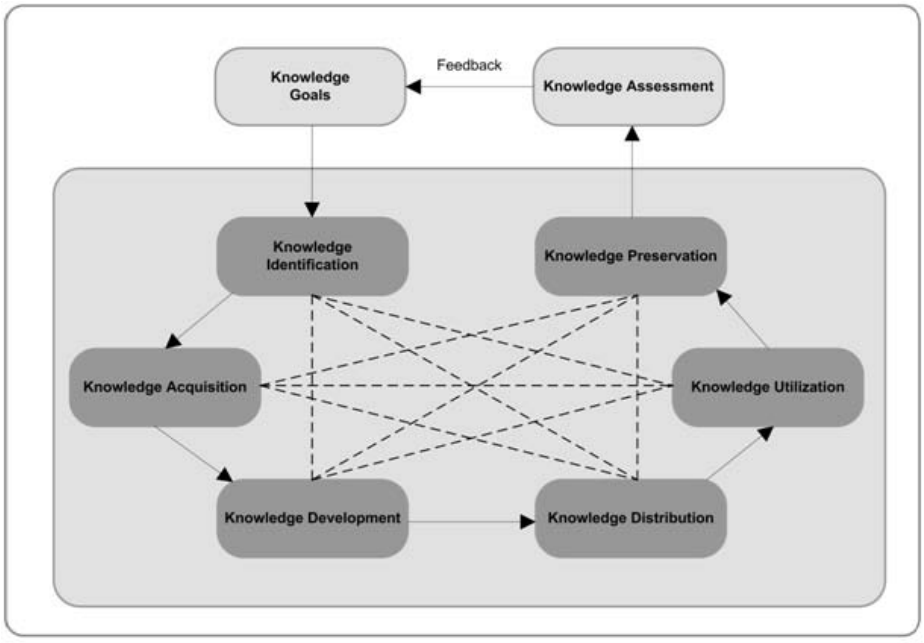
with the description of the knowledge processes (Figure 1). Involved are eight components that form two cycles: an inner cycle and an outer cycle. The inner cycle is composed of six key knowledge processes:

- *Knowledge identification* is the process of identifying external knowledge for analyzing and describing the company's knowledge environment.
- *Knowledge acquisition* refers to what forms of expertise the company should acquire from outside through relationships with customers, suppliers, competitors and partners in co-operative ventures.
- *Knowledge development* is a building block which complements knowledge acquisition. It focuses on generating new skills, new products, better ideas and more efficient processes. Knowledge development includes all management actions consciously aimed at producing capabilities.
- *Knowledge distribution* is the process of sharing and spreading knowledge which is already present within the organization.
- *Knowledge utilization* consists of carrying out activities to ensure that the knowledge present in the organization is applied productively for its benefit.
- *Knowledge preservation* is the process where the selective retention of information, documents and experience required by management takes place.

In addition, there are two other processes in the outer cycle, knowledge assessment and knowledge goals, which provide the direction to the whole knowledge management cycle:

- *Knowledge assessment* completes the cycle, providing the essential data for strategic control of knowledge management.
- *Knowledge goals* determine which capabilities should be built on which level.

Figure 1. Knowledge building block approach by Probst, Raub and Romhardt (2002)



Among other knowledge process models (Nonaka & Takeuchi, 1995; Laudon & Laudon, 2006; Jennex, 2007), the building block approach of Probst, Raub and Romhardt (2002) has the advantage that it is well known in European companies as well as in SMEs and furthermore it is a very unique and complete design of knowledge processes. Business process modeling (Hammer & Champy, 1993) has become a major research field in the information systems discipline in the last ten years. Davenport sees the term business process as 'a structured, measured set of activities designed to produce a specified output from a particular customer or market' (Davenport, 1995). The linkage of business process modeling and knowledge management is called knowledge process modeling. Richter-von Hagen et al. describes knowledge-intensive processes as sequences of activities based on knowledge intensive acquisitions and handling (Richter-von Hagen, Ratz, & Povalej, 2005). Edwards and Kidd (Edwards & Kidd, 2003, p. 124) named the following five characteristics to enforce the argument that knowledge management and business process management should be integrated:

- Knowledge management is important for business if the initiative implied an advantage for the customers. The idea to implement the customer's requests—may be internal or external—is the base for including the customer (Fink, Roithmayr, & Ploder, 2006).
- Knowledge does not follow the business borders. Business processes also model activities by global trading companies and build the base for modeling knowledge intensive processes.
- Knowledge management can only be efficient if it follows a structured model. Business processes are modeled by structured actions and they are necessary to deduce knowledge-intensive processes.
- The success of knowledge management depends on the measurement of knowledge. There exists a similarity to the measurement of business processes. The measurement of the knowledge potential provides a central position and biases the success (Fink, 2004).
- Knowledge management is affected by a holistic approach. Every part of the business process modeling is important for success but every aspect should be considered.

Data Collection for Knowledge Processes

At the beginning of our research was the identification of knowledge processes for SMEs. Therefore in the first step, the authors conducted a study with the objective to find the key knowledge processes—based on the framework of (Probst et al., 2002)—for SMEs. In a second step, the authors conducted empirical studies in order to identify which software products support the identified knowledge processes and can be used in practice. The interviews were conducted at the Department of Information Systems (University of Innsbruck) in 2005. The key objective of the expert interview was to analyze which of the eight knowledge processes from Probst et al. (2002) are relevant for SMEs. The data sample was 20 expert interviews which were conducted by the authors in summer 2005. Ten experts from science and ten experts from practice were asked about the most important knowledge processes in SMEs. The result of these expert interviews showed that SMEs are only determined by three key knowledge processes: (1) knowledge identification, (2) knowledge acquisition, and (3) knowledge distribution. In addition, for SME the concept of (4) knowledge disposal played a key role during the expert interviews and was extended as the fourth process called "knowledge preservation" indicating the disposal as well as actualization of knowledge. This knowledge process model for SMEs was the first step in the research work and the general research framework. The second step

was to find out which process can be supported by which knowledge method. The research method was a literature review for the identification of knowledge methods (Coakes & Clarke, 2006; Smolnik, Kremer, & Kolbe, 2007) in order to build a method repository for each knowledge process.

Figure 2 describes the four key knowledge processes with the corresponding method repositories for SMEs (Fink & Ploder, 2006; 2007a) illustrating the validated research framework through interviews by the experts.

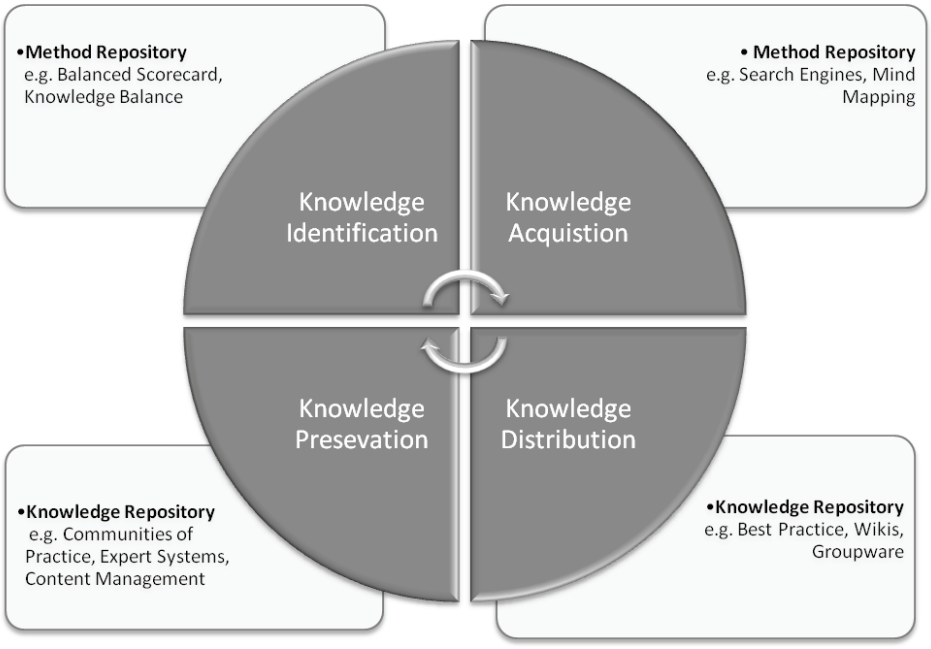
Quality Model (ISO/IEC 9126) for the Evaluation of Software Products

In a third step, the objective was to match a cost-efficient software product to each knowledge method which are usable in practice. In the research design the focus lies on Freeware and Shareware software products in order to fulfil the pre-setting of cost-efficient software support. The research method was an online research with the result of a list of evaluated cost-efficient software products. The evaluation of each software product was conducted by applying the ISO/IEC 9126 norm. The quality model of the norm (ISO/IEC 9126-1) is divided into two parts which are important for the evaluation of the software products to support knowledge methods:

- the internal and the external quality of the software
- the quality for use

The ISO norm lists five characteristics to evaluate software products: (1) functionality, (2) reliability, (3) usability, (4) efficiency and (5) assign ability. For each characteristic, a different number of items were assessed by a Likert scale from -2 to +2. The data sample of the quality model was

Figure 2. Theoretical concept of knowledge process model and method repositories for SMEs



more than 200 different software products. A key research finding was that some of the software products cannot be used in practice because their quality was not sufficient. Finally there were 45 software products which are efficient for use in SME.

Data Collection for Cost-Efficient Software Products

The 2006 survey was developed and executed by the authors and is an update and extension of the empirical study conducted in 2004-2005. Balmisse et al. (2007) present a knowledge management tool review including the vendor perspective. The article focuses on eight tool clusters. In comparison to our research, the authors focus primarily on the tool with the corresponding vendor side, while our research framework concentrates on the methods used in SMEs with a cost-efficient software support. So the objective of the empirical study was to find out which cost-efficient software products can support the efficient methods of the four knowledge processes. For this approach the authors differ between two categories of software. At the one hand side there are the standard software products which are already in use in SMEs (for example: MS Office, Internet Explorer, Operating System, etc.) and on the other hand there are software products like Shareware, Freeware and Open Source products characterized by the issue of cost-efficient software installation in SME. This described issue is the key objective of the empirical study. The research method for this study was the online questionnaire technique. The questionnaire was built with HTML, PHP and based on a MySQL database.

The data sample of 537 SMEs were the average allocated over the regional federal states of Austria, Switzerland and Liechtenstein to get a representative result for the whole sector and were opted stochastically. The total number of SMEs was 540,000. The online questionnaire was carried out in summer 2006 after a successful pre-test with 20 respondents. The online questionnaire was partitioned into three parts:

- Generally questions referring to the IT support and application of knowledge management within the enterprise itself
- Rating relevance of the methods concerning the four knowledge processes for SME and get an idea of the favor supporting software tool
- Information about future capital investment plans referring to knowledge management

The return quote of the survey was 40%. This means that 220 SME filled out the questionnaire. The failure rate was calculated as 6.63%. So, all statements out of the survey are correct at a percentage of 93.61%. In the following section the research findings of the methods and the supporting software tools are presented and discussed. The knowledge toolkit for SMEs integrates processes, methods and software tools in a decision support framework.

RESULTS

The distribution of industries can be described as follows. Thirty percent of the SMEs were from the industry sector and 22% from the consulting and information technology sector. The retail sector was represented by 13% and the trade and handcraft sector by 19%. The rest of 21% were divided to banks and insurances with 9%, transportation 2% and Tourism 10%. Fifty-seven percent of the SMEs already use knowledge management and 85% of the SMEs use a connected infrastructure. A Web space is (hosted intern or extern) available in 78% which is necessary to deal with software products which need such an IT-infrastructure.

Mapping of Cost-Efficient Software Products with Knowledge Processes

Table 1 gives an overview of all methods supporting the four knowledge processes for SMEs and the corresponding cost-efficient software products (Fink & Ploder, 2007c). The ranking of each method is the calculated value based on the Likert scale ("absolutely adequate": +2 pt. – "not adequate": -2 pt.). The "ISO ranking" illustrates the assessment of the software based on the quality model of the ISO/IEC 9126 norm ("absolutely appropriate": +2 – "not appropriate´: -2). For example, the Software Tools Gama for supporting business games is ranked with 15 points in the ISO/IEC 9126 and 75 of the data sample find Gamma is a good tool to support business games. The absolute frequency of naming of the software through the respondents can be seen in the last column (ranking survey). The naming of "no cost-efficient software support" indicates that only high-priced software products are available on the market.

Knowledge balance (92) was ranked highest among the methods for the first process of the *identification of knowledge*. Fifty-six percent of SMEs think that this is the best method. Further methods are the balanced scorecard (89) and the Skandia navigator (74). The methods market-asset value-method (-5) and Tobin`s q (-15) were rated by less than 30% to be of good use in SMEs.

Brainstorming (225) and knowledge network (203) are popular methods for the *knowledge acquisition*. Mind mapping (195), e-mail systems (134), scenario technique (126) and system simulation (98) are also suitable methods for this knowledge process, while business games (91) are also a possibility. The method of "Synektik" was rated very low because of its complexity. The favorite for the knowledge acquisition is the search engine (232) with over 70% for efficient use in SMEs. In this case, the Google desktop search engine was the prior selection software. Sixty percent of the respondents chose e-mail systems which can be supported, for example, by the software Thunderbird1.5. For brainstorming a practical tool is Concept X7, while for mind mapping the tools Free Mind (42%) and Think Graph (41%) were rated highly. As support software to a business game, 64% rated Gamma as a possible software tool.

As illustrated in Table 1 the methods e-mail system (185), handbook FAQs (159), communities of practice (152), groupware (139), questionnaire (110) and best practice (108) are the favorites for the k*nowledge distribution*. It has to be pointed out, that the methods micro article (2) and chat room (29) are rated not as well in the survey. The software products for the methods of transferring knowledge are InfoRapid supporting knowledge maps, EasySurvey supporting questionnaire, Skype and MSN supporting chat room, eGroupware 1.2 and AlphaAgent 1.6.0 supporting groupware, CUCards 2000 supporting checklists and Pegasus Mail, Thunderbird 1.5 and Amicron Mailoffice 2.0 for the support of e-mail systems.

Databases (242) are a recognized method of *the knowledge preservation process*. Eighty percent of the SMEs think that they will organize their knowledge with databases. Mind mapping (200), document management system (195) and checklists (164) are further efficient methods. Content management systems (126), project review (122), expert systems (74) and conceptualization (40) are methods which can be chosen but are not the prior choice. Neural network (-10) is not an adequate method for preserving knowledge. There were many different software products to support this process. MySQL is the favorite database software followed by the MSDE from Microsoft. Document management can be realized by Office Manager, UDEX dotNETContact or QVTutto.

Table 1. Ranking of methods and cost-efficient software products (Fink & Ploder, 2007a)

	Ranking	Supporting cost-efficient software products	ISO Ranking	Ranking Survey
Knowledge Identification				
Knowledge Balance	92	no cost-efficient software product, Office similar products		
Balanced Scorecard	89	no cost-efficient software product, Office similar products		
Skandia Navigator	74	no cost-efficient software product, commercial Software		
Market - Asset Value - Method	-5	no cost-efficient software product, Office similar products		
Tobin's q	-15	no cost-efficient software product, Office similar products		
Knowledge Acquisition				
Search Engine	232	Google Desktop Search; MSN Toolbar; Yahoo Desktop Search	not possible	25; 12; 10
Brainstorming	225	Brainstorming Toolbox; Concept X7	6;17	44; 88
Knowledge Network	203	no cost-efficient software product		
Mind Mapping	195	Free Mind; Think Graph, Tee Tree Office	16; 12; 8	69; 53; 28
E-mail System	134	Pegasus Mail; Thunderbird Mail; Amicron Mailoffice 2.0	21; 21; 12	63; 165; 26
Scenario Technique	126	no cost-efficient software product, Office similar products		
System Simulation	98	no cost-efficient software product, commercial Software		
Business Game	91	Gamma	15	75
Synektik	-17	no cost-efficient software product, commercial Software		
Knowledge Distribution				
E-mail System	185	Pegasus Mail; Thunderbird Mail; Amicron Mailoffice 2.0	16; 12; 8	63; 165; 26
Handbook FAQs	159	no cost-efficient software product, Office similar products		
Communities of Practice	152	no cost-efficient software product, Office similar products		
Groupware	139	eGRoupware1.2; AlphaAgent 1.6.0; Tiki CMS - Groupware	15; 14; 16	40; 26; 24
Questionnaire	110	Easy Survey	10	61
Best Practice	108	no cost-efficient software product, Office similar products		
Checklist	103	CUEcards 2000	8	128

continued on following page

Experts System	74	KnowIT; KnowME	10; 7	38; 52
Conceptualization	40	no cost-efficient software product		
Neural Network	-10	no cost-efficient software product, commercial Software		

Investment Allocation

Seventy-five percent of the respondents assumed that they are still using knowledge management in their SME. As shown in Figure 3, the attendance to invest into knowledge management in the next year exists with 60% and up to 40% cannot imagine to invest into knowledge management in the next year. Twenty percent of SMEs are planning an investment in the future and want to spend less than 500 euro, 58% will spend between 500 euro and 3,000 euro and only 22%will invest more than 3,000 euro.

SME Knowledge Toolkit

The SME knowledge toolkit (Figure 4) is one of the results of our empirical research. Tiwana (2002) discusses in her book *The Knowledge Management Toolkit* a 10-step roadmap for implementing knowledge management in a company. The key objective of the toolkit is to guide a company through the complex process of analyzing the infrastructure, designing the knowledge system and linking the business strategy to knowledge management and make a performance evaluation. Jashapara (2004, p. 92) uses the term knowledge management suite that should offer a multitude of knowledge management systems in order to build an individualized toolset. The toolkit developed by the authors is an implementation for portraying knowledge processes, methods and software tools for SMEs. Therefore, the use of the toolkit can reveal the gap between the defined knowledge processes and implemented knowledge methods that could trigger further evidence to use different knowledge methods or to rearrange the knowledge processes. The explicit identification of knowledge processes allows the user of the toolkit to match knowledge methods with cost-efficient software products that fit into the culture of SMEs. At the

Figure 3. Investment allocation in SMEs for knowledge initiatives

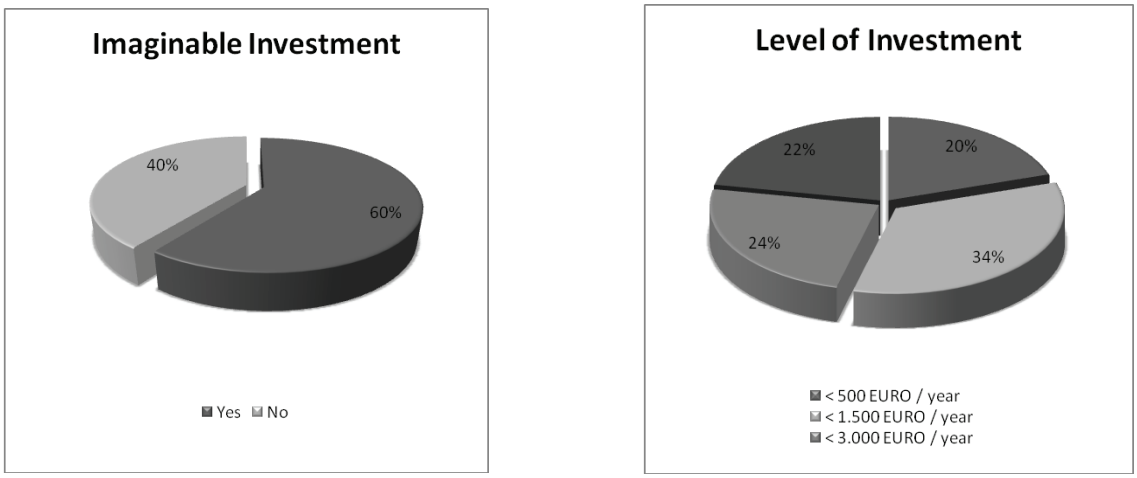

Figure 4. SME knowledge toolkit

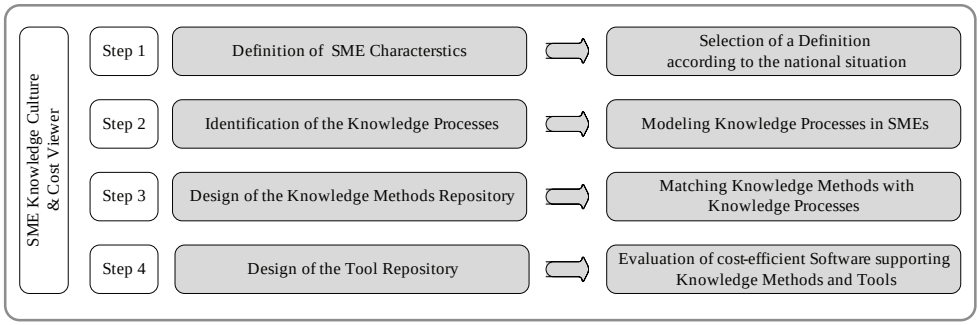

same time, the knowledge toolkit calculates the estimated costs for changes. The SME knowledge toolkit (Figure 4) supports all aspects of knowledge management relevant for SMEs and is divided into four key steps:

Step 1: Definition of the characteristics by applying the national limitations and definitions
Step 2: Identification of the knowledge processes and modeling of these processes in the SME context
Step 3: Designing a knowledge method repository which enables SMEs to match the methods with the supporting knowledge processes
Step 4: Designing of a software repository which helps to evaluate cost-efficient software products for knowledge management in SMEs

These four key steps are supported by the knowledge culture in an SME and by a knowledge cost viewer which has the function of a controlling instrument. The SME knowledge toolkit is tailored toward the special needs of SMEs during knowledge management initiatives.

DISCUSSION AND FUTURE RESEARCH

Knowledge process modeling for SMEs uses the building block approach from Probst, Raub and Romhardt (2002) and models corresponding knowledge methods for the SME-domain. A significant emphasis in this empirical study has been the development of a flexible and usable knowledge management toolkit to implement knowledge initiatives in SMEs. This chapter addresses one of the currently perceived issues surrounding knowledge management, namely the lack of defining key knowledge processes for SMEs to handle knowledge methods in specific settings. The study has drawn on an extensive review of the literature as well as reported on empirical studies concerning the Austrian and Swiss SME sector.

Social Impact to SMEs

Even if the information technology infrastructure is a key dimension of knowledge management, the social and cognitive aspect may also be considered. Cognitive activity takes place in a complex, information-rich, and ever-changing environment. Tomasello (1999) notes that all human beings share their cognitive skills and knowledge with other individuals. The try to understand other persons, changes the way of interaction and social learning. A successful implementation of knowledge management only can be achieved in a culture (Holden, 2002) that supports knowledge sharing and transfer. Nakra (2000) addresses the issue that a knowledge culture is the most important value for the implementation of knowledge management because one important aspect of knowledge management is having a culture that fosters collaboration and sharing. Organizations often fail to acknowledge that it is the people, not technologies, that are the source of knowledge" (Nakra, 2000, p. 54). Organizational knowledge resides in the culture, structure, and individuals who make up the organization.

Especially in SMEs the success depends on the social system in which a knowledge worker operate. SMEs need a culture that facilitates a knowledge transfer through a more human factor because knowledge workers want to share their knowledge through communication and interaction. The social ecology of the company drives people's expectations, defines their motivation to share knowledge and pursues actions to interact with others inside or outside the organization. Ein-Dor (2005, p. 848ff) defines taxonomies of knowledge and sees the social-individual dimension as a key success factor to knowledge diffusion. A similar view is presented by Alavi und Leidner (2001). SMEs need a culture that facilitates a knowledge transfer through a more human factor because knowledge workers want to share their knowledge through communication and interaction (Trompenaars & Hampden-Turner, 2006). The use of information technology, especially Web sites, is recognized as a critical success factor for knowledge management initiatives in the SME sector (Wong & Aspinwall, 2005). Wong (2005) sees information technologies as a key enabler for the implementation of knowledge management, and considers in the development of a knowledge management system factors such as the simplicity of technology, ease of use, suitability of users' needs, relevancy of knowledge content, and standardization of a knowledge structure as key factors for knowledge diffusion. The SME culture greatly influences the communication processes inside and outside the organization. The impact of the culture to networking processes is highly significant. Skyrme (1999, p. 15) lists two fundamental descriptions of networking:

- Networking organizations are less about organizational structures per se, and more about the informal human networking processes

- The technology of computer networking undergirds and enhances human networking.

Knowledge networking is a dynamic process in which knowledge, experiences, and expertise are shared, developed, and evolved. A knowledge-sharing culture can be developed through human interaction supported by information technology to foster new and innovative knowledge. Knowledge networking is connectivity to achieve new levels of interactivity, usability, and understanding across organizations and communities. The first results of an empirical study conducted by the authors (Fink & Ploder, 2007b) indicate that the social view is almost not taken into consideration for European SMEs. The focus lies primarily on the technical solution of knowledge management, meaning that an IT support is essential for knowledge initiatives.

Therefore, future research will direct into the development of a framework for SMEs that integrates the information technology view with the social-cognitive view. One future problem for the implementation of different software products are the interfaces of the different applications. With service-oriented architecture (SOA), it would be possible to solve this problem of interoperability and the problem of security (Kang, Kim, Lo, Montrose, & Khashnobisch, 2006). Future research will deal with SOA and should also consider open source software (OSS) (Ploder & Fink, 2007) and extending the knowledge toolkit for SMEs.

ACKNOWLEDGMENT

This chapter is an extended version of the paper presented at the International Resource Management Conference (IRMA) May 2007 in Vancouver. Sincere thanks to Dr. Murray Jennex for the opportunity of consideration it in the *International Journal of Knowledge Management.*

Chapter 3.2
Information Communication Technology Tools for Software Review and Verification

Yuk Kuen Wong
Griffith University, Australia

INTRODUCTION

While information communication technology (ICT) can be considered a well-established discipline, software development projects are still prone to failure. Even if a software project is not classified as a failure, the general level of software quality leaves room for much improvement. It has been suggested that one of the most prevalent and costly mistakes made in software projects today is deferring the activity of detecting and correcting software problems until the end of the project. Hence, the cost of rework in the later stages of a project can be greater than 100 times the project costs. About 80% of avoidable rework comes from 20% of defects. As a result, techniques such as software review for improving software quality are important.

Software review (inspection/verification) was originally introduced by Fagan (1976). The review process essentially includes six major steps:

1. **Planning:** Organize and prepare the software review, typically for preparing the review materials and review procedure, forming review team and scheduling review meeting, selecting review participants, and assigning roles.
2. **Overview:** Author explains overall scope and the purpose of the review.
3. **Individual preparation:** Individual reviewers analyze and review the software artefact.
4. **Group review meeting:** Find errors, sometimes also called "logging meeting." Review teams correct and the reader summarizes the work.
5. **Rework:** Defect correction, which involves the author in resolving problems by reviewing, revising, and correcting the identified defect or by decreasing the existence of errors of the software artefact.
6. **Follow-up:** Validate the correction quality and decide if re-inspection is required

Since Fagan (1976) introduced software review and verification as an important technique to assure the quality of software projects, researchers have investigated ways to improve software review performance. It has been suggested that ICT software review tools are one of the important elements to the support software review process. This article overviews ICT tools to assist software review and verification during this software review process. The overall objective of this article is to identify various ICT tools that support software review and verification. This includes a discussion of the importance of software quality and identifies ICT tools for effective software reviews and verification.

ICT TOOLS FOR SOFTWARE REVIEW AND VERIFICATION

Intelligent Code Inspection in a C Language Environment (ICICLE)

The ICICLE (Intelligent Code Inspection in a C Language Environment) is the first published software review tool, which was developed at Bellcore (Brothers, Sembugamoorthy, & Muller, 1990). The ICICLE tool is designed to support code review and assists reviewers in both individual preparation and group meetings. ICICLE provides a synchronous communication support to group meetings. It has been argued that traditional code review meeting is manually documented (i.e., using paper and pen to record defects detected). This documentation procedure is very time consuming, tedious, and could be inconsistent recording (Brothers et al., 1990). One of the aims of this tool helps software reviewers to find obvious defects. Brothers and his team (1990) suggested that ICICLE provide several benefits to code review:

- To detect routine sorts of errors, with the goal of freeing the code inspector (reviewer) to concentrate on verifying the correct implementation of requirement, specifications, and designs.
- To offer various forms of knowledge about the code being inspected (reviewed), including domain and environment knowledge, and information from various forms of analysis such as cross-referencing.
- To allow code inspectors (reviewers) to easily traverse source code in a windowed environment instead of riffling through hard copy from many different files.
- To render the code inspection (review) meeting paperless through a shared window interface which enables the code inspectors (reviewers) to fulfill their roles electronically.

The ICICLE tool consists of two phases in the review process: the individual review and group review meeting. The group review meeting takes in the same location/venue, usually a reviewers' seat at nearby computers. An individual reviewer allows entering comments on each line of code. According to MacDonald, Miller, Brooks, Roper, and Wood (1995), the researcher found that "the computer supported meeting format appeared to cause substantial changes in the dynamics of the code inspection (review) meeting." In other words, the procedures of the code review meeting using ICICLE can enable roles during the group meeting process (Brothers et al., 1990). For example, the additional duty of a moderator is to record statistics relating to coding defects discovered during code review. The reader can direct the attention of the other reviewers to areas of interest in the source code. The scribe's records must be agreed on by the review team. The author should present in the code review meeting and answer the reviewers' question. Any additional reviewers can participate and share meeting discussions.

Scrutiny

Scrutiny is an online collaborative software review tool, which was developed at Bull HN Information Systems in conjunction with the University of Illinois (Gintell, Houde, & Mckenney, 1993). It is a synchronous meeting review tool. It is one of the early comprehensive collaborative process software review tools (MacDonald et al., 1995). Scrutiny currently supports text documents only.

Scrutiny can be used in the formal review process, and it supports multi-users review but does not support for rules and checklists. It provides a "petri-net based process modeling language" that allows the system to implement alternative software review methods, such as a "shared preparation" phase in which reviewers have access to each other's preliminary findings (Gintell et al., 1993; MacDonald et al., 1995). However, in comparison with the ICICLE, the Scrutiny usage can depart radically from manual software review processes, such as geographically distributed software reviews (MacDonald et al., 1995).

Collaborate Software Inspection (CSI)

Collaborate software inspection (CSI) was built and used in a case study to compare online distributed computer-mediated software review meetings vs. face-to-face software review meetings at the University of Minnesota (Mashayekhi, Feulner, & Riedl, 1994). As with other software review tools, the CSI provides the similar process characteristics of Humphrey's software review method with hypertext capability. CSI is developed for group review meetings in the (1) same time and place, (2) same time and place, (3) same time and different place, and (4) different time and same place. CSI supports both asynchronous and synchronous activities that include materials distribution, individual preparation/individual review, group review meeting, recording, and reporting (Mashayekhi et al., 1994).

InspeQ

InspeQ was developed to support the phased software review process (Knight & Myers, 1993). The InspeQ was executed on "Sun 3, Sun 4, and IBM RS/6000 computers running various forms of Unix and the X-window display system and the OSF/Motif widget set" (Knight & Myers, 1993). Although the InspeQ achieves the goals of efficiency and rigor in the phased review process, it is not viewed as essential to the "phased inspection" method (MacDonald et al., 1995). Similar to other software review tools, InspeQ provides numbers of facilities to support software review process. These include work product display (views the documents), checklist display (allows the status of each checklist to be displayed and modified), standard display (review rational and a detailed descriptions), highlight display (helps locating particular aspects of the documents), and comments display (comments on the documents) (Knight & Myers, 1993).

CSRS

CSRS is developed to support computer-mediated communication formal software review process (Johnson, 1994). The CSRS is heavily used in academic research and laboratory experiments studies. The goals of CSRS is to reduce the human effort in review process by conducting software review incrementally during the development and provide online capabilities to collect metrics (Stein, Riedl, Harner, & Mashayekhi, 1997). The CSRS is similar to Scrutiny; it provides an internal process modeling mechanism to support a variety of review methods. CSRS's primary method is FTArm, which "is unique among methods by being designed explicitly to support properties of computer-mediated communication and review"

(Johnson, 1994). CSRS automatically collects data (e.g., number of defects/issues found, comments made, time spent on software review, starting time, finishing time, event logs, etc.). Another feature of CSRS is that it supports a variety of software review processes and handles several types of documents and languages.

Requirement Traceability Tool (RADIX)

Requirement traceability refers to the "ability to describe and follow the life of a requirement, in both a forwards and backward direction" (Gotel & Finkelstein, 1994). The requirement traceability tool (RADIX) is designed for verifying software requirements (Yu, 1994; Yu, Smith, & Huang, 1990). A requirement tracing method is a systematic method to assist 5ESS Switch scientist and engineers to deliver quality software (Yu, 1994).

Asynchronous Inspector of Software Artefacts (AISA)

Asynchronous Inspector of Software Artefacts (AISA) was the early Web-based software review tool (Stein et al., 1997). AISA supports asynchronous and distribution software review as well as reviewing both textual and graphical documents (e.g., entity-relationship diagram or class diagram) (Stein et al., 1997). The AISA Web-based tools can be built using existing structures and were reasonably easy to develop.

Web Inspection Prototype (WiP)

Web inspection prototype (WiP) is another Web-based tool, which provides a set of functions for distributing the requirement documents to be reviewed (Harjumaa & Tervonen, 1998). The WiP is developed to support distributed software review processes. It utilizes the WWW to distribute the review document, tailors the software review process model according to the development environment, can assign roles, adds or removes a checklist, allows reviewers to add, modify, and remove comments, has searching, cross-referencing, e-mail notification, combining comments/annotations using hypertext and reporting capabilities, and generates metrics and statistics summary (Harjumaa & Tervonen, 1998).

InspectA

InspectA is a completed automation tool, which allows the whole software review process to be automated (Murphy & Miller, 1997) from planing, such as selecting a moderator and communications between software review team, through follow-up stage, where the moderator verified and finalized that all the defects raised during the software review have been resolved.

InspectA is an e-mail-based and asynchronous tool for software review (Murphy, Ferguson, & Miller, 1999). The tool is not based on the World Wide Web approach (all reviewers can view other individual reviewer comments). The argument is when reviewers can view other reviewers members defect lists during the individual preparation that they may discourage (Murphy et al., 1999). Another reason is that reviewers may focus or discuss other reviewers' comments rather than focus their own individual reviews (Murphy et al., 1999). Miller and their team believed that e-mail-based tools provide a number of advantages. These include (Stein et al., 1997, p. 108):

- **Sharing information:** Allow exchange and sharing information via e-mail tool
- **Threads of discussion:** Allow individual reviewers to contribute and free feel to comments during the individual preparation
- **Visual cues:** Easy to format in the document such as bold or italics
- **Train of thought:** Offer other reviewers to response and reply

- **Reaching a consensus:** Voting can be sent via e-mail tool
- **Coordination:** Moderator can easily send information to all reviewers
- **History:** Allow reviewers to keep a record of their comments

HyperCode

HyperCode is another one of the earliest Web-based software review tools (Perpich, Perry, Porter, Votta, & Wade, 1997). It uses the common gateway interface (CGI), and the HyperCode system allows software reviewers using WWW browsers for software review (Perpich et al., 1997). It is used for code review and very similar to the WiP. Reviewers can comment on the Web, and material is delivered via the Web (Perpich et al., 1997). The process contains only asynchronous phases, and other reviewers are able to see the comments, so there is no software review meeting required when in HyperCode (Perpich et al., 1997). After individual review, the results are collated together into a report containing links from the original material to the comments (Perpich et al., 1997).

Perry and his team (Perry, Porter, Wade, Votta, & Perpich, 2002) suggested that there are four primary differences between paper-based and HyperCode software review processes. First, HyperCode provides an automated approach to the support software review process; this can reduce time and amount of review effort. Second, notification between software review team can be a useful e-mail tool. Third, all comments or annotations are visible to all participated software reviewers in the whole review process. Fourth, there is no meeting requirement needed in the HyperCode process. In other words, the review discussion is asynchronous communication.

ASYNCHRONOUS/SYNCHRONOUS SOFTWARE INSPECTION SUPPORT TOOL (ASSIST)

Asynchronous/Synchronous Software Inspection Support Tool (ASSIST) is built to provide both individual and group software review (MacDonald et al., 1995). It can perform both synchronously or asynchronously with either different place or same place meeting. It uses a costumed designed modeling language, the Review Process Definition Language (RPDL) and a flexible document type system to allow support of any software review process (MacDonald & Miller, 1999). ASSIST is a client/server architecture, where the server is a central database to store documents and data. Table 1 shows details of four features of the ASSIST tool.

Fine-Grained Software Inspection Tool/CodeSurfer

The fine-grained software review tool is designed for "exposing the results of sophisticated whole-program static analysis" (Anderson, Reps, & Teitelbaum, 2003) to the software review. This is also known as CodeSurfer. The idea was originally developed from the "dependence graphs" which applications activities include parallelization (Burke & Cytron, 1986), optimization (Ferrante, Ottenstein, & Warren, 1987), program testing (Bates & Horwitz, 1993), and software assurance (Horwitz & Reps, 1992). A description of how this tool work is summarized in the following section.

CORD

The CORD is developed for increasing the consistency between requirements and a detailed design (Chechik & Gannon, 2001). The CORD creates a "finite state abstraction" of a detailed design and checks it against a set of properties

automatically generated from the requirements (Anderson et al., 2003). Its features are similar to other static analysis tools such as CodeSuper. The aim of CORD is to "simplify the verification of properties of program; this system abstract the forms of their formal specification notations or create abstract models from program that could be analysed with state-exploration" (Chechik & Gannon, 2001, p. 669).

Agent-Based Software Tool

Agent-based software tool in code review is designed by Chan (2001). Chan (2001) recently proposed the agent-based software tool that can help reduce the cost and increase the number of defects detected in the software review process. The main focus of the intelligent agent software tool (Chan, 2001) is to:

- Automate as much of the paper work and administrative tasks as possible
- Enable the inspection (review) to perform inspection (review) according to their schedules. This aims to reduce the inspection (review) interval, and thus reducing the turn around time for obtaining inspection (review) results
- Provide as much assistance to the inspector (reviewer) as possible during preparation
- Maximize the number of major faults found while keeping the time costs of the process low

INTERNET-BASED INSPECTION SYSTEM (IBIS)

Internet-based inspection system (IBIS) is developed to support geographically distributed software review (Lanubile & Mallardo, 2002). IBIS was originally designed by Cavivano, Lanubile, and Visaggio (2001). This tool is another Web-based application which is "based on a lightweight architecture to achieve the maximum of simplicity of use and deployment" (Lanubile & Mallardo, 2002). The IBIS can support Fagan's Software Review Process. There are a several advantages of deploying IBIS (Lanubile & Mallardo, 2002):

- IBIS is Web-based software review tool; it allows reviewers access from their desktop. This could improve the chance of reviewers participating in software review
- It allows the software review to be performed in different places, even in different countries
- Allow different experts participate in the software review process. Those experts could from outside the organization or different department.

VisionQuest

VisionQuest aims to support the experimentation formal anonymity technical review (Vitharana & Ramaurthy, 2003). The advantages of anonymity in group collaboration are (Er & Ng, 1995):

- Each reviewers has equal weight
- Avoid the dominance group or status effect during the review process
- Since the comments are made by an anonymous person, criticisms are the issues rather than people
- Voting is anonymous; the final decision is more likely to be objective and based on merit

FUTURE

A number of computer support tools have been developed to support the software review meeting process. Many tools provide documentation facilities that allow software review documents to be shared across networks, browsed online,

and edited by reviewers. The current trend of software review is for using software review tools to the support software review process. Past research has shown a spectrum of advantages of using software review tools supporting technical review. First, a computer-support tools review environment can reduce paper work and clerical costs, decrease error rates of recording review meeting and comments, and allow computerised data collection and data analysis. Software review tools can integrate the review method with other components of the specific software development method such as asynchronous review and facilitating both metrics collection. Companies will adopt software review tools simply because of such potential benefits over manual software review techniques.

CONCLUSION

In summary, this article described modern software review tools and techniques and the different types of software review tools and how they work. To achieve better software review performance, it is important to understand use of inputs and the software review process.

KEY TERMS

Asynchronous Review: The review activities can be performed at the same time. Asynchronous review must rely on the ICT tools supported.

Defects: The term "defect" is defined as any issue or problem that does not meet the requirements.

Fagan Inspection: Software review was originally proposed by Michael Fagan at IBM in the early 1970s. Fagan's software review and forms of review structures. Fagan's software review includes six-step review processes: planning, overview, preparation, group meeting, re-review, and follow up.

Information Communication Technology (ICT) Review Tools: Tools provide documentation facilities that allow software review documents to be shared across networks, browsed online, and edited by reviewers. The current trend of software review is for using software review tools to support the software review process.

Online Software Review: Online software review tools support some major functions: document support, individual preparation, and meeting support. It can meet online and share data and documents in flexible time, thus it may reduce time of review.

Software Review: Software review or inspection is one of the techniques for improving software quality. Software review is an industry-proven process for eliminating defects. It has been defined as a non-execution-based technique for scrutinizing software products for defects, deviations from development standards.

Software Verification: Aims to find and remove defects during the software development cycle.

Synchronous Review: All review activities in the synchronous software review happen in a linear fashion, and the meetings are located in same place at the same time.

Chapter 3.3
SurveyTracker E-Mail/ Web Survey Software

Eun G. Park
McGill University, Canada

ABSTRACT

This chapter offers an introductory description of SurveyTracker software. Comparisons are made to competitor software programs. The central focus is an explanation of the functions, features, and advantages of the software application.

INTRODUCTION

SurveyTracker is one of the most popular software applications in the current field of online survey, developed from Pearson NCS Inc., and currently registered from Training Technologies, Inc. This company provides the integrated and powerful SurveyTracker line of software applications on survey, including SurveyTracker, SurveyTracker Plus, SurveyTracker E-Mail/Web, SurveyTracker Plus E-Mail/Web and Survey-by-Disk. One advantage of using this comprehensive software is to provide many functions as one module, and offer flexibility and extensibility for prewritten survey modules, specialized training, survey design and distribution services, and survey consulting.

As an introductory description of SurveyTracker, this chapter explains the functions, features, and advantages of the software application. The software supports functional requirements that educational software needs, including survey authoring and design, interface, data management, and multiple electronic and paper data collection technologies. It can especially integrate all forms of data collected from e-mails in text and images, the Internet, networks, and scanning forms. This software can be easily applicable to a variety of survey-based research on schools, higher education, government, business, and healthcare.

FUNCTIONS

The latest versions of the SurveyTracker line of software are SurveyTracker E-Mail/Web 4.5, SurveyTracker Classic 4.5, and SurveyTracker E-Mail/Web Network 4.5. These software applications support several advantageous features in terms of interface, data management, reporting, and distribution.

Interface. SurveyTracker is based on user-friendly and graphic-based design so that users can design a survey form with the overview, questions, notes, sections, and a summary, quickly and easily with a simple click of the mouse. Users can get screen views as designed and displayed in the mode of what-you-see-is-what-you-get in 32-byte interface. Regarding editing, the software is flexible, with text-editing functions including character sets, fonts, color, size, and other editing settings. Graph provides enhanced color support, a variety of data marker shapes, and improved flexibility. Convenient shortcuts and standard text-editing functions allow survey designers to create and modify texts fast. It displays overall updates of ongoing projects. The built-in question library is chosen by a drag-and-drop interface. The built-in image library also provides quick access to commonly used graphics. Users can create global layout settings for all current and future surveys.

Data collection and management. File import is fast and easy from the previous version or other software applications. Data and report export is easy for use in Microsoft Office and other products. Automatic recording of returned surveys is possible to directly send reminder messages. The survey forms and reports are printed, distributed, collected, and read back into SurveyTracker. There are many options for creating, managing, distributing, responding to, analyzing, and reporting from response data. Spreadsheet-style data collection for rapid manual data entry can be changed to different layouts. The data collection screen offers instant electronic survey retrieval, and convenient manual response entry for paper-based surveys. Open-ended questions can be coded for quantitative data analysis, or printed out verbatim in a report. Regarding coding, the built-in codebook supports up to 300 codes per question, as defined as single response or multiple response for multiple code entry. Automatic filtering and batch reporting are possible for the Web. It is easy to customize score values after data collection. Identification bar codes on scannable forms and unique lithocodes on each survey are used to trace printed forms. A number of statistical analyses are built in, such as frequency, variance, minimum, sum, maximum, skewness, range, correlation, chi-square, standard deviation, significance, and so on. SurveyTracker can analyze through manual configuration or autofiltration for maximum reporting flexibility. Tables and graphs for reports are used with multitable forms. All distribution is handled by conducting multiple distributions. E-mail responses can be sent directly through e-mail systems.

Access and retrieval. A single source database holds all project information for faster access and better organization. The message library allows users to store and retrieve survey and report notes/instructions, as well as distribution.

SYSTEM REQUIREMENTS

To install SurveyTracker, systems require an IBM PC or compatible with at least a Pentium® 200 MHz processor (Pentium class processor running at 300MHz or better strongly recommended), at least 64MB RAM (128MB or more is strongly recommended), in Microsoft Windows 95, 98 SE, ME, Windows NT® or 2000 (Professional), at least 100MB hard disk space (more may be needed depending on the size of the survey and the number of respondents).

FEATURES FOR EDUCATIONAL RESEARCH

SurveyTracker has competitive advantages over the following three aspects:

Flexibility. Most of all, SurveyTracker can support a variety of survey forms. It is compatible with traditional paper surveys, e-mail surveys, and Web surveys. Each respondent opens a program on the disk to access and complete the survey. When the survey is returned, the survey administrator reads it into SurveyTracker. Survey answers are created in SurveyTracker and then converted to scannable forms, using the fully integrated features of the other software application. In network environments, surveys are possible to distribute on network or placed on a disk individually. Surveys can also be carried in intranet or extranet. Paper surveys directly support optical mark recognition scanners and data sheets.

Compatibility. Different survey forms are compatible with Web survey forms. For example, disk surveys, and html-based e-mail surveys deliver the same look and feel directly to the respondent's e-mail inbox. The software works directly with a personal computer's e-mail system to send out the survey questionnaire in text-based messages, form-based messages, or html-based message.

Extensibility. The new SQL database engine handles millions of records for larger projects, audience lists, and more extensive reporting. Audience supports up to 200 fields per record. It is easy to enter a list of potential respondents directly, and to import an existing list from another software program up to 1.6 million people in an audience list. The audience list can be narrowed down as well. Users can create surveys with six scales per question up to 300 choices per scale. SurveyTracker includes a comprehensive library of prewritten questions and scales. Scale types in SurveyTracker include horizontal numerical, Likert, multiple choices, semantic differential, fixed sum, forced ranking, ordinal, and paired comparison.

COST AND LOCATION

Information on price and additional consulting services is available at the Web site of Training Technologies, Inc (http://www.SurveyTracker.com).

COMMENTARY

Currently, there are other survey software applications that are available in the market. For example, popular alternatives include WebSurveyor 5.0, Perseus SurveySolutions, Ultimate Survey, and WebSurveyor. Among them, SurveyTracker is recommended as a better way to integrate all forms of separate surveys, and to maximize many compatible functions. Next step will be needed to examine their comparative usage and implementation in depth on how to apply these software applications' functions to research on schools, higher education, government, business, and healthcare for ultimate results.

KEY TERMS

Compatibility: The ability of two or more systems or components to perform their required functions while sharing the same hardware or software environment.

Extensibility: A property of a system, format, or standard that allows changes in performance or format within a common framework, while retaining partial or complete compatibility among systems that belong to the common framework.

Flexibility: The ease with which a system or component can be modified for use in applications or environments other than those for which it was specifically designed.

Online Survey: To conduct a statistical survey by means of online tools or methods in the procedures of survey, such as data gathering, data analysis, summary reports, distribution of results, and so forth.

What-You-See-is-What-You-Get (WYSIWYG): A user interface that allows the user to view something very similar to the end result, while the document or image is being created.

Chapter 3.4
A Survey of Selected Software Technologies for Text Mining

Richard S. Segall
Arkansas State University, USA

Qingyu Zhang
Arkansas State University, USA

ABSTRACT

This chapter presents background on text mining, and comparisons and summaries of seven selected software for text mining. The text mining software selected for discussion and comparison in this chapter are: Compare Suite by AKS-Labs, SAS Text Miner, Megaputer Text Analyst, Visual Text by Text Analysis International, Inc. (TextAI), Magaputer PolyAnalyst, WordStat by Provalis Research, and SPSS Clementine. This chapter not only discusses unique features of these text mining software packages but also compares the features offered by each in the following key steps in analyzing unstructured qualitative data: data preparation, data analysis, and result reporting. A brief discussion of Web mining and its software are also presented, as well as conclusions and future trends.

INTRODUCTION

The growing accessibility of textual knowledge applications and online textual sources has caused a boost in text mining and Web mining research. This chapter presents comparisons and summaries of selected software for text mining. This chapter reviews features offered by each package in the following key steps in analyzing unstructured qualitative data: data preparation including importing, parsing, and cleaning; data analysis including association and clustering; and result presenting/reporting including plots and graphs.

BACKGROUND OF TEXT MINING

Hearst (2003) defines text mining (TM) as "the discovery of new, previously unknown information, by automatically extracting information from

different written sources." Simply put, text mining is the discovery of useful and previously unknown "gems" of information from textual document repositories. Also Hearst (2003) distinguishes text mining from data mining by noting that with "text mining the patterns are extracted from natural language rather than from structured database of facts." A more technical definition of text mining is given by Woodfield (2004) author of SAS Notes for Text Miner, as a process that employs a set of algorithms for converting unstructured text into structured data objects and the quantitative methods used to analyze these data objects.

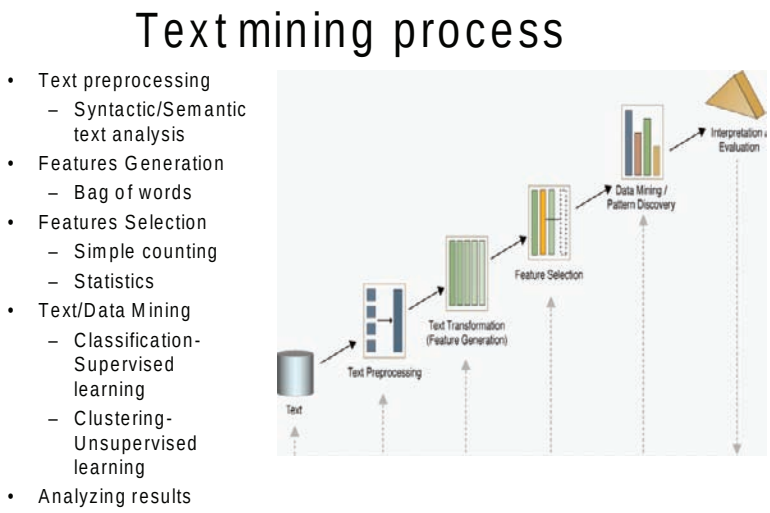
Text mining (TM) or text data mining (TDM) has been discussed by numerous investigators that include Hearst (1999), Cerrito (2003) for the application to coded information, Hayes et al. (2005) for software engineering, Leon (2007) for identifying drug, compound, and disease literature, and McCallum (1998) for statistical language modeling. Firestone (2005) emphasizes the importance of text mining in the future knowledge work. Romero and Ventura (2007) survey text mining applications in the educational setting. Kloptchenko et al. (2004) use data and text mining techniques for analyzing financial reports. Mack et al. (2004) describe the value of text analysis in biomedical research for life science. Baker and Witte (2006) discuss the mutation mining to support activities of protein engineers.

Uramoto et al (2004) utilized a text-mining system adopted from that developed by IBM and named TAKMI (Text Analysis and Knowledge Mining) for use with very large text biomedical text documents. In fact the extension of TAKMI was named MedTAKMI and was capable of mining the entire MEDLINE of 11 million biomedical journal abstracts. The TAKMI system allows extracting deeper relationships among biomedical concepts by the use of natural language techniques. Scherf et al. (2005) discuss the applications of text mining in literature search to improve accuracy and relevance. Kostoff et al. (2001) combine data mining and citation mining to identify user community, and its characteristics by categorizing articles.

There is a Text Mining Research Group (TMRG) (2002) at the University of Waikato in New Zealand that maintains a Web page of related publications, links, and software. Similarly there is National Centre for Text Mining (NaCTeM) at the University of Manchester in United Kingdom (UK). The Aims and Objectives of NACTeM is described in article by Ananiandou et al (2005) in which it extensively discusses a need for text mining in biology. According to their Web site of 2002, "text mining uses recall and precision (borrowed from the information retrieval research community) to measure the effectiveness of different information extraction techniques, allowing quantitative comparisons to be made." A Text Mining Workshop was held in 2007 in conjunction with the Seventh Society of Industrial and Applied Mathematics (SIAM) Conference on Data Mining (SDM 2007). Textbooks in text mining have included applications to biology and biomedicine by Ananiadou and McNaught (2006).

Figure 1 of this paper from Liang (2003) shows the text mining process from text preprocessing to analyzing results. Saravanan et al. (2003) discuss how to automatically clean data, i.e., summarizing domain-specific information tailored to user's needs, by discovering classes of similar items that can be grouped into prescribed domains. Hersh (2005) evaluates different text-mining systems for information retrieval. Turmo et al. (2006) describe and compare different approaches to adaptive information extraction from textual documents and different machine language techniques. Amir et al. (2005) describe a new tool called maximal associations which allows the discovering of interesting associations often lost by regular association rules. Spasic et al. (2005) discuss ontologies and text mining to automatically extract information and facts, discover hidden associations and generate hypotheses germane to user needs. Ontologies specify the interpretations of terms, echo the structure of the domain, and thus can be used to

Figure 1. Text mining process source: Liang (2003)



support automatic semantic analysis of textual information. Seewald et al. (2006) describe an application for relevance assessment for multi-document summarization. To characterize certain document collections by a list of pertinent terms, they have proposed a term utility function, which allows a user to define parameters for continuous trade-off between precision and recall.

Visa et al. (2002) develop a new methodology based on prototype matching to extract the document contents. Hirsch et al. (2005) describe a novel approach for using genetic programming to create classification rules and provide a basis for text mining applications. Yang and Lee (2005) develop an approach to automatically generate category themes and reveal the hierarchical structure. Category themes and their hierarchical structures are most determined by human experts, however, with this approach; text documents can be categorized and classified automatically. Fan et al. (2005) describe a method using genetic programming to discover new ranking functions in the information-seeking task for better precision and recall. Wu at al. (2006) describe a key phrase identification program to extract document key phrases for effective document clustering, automatic text summarization, development of search engines, and document classification. Cody et al. (2004) discuss the integration of business intelligence and knowledge management based on an OLAP model enhanced with text analysis.

Trumbach (2006) uses text mining to narrow the gap between the information needs of technology managers and analysts' derived knowledge by analyzing databases for trends, recognizing emerging activity, and monitoring competitors. Srinivasan (2006) develops an algorithm to generate interesting hypotheses from a set of text collections using Medline database. This is a fruitful path to ranking new terms representing novel relationships and making scientific discoveries by text mining. Metz (2003) indicates text mining "applications are clever enough to run conceptual searches, locating, say, all the phone numbers and places names buried in a collection of intelligence communiqués. More Impressive,

the software can identify relationships, patterns, and trends involving words, phrases, numbers, and other data." Guernsey (2003) in an article that appeared in *The New York Times* stated Text-mining programs go further than Google and other Web search engines by "categorizing information, making links between otherwise unconnected documents and providing visual maps (some look like tree branches or spokes on a wheel) to lead users down new pathways that they might have been aware of."

MAIN FOCUS OF THE CHAPTER: BACKGROUND OF TEXT MINING SOFTWARE

A comprehensive list of text mining, text analysis, and information retrieval software is available on Web page of KDnuggets (2007a) and similarly for Web mining and Web usage mining software of KDnuggets (2007b). Selected software from these and other resources are discussed in this chapter.

Some of the popular software currently available for text mining include Compare Suite, SAS Text Miner, Megaputer Text Analyst, Visual Text by Text Analysis International, Inc. (TextAI), Megaputer PolyAnalyst, WordStat, and SPSS Clementine for text mining. These software provide a

Table 1. Text mining software

Features	Software	Compare Suite	SAS Text Miner	Text Analyst	Visual Text	Megaputer PolyAnalyst	WordStat	SPSS Clementine
Data Preparation	Text parsing and extraction	x	x	x	x	x	x	x
	Define dictionary			x	x	x	x	x
	Automatic Text Cleaning		x		add-on			
Data Analysis	Categorization	x			x	x	x	
	Filtering				x	x	x	
	Concept Linking		x		add-on	x		x
	Text Clustering		x	x	add-on	x	x	x
	Dimension reduction techniques		x			x		
	Natural language query			x	x			
Results Reporting	Interactive Results Window		x	x	x	x	x	
	Support for multiple languages		x		x	x	x	x
Unique features		Report Generation, compare two folders feature			Multi-path multi-paradigm analyzer		Export any table to Excel	Linguistic approach rather than statistics-based approach

variety of graphical views and analysis tools with powerful capabilities to discover knowledge from text databases. The main focus of this chapter is to compare, discuss, and provide sample output for each as visual comparisons.

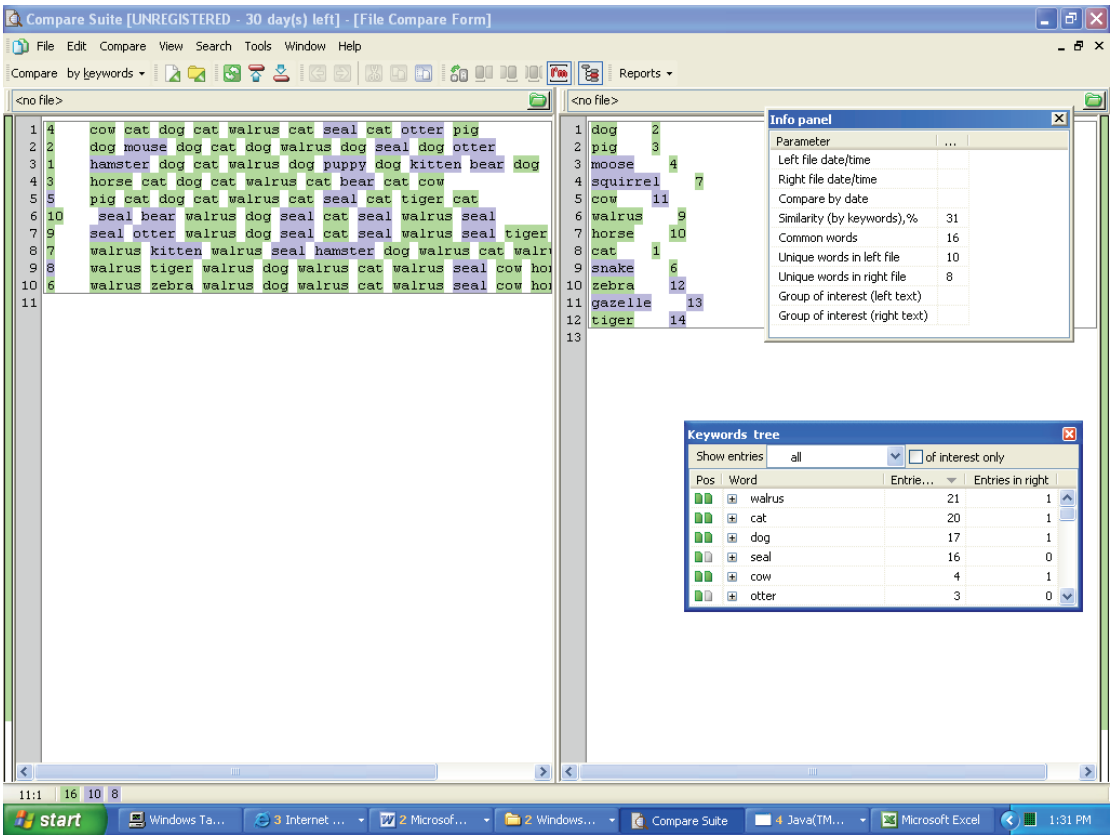
As a visual comparison of the features for these seven selected text mining software, the authors of this chapter constructed Table 1, where essential functions are indicated as being either present or absent with regard to data preparation, data analysis, results reporting, and unique features. As Table 1 shows, Compare Suite and Text Analyst have minimal text mining capabilities while Megaputer PolyAnalyst, SAS Text Miner, WordStat, and SPSS Clementine have extensive text mining capabilities. Visual Text has add-ons to make this software have versatile.

RESULTS

1. Compare Suite

Compare Suite is text mining software developed by AKS-Labs, headquarters of which are located in Raleigh, USA. The software allows comparing any to any file including formats such as text file, MS Word, MS Excel, pdf, Web pages, zip archives, and binary files. It allows comparing two files character by character, word by word, or by key words. Two folders can also be compared to find changes made and contained files. A report can be created after comparison including detailed comparison information. Documents can be compared online by server-side comparison.

Figure 2. Compare Suite with two animal text files



Compare Suite is able to provide to user a window for option of file comparison of text. Illustrated in Figure 2, two animal files are compared by words and results are reported. From the results, the same words that appear in both the files are highlighted with green color and the words that only appear in one of two files are highlighted with purple color.

2. SAS Text Miner

SAS Text Miner is actually an "add-on" to SAS Enterprise Miner with the inclusion of an extra icon in the "Explore" section of the tool bar. SAS Text Miner performs simple statistical analysis, exploratory analysis of textual data, clustering, and predictive modeling of textual data. SAS Text Miner uses the "drag-and-drop" principle by dragging the selected icon in the tool set to dropping it into the workspace.

The workspace of SAS Text Miner was constructed with a data icon of selected animal data that was provided by SAS in their Instructor's Trainer Kit. Figure 3 shows the results of using SAS Text Miner with individual plots for "role by frequency", "number of documents by frequency", "frequency by weight", "attribute by frequency", and "number of documents by frequency scatter plot." Figure 4 shows the interactive mode of SAS Text Miner, which includes the text for each document, the respective weight for each term and also the concept linking figure using SASPDFSYNONYMS text file. Figure 5 shows regression results window in SAS Text Miner

Figure 3. Results of SAS Text Miner for animal text

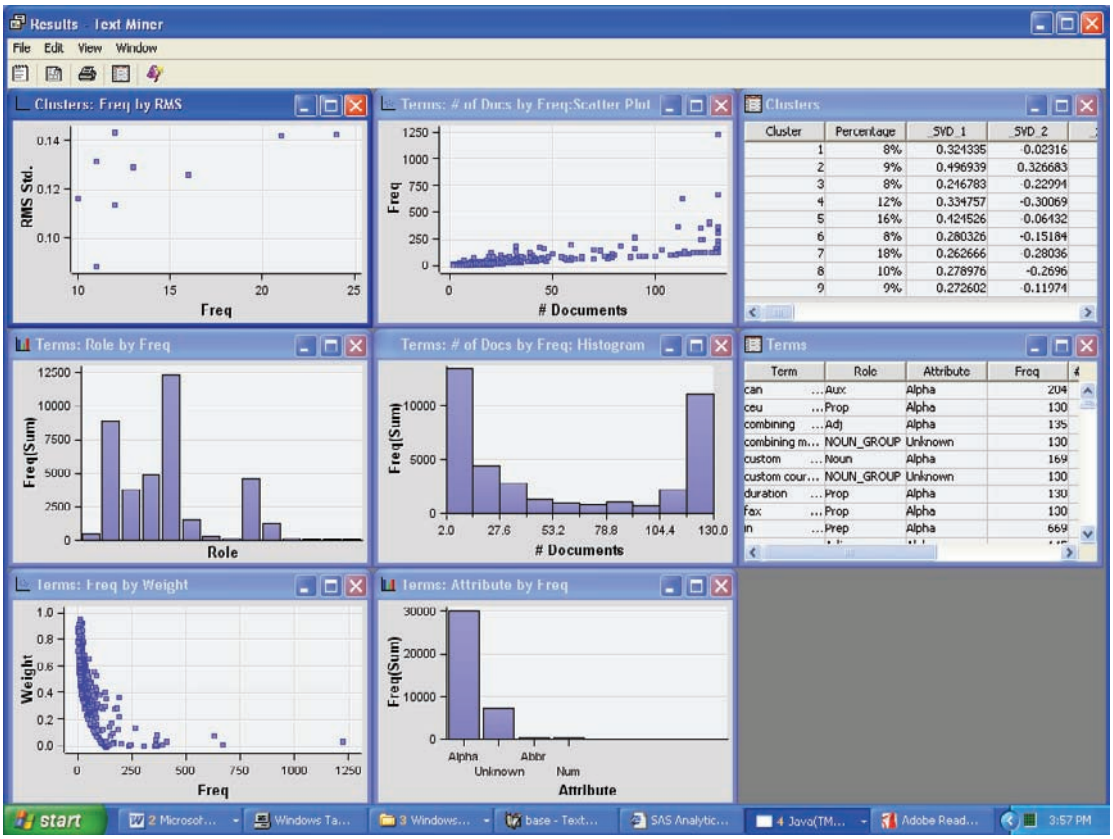


Figure 4. Interactive window of SAS Text Miner for animal text

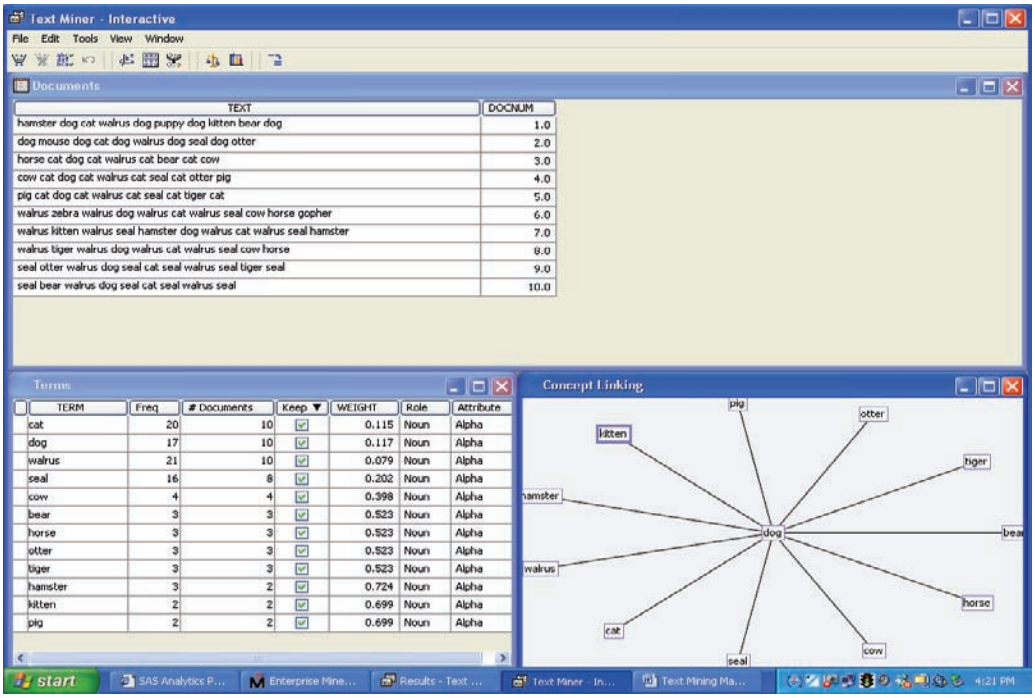

Figure 5. Regression results of SAS Text Miner using Federalists Papers

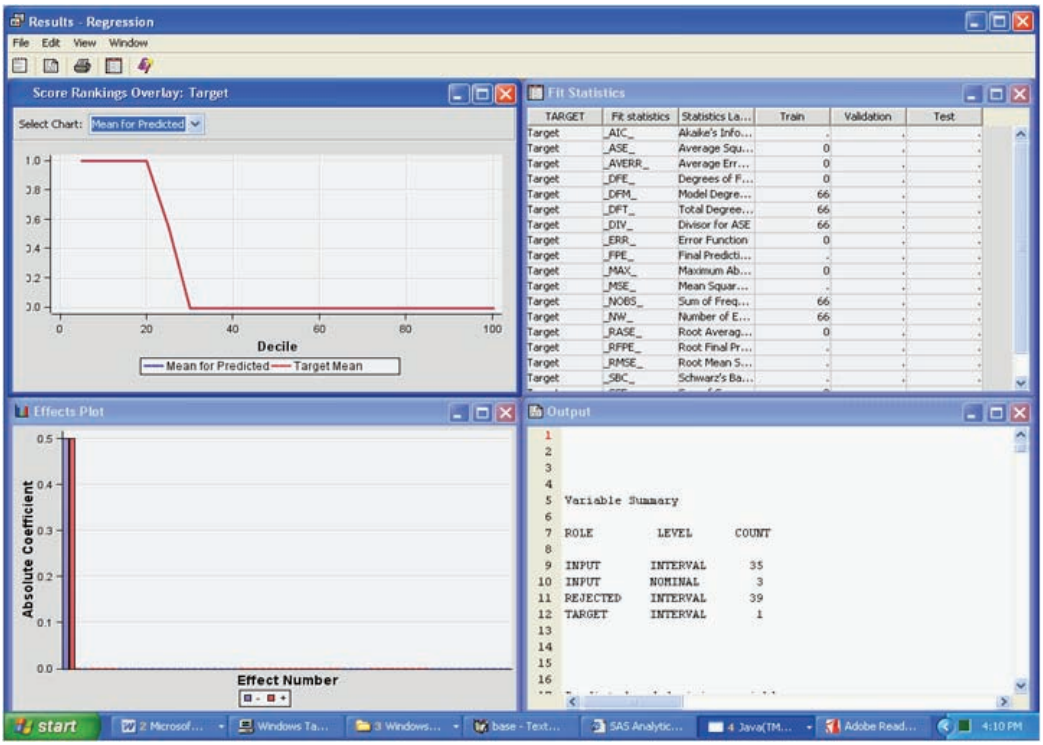


using data for *Federalists' Papers* from their instructor's trainer kit.

3. Megaputer Text Analyst

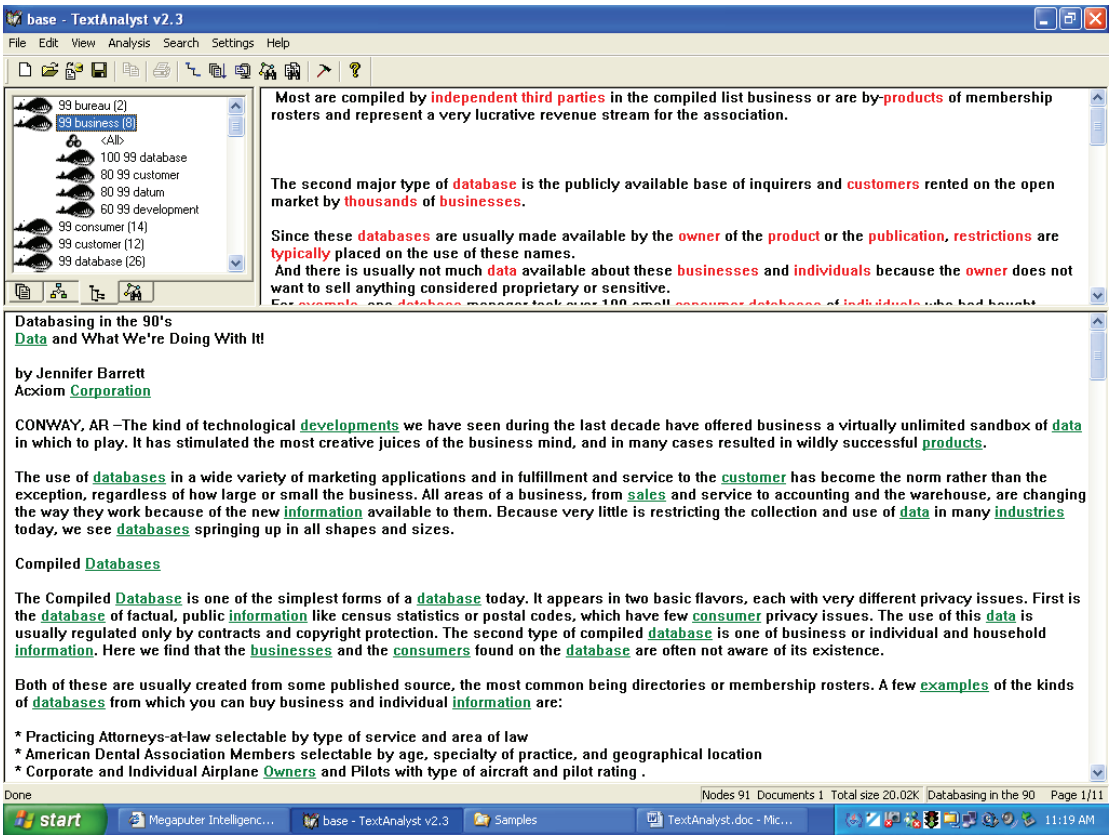
TextAnalyst has an ActiveX suite for dealing with text and semantic analysis. According to Megaputer (2007c) Web page, TextAnalyst uses a Semantic Network similar to a molecular structure, and determines the relative importance of a text concept, solely by analyzing its connection to other concepts in the text, and also implements algorithms similar to those used for text analysis in the human brain.

Figure 6 show a representative screen shot of Megaputer TextAnalyst which consists of a view pane in top left, results pane in top right, and a text pane in the bottom part of the window. The view pane shows each of the nodes in the semantic tree which each can be expanded. Megaputer Text Analyst uses a semantic search window where a query can be entered either as full sentences or questions instead of having to determine key word or phrases. A summary file in the top left pane of Megaputer Text Analyst window can list the most important sentences in the context of the original document. The Summary chooses the sentences on the basis of concepts and relationships between concepts in the full text.

4. VisualText by TextAI

VisualText by TextAI (Text Analysis International, Inc.) uses national language processing including "analyzers" for extracting information from text repositories. Some applications

Figure 6. Text Analyst semantic network window of document databasing in the 90's



include databases of resumes, Web pages, or even e-mails or Web chat databases. VisualText allows the user to create their own text analyzer, and also includes a TAI Parse for tagging parts of speech and chunking. Voice processing needs to be converted to text first before text processing can be performed.

According to VisualText Web page (2005), it can be used for combating terrorism, narcotic espionage, nuclear proliferation, filtering documents, test grading, and automatic coding. VisualText also allows natural language query, which is the ability to ask a computer questions using plain language.

Figures 7 and 8 provide screen shots of VisualText. Figure 7 shows the analyzer on the left and the root of the text zone on the right. Figure 8 shows parsing trees. A window in VisualText can show dictionary with an expansion of the root of the text zone on the right part of this window.

5. Megaputer PolyAnalyst

Previous work by the authors Segall and Zhang (2009) have utilized Megaputer PolyAnalyst for data mining. The new release of PolyAnalyst version 6.0 includes text mining and specifically new features for Text OLAP (on-line analytical processing) and Taxonomy-based categorization which is useful for when dealing with large collections of unstructured documents as discussed in Megaputer Intelligence Inc. (2007). The latter cites that taxonomy-based classifications are useful when dealing with large collections of unstructured documents such as tracking the number of known issues in product repair notes and customer support letters.

Figure 7. Screen-shot of Visual Text window

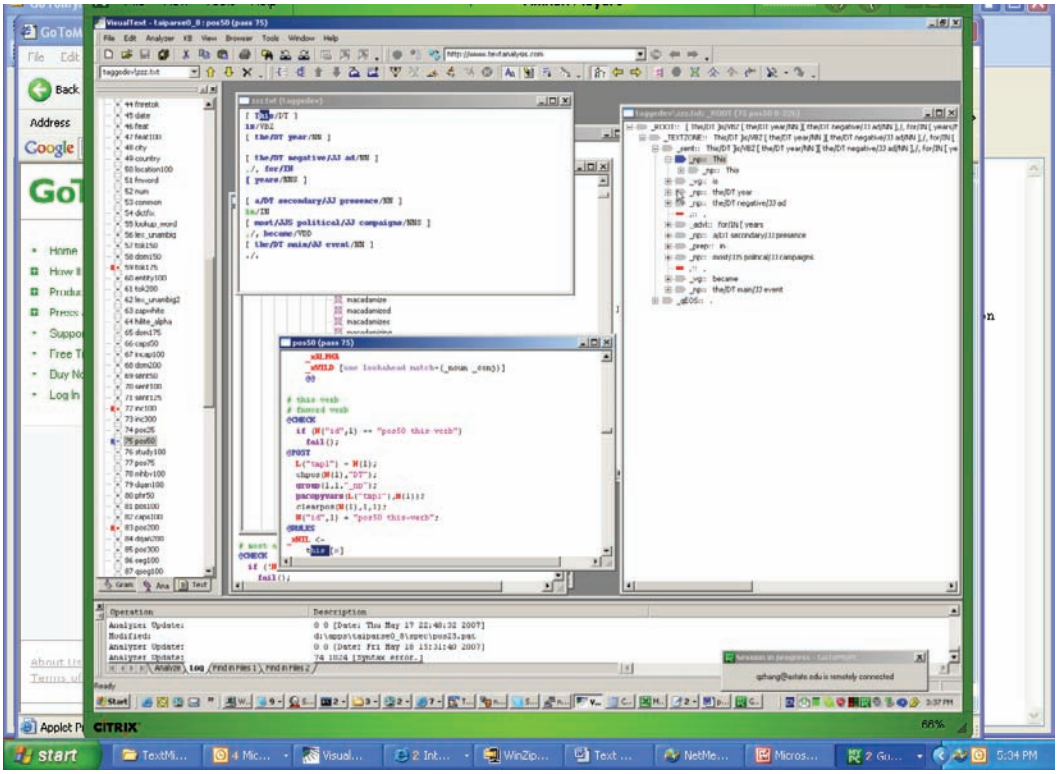


Figure 8. Parsing trees in Visual Text

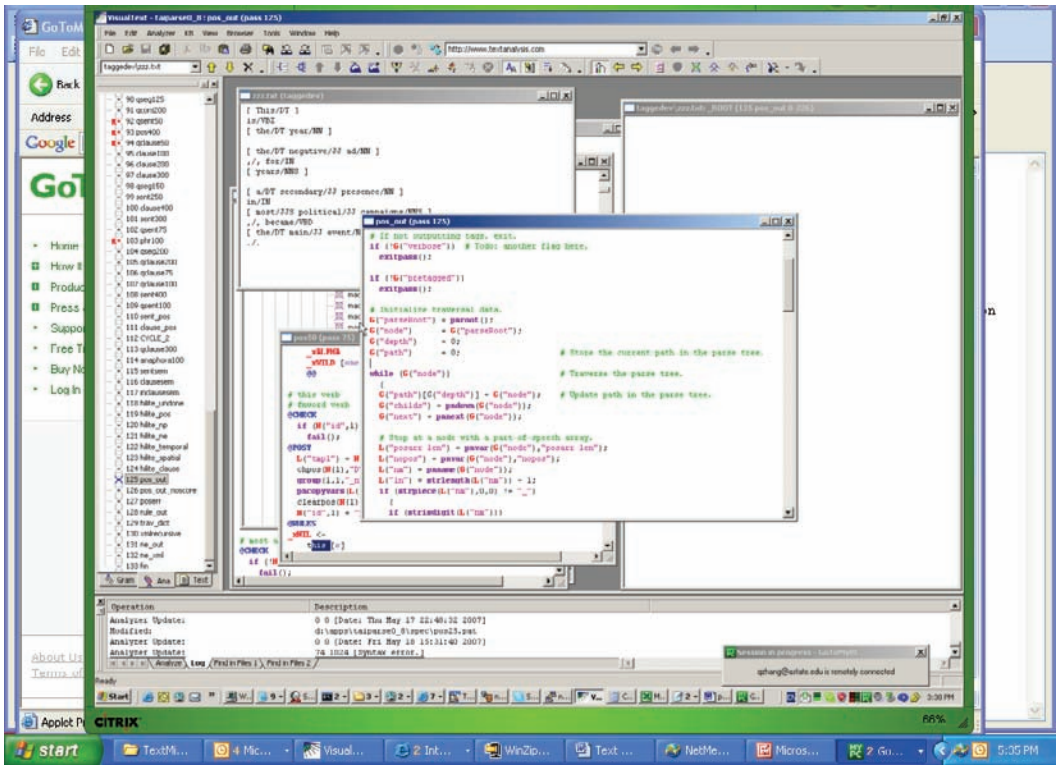


According to Megaputer Intelligence Inc. (2007), PolyAnalyst "provides simple means for creating, importing, and managing taxonomies, and carries out automated categorization of text records against existing taxonomies." Megaputer Intelligence Inc. (2007) provides examples of applications to executives, customer support specialists, and analysts. According to Megaputer Intelligence Inc. (2007), "executives are able to make better business decisions upon viewing a concise report on the distribution of tracked issues during the latest observation period."

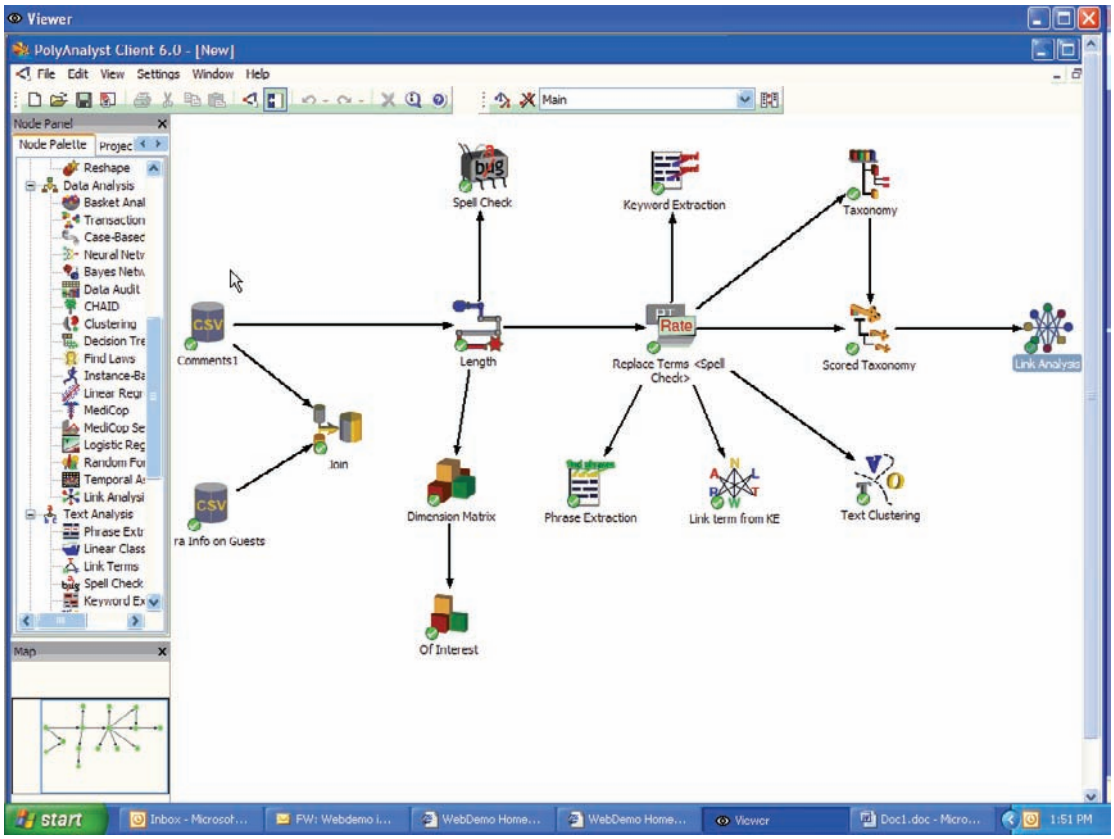
This chapter provides several figures of actual screen shots of Megaputer PolyAnalyst version 6.0 for text mining. These are Figure 9 for workspace of text mining of Megaputer PolyAnalyst, Figure 10 for key word extraction window for the word "breakfast" from customer written comments, and Figure 11 for initialization of link term report. Megaputer PolyAnalyst can also provide screen shots with drill-down text analysis and histogram plot of text analysis.

6. WordStat

WordStat is developed by Provalis Research. It is a text analysis software module run on a base product of SimStat or QDA Miner. It can be used to study textual information such as interviews, answers to open-ended questions, journal articles, electronic communications, and so on. WordStat may also be used for categorizing text automatically using a dictionary approach, or for developing and validating new categorization dictionaries or taxonomies.

WordStat incorporates many data analysis and graphical tools that can be used to explore relationships between document contents and

Figure 9. Workspace for text mining in Megaputer PolyAnalyst



information amassed in categorical or numeric variables. Hierarchical clustering and multidimensional scaling analysis can be used to identify relationships among categories and document similarity. Correspondence analysis and plots can be used to explore relationships between keywords and different groups.

An input file (e.g., excel file) can be imported into the software for analysis. An important preliminary to WordStat analysis is to create a categorization dictionary (which needs domain knowledge). WordStat analysis consists of many tabulations or cross-tabulations of different categories. Figure 12 shows a screen shot of a categorization dictionary window. Correspondence analysis results and 3-D plots by WordStat are illustrated in Figure 13.

7. SPSS Clementine

Text mining for Clementine is text mining software developed by SPSS Inc. It can be used to extract concepts and relationships from textual data. It can also be used to convert an unstructured format to a structured one for creating predictive models. Text mining for Clementine can be accessed directly from the interface of SPSS Inc.'s leading data mining software "Clementine".

Text mining for Clementine can process many types of unstructured data, including texts in MS office files, survey text responses, call center notes, Web forms, and Web logs, blogs, Web feeds, streams, and so on. It uses a natural language processing (NLP) linguistic extraction process. It has a graphical interface and is easy to

Figure 10. Keyword extraction window of text analysis in Megaputer PolyAnalyst

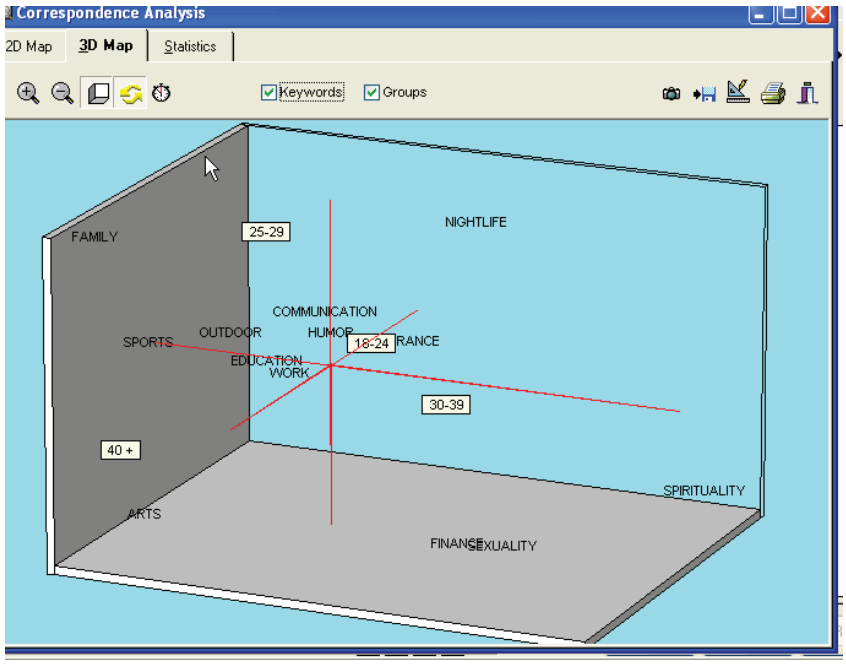

Figure 14. Screen shot of SPSS Clementine for text analysis (Source: http://www.spss.com/textanalysis_surveys/demo.htm)

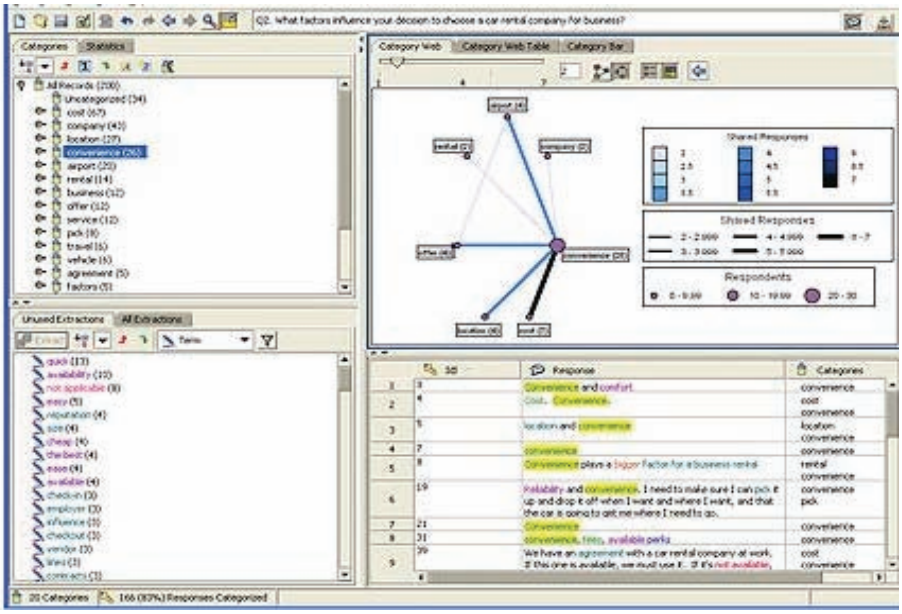

use. Dictionaries can be customized for specific domain areas by using the built-in Resource Editor. It allows extracting text from **multiple languages** such as Dutch, English, French, German, Italian, Portuguese, or Spanish. It can also process text translated into English from 14 languages including Arabic, Chinese, Persian, Japanese, and Russian. Figure 14 shows a screen shot of category analysis using SPSS Clementine.

FUTURE TRENDS/CONCLUSION

This chapter has shown that software for text mining is a new and expanding area of technology that numerous vendors are in competition with each other in providing both unique and common features. Users needing to use text mining are fortunate to have such resources available for needs that were unthinkable a decade ago. Future trends are that text mining software will continue to grow in dimensionalities of features and available software. The applications of software for text mining will be extremely diverse ranging from uses in customer survey responses to drill-downs in medical records or credit or bank reports.

A future direction of this work is to pursue the area of Web mining software and contrast with that of text mining. Web mining is according to the TMRG (Text Mining Research Group) Web site defined to be "the slightly more general case of looking for patterns in hypertext and often applies graph theoretical approaches to detect and utilize the structure of Web sites." Web mining entails mining of content, structure, and usage. Web content mining entails both Web page content mining and search result mining. Web structure mining uses interconnections between Web pages to give weight to pages. Web usage mining is the application that uses data mining to analyze and discover interesting patterns of user's usage of data on the Web.

Some of the popular software that could be selected for Web mining for future comparison include Megaputer WebAnalyst, SAS Web Analytics, SPSS Web Mining for Clementine, WebLog Expert 2.0, and Visitator.

ACKNOWLEDGMENT

The authors would like to acknowledge funding for support of this research from the Summer Faculty Research Grant as awarded to both authors from the College of Business at Arkansas State University. The authors would also like to acknowledge their gratefulness to those at SAS Inc. for the Mini-Grant provided for SAS Text Miner, TextAI and Megaputer Inc. for their extremely helpful technical support.

KEY TERMS

Compare Suite: AKS Labs software that compares texts by keywords, highlights common and unique keywords.

Megaputer TextAnalyst: Software that offers semantic analysis of free-form texts, summarization, clustering, navigation, and natural language retrieval.

Natural Language Processing: Also know as computational linguistics that is, using natural language, e.g., English, to do query or search**.**

SAS Text Miner: Software by SAS Inc. that provides a suite of text processing and analytical tools.

SPSS Mining for Clementine: Enables you to extract key concepts, sentiments, and relationships from call center notes, blogs, e-mails and other unstructured data, and convert it to structured format for predictive modeling.

Text Mining: Discovery by computer of new, previously unknown information by automatically extracting information from different written resources.

Visual Text: Software manufactured by TextAI that uses a comprehensive GUI development environment (www.textanalysis.com)

WordStat: Analysis module for textual information such as responses to open-ended questions, interviews, etc.

Chapter 3.5
A Software Tool for Reading DICOM Directory Files

Ricardo Villegas
Universidad de Carabobo, Venezuela

Guillermo Montilla
Universidad de Carabobo, Venezuela

Hyxia Villegas
Universidad de Carabobo, Venezuela

ABSTRACT

DICOMDIR directory files are useful in medical software applications because they allow organized access to images and information sets that come from radiological studies that are stored in conformance with the digital imaging and communication in medicine (DICOM) standard. During the medical application software development, specialized programming libraries are commonly used in order to solve the requirements of computation and scientific visualization. However, these libraries do not provide suitable tools for reading DICOMDIR files, making necessary the implementation of a flexible tool for reading these files, which can be also easily integrated into applications under development. To solve this problem, this work introduces an object-oriented design and an open-source implementation for such reading tool. It produces an output data tree containing the information of the DICOM images and their related radiological studies, which can be browsed easily in a structured way through navigation interfaces coupled to it.

INTRODUCTION

The digital imaging and communications in medicine (DICOM) standard (National Electrical Manufacturers Association (NEMA0, 2004a; Revet, 1997) was published in 1993. Its main goal was to establish norms for handling, storing, and interchanging medical images and associated digital information within open systems. Also it was to facilitate the interoperability among acquisition

equipments and other medical devices, as well as their integration within specialized information systems in the medical and health care area.

Since then, the appearance and use of computer-assisted medical applications have increased, as a result of the accelerated technological development and the standardization process of medical information representation and handling, which generated a greater demand of development tools for those applications.

These applications range from health care information systems and picture archiving and communication systems (PACS) () solutions, to technological support systems for medical procedures, such as image-based diagnosis and surgical planning, which previously depended on the knowledge and expertise of the physicians.

In such applications, the handling of images coming from different acquisition modalities is essential. These images generated from radiological studies and stored according to the specifications of parts 10, 11 and 12 of the DICOM standard (NEMA, 2004e, f,& g) must be retrieved from storage media as a bidimensional display or in tridimensional reconstructions and other special processes, such as fusion and segmentation of images. The use of DICOMDIR directory files is almost mandatory for searching, accessing, and browsing medical images because they index the files belonging to the patient on whom the studies were performed, thus making it easier to access to those images and their associated medical information.

During the medical application software development, the use of programming interfaces (APIs) or class libraries is frequent in order to solve the computation and visualization needs, as well as for providing DICOM support to the applications. In that sense, there exist numerous public domain applications that can be used by radiologists and other specialists for reading and displaying DICOM images files and even for reading DICOMDIR index files, which cannot be integrated into applications under development because of their proprietary code.

Companies, such as Lead Technologies, ETIAM, Merge, Laurel Bridge, and DeJarnette, have commercial software development kits (SDKs) that provide complete implementations of the DICOM standard, but the acquisition costs for these SDKs are high. Open-source libraries are an alternative choice for integrating DICOM support into applications. Regarding this matter, libraries, such as visualization tool kit (VTK) (), insight segmentation and registration tool kit (ITK), DICOM tool kit (DCMTK), and virtual vision machine (VVM), allow the reading of DICOM images, but they do not provide mechanisms for reading DICOMDIR files. Like in the DCMTK case, there are other libraries that provide tools for a basic and low-level access to the information contained in the files. However, they have disadvantages, such as troublesome information retrieving process and reading tools, which are difficult to integrate into the applications.

Due to the lack of an adequate tool for reading and handling DICOMDIR files in a structured and simple way, which could be also easily coupled to browsing interfaces and attached to medical application under development, we introduce in this article the design and implementation of a DICOMDIR files reader. This tool has been successfully integrated into an application for neurosurgery preoperative planning (Montilla, Bosnjak, Jara, & Villegas, 2005), but it also can be attached to any other software under development that requires the handling of DICOM images and DICOMDIR directory files.

The next sections include the revision of related works, the essential theoretical background that frames this work within the DICOM standard context; the description of the methodology used for the implementation of the tool; and, finally, the discussion and conclusions obtained from the integration and test of the implemented reader into a medical application.

ANTECEDENTS AND RELATED WORKS

The creation of the American College of Radiology (ACR)-NEMA committee in 1983 was the product of earlier attempts by the American College of Radiology (ACR) and the National Electrical Manufacturers Association (NEMA) to establish a normative for exchanging, transmitting, and storing medical images and their associated information. The version 1.0 of the standard was published by this joint committee in 1985, under the document ACR-NEMA No. 300-1985, followed in 1988 by the document ACR-NEMA No. 300-1988 of version 2.0. Previous to these normatives, medical images were stored in files by the acquisition devices under their own proprietary formats and transferred through point-to-point communication or by removable storage media. Versions 1.0 and 2.0 established a standardized terminology and information structure, as well as hardware interfaces, software commands sets, and consistent data formats.

The most recent version, known as DICOM 3.0 (NEMA, 2004a) was published in 1993, and it was structured in parts, or documents, to facilitate its support and extension. In the last version, objects for the representation of patients, studies, reports, and other data sets were added, as well as unique identifiers for these objects, enabling the transmission of information through communication networks using the TCP/IP protocol. The DICOM 3.0 standard facilitates the transfer of images and related information within open systems containing different medical equipments and the integration with medical information systems and applications.

DICOM parts 3, 6, 10, and 12 (NEMA, 2004b, d, 4e, & g) were of particular interest for our tool design. They define and describe the DICOMDIR directory object and other information objects; attributes and representation values of DICOM information model entities; and specifications for files formats and information storage in physical media.

We have not found formal research papers related to the design and implementation of open-source tools for reading DICOMDIR files and their integration within medical applications. Nevertheless, there exist documented development libraries that include support for this kind of file. On the other hand, regarding the complexity of searching and decoding information contained in DICOM files and the fact that the tool had to be integrated into a medical application developed with C++ language, we decided to search for open-source development libraries, based upon C++ and with DICOM support in order to use them as a base for the tool development.

Just a few development libraries, besides the expensive commercial ones, enable the reading and analysis of DICOMDIR files. Due to their structures or features only three open-source libraries, based upon C++ language, were deemed appropriate to be used as reference for the tool design and implementation; the remaining APIs were found either to have a complicated structure or were based upon Java language.

GDCM (GDCM, 2005) is an API supported by Centre de Recherche et d'Applications en Traitement de l'Image et du Signal (CREATIS), which provides a fairly complete support for reading DICOMDIR files and a simple access to the information extracted from them. However, it implements only part 5 of the DICOM standard; therefore, it would be of little use as a base library for medical applications that require the implementation of other features defined by the standard.

Dicomlib library (DicomLib, 2005) provides a fuller implementation of the DICOM standard, and it also features the reading of DICOMDIR files. Although this library tries to ease the huge intrinsic complexity in the use of the DICOM standard, its access and presentation of the DICOMDIR compiled information is not the best one to be integrated into the applications.

Finally, DICOM tool kit (DCMTK) (DCMTK, 2005) from Oldenburger Forschungs und Entwicklungsinstitut für Informatik-Werkzeuge und Systeme (OFFIS) is another complete library, having several years of evolution and continous use in medical applications development. Although DCMTK provides support for the creation, modification, and opening of DICOMDIR files, it does not offer structured and simple access to the information gathered from the files. However, we selected DCMTK as the base library for the reader development due to its robustness, flexibility, and ability to handle of DICOM images.

Thus, starting from the basic functions for information searches and decoding that provides DCMTK, it was possible to develop the tool for reading the information contained in DICOMDIR files and attach this tool to medical applications that require organized access to DICOM image sets from medical studies.

THEORETICAL BACKGROUND

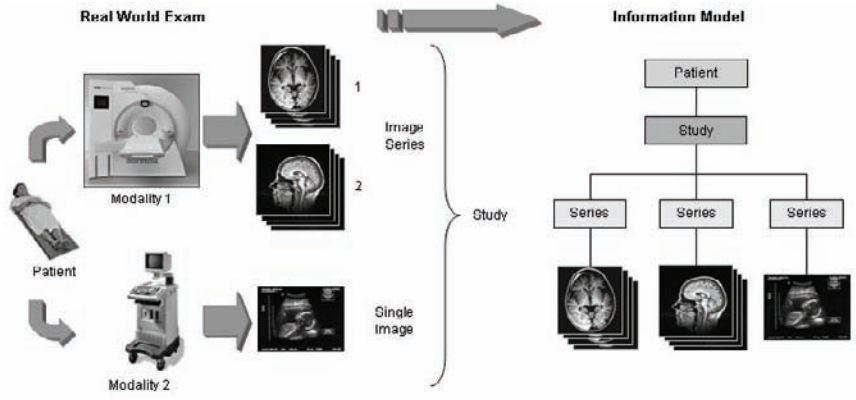
A lot has been written about the DICOM standard ever since it was published, including revisions and extensions. The scope of DICOM is so wide that the researcher certainly gets overwhelmed by the amount and complexity of the information contained in the standard documents. In our case, as in any other case of software development that involves the handling of information within the DICOM scope, the revision of basic fundamentals for real-world information representation according to the DICOM standard was necessary.

Within DICOM's structure, the term "information" refers to medical images coming from different acquisition modalities, signals, curves, look-up tables, and structured reports, as well as to other information gathered during patient visits to the healthcare specialist and the studies derived from them. This information and its generating agents are represented by the standard through models.

DICOM Application and Information Models

DICOM structures and organizes medical data and information through models that emulate the real-world hypothetical situation, where a patient visits a health care specialist, who later orders a set of radiological studies as shown in Figure 1.

Figure 1. Correspondence between the radiological exam environment and the DICOM Information Model



An application model is defined as an entity/relationship diagram (see Figure 2) that relates real-world objects inside the standard scope. Its diagram derives from the way hospitals' radiology departments handle images from one or more acquisition modalities. Those images are ordered in a series, according to some spatial or temporal relationship, and then stored in a folder for each patient.

Although the application model contains entities for representing several DICOM objects, such as exams results, medical reports, and study procedures, in this work only the patient, study, series, and image entities were considered because they are directly associated to data contained within the images. This consideration produces the simplified version of the DICOM application model shown in Figure 2, where the dashed region contains the entities of interest.

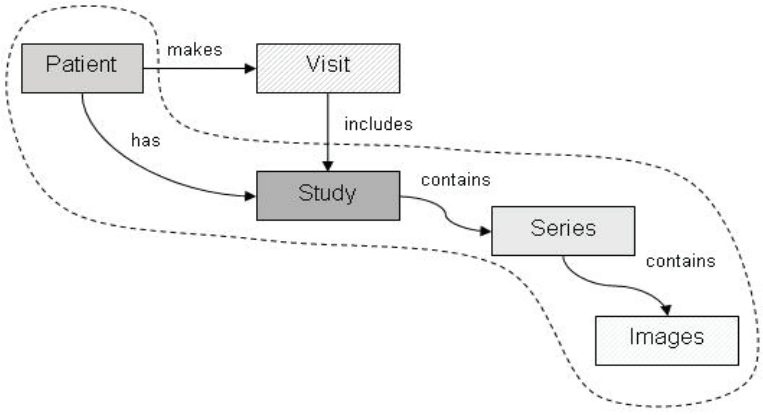
The DICOM information model derives from the application model and its entities are known as information object description (IOD). In an abstract way, an IOD describes real-world objects that share the same properties (NEMA, 2004b). This abstraction keeps a close relationship to the object-oriented design and programming paradigm.

Information model entities are featured by attributes whose types, multiplicities, and contents change depending upon the entity to which they belong. Attributes or data elements are defined in part 5 of the standard (NEMA, 2004c), and they are cataloged in part 6 of the data dictionary (NEMA, 2004d). An attribute is classified according to its presence in obligatory (types 1 and 2), conditional (types 1C and 2C), and optional (type 3).

Attributes are identified in the data dictionary through a tag composed from an ordered 16-bit number duple (*gggg,eeee*) expressed in hexadecimal form. These numbers represent the group and the element number within that group. The standard attributes have an even group number, different from 0000, 0002, 0004, and 0006, whereas private attributes, not contained in the data dictionary, have an odd group number, different from 0001, 0003, 0005, 0007, and FFFF. All aforementioned group numbers are reserved by the standard.

In addition to the tag, there are other data fields that also belong to the attributes structure, such as value representation (VR), value multiplicity (VM), length, and contained value. The VR describes, through a 2-byte character string,

Figure 2. Simplified DICOM application model showing information entities and relationships among them



the type and format of the data contained in the attribute value field, such as integer or floating numbers, dates, string characters, and sequences. The VM specifies the cardinality or number of values that are codified in the value field. The length contains the attribute's value size in bytes. Finally, the value field stores the attribute data, according to its respective presence type.

For each IOD there are defined operation sets and named services that are executed on the information objects. When an entity needs to perform an operation over an IOD, it must request the proper service to another entity, which behaves as a server. Each object-defined service establishes a service-object pair (SOP), and the whole service set that is applicable to a particular IOD is a named SOP class.

The *media storage service class* and the *queryrRetrieve service class* are examples of SOP classes. The first one comprises the M-READ, M-WRITE, and M-DELETE services set, applied to the reading, writing, and deleting of files with image IODs coming from acquisition modalities. The second class groups the C-FIND, C-MOVE, and C-GET services that can be requested for querying and transferring information from IODs associated with different entities.

An SOP instance is the occurrence of an IOD that is operated within a communication context, through a specific service set. For example, DICOMDIR directory files are SOP products from requesting the information writing service from a directory IOD to a physical storage media.

The simplified model from our research considers only four entities and their corresponding IODs. The patient entity contains data of the patient for whom radiological studies were performed as described by the study entity. The series entity models information resulting from radiological studies, such as images or signals, and keeps some kind of spatial or temporal relationship among them. The image entity represents the images coming from some of the existing acquisition modalities, for example, computed tomography (CT), magnetic image resonance (MRI), or ultra sound (US).

DICOM File Format

The DICOM file format, described in part 10 of the standard (NEMA, 2004e), defines the way data representing a SOP instance is stored in a physical storage media. The data is encapsulated as a stream of bytes, preceded by a header with metainformation required for identifying the SOP instance and class.

The header has an organized sequence of components, named file ID, which organizes files hierarchically. An ID has up to eight components, where each one is a string of one to eight characters separated by backslashes. The file ID generally corresponds to a directory path and to a filename, for example, SUBDIR1\SUBDIR2\SUBDIR3\ABCDEFGH.

Located after the header is the data set associated with the information model entity that is stored in the file. Depending upon the entity nature, this stream of bytes could represent some of the following objects: images, curves, signals, overlay annotations, lookup tables for transforming images pixel values according to acquisition modalities or values of interest, presentation images descriptions, structure reports, or raw data.

Within the context and scope of our research, we considered only DICOM files containing images associated with studies performed on patients. Therefore, the stored data describes the image plane and the pixels features, as well as values for mapping the image to color or gray scales, overlay planes, and other specific features.

DICOM files are gathered in collections sharing a common name space, such as storage volumes or directory trees, and having unique file identifiers within it. The file collection is an abstraction of a container where files can be created or read. Each collection must be accompanied by an index file with a DICOMDIR identifier, corresponding to a

DICOM directory object instance. Part 12 of the standard (NEMA, 2004g) describes the way the DICOM file information is encoded inside the physical storage media. It depends upon the file system used by the computer system for the files creation and interchange, as well as the physical media used for it.

DICOMDIR File Format

The DICOM standard defines a special object class as a named basic directory object, whose purpose is to serve as an organizing index for DICOM files stored in a physical media. The instance of a DICOM directory class object is a file with a unique filename and ID named DICOMDIR. The formal definition of the DICOMDIR object and its content are in part 3 annex F of the DICOM standard (NEMA, 2004b), whereas its structure complies with the DICOM files format specified in section 7 of part 10 (NEMA, 2004e).

There are registers in the DICOMDIR file with the information associated to objects stored in a DICOM files set, and it does not make reference to files that do not belong to the set. Each register contains a field identifying the represented information type, such as patient, study, series, and image, besides a group of specific fields with attributes extracted from the stored SOP instance. The registers are hierarchically sorted, and they are linked among themselves in the same hierarchy level and to the next lower level in the hierarchy (Figure 3).

The preceding information is generally present in the file, such as indicated in the standard, but some data fields can be optional, such as those related to the complementary information of the patient (birth date, sex, and age) and the studies (referring physician, institution, protocols, and diagnoses), as well as image descriptive information, for example, dimensions, samples by pixel, photometric interpretation, and gray-level window.

There should be a unique DICOMDIR file for each DICOM files set contained in a storage media. The DICOMDIR file location is related to the storage media directory organization, and it is commonly found at the root directory. DICOMDIR files help to make fast queries and searches throughout media contained images, without the need for reading whole file sets. Otherwise, searching and browsing images and information

Figure 3. Structure of a DICOMDIR file and its representation in a physical storage media

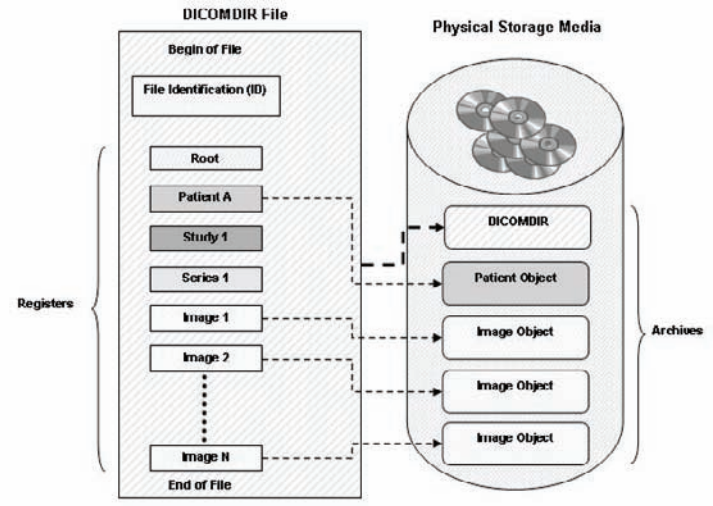


Figure 4. Structure of the data tree structure built by the reading tool

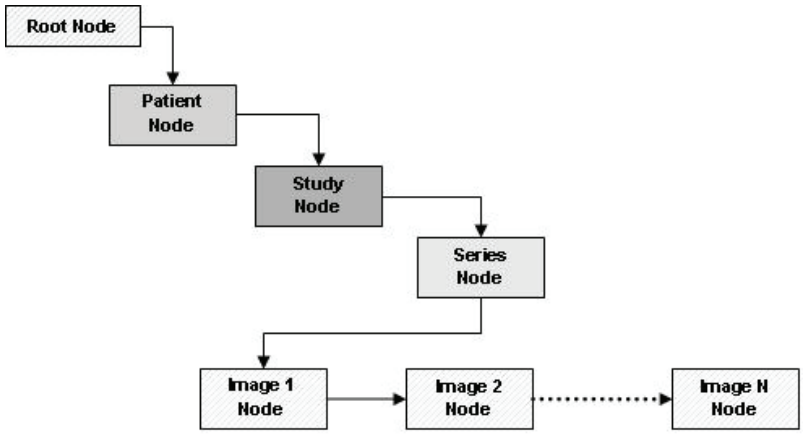


within file sets becomes an intensive, tedious, and difficult task.

DICOMDIR FILE READER IMPLEMENTATION

Description

The implemented tool enables DICOMDIR files to be opened in order to obtain the most relevant information from the DICOM-file collection they index. This information is organized in a hierarchical data structure, which can be easily consulted, and when coupled to a suitable graphic interface, permits the interactive browsing of the information related to the collection. The implementation was made using C++ language, based upon an object-oriented design that allows new DICOM data fields to be added to the reader. Some DCMTK library classes and methods (DCMTK, 2005) were used to facilitate the searching and decoding of the data contained within DICOMDIR files, thus avoiding the inherent complexity in the handling of the information stored under DICOM standard specifications.

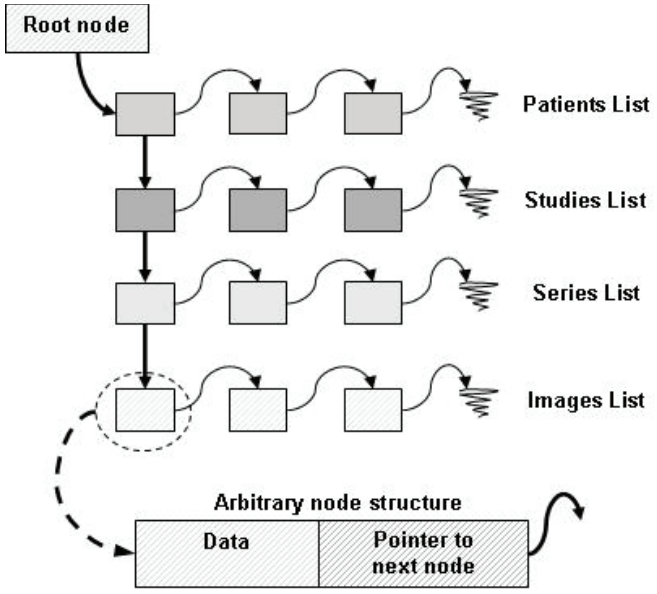
Data Structures

The references to SOP instances contained in DICOMDIR files are linked according to the entities' hierarchy of PATIENT-STUDY-SERIES-IMAGE, which is implicitly established in the DICOM information model, thus establishing a natural correspondence between the hierarchy and a tree data structure. This tree has heterogeneous content nodes that correspond to the DICOM simplified application model (Figure 2), so there are five node types: root, patient, study, series, and image. The entities' relationship cardinality sets the offspring multiplicity, that is, a patient could be object from several studies, whereas each one of them could have several image series.

During the reading of a directory file, all of the file's hierarchical links are traveled, and the related collection file information is gathered for filling the nodes' specific fields, thus building the data tree structure. At the end of the reading process, the tree has the relevant collection information, having a structure similar to that shown in Figure 4. This data structure could be browsed in order to consult the information without the need of accessing the whole file set again.

An approach was considered for the tree structure implementation where the nodes behave

Figure 5. Data tree implementation using linked node lists as data containers



simultaneously as structural elements and data containers. In this way, the nodes establish the tree hierarchical structure and each one of them also stores the information associated to the corresponding entity. Hierarchy levels are made up of linked node lists, and each one of these lists have a children's list, corresponding to elements from the next lower hierarchy level (Figure 5). This approach facilitates the travelling of the tree and its coupling to browsing interfaces.

A class hierarchy was defined for enabling the nodes polymorphic handling through virtual methods. In this hierarchy, the base class, DICOMDIRNode, defines the basic structure for the other nodes, as well as the virtual methods for accessing and travelling the tree. All subclasses deriving from it, that is, DICOMDIRRootNode, DICOMDIRPatientNode, DICOMDIRStudyNode, DICOMDIRSeriesNode, and DICOMDIRImageNode, redefine their contents and behavior according to the corresponding DICOM application model entity to which they belong.

Collected DICOM Data Fields

DICOM files contain rather large data-element groups that are cataloged in the DICOM data dictionary (NEMA, 2004d). However, not all of these elements are useful in the scope of software applications that handle medical images, and for that reason, a selection of relevant elements was made in order to limit the number of data fields gathered during the DICOMDIR files reading process. Table 1 shows the collected data fields with their tags, value representations, multiplicities, presence attributes, and corresponding DCMTK classes and C++ standard types.

One selection criteria for the data fields is based upon the information provided by the image processing. Among the selected fields are the image dimensions, the samples per pixel number, and the gray-level window. Another criterion is the general information that guides the user during the search and selection of images, for example, patient's data, description, and modality of the study. Complementary fields that do not provide

Table 1. DICOM attributes compiled during DICOMDIR file reading process. Attributes are grouped by node type, showing main DICOM data fields and corresponding DCMTK/ C++ data types for each one of them

```

significant information for the image processing or to the user applications were not used for the gathering process, for example, address, occupation, and medical antecedents of the patient, and the technical information from the image acquisition devices.

Reading Process

The reader uses Algorithm 1 for the DICOMDIR information retrieving process.

It can be observed that in this algorithm starting from the parent nodes, each tree node and its children's nodes are recursively travelled, level by level, until reaching the deepest tree level. Only nodes from PATIENT, STUDY, SERIES, and IMAGE types are taken into account, though it is possible to extend the consideration to other types of nodes. For each visited node, the selected fields are compiled according to the node type (see Table 1). However, as explained in the DICOMDIR File Format section, not all the fields have an obligatory presence inside the DICOMDIR file, therefore the missing information must be completed from the corresponding DICOM image file, once its file identifier is known.

Some methods from the DCMTK library are used to travel through the DICOMDIR structure and retrieve its data. These methods can handle data elements encoded either in *big Endian* or *little Endian* byte ordering, or with any kind of representation values and cardinalities. The retrieving methods are invoked by the data element tag each time a node is visited, whereas the travelling methods are used during recursive calls to the tool's main reading method.

RESULTS AND DISSCUSSION

The DICOMDIR reader was integrated for its test and validation into software for neurosurgery and brachytherapy planning, developed with the VVM library (Montilla, Bosnjak, & Villegas, 2003). A graphical interface was coupled to the reader in order to enable the navigation of the information in a simple way. By just opening the associated DICOMDIR file, users will be able to have the interface display the patients' study images and their related medical information. Control widgets provided by the interface were used for interactively browsing and selecting the images.

The reading process was verified with DICOMDIR files associated to several image sets, coming from studies of CT and MRI performed on different patients. It could be proved that the reader recollected the information specified by the class definitions for each type of node, enabling display of its structure through the interface. Two examples from the tests are shown in Figure 6. In both examples, the studies were made on the patient's head but with two different modalities. The CT study has an eight-image series, whereas the MRI study contains 14 images.

It was observed that access to the information collected from the studies can be made in an organized and fast way, making transparent the navigation process of data structures and improving the efficiency in the use of the software. The tool is able to be integrated with other applications under development that require the handling of DICOM images and DICOMDIR files.As is usual in software projects implying code reusability, benefits from using our tool are going to be directly reflected in ease and speed of development.

CONCLUSION

The design used for the DICOMDIR file reader allows the medical application programmer to effortlessly incorporate the feature for the handling of this kind of file in software under development. Also, it avoids exhaustively understanding the DICOM standard and DCMTK classes and methods, which can be really hard and bothersome, enabling the programmer to focus on the integration of the

tool into the application, as well as on the development of a navigation interface, according to the application's needs. Because the reading tool has open-source code, it can be reused and modified at will by the programmers. In addition, the design used for the tool development enables inclusion of new data fields to the presently used entities, as well as to add other information model entities to the data tree structure.

By integrating the tool into a medical application that handles DICOM image sets, it was proved it facilitates the browsing and searching of the information contained in the image sets, accelerating the fulfillment of these tasks and improving the efficiency and performance of the application. Open-source programming tools of this type also facilitate the development of medical applications and help to reduce software costs, thus making it more accessible to health institutions, physicians, and patients, particularly in regions where investment in health care solutions is either limited or not a priority issue.

FUTURE WORKS

We are considering the future implementation of tools for converting images from other formats to the DICOM format and for the creation of DICOMDIR files from nonindexed studies files. A tool for anonymization of DICOM fields also could be useful in protecting patient confidentiality during the sharing of clinical data among research teams. We hope that the implementation and subsequent use of this tool set will represent an incremental increase in the efficiency, quality, and speed of development of medical informatics software, producing applications that will be more complete and flexible at same time.

ACKNOWLEDGMENT

The authors want to express their gratitude to Dr. Luis Iván Jara, a neurosurgeon appointed to the Hospital Metropolitano del Norte (Valencia-Venezuela), for providing us the DICOM image sets used for the functional verification and evaluation of the reading tool. Financial support for this research was granted by Scientific and Humanistic Development Council of the University of Carabobo, Venezuela, under project CDCH-UC No. 0461-06.

APPENDIX

Glossary of Terms

American College of Radiology(ACR)/ National Electrical Manufacturers Association (NEMA)(ACR): This joint committee is responsible for the development and maintenance of the DICOM standard.

Acquisition modalities: These imaging techniques and devices provide radiological images from patients' anatomy. Most commonly used modalities are CT (computed tomography), MRI (magnetic resonance imaging) and US (ultra sound).

Application programming interfaces (APIs): A set of specialized functions, class libraries, and tools used by software programmers to facilitate the application development process.

Attribute: A property of an information object represented as a data element.

Big Endian: An encoding scheme where multiple byte values are encoded with the most significant byte first, followed by the remaining bytes in decreasing order of significance.

Browsing interfaces: These mechanisms and widgets provide a way to navigate information within software applications.

Data element: This is a single atomic information unit that is related to a real-world object attribute and is defined by an entry in the DICOM data dictionary.

Digital imaging and communications in medicine (DICOM): This standard establishes norms for handling, storing, and interchanging medical images and associated digital information.

DICOM application model: An entity/relationship diagram used to model the relationships existing between real-world objects within the DICOM standard's scope.

DICOM data dictionary: This is a catalog of DICOM data elements that describes the semantics and contents of each one of them.

DICOM information model: An entity/relationship diagram used to model the relationships between the information-object definitions representing classes of real-world objects defined by the DICOM application model.

DICOMDIR file: This is a unique and mandatory file that accompanies a file set and indexes these files.

Entity/relationship diagram: This is a graphical representation of a set of objects and the relationships existing among them.

Image-based diagnosis: Techniques used by health care specialists to diagnose patients' diseases through analysis of radiological imaging studies.

APPENDIX CONTINUED

I**nformation object description (IOD):** This is an abstract definition for real-world objects that share the same properties.

Little Endian: An encoding scheme where multiple byte values are encoded with the least significant byte first, followed by the remaining bytes in increasing order of significance.

Open source: Programming paradigm based upon software engineering principles that pursues software code reutilization to facilitate the development of applications.

Proprietary code: Programming paradigm that establishes that the software applications code is protected and is not available either for modification or reutilization.

Software development kits (SDKs): See APIs.

Service: This is an operation that can be requested for acting over an information object.

Service-object pair (SOP): This is a relationship that is established between an information object and an operation or the service applicable over it.

SOP class: This is the whole set of services applicable over an information object.

Surgical planning: This describes the preoperative procedure where the surgeon determines surgical protocols and approachg trajectories to be followed during the intraoperative stage of the surgery.

Value multiplicity (VM): This is the DICOM data field that specifies the cardinality or number of values existing for a data element.

Value Representation (VR): This is the DICOM data field that specifies the data type and format of values existing for a data element.

ABSTRACT

Due to the open nature of Free/Libre/Open Source software projects, researchers have gained access to a rich set of development-related information. Although this information is publicly available on the Internet, obtaining and analyzing it in a convenient way is not an easy task and many considerations have to be taken into account. In this paper we present the most important data sources that can be found in libre software projects and that are studied by the research community: source code, source code management systems, mailing lists and bug tracking systems. We will give advice for the problems that can be found when retrieving and preparing the data sources for a posterior analysis, as well as provide information about the tools that support these tasks.

INTRODUCTION

The fact that communication and organization are heavily tied in libre software[1] projects to the use of telematic means and that these interactions are, in general, stored and publicly offered over the Internet makes the number of data sources where development information can be extracted from

grow beyond source code. In addition, the ability of having memory (as data from activities in the past can be obtained) offers the possibility of performing longitudinal analysis as well. Research groups from all around the world have already taken benefit from the availability of such a rich amount of data sources in the last years. Nonetheless, the access, retrieval and fact extraction is by no means a simple task and many considerations have to be considered to successfully mine the data sources.

This chapter is probably the first attempt to have a detailed description of the most common data sources that can generally be found for libre software projects on the Internet and the data that can be found in them. In addition, we present some available tools that might help researchers obtaining and partially analyzing the described data sources. These data sources comprise **source code**, **source code management** (in the following, SCM), **mailing lists archives**, and **bug tracking system** (in the following, BTS).

Mining and analyzing these data sources offer an ample amount of possibilities that surpass or complement other data-acquiring methodologies such as surveys, interviews or experiments. The amount of data that can be obtained, in a detailed way and in many cases for the whole lifetime of a software project, gives a precise description of the history of a project (Bauer and Pizka, 2003). In this sense, we have access to the activities (the what), the points in time (the when), the actors (the who) and sometimes even the reason (the why) (Hahsler and Koch, 2005). Compared to surveys, mining these data sources allows to access data for thousands of developers and a wide range of software projects. Most of these efforts can be considered as non-intrusive, as researchers can analyze the projects without interacting with developers. But even in a small environment, e.g., when evaluating the impact of software tools in a small team (Atkins et al., 2002), the use of data from one or more of these sources provides additional insight. Furthermore, mining software repositories has many advantages compared to conducting experiments as real-world software projects are taken into consideration (Mockus and Votta, 2000, Graves and Mockus, 1998).

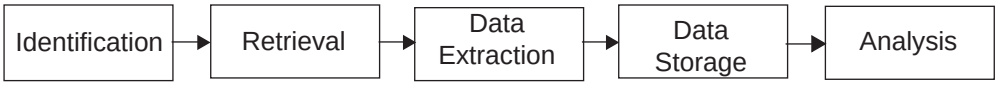
The structure of this chapter is as follows: the next section handles the identification of the data sources as well as its retrieval process. Next, various analysis on source code are introduced (hierarchy, file discrimination, analysis of *traditional* source code files, analysis of the rest of files (such as documentation, multimedia, etc.), and authorship). The fourth section presents how SCM systems can be mined, putting special attention on the CVSAnalY tool and some details to be considered when performing analyses on CVS. The fifth section presents the most common format in which mailing lists are stored (MBOX), while the sixth one is devoted to present the data to be found in a BTS. Finally, the reader can find a short summary of the chapter in the last section.

IDENTIFICATION OF DATA SOURCES AND RETRIEVAL

There are some steps before the analysis of data from libre software projects can be started that should be considered: identification and retrieval. It should be noted that there may be several ways of accessing the data, depending on the projects. This is because of the use of the several development-supporting tools that projects use and of having different usage conventions (for instance, the use of tags, comments, among others, may differ from one project to another). The complexity and feasibility of both activities depend on the data source and on the project. Figure 1 gives a diagram that shows the steps that have to be accomplished for any source considered in our study.

In general terms, the identification of the data source depends mostly on its significance for the software development of a project. Hence, identifying the source code, the SCM system, the mailing lists or the BTS is in no way problematic

Figure 1. Whole process: from identification of the data sources to analysis of the data



as it lies in the interest of the projects that feedback is provided by users in an easy and fast way. In these cases, the biggest drawback is the lack of historical data. Sometimes we only have a partial set of the data, and in the worst cases nothing at all. This situation is common for software releases, where finding historical versions of the software is sometimes not possible. Other situations where this might happen is when a development tool has not been used in the early stages of development. This is the case of many projects that start using a SCM system once the project has gained certain momentum. Having only partial data can also be the result of a migration from one tool to another, losing in the way some information if not all. When researching libre software projects, these considerations have to be taken into account.

But there exist other data sources for libre software projects that are not so obvious and hence their identification is not that straightforward. For instance, organizational information that is embedded into some format and that is beyond the use of standard tools as SCM systems, mailing lists and BTS. In general, such type of information is project-dependent and can be only obtained for one project or a small number of them. This is the case for packaging systems such as the .deb format used in Debian and Debian-based distributions or the .rpm Red Hat package system in use in Red Hat and other distributions. But beyond this, we can find project-related information in other places such as the Debian Popularity Contest (Robles et al., 2006b) or the Debian Developer database (Robles et al., 2005). Other data sources may also be considered; for instance, in KDE there is a file that is used to list all the ones who have write access to their SCM repository. Another example is given in a study by Tuomi (Tuomi, 2004) in which the credits file, a text file listing all important contributors to the project, of the Linux kernel are studied in detail. Identification of the data source requires in such cases specific knowledge on the project and is difficult if not impossible to be generalized.

Once the data source has been identified, it has to be retrieved to a local machine in order to be analyzed (see Figure 1). Although this process may not seem to be very difficult at first, previous experiences have shown that some considerations and good practices should be followed in this step as reported by Howison et al. in the retrieval of information from the web pages hosted at SourceForge (Howison and Crowston, 2004). For instance, the analysis of the credits file, which can be found together with the sources in many projects, has to deal with the complexity that there is no standardized way of naming the authors, so projects follow their own conventions.

In the next sections we will enter into detail in the process of data extraction and data storage once the data have been properly retrieved from the information source to a local machine.

SOURCE CODE

We should begin with the concept of release. It is important due to the fact that it points out the main milestone happened during the life of a project. It usually has a common nomenclature which is akin to "MM.mm.bb". Where "MM" means the number of the major release, "mm" means the number of minor releases and "bb" connotes some bug fixes and small improvements.

As software development projects, source code is the central point of all interactions, being

a primary way of communication and playing a major signaling and coordination role. According to (Lanzara and Morner, 2003), source code "is transient knowledge: it reflects what has been programmed and developed up to that point, resuming past development and knowledge and pointing to future experiments and future knowledge.".

The study of the source code, as the main product of the software development process, is a matter that has been done for over thirty years now. But not only *traditional* source code (i.e., programmed in a programming language) can be taken into account, but also all the other elements that make the software, such as documentation, translation, user interface and other files (Robles et al., 2006a).

The analysis usually starts with a source code base that is stored in a directory (or alternatively in a compressed directory, usually in tar.gz or tar.bz2 format common in the libre software world). After decompressing the tarball, if needed, the hierarchical structure of the source code tree is identified and stored.

Then, files can be grouped into several categories depending on type (as will be described below) which allows for a more specific analysis. This means, for instance that source code files in a programming language can be analyzed differently than images or documentation files. On the other hand, the discrimination for files with source code can be finer, identifying the programming language and offering the possibility of using alternative metrics depending on it. As a consequence, object oriented metrics could be applied to files containing Java code, but would not be required for files that are written in assembler language.

The whole process can be observed in Figure 2: after (possibly) decompressing, the directory and file hierarchy is obtained, then files are discriminated by their type and finally analyzed, if possible taking into consideration the file type that has been identified in the previous step. In the following subsections the different steps are described more in detail.

Hierarchical Structure

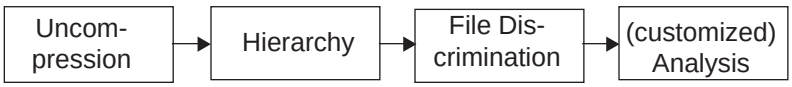
The structure of directories and files of a software program (and how it changes over time) has already been the focus of some research studies (Capiluppi, 2004, Capiluppi et al., 2004). The idea is that the technical architecture and probably therefore the organization of the development team is mapped by the tree hierarchy of directories. So, from a directory hierarchy, we could infer the organizational structure of a libre software development project.

File Discrimination

File discrimination is a technique that is used to specifically analyze files on behalf of their content (Robles et al., 2006a). The most common way of discriminating files is by using heuristics, which may vary in their accuracy as well as in the granularity of their results.

A first set of heuristics may determine the type of a file by considering its extension. File extensions are non-mandatory, but usually conventions exist so that the identification of the content of a file can be made easier and to enable the automation of administrative tasks.

Figure 2. Process of source code analysis



Hence, a first step for file discrimination consists of having a list of extensions that links to the content of the file. In this context, the *.pl* extension is indicative for a file that contains programming instructions while a *.png* can be considered as an image file. Of course, this can be done at several granularity levels, meaning that a *.c* file is a file that with high probability contains programming language, being that the programming language C code. Table 1 shows an excerpt of the list of file extensions that can be used.

The file types that can be considered are documentation, images, internationalization (i18n) and localization (l10n), user interface (ui), multimedia and code files. For the latter type, a more detailed analysis and discrimination between source code that is part of the software application (code) from the one that helps in the building process (generally Makefiles, configure.in, among others) and from documentation files that are tightly bound to the development and building process (such as README, TODO or HACKING) can be made.

A second step in the process of file discrimination includes inspection of the content of the files both to check if the identification made by means of matching file extensions is correct and to identify files that have no extension or whose extension is not included in the previous list.

Table 1. (Incomplete) set of matches performed to identify the different file types

File type	Extension/file name matching
documentation	*.html *.txt *.ps *.tex *.sgml
images	*.png *.jpg *.jpeg *.bmp *.gif
i18n	*.po *.pot *.mo *.charset
ui	*.desktop *.ui *.xpm *.theme
multimedia	*.mp3 *.ogg *.wav. *.au *.mid
code	*.c *.h *.cc *.pl *.java *.s *.ada
build	configure.* makefile.* *.make
devel-doc	readme* changelog* todo* hacking*

In this case, heuristics are generally content-specific and may go more in depth depending on the detail of discrimination we are looking for. One of the most common ways to improve file discrimination by looking at the file content is to analyze the first line. There exists some convention in source code files that denotes that the programming language that they contain. For instance, in the case of a file written in the Python, *Bourne again* shell or Perl programming language (examples can be found in Table 2), the first line could contain respectively the following information[2].

In the case of programming languages, further information can be gained from the structure of the code, by the identification of specific keywords or other elements such as specific comments. For text files (especially the ones that are based on mark-up languages), tags and other specific elements may help in the identification process. Finally, other algorithms can be taken into account, as the information returned by the UNIX *file* command on the file type (which also identifies some of the binary formats, especially useful in the case of images).

Some of the previous discrimination techniques are already in use in some tools, most notably in SLOCCount (see (Wheeler, 2001, Robles et al., 2006b)). As SLOCCount counts the number of lines of code it is only concerned with identifying source code files and identifying the programming language in which they are written, not considering all other file types that we have taken into consideration in this work (documentation, translations, and other).

Analysis of Source Code Files

The analysis of source code files is one of the most known tasks. There exist an ample number of measures that can be and have been extracted directly from the source code, among other its length (in lines of code or source lines of code), complexity measures (as the popular

Table 2. Examples of first line indicating that the file is written in Python, Shell or Perl respectively

```
#! /usr/bin/python
#! /usr/bin/sh
#! /usr/bin/perl
```

ones proposed by Halstead (Halstead, 1977) and McCabe (McCabe, 1976)) or even composite metrics such as the Maintainability Index (Oman and Hagemeister, 1992).

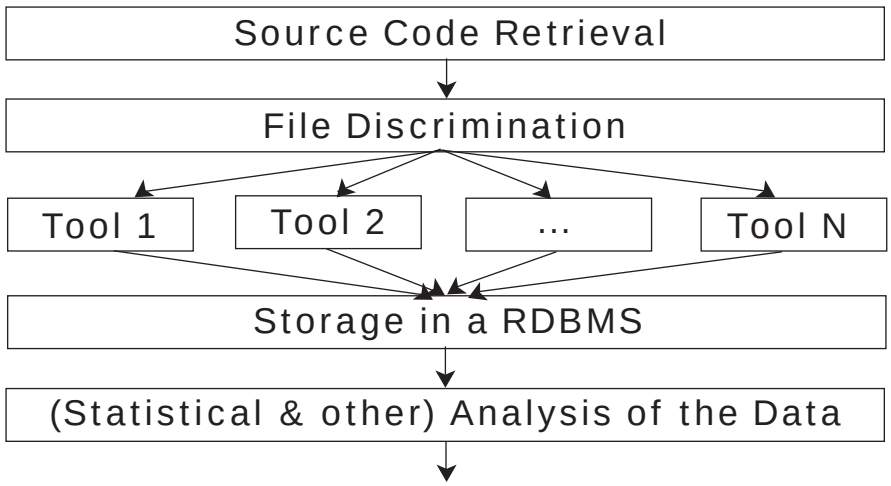
The availability of a certain range of tools for this purpose makes the conception of a tool that integrates all of them a primary task. The goals of the integration is to make it possible to extract all the metrics and facts from source code files by using several tools in a simple and most uniform way. The tools used to measure the code should be, if possible, used as *black boxes*, so that the integration tool does not need to know or adapt its inner functioning. In addition, the integration tool should handle the input to and the output from the measurement tools to ease its use.

That is precisely what can be done with GlueTheos[3], a tool designed and implemented by the authors of this chapter: a system with an architecture that allows the data retrieval and analysis of public software development data repositories. The structure of the GlueTheos tool is presented in Figure 3, and consists of a module for downloading (if required, with a periodical pattern) the sources to be analyzed, to examine the content of the sources on a file basis, to run the tools depending on the file type, to identify the results and store them properly in a relational database system and finally to provide results.

The current version can access *CVS*, *Subversion* and *git*. File discrimination allows to run the tools specifically on the files where this makes sense. Hence, if we had a tool that returns object oriented measures from Java files it would make no sense to run it on a shell script. This step then optimizes the analysis to be performed.

The next step is the heart of GlueTheos and consists of running the different tools on the source code and retrieving the data that these tools return. GlueTheos has been designed in a way in which it does not require to adapt the tools it integrates, hence facing the complexity of the various ways of calling them and the various ways of obtaining their results. Both calling and returning have been solved following an object-oriented approach, so that for any tool only the differences have to be implemented.

Figure 3. Architecture of the GlueTheos tool



The calling procedure requires information such as the way a tool has to be called (mainly the path to the executable), the input that the tool requires (usually a file or a directory) and the type of output that the tool returns (again, usually a file or a directory).

The returning methods depend on the type of output that the analysis tools provide. If it is a file, the number of returning elements has to be given and the special character that is used to separate them (usually a tabulator, a white space or a comma). In general, the path that gives the filename of the file that has been analyzed is also returned, so its position has to be specified.

After retrieving and storing the data from external tools, GlueTheos has to consider only the data in the database to obtain statistical and other results from the data set. This includes some procedures to enhance the database structure in order to normalize the fields or to obtain intermediate tables with statistical information that is of common use.

Analysis of Other Files

Besides source code written in a programming language, we identify other artifacts that compose the sources of libre software projects. (Robles et al., 2006a) shows the many possibilities that arise from the study of those files, but other references to this issue may be found in related literature. Some authors have focused on the analysis of the change log files (Capiluppi et al., 2003) as they usually follow a common pattern in libre software projects, although sometimes this pattern is slightly different from the standardized way used in GNU projects[4].

Translation files may be used to keep track of the amount of translation work that has been accomplished to the moment and hence have a quantitative manner of knowing the support of that software in a given language.

Regarding licenses, in addition of a reference to the licensing terms that can be found at the top of the code files, usually projects have a text file which includes the full text of the license. The filename may give enough evidence for the type of license that a project uses, but other ways can also be considered. One that we have been trying with is the use of a locality-sensitive hash like nilsimsa (Chang and Mockus, 2008). This type of hashes return codes with small changes for inputs that differ only slightly. As intellectual property issues have become a recent area of interest among industry, some approaches (and tools, such as FOSSology) have been presented that target these problems (Gobeille, 2008).

Finally, the amount of documentation for a software system could be a good topic for empirical research. In this sense, the *doceval*[5] tool offers a way of assessing and partially evaluating the documentation that can be found in the sources of libre software projects (Robles et al., 2006c).

Authorship Analysis

Usually, source code files contain copyright and license information in their first lines (Spinellis, 2003). So, for instance, the notice in the apps/units.c file of the GIMP project shown in Table 3 clearly states that the copyright holders are Spencer Kimball and Peter Mattis and that the license in use is the GNU General Public License.

CODD[6] is a tool that searches for authorship information in source code by tracking copyright notices and other information in the headings of files (Ghosh and Prakash, 2000, Ghosh et al., 2002). It assigns the length (in bytes) of each file to the corresponding authors. The process that CODD follows to obtain these results are shown in Figure 4.

File extraction is composed of the *init* subroutine which takes the source code package (or packages) that are given through the command line by the user, decompresses them if necessary, and tries to identify recursively the files that the package contains.

Table 3. Excerpt of a copyright statement found in the GIMP project

```

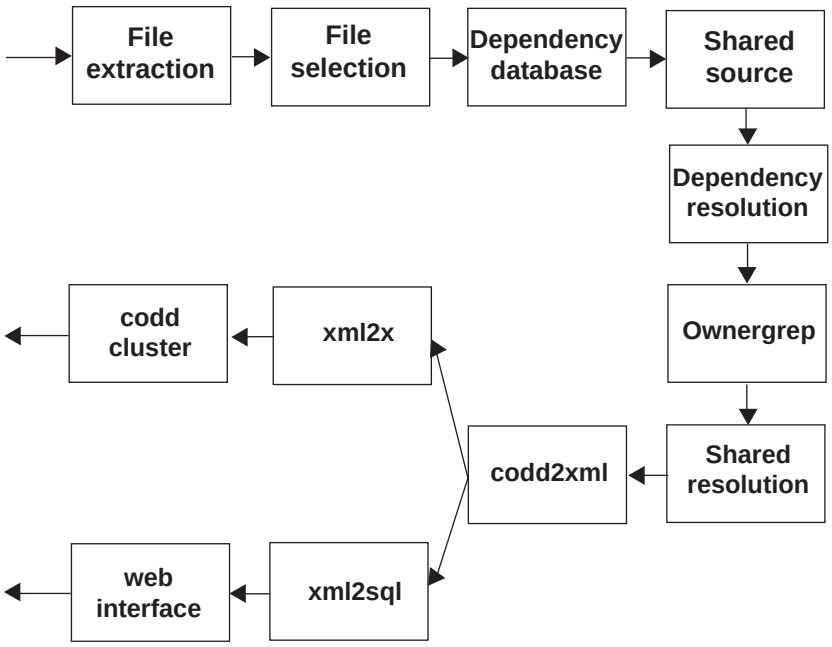
 * Copyright (C) 1995 Spencer Kimball and Peter Mattis
 *
 * This program is free software; you can redistribute it and/or modify
[...]
```

Figure 4. Process of the CODD tool



During the file selection all source code files, documentation, interfaces and not-resolved implementations are taken together with their size in bytes, their MD5 sum and their relative route in the package and stored in a *codd*[7]. Files are selected by means of their extension, so for instance the *.c* file extension is categorized into source code files (usually they correspond to C files). CODD stores the *.h* files that have a *.c* in the same package as interfaces (the algorithm that is used here depends partially on the programming language that is being analyzed). Calls to an interface in source code files (for instance *.c* files for C) that do not have their corresponding interface in the same package (a *.h* for C) will be classified in the non-resolved implementations category, that in a future step will be handled for dependency resolution.

In a third step two databases are created in order to find shared source code and dependencies. In the first one, named *codefile_signatures*, all the MD5 sums of the files are stored. The second

one contains all the interfaces that were found in the previous step. MD5 is a type of hash that allows to know if two files are equal; if they are they will have the same MD5 hash value. MD5 hashes are very interesting when the source code file is exactly the same, but a single modification (i.e., when it is committed into the SCM of the new project the RCT-type id changes) makes it impossible to recognize it as a shared file.

In order to find shared source code, CODD runs another time through all codds and looks if the source code files appear more than once in the database (really it looks if the name and MD5 sum appear more than once). If this occurs, the file is located in at least two different packages. A similar process is used to resolve dependencies. CODD will search for not-resolved implementations in the codds and compare their MD5 sums with the ones that are stored in the interfaces database. A list with all the packages where this interface is implemented will be inserted as well.

The owner grep block is the one that is responsible for looking for authorship contributions. It runs again through all source code and documentation files and scans authorship attribution by means of certain heuristics. Mainly the heuristics look for several patterns: email addresses [a], copyright notices [b] and software control versioning ids [c]. Information about the authors is stored in the *credits* section of the codds. The regular expressions that have been used are following:

[a] Email grep: [\d\w_\=\.\%]+?\@[\d\w\._\-]+?\.\w+?)(?=[\s:>\n\r\)]|$

[b] Copyright grep: .*copyright (?:\(c\))?[\d\,\-\s\:]+(?:by\s+)?([?\d]*)

[c] Id grep: (?:Id|Header).*?\d\d\:\d\d\:\d\d (\S+?) \S+?

Next, the resolution of shared source code is done. In the *shared* source code section of the codds we still have files and a list of packages that contain these files. As these files can only be assigned to a single package (in order to avoid double counting the contribution of an author), CODD looks for its author (running again the *ownergrep* algorithm) in the file and assigns it to the package in which the author is the main contributor.

The last blocks of Figure 4 show that the codds can be then transformed to an intermediate and independent format (as for instance XML and SQL).

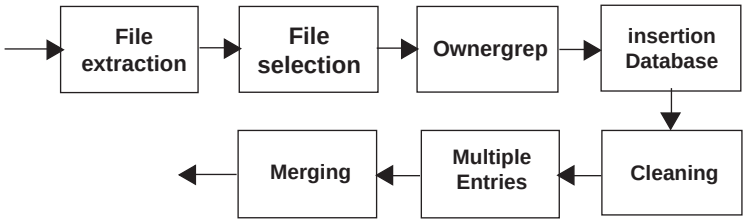
CODD is a very powerful tool, but it has some weaknesses. The most important one is that it lacks a way of merging the various ways in which an author may appear. So, authors may appear several times with different names or e-mail addresses. For instance, we have found that some developers have up to 15 e-mail addresses. In the case of companies, the same may happen; so, IBM or the MIT appear in several ways (up to ten times!) with slightly different wordings (Robles et al., 2007).

Cleaning of the data should also be enhanced. The heuristics that are used in CODD have proved to be very powerful, but cannot avoid that developers use different conventions to assign copyright. Most of these problems could be solved by a set of more powerful heuristics.

As *CODD* raises some limitations regarding authorship identification, the authors decided 2004 to create a new tool from scratch based on the heuristics given by CODD. This tool has been called *pyTernity*[8]. The architecture of pyTernity is identical to the one described for CODD as it can be seen from Figure 5, although it lacks of all the procedures for identifying dependencies among files.

The most innovative elements are the ones that consider data cleaning and the identification of multiple entries. For the former, entries in database are removed from elements that make them different; this goes from additional white-spaces to the avoidance of dots. Some heuristics have been set up for this, although they have been complemented with a database of frequent changes. Cleaning includes splitting up an entry

Figure 5. Process of the pyTernity tool



when it is due to two or more authors. So, the entry "Spencer Kimball and Peter Mattis" will result in two, one for Spencer Kimball and another one for Peter Mattis. If this is the case, both names appear as authors of the file and get attributed half of its length (in bytes or lines of code).

The latter part comprises the identification of multiple entries. Developers may appear in several ways, making results very unsatisfactory. The first efforts in this sense went into the construction of a large database where the various entries identified for a given developer were merged into a unique one. This has proved to enhance results in a prominent way. Other, more complex, routines may be used for extracting names from e-mails, with procedures from the machine learning world as for instance applying *named entity recognition* (Minkov et al., 2005).

Once cleaning has been performed and multiple entries have been identified, pyTernity merges the entries in the database so that authors appear only once in a file. This procedure implies to add all the contributions by an author, so it adds the lengths of each entry (in bytes or lines of code).

SCM SYSTEM META-DATA

Generally speaking, most libre software projects use a SCM system to manage file versions during the development process. They allow to track changes and past states of a software project. Thus, obtaining the current and any past state of the code is made possible by the use of a SCM system. This allows to make source code analyses as we have presented them in the previous section in a longitudinal manner and to extract facts on the evolution of a software project.

But beyond this, SCM systems store a set of meta-data of the changes. These meta-data can be tracked and analyzed. This information is usually related to the interactions that occur among developers and the SCM systems. In general the information is only related to actions that comprehend write access while reading (downloading the sources) or obtaining other information (diffs, among others) cannot be tracked in that way. For instance, along with a change, valuable information is recorded, like the date of change, the full path where the change occurred, user who committed or the comment written by the committer[9].

Here, we present a tool that analyzes the interactions that occur between developers and the most used SCM systems used in libre software projects at the current time, CVS, Subversion, *git* and *Bazaar*. This tool, which has been labeled CVSAnalY, is based on the analysis of the SCM system log entries and implements all the theoretical details that will be presented in this section (Robles et al., 2004). Another tool, called SoftChange, has been used for similar purposes by German *et al.* (Germán and Hindle, 2005).

In CVSAnalY any interaction -also called commit- a committer does with the central SCM system repository is logged with following data

Figure 6. Process of the CVSAnalY tool

associated (some aforementioned): committer name, date, file, revision number, lines added, lines removed and an explanatory comment introduced by the committer. There is some file-specific information that can also be extracted, as for instance if the file has been removed[10]. On the other hand, the human-inserted comment can also be parsed in order to see if the commit corresponds to an external contribution or even to an automated script.

Basically CVSAnalY consists of three main steps, preprocessing, insertion into database and post-processing, but they can be subdivided into several more as it has been done in Figure 6. In the following subsections the inner functioning of CVSAnalY will be presented, focusing on details of its use with CVS. Its use with other SCM systems should be similar.

Preprocessing: Retrieval and Parsing

Preprocessing includes downloading the sources from the repository of the project in study. Once this is done, the logs are retrieved and parsed to transform the information contained in log format into a more structured format (SQL for databases or XML for data exchange).

Besides the information for every commit, other data obtained from the parsing requires some attention. Although committers seldom change their username, sometimes this happens, so the various usernames have to be merged into a unique one. For instance, in the KDE project committers usually get an account prior to a *kde.org* e-mail address. If a developer is afterwards assigned an e-mail address the username of e-mail and SCM system have to be identical for organizational and practical reasons. If the username in the e-mail address is different from the CVS username, CVSAnalY syncs with the former one and the actions done with both usernames are considered as done by a unique developer.

The following is a CVS log excerpt for the AUTHORS file of the KDevelop project[11]. It gives the last three revisions (from revision 1.47 to 1.49) done during the last months of the year 2003 until mid-2004. Log messages from other SCM systems, such as Subversion, *git* or *Bazaar* look similar.

While being parsed each file is also matched for its type. Usually this is done by looking at its extension, although other common filenames (for instance README or TODO) are also looked for. The goal of this separation is to identify different contributor groups that work on the software, so besides source code files the following file types are also considered: documentation (including web pages), images, translation (generally internationalization and localization), user interface and sound files. Files that do not match any extension or particular filename are accounted as unknown. This discrimination follows the criteria that have been presented in section 3.2, although it lacks the possibility of looking at the content of the files as we only consider filenames (because this is the only information that appears in the CVS logs).

CVS also has some peculiarities when introducing contents for the first time (this action is called initial check-in). The initial version (with version number 1.1.1.1) is not considered in our computation as it is the same as the second one (which has version number 1.1). The number of aggregated and removed lines in CVS are computed from this initial version. This means that the first commit (the initial check-in) logs as if 0 lines were added. This does not correspond to reality. In order to obtain the actual number of LOCs in the first version we count the LOCs by means of the UNIX *wc* tool[12] of the latest version, subtracting the added lines and adding the removed lines of all the other commits.

Comments attached to commits are usually forwarded to a mailing list so that developers keep track of the latest changes in CVS. Some projects have established some conventions so that certain commits do not produce a message to the mailing list. This happens when those commits are supposed to not require any notification to the rest of the development team. A good example of the pertinent use of *silent* commits comes from the existence of bots that do several tasks automatically.

In any case, such conventions are not limited to non-human bots, as human committers usually may also use them. In a large community -as it is the case for the ones we are researching- we can argue that *silent* commits can be considered as not contributory (i.e., changes to the head of the files, for instance a change in the license or the year in the copyright notice, or moving many files from one location to another). Therefore, we have set a flag for such commits in order to compute them separately or leave them out completely in our analysis.

For instance, the developers of the KDE project mark such commits with the comment *CVS_SILENT* as it can be seen from following log excerpt extracted from the kdevelop_scripting.desktop file of the KDevelop CVS module. In this case it is due to a change to a *desktop* file, a file type that is related to the user interface. Being this change not considered interesting for other developers to know about, the author of this commit decided to make this commit *silently*.

Write access to the SCM system is not given to anyone. Usually this privilege is granted only to those contributors who have reached a compromise with the project and the project's goals. But external contributions -commonly called patches, that may contain bug fixes as well as implementation of new functionality- from people outside the ones who have write access (committers) are always welcome.

It is a widely accepted practice to mark an external contribution with an authorship attribution when committing it. Thus, we have constructed certain heuristics to find and mark commits due to such contributions. The heuristics we have set up are based on the appearance of two circumstances: patch (or patches in its plural form) together with a preposition (from, by, of, and other) or an e-mail address or an indication that the code had been attached to a bug fix in the BTS. The regular expressions that have been used are following:

[a] patch(es)?\s?.* from [f] patch(es)?\s?.* by
[b] patch(es)?\s.*@ [g] @.* patch(es)?
[c] ?s.* patch(es)? [h] s? .* patch(es)?
[d] patch(es)? of [i] <.* [Aa][Tt] .*>
[e] attached to #

As an example, the following slightly modified excerpt taken from the kdevelop.m4.in file from the KDevelop module in the KDE CVS repository shows a patch applied by a committer with username "dymo" that was submitted originally by Willem Boschman:

[...]

Applied patch from Willem Boschman -
fix builddir != srcdir configuration problem.

[...]

All these efforts have in common that they perform text-based analysis of the comments attached by committers to the changes they perform. The range of possibilities in this sense is very ample. For instance, Mockus *et al.*, and later on in an enhanced manner Amor *et al.*, have tried to identify the reasons for changes (classifying changes as adaptative, perfective or corrective) in the software using text-analysis techniques (Mockus and Votta, 2000, Amor et al., 2006).

Data Treatment and Storage

Once the logs have been parsed and transformed into a more structured format, some summarizing and database optimization information is computed and data is stored into a database.

Usually the output of the previous parsing consists of a single database table with an entry per commit. This means that information is stored in a raw form, the table containing possibly millions of entries depending on the size and age of a project. Information is hence in a raw format and in an inconvenient way if we consider getting statistical information for developers and projects from it.

A first step in this direction is to make use of normalization techniques for the data. In this sense, committers are assigned a unique numerical identification and if further granularity is needed, procedures have been implemented to do the same at the directory and file level. For the sake of optimization this has been introduced during the parsing phase so additional queries do not have to be performed. The next step is to gather statistical information on both committers and modules. These additional tables will give detail on the interactions by contributors or to modules,

which is one of the most frequent information that is asked.

Additional information that makes longitudinal analyses possible is the evolution of contributions by developers and to modules. Hence, the same statistical queries that have been obtained for committers and modules for the summarizing tables can be obtained in a monthly or weekly basis since the date the repository was set up.

On the other hand, unfortunately CVS does not keep track of which files have been committed at the same time. The absence of this concept in CVS may bring some distortion into our analysis. We have therefore implemented the sliding window algorithm proposed by German (Germán, 2004) and Zimmermann et al. (Zimmermann et al., 2005) that identifies atomic commits (also known as *modification requests* or transactions) by grouping commits from the CVS logs that have been done (almost) simultaneously. This algorithm considers that commits performed by the same committer in a given time interval (usually in the range of seconds to minutes) can be considered as an atomic commit. If the time window is fixed, the amount of time that is considered from the first commit to the last one is a constant value. For a sliding time window, the time interval is not constant; the time window is restarted for every new commit that belongs to the same transaction until no new commit occurs in the (new) time slot (Zimmermann et al., 2005).

The post-process is composed of several scripts that interact with the database, statistically analyze its information, compute several inequality and concentration indexes and generate graphs for the evolution over time for a couple of interesting parameters (commits, committers, LOCs...). Results are shown through a publicly accessible web interface that allows easy inspection of the whole repository (general results), a single module or by committers[13]. Therefore results are available for remote analysis and interpretation by project participants and other stakeholders.

MAILING LISTS ARCHIVES (AND FORUMS)

Mailing lists and forums are the key elements for information dissemination and project organization in libre software projects. Without almost any exception, libre software projects provide one or more mailing lists. Depending on the project, many mailing lists may exist for several target audiences. So, for instance, SourceForge recommends to open three mailing lists: a technical one for developers, another one to give support to users and and a third one that is used for announcing new releases.

Mailing lists are programs that forward e-mail messages they receive to a list of subscribed e-mail addresses. More sophisticated mailing list managers have plenty of functionality which allows for easy subscription, unsubscription, storage of the messages that have been sent (known as the archives), and avoidance of spam, among others.

Forums are web-based programs that allow visitors to interact in a similar manner as in an e-mail thread with the difference that in this case all the process goes through HTML forms and that results are visible on the web.

Both mailing lists and forums are based on similar concepts and their differences lie in their implementation and the need for different clients to participate in them. Mailing lists require the use of an e-mail client, while forums can be accessed through web browsers. As their concept is the same, there exist some software programs that transform mailing lists messages to a forum-like interface and vice-versa. Because of that, in this chapter we will only focus on mailing lists, specifically on one of the most used mailing lists managers called GNU Mailman[14] and the RFC 822 (also known as MBOX) format in which it generally stores and publishes the archives.

The RFC 822 Standard Format

As mentioned above, generally all mailing list managers offer the possibility of storing all posts (the archives) and making them publicly available through a web interfaces. This offers the possibility for newcomers to go through the history and to gain knowledge on technical as well as organizational details of a project.

The archives are also offered in text files following the MBOX format. MBOX is a format used traditionally in UNIX environments for the local storage of e-mail messages. It is a plain text file that contains an arbitrary number of messages. Each message is composed of a special line followed by an e-mail message in the RFC-822 standard format. The special line that allows to differentiate messages consists of the keyword "From" followed by a blank space, the poster's e-mail address, another blank space and finally the date the message was sent. The RFC-822 format can be divided into two parts: (a) headers, that contain information for the delivery of the message and (b) the content, which is the information to be delivered to the receiver; the standard only allows lines of text, so filtering has to be implemented if an image or other information is attached.

Mailing lists in MBOX format can be analyzed by means of the MailingListStats, or *mlstats* for short, tool[15]. Given an URL of the archives of the mailing lists, *mlstats* outputs the information extracted from the headers and the content of the message in database format for further processing and analysis.

Below is an excerpt of a post sent to a mailing list that has been stored following the RFC-822 standard. Is is an automatic message sent April 30 2005 to the GNOME CVS mailing list. This list keeps track of all the commits that are done to the CVS system of the GNOME project. This assures that subscribers are aware of the latest changes in the CVS. The content of the message, the description of the modification that had been performed, has been omitted in the excerpt.

[Here comes the body of the post which has been omitted in this excerpt]

From the message excerpt above, we can see some of the headers that are described in the standard. The most important ones are following: *From* (e-mail address, sometimes also real name, of the sender), *Sender* (address of the responsible entity for the last transmission), *Reply-To* (address the author wants to be replied), *To* (address(es) of the receiver(s)), *Cc* (e-mail address(es) of the receiver(s) that should receive a copy), *Bcc* (addressee(s) with *carbon* copy), *Subject* (usually contains a brief description of the topic), *Received* (contains address of the intermediate machine that has transferred the message), *Date* (when the message was sent given by the sender machine), *Message-ID* (unique identifier of this message), *In-reply-to* (Identifier of the parent message to which the current one is a response), and *References* (identifications (message-IDs) of all the other messages that are part of the conversation thread).

In addition to the data that can be found in the headers, some other information could be obtained from analyzing the content of the messages. In this regard, Weißgerber *et al.* analyze the type of patches first sent to mailing lists and later on integrated into the source code tree of the project (Weißgerber et al., 2008).

BUG-TRACKING SYSTEMS

BTS are used in libre software projects to manage the incoming error and feature enhancement reports from users and co-developers. The use of BTS is relatively extended and the most known tool in this area is BugZilla[16], a BTS developed by the Mozilla project that has been adopted by other large projects as well. Hence BugZilla is the system we study in this chapter, although conceptually all other systems should work similarly.

BugZilla allows to manage all bug reports and feature requests by means of a publicly available web interface. Besides the reports, it also offers the possibility of adding comments so that developers may ask for further information about the error or other end-users may comment it. Beyond BugZilla, other tools exist with similar features, as for instance GNATS (the one used in the FreeBSD project). SourceForge and other web platforms that support software development have implemented their own BTS for the projects they host.

Data Description

BugZilla stores in its database specific information for each bug report. The fields that can be usually found are following[17]:

- **Bugid:** Unique identifier for any bug report.
- **Description:** Textual description of the error report.
- **Opened:** Date the report was sent.
- **Status:** Status of the report. It can take one of the following status: new, assigned (to a developer to fix it), reopened (when it has been wrongly labeled as resolved), needinfo (developers require more information), verified, closed, resolved and unconfirmed.
- **Resolution:** Action to be performed on the bug. It can take following status: obsolete (will not be fixed as it is a bug to a previous, already solved issue), invalid (not a valid bug), incomplete (the bug has not been completely fixed), notgnome (the bug is not of GNOME, but of a component of another project, as for instance X window system or the Linux kernel), notabug (the issue is not really a bug), wontfix (the developers consider not to correct this error for any reason) and fixed (the error has been corrected).
- **Assigned:** Name and/or e-mail address of the developer in charge of fixing this bug.
- **Priority:** Urgency of the error. It can take following values: immediate, urgent, high, normal and low. Usually this field is modified by the bugmaster as users do not have

sufficient knowledge on the software to know the correct value.

- **Severity:** How this error affects the use and development of the software. Possible values are (from high severity to lower one): blocker, critical, major, normal, minor, trivial and enhancement.
- **Reporter:** Name and e-mail address of the bug reporter.
- **Product:** Software that contains the bug. Usually this is given at the tarball level.
- **Version:** Version number of the product. If no version was introduced, *unspecified* is given. Also, for enhancements the option *unversioned enhancement* may be chosen.
- **Component:** Minor component of the product.
- **Platform:** Operating system or architecture where the error appeared.

Usually all fields (besides the automatic ones like *bugid*, the opening date or its status) are filled out the first time by the reporter. Larger projects usually have some professional or volunteer staff that review the entries in order to adjust the information (Villa, 2003, Villa, 2005). This is especially important for fields like priority or severity as end-users hardly have no knowledge or experience on how to evaluate these fields.

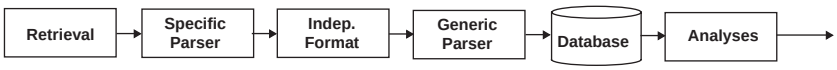
Data Acquisition and Further Processing

For the analysis of the data stored in a BTS, we have created a preliminary tool that is specifically devoted to extract data from BugZilla. The architecture of the BugZilla Analyzing Tool is described in Figure 7. Although the retrieval of the data could theoretically be simplified by obtaining the database of the BugZilla system from the project administrators, we thought that retrieving the data directly from the web interface would be more in accordance with the non-intrusive policy that all other tools described in this chapter follow.

We had to deal with several problems while retrieving the BugZilla data. After crawling for all web pages (one per bug) and storing them locally, we had to transform the HTML data into an intermediate log-type format, as not all fields were given for all bugs due probably to a transition from a previous system. Probably also because of this, there may have been some information loss and some ids could not be tracked. Other problems that we found, were the existence of wrong date entries for some bugs and comments. As the bug report ids are sequential, we could fix these entries when we found out that the date was wrong. We applied the same solution to comments with erroneous dates, as comments are also posted sequentially and cannot be introduced before the bug report has been submitted.

In recent versions of BugZilla, it is possible to obtain the data in XML format which simplifies in a great manner the data extraction[18]. When writing this chapter, the use of the XML interface was not as common as the author would wish, so retrieving the data from parsing web pages was the unique non-intrusive manner at that time. In any case, the BugZilla analyzing tool has been designed in such a way that only by removing some parts (specifically the specific HTML-parser which parses into the independent format) and by modifying the generic parser we could reuse

Figure 7. Architecture of the BugZilla analyzer



the rest of the modules without major changes using the XML query format. This is also valid for other BTS, as GNATS.

One of the issues of BTS is that in general the most relevant information in a bug report is included in natural language (usually in English) in the *Description* field . Bettenburg *et al.* have proposed a tool that extracts structural information such as source code (i.e., patches), listings, etc. from it (Bettenburg et al., 2008).

SUMMARY

Libre software projects offer a vast amount of information about their development process and the resulting product. Although this information is publicly available over the Internet, researchers should take into consideration the many *hidden* problems that may occur when obtaining and properly analyzing these data. In this chapter we have given some insight into the most data sources in research, its problems, how to circumvent them and, if possible, have provided and introduced tools that may help when researchers mine them.

Table 4 summarizes the data sources described in this chapter and the tools that can help researchers in their analysis. Regarding source code, there exist an ample amount of tools that have been used for years in corporate software engineering environments. The ones presented here have a specific target on libre software, as they address issues such as licensing of the files (FOSSology), the identification of the authors – or copyright holders – (CODD and pyTernity) or the presence of absence of documentation (*doceval*).

SCM systems are widely used in libre software projects and provide much information about the software development. The analysis of the logs of these systems, by means of tools like CVSAnalY, gives insight on the dynamics of the projects. The combination of source code and information from the SCM offers a wide range of analysis, especially concerning patterns over time. In this sense, GlueTheos and SoftChange, retrieve the sources for various points in time and extract some metrics. The final result allows to analyse how software projects have evolved over time in respect to measurements related to source code (growth, complexity, etc.), human resources (number of developers, inequality of contributions, etc.) and activity (number of commits, number of patches, etc.).

Finally, mailing lists and forums are usually the main communication channels used in libre software projects. In this chapter, we have discussed a tool, mlstats, that analyzes the information that can be found in the header of the mail messages.

Table 4. Summary of data sources, tools and purpose

Data Source	Tool	Purpose
Source Code	FOSSology	Licensing
Source Code	CODD/pyTernity	Authorship (copyright hlder) analysis
Source Code	doceval	Assessment and partial evaluation of documentation
SCM	CVSAnalY	SCM log messages analysis (evolutionary analysis)
Source Code & SCM	GlueTheos	Evolutionary analysis
Source Code & SCM	SoftChange	Evolutionary analysis
Mailing lists & forums	MailingListStat	Analysis of MBOX headers

Despite the possibilities that the vast amount of publicly available information from libre software projects offer, there are a number of problems, threats and challenges that researchers have to consider when using these data for their activities.

The first major problem comes from incomplete data sets. The cause for this is due to the fact that projects may have switched development-supporting systems and have not migrated old contents into the new system.

A threat to the use of SCM data comes from the necessity of having an account to perform changes. The original developers are in these scenarios not the ones who commit the code into the repository (committers). The validity of some research may be affected by the policies of projects, as for example the inequality of contributions may be artificially skewed towards those who have permission to do the changes in the SCM.

There is a big challenge in merging information from various sources. For instance, correlating bugs in the BTS to commits in SCM and to code in the source code is a tricky task that requires complex methods. In addition, these methods may have to be changed from project to project as the dynamics may be different among them (i.e., in some projects, committers indicate the bug report number in the commit message, while in others patches are not handled via a BTS but through a mailing list)

Finally, as mining libre software projects has become popular among scientists, many projects have suffered from an overflow of data gathering petitions, both automatically by means of tools or directly from humans in the sense of invitations to participate in surveys. In the specific case of tools, sometimes retrieving data has caused the slow down, or denial of service, of servers where the infrastructure of the project is installed, resulting in the tool being banned.

Some of the aforementioned issues are being addressed by the FLOSSMetrics[19] and the FLOSSMole (Conklin et al., 2005) projects, that have as objective to construct, publish and analyse a large scale database with information and metrics about libre software development coming from several thousands of software projects. If such initiatives succeed, researchers wanting to study the libre software phenomenon will have an ample amount of data ready to be analyzed, avoiding many of the tasks (identifications, acquisition, extraction and storage) and the threats discussed in this chapter.

ACKNOWLEDGMENT

We thank the anonymous reviewers for their helpful comments and suggestions. This work has been funded in part by the European Commission, under the FLOSSMETRICS (FP6-IST-5-033547), QUALOSS (FP6-IST-5-033547) and QUALIPSO (FP6-IST-034763) projects, and by the Spanish CICyT, project SobreSalto (TIN2007-66172) and by SEDEPECA.

ENDNOTES

[1] In this chapter the term "libre software" is used to refer to any software licensed under terms that are compliant with the definition of "free software" by the Free Software Foundation, and the definition of "open source software" by the Open Source Initiative, thus avoiding the controversy between those two terms.

[2] The location of the binaries may depend from system to system, although the standard location for them is the /usr/bin directory.

[3] GlueTheos is named after its purpose to glue different tools together in an easy way. Hence, this program is the *god*, *theos* in Greek, of gluing some already existing tools together. It can be retrieved from http://tools.libresoft.es/gluetheos.

[4] In the GNU coding standards, some conventions for change log files are given, see http://www.gnu.org/prep/standards/html_node/Change-Logs.html

[5] *doceval* can be obtained from https://forja.rediris.es/projects/csl-doceval/.

[6] The most current version of CODD may be found at http://libresoft.es/Tools/CODD.

[7] CODD uses as intermediate storage a file for each source package which are called the *codd* files.

[8] The most current version of pyTernity may be found at http://tools.libresoft.es/pyternity.

[9] A committer is a person who has write access to the repository and does a commit -an interaction- with it at a given time.

[10] In a SCM system there is actually no file deletion. In the case of CVS, files that are not required anymore are stored in the *Attic* and may be called back anytime in future.

[11] KDevelop is an IDE (Integrated Development Environment) for KDE. More information can be obtained from http://kdevelop.org/.

[12] *wc* is a standard UNIX tool to count lines of files, among others.

Chapter 3.7
Software Platforms for Mobile Programming

Khoo Wei Ju
Malaysia University of Science and Technology, Malaysia

K. Daniel Wong
Malaysia University of Science and Technology, Malaysia

INTRODUCTION

Java 2 Micro Edition (J2ME), .NET Compact Framework (.NET CF), and Active Server Pages .NET (ASP.NET) Mobile Controls are commonly used alternatives in mobile programming. They provide an environment for applications to run on mobile devices. However, they are different in many ways, such as supported mobile devices, architecture, and development. Hence, it is important for mobile application developers to understand the differences between them in order to choose the one that meets their requirement. Therefore, in this article we will discuss the general architecture of J2ME, .NET CF and ASP.NET Mobile Controls and compare the three alternatives.

BACKGROUND AND INTRODUCTION

Since the mid-1990s, the growth of wireless communications has led to the mushrooming of mobile devices in the market. Initially, the mobile devices were mainly cell phones with limited programmability. However, many analysts and company executives were worried that mobile phone sales would eventually slow down, prompting research and development into software suitable for cell phones (Grice & Charny, 2001). Hence, now, there is a rise of programmable mobile devices. Furthermore, programmable mobile devices these days include not just cell phones but smartphones, PDAs, and pocket PCs. There are three well-known alternatives in mobile programming for general-purpose applications: J2ME, .NET CF, and ASP.NET Mobile Controls.

J2ME is a version of Java that provides an application environment running on consumer devices and embedded devices. It targets machines with as little as 128KB of RAM (Tauber, 2001). J2ME consists of Java virtual machines (JVMs) and a set of standard Java application program interfaces (APIs) defined through the Java community process (JCP). J2ME can be used with different configurations and profiles, which provide specific information to a group of related devices. Configurations support the Java core

APIs. Profiles are built on top of configurations to support device-specific features like networking and user interfaces. The J2ME is available in two main configurations: connected limited device configuration (CLDC) and connected device configuration (CDC). Figure 1 shows the hierarchical structure of J2ME.

.NET CF is a lightweight version of Microsoft's .NET framework. It provides an environment for executing client-side code and eXtensible Markup Language (XML) Web services to smart devices. It is compatible with C# and Visual Basic.NET (VB.NET), and it supports (.NET Compact Framework Team, 2005):

- Windows mobile (2000, 2002, 2003)-based pocket PC,
- Windows mobile-based smartphones, and
- embedded systems running Windows CE .NET 4.1 and later.

.NET CF consists of two main components: the development environment and the runtime environment. The development environment, known as smart device extensions (SDEs), is a Visual Studio .NET (VS.NET) 2003 project type that allows .NET CF applications to be developed rapidly by simply dragging appropriate controls into the application. The runtime environment is the common language runtime (CLR). The size of the CLR and relevant class libraries is smaller than 2MB, which is suitable for mobile devices. The architecture of .NET CF is shown in Figure 2.

Active server pages (ASPs) is Microsoft's server-side scripting technology. An active server page has an .asp extension, and it mixes HyperText

Figure 1. Hierarchical structure of J2ME

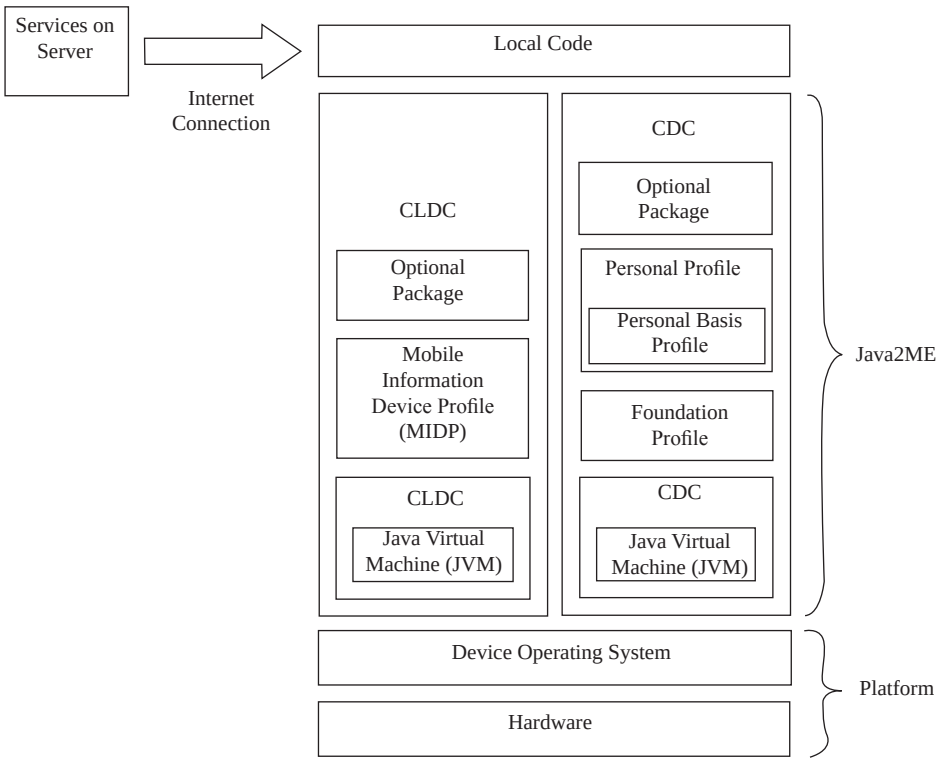

Figure 2. .NET compact framework

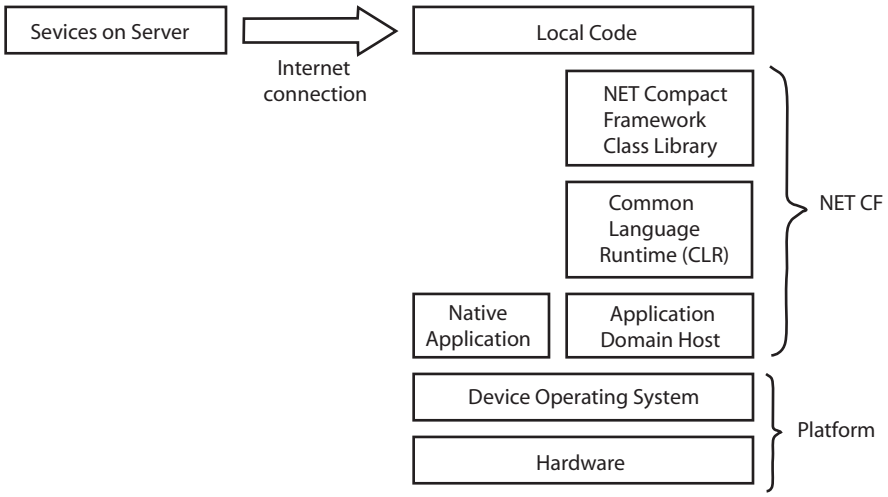


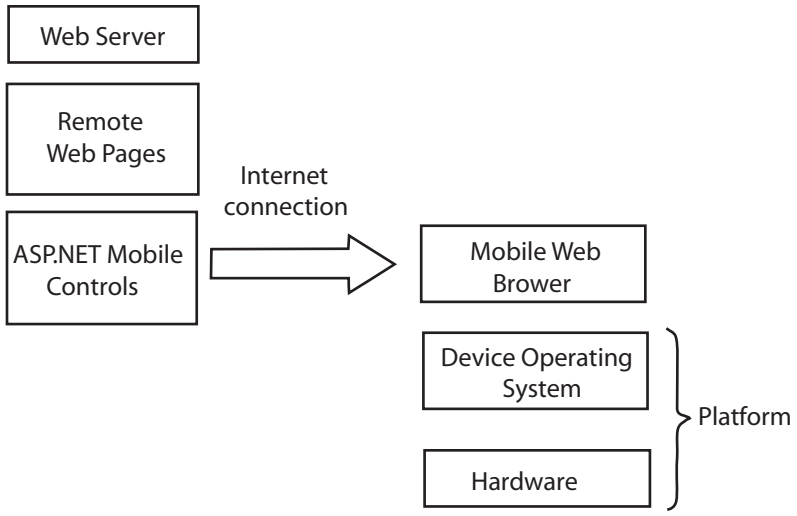
Markup Language (HTML) and scripting code that can be written in VBScript or JavaScript. ASP is distributed with Microsoft's Internet information services (IIS) Web server, so most hosts using IIS will also offer ASP for dynamic Web programming. ASP.NET is the version of ASP that works with Microsoft's .NET Framework.

ASP.NET Mobile Controls was previously known as Microsoft mobile Internet toolkit (MMIT). It was renamed as ASP.NET Mobile Controls to reinforce the concept that it is a collection of ASP.NET controls designed for mobile applications. It extends the ASP.NET server-side technology to allow developers to develop applications for a variety of mobile devices. Executing on the IIS Web server, ASP.NET Mobile Controls allows Web applications to be accessed by almost any Internet-enabled mobile device. During runtime, it will automatically detect the device running the application. The application is then transformed into a form suitable for that device. This frees the developer to concentrate on the application logic and leaves the user interface rendering to the runtime (Lee, 2002a). Furthermore, it allows developers to visually drag and drop controls on forms aimed at mobile devices using VS.NET. The rest of the work, such as writing the proper markup language (e.g., Wireless Markup Language (WML), wireless application protocol (WAP)), is handled by the toolkit. The application development environment for ASP.NET Mobile Controls should be familiar to most ASP.NET programmers. Figure 3 shows the architecture of ASP.NET Mobile Controls.

FEATURE COMPARISON

J2ME, .NET CF, and ASP.NET Mobile Controls cannot be easily compared feature-to-feature because the analysis must include non-technology aspects such as market acceptance, development and testing tools, reach, standardization, and platform coherence. Besides, the final releases of J2ME's mobile information device profile (MIDP), personal basis profile, and personal profile are still in production (Sun, 2005). On the other hand, .NET CF is in the final stages of its beta tests. Nevertheless, a feature comparison, although limited, should still be useful.

Figure 3. ASP.NET mobile controls



Flexibility of Machine Control and Scope of Applications

Virtual Machines, Pointers, Native Features

In the .NET Compact Framework, the common language runtime (CLR) environment executes .NET's Microsoft Intermediate Language code. The CLR also offers support services, such as code verification, memory, and code security. The managed code is always translated into native machine code rather than interpreted. CLR supports interfaces and pointers. As for security policy, .NET CF grants full trust to all code (Microsoft, 2005b). The standard frameworks cover only a limited set of commonly used mobile device features. Other features are accessible via native methods. Besides, it is believed that .NET CF has better support for native methods than J2ME because Microsoft controls both .NET CF and the Windows operating system (Yuan, 2002).

With J2ME, Java source code is compiled into machine-independent byte code. The byte code is then interpreted by the Java virtual machine (JVM) during runtime. J2ME employs different versions of the JVM based on the needs of a particular situation. The configuration specifications define the characteristics of the J2ME virtual machines. In most cases, features of the JVM are removed to accommodate the needs of a configuration. The CDC runs on a C-virtual machine (CVM) that is fully compliant with the Java virtual machine specification. The CDC profile accommodates devices with as little as 512kB of memory, although it is really designed for platforms with about 2 MB of available memory (White & Hemphill, 2002). Sun provides a reference implementation of the CLDC specification that is based on the KVM, a small footprint of JVM that satisfies the CLDC requirements. However, products need not be based on KVM—any virtual machine that has the features required by the specification and can work within the resource restrictions of the CLDC environment can be used (Topley, 2002). Although JVM supports interfaces, it does not support pointers because it can result in unsafe code. The Java native interface (JNI), which allows access to native methods, can be used but only by CDC. For CLDC, the native features must be built into the runtime.

Consumer Applications, Multimedia, Gaming

.NET CF supports direct draw on canvas, double buffering, and device button remapping through its rich Windows Forms User Interface library. It also supports multimedia playback by using the native methods from Windows Media Player on Pocket PC (Yuan, 2002).

In J2ME, the mobile information device profile (MIDP) 2.0 for CLDC includes animation and game controls in the javax.microedition. lcdui.game package. Multimedia playback is supported via the Java media framework (JMF) on the CDC or the multimedia optional package for the CLDC. Many game developers prefer J2ME, because it is supported by a wider range of mobile platforms.

Development Support

Programming Languages

ASP.NET supports any language supported by the .NET Framework, including C, C++, C#, Visual Basic, and even Java. However, .NET CF currently supports only two major .NET languages: C# and VB.NET (Microsoft, 2005a). C# and VB.NET are standardized by EMCA and ISO/IEC. Hence, Microsoft has long been criticized for tightly controlling its technologies. However, the support of multiple standardized languages allow developers flexibility in programming in .NET CF.

J2ME only supports Java. Anyone can propose a Java specification request (JSR) to the Java community process (JCP) for a new platform extension. Unlike with the tightly controlled development of .NET compact framework and ASP.NET, it may appear that under a more free process like the JCP, developers have to spend much time understanding the features to make use of all extensions in the language. However, J2ME APIs undergo rigorous standardization processes to ensure wide industry support and minimum learning for developers.

Platforms

.NET CF supports high-end PDAs such as Windows pocket PCs, Windows smartphones, and embedded devices running on the Windows CE .NET platform (Microsoft, 2005a). Windows devices consist of only a small part of today's mobile device population.

With J2ME, most of the cell phone devices (Motorola iDEN, Nokia Symbian OS, and Qualcomm Brew platforms) and low-end PDAs (Palm OS and Real-Time OS platforms) have built-in Java support because Java allows developers to be productive across many mobile platforms.

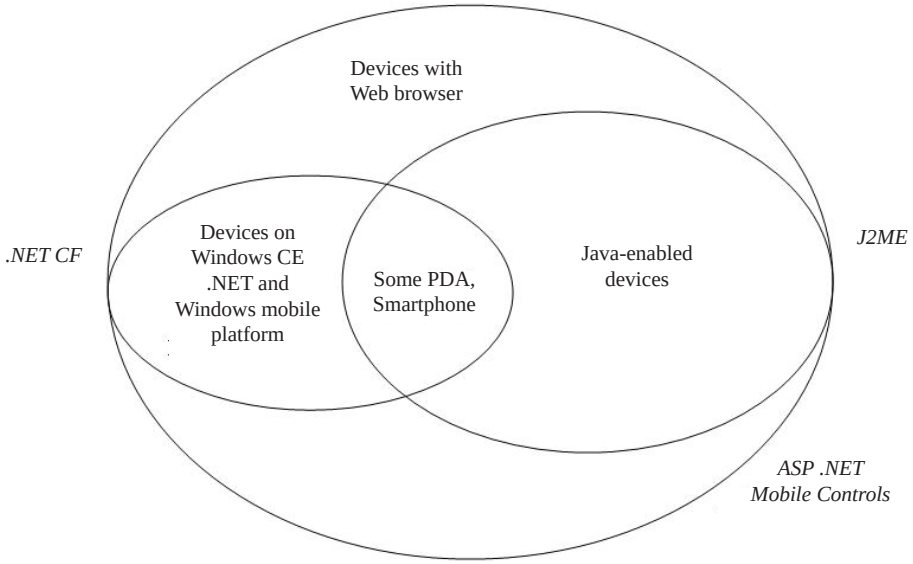
Because it is server-side based, placing minimal requirements on the client, ASP.NET is supported by the widest range of mobile devices, including all devices that support .NET CF, all devices that support J2ME, and more. However, each of these devices may present the output of the ASP.NET controls differently due to their different limitations and capabilities.

Development Tools

Regarding .NET CF and ASP.NET, Visual Studio .NET provides similar design interfaces for both mobile and non-mobile applications. It supports Web services integration and relational database access, and VS.NET is tightly integrated with Visio Enterprise Network Tools edition, which can generate C# or VB.NET code from UML (Unified Modeling Language) diagrams. Furthermore, VS.NET supports debugging on both emulators and real devices. However, VS.NET is not free.

Sun's J2ME Wireless ToolKit is a widely used MIDP development tool. Furthermore, command-line tools and vendor-specific toolkits are readily available. All major Java integrated development environments (IDEs) have J2ME modules or plug-

Figure 4. Devices supported by .NET CF, J2ME, and ASP.NET mobile controls



ins. A big challenge for all J2ME IDEs is vendor software development kit (SDK) integration. Every device vendor provides SDKs for their device emulators and proprietary J2ME extensions. The unified emulator interface (UEI) is designed to standardize the interfaces between IDEs and device SDKs. However, the UEI is available only through a Sun licensing program.

Miscellaneous

Specification Process

When a new technology emerges, Microsoft has the veto power to make decisions and make it available on .NET CF and/or ASP.NET. This saves time and effort. On the other hand, this also means that developers have no say on the specification process.

The Java community process (JCP) decides the new J2ME standard APIs, whereas Sun has veto power on only Java language specifications. The JCP develops all current J2ME configurations, profiles, and optional packages, so the specification process is arguably very lengthy and inefficient. However, some developers like this because more people are allowed to contribute and decide.

Gateways

There are technical difficulties in using .NET CF in mobile gateways because it was not designed to run lightweight application servers required in mobile gateways. Although Microsoft mobile information server (MIS) is a powerful gateway, messaging, and synchronization server, .NET CF lacks built-in APIs to interact with Microsoft MIS (Yuan, 2002).

For J2ME, the primary mobile service gateway product is from IBM. The Oracle9i wireless application server and Oracle J2ME SDKs provide gateway integration points for mobile devices to many other Oracle or third-party application servers (Yuan, 2002).

Additional Comparisons Between .NET CF and ASP.NET Mobile Controls

Server-Client Side

.NET CF uses client-side technology. Code is executed on the mobile device using just-in-time (JIT) compilation and native execution. ASP.NET uses server-side technology. Code is executed on the server, producing markup-language-based output such as HTML to be interpreted by a Web browser.

Web Server

For .NET CF, a Web server is not needed because code is executed directly on the device. For ASP.NET, a Web server (such as Microsoft IIS 5.0 or 6.0) that supports ASP.NET is required. The ASP.NET HTTP runtime is used to handle and process requests via a set of ASP.NET server controls.

Device Support

Only devices that have .NET CF runtime can execute programs written on .NET CF. On the other hand, since ASP.NET is server-side based, less processing is required on the client side compared to .NET CF. However, each of these devices may present the output of the ASP.NET controls differently due to their different limitations and capabilities.

Connectivity

For .NET CF, standalone applications can be created and installed on portable devices such as the pocket PC, pocket PC phone, and smartphone. By having the applications downloaded into such devices, the devices can either be connected or not connected. The XML or SQL Server 2000 Windows CE editions are used for local storage when working off-line. With ASP.NET Mobile Controls, an HTTP connection is required to request an ASP.NET page that uses the Mobile Controls.

FUTURE TRENDS

In recent years, a strange trend can be seen in the design of mobile devices; they are getting bigger and bigger. They are gradually taking on more

Table 1. Comparison summary between .NET CF, J2ME (CDC and CLDC) and ASP.NET Mobile Controls

	.NET Compact Framework	**J2ME Connected Device Configuration**	**J2ME Connected Limited Device Configuration**	**ASP.NET Mobile Controls**
Virtual Machine	Common Language Runtime (CLR)	Java Virtual Machine (JVM)		Common Language Runtime (CLR)
Portable Code	Intermediate Language (IL)	Byte code		Intermediate Language (IL)
Just-In-Time (JIT) Compiling	Yes	Yes		Yes
Garbage Collection	Yes	Yes		Yes
Portability	No	Yes		Yes

Location API	APIs provided by carriers	Location API	Location API	-

of the features of regular computers. We say this is a strange trend because mobile devices were originally meant to be stripped down, barebones devices with only the most useful features for mobile usage. Nevertheless, this trend is getting encouraging responses from users because the mobile devices are able to hold all the files they need to carry around. Due to the encouraging response from the users and the advances in technology, it is predicted that the trend will continue.

Besides, the sales of traditional PDAs have declined in the past few years (ETForecasts, 2003). This is because the PDA market is gradually being taken over by the smartphone, also known as the PDA phone. Users favor phones with computer features, such as storage capacity and clearer display (Kewney, 2005).

Currently, non-Microsoft operating systems like Symbian dominate the smartphone operating system market. As the sales and variety of smartphones are increasing worldwide, assuming Windows mobile platform keeps the same percentage of the market, the usage of Windows mobile platform will grow as well. Besides, given

the past success of Microsoft to expand into new related markets, it is quite likely that they could increase their market share over the next few years, and there is much room for them to grow. Since Windows mobile platform will support only .NET CF (Java is not included), the growth of Windows mobile platform will directly lead to the increase in the use of .NET CF in mobile programming.

Furthermore, the current versions of .NET CF grant full trust to all code. However, the upcoming versions of .NET CF will offer a subset of the policy-driven, evidence-based code access security of the full .NET framework (Microsoft, 2005b). This is a good feature from the security point of view; however, it may be less convenient for developers compared to the current version.

Hopefully in the future, both Microsoft and Java applications can coexist in the same mobile device.

CONCLUSION

.NET CF and J2ME are both excellent platforms for developing smart clients for mobile commerce applications. J2ME has already gained a lot of industry support as the most favorable platform for developing mobile applications, and there are over 500,000 skilled Java developers around the world (Wishart, 2002). J2ME implements a modular design and is portable across a variety of devices. The platform provides balanced support for both enterprise and consumer applications. J2ME vendors offer excellent selections of mobile databases and gateway application server products.

On the other hand, .NET has the advantage over J2ME where it provides a single development platform and common coding practices based around Visual Studio. There are more than 1.5 million skilled developers worldwide (Wishart, 2002), and Microsoft has the largest tools and third-party developers program. The .NET CF platform focuses on enterprise applications with rich user interface, database, and XML Web services support. Hence, .NET CF is suitable for cash-rich customers with controlled mobile environments. However, .NET CF runs only on Windows-powered high-end PDAs. As a young platform, it currently lacks support for gateway servers and choices for mobile databases.

For the near future, the choice between .NET CF and J2ME is not so much a question of the desired platform features (both are excellent in this respect) as the targeted devices. In the short run, J2ME is supported by more devices than .NET CF. In the long run, most experts expect both platforms to coexist in all market sectors. Developers must choose the right tools and make them all work in heterogeneous environments. For example, J2ME clients would need to work with .NET backend servers and vice versa. So it would ultimately not come down to a choice between J2ME or .NET CF.

Both .NET CF and J2ME have advantages over ASP.NET Mobile Controls in supporting code that will execute on the device, and that can run in disconnected, connected, or occasionally connected modes. Therefore, for most enterprise mobile solutions, .NET CF and J2ME are more appropriate.

On the other hand, if browser-based applications are required, Microsoft ASP.NET Mobile Controls can be used to develop mobile Web applications that adapt their page rendering for a range of devices, such as micro-browsers on PDAs, smartphones, and WAP phones. ASP.NET Mobile Controls allows the developers to target the users they need to target, without worrying about the device they are using.

KEY TERMS

Active Server Page (ASP): Microsoft's server-side technology that allows scripting language for dynamically generated Web.

Cell Phone (Mobile Phone): Electronic telecommunications device that is able to move over

a wide area, connected using wireless radio wave transmission technology.

Personal Digital Assistant (PDA): Mobile device that serves as personal organizer. The basic features of a PDA include phone book, address book, task list, memo pad, clock, and calculator software.

Pocket PC: Operating platform for handheld devices introduced by Microsoft, based on the Windows CE operating system.

Smartphone: Mobile device that integrates the functionality of a mobile phone and PDA by adding telephone functions to a PDA or including the PDA capabilities on a mobile phone.

Web Service: Software system designed to support interoperability among machines over a network using a standardized interface.

Windows CE: A simplified version of the Windows operating system designed to run on handheld-size computers.

Windows Mobile: Operating system that replaced the Windows CE operating system on mobile devices. It includes a suite of basic applications for mobile devices based on the Microsoft Win32 API.

ABSTRACT

This chapter aims to define a research agenda regarding the software graphics architecture for interactive digital television (iDTV). It is important to note that by iDTV we do not refer to the provision of a return path, but rather to the potential impact the user has over the television (both video stream and applications) content. We can differentiate three major topics to be included in the agenda: (1) to define a suitable declarative environment for television receivers, (2) to research television input (as multiple input devices) and output (multiple display devices) capabilities, and (3) to rethink the models of television distribution and post-distribution (e.g., peer-to-peer [P2P] networks and optical storage technologies). This

chapter elaborates on these topics.

INTRODUCTION

Digital television receivers are starting to show a reasonable level of maturity and their market penetration is becoming significant (e.g., Italy, Finland, UK, and Korea). A number of multimedia home platform (MHP) (European Telecommunications Standards Institute [ETSI], 2003, 2005) compliant receivers exist and regional standardization initiatives have joined forces by creating the Globally Executable MHP (GEM) standard (ETSI, 2004).

Still, a number of questions regarding the graphics engine (that is, the low-level software presentation control engine) and the interactive capabilities of next-generation receivers arise from both the research community and the industry. Some of the research topics include:

- Definition of a suitable declarative environment for digital television receivers, such as the synchronized multimedia integration language (SMIL) and the World Wide Web Consortium (W3C) recommendation (Bulterman & Rutledge, 2004).
- Integration of other standards, such as Moving Picture Experts Group (MPEG)-4, and Multimedia and Hypermedia information coding Expert Group (MHEG) in current standardization efforts.
- Interaction/visualization using other devices than the remote control/television set (e.g., mobile devices, tablet augmenters).
- Definition of new distribution and post-distribution models, such as P2P and optical storage devices, apart from the typical broadcast model.

This chapter is structured as follows. First, section 2 discusses the state of the art in terms of the broadcast environment, the receiver middleware, and services. Then, based on the state of the art, section 3 identifies relevant research topics in the area. Next, section 4 proposes a research agenda, and section 5 concludes the chapter.

STATE OF THE ART

Jensen (2005) has written an interesting study that categorises and defines iDTV services. He differentiates three different iDTV forms:

- **Enhanced:** Enhanced information that is sent via the broadcast channel (e.g., banners)
- **Personalized:** Automatic selection of programs by the receiver (recommendations) and personal digital recording (PDR) capabilities such as play/pause
- **Complete Interactive:** Return channel provision

He points out that, currently, only "low-technology discount solutions," referring to Nielsen usability evaluation methods, are provided. The most important discount solution today is SMS mobile phone return channel, which can evolve in the future to multimedia messaging service (MMS) solutions.

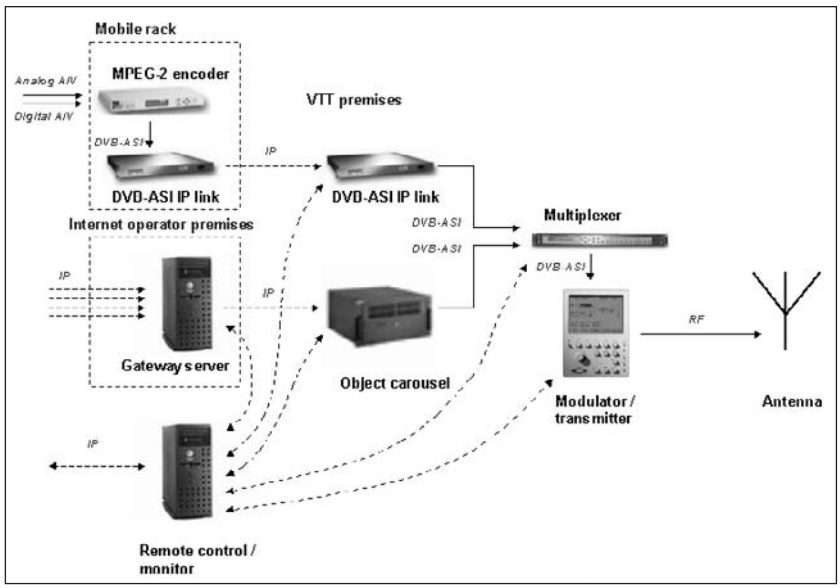
The following subsections describe the state of the art in terms of broadcast environment, software middleware, and services.

Broadcast Environment

Figure 1 depicts a typical example of a terrestrial digital television broadcast system.[1] It is composed of the following components: MPEG2 encoder, digital video broadcasting (DVB) asynchronous serial interface (ASI) internet protocol (IP) link pair, gateway server, remote control/monitor unit, object carousel, multiplexer, modulator/transmitter, and antenna.

First, the audiovisual stream is encoded with

Figure 1. Broadcast system (Cesar, 2005)



the MPEG-2 encoder. Because people in several locations might encode the audiovisual content, the encoder is stored in a mobile rack and connected to the broadcast system by using the DVB-ASI IP links. The object carousel contains application code and data. It can be uploaded using the gateway server. Next, the multiplexer generates the final MPEG-2 transport stream by combining the audiovisual content (output of the DVB-ASI IP link) and the applications (output of the object carousel). Finally, the modulator/transmitter feeds the multiplexed MPEG-2 transport stream to the antenna. The remote control/monitor can be used to remotely monitor the whole system.

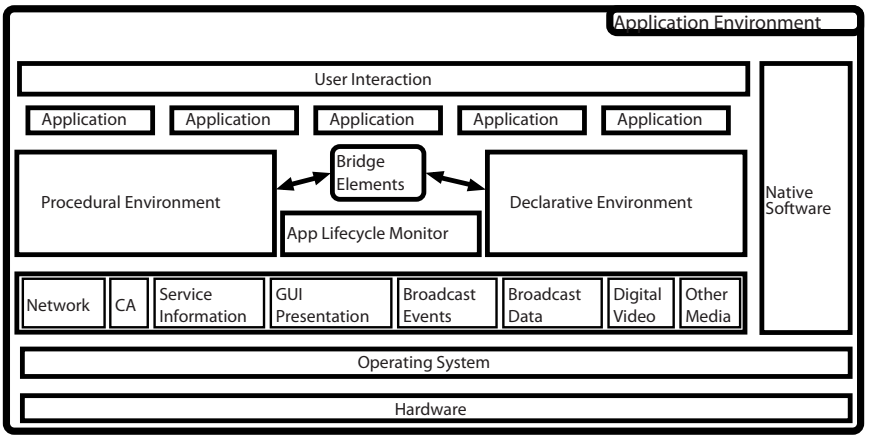
Software Middleware

Third-party development of services requires the digital television receiver to incorporate an interoperable middleware component. Three major regional initiatives exist: MHP[2] in Europe,[3] Advanced Common Application Platform (ACAP[4]) in the USA, and Association of Radio Industries and Business (ARIB[5]) in Japan.

These standardized solutions are composed of a procedural and a declarative environment, as depicted in Figure 2. The two environments do not have to be separated; bridge functionality might link them. In addition to the environments, native applications, proprietary formats, and service-specific software and content can be supported.

The procedural component includes a Java Virtual Machine (JVM) and a set of Java Application Programming Interfaces (APIs), while the declarative corresponds to an extensible markup language (XML) user agent. The declarative environment of the three mentioned standards is based on extensible hypertext markup language (XHTML), cascading style sheets (CSS), and

Figure 2. Application environment of interactive digital television receivers (Cesar, 2005)



television-specific extensions to the Document Object Model (DOM) (Cesar, 2005; International Telecommunication Union [ITU]-T, 2001, 2003, 2004; Morris & Smith-Chaigneau, 2005).

In the case of MHP, the procedural environment is called DVB-Java (DVB-J) and the declarative one is named DVB-HTML. Since the regional standards (MHP, ACAP, and ARIB) share a common approach, DVB has collaborated with the American and Japanese standardization bodies in defining a worldwide application environment: GEM. GEM has been ratified by the ITU in the J.200 (ITU-T, 2001) and J.202 (ITU-T, 2003) recommendations. GEM defines a procedural environment, DVB-J, which includes two Java APIs for graphics: Java Media Framework (JMF) and Home Audio/Video Interoperability (HAVi) (Cesar, 2005; Morris & Smith-Chaigneau, 2005).

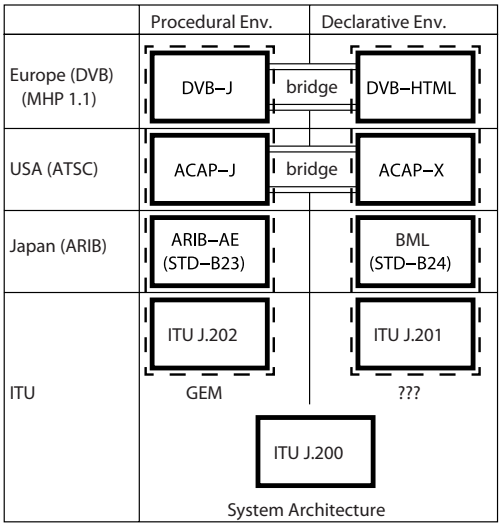
GEM defines the television display as three overlapping planes, ordered from bottom to top: background, video, and graphics. The broadcast video is normally hardware decoded and demultiplexed, and then rendered in the video layer by JMF. Alternatively, the applications are developed using HAVi and rendered in the graphics layer, requiring an alpha channel for composition purposes. HAVi extends Personal Java's *java.awt* package, including, for example, remote control events and a television-specific set of widgets.

Still, one of the challenges ahead is the definition of a common declarative environment. In order to clarify the goals of the standardization activities, their relationships are depicted in Figure 3.

Apart from conventional digital television receivers such as set-top boxes, companies are producing the next generation of optical storage devices. The two major options are Blu-ray and interactive high definition (iHD). In the case of Blu-ray, its application environment is based on the procedural environment of GEM. In the case of iHD, the application environment is HTML + Time (based on the XHTML + SMIL profile.)

Other technology options for the digital television application environment include MPEG-4, Flash, and MHEG. First, MPEG-4 video codecs are already part of the standards, while the interac-

Figure 3. Worldwide standardization situation of the application environment for iDTV (Cesar, in press)



tive part of MPEG-4 is a popular research topic, but it is not (yet) a real commercial alternative (Cesar, 2005; Baker, 2006).

Flash, on the other hand, is a popular solution for interactive multimedia on the Internet. Still, it has major problems such as: it is a non-structured technology, it uses a scripting language, it is a proprietary format, and dynamic modifications to a presentation are difficult to manage. Finally, MHEG, because of its popularity on digital television in the UK region, is a standard that will be supported by MHP.

Services

The development of MHP applications have become a lucrative business, as can be seen from the number of graphical authoring tools available on the market (e.g., Cardinal Studio[6]). The range of available services is ample;[7] some examples include games, commercials, home shopping, and banking. Nevertheless, the two major services are the electronic program guide (EPG) and the Super Teletext. The former shows information related to the scheduled audiovisual content. The latter is a new version of the traditional teletext service, in which multimedia content is broadcast within the MPEG-2 stream.

This subsection illustrates current services by taking a look at the work of a Dutch digital television company called Stoneroos. First, we will describe an adaptable EPG and then an interactive application called C-Majeur.

Stoneroos has developed a personalized program guide that uses XML TV. This way, the graphical layout of the application can be adapted. Figure 4 shows the Dutch layout, while Figure 5 shows the British Broadcasting Corporation (BBC) layout.

C-Majeur is a weekly television program about classical music. Stoneroos created an interactive episode of C-Majeur, shown in Figure 6. View-

Figure 4. Screen shot of Stoneroos program guide (Dutch layout)

Figure 5. Screen shot of Stoneroos program guide (BBC layout)

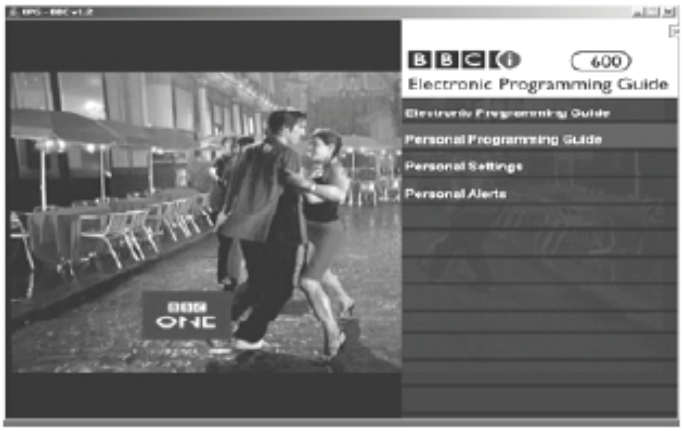


Figure 6. Screen shot of C-Majeur

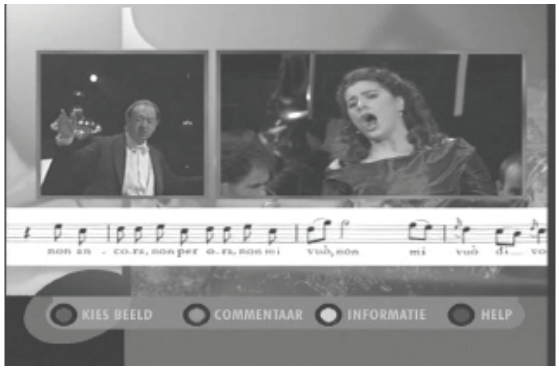


ers could select extra commentary and a karaoke version of the content in which a scrolling score of the vocals was shown along with close-ups of the soloist and conductor. The interactive extras were available during the entire week following the initial broadcast.

Summary

The following list summarizes the state of the art:

- **Standards:**
  - **Procedural:** Java-based
  - **Declarative:** Based on XHTML(+SMIL), CSS, and DOM extensions
- **Services:** A number of selection-based services (e.g., EPG and Super Teletext) plus discount interactive solutions such as SMS voting
- **Current configuration:** Low-print hardware configuration (around 250MHz, 16MB-64MB of RAM, and 8MB-32MB of flash memory), remote control (input), and television set (output). Some models include storage capacity and PDR capabilities (e.g., Tivo, iHD, and Blu-ray devices).
- **Distribution mechanisms:** Broadcast

As a final summary of the current state of the art, Figure 7 depicts the current model of interactive television. The interactive content is broadcasted to the receiver, which includes an application environment. Then, this content is visualized through the television set and the user can interact with the receiver using a remote control. The thickness of an arrow represents the amount of content that is transmitted. The receiver might have a return path connected to a server. Finally, as the figure shows, even though many people can watch the television set at once, only one person can interact with it.

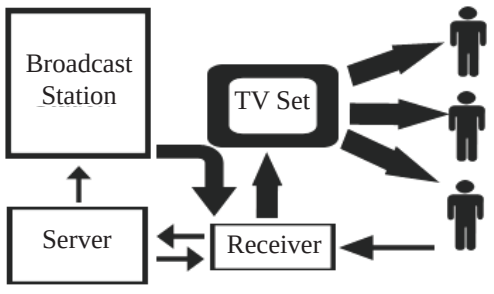
FUTURE OF INTERACTIVE DIGITAL TELEVISION

We can distinguish four different topics on which research should be focused: (1) definition of the concept interactive digital television (IDTV), (2) extensions of current standards, (3) service development, and (4) configuration of digital television receivers. The following subsections elaborate on those issues.

Definition of iDTV

One of the most important questions to be answered by this chapter is: *what do we mean by iDTV? Is it IDTV a dodo of history like the paper-*

Figure 7. Current model of iDTV



less office and the information superhighway? Have we already made of IDTV a meaningless concept?

In our opinion, IDTV is not about plugging your television to the phone line, to use your mobile phone for voting, or for that matter, to use your normal telephone to call to a television program and achieve your 15 seconds of fame. IDTV is about the potential impact a user has on the digital content. Some forms of interaction include applications that enhance the broadcast content and possibility of selecting different subtitles streams. Higher level of interaction is provided by PDR equipment in the form of pause, play, and skip content (Agamanolis & Bove, 2003) since the user actually affects the status of the content.

Further interactive capabilities include, for example, the possibility to control the content that the user consumes (i.e., personalized television) and end-user enrichment of the incoming material (Cesar, Bulterman, & Jansen, 2006). In our opinion, the research community should focus on the definition of new models that define the iDTV paradigm such as Chorianopoulos (2004) has done with his virtual channel proposal.

Standards

All in all, the definition of the GEM standard is good news for the digital television community. It is a worldwide solution for a digital television application environment. Even though its market penetration is low, apart from the Italian market in which proper subside policies have been applied, its procedural environment is a technology success (e.g., Blu-ray Java intends to reuse it).

Nevertheless, the definition of a suitable declarative environment is a challenge. Currently, apart from the structure and the visual style of the documents, the regional standards define three types of DOM events: user, internal, and broadcast generated (e.g., starting of a show). The major limitation of these standards is that they require the use of scripting for handling these events. For example, in order to synchronize the audio-visual content and an application, a script is activated when a broadcast event is received. This limitation can be overcome by adopting multimedia declarative approaches such as SMIL (Bulterman & Rutledge, 2004) or nested context language (NCL) (Soares & Rodrigues, 2005).

SMIL is the W3C standard for multimedia presentations. SMIL is a declarative format: rather than encoding the functionality of an (interactive) piece of content as a script or within the definition of a particular media codec, SMIL describes the set of interactions among media objects. Then, SMIL allows a particular renderer (or player) to implement this functionality in a manner that best suits the needs of the application runtime environment. The structure of an SMIL presentation follows the simple standard XML form:

```
<smil... >
  <head>
    general declarations for metadata,
    layout and interactive control
  </head>
  <body>
    temporal schedule of contents and
    content events
  </body>
  </smil>
```

Any object within a time container (i.e., *par*, *seq*, and *excl*) can have a scheduled or interactive begin time. The events associated with interactive begin times can be triggered by user interactions, by external script objects (via a set of SMIL DOM events), or by events that are triggered within associated content streams.

Hence, the main advantage of using SMIL is two-fold:

1. SMIL is a well-developed and widely deployed language, available on desktop and mobile devices.
2. Being declarative, SMIL code is small

(compared with Java), and it is easily verifiable—meaning that the risk of introducing viruses and other unwanted interaction side effects is limited.

As shown in Figure 8, SMIL defines 10 major functional grouping elements and attributes (modules). This results in the definition of a number of profiles. Each profile provides a fixed collection of elements and attributes, drawn from one or more modules. The purpose of the profile model is to enable the customizing of the integration of SMIL's functionality into a variety of XML-based languages. The major profiles are:

- **SMIL 2.1 Language:** The host-language version of SMIL 2.0
- **SMIL 2.1 Extended Mobile:** A rich language subset for advanced mobile devices
- **SMIL 2.1 Mobile:** A baseline set of features for general mobile devices
- **SMIL 2.1 Basic:** A baseline set of features for low-powered devices with a minimal set of elements and attributes.

In order to facilitate the use of SMIL in an IDTV application environment, W3C is working on two new profiles for SMIL:

- **SMIL iDTV:** A profile containing the major modules to support a broad range of interaction facilities in a lightweight set-top box
- **SMIL Enhanced iDTV:** A profile containing additional enhancements to allow a richer processing across a set of devices

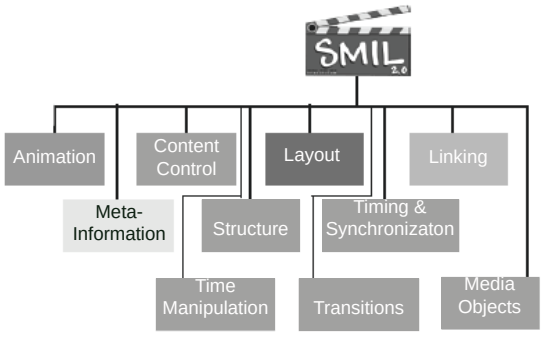
Some of the services these profiles are intended for include stand-alone applications (e.g., photo slides visualized in the television set), semi-synchronized applications (e.g., Teletext with extra audio files and animations), and services synchronized with the broadcast stream (e.g., statistics of a football match).

Another declarative solution for IDTV, similar to SMIL, is NCL. NCL claims to do for nonlinear television programs what HTML did for the Web. But, NCL is focused on temporal synchronization of multimedia objects in general and not on user interaction in particular. NCL supports the typical media objects (e.g., video and image), as well as HTML objects.

The Brazilian[8] government is currently standardizing the application environment for their digital television system. One of the alternatives is MAESTRO. MAESTRO is a complete solution, based on NCL.

There are several alternatives for the procedural and declarative middleware by using MAESTRO. The first one, shown in Figure 9, is

Figure 8. SMIL module architecture



a resident middleware with only the declarative module. Procedural codes could be launched from declarative applications because MAESTRO allows procedural objects in NCL documents.

The second alternative, shown in Figure 10, is MAESTRO coupled with a procedural middleware. Of course this alternative will require a set-top box with better performance. However, a better support for all kinds of applications is achieved.

It must be mentioned that both alternatives already presented can run not only NCL but also HTML applications. This means that any content developed for the three main digital TV systems (ARIB, ACAP, and MHP) is supported by MAESTRO.

The third alternative runs MAESTRO triggered by a procedural middleware in Java, as shown in Figure 11. MAESTRO was also implemented as an XLET that can be exported to the user set-top box. Therefore, any application developed in NCL will be able to run in any of

Figure 9. MAESTRO alone

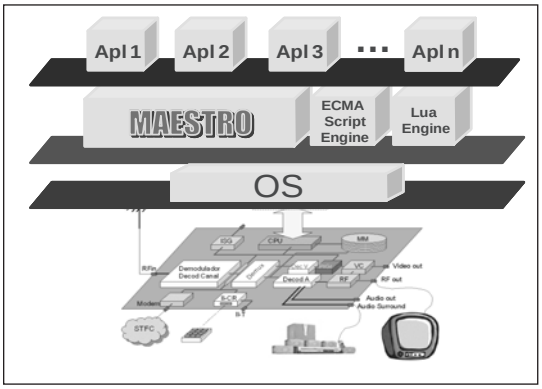


Figure 10. MAESTRO + procedural middleware

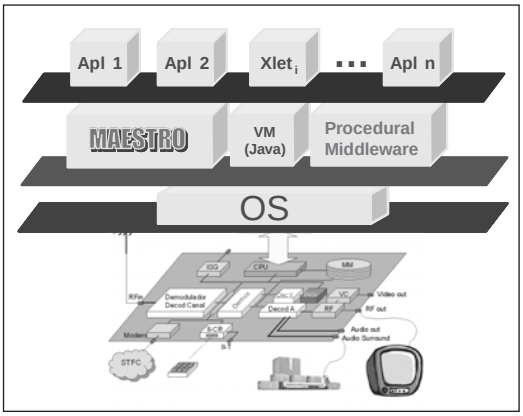

Figure 11. MAESTRO as XLET

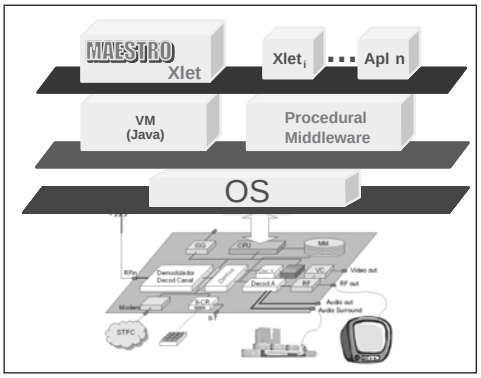


the main digital TV systems.

Both SMIL and NCL are interesting proposals for a declarative solution that fits the television model; both are focused on the temporal synchronization of multimedia objects, while HTML was mostly intended for text content. They are different, though, in a number of issues. For example, while SMIL defines strict temporal and spatial semantics (e.g., par and seq), NCL uses templates. These templates can include any kind of semantics.

Finally, another interesting extension to current standardization efforts is to include multi lingual information framework (MLIF) (ISO AWI24616)[9] (Cruz-Lara, Gupta, & Romary, 2005) support. MLIF defines an abstract model to encode the textual information of multimedia services (e.g., subtitles, captions, and t-learning resources). Currently, different groups are working on this issue (e.g., Timed Text in W3C). Hence, MILF does not create a new format from scratch, but deals with the issue of overlap between the formats. The final intention is to create a core framework, in which all the other formats will be integrated. Their research is especially relevant in the case of services serving multilingual communities (e.g., Spain) and in the case of reusing services for different countries (e.g., European services).

Services

A number of innovative services can be provided to the digital television viewers. In this chapter we concentrate on one important topic: recommender systems (Smyth & Cotter, 2000).

Because the amount of content available to end users is continually increasing, there is a need of content personalization. This personalization is a filter and takes place prior to the actual decision of what to watch. For example, Stoneroos has developed I-Fancy. I-Fanzy is a personalized program guide shown in Figures 4 and 5. It uses TV Anytime metadata and its content can be accommodated to different layouts (e.g., Dutch and BBC layout). In our opinion, personalized television is an essential research topic because of its non-intrusive nature and the big amount of available digital content.

Other Distribution Methods

The long unforeseen threat to iDTV is the P2P network. P2P networks have proven to be the killer application of broadband access. These networks are proving to be economically very efficient, and with the BBC leading adoption, this will provide a serious alternative to internet protocol television (IPTV) networks based on client-server technologies.

P2P networks are starting to offer a complete triple play to users for TV, voice, and related IP services. Unfortunately, the type of person-to-person interactivity that a P2P network can sustain is poorly supported by an iDTV platform. If P2P networks based on "Super-peers" are the future of TV, as the BBC's iMP experiment would suggest, the research community has a clear set of challenges to address. These are challenges that can only be addressed from a user-centric viewpoint, commercial and business interests will not design these networks, they will evolve as memes. They will evolve directly in response to user needs, and if not driven by common open innovation platforms, then by the open source communities alone.

One interesting project researching these issues is the I-Share project (Pouwelse, Garbacki, Epema, & Sips, 2005).

Other Devices

In addition to traditional input/output devices, research should be focused on extended user interaction in the television domain. For example, Figure 12 shows two devices already at home that can be used for enriching the television experience.

In relation to their output capabilities, one interesting research topic is that of personal devices. Personal devices, apart of incorporating rendering capabilities, are aware of the identity of the user. Thus, these devices (e.g., a handheld device) can personalize television content in a non-intrusive manner. We propose a number of scenarios:

1. **Extra information:** Personal devices can provide enhanced information a user might be interested in, while watching a television program (Finke & Balfanz, 2002, 2004), for example, the statistics of a player during a football match. The key issue is that the information is displayed in the personal device, as thus, it does not disturb the other television viewers in the room.
2. **Audio:** Because the personal device knows the identity of the viewer, it can provide a subset of the content. Imagine, for example, an elderly man who is watching television. He might have lost some of his auditory

Figure 12. Interactive devices at home

capabilities. In this case, the personal device might render the audio of the program to the headphones of the elderly person. But, the actual shared volume is maintained at the same level for the other members of the family.

3. **Text:** Similar to the previous example, the personal device might render personally the subtitles of a movie. For example, if I am in a foreign country watching a movie with some foreign friends. I would like to receive the subtitles in my mother tongue, but, not necessarily the rest of the people watching television would like to see those subtitles.

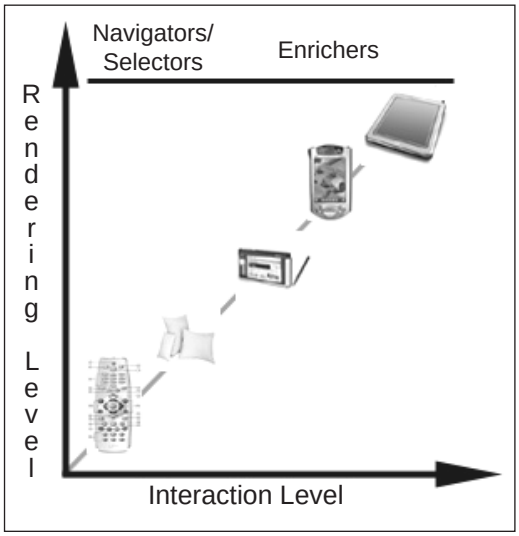
In order to implement the scenarios presented previously, we need a non-monolithic[10] renderer. A nonmonolithic renderer is one that it is capable of deliver parts of a multimedia presentation and extra information to several renderers. The audiovisual content is delivered to the television set. While, user interfaces, extra information, and specific parts of the content are delivered in a synchronized manner to other personal devices.

In addition to output devices, other devices can extend the limited remote control interaction provided by current television systems. For example, gesture recognition and voice interaction (Berglund, 2004; Berglund & Johansson, 2004) are interesting topics that need to be further researched.

Figure 13 shows a categorization of devices depending on their rendering and interaction capabilities. We can differentiate two levels of user interaction, when watching content:

- **Navigation/selection.** This level of interaction allows the user to navigate and select content (e.g., go to the next scene).
- **Enrichment.** This level of interaction allows the user to produce his/her personalized copy of the television content. Some examples of this augmentation includes subsetting the

Figure 13. Classification of devices at home



content (e.g., deleting scenes) and adding new content (e.g., to include your own audio commentary of a movie).

One example of navigation/selection is ambient technology. We can use everyday objects at home, such as an intelligent pillow, to gather information about the user. These devices can gather context-based information such as the level of excitement of a user. Then, the television renderer can act accordingly to the gathered data (e.g., by pausing the television program in case the level of excitement is too high).

Personal devices can be used to enrich content (Cesar et al., 2006). Figure 14 shows a screen shot of content augmentation (in the form of an image) over television content. In this case, the end user has highlighted one part of the screen (in this case a tie). For example, he could include, as well, some text such as "I would like this tie for my birthday!" Research in this topic is related to social TV and collaborative work. The major requirement for a content enrichment system is that the base content must not be altered (personal copies should be generated as overlapping layers of content). In addition, because television watching is an entertainment activity, the enrichment process should be fast and simple. We have termed this process as *Authoring from the Sofa*.

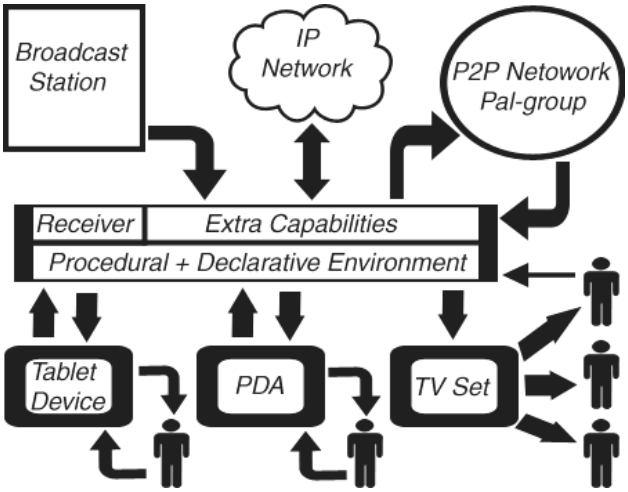
Apart from the inclusion of media objects, content enrichment includes virtual edits (e.g., alteration of the presentation timeline and exclusion of media objects) and creation of conditional navigation paths. These capabilities are researched within the European Passepartout[11] project. The scenario in this project is called Maxima. Maxima is the content manager in the house. She selects content and edits it for her children.

AGENDA

As a summary, the agenda we propose in this chapter for the future research in iDTV is depicted in Figure 15. From the distribution/post-distribution of content, digital television content (and services) can be transmitted using any kind of network (e.g., broadcast, P2P networks, and mobile networks). Then, the user can utilize any kind of device to interact with and visualize the

Figure 14. Screen shot of end-user content augmentation

Figure 15. Proposed agenda for iDTV



television content. Each of the devices provides different levels of interaction depending on their limitations. For example, the user can interact with one remote control and one television set (rather limited scenario). But, the user might interact, as well, with a personal tablet augmenter or a personal digital assistant (PDA), non-intrusive interaction is the concept to describe this kind of interaction. Finally, the receiver (and the interactive devices) includes a suitable declarative environment (e.g., SMIL, MAESTRO) and storage capabilities. The receiver might well include extra capabilities such as a recommender engine based on TV Anytime standard and a multilingual framework.

CONCLUSION

The traditional definition of iDTV as the provision of a return path focuses on the receiver capabilities instead of on the user potentiality. In order to avoid that iDTV becomes a dodo of history, we should move our focus from the receiver to the user. iDTV should not be restricted to one television set and a remote control (intrusive interaction), but extended to other digital devices at home (non-intrusive interaction).

One essential research area is to rethink the validity of the current standards and their evolution. Based on their market penetration of MHP, for example, we might conclude that they are similar to the European Constitution; the parliament of each country approves it, but the citizens are not so sure about it. In our opinion, the problem is in the acceptance timetable of new technologies. Nevertheless, standards should continue evolving (e.g., declarative environment) in order to provide the users the best possible alternatives.

Finally, we should try to model the current situation, in which the traditional role of users as consumers is shifting to become producers (e.g., blogging and personal Web pages) and distributors (e.g., iPod). Much research is needed in topics such as television content enrichment, post-distribution

mechanisms (e.g., P2P networks), adaptability of interactive services to other devices, and providing an ambient experience (Baker 2006b).

ACKNOWLEDGMENT

Chapter 3.9
Design Diagrams as Ontological Sources:
Ontology Extraction and Utilization for Software Asset Reuse

Kalapriya Kannan
IBM India Research Labs, India

Biplav Srivastava
IBM India Research Labs, India

ABSTRACT

Ontology is a basic building block for the semantic web. An active line of research in semantic web is focused on how to build and evolve ontologies using the information from different ontological sources inherent in the domain. A large part of the IT industry uses software engineering methodologies to build software solutions that solve real-world problems. For them, instead of creating solutions from scratch, reusing previously built software as much as possible is a business-imperative today. As part of their projects, they use design diagrams to capture various facets of the software development process. We discuss how semantic web technologies can help solution-building organizations achieve software reuse by first learning ontologies from design diagrams of existing solutions and then using them to create design diagrams for new solutions. Our technique, called OntExtract, extracts domain ontology information (entities and their relationship(s)) from class diagrams and further refines the extracted information using diagrams that express dynamic interactions among entities such as sequence diagram. A proof of concept implementations is also developed as a Plug-in over a commercial development environment IBM's Rational Software Architect.

INTRODUCTION

A Scientific American article describes evolution of Web that consisted largely of documents for humans to read and that included data and infor-

mation for computers to manipulate. In order, to help the people and machines to communicate concisely, this huge repository of information (Web) have to be re-engineered to define shared and common domain theories that are machine processable. This is the precise aim of Semantic Web to build metadata – rich Web where presently human-readable content will have machine-understandable semantics. Semantic Web achieves the increased demand of shared semantic and a web of data and information derived from it through the adaptation of common conceptualizations referred to as Ontologies. Ontologies are fundamental building blocks of Semantic Web and therefore cheap and fast construction of domain-specific ontologies is crucial for the success and the proliferation of the Semantic Web. We explore how a semantic web may impact software engineering where common conceptualizations (e.g., software, work products, experience) from previous projects need to be reused in new projects.

The chapter will contribute in the following ways: (a) It will introduce an ontology learning technique from design diagrams (specifically UML) which is in line with the research direction of building ontologies from different sources to enable a rich semantic web; (b) It will show a concrete semantic web application how the semantic web technology of ontology can promote software reuse; (c) It will put recent research on transformations from UML to OWL and vice-versa in perspective; and (d) it will motivate more research effort in semi-automatically building integrated information models.

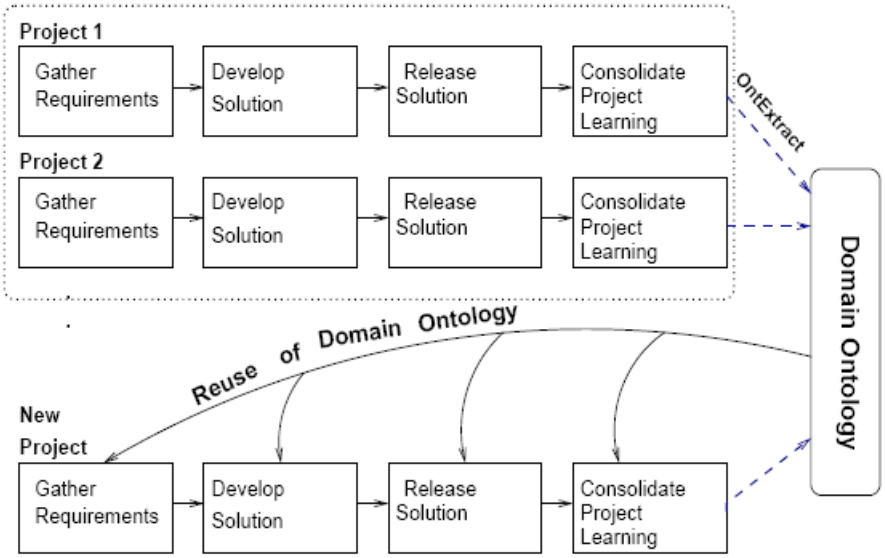
Ontology Learning and Sources

Ontology learning facilitates the construction of ontologies by ontology engineering. Ontology learning includes a number of complementary disciplines that feed on different types of unstructured, semi-structured and fully structured data in order to support a (semi -) automatic, cooperative ontology engineering process. Ontology learning is quiet a tedious task and often requires manual intervention. Ontology learning algorithms have concentrated in finding efficient methods of automatically extracting ontology information. Today, research apart from automatic ontology learning has also focused on finding sources (RDF, html, unstructured text etc) of ontological information. In our work we concentrate on identifying one such source i.e., design diagrams and provide an (semi-) automatic technique to extract (domain) ontological information. In the process of software solution development, large amount of ontological information is implicitly modeled in design diagrams. Our work aims at extracting this implicit ontology from the design diagrams. It largely helps reuse of the concepts in other software solutions.

In Figure 1, a simplified project cycle is shown. The project requirements are collected; the solution is developed and tested, and finally released to the customer. At the end of the project, a report is generated to capture the learning. However, it is rare that project-end deliverables or reports are explicitly used to improve the solution development process for new projects.

Our key observation is that the similarity among the projects alludes to the existence of a veritable domain of discourse whose ontology, if created, would make the similarity across the projects explicit. However, manually creating such domain ontologies is infeasible due to the training needed for the software professionals and the efforts required. Although many ontology engineering tools have matured over the last decade, manual ontology acquisition remains a tedious, cumbersome task that can easily result in domain knowledge acquisition bottleneck. We note that design diagrams are integral part of software project deliverables as they document crucial facets of the solution dealing with software artifacts, their relationships and runtime behavior. Much, but not all, information in theses diagrams are ontological information. If one were to extract and explicitly represent them, they would enable

Figure 1. Custom Software Projects and the Impact of OntExtract



shared and common domain theories that would not only enable better understanding of the domain but also allow software professionals to reuse the domain theories in creation of new solutions over their project cycle. This is illustrated in the lower half of Figure 1.

Using UML-2 as the design diagram representation, we present the OntExtract tool to extract ontologies from project deliverables and show that they can be reused for new projects. UML has become a de-facto standard for modeling software development activities. In UML, static behavior of the solution is captured by diagrams like the class diagram and dynamic behavior by diagrams like the sequence diagram. Two types of elements are present in UML diagrams: (a) those representing environmental artifacts representing characteristics of the problem space, and (b) those representing implementation artifacts introduced to ease a form of software implementation. We assume that the generated ontology should be general enough to span implementation trends. Our method, OntExtract, reads UML diagrams and proceeds by preserving the environmental artifacts, removing the implementation artifacts and maintaining the consistency of the resulting diagram. The output ontology is represented using UML class notations to ease the understanding by developers who may not be familiar with a new (ontology) representation language like OWL. However, using emerging UML to OWL (and vice-versa) transformation methods, the ontology can be maintained in multiple representations. Moreover, with UML diagrams from multiple projects, the emergent ontology can be refined. Over time, the ontology will capture the learning from previous projects.

The ontology can be used for any purpose including software reuse for new solution creation. For reuse, as the solution process is being followed, the initial UML diagrams for the new solution can be created by filtering the relevant

content from the ontology. As an example, we show how the sequence diagram from the new solution can be used as a requirement over the ontology and an initial class diagram for the solution can be created.

Contributions

The main contributions of our work can be listed as follows:

1. Concept of Design diagrams (in specific UML diagrams) as sources of ontological information.
2. An automatic ontology extraction technique called 'OntExtract.
3. OntExtract Methodology from UML diagrams of a single solution of a specification:
    a. Concept of identifying the elements that relate to concepts in domain.
    b. Preserving those elements that express domain concepts.
    c. Eliminating and reducing the impact of elimination of components that doesn't relate to concepts.
4. Ontology aggregation methodology from Multiple UML diagrams.
5. The impact of extracted ontology in solution building. Hence, it is important to apply semantic techniques in this domain.
6. Relationship with approaches for information transformation: UML to OWL and vice- versa, UML as ontology language.
7. Challenges in extending information models with more ontological data sources.

We have implemented OntExtract as a plug-in using IBM Rational Software Architect. It benefits two groups of people: (a) Software professionals and (b) Ontology engineers. Software professionals benefit by using this tool to obtain domain models that allow reuse of design decisions at all stages of a new software project. Ontology engineers can use our tool to create/ maintain domain ontology considering design diagrams as a new source of information. Initial results show that the created ontologies are accurate and help in better software reuse for new solutions.

BACKGROUND

In this section we provide the background knowledge about the design diagrams and the standards used for creating and representing design diagrams and ontology. We also provide the same example considered in our work for evaluation purpose.

Design Diagrams and UML 2

Design Diagrams are used to represent visually software solution for a problem. They express environmental relationship (entities and relationship among entities that represent domain concept in domain ontology) among entities in the solution developed for requirement specification of a problem. In addition design diagrams express implementation artifact that model implementation entities and relationship needed for development of software solutions. We use UML 2 since it has become a de-facto standard for modeling software development activities. UML (Terry Quatrani, 2001), is a standard modeling language for specifying, constructing, visualizing and documenting artifacts of the software system. UML consists of 9 set of diagrams to model various software artifacts. In our work we use class diagram that belongs to the category of the structural diagrams that represents static behavior of the system to extract domain concepts. Sequence diagrams are used for further refining the extracted ontology. OCL is the constraint language with UML but it is not used widely in commercial projects.

Ontology

Ontologies are meta data schemes, providing controlled vocabulary of concepts, each with an explicitly defined and machine processable semantics and inter-relationships with other concepts. Ontology uses the following elements to express environmental artifacts: Classes represents general things in the domain of interest, Individuals defines instance of an class and includes concrete objects such as people, animals etc., Attributes describes the general properties of the classes, Relationship represents the relationships in terms of subsumption (IS-A) relationship, meronymy (HAS-A) relationship that exists among things. The OWL language (Deborah, 2004) is a leading standard for ontology representation.

Example Domain

We use the case study of student course registration taken from the Rational tutorial (Terry, 2002) as the running example in the chapter:

At the beginning of each semester students may request a course catalogue containing a list of course offerings for the semester. Information about each course, such as professor, department, and prerequisites will be included to help students make informed decisions. The new on-line registration system will allow students to select four course offerings for the coming semester. In addition, each student will indicate two alternative choices in case a course offering becomes filled or canceled. No course offering will have more than ten students. No course offering will have fewer than three students. Once the registration process is completed for a student, the registration system sends information to the billing system, so the student can be billed for the semester. Professors must be able to access the on-line system to indicate which courses they will be teaching. They will also need to see which students signed up for their course offering. The billing system will credit all students for courses dropped during this period of time.

For purpose of experimentation and evaluation, in this work we consider several solutions for the above problem. Figure 3 gives the UML class diagram for a solution we have proposed. This solution is henceforth referred to as Solution A (SolA). We consider two other solutions (class diagrams) taken from tutorial website of Rational Software Corporation (Rational, 2000), (referred to as Solution B (SolB) and class room lecture of Prof. Dr. Bettina Berendt (Bettina, 2005), (referred as Solution C (SolC)). We assume that these input class diagrams are correct. We represent classes and association between two classes as nodes and edges, respectively.

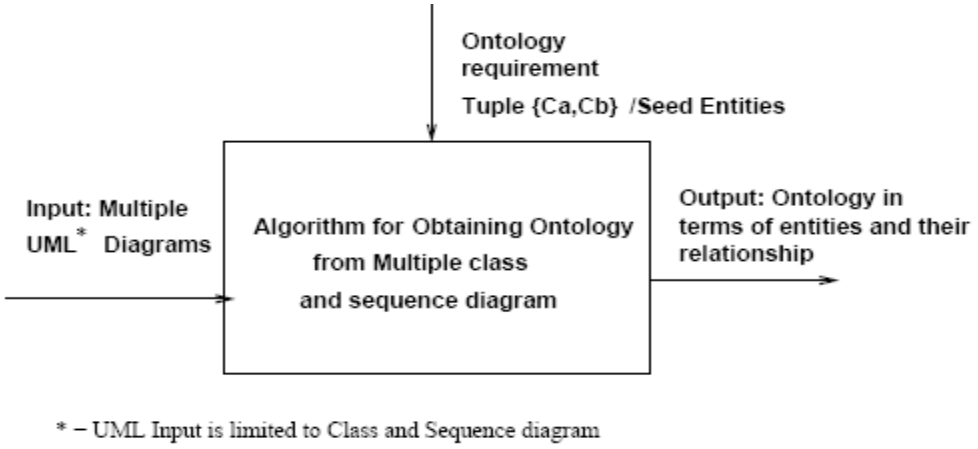
We use the terms nodes and classes interchangeably, and similarly the terms edges and associations. The term Root node is used to refer to a node that is placed at the highest level of the tree and has no parents.

USING UML DIAGRAMS AS ONTOLOGICAL SOURCES

Figure 2 gives the system architecture of OntExtract. OntExtract takes UML diagrams (class and sequence diagram) of multiple projects and extracts the domain ontology. Domain requirements are taken as a tuple of keywords.

UML elements can be classified broadly into two categories: (a) Implementation Artifacts: They are introduced by the architect of the software solution to capture those elements that represent low-level details of the solution such as messages exchanged and their behavior. Such artifacts are either full-fledged classes or specific attributes of a class. (b) Environmental Artifacts:

Figure 2. System overview



They include ontological entities and relationship among such entities. Relationship includes generalization (IS-A), aggregation/composition (HAS-A) and USING association. We use the stereotypes to identify UML elements. Implementation artifacts do not contribute to domain concepts while environmental artifacts such as IS-A, HAS-A, USING relationship and entities participating in such relationship reflects domain concepts. All UML diagrams have implementation or environmental artifacts. However, static information such as classes (concepts), attributes and relations (semantics) can be obtained from class diagrams. Therefore, in our we use class diagrams to extract domain information (ontology) and explore whether interaction diagrams such as sequence diagram would help identify more domain concepts.

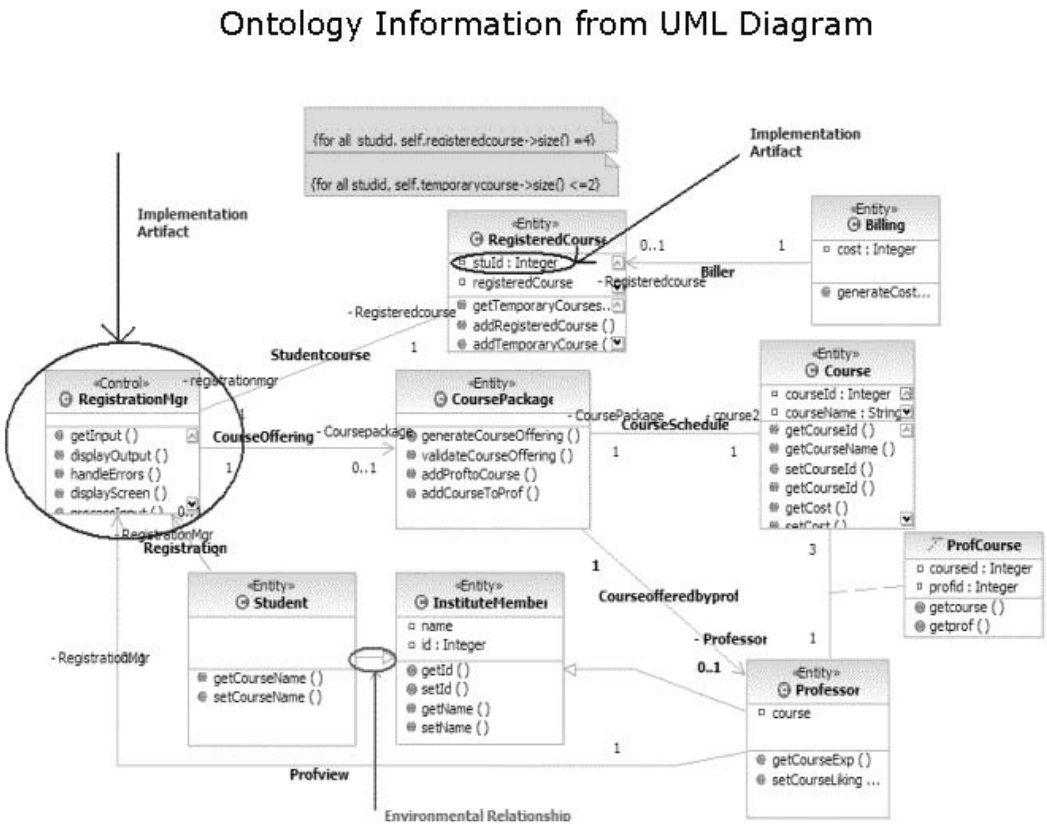
Ontology Extraction from Class Diagram

Class level implementation artifact: UML defines three types of stereotyped classes (a) Boundary class (b) Controller class and (c) Entity class. A boundary class models interaction between the software system and the environment. A control class acts as coordinator of activities. An entity class models information that has been stored by the system and its associated behavior. By and large, entity classes reflect real world entity and are part of environmental artifacts. Boundary and Controller classes are implementation artifacts, used to ease software development.

Attribute level implementation artifact: Attributes are storage elements of a class instance. Some attributes are introduced to maintain property values of an entity class while others are used purposes such as maintaining uniqueness, class level state, providing identities to entities. Attributes of the form of second category are implementation artifacts.

In Figure 3 we identify some of the implementation and environmental artifacts. In this Figure, the class RegistrationMgr is a class level implementation artifact (co-ordinates messages between other entities). Attribute 'stuID' in the class RegisteredClass is an attribute level implementation

Figure 3. Ontology information from class diagram

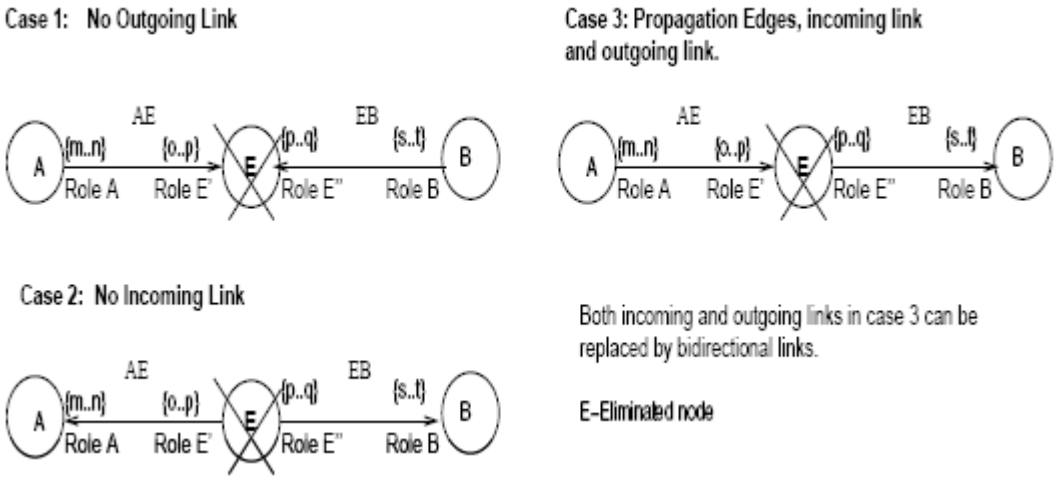


artifact introduced to maintaining uniqueness of the entity. Environmental artifacts such as class 'Student' inherits from 'InstituteMember' can also be seen in this Figure. Environmental artifacts reflecting domain concepts, OntExtract proceeds by removing implementation artifacts and preserving environmental artifacts.

OntExtract: Elimination of Implementation Artifact

Elimination of a class level attribute affects nodes that are associated with the eliminated node through inheritance, aggregation/composition and USING relationship. Nodes that are related to eliminated node through the above relationships is also eliminated. Links representing USING relationship between the neighbors of eliminated node result in dangling edges. In order to build relationship rich ontology, we aim to preserve this relationship by the process of propagation. Propagation results in new relationship (edges) among neighbors. The properties of the new relationship depends on the properties of two dangling edges that results in propagation. Figure 4 shows the nature of edges that are atypical of

Figure 4. Elimination of a node and its dangling edges



a relationship. In Figure 4, case 1 and case 2 do not have propagating links. We are interested in case 3 that has propagation edges where a new association is created between every incoming, bidirectional and outgoing links.

The attributes such as name, direction, cardinality, role names of the new association are obtained as follows: Direction: The direction of the new edge depends on whether the dangling edges were bidirectional or directed. New edge assumes the direction of the dangling edge(s) if the dangling edges were directed otherwise it is bidirectional. Role name: The new edges assume the role name of the nodes that the new edge connects. Cardinality: Cardinality of the new edge is obtained by finding the minimum and maximum number of instances of nodes that the new edge connects, can be associated through the node that is eliminated. In other words, the cardinality is calculated as the cross product of cardinality of the two links that results in propagation. Figure 5 (a) shows the propagation of cardinality constraints among the dangling edges.

Figure 5 (b) shows the new edges with the properties after elimination of a node (refer case 3 of Figure 4) and Figure 6 shows the class diagram of the student registration example after elimination of the class level implementation artifacts.

We leave the elimination of attribute level implementation artifacts as future work. Identifying these artifacts is difficult since there is no explicit notation is available in UML to annotate attributes according to intended usage and requires profiling of the code.

Algorithm 1 describes the steps for removing class level implementation artifact and propagating relationships. The algorithm gets and removes controller and boundary classes in the UML diagrams (line 1). A new association is created for every incoming (line 12), bidirectional edge (line 17) (to the controller/boundary class) to outgoing edge (from the controller/boundary class) line 4. The properties of the new association are obtained from the incoming/bidirectional - outgoing edge pair. In the algorithm, the terms ‘this end’ refers to the end associated with a neighbor nodes and

```

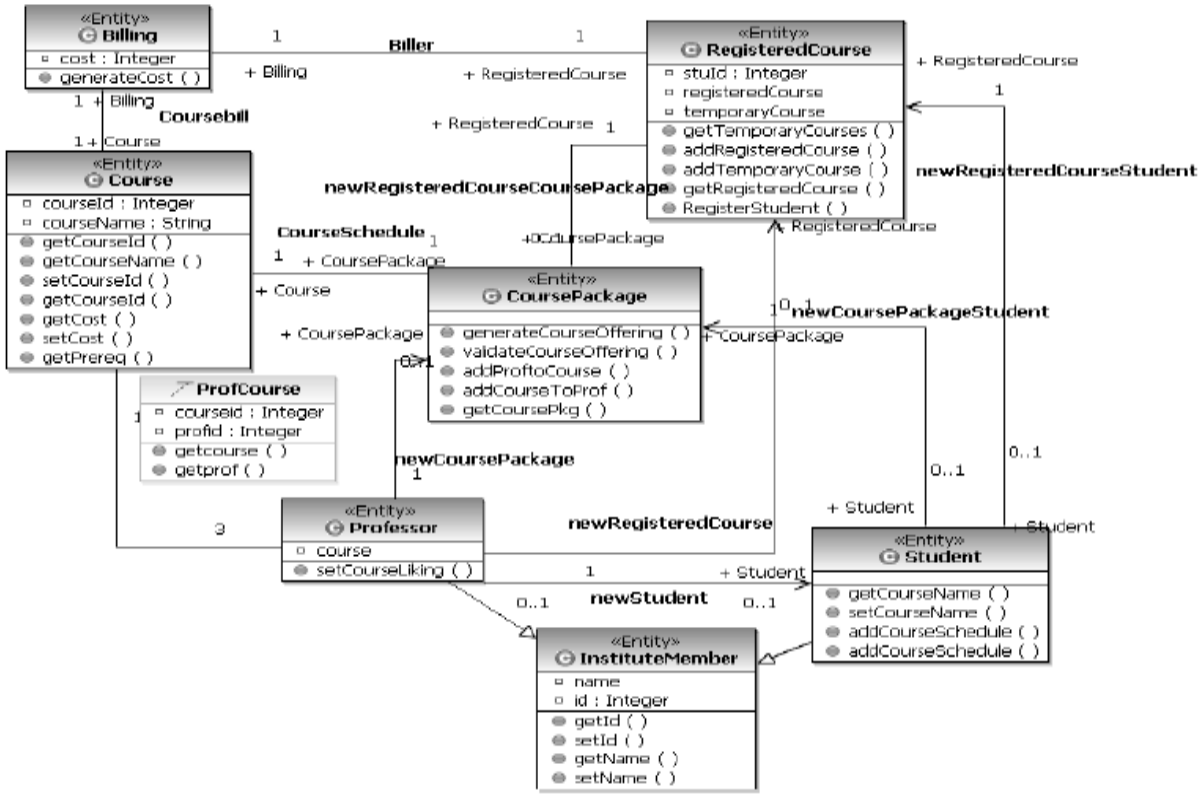
Figure 6. Student registration class diagram after elimination of class level implementation artifacts



'other end' refers to the end associated with the other neighbor, between which a new association is created. Property role name, cardinality constraints are obtained in line 8 and 16. The new association assumes a new name for reference. The resultant class diagram is henceforth referred as Eliminated Entities Class Diagram (EECD).

OntExtract: Preserving Environmental Artifact

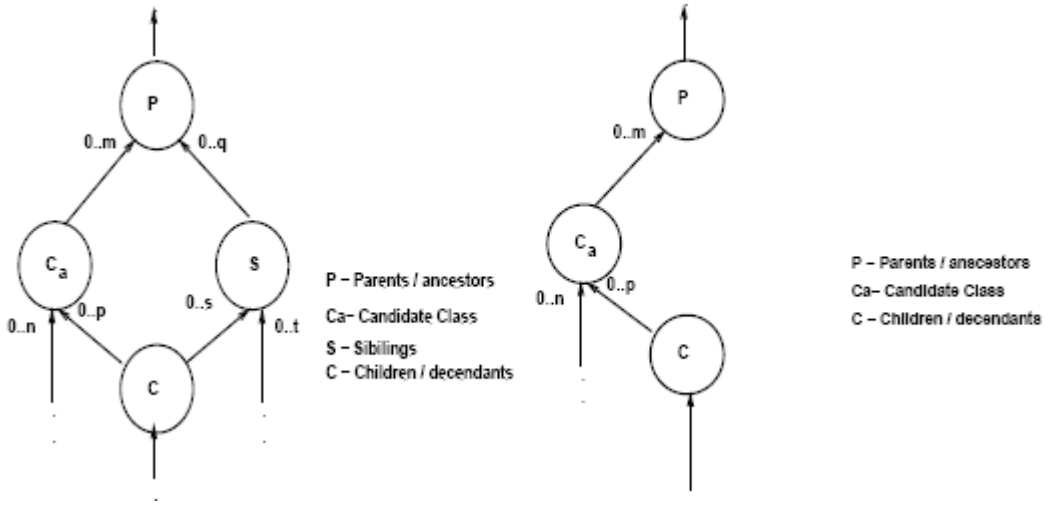
The EECD obtained as a result of elimination of implementation artifact represents in general all conceptual entities which can be directly reused in other similar software projects. In addition to this, we provide provisions for extraction of ontological information for specific domain requirements provided by the software professional. For example, in the context of 'professor' (in Figure 3) students billing information is not relevant.

The domain requirement is provided by the architect as a tuple of keywords. Let us consider an example in which we are interested in extracting student domain information i.e., input keyword is {student}. We assume that this input keyword directly maps to an entity class in EECD. This

class is henceforth referred to as the candidate class. Preserving environmental artifact includes identifying those entities that reflect domain concepts in the resultant EECD. All entities that are related through inheritance (IS-A), aggregation/ composition (HAS-A) and USING relationship (collectively known as environmental relationship) directly reflects domain information with respect to the input tuple.

For inheritance relationship, all ancestor classes influence the candidate class and all descendants classes are influenced by candidate class. Figure 7 (a) gives the generic graph of the candidate class and its neighbors in a class diagram. Therefore, with respect to inheritance relationship all ancestors and descendants of the candidate class are preserved. The siblings of the candidate class do not affect the candidate class

Figure 7. Generic Model (a) neighbors (b) inheritance output



(a) *(b)*

Algorithm 2.

Algorithm 2 Inheritance - obtaining neighbors for candidate class

```
1: ancestorNodes = getNodes(getallPathstoRoot(candidateClass)); {Get all ancestor nodes}
2: addNodestoInheritance (ancestorNodes, InheritanceRelationshipGraph);
3: for all (nodes) do
4:     if isPathtoCandidateClass(node,candidateClass) then
5:         addNodestoInheritance (nodes,InheritanceRelationshipGraph);
6:     end if
7: end for
```

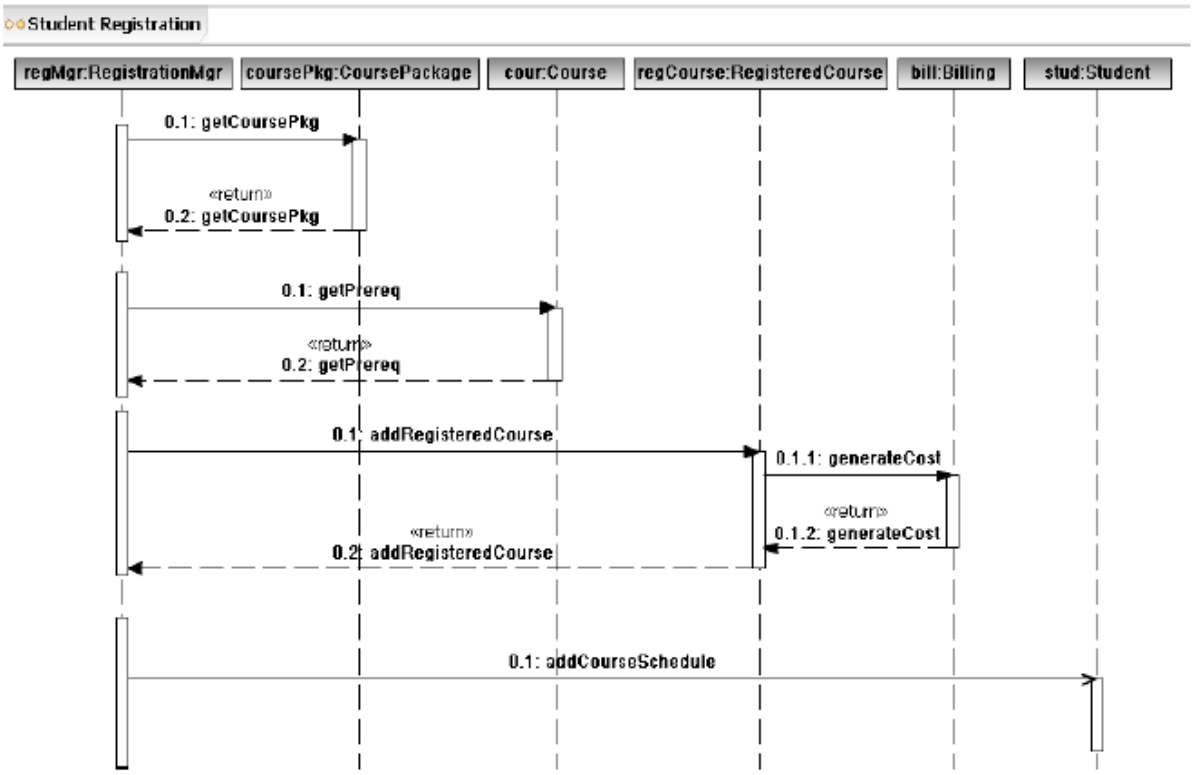
and therefore do not reflect concepts of the domain represented by the candidate class. Algorithm 2 presents the algorithm to obtain all ancestors and descendants for the candidate class. To extract the nodes that are ancestors for the candidate class, the algorithm finds all the paths from the candidate class to the root node (line 1). To find a descendant node the algorithm checks if a node has route to the candidate class in line 4. Figure 7 (b) gives the generic output structure (tree) after preserving inheritance relationship.

Preserving aggregation/composition relationship is similar to the technique presented for extracting inheritance relationship. 'USING' relationship is denoted by Directed and Bidirectional links. It represents exchange of messages between two classes during execution. We are interested in the classes that help to achieve the functionality (use case) by the relationship. Run time information such as classes related to candidate class through 'USING' relationship is not directly available from class diagram. The actual set of related classes can only be obtained from diagrams that reflect dynamic behavior (diagrams that describe the behavior of classes). Two UML diagrams, activity diagrams and sequence diagrams are candidates that provide dynamic information.

Ontology Refinement Using Sequence Diagram

Sequence diagrams describe the services provided by objects through exchange of messages.

Figure 8. Sequence diagram for functionality 'course registration'

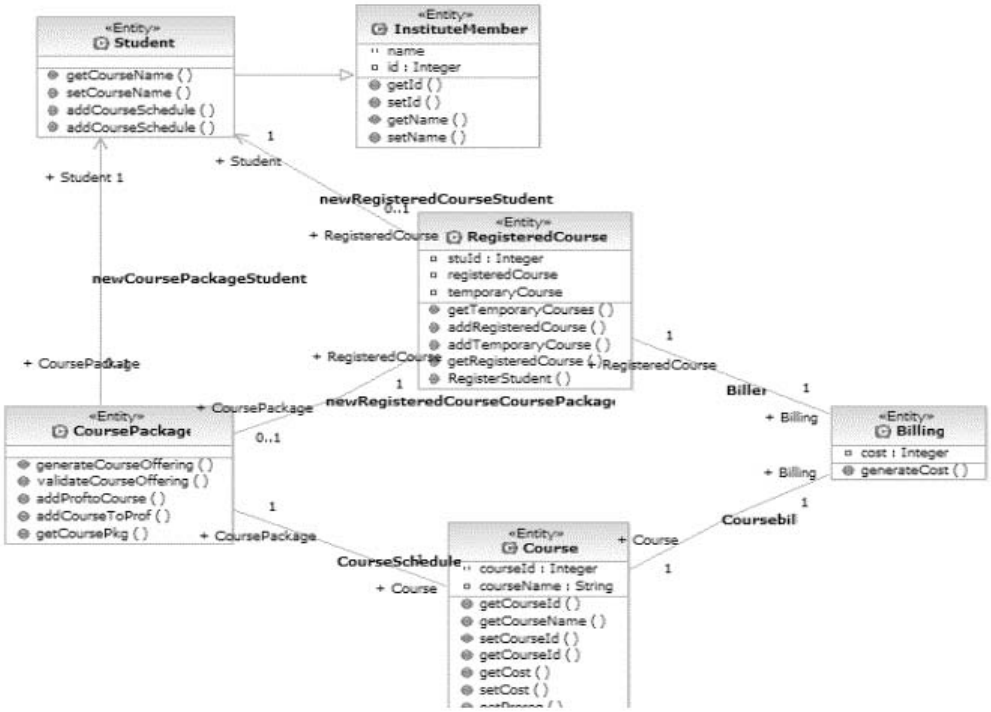


Activity diagram describe sequence of activities and is generally more expressive than the state diagram. Based on the above comparison, we propose to use sequence diagram to extract classes that are related to the candidate class through 'USING' relationship. All sequence diagrams that has the candidate class are considered. Figure 8 gives the sequence diagram for the use case 'course registration'. Classes CoursePackage, Course, RegisteredCourse, Billing that are related to the candidate class {Student} through these sequence diagrams are preserved as ontological information.

Figure 9 gives the Ontology Diagram (OD) that represents the extracted ontology information for domain requirement {Student}.

Sequence diagrams acts as filters for extracting entities that are associated with the candidate class to achieve a certain functionality (use case) or to provide a service. Using Model Driven Architecture (MDA), the architects/professionals begin by describing the use cases (functionalities/services) from the functional requirements of a problem. By modeling these services into a set of sequence diagrams our approach can be used to obtain ontology customizable for the new problem. This helps to obtain existing solution approaches for the new problem and thereby largely help software reuse.

Figure 9. Extracted Ontology Diagram (OD)



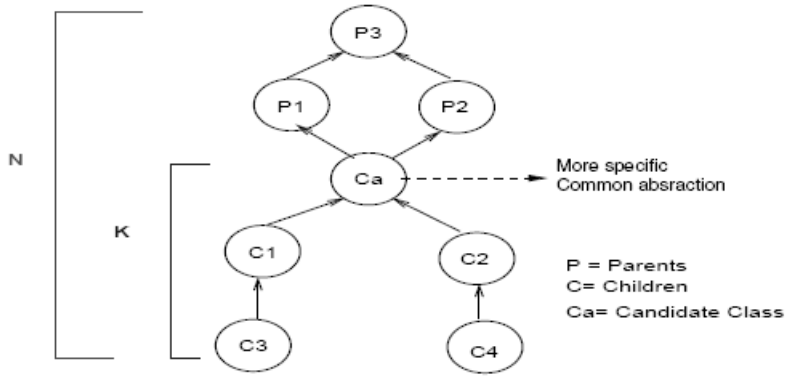
ONTOLOGY EXTRACTION FROM MULTIPLE UML DIAGRAMS

Methodology

With view of improving the quality of the extracted ontology, we propose an ontology refinement technique in which OntExtract extends to aggregate ontology from multiple Ontology Diagrams (OD) with respect to a domain requirement. The refinement process helps to correct/update/change to a fine granularity and increases the confidence of the correctness of the extracted ontology. These design diagrams can be different solution of same problem or solution(s) of different problem(s). Ontology aggregation from multiple OD can be done in two ways (a) Incremental approach, aggregates ontology by considering one relationship at a time, (b) Consolidated approach, aggregates ontology by considering all relationship in an ontology diagram. Consolidated approach increases the complexity of analysis of relationships since a single node can have multiple types of relationship. In addition, the consolidated approach does not handle propagation of relation inherently (explicit/ manual invention is required to handle propagation) whereas incremental approach handles propagation inherently (aggregation is based on all relationship but incrementally). Therefore, we use incremental approach by taking one relationship from multiple ontology diagrams to aggregate ontology.

Aggregation of ontology from multiple ontology diagrams requires adding/deleting/ updating ontology entities. We use the metric semantic distance to arrive at a decision whether to add/delete/update entities. Semantic distance measures the closeness of two entities in ontology diagram. Semantic Distance between nodes is reduced to distance between concepts in a graph. The distance between concepts is determined according to their positions (measured as levels). When a hierarchy is N = (n+1) layered, K/N nodes is connected to the class in the K^{th} level where ($0 < K < N$). Figure 10 (refer to output inheritance diagram Figure 9) diagram shows a sample inheritance graph in the ontology diagram with the candidate class in the K^{th} level. Value of K/N determines the characterization of the graph, if K/N is very low, then the relationship structure represents more generalization then specialization with respect to candidate class and vice-versa. The more general is the structure, the more re-usable is the extracted ontology. Therefore, our algorithm aims to keep

Figure 10. Semantic distance desired

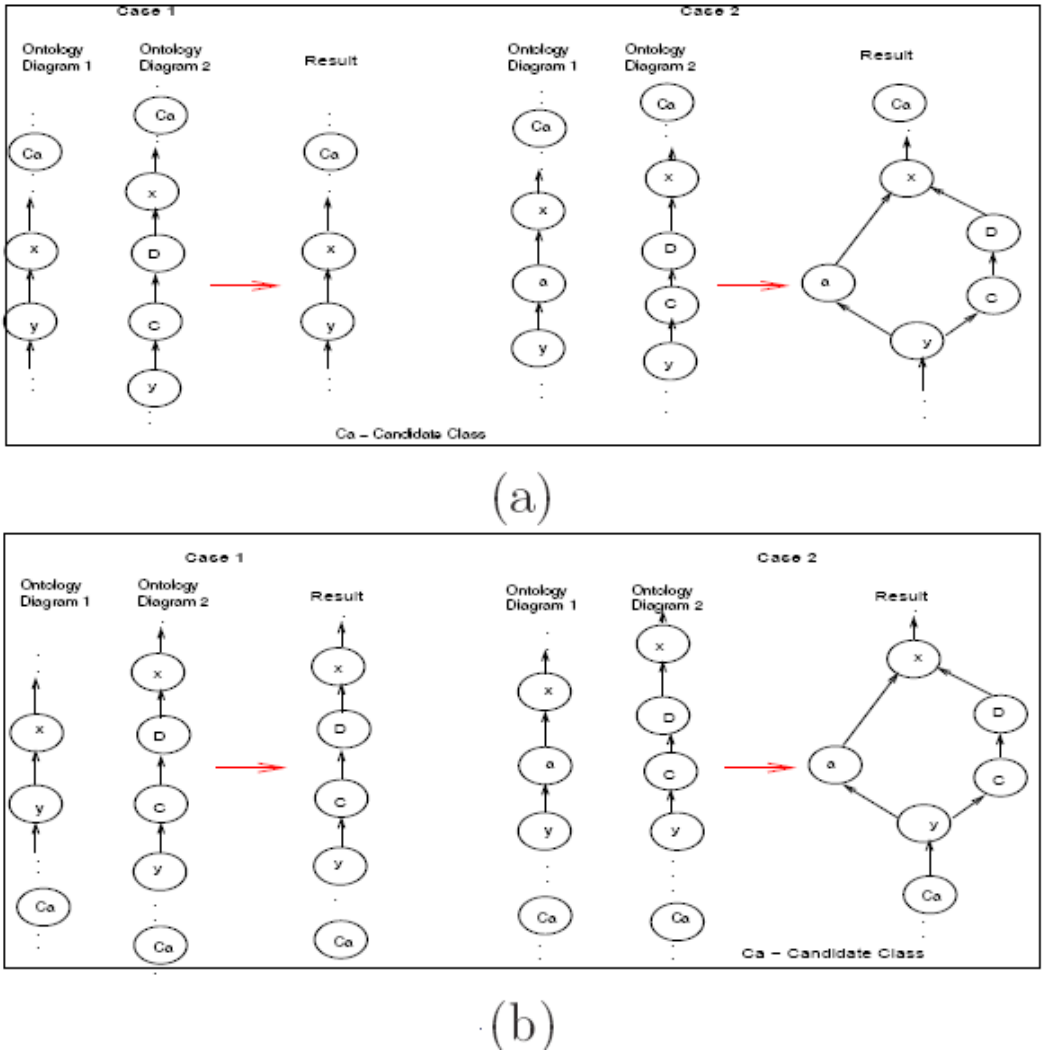


the K/N as low as possible. More generalization the structure represents more re-usable is the extracted ontology. Therefore, our algorithm aims to keep the K/N as low as possible.

Aggregating Ontology from Multiple Inheritance/ Aggregation/ Composition Relationship Graph

We use the edge counting graph (Rada, 1989) method to calculate the semantic distance between the nodes since it gives a good estimate of how close two nodes are. In edge counting method, semantic distance between two nodes is measured as the number of edges between two nodes. In order to maximize generalization nodes, a smaller path between any two nodes in the levels above the level of the candidate class in a ontology diagram is replaced by a longer path (if one exists) from another ontology diagram(s). Figure 11(a) gives various input and output diagram for generalization nodes in an inheritance. The Figure shows the

Figure 11. Ontology aggregation (a) specialization (b) generalization



replacement of the smaller paths by longer paths if present in the input diagrams. The Figure also shows that if there are no common nodes, all the paths are preserved. In order to keep specialization nodes as low as possible, a longer path between two nodes below the level of the candidate class in a ontology diagram is replaced by a shorter path (if one exists) from another ontology diagram(s). Figure 11(b) shows the replacement of longer path(s) between any two nodes by shorter paths if available in the input diagrams. If no common nodes are present all the nodes in the ontology diagrams are preserved in the resultant structure. The resultant diagram obtained by aggregating inheritance/aggregation/com position relationship is referred to as the Partial Aggregated Relationship Diagram (PARD).

Aggregating Ontology from Multiple 'USING' Relationship Graphs

For aggregating 'USING' relationship, all the elements that are related to the candidate class through 'USING' relationship from the ontology diagram(s) are added to PARD. The resultant diagram is the final Aggregated Ontology Diagram (AOD).

Inconsistency

In general, aggregating information from multiple ontology diagrams would give rise to two kinds of inconsistencies: Class Level Inconsistency: This inconsistency arises when a class (identified by name) appears in multiple ontology diagrams but the attributes of the class are different in different in ontology diagrams. For example Registered-Course in an ontology diagram has {StudentId, CourseId} as two attributes and has {StudentId, CourseId, BillAmt} in another ontology diagram. Our aggregation algorithm handles this inconsistency by merging the list of attributes (attribute richness) in the resultant AOD. Association Level Inconsistency: This inconsistency arises when association between two nodes in one ontology diagram is different than in another ontology diagram. If such association exists between two nodes we preserve all the associations between the two nodes. In ontology each association is represented as a property. Properties are first class elements in ontology and therefore can exist independent (of the class). In ontology end points of the property are defined by defining the domain (source) and range (destination) for the property. This implies there can be multiple properties whose end points and range are same, but their utilization depends on the context. By maintaining these associations (as properties) we are precisely extracting the domain (context) in which a entity exits. This is one of the important benefits of aggregating domain information from multiple ontology diagrams.

ONTEXTRACT: IMPLEMENTATION, EVALUATION AND ASSESSMENT

To put our approach into practice, we have implemented our approach as a plug-in using IBM Rational Software Architect (IBM Enterprise Architect Kit for SOA, 2006) using Java language. The plug-in reads in the class and outputs an ontology diagram that is represented using UML notation. Our tool provides provisions for software professionals to extract relevant ontology as applicable to a new problem by providing two optional input holders: (a) sequence diagram holder and (b) domain requirement holder. Both these inputs help extract refined or customized ontology. We have evaluated two cases: (a) Sample Domain - Student course registration, (b) Large scale real world example from IBM. We refer to the extracted ontology of SolA as Base Ontology [BaseOnt] (Figure 6). In general ontology evaluation approaches are classified into four categories (i) those that evaluate the ontology by comparing it to the golden standard, (ii) those that evaluate the ontologies by plugging them in

an application and measuring the quality of the results that the application returns, (iii) those that evaluate ontologies by comparing them to unstructured or informal data (e.g. text documents) and (iv) and those based on human interaction to measure ontology features not recognizable by machines. In our work we have used all the above mentioned work to prove two main aspects described as follows:

1. First we proceed to show that our extracted ontology by OntExtract is reasonable and correct.
2. The extracted ontology is reusable in new solutions (due to the fact that the created ontology overlaps with the design requirements of a new solution).

The first aspect evaluates the validity of the extracted ontology. We use the approach of comparing the extracted ontology with the golden standard to show that our algorithm extracts ontology similar to existing standard ontologies. In the second aspect, we use the approach of plugging the extracted ontology in an application and measuring the quality of results to evaluate the useful of the extracted domain ontology. Finally, we take the help of domain experts (humans) and bring out the importance of our tool in help them with defining better UML diagrams.

OntExtract Extracts Reasonable Ontology

The aim is to show that OntExtract extracts reasonably accurate ontology (serves the intended purpose of extracting ontology). By this we also show that our approach is correct.

Methodology

We evaluate our approach for correctness of is-a, has-a and other associations between entities relations by comparing the extracted ontology with manually built Golden standard (ontology). Golden standard ontology consists of set of entities and relationships that are considered as a good representation of the concepts of the problem domain under consideration. The golden ontology is often manually created by experts (Hassell, 2006) or obtained by merging multiple individual ontologies that are correct. We compare the extracted ontology to a golden ontology, considered as a good representation of the concepts of the problem domain under consideration. High values of matching entities between the two ontologies indicate that our approach OntExtract extracts similar ontology to existing ones.

In our case we consider domain 'University' (whose subset is the course registration) and obtain the golden standard ontology by aggregating several individual 'University' ontologies from (Jeff, 2000; University Ontology, 2002; Donnie Dorr, 2000). Let UML1, UML2 and UML3 be notations that represent these ontologies respectively. We first show that these individual ontologies are correct and therefore the aggregation of these ontologies results in golden standard ontologies. We use the evaluation method presented by Bruno et al (2005) to measure the correctness of individual ontologies. This method assigns grades (depending on the correctness) to individual ontologies and determines the corrections based on these grades. It uses the combined approaches proposed in (Gmez-Prez, 1994; Oltramari, 2002) considered as traditional evaluating methodologies. To begin with it assigns each ontology a grade starting at 20. For each error encountered the grade value is decreased.

Table 1 presents the various criteria s considered for assigning grades. Ontologies that have grades greater than 13 are considered to be satisfy correctness conditions.

Table 2 presents the consolidation of the grades obtained for individual ontology diagrams that we have considered to obtain the golden ontology. From Table 2 it can be seen that the UML diagrams that we have considered to obtain the

Table 1. Criteria considered for grade assignment

Criteria	Points
Completeness Errors (not satisfying the requirements)	-1
Wrong usage of is-a relationship	-1
Wrong usage of has-a relationship	-1
Wrong usage of association	-1
Modeling errors	-2
Clarity errors	-1
Consistency errors	-10

Table 2. Grades for UML diagrams considered for merging

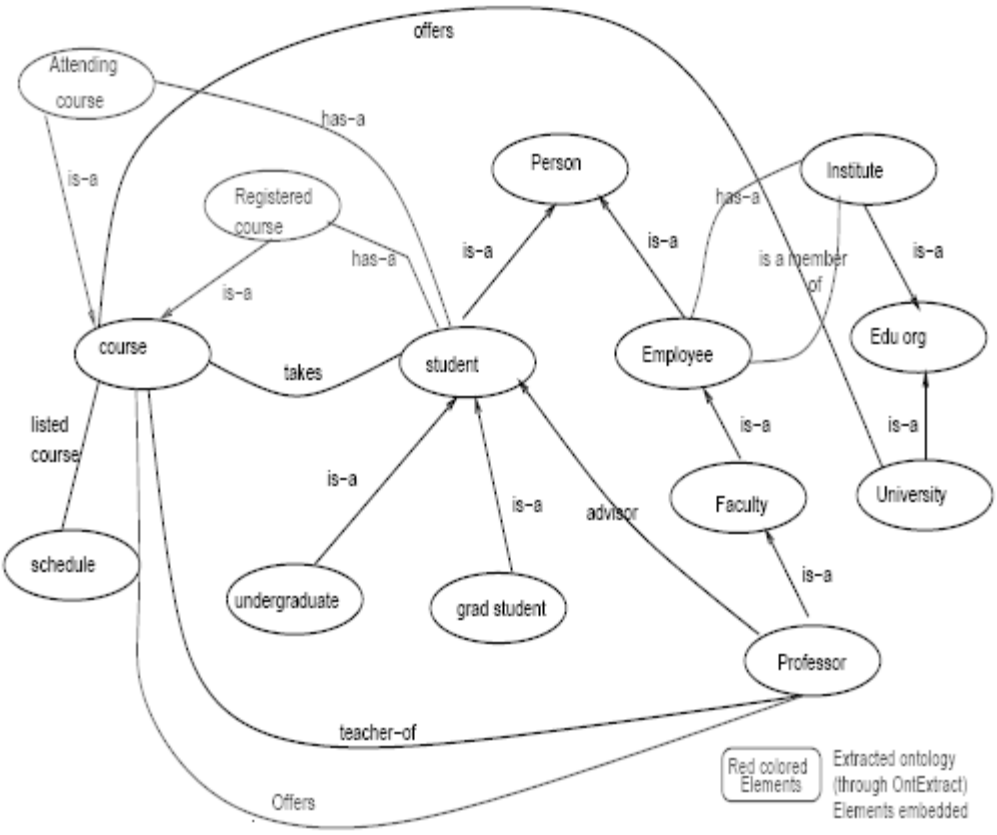
Criteria	UML 1	UML 2	UML 3
Completeness error	0	0	0
Wrong usage of is -a relationship	0	0	0
Wrong usage of has-a relationship	0	0	0
Modeling errors	-2	-2	-1
Clarity errors	-1	0	-1
Consistency errors	0	0	0
Total grade	**17**	**18**	**18**

golden ontology are correct (have grade points greater than 13). We aggregate these individual ontologies to obtain the golden standard. The reason why consider a golden ontology and not individual UML diagrams considered to aggregate is primarily because the individual ontologies considered might be not include all/most of the components of the domain. Complete or partially complete domain ontology can be obtained by merging multiple ontologies.

We present the rules considered for aggregating these correct UML diagrams to obtain a golden standard. The aggregation of these individual ontologies is done using the following rules: (a) union of all relationships is considered between two similar classes (b) for any association all the classes that it connects are considered. A golden ontology thus obtained is shown in Figure 12.

For purposes of comparison, we define Entity Level Relationship Diagram (ELRD), which is a high level abstracted diagram of the extracted ontology containing only the entities and relationship after removing the properties of class and associations. The following rules are used to obtain ELRD from either EECD or OD. (a) Properties of a class in a UML diagram (attributes) are specific to

Figure 12. Golden Ontology – University



a specification. For example, property 'studentid' may appear in some university diagram. In some other university it may be 'studentName'. Since our aim is show that the extracted information is ontology we omit the properties and consider only the entity and relationships. Similarly, attributes of associations are omitted. (b) Inheritance link is replaced by a directed link; Aggregation, composition and using are replaced by just a link. (c) Inheritance is replaced by text 'is-a', Aggregation/compositions is replaced by text 'has-a', using is replaced by the appropriate verb (d) 'has-a' and 'is-a' relationship is given high priority. If two nodes are connected by has-a or is-a, then all other relationship is ignored. (e) Any variable containment is treated (including pointer containment) as 'has-a' relationship. (f) CASE is ignored (g) Naming conflicts are manually resolved through annotations using external sources. (h) Terms are extended with meanings to increase the scope of matching Figure 13 presents the ELRD of the BaseOnt. Base-ELRD is the term used to refer to this ELRD. We compare Base-ELRD with the golden ontology of university (Figure 12). Table

Figure 13. ELRD for student course registration

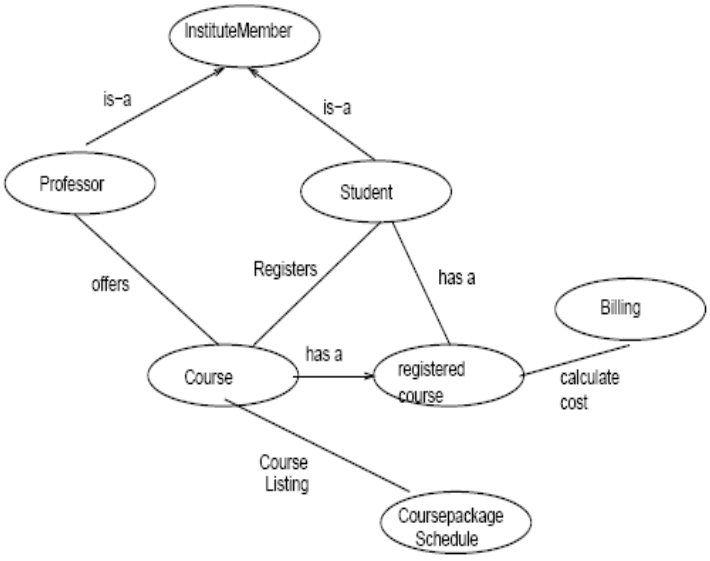


Table 3. Inference rules applicable for matching

Criteria	Name	Extensions to criteria
is-a, has-a		Matched as such
Other IS-A relation-ship(s)	Inference 1	A is-a B is-a C implies A is-a C
	Inference 2	In the above, Property of C is inherited by A
	Inference 3	A has-a B has-a C =) A has-a C
Using relationship	Offer	Matches offer of the standard ontology
	Registers	Since student has registered course and registered course has course, one can conclude that student has course

3 presents the inference criteria for determining matches between the golden ontology and the ELRD elements.

Results

Equation 1 gives the quantitative measure of entity level similarity (E_{sim}) observed as the ratio of the number of matching entities(s) between the golden ontology and Base-ELRD to the total number of entities present in the Base-ELRD of the extracted ontology:

$$E_{sim} = n^{E}_{match} / n^{E}_{ELRD} \quad (1)$$

where n^{E}_{match} is the matching entities between the golden ontology and Base-ELRD and n^{E}_{ELRD} give the number of total number of entities present

in the Base-ELRD diagram. In the similar way, Equation 2 gives the quantitative measure of relationship level similarity (R_{sim}):

$$R_{sim} = n^{R}_{match}/n^{R}_{ELRD} \quad (2)$$

where n^{R}_{match} is the number of matching relationship(s) between the golden ontology and the Base-ELRD and n^{R}_{ELRD} gives the number of total number of relationship elements present in the Base-ELRD diagram.

Table 4 gives the number of matching entity and relationship elements between the golden ontology and Base-ELRD (Figure 12 and Figure 13). The class Course is related to registered course through inference property of 'HAS-A' relationship. Using Table 4 and Equations 1 and 2, we calculate the matching (similarity) entities and relationships metrics as presented in Table 5.

The extracted ontology from the UML diagrams by preserving relationship and entities shows about 85.7% match with the golden standard and about 75% match with the relationships. High values of matching entities and relationships between the extracted ontology through OntExtract and golden ontology show that our approach extracts ontology similar to existing (golden) ontologies. In addition, our method detects other elements that do not have corresponding matches in the golden ontology thereby enriching the existing ontologies with additional elements. This directly proves that our OntExtract method is correct since otherwise there would have been large mismatch between the golden ontology and ontology extracted through OntExtract.

Reusability Evaluation

Design of software solutions is greatly enhanced if the software architect has/gets 'a-priori' knowledge about concepts involved in the problem specification (Marcus A. Rothenberger, 1999). The aim is to show that the extracted ontology is reusable in a number of situations like: (a) Reuse in new solution development (b) Reuse in new problem scenario.

Reuse In New Solution Development

Let us consider a solution for a problem domain to be developed by different group of architects. A solution provided by a group will greatly help the other architects to detect artifacts and provide better solution in the problem. We illustrate this by showing that there exists large amount of common concepts among the solutions, if the solution is developed by different group of architects.

Table 4. Matching found for golden ontology and extracted ontology

Matching entities	Matching Relationship
Student, Professor, Course (registered course, through inference property of 'HAS-A' relationship), schedule/courselisting, Institutemember. Total: 6	is-a (Professor, institutemember), is-a(Student, institutemember) , has-a (student,course ;sub-Category registered course), Offer (professor, course) term 'offer' is matched with 'teacher-of', has-a (course, registered course), has-a (course [subcategory: registeredcourse], courselisting). Total:6

Methodology: We take two different solutions SolB and SolC provided by different group of experts for the course registration problem specification. Comparisons are made to determine the number of common matching entities between these solutions and the BaseOnt. High value of this metric indicates that the ontology from one solution is highly re-usable for new solutions of the problem.

We measure entity reuse (E_{reuse}) as the ratio of number of matching entities with the BaseOnt (n^{BE}_{match}) to total number of entities present in the solution (n^{SE}_{sol}) and is given by Equation 3. In the similar way, Equation 4 gives the relationship reuse R_{reuse}:

$$E_{reuse} = n^{BE}_{sim} / n^{SE}_{Sol} \quad (3)$$

$$E_{reuse} = n^{BR}_{sim} / n^{SR}_{Sol} \quad (4)$$

where n^{BR}_{sim} is the number of matching relationship(s) with the BaseOnt and n^{SR}_{Sol} is the number of relationship(s) present in the solution. Table 3 was used to obtain the matching entities.

SolB with Base Ontology: The ERLD of the extracted ontology for Solution 1 is provided in Figure 14.

Figure 14. Sol B ELRD diagram

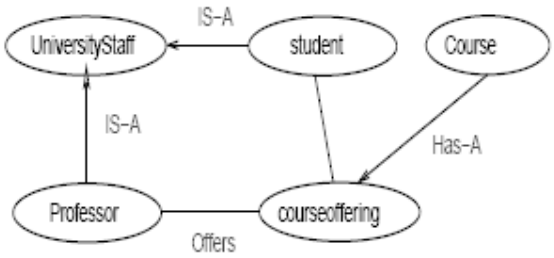

Table 6. Matching for SolB and BaseOnt

Matching Entities	Matching Relationship
Course, Student, courseoffering, Professor, Universitystaff	is-a (professor,university staff),is-a(professor, univeristystaff), has-a(course, courseoffering), Using (Courselisting, student)

Table 7. Comparison of Solution 1 with BaseOnt

Criteria	Number value
Number of entities present in solution 1 ELRD Number of entities matching with base ontology Number of relationship(s) present in the solution 1 ELRD Number of relationship(s) matching with base ontology	5 5 5 4
Re-use of entities present E_{reuse} Re-use of relationship present R_{reuse}	5/5 * 100 = 100% 4/5*100 = 80%

Table 6 presents the matching elements between the ELRD of SolB and Base Ontology. In some cases, inference rules were extended to find similar relationships. For example has-a(course, courseoffering) in Solution 1 is similar to has-a(course, courseoffering) in the BaseOnt through 'courseSchedule'. Classes universityStaff in Solution 1 and instituteMember in BaseOnt represent the same entity and is resolved manually.

Equation 3 and 4 are used to measure re-usability as presented in Table 7. Reuse of entities and relationship(s) has been observed as high as 100% and 80% respectively.

SolC with Base Ontology: Figure 15 gives the ELRD diagram for Solution 2. Table 8 gives the matching elements between ELRD of Sol2 and BaseOnt. Class person match is obtained using extended annotations using external source. Reusability is calculated as shown in Table 9.

Our results indicate that there is indeed great amount of reuse ranging from 70% -100% entity level and 57% to 80% relationship level reusable

Figure 15. Sol C ELRD diagram

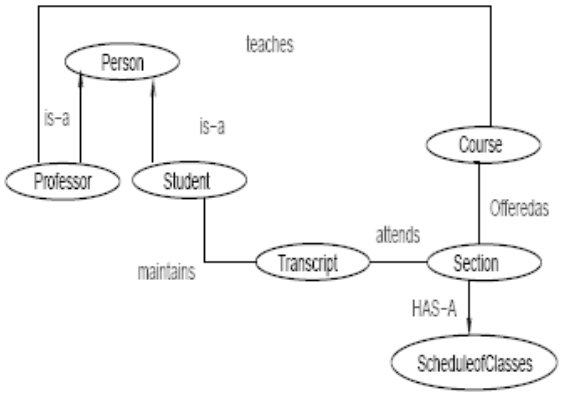

Table 8. Matching for Solution C and BaseOnt

Matching entities	Matching relationships
student, professor, person, course, scheduleclass	is-a(student, person), is-a(professor, person), teaches(professor,course), has-a(course, schedulecourse)

Table 9. Comparison of Solution 2 with BaseOnt

Criteria	Number value
Number of entities present in solution 2 ELRD Number of entities matching with base ontology Number of relationship(s) present in the solution ELRD Number of relationship(s) matching with base ontology	7 5 7 4
Re-use of entities present E_{reuse} Re-use of relationship present R_{reuse}	5/7 *100 = 71.4% 4/7*100 = 57.14%

components. This shows OntExtract provides provisions for reusing previously available ontology to new solutions.

Reuse in New Problem Scenario

Our approach provides provisions for the software professionals to model the use cases of the new problem as sequence diagram and extract related ontology.

Methodology: The architect provides his solution as design diagrams. We extract the domain concepts through OntExtract and call the ontology as ArchitectOnt. We model the use-case requirement as a sequence diagram and use this as a filter to extract ontology from the BaseOnt. We call this ontology as NewScenarioOnt. We find the number of elements of NewScenarioOnt is present in the ArchitectOnt. High values of this metric indicate that large number of domain entities can be reused.

We take an example where the software architects want to design requirements to implement 'ClearDues' use-case of the administration department. The 'ClearDues' checks if the student is valid and have cleared all the courses with clear grades. The architect intends to design new classes and relationship with existing course registration system. For the sake of brevity, only the ELRD diagram (Figure 16) of the class diagram developed by the architect (ArchitectOnt) is provided.

Figure 16. Class diagram by architect

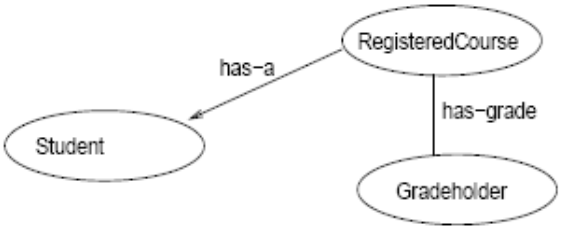

Figure 17. Relevant ontology extracted

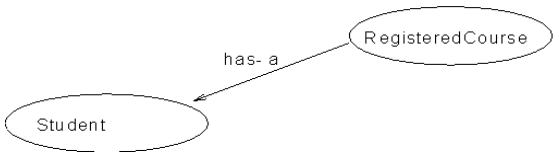

Table 10. Reuse in similar but different domain

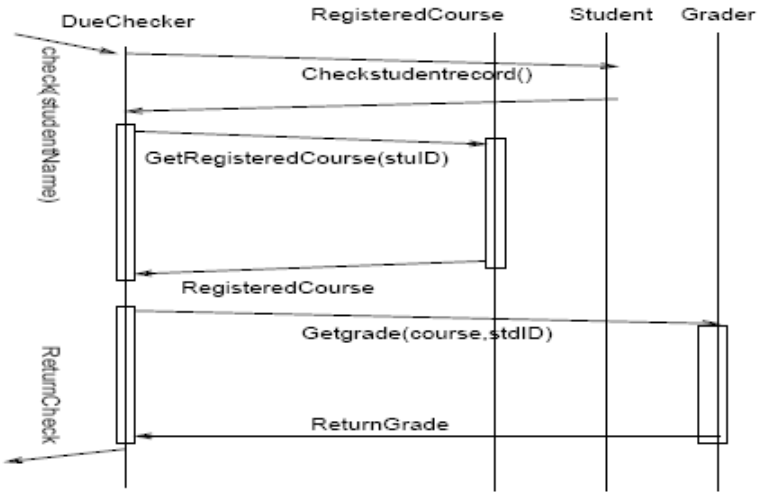
Criteria	Number value
Number of matching entities between the NewScenarioOnt and ArchitectOnt Number of matching relationship(s) between the NewScenarioOnt and ArchitectOnt Total number of entities present in the NewScenarioOnt Total number of relationship present in the NewscenarioOnt	2 1 2 1
Reuse of entities Ereuse Reuse of relationship Ereuse	2/2*100 = 100% 1/1*100 = 100%

Figure 18. Sequence diagram for Use case "ClearDues"



We use the sequence diagram pertaining to 'ClearDues' (Figure 18) as a filter to extract ontology from Figure 6. This ontology extracted is henceforth referred to as the NewScenarioOnt. All the classes in the sequence diagram are considered to extract NewScenarioOnt. The NewScenarioOnt extracted in ELRD form is given in Figure 17.

The results presented in Table 10, indicates that the sequence diagram of a new functionality helps identifying reusable components from previously available solutions. Though this situation is ideal and has 100% reusable components, in practice the amount of re-usability might be less than the one presented here. However, the domain ontology is intended for reuse of domain concepts wherever required; one might expect high values of reusability.

Evaluation on Real World Example

We have taken a real world scenario called "Secure Trade Lanes" (Schaefer, 2006). The description is public but the design diagrams are confidential. It was made available from a business unit in IBM to evaluate our approach on a large scale problem. There were 25 component level diagrams, interaction diagrams (sequence diagram) for use cases. Practical limitations were observed in applying our approach to the real world scenario. The classes were not stereotyped. We had stereotyped the classes manually, since our tool relies on the stereotypes for identifying class level implementation artifacts. The sequence diagrams were at the component level. With the help of architects we had interpreted class level sequence diagrams before using our tool.

The work on real world problem was presented to a group of architects and developers to demonstrate the utility of our plug-in. Their feedbacks indicate that our tool will be useful to develop better software solution architecture.

Finally as a part of evaluation we present the practical usability of our tool. Table 11 provides the benefits of work for different category of

Table 11. Advantages and relevance for practice of OntExtract

Users	Advantages	Impact on software development process
Architects	• Provides Domain View from previous knowledge base (rather than implementation) • Provides existing solution approaches for the new problem and helps extract customized ontology	• Obtaining complete domain prior to development is complicated. Our plug-in helps to provide domain view. • Better architectures by providing view of constraints, entities and relationships that would have been otherwise omitted.
Developer	Helps justify implementation decisions and model constraints from existing solutions	Re-usability
Reasoners	• Uniform understanding of the domain • Aggregation of ontology diagrams provides reuse through inference	• Aggregated Domain view from multiple design diagrams • Fosters reuse of components across different but related problems

people involved in design and development of software solutions.

CONTRIBUTIONS, LIMITATIONS, RELATED AND FUTURE WORK

We have introduced a novel automatic approach for extracting domain ontology for software asset reuse from multiple design diagrams like UML. We observe that dynamic behavior diagrams act as powerful filters in extracting customizable ontology for new scenario. Our OntExtract extends to aggregate ontology from multiple design diagrams. We have developed an ontology extraction plugin over IBM Rational. We have evaluated our work with a sample domain and a real world example. Our approach shows promising results to provide domain view and reuse of the domain theories to develop new scenarios.

Our main contribution in this article can be summarized as follows:

1. An approach for extracting ontology from UML class diagrams.
   - An approach to refine the extracted ontology using sequence diagram.
   - To obtain ontology relevant to a domain by specifying domain requirements as a set of key words.
   - To generate ontology customizable to a new problem domain.
2. An approach to aggregate the extracted ontology using multiple class diagrams of either same or different solutions.

Limitations

The following are the limitations of our work:

1. In our work we have shown extraction of ontology as relevant to a single domain requirement. An incremental approach of extracting ontology with respect to individual domain requirements followed by aggregation of these models will not satisfy the requirements of obtaining single unified ontology with respect to both domains. This is primarily due to fact that individual domain ontology can vary a lot. There will be missing associations between those entities that were extracted with respect to a domain requirement and those entities that were extracted with respect to other domain requirements. A different approach is required to capture more than one domain requirement and extract ontology with respect to both of them.
2. Although we have used analysis class diagram in our work, we are currently working on methodologies that would help identification of stereotypes for classes. For example, we are exploring methods such as code analysis, pattern analysis to categorize classes. In the code analysis methodology, we map the classes in UML diagram to specific stereotype based on the implementation. For example, entity beans can be categorized as entity class, session beans as controller class and servlets and JSPs are boundary class. In pattern based analysis, we analyze the interaction pattern among the class to arrive at a decision of the category of the classes. Such methodologies would enable and promote usage of more commonly available implementation class diagrams as sources of ontology.

Related Work

Significant work has been done in the area of ontology learning and extraction (Alexander, 2001). Various approaches have been used to extract and learn ontology: (a) pattern based approach (Morin, 1999) where a relation is recognized when a sequence of words in the text matches a pattern, (b) association rule approach (Adriaans ,1996) where rules are used to match the query, typically used for data mining process, (c) conceptual pruning approach (Faure D, 2000) where the concepts are grouped according to semantic distance, (d) ontology pruning approach (Kietz, 2000), where the objective is to build a domain ontology based on different heterogeneous sources, (e) concept learning approach (Hahn, 2000), where the ontology is incrementally updated with new concepts. OntExtract is precisely an extraction technique that combines rule based approach along with conceptual pruning. Rules define the UML entities to be removed and preserved, while concept pruning groups entities based on semantic distance.

While the above-mentioned work concentrates on ontology sources and techniques to obtain ontological information, there has been significant amount of work done in using UML as an ontology language (Baclawski, 2002). Some work, such as presented in (Cranefield, 2001), aim at converting an UML specification to an Ontology language specification such as OWL (Deborah 2000). Our work does not concentrate on converting or mapping the UML notation (specification) to ontology language specification but concentrate on identifying and preserving elements that represents domain knowledge (ontology).

Close to our work along the lines of using UML diagrams in the field of domain engineering is the work presented in (Cranefield, 2003). The aim of their work is to express the ontology using UML and to automatically generate related ontology

specific content language along with corresponding java classes and an RDF based serialization mechanism. The work in (Maurizio, 2000) aims at providing a domain engineering approach and the supporting tools to define software product lines. The approach concentrates on domain engineering (identifying domain, domain analysis, and reusable domain components) and expressing these entities using UML.

Future Work

The work presented in this article brings forward various promising areas as follow-up work which we have set as for exploring in the future. We present some of them below:

1. Exploring extraction of ontology by considering other UML diagrams such as object diagrams and use case diagrams has been left for future work. For example, object diagrams provide information about individuals which are one of the constituents of ontology. Time dependent activities can be captured as ontology from dynamic UML diagrams such as activity and use case diagrams. State diagrams are excellent sources of events that can be captured as ontology.
2. Our experience from the real world example that classes are not stereotyped point out that learning stereotype can also be a promising direction. Learning stereotypes are important not only in the context of ontology learning but also in the context of developing readable models.

Summary

Ontology extraction methods are of great importance to the Semantic Web, because it establishes (semi-) automatic methods of constructing fast and confident ontologies. We have presented a novel automatic ontology extraction methodology (OntExtract) that exploits commonalities in the domain software solutions to build ontologies which would not only help ontology engineers but greatly fosters software reuse. Our work uses design diagram as ontological sources to extract and explicitly represent these common domain concepts.

OntExtract tool provides software professionals a-priori information about domain theories thereby helping them to build faster and improved software solutions. With OntExtract, software professionals can extract domain ontology and ontologies customized to new scenarios. The prime target application of our ontology extraction being software reuse, it by itself serves as a measure for evaluating the resultant ontology. Evaluation results indicate that our method greatly promotes software reuse.

ABSTRACT

This chapter describes our approach to model-driven engineering (MDE)-based product line architectures (PLAs) and presents a solution to address the domain evolution problem. We use a case study of a representative software-intensive system from the distributed real-time embedded (DRE) systems domain to describe key challenges when facing domain evolution and how we can evolve PLAs systematically and minimize human intervention. The approach uses a mature metamodeling tool to define a modeling language in the representative DRE domain, and applies a model transformation tool to specify model-to-model transformation rules that precisely define

metamodel and domain model changes. Our approach automates many tedious, time consuming, and error-prone tasks of model-to-model transformation, thus significantly reducing the complexity of PLA evolution.

INTRODUCTION

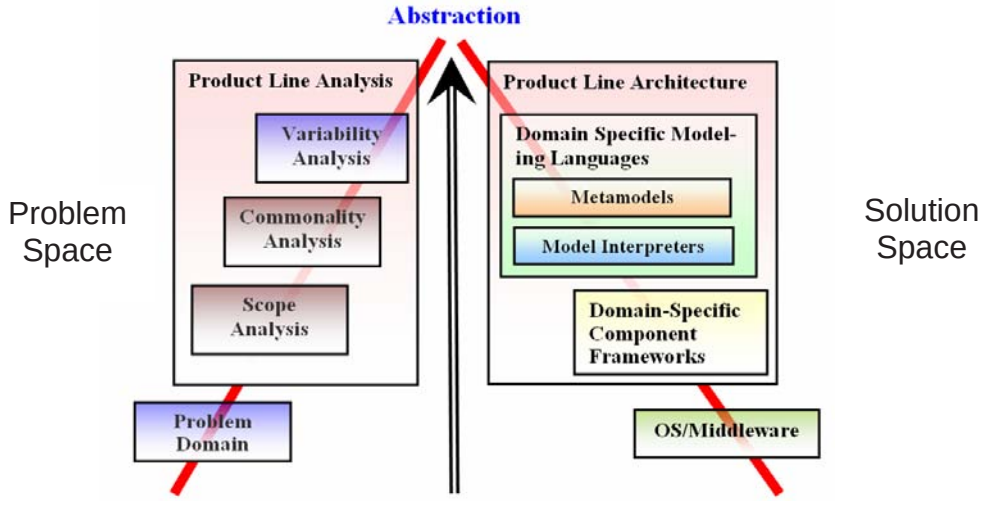
Software *product-line architectures* (PLAs) are a promising technology for industrializing software-intensive systems by focusing on the automated assembly and customization of domain-specific components, rather than (re)programming systems manually (Clements & Northrop, 2001). A PLA is a family of software-intensive product variants developed for a specific domain that share a set of common features. Conventional PLAs consist of *component frameworks* (Szyperski, 2002) as core assets, whose design captures recurring structures, connectors, and control flow in an application domain, along with the points of variation explicitly allowed among these entities.

PLAs are typically designed using *scope/commonality/variability* (SCV) analysis (Coplien, Hoffman, & Weiss, 1998), which captures key characteristics of software product-lines, including: (1) *scope*, which defines the domains and context of the PLA, (2) *commonalities*, which name the attributes that recur across all members of the product family, and (3) *variabilities*, which contain the attributes unique to the different members of the product family.

Motivating the Need for Model-Driven Software Product-Line Architectures

Despite improvements in third-generation programming languages (such as C++, Java and C#) and runtime platforms (such as CORBA, J2EE and Web Services middleware), the levels of abstraction at which PLAs are developed today remains low-level relative to the concepts and concerns within the application domains themselves, such as manually tracking the library dependency or

Figure 1. Using DSMLs and domain-specific component frameworks to enhance abstraction and narrow the gap between problem and solution space of software-intensive systems



ensuring component composition syntactical and semantic correctness. A promising means to address this problem involves developing PLAs using *model-driven engineering* (MDE) (Schmidt, 2006), which involves systematic use of models as key design and implementation artifacts throughout the software lifecycle. MDE represents a design approach that enables description of the essential characteristics of a problem in a manner that is decoupled from the details of a specific solution space (e.g., dependence on specific OS, middleware or programming language).

As shown in Figure 1, MDE-based PLAs help raise the level of abstraction and narrow the gap between the problem space and the solution space of software-intensive systems by applying the following techniques:

- **Domain-specific modeling languages:** A *DSML* (Gray et al., 2007) consists of *metamodels* and *model interpreters*. A metamodel is similar to the grammar corresponding to a programming language that defines a semantic type system that precisely reflects the subject of modeling and exposes important constraints associated with specific application domains. Model interpreters can read and traverse the models, analyze them, and help create the executable system based on these models. DSMLs help automate repetitive tasks (Gray, Lin, & Zhang, 2006) that must be accomplished for each product instance, including generating code to glue components or synthesizing deployment and configuration artifacts for middleware platforms and the underlying operating systems (Balasubramanian et al., 2006).
- **Domain-specific component frameworks:** Through SCV analysis, object-oriented extensibility capabilities are often used to create domain-specific component frameworks, which factor out common usage patterns in a domain into reusable platforms (Clements & Northrop, 2001). These platforms, in turn, help reduce the complexity of designing DSMLs by simplifying the code generated by their associated model interpreters and addressing the product-line specific functional and systemic concerns, including quality of service (QoS) concerns, such as latencies, throughput, reliability, security, and transactional guarantees. Throughout the rest of the chapter we use the two terms "domain-specific component frameworks" and "component frameworks" interchangeably.

MDE helps software developers explore various design alternatives that represent possible configurations for a specific instance of the product family. For example, a product instance ultimately needs to be deployed into a specific target running environment, where all software components must be deployed and mapped to available hardware devices and configured properly based on the specific software/hardware capabilities of the devices. If the PLAs are intended for use with different hardware devices, however, the mappings between the software components and hardware devices cannot be known *a priori* when the software PLAs are developed. Instead of analyzing every product instance individually and manually writing source code or scripts repetitively for every different target execution environment, an MDE-based approach to PLA deployment and configuration automates such repetitive and labor-intensive tasks by integrating domain knowledge and expertise into metamodels and model interpreters. Hence, a DSML infuses intelligence into domain models, which helps address many "what if" problems, such as "what glue code or configuration scripts must be written if the product is to be deployed into an environment with XYZ requirements?" These "what if" scenarios help developers understand the ramifications of

design choices of software-intensive systems at a higher level of abstraction than changing source code manually at the implementation level.

Challenges with Evolution of Model-Driven Software Product-Line Architectures

Although an MDE-based approach helps improve productivity of software-intensive systems by raising the level of abstraction through composition of DSMLs and domain-specific component frameworks, it is hard to evolve software PLAs by incorporating new requirements. Examples of such requirements include using new software platforms or applying the current PLA in a new use case that may impose a different set of concerns than those handled by the current PLA. Consequently, in addition to assisting in the exploration of design alternatives among product instances, an MDE-based PLA technology must also address the *domain evolution problem* (Macala, Stuckey, & Gross, 1996), which arises when existing PLAs must be extended or refactored to handle unanticipated requirements.

Depending on the scopes of the DSMLs and domain-specific component frameworks, unanticipated requirements can be either functional requirements or nonfunctional requirements, or both. For example, consider an MDE-based PLA that is available on two different component middleware technologies, such as Enterprise Java Beans (EJB) (Sun Microsystems, 2001) and CORBA Component Model (CCM) (OMG, 2006). A goal of a DSML that supports PLA is to selectively use the technologies within a product instance based on the system requirements. The metamodel of the DSML must define proper syntax and semantics to represent both component middleware technologies. With domain evolution, if the CCM technology must be replaced by another emerging middleware technology such as Web Services, the MDE-based PLA must evolve accordingly to satisfy the new requirements, that is, new syntax and semantics must be introduced into the metamodel and new domain-specific component frameworks must be developed based on the emerging Web Services technology.

Unfortunately, adding new requirements to MDE-based PLAs often causes invasive modifications to the PLAs in the DSMLs and component frameworks if DSMLs and component frameworks were not initially designed to be extensible to incorporate such new requirements. Conventional MDE tools do not handle the domain evolution problem effectively because they require significant handcrafted changes to existing PLAs, at both the component framework level and the DSML level. The domain evolution problem is particularly hard because the coupling of architecture and infrastructure concerns often *crosscut* the component framework layer and the DSML layer (Deng, Lenz, & Schmidt, 2005) within a PLA.

Moreover, changes made on metamodels in a PLA often invalidate existing domain models based on previous versions of the metamodels (Sprinkle & Karsai, 2004), which makes the evolution process of model-driven software PLAs hard. Other examples of this problem occur in programming language or object-oriented framework design, where changes to a grammar or class hierarchy for a programming language or framework may introduce errors in existing legacy source code (Klusener, Laemmel, & Verhoef, 2005). Another example is schema evolution in a database, where changes to a database schema may render the contents of the database useless (Roddick, 1992). Just like legacy source code and contents of database, domain models are crucial assets of an organization, so they must be handled well during the metamodel evolution process.

From these observations, there are many complexities involved when MDE-based software PLAs need to evolve. Although software developers can manually update their metamodels, domain models, and component frameworks for small-scale systems, this approach is clearly tedious,

time consuming, error-prone, and nonscalable for software-intensive systems.

Solution → Systematic PLA Evolution with Automated Domain Model Transformation

To address these challenges, a layered and compositional architecture is needed to modularize system concerns and reduce the effort associated with domain evolution. With the help of this architecture, different layers of PLAs can evolve systematically and tool supported domain model evolution also becomes feasible. The overall approach can be characterized in the following ordered steps:

1. The first step deals with component framework evolution. Because component frameworks provide core functionalities to the product instances, they have the most direct impact on the PLAs. As a result, whenever PLAs need to incorporate new requirements, component frameworks must first be refactored. To reduce the impact of such evolution outside the component frameworks, the key point is using pattern-oriented software architecture (Gamma, Helm, Johnson, & Vlissides, 1995; Schmidt, 2000).
2. The second step deals with metamodel evolution. Because metamodels are used to define type systems of particular domains based on proper language syntax, a language can be decomposed into smaller units to localize the evolution impact, and allow such smaller units to be composed to form the new metamodel.
3. The third step deals with the domain model transformation. This step applies automated model transformation techniques to specify model-to-model transformation rules that define metamodel changes. The application of automated model transformation alleviates many tedious, time consuming, and error-prone tasks of model-to-model transformation to reduce the complexity of PLA evolution. In particular, when an existing DSML in a PLA is changed, the domain models defined by this DSML can be migrated automatically to the new DSML by applying a set of model transformation rules.

While the three-step approach above could be applied to any model-driven software PLAs, this chapter focuses on distributed real-time embedded (DRE) PLAs, which are among the most difficult software-intensive systems to develop because such systems have limited resources and must communicate via the network to meet stringent real-time quality-of-service (QoS) assurance and other performance requirements. A representative software-intensive DRE system is used throughout the chapter as a case study to describe how to evolve PLAs systematically and minimize human intervention. Along with presenting the approach for domain evolution of MDE-based PLAs, the chapter also describes key concepts, such as model-driven engineering, product-line architectures, and model transformations that are important for developing and evolving PLAs for large-scale software-intensive systems.

The remainder of this chapter is organized as follows: We first evaluate related work that supports evolution of software PLAs for DRE systems and compare it with our approach. Then, we describe a conceptual architecture of MDE-based PLAs for DRE systems and define the key elements in this architecture as background of this chapter. After that, we introduce a representative case study of a PLA for avionics mission computing used throughout the chapter. Then, we describe the challenges involved when facing evolving model-driven PLAs and present the solutions to address these challenges. Lastly, we present our concluding remarks and lessons learned.

RELATED WORK

This section surveys the technologies that provide solutions to MDE-based software PLA evolution for software-intensive systems. The related work has been categorized along two dimensions based on the syntax of the modeling mechanism the software PLA evolution relies on, that is, a graphical based modeling approach or a text-based modeling approach.

Graphical Modeling Approaches

A UML metamodel for software PLA evolution (Mens & D'Hondt, 2000) has been developed based on the concept of an *evolution contract*. The idea of an evolution contract is that when incremental modifications and evolution of software artifacts are made on a software product line, a formal contract must be defined between the provider and the modifier. The purpose of the contract is to define the evolution behavior formally. A UML metamodel has been defined to capture the formal evolution contract. This offers a generic MDE-based mechanism for dealing with unanticipated evolution. By documenting model evolution through formal models, incompatibilities or undesired behavior across different modeling artifacts can be detected when models are upgraded, or when different software developers independently make changes to the same or related parts of a model. This approach allows conflicts to be detected regardless of the specific kind of model that is under consideration. The approach has been integrated into third-party CASE tools, such as IBM Rational Rose (IBM, 2007).

KobrA (Atkinson et al., 2002) is another approach based on UML for component-based software PLAs that support model-driven representation of components. In this method, evolution management in software PLAs is divided into three activities, that is, configuration management, change management, and maintenance planning. Configuration management in KobrA is a static method for bringing together different artifacts within a PLA. Change management consists of techniques to evaluate evolution requests. The use of appropriate formal change operators to evolution requests assists in traceability within change propagations in a PLA. Maintenance planning is responsible for constructing infrastructure for the change and configuration management activities. The idea of KobrA is based on a change-oriented model, that is, new versions are obtained from changes applied to some artifacts in the product line. To support the evolution in KobrA, the *evolution graph* technique (Atkinson et al., 2002) is proposed to capture version histories of different artifacts of the PLA and trace the dependencies.

Another technique similar to the evolution graph is called *design decision tree* (DDT) (Ran & Kuusela, 1996), which is a formal approach to incrementally document, refine, organize and reuse the architectural knowledge for software design. The formalism is a hierarchical organization of design patterns that is a partial ordering of design decisions put in the context of the problem requirements and the constraints imposed by earlier decisions. This model integrates architectural knowledge of software design into a software development process. A DDT contains system-wide design information in a form that can be used to analyze change requests and determine their impact on system structure. Because the tree is maintained throughout the lifecycle of a PLA, it can be used as the main repository of design knowledge (Karhinen & Kuusela, 1998). Such a repository can be used to analyze the impact of new requirements to the existing requirement space and to investigate the changes that different implementation strategies may cause to the system structure, which makes it possible to classify different options and to react to them and analyze their architectural implications.

Summary

The related work described above adopts a domain-independent modeling technique to capture the software PLA evolution requirements either explicitly or implicitly. Our approach is similar to these related works in the sense that they all provide visualization capabilities through graphical modeling tools for PLAs. Our approach, however, uses a domain-specific modeling technique that adds additional abstractions representing domain concepts to the modeling languages that are not available in general-purpose domain-independent modeling languages such as UML. DSMLs thus require less effort and fewer low-level details to specify a given system (Tolvanen & Kelly, 2005).

Text-Based Modeling Approaches

Architectural Description Language (ADL) is an important technique in this dimension that facilitates software PLA evolution. The Mae environment (Hoek, Mikic-Rakic, Roshandel, & Medvidovic, 2001), for example, uses ADL to facilitate incremental evolution by capturing all changes made to any architectural elements within a PLA. A key concept in the Mae environment is a system model that allows architectural concepts and configuration management to be mapped with each other through ADL syntax, that is, the ADL allows users to describe what and how the changes should be made to the model. The essence of the approach lies in the use of this model to integrate change management concepts (such as revisions, variants, and configurations) with architectural concepts (such as components, connectors, subtypes, and styles) through ADL descriptions. By mapping the generic system model onto a specific ADL, the design analyses of a software PLA and its evolution can be adapted for the purpose of maintaining the consistency of the architectural configurations captured by the model.

Similar to the idea of the Mae environment, the Koala Component Model (Ommering, Linden, Kramer, & Magee, 2002) also uses ADL to explicitly describe the architecture and provides a platform-centric approach to the design of PLAs for consumer electronics software. Specifically, the Koala Component Model allows variability options to be modeled explicitly via a property mechanism. Using a third-party versioning system, Koala can be used to capture the evolution of a PLA.

XADL (Dashofy, Hoek, & Taylor, 2003) is an XML-based ADL that is constructed from a set of extensible XML schemas. XADL also defines a set of associated libraries that provide a programmatic interface to XADL documents, and provide runtime facilities to create, store, and modify XADL documents. XADL and its associated libraries provide three important benefits for the purposes of supporting software PLA evolution: (1) the core of the XADL language supports variability in both space and time; in XADL, variabilities of artifacts are a natural and integral part of the language, (2) the language can be extended, which allows individual activities in the lifecycle to be able to attach additional information, and (3) the library provides a generic interface to easily access XADL documents, which supports the rapid construction of new tools supporting PLA evolution.

Summary

The related work described in this section all use text-based languages (such as structural languages or XML) to either explicitly capture the PLA evolution activities, or implicitly associate the evolution requirements with actual software components. Our approach is similar to this dimension of the related work in the sense that PLA evolution can be captured through the software PLA architecture itself, rather than through a separate dedicated language.

Hybrid Approaches

Some technologies span both text-based and graphical-based approaches. A well-known example in this category is called QVT (Query/View/Transformation) (OMG, 2005b), which is the OMG standard for model-to-model transformations. This technology provides a standard language to transform UML or custom model types from one type to another. It accepts XML Interchange (XMI) (OMG, 2005b) as input and output. Typical usage scenarios include automating transformation of a high-level design model into a more detailed model, transforming a UML model into a custom data model, or transforming one custom model type into another. The core benefits of this feature set are a standards-based language to express common model transformations with traceability, which provides repeatable results.

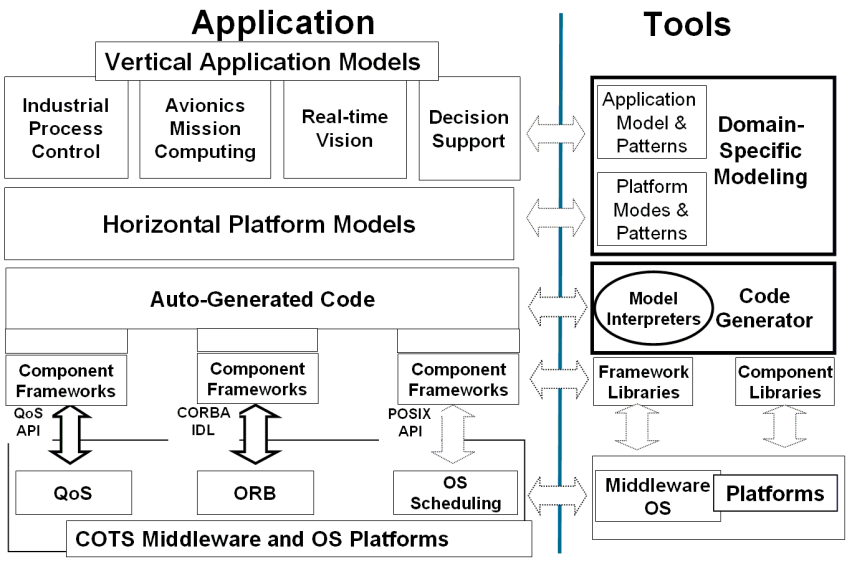
Summary

The specification of QVT defines both graphical syntax and textual syntax for the transformation language, but so far there lacks a full implementation of the specification. Moreover, while QVT is restricted to only XMI to XMI transformations, our approach does not have this restriction, so it can exploit any internal representation of the DSMLs.

MDE-BASED PRODUCT LINE ARCHITECTURE FOR DRE SYSTEMS

This section introduces an architecture of a MDE-based product line architecture for software-intensive DRE systems, focusing on the design concepts, common patterns, and software meth-

Figure 2. MDE-based product-line architecture for DRE systems



odology. An MDE-based design and composition approach for DRE systems entails the combination of DSMLs with reusable component frameworks. Figure 2 illustrates the high-level design principles and an overall architecture of an MDE-based PLA solution for software-intensive DRE systems that exploits a *layered* and *compositional* approach. This architecture takes advantage of layering and composition design principles (Krueger, 2006) to make the associated PLAs easier to develop and evolve than *ad hoc* approaches.

As shown in Figure 2, the PLA architecture is based on a core set of COTS middleware and OS platforms, component frameworks and domain-specific modeling languages. The right side of the figure shows the technologies available to implement the design artifacts on the left side. For example, the "Generator Technology" shown on the right can be used to build model interpreters that automatically generate code to bridge the gap between models and component frameworks.

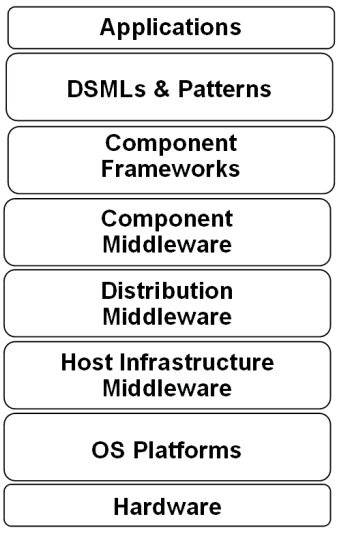
The remainder of this section introduces and defines key terms and concepts in the architecture shown in Figure 2.

Commercial-Off-The-Shelf (COTS) Middleware and OS Platforms

COTS middleware and OS platforms provide the infrastructure upon which DRE systems run. Many DRE systems are based on OS platforms with real-time scheduling capabilities. Examples of such OS platforms include *VxWorks* (Wind River Systems, 1998), *Timesys Linux* (Timesys, 2002), and *Windows CE* (Microsoft, 2007). Middleware is an enabling technology that allows multiple processes running on one or more machines to interact across a network. Middleware can be further decomposed into multiple layers (Schmidt, 2002), such as those shown in Figure 3 and described below:

- **Host Infrastructure Middleware:** The host infrastructure layer resides directly atop the operating system and provides a set of higher-level APIs that hide the heterogeneity of different operating systems and network protocols. The host infrastructure layer provides generic services to the upper middleware layers by encapsulating functionality that would otherwise require much tedious, error-prone, and nonportable code, such as socket programming and thread manipulation primitives. Examples of such middleware include ACE (Schmidt, 1993), Real-time Java (Bollella et al., 2000) and Rocks (Zandy & Miller, 2002).
- **Distribution Middleware:** The distribution layer resides atop the host-infrastructure layer and provides high-level programming abstractions, such as remote object operations. Using the distribution layer, a developer can write a distributed application in a similar way to a stand-alone application.

Figure 3. OS, middleware, DSML and application layer relationships



CORBA 2.x (OMG, 2003), DCOM (Microsoft, 2000), Java RMI (Sun Microsystems, 2000) and Data Distribution Service (DDS) (OMG, 2004a) are the main solutions to distribution middleware.

- **Component Middleware:** The component middleware layer resides atop the distribution middleware layer and adopts the component-based software engineering approach (Heineman & Councill, 2001) to allow maximum reuse of software components. Component middleware also provides mechanisms to configure and control key distributed computing aspects, such as connecting event producers to event consumers and managing transactional behavior, separate from the functional aspects of the application. Examples of component middleware platforms include Enterprise Java Beans (EJB) (Sun Microsystem, 2001) and OMG Corba Component Model (CCM) (OMG, 2005a).

Because many DRE systems require a loosely-coupled distribution architecture to simplify extensibility, COTS middleware typically provides event-driven publish/subscribe communication mechanisms, which help reduce ownership costs by defining clear boundaries between the components in the application. Such mechanisms reduce dependencies and maintenance costs associated with replacement, integration, and revalidation of components. COTS middleware and OS platforms are designed to maintain the commonality, portability, reusability, and applicability of software for different domains.

Component Frameworks

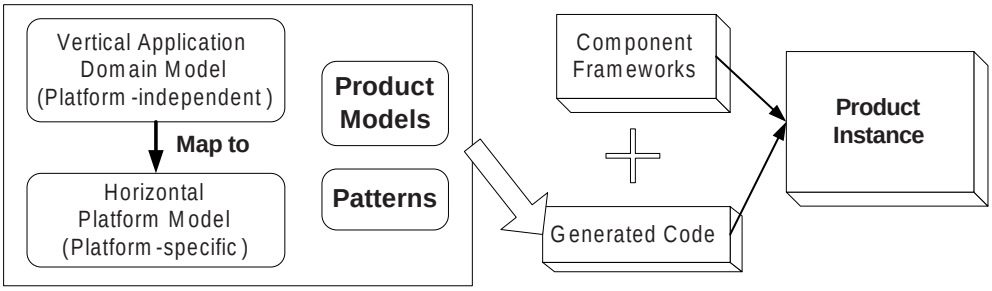
Component frameworks provide reusable domain-specific building blocks for PLAs of DRE systems. As illustrated in Figure 3, component frameworks reside atop COTS middleware and OS platforms. The key difference between component frameworks and component middleware is that the latter is domain independent while the former is domain-specific. Component frameworks define "semicomplete" applications that embody domain-specific object structures and functionality to raise the level of abstraction at which the software product instance is composed, and offer product-line specific environments to capture the variabilities. Components in such a framework coordinate with each other to provide core functionalities for a family of related applications. Complete applications can be composed by inheriting from or instantiating framework components.

Examples of component frameworks include the Boeing Bold Stroke product line architecture (Schulte, 2003) in the avionics mission computing domain and Siemens Building Technology APOGEE product line architecture (Siemens, 2007) in the building automation domain. For example, the Boeing Bold Stroke PLA supports many Boeing product variants using a component-based platform. The Boeing Bold Stoke PLA supports systematic reuse of mission computing functionality and is configurable for product-specific functionality and execution. The philosophy of component frameworks is to develop reusable components that are well-defined and have specific use contexts and variability points, which helps reduce the effort associated with using low-level middleware interfaces or OS APIs.

Domain-Specific Modeling Languages (DSMLs) and Patterns

DSMLs and patterns facilitate the model-based design, development, and analysis of DRE systems. Figure 4 shows how DSMLs and patterns can be combined with component frameworks to build product instances. A DSML can represent either a vertical application domain model (specific to

Figure 4. Integration of domain-specific modeling and component frameworks



concerns within a specific industry or domain) or a horizontal model (generic to concerns that span several domains).

Vertical application domain models address the problems arising within a particular domain, and they are often modeled in a platform-independent manner (Frankel, 2003). Examples of such vertical application domains include industrial process control, telecommunications, and avionics mission-critical systems. Some DSML examples developed for vertical domains include the *Saturn Site Production Flow* (SSPF), which is a manufacturing execution system serving as an integral and enabling component of the business process for an automotive factory (Long, Misra, & Sztipanovits, 1998). Another example is the *Embedded System Modeling Language* (ESML) (Karsai, Neema, Abbott, & Sharp, 2002), which models mission computing embedded avionics applications in the Boeing Bold Stroke PLA.

Horizontal platform domain models are also called platform-specific models (Frankel, 2003). A platform-specific model is a model of a system that is linked to a specific technological platform (e.g., a specific middleware platform, operating system or database). An example of a DSML for horizontal platforms is the *Rhapsody* modeling environment (iLogix, 2006), which allows application generation for embedded software platforms based on many real-time operating systems. Other examples of DSMLs for horizontal platforms include the *Platform Independent Component Modeling Language* (PICML) (Balasubramanian et al., 2005a) and J2EEML (White, Schmidt, & Gokhale, 2005), which facilitate the development, deployment, and configuration of QoS-enabled component-based DRE systems based on CCM and EJB, respectively.

The main idea is that it should be possible to use a model transformation technique to transform vertical application domain models to a horizontal platform domain model. Regardless of whether the DSMLs target horizontal or vertical domains, *model interpreters* can be used to generate various artifacts (such as code and metadata descriptors for deployment and configuration), which can be integrated with component frameworks to form executable applications or simulations. Key advantages of using DSMLs and patterns in PLAs are to rigorously capture the key roles and responsibilities of a product instance and help automate repetitive tasks that must be accomplished for each product instance.

In summary, an MDE-based PLA for software-intensive systems must be based on an architecture that adheres to well-documented

principles of architectural design with a clear separation of commonalities and appropriate provisions for incorporating variations by integrating vertical/horizontal DSMLs, component frameworks, middleware and OS platforms. In this architecture, MDE technologies are used to model PLA features and glue components together; for example, they could be utilized to synthesize deployment artifacts for standard middleware platforms (Balasubramanian et al., 2006).

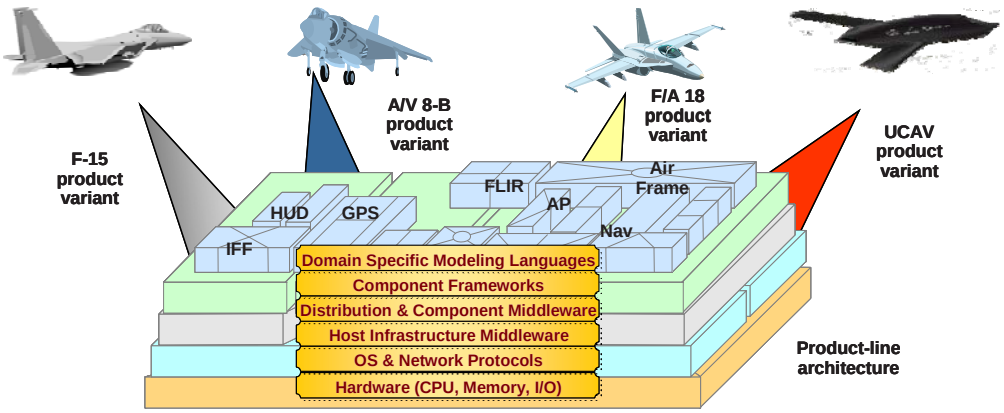
OVERVIEW OF THE BOEING BOLD STROKE PLA AND EQAL MDE TOOL

This section introduces a case study based on a real-time avionics mission computing product line called Boeing Bold Stroke and describes the structure and functionality of the *Event QoS Aspect Language* (EQAL) MDE tool based on this product line. The Boeing Bold Stroke PLA supports many Boeing product variants (e.g., F/A-18E, F/A-18F, F-15E, and F-15K) using a component-based publish/subscribe pattern (Gamma et al., 1995). The EQAL MDE tool is intended to reduce many complexities associated with the integration, deployment and configuration of different implementations of publish/subscribe mechanism. The Bold Stroke PLA and its associated models in EQAL will serve as the case study throughout this chapter.

Overview of Boeing Bold Stroke Product Line Architecture

Figure 5 illustrates the Boeing Bold Stroke PLA (Sharp, 1999), which was developed by Boeing in the mid-1990s to support systematic reuse of avionics mission computing functionality and is configurable for product-specific functionality (such as heads-up display, navigation, and sensor management) and execution environments (such as different networks/buses, hardware, operating systems, and programming languages) for a variety of military aircraft. Bold Stroke is a very complex framework with several thousand components implemented in several million lines of C++ code.

Figure 5. Boeing bold stroke product line architecture



The Boeing Bold Stroke architecture contains a set of event-driven component-based component frameworks built atop (1) The ACE ORB (TAO) (Schmidt, Levine, & Mungee, 1998), which implements key Real-time CORBA (OMG, 2005a) features, and (2) TAO's Real-time Event Service (Harrison, Levine, & Schmidt, 1997), which implements the publish/subscribe architectural pattern. Bold Stroke uses a Boeing-specific component model called PRISM (Roll, 2003), which implements a variant of the CORBA Component Model (CCM) atop TAO.

Following the CCM specification, PRISM defines the following types of ports, which are named interfaces, and connection points components used to collaborate with each other:

- **Facets**, which define named interfaces that process method invocations from other components.
- **Receptacles**, which provide named connection points to facets provided by other components.
- **Event sources and event sinks**, which indicate a willingness to exchange event messages with one or more components via event channels.

Bold Stroke is a representative PLA for DRE systems in the real-time avionics mission computing domain. Its event-driven communication architecture employs a control flow/data flow (Sharp, 1999) principle, where control flow represents the movement of execution through a software system, while the data flow represents the movement of data through a software system. Depending on requirements, different product variants in the Boeing Bold Stroke PLA may require different levels of QoS assurance for event communication, including timing constraints, event delivery latency, jitter, and scalability. Even within the same product variant, different levels of QoS assurance must be ensured for different communication paths, depending on criticality of the data. For example, the communication path between a collision radar component and the LED display component must have much more stringent timeliness deadline requirements than regular GPS components and navigation display components.

To alleviate the complexity in provisioning the event-driven publish/subscribe services and their QoS assurance in the Boeing Bold Stroke PLA, we designed an MDE-based tool called the Event QoS Aspect Language (EQAL) that can automate and simplify the integration of publish/subscribe services into QoS-enabled component-based systems.

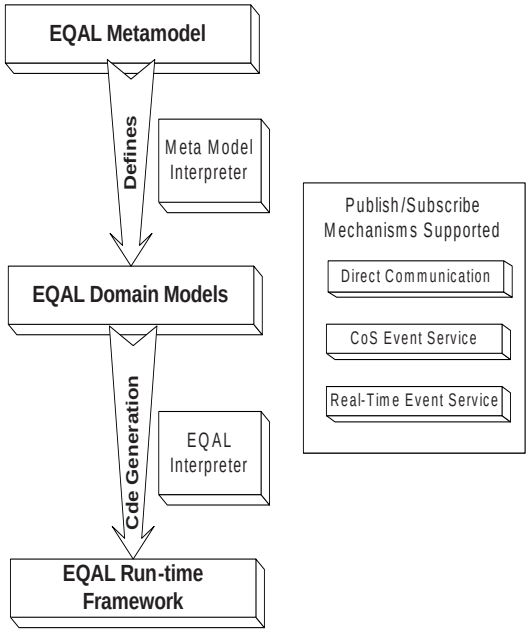
Overview of the EQAL MDE Tool

One core part of the EQAL MDE tool is the EQAL DSML (Edwards, Deng, Schmidt, Gokhale, & Natarajan, 2004), which is implemented using the Generic Modeling Environment (GME) (Lédeczi, Nordstrom, Karsai, Volgyesi, & Maroti, 2001). The GME is a toolkit that supports the development of DSMLs. The EQAL DSML provides an integrated set of metamodels, model interpreters, and standards-based component middleware that allow DRE system developers to visually configure and deploy event-driven communication mechanisms in DRE systems via models instead of programming them manually. The EQAL DSML is an example that supports a horizontal platform domain; that is, it is not restricted to a particular vertical application domain, but instead can be leveraged by multiple vertical domains. In this case study, we describe how EQAL was applied to the Bold Stroke avionics mission computing PLA.

As shown in Figure 6, EQAL is a layered architecture that supports several types of abstractions, which are subject to change stemming from domain evolution as explained below:

- The *bottom layer* in the architecture is the EQAL Runtime Framework, which is a por-

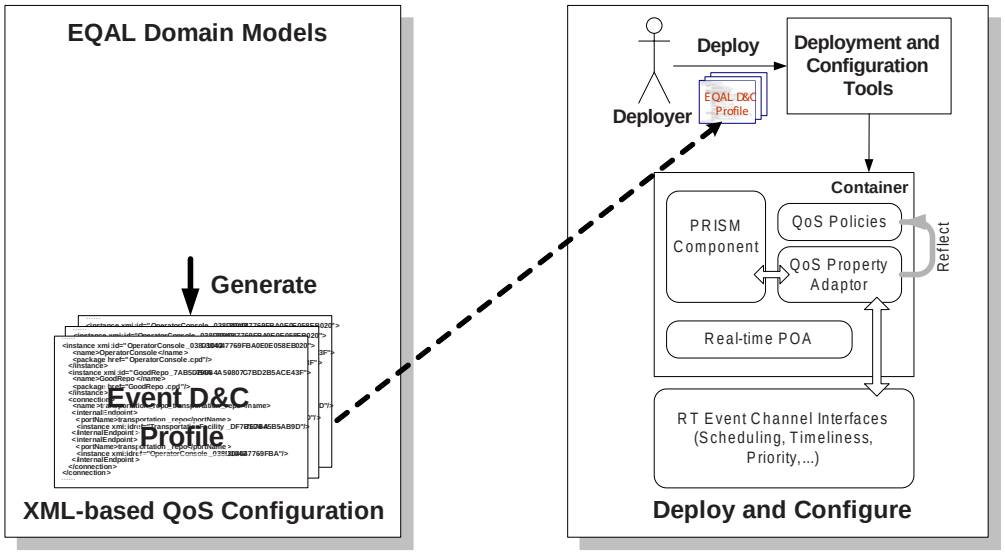
Figure 6. EQAL MDE tool architecture



table, OS-independent middleware framework based on light-weight CCM (OMG, 2004b). The EQAL Runtime Framework provides an extensible way to deploy various event-driven publish/subscribe mechanisms, including a two-way event communication mechanism based on direct method invocation instead of using a mediator channel.

- The *middle layer* in the EQAL architecture is a set of domain models that represent instances of the modeled DRE systems. These models are created using the EQAL DSML and are used to capture the structural and behavioral semantic aspects of event-driven DRE systems.
- The *top layer* of the EQAL architecture consists of a metamodel that enables developers to model concepts of event-driven DRE systems, including the configuration

Figure 7. Code generation from EQAL domain model



and deployment of various publish/subscribe services. This layer also contains several model interpreters that synthesize different types of configuration files that specify QoS configurations, parameters, and constraints, such as the threading model for event dispatching, event filtering configuration, and event channel federation configurations (Edwards et al., 2004). The EQAL interpreters automatically generate publish/subscribe service configuration files and service property description files needed by the underlying EQAL Runtime Framework and selected middleware.

As shown in Figure 7, EQAL allows DRE system deployers to create and synthesize publish/subscribe QoS configurations and deployments via graphical models (i.e., EQAL domain models) that are much easier to understand and analyze than hand-crafted code. During the modeling phase, EQAL ensures that dependencies between configuration parameters are enforced by declaring constraints on the contexts in which individual options are valid (e.g., priority-based thread allocation policies are only valid with component event connections that have assigned priorities). EQAL can then automatically validate configurations and notify users of incompatible QoS properties during model validation, rather than at component deployment and runtime. The generated XML-based QoS configuration and deployment descriptors can then be fed into deployment and configuration runtime tools to deploy and configure the components and real-time event channels within the Boeing Bold Stroke.

SUPPORT MDE-BASED PLA EVOLUTION WHEN FACING DOMAIN EVOLUTION

This section examines the following challenges associated with evolving MDE-based PLAs:

1. Challenges stemming from capturing new requirements into existing MDE-based PLAs for DRE systems.
2. Challenges stemming from migrating existing domain models with MDE-based PLA evolution.

For each challenge, we explain the context in which the challenge arises and identify key problems that must be addressed. Many of these challenges also exist in MDE-based PLAs for DRE systems, so they are not limited solely to event-driven DRE systems as described in our case study. In the remainder of this section, we first discuss the challenges and solutions associated with domain-specific component framework evolution and DSML evolution, then the challenges and solutions associated with domain model evolution.

Challenges Stemming from Capturing New Requirements into Existing MDE-based PLAs for DRE Systems

Context

Evolution is a natural occurrence in software development and an inevitable part of the software PLA lifecycle (Chapin, Hale, Kham, Ramil, & Tan, 2001). The changes may be initiated to correct, improve, or extend assets or products. Because assets are often dependent on other assets, changes to one asset may require corresponding changes in other assets. Moreover, changes to assets in PLAs can propagate to affect all products using these assets. A successful process for PLA evolution must therefore manage these changes effectively (McGregor, 2003).

Problem: New Requirements Impact Metamodels and Component Frameworks

DRE systems must evolve to adapt to changing requirements and operational contexts such as supporting new features. In addition, when some emerging technologies become sufficiently mature, it is often desirable to integrate them into existing PLAs for DRE systems. Figure 8 shows different affected scopes caused by such evolution.

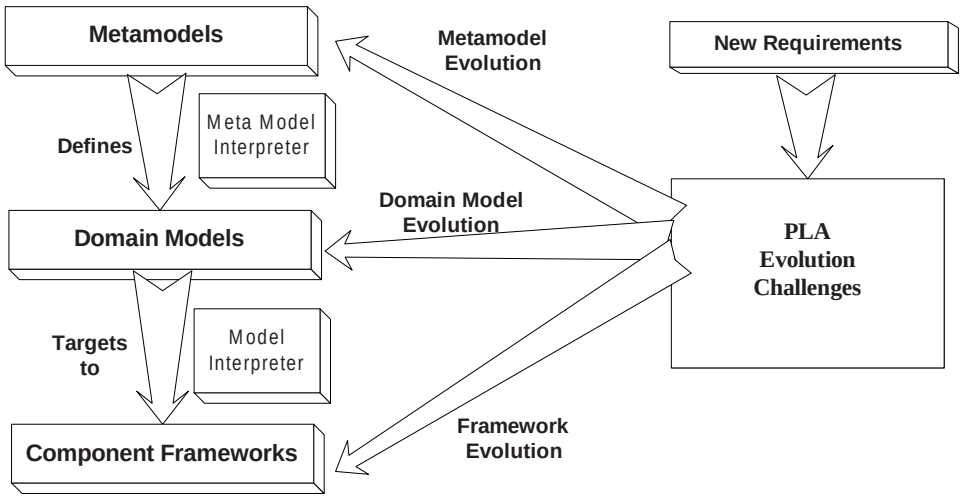
In our Boeing Bold Stroke case study, for example, depending on system requirements, different product variants in the Bold Stroke PLA may require different levels of QoS assurance for event communication, including timing constraints, event delivery latency, jitter, and scalability. Even within the same product variant, different levels of QoS assurance may be required for different communication paths, depending on system criticality (e.g., certain communication paths between components may require more stringent QoS requirements than others).

Solution: Evolve a PLA Systematically Through Framework and Metamodel Enhancement.

A layered PLA can reduce software design complexity by separating concerns and enforcing boundaries between different layers. Because different layers in a PLA need to interact with each other through predefined interfaces, to integrate new requirements into a PLA, all layers must evolve in a systematic manner. This evolution can be generalized to the following three steps:

1. **Component framework evolution.** As discussed earlier, frameworks are often built atop middleware and OS platforms to provide the runtime environment of DRE systems. As a result, whenever a DRE system must evolve to adapt to new requirements, component frameworks are often affected because they have direct impact on the system.
2. **DSML evolution.** DSML metamodels and interpreters are often used to capture the

Figure 8. Challenges stemming from adding new requirements into model-driven software PLAs



variability and *features* of DRE systems to expose different capabilities for different product variants. As discussed previously and shown in Figure 2, typically the DSMLs for vertical application domains have a higher level of abstraction than DSMLs for horizontal platform domains. These lower level DSMLs are built atop domain-specific component frameworks and are often used to glue different component framework entities together to form a complete application. Therefore, the evolution of lower level DSMLs should be performed after framework evolution is completed.

3. **Domain model evolution.** The DSML metamodel defines a type system to which domain models must conform. Because the changes to the metamodel of a DSML often invalidate the existing domain models by redefining the type system, domain model evolution must be performed after the DSML evolution.

In the remainder of this section, we further elaborate the solution approach and describe how it applies to our case study.

Component Framework Evolution

Component frameworks consist of a set of core reusable components that can be configured using well-defined interfaces. In order to capture the commonalities of software PLAs, one must formulate a set of usage patterns. The component frameworks encapsulate these usage patterns and provide reusable libraries that contain wrapper façades for the underlying implementation classes and shield component developers from tedious and error-prone programming tasks associated with lower-level details. Component frameworks are typically designed by analyzing various potential problems that the frameworks might address and identifying which parts of each solution are the same and which areas of each solution are unique through the SCV analysis.

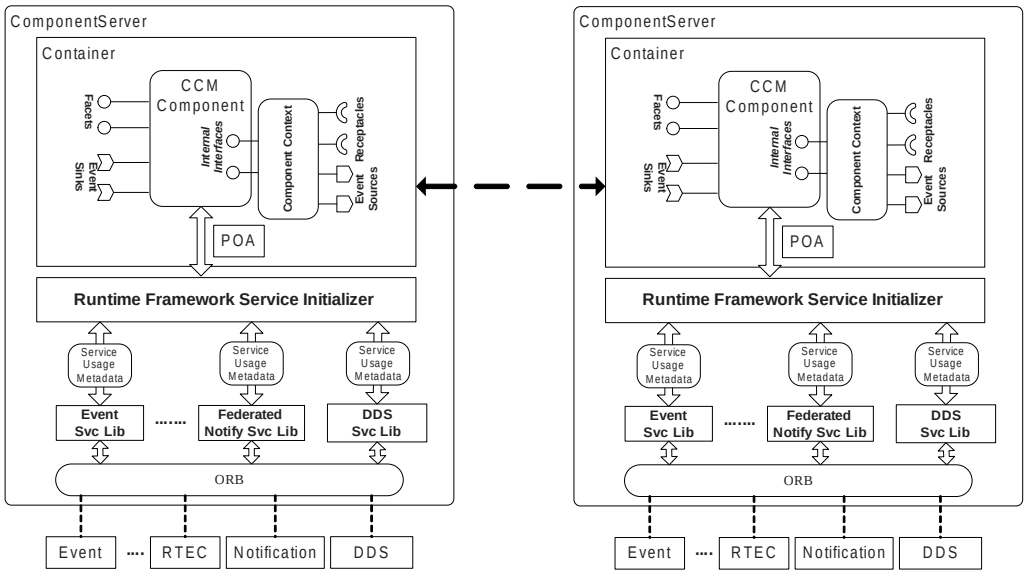
The first step is to define the domains (i.e., the problem areas a framework addresses) and the context of the framework. The next step is to define the attributes that recur across all members of the family of products based on the framework. The final step is to describe the attributes unique to the different members of the family of products. The SCV analysis requires extensive knowledge about the domain and the PLA requirements so one can reason what parts of the system should be implemented by the framework (commonalities) and what parts of the system should be specialized in subclasses or parameters (variabilities). To implement such design usually requires effective and skillful use of programming language features, such as templates and virtual functions, in conjunction with design patterns (Gamma et al. 1995).

Applying the Solution to the EQAL Case Study

In our EQAL case study, the scope is to design a framework to simplify the event communication between the event sources and event sinks of PRISM components. The commonality in this scope is straightforward, that is, every software product instance should implement an event-driven publish/subscribe pattern. The variability of the EQAL Runtime Framework results from different concrete service types that provide different interfaces and different QoS mechanism for the event communication, as shown in Figure 9. Because different real-time publish/subscribe services depend on different representations of real-time QoS properties, the EQAL Runtime Framework implements the adapter pattern that converts a service-independent representation of real-time properties into a service-specific representation.

The benefits of EQAL's design are twofold: (1) component developers need not concern

Figure 9. Component framework architecture of EQAL

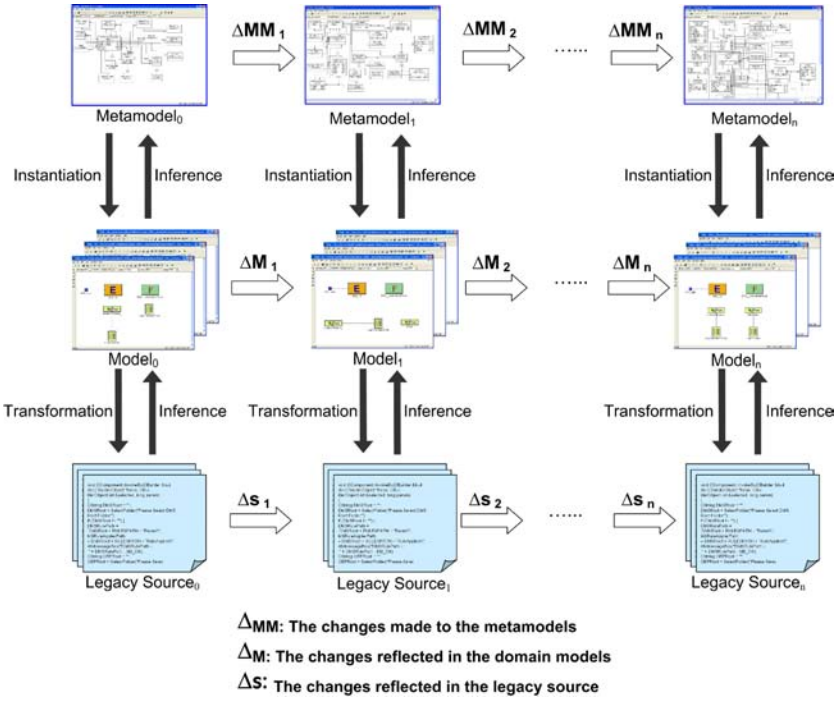


themselves with peculiar configuration interfaces, and (2) no matter what changes occur to the underlying publish/subscribe services, the interface exposed to components does not change. The EQAL Runtime framework also implements the strategy pattern to enhance the extensibility by allowing new publish/subscribe services to be easily plugged-in. This design results in a pluggable publish/subscribe service implementation that is interchangeable and extensible, and enables all event communication mechanisms supported by EQAL to provide the same interface, yet can also be configured with different strategies and QoS configurations even facing the domain evolution of adding new publish/subscribe service types.

DSML Evolution

The core component in the DSML is the metamodel. To help understand the context of domain evolution, Figure 10 presents a matrix of several evolution tasks that require automated assistance to manage the various dependencies among metamodels, instance models, and corresponding source code. As shown at the top of Figure 10, a metamodel represents a modeling language definition that is instantiated to represent end-user intentions in a specific domain. Elements in the instance models (middle of figure) have metatypes that are specified in the metamodel. A vertical transformation (i.e., a transformation that goes across abstraction layers) exists between the instance models and the legacy source code at the bottom, which represents updates that are needed in one artifact that are triggered by a change at a different layer of abstraction. Correspondingly, horizontal transformation occurs at the same layer of abstraction to address changing requirements (i.e., the Δ at each layer represents a horizontal transformation).

Figure 10. A matrix of evolution activities within DSMLs



To simplify the evolution of DSMLs, the reusability of metamodels is crucial when the domain becomes complex. Ideally, a metamodel can be developed based on a set of reusable (usually smaller) metamodel units, with different units capturing different aspects in the domain of interest. For example, these metamodel units might include different variations of signal flow, finite state machines, data type specifications, and petri-nets. The unified metamodel can then extend these units and glue them together. This technique is called *compositional metamodeling* (Karsai et al., 2004), and the main motivation of this technique is to make metamodels more scalable and easier to evolve.

Composition metamodeling provides a capability for reusing and combining existing modeling languages and language concepts. When changes need to be made in the metamodel units to reflect a better understanding of the given aspect in the domain, such changes can be propagated automatically to the metamodels that utilize them. Furthermore, by precisely specifying the extension and composition rules, models specified in the original domain language can be automatically translated to comply with the new, extended and composed, modeling language. Another important benefit of compositional modeling is its ability to add new capabilities while simultaneously leveraging prior constraints and model generators of existing DSMLs. Thus, it is ideal for evolving existing DSMLs to address new requirements.

Applying the Solution to the EQAL Case Study

EQAL is implemented within GME, which offers the compositional modeling capability. When new publish/subscribe services are integrated, a new DSML can be designed within GME and import the old EQAL metamodel as a reusable "library." Apart from being read-only, all objects in the metamodel imported through the library are equivalent to objects created from scratch. Because the new publish/subscribe services share much commonality between the existing publish/subscribe services that EQAL already supports, when the old EQAL metamodel is imported as a library, subtypes can be created and instances from the metamodel library can refer to library objects through references.

Challenges Stemming from Migrating Existing Domain Models with MDE-Based PLA Evolution

Context

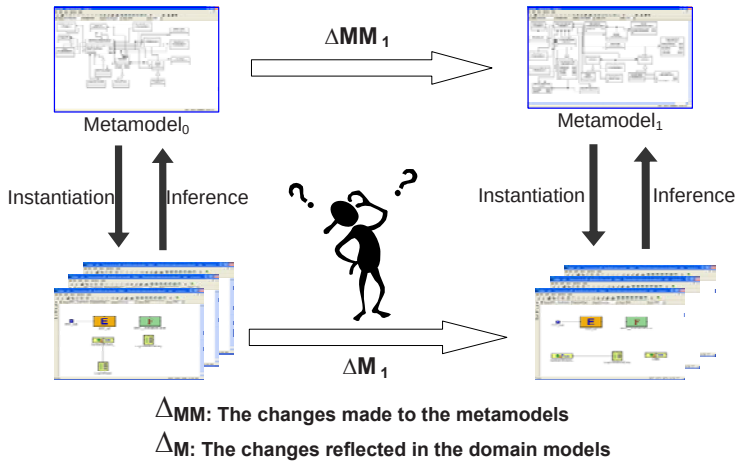
The primary value of the MDE paradigm stems from the models created using the DSML. These models specify the system from which the executable application can be generated or composed. Changes to the system can be modeled and the resulting executable model is thus a working version of the actual system. Unfortunately, if the metamodel is changed, all models that were defined using that metamodel may require maintenance to adapt to the semantics that represent the system correctly. Without ensuring the correctness of the domain models after a change to the domain, the benefits of MDE will be lost. The only way to use instance models based on the original metamodel is to migrate them to use the modified metamodel. During this migration process, we must preserve the existing set of domain model assets and allow new features to be added into domain models; ideally, with as little human intervention as possible.

Problem: Existing Domain Model Evolution Techniques Require Excessive Human Intervention

As illustrated in Figure 11, to preserve the existing set of domain model assets, old domain models must be transformed to become compliant with the changed metamodel. In the MDE research community, particularly in the DSML community, research has been conducted on using model transformation to address metamodel evolution (Sprinkle et al., 2003, Gray et al., 2006, Jouault & Kurtev, 2006). The underlying structure of models, particularly visual models, can be described by graphs. Model transformation research has therefore often been conducted in the context of graph transformation. In particular, recent research (Balogh & Varro, 2007; Vizhanyo, Agrawal, & Shi, 2004) has shown that graph transformation is a promising formalism to specify model transformations rules.

Most existing model transformation techniques, however, require the transformation be performed *after* the domain metamodel has changed. For example, when an old metamodel is modified and a new metamodel based on it is created, the model transformation must consider both the old metamodel and new metamodel as input, and then manually specify the model transformation rules based on these two metamodels by using a transformation specification language provided by the transformation tool. Although such a design approach could solve the model transformation problem, it introduces additional effort in specifying the model transformation rules, even if the metamodel evolution is minor (e.g., a simple rename of a concept in the metamodel). This additional effort is particularly high when the metamodels are complex, because the transformation tool must take both complex metamodels as input to specify the transformation.

Figure 11. Domain model evolution problem



Solution: Tool-Supported Domain Model Migration

To preserve the assets of domain models, our approach is to integrate *model migration* capabilities into the metamodeling environment itself. This approach is sufficiently generic to be applied to any existing metamodeling environment. A description of the change in semantics between an old and a new DSML is a sufficient specification to transform domain models such that they are correct in the new DSML. Moreover, the pattern that specifies the proper model migration is driven by the change in semantics and may be fully specified by a model composed of entities from the old and new metamodels, along with directions for their modification.

Below we describe how syntactic and semantic based model transformation approaches can be integrated to address the domain model migration problem.

Integration of Syntactic-Based and Semantic-Based Domain Model Evolution

The purpose of a DSML metamodel is to properly define the syntax and semantics to precisely describe software-intensive systems at a higher level of abstraction. As a result, both the syntax and the semantics of a metamodel can be affected when it is migrated from one version to another version. Consequently, to migrate a source domain model to the destination model, we must deal with both the syntax aspect and the semantics aspect.

Based on the characteristics of metamodel change, we have classified 8 atomic types of metamodel changes, as shown in Table 1. From this table, we can see that the all "additions" (addition of new type, new attribute or new association between types) to the metamodel will not affect the domain models because the target metamodel is a *superset* of the source metamodel and all the relationships of the source metamodel will still

Table 1. How atomic types of metamodel changes will affect domain models

Type of Metamodel Changes		Domain Model Change Required?
Additions		
1	Addition of new type	No
2	Addition of new attribute of a type	No
3	Addition of association between types	No
Deletions		
4	Deletion of an existing type	Yes
5	Deletion of an attribute of a type	Yes
6	Deletion of association between types	Yes
Modifications		
7	Replacing one type with another type	Yes
8	Replacing one association with another	Yes

be preserved. On the other hand, other types of metamodel changes including all "deletion" and "modifications" will result in unavoidable domain model change because the target metamodel is no longer a *superset* of the source metamodel.

These results provide intuition into the problem of domain model evolution. In some cases, the semantics can be easily specified. For example, if the metamodel designer deletes an atom called "foo" in the metamodel and creates a new atom called "bar" we can then specify the semantics of the change as:

```
replace(Atom("foo") -> Atom("bar"));
```

Syntactic metamodel changes, however, can often affect semantic changes, which result in a highly challenging task in model migration, that is, *semantic migration*. Semantic migration requires that the meaning of the old domain models be preserved after the transformation and that the new domain models conform to the entire set of static constraints required in the new domain.

For model migration, we generalized two approaches to perform model transformation with semantic migration. In the first approach, given two *distinct* metamodels, source metamodel and destination metamodel, we can perform a transformation that converts the source models in entirety to the destination models. This means that a complete set of rules is needed to convert each entity in the models. In the second approach, we create a *unified* metamodel (*old + new*), such that both old and new domain models are valid. Developers can then write transformation specifications that convert those parts of the model belonging to the source part of the paradigm to equivalent models in the destination part of the paradigm.

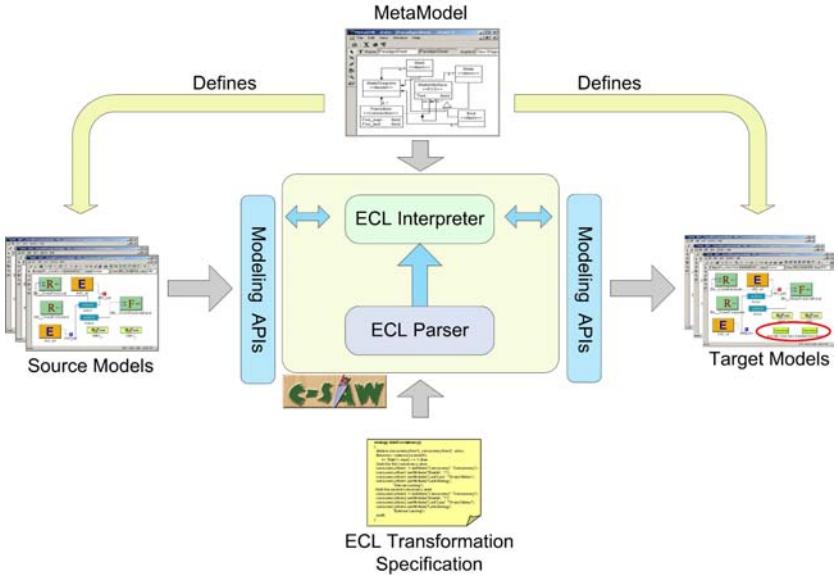
We have found that the second approach is much cleaner and user-friendly than the first approach because it requires much less human effort. In particular, in this second approach, after the unified metamodel is formulated, we can use an "SQL-like" declarative language that allows one to query and change the model to define model transformation rules. The *Embedded Constraint Language* (ECL), used by the C-SAW GME plug-in (Gray, Bapty, Neema, & Tuck, 2001), is such a language. ECL is a textual language for describing transformations on visual models. Similar to the Object Constraint Language (OCL) defined in OMG's UML specification, ECL provides concepts such as collection and model navigation. In addition, the ECL also provides a rich set of operators that are not found in the OCL to support model aggregations, connections, and transformations. ECL is a declarative language that allows one to specify the formal transformation rules of the syntax translator to capture the semantic migration.

In previous work, we showed how ECL can be used to accomplish several model transformation tasks (Gray et al., 2006). As an input language to C-SAW, ECL can support aspect modeling, as well as the ability to scale a base model to a larger model with replicated structures. Figure 12 illustrates an input source model being transformed by an ECL transformation rule to generate a new target model. An example of using ECL to handle the domain model migration in our case study is described in the next subsection.

Applying the Solution to the EQAL Case Study

In an old version of the EQAL metamodel there is a modeling object type called "`EventChannelGateway`," which can be used to federate different event channels together (Edwards et al., 2004). The definition of such a modeling element in a metamodel is similar to defining a class in C++ or Java. With domain evolution, this

Figure 12. Model transformation using the ECL (Gray et al., 2006)

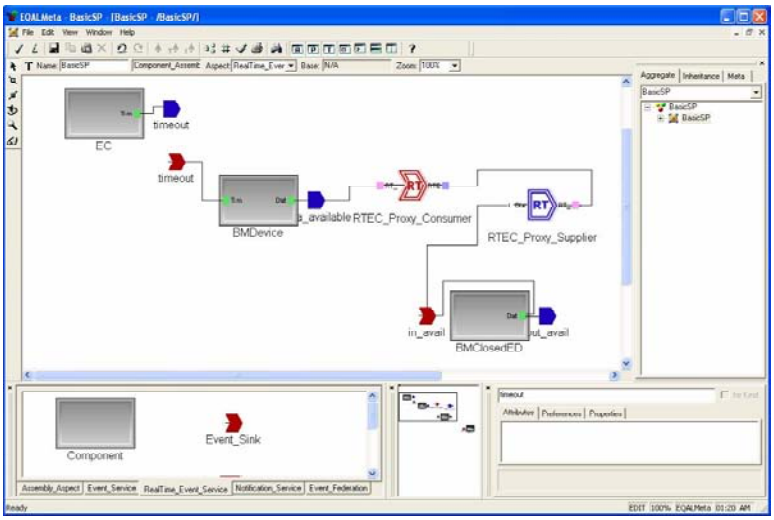


`EventChannelGateway` object type needs to be defined as an *abstract base* type (similar to the *abstract base* class concept in C++ or Java), and two new derived types called `IIOPGatway` and `UDPGateway` are defined in order to configure different underlying transport protocols between event channels. An issue arises regarding the type assignment of `EventChannelGateway` elements; depending on the context, these elements could be migrated to either the type of `IIOPGatway` or `UDPGateway`. In cases like these, it is quite challenging to discover the semantics of the change, that is, the semantics of the model elements cannot be deduced from the syntax. To require that such algorithms provide actual semantic migration capabilities necessitates human input because semantic changes in metamodels cannot be captured through syntactic changes alone.

Figure 13 shows the BasicSP application scenario (Balasubramanian et al., 2005b) in the Boeing Bold Stroke PLA. We use the BasicSP scenario as an example to showcase the problems encountered when evolving PLAs for component-based DRE systems and motivate the need of ECL for model transformation. In this figure, two component instances named `BMDevice` and `BMClosedED` are connected with each other through a real-time event channel provided by TAO's Real-time Event Service. An event channel consists of one `RTEC_Proxy_Consumer` module and `RTEC_Proxy_Supplier` module, which could be configured with various QoS settings, such as event dispatching threading models, priority configuration and periodic event processing configurations. Consider a domain evolution scenario, where the Real-time Event Service is not the desired choice for a particular Bold Stroke product variant, so it must be replaced with the TAO Federated Notification Service. In this case, the current domain model of Figure 13 will become invalid and must be migrated to the new EQAL DSML that supports the configuration of TAO's Federated Notification Service.

With ECL, a model transformation rule can be defined to accomplish the model migration task

Figure 13. EQAL configuring real-time event service between two components



Box 1.

```
 1. strategy ChangeToFNS() {
 2.    declare FNS_Proxy_Consumer, FNS_Proxy_Supplier : model;
 3.
 4.    // Find interested model elements…
 5.    if(atoms()->select(a | a.kindOf() = “RTEC_Proxy_Consumer”)->size() >= 1) then
 6.
 7.    //get the RTEC_Proxy_Consumer model element
 8.    //and its connections
 9.    …
10.    //delete the RTEC_Proxy_Consumer model element
11.    RTEC_Model.deleteModel(“RTEC_Proxy_Consumer”, “RTEC_proxy_consumer”);
12.
13.    //add the FNS_Proxy_Consumer model
14.    FNS_Proxy_Consumer:= addModel(“FNS_Proxy_Consumer”, “FNS_proxy_consum-
er”);
15.    FNS_Proxy_Consumer.setAttribute(“Reactive”, “1”);
16.    FNS_Proxy_Consumer.setAttribute(“LockType”, “Thread Mutex”);
17.
18.    //add the connections
19.    RTEC_Model.addConnection(“Event_Source_Proxy_Consumer”, event_source, FNS_
Proxy_Consumer);
20.    RTEC_Model.addConnection(“Proxy_Supplier_Event_Sink”, FNS_Proxy_Consumer,
event_sink);
21.
22.    //do similar to the FNS_Proxy_Supplier model
23.    …
24.    endif;
25. }
```

noted above. In the ECL, a strategy represents a transformation rule that is applied to a specific location of a model. A query can be written in the ECL to define a collection of models that need to be transformed, and a strategy can be invoked on the collection. The strategy in Box 1 specifies the desired model migration. The semantic meaning of this transformation is straightforward, that is, line 1 declares the strategy based on the ECL syntax; lines 4-10 find the interested model elements and their associations that are based on TAO's Real-time Event Service; line 11 removes the found model elements, and lines 13-20 replace these model elements and associations with TAO's Federated Notification Service. (see Box 1)

CONCLUSION

Change is a natural and inevitable part of the software-intensive system lifecycle. The changes may be initiated to correct, improve, or extend assets or products. Because assets are often dependent on other assets, changes to one asset may require

corresponding changes in other assets. Moreover, changes to assets in PLAs can propagate to affect all products using these assets.

To use MDE-based PLA technologies effectively in practice requires practical and scalable solutions to the *domain evolution problem*, which arises when existing PLAs are extended or refactored to handle unanticipated requirements or better satisfy existing requirements. For example, changing metamodels in a PLA often invalidates models based on previous versions of the metamodels. Although software developers can manually update their models or components developed with a previous metamodel to work with the new metamodel, this approach is clearly tedious, error-prone, and nonscalable. A successful process for PLA evolution must therefore manage these changes effectively.

To rectify these problems, this chapter describes a layered and compositional architecture to modularize system concerns and reduce the effort associated with domain evolution. This chapter illustrates via a case study how systematic evolution with three ordered steps can maintain the stability of domain evolution against MDE-based software PLAs, and how structural-based model transformations help reduce human effort by automatically transforming existing domain models based on metamodel-based rules.

The following is a summary of lessons learned from our experience in evolving product-lines using MDE tools:

- **DSMLs and component frameworks are highly synergistic:** An MDE approach expedites PLA development with the proper integration of DSMLs and component frameworks. The component frameworks help shield the complexities of the design and implementation of modeling tools, and decouple many aspects of concerns between the modeling tools and the executable systems. In our case study, if the publish/subscribe service type is the only missing or changing concern in the Boeing Bold Stroke PLA (which is typical in our case), little new application code must be written, yet the complexity of the generation tool remains manageable due to the limited number of well-defined configuration "hot spots" exposed by the underlying infrastructure. Likewise, when component deployment plans are incomplete or must change, the effort required is significantly less than starting from the raw component middleware without MDE tool support.
- **Declarative-based model transformation alleviates transformation effort:** Structural-based model transformations help maintain the stability of domain evolution of MDE-based DRE systems by automatically migrating domain models. A declarative-based model transformation language like ECL is an ideal approach in such a case. The case study presented in this chapter highlights the ease of specification and the general flexibility provided by the transformation engine.
- **Testing and debugging of transformation specification is still hard:** Transformation specifications, such as those used to specify the transformation strategy in this chapter, are written by humans and prone to error. To improve the robustness and reliability of model transformation, there is a need for testing and debugging support to assist in finding and correcting the errors in transformation specifications. Ongoing and future work on ECL focuses on the construction of testing and debugging utilities to ensure the correctness of ECL transformation specifications.

All software in this chapter can be downloaded from our Web sites. The EQAL framework is shipped as part of the CIAO and is available at http://download.dre.vanderbilt.edu. The EQAL DSML is available at http://www.dre.vanderbilt.

FUTURE RESEARCH DIRECTIONS

This section discusses the future trends in the areas of MDE and component middleware, and how together they are impacting MDE-based PLAs, particularly for DRE systems.

Emerging Interest in Domain-Specific Modeling

The interest and adoption of DSMLs over the past decade has surged. Strong support for basic research has been committed by the large European Union ModelWare and ModelPlex projects, which are funded at 30M Euros (ModelWare Project, 2006). Metamodeling tools that support DSM continue to emerge from both commercial and open source projects (e.g., Microsoft's DSL Toolkit (Microsoft, 2006) and the Eclipse Modeling Project (Eclipse, 2007)), as well as numerous academic research projects (e.g., Vanderbilt's Generic Modeling Environment (GME, 2007)). Initial success stories from industry adoption of DSM have been reported: The newly created DSM Forum (DSM Forum, 2007) serves as a repository of several dozen successful projects (mostly from industry, such as Nokia, Dupont, Honeywell, and NASA) that have adopted DSM. Over the past 5 years, the annual DSM workshop at OOPSLA (52 international participants in 2007) provides a venue for reporting experiences in DSM research and practice.

Future Research Directions of MDE Tools for DRE Systems

MDE has already played an important role in the assembly, configuration and deployment lifecycle stages of today's DRE systems. We envision next generation MDE tools will seamlessly integrate all lifecycle stages of software product lines, including requirement management, functionality specification, QoS specification, system partitioning and implementation, component assembly and packaging, system configuration, system planning and analysis and runtime system management. With such seamless integration, models will become vital artifacts in all aspects of software PLA development lifecycle, and sophisticated model transformation techniques will bridge the gap between models in different lifecycle stages. The need for seamless integration of models across the lifecycle is driving the need for integration across a collection of different modeling tools, where each offers some advanced capability not found in another tool. The need for tool integration will continue to heighten the role that model transformation plays as the key enabler of model sharing (Sendall & Kozaczynski, 2003).

Future Research Directions of Component Middleware for DRE Systems

The success of component middleware technologies has resulted in DRE systems created by customizing pre-existing COTS components rather than creating them from scratch. The increased use of pre-existing components shifts the focus from development to configuration and deployment of COTS components. With more COTS components provided by different vendors, the capability of *heterogeneous* deployment becomes a challenging task to evolve today's DRE systems.

Future component middleware technologies will enable rapid development of adaptive large scale DRE systems to accommodate changing operating environments. To facilitate the development of large-scale DRE systems, component middleware must support the agility in business service provisioning within and across organizations while ensuring the quality of service. The combination of these two techniques will finally enable software PLA developers to capture and

represent adaptability of DRE systems at the business level and automatically translate this business adaptability into component and process adaptability.

As PLAs become more complex, they will be adopted into software-intensive systems of very large-scale, as typified by the focus of Ultra Large-Scale systems (Ultra Large-Scale, 2007). In such cases, it is not unrealistic to imagine the PLAs using multiple different middleware platforms. To accommodate these requirements demands new investigation in deployment and configuration across heterogeneous middleware platforms. This heterogeneity also adds to the challenges in provisioning QoS end-to-end for these PLAs. All these require novel modeling capabilities that can abstract away the heterogeneity.

We envision these future research directions will greatly simplify the development of MDE-based PLAs and make next generation DRE systems more robust.

Chapter 3.11
Reverse Engineering from an XML Document into an Extended DTD Graph

Herbert Shiu
City University of Hong Kong, Hong Kong

Joseph Fong
City University of Hong Kong, Hong Kong

ABSTRACT

The extensible markup language (XML) has become a standard for persistent storage and data interchange via the Internet due to its openness, self-descriptiveness, and flexibility. This article proposes a systematic approach to reverse engineer arbitrary XML documents to their conceptual schema, extended DTD graphs, which are DTD graphs with data semantics. The proposed approach not only determines the structure of the XML document, but also derives candidate data semantics from the XML element instances by treating each XML element instance as a record in a table of a relational database. One application of the determined data semantics is to verify the linkages among elements. Implicit and explicit referential linkages are among XML elements modeled by the parent-children structure and ID/IDREF(S), respectively. As a result, an arbitrary XML document can be reverse engineered into its conceptual schema in an extended DTD graph format.

INTRODUCTION

As the extensible markup language (XML; Bray, Paoli, Sperberg-McQueen, Maler, & Yergeau, 2004) has become the standard document format, the chance that users have to deal with XML documents with different structures is increasing. If the schema of the XML documents in a document type definition (DTD; Bosak, 1998) is given or derived from the XML documents right away (Kay, 1999; Moh, Lim, & Ng, 2000), it is easier

to study the contents of the XML documents. However, the formats of these schemas are hard to read and not very user friendly.

XML has been the common format for storing and transferring data between software applications and even business parties as most software applications can generate or handle XML documents. For example, a common scenario is that XML documents are generated and based on the data stored in a relational database; there have been various approaches for doing so (Fernandez, Morishima, & Suciu, 2001; Thiran, Estiévenart, Hainaut, & Houben, 2004). The sizes of XML documents that are generated based on the data stored in databases can be very large. Most probably, these documents are stored in a persistent storage for backup purposes as XML is the ideal format that can be processed by any software applications in the future.

In order to handle the above scenario, it is possible to treat XML element instances in an XML document as individual entities, and the relationships from the different XML element types can be determined by reverse engineering them for their conceptual models, such as extended DTD graphs with data semantics. As such, users can have a better understanding of the contents of the XML document and further operations with the XML document become possible, such as storing and querying (Deutsch, Fernandez, & Suciu, 1999; Florescu & Kossmann, 1999; Kanne & Moerkotte, 2000).

This article proposes several algorithms that analyze XML documents for their conceptual schema. Two main categories of XML documents exist: data centric and narrative. As the contents of narrative XML documents, such as DocBook (Stayton, 2008) documents, are mainly unstructured and their vocabulary is basically static, the necessity of handling them as structured contents and reverse engineering them into conceptual models is far less than that of handling data-centric ones. Therefore, this article will concentrate on data-centric XML documents.

Referential Integrity in XML Documents

XML natively supports one referential integrity mechanism, which is the `ID/IDREF(S)` type of attribute linkages. In every XML document, the value of an `ID` type attribute appears at most once and the value of the `IDREF(S)` attribute must refer to one `ID` type attribute value. An `IDREF(S)` type attribute can refer to any XML element in the same document, and each XML element can define at most one `ID` type attribute. Due to the nature of `ID/IDREF(S)` type attributes in XML documents, relationships among different XML element types can be realized and it is possible to use them to implement data semantics.

This article will discuss the various data semantics and the possible ways to implement them. The algorithms presented are based on observations of the common XML document structures:

1. Due to the nested structure of an XML document (the relationship between a parent element and its child elements), the child elements implicitly refer to their parent element.
2. For an `IDREF` or `IDREFS` type attribute, the defining element is referred to the element(s) with an `ID` type attribute by the referred value. Such linkages are similar to the foreign keys in a relational database. The two associated element types are considered to be linked by an explicit linkage.
3. As an `IDREFS` type attribute can refer to more than one element, there is a one-to-many cardinality from the referring element type and the referred element type(s).

The schema of an XML document can restrict the order of the XML elements, which may be significant; the order depends on the intentions of the original XML document designer. For example,

Table 1. Two equivalent XML documents that can represent the same data

DTD	XML Document
<!ELEMENT couples (husband*,wife *,couple*)> <!ELEMENT husband EMPTY> <!ELEMENT wife EMPTY> <!ATTLIST husband hid ID #REQUIRED name CDATA #REQUIRED> <!ATTLIST wife wid ID #REQUIRED name CDATA #REQUIRED> <!ATTLIST couple hid IDREF #REQUIRED wid IDREF #REQUIRED>	<?xml version=”1.0”?> <couples> <husband hid=”A123456” name=”Peter”/> <husband hid=”B234567” name=”John”/> <wife wid=”X123456” name=”Amy”/> <wife wid=”Y234567” name=”Bonnie”/> <couple hid=”A123456” wid=”X123456”/> <couple hid=”B234567” wid=”Y234567”/> </couples>
<!ELEMENT couples (husband,wife)*> <!ELEMENT husband EMPTY> <!ELEMENT wife EMPTY> <!ATTLIST husband hid ID #REQUIRED name CDATA #REQUIRED> <!ATTLIST wife wid ID #REQUIRED name CDATA #REQUIRED>	<?xml version=”1.0”?> <couples> <husband hid=”A123456” name=”Peter”/> <wife wid=”X123456” name=”Amy”/> <husband hid=”B234567” name=”John”/> <wife wid=”Y234567” name=”Bonnie”/> </couples>

two XML documents with their corresponding DTDs are shown in Table 1.

The two XML documents shown in Table 1 are storing the same data, which are the data of two couples. For the first one, its couple elements use the two `IDREF` type attributes to denote the corresponding `husband` and `wife` elements. However, the use of `ID/IDREF` cannot ensure that a particular `husband` or `wife` element is referred by one `couple` element only. For the second XML document, the DTD restricts the `husband` and `wife` elements to exist as a pair. Furthermore, the use of `ID` type attributes `hid` and `wid` ensures any husband and wife element instance must exist in the document at most once.

Extended DTD Graph

As XML element instances are treated as individual entities, the relationships of the element

types are therefore related not only to the structure of the XML document, but also to the linkages of the different types. As such, DTD cannot clearly indicate the relationships.

An extended DTD graph for XML is proposed to add data semantics into a DTD graph so that the data semantics can be clearly identified, which is an excellent way of presenting the structure of an XML document. As such, in order to visualize the data semantics determined based on the XML document with its optional schema, it will provide the notations to be used for presenting the various data semantics. This article uses the authors' notations of the extended DTD graph for presenting the structure and the data semantics of the elements:

1. The vertexes as squares are drawn on the graph for elements, and vertexes as circles are drawn for the occurrence operators (?, +, and *) and selection operator (|).
2. Attributes and simple elements are omitted from the graph as they specify a particular attribute of their defining and parent elements, respectively.
3. Data semantics, other than one-to-one and one-to-many cardinality relations, are presented in the graph as arrows pointing from the referring element to the referred element with suitable descriptions as legends.

Based on the above criteria, it is possible to consider the ELEMENT declarations only for constructing the extended DTD graph. Three types of ELEMENT declarations can be identified as follows:

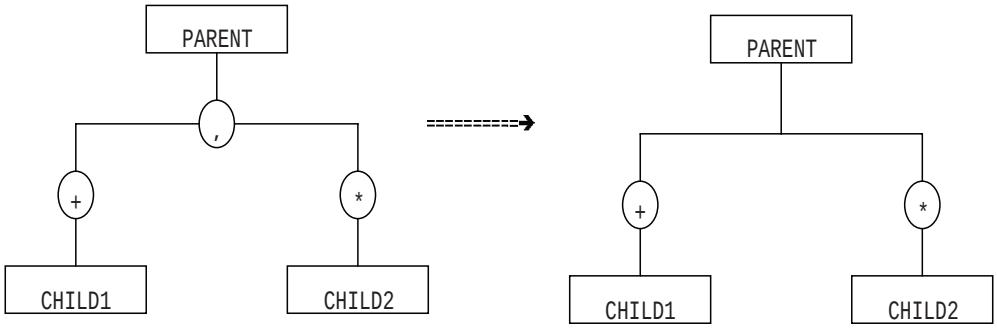
1. An ELEMENT declaration defines subelements only.
2. An ELEMENT declaration involves subelements and #PCDATA as its contents.
3. An ELEMENT declaration defines #PCDATA as its contents only.

The above three types correspond to the following three examples.

```
<!ELEMENT PARENT (CHILD1+, CHILD2*)>
<!ELEMENT MIXED_ELEMENT (#PCDATA | CHILD1
    | CHILD2)*>
<!ELEMENT SIMPLE_ELEMENT (#PCDATA)>
```

For each ELEMENT declaration of the first type, the content model expression can be tokenized as individual elements, occurrence indicators, and sequence separators (,), and represented as a tree structure with the element name as the root node. For example, the first example above can be visualized as a tree diagram. In Figure 1, the sequence (,) is implied in the diagram.

Figure 1. A sample extended DTD graph



DTDs mostly contain more than one `ELEMENT` declaration, but each element type can only appear once. Therefore, to construct the complete DTD graph for a DTD, the tree structures of all `ELEMENT` declarations in a DTD are constructed first and are eventually merged by replacing each subelement node in a tree with the tree structure of that element. Such merging is repeated until there is only one tree structure or all subelements have been replaced with their corresponding tree structures.

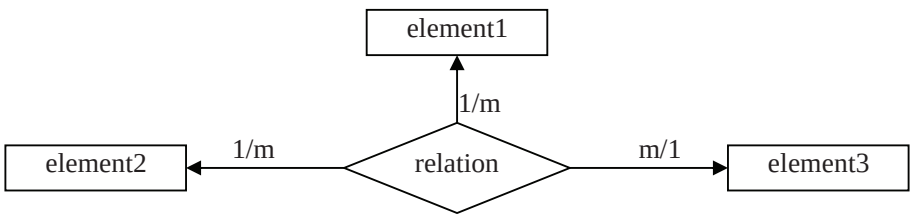
Cardinality and Participation

Element types are visualized as rectangles in the graph and a cardinality relationship is presented as an arrow pointing from the referring element type to the referred element type, with a double line and single line for total participation and partial participation, respectively. The cardinality types, including one to one (`1/1`), one to many (`1/m`), many to one (`m/1`), and many to many (`m/m`), are shown as legends of the arrows. If the cardinality relationship is implemented as explicit `ID/IDREF(S)` linkages, the name of the `ID` type attribute of the referring element is appended to the legend, such as `1/m (parent_id)`. To identify explicit linkages from implicit linkages, cardinality relationships due to `ID/IDREF(S)` type attributes are shown as arrows with curved lines. Table 2 presents the eight possible combinations of arrows and legends.

Table 2. The arrows illustrating various cardinalities with participation types

Participation / Cardinality		
One to one	1/1	1/1
One to many	1/m	1/m
Many to one	m/1	m/1
Many to many	m/m	m/m

Figure 2. A sample diagram with an n-ary relationship



N-ary Relationship

An *n*-ary relationship is implemented as a particular element type involved in more than two binary relationships. To represent such a relationship, a diamond-shaped vertex is used for such element types. Figure 2 presents a sample diagram with an *n*-ary relationship.

Aggregation Relationship

An aggregation relationship denotes that the involved element types must exist as a unity. In Figure 2, an aggregation exists as the defining characteristic of mandatory participation between parent and child elements. As such, a rectangle is to be drawn enclosing all involved element types.

RELATED WORK

In order to have a complete picture of the reasons behind the algorithms for determining various data semantics, this article explains the existing approaches of constructing XML documents, especially those exported from relational databases.

The Determination of XML Schema

There is some existing work concerning the extraction of schema, such as DTD, from XML documents (Chidlovskii, 2001; Min, Ahn, & Chung, 2003). The outputs of these algorithms are the schemas that can validate the XML documents. However, the derived schemas provide no semantic interpretation other than the containment structures of the XML documents. The algorithms proposed in this article concern the determination of data semantics from the XML element instances rather than simply XML schema among XML elements. Compared to the approach proposed by Goldman and Widom (1997) that directly manipulates semistructured databases, such as an XML document, the algorithm proposed here provides the user with a clear picture of the data semantics from the XML element instances before further manipulating them.

The Determination of Data Semantics from XML Documents

One approach exists that can reverse engineer data semantics from XML documents (Fong & Wong, 2004), but the algorithm maps some predefined templates of document structures to data semantics, and the algorithm can only be implemented with DOM (World Wide Web Consortium [W3C], 2003), which needs to read the entire XML document to the memory and therefore is inappropriate for huge documents. The methodology presented in this article, however, determines basic candidate data semantics from arbitrary XML documents with SAX (W3C, 2004), which is applicable to XML documents of any size. Some of the determined data semantics may not be the intentions of the original writer and need user supervision for verification.

The Implementation of Inheritance among XML Elements

Schema for object-oriented XML (SOX; W3C, 2005) introduced the idea of element and attribute inheritance, which enables an element to extend another element so that the derived element can have all attributes defined by the base element with its own new attributes.

Due to the limitations and low extensibility of DTD (Sahuguet, 2000), XML schema definition (XSD; Sperberg, 2000) is becoming the popular replacement schema of DTD. Unlike DTD, XSD is an XML document itself and can define more restrictive constraints and clear definitions of the XML documents to be validated. In other words, the set of capabilities for defining the structures and data types of XSD are the superset of that

of DTD. As such, there has been research and software for converting DTD to XSD (Mello & Heuser, 2001; W3C, 2000).

There are other alternative schemas, such as RELAX NG (*RELAX NG*, 2003) and Schematron (Shanmugasundaram et al., 2008). Lee and Chu (2000a) evaluated six common XML schemas, including DTD and XSD. As the others are not as popular as DTD and XSD, they are not discussed in this article.

By constructing a graph by placing vertexes for elements—and the elements that are involved in a parent-child relation, which is defined by `ELEMENT` declaration in DTD, are connected with edges—it is possible to derive a graphical representation of the DTD that is commonly known as a DTD graph. Up to now, there has been no formal standard for DTD graphs, and various researchers are using their own conventions, as in Klettke, Schneider, and Heuer (2002), Shanmugasundaram et al. (2008), Lu, Sun, Atay, and Fotouhi (2003), and Böttcher and Steinmetz (2003); the graph introduced in Funderburk, Kiernan, Shanmugasundaram, Shekita, and Wei (2002) is the first one that was denoted as a DTD graph.

There is a graphical representation of XSD (Fong and Cheung, 2005) that derives an XML conceptual schema of an XML tree model from an XML schema of XSD. Its approach is different from this article's approach, which derives an extended DTD graph from an XML document.

As the conventions of most graphs for presenting the structure of an XML document are applicable to different schema languages, the graph is also known as a semantic graph (An, Borgida, & Mylopoulos, 2005). Some researchers proposed other graphical representations of XML schemas, such as the use of UML (unified modeling language; Booch, Christerson, Fuchs, & Koistinen, 1999).

The Application of Extended DTD Graphs

A data graph is a DTD in a graph. Zhao and Siau (2007) described DTD as a good common data model when the majority of data sources are XML sources for the interoperability between relational databases and XML databases. Reverse engineering an XML document into a DTD graph

Table 3. A comparison between the proposed and other existing approaches

	Proposed Approach	**Other Approaches**
Input	XML document with optional schema	XML document
Output	Conceptual schema with data semantics	Schema without data semantics
Completeness	All common data semantics can be determined.	Schemas that can validate the XML document can be derived.
User friendliness	Algorithms can be implemented with a user-friendly GUI (graphical user interface), such as the prototype.	Commercial products exist that provide a user-friendly GUI.
Performance	Good	Not available as no mathematical proofs were provided

is similar to data mining an XML document into a data tree (Zhang, Liu, Ling, Buckner, & Tija, 2006). The former is a database schema while the latter is internal data in tree structure. Trujillo and Luján-Mora (2004) demonstrated that a DTD can be used to define the correct structure and content of an XML document representing the main conceptual multidimensional model for data warehouses.

Compared to the approach proposed by Goldman and Widom (1997) that directly manipulates semistructured databases such as an XML document, the algorithm proposed in this article enables the user to have a clear picture of the data semantics from the XML element instances before further manipulating them. Table 3 provides a comparison between the proposed algorithms and other existing approaches.

REVERSE-ENGINEERING METHODOLOGY

There are basically two different definitions in a DTD: `ELEMENT` and `ATTLIST`. Each `ATTLIST` definition defines the attributes of a particular element, whereas `ELEMENT` defines its possible containments. Each `ELEMENT` definition can be represented in a tree structure with the element name as the root and its child subelements as leaves; there must be another `ELEMENT` definition for each of the child elements.

It is not mandatory to define the `ELEMENT` declaration prior to all its child elements, and it is actually uncertain which element is the root element of the corresponding XML documents. The root element of the XML document is defined by the `DOCTYPE` declaration before the root-element start tag.

Implementations of Various Data Semantics in XML

The following subsections provide all possible implementations of various data semantics, some of which are consistent with those proposed by other researchers (Lee, 2000; Lee, Mani, & Chu, 2003).

Cardinalities

One-to-many cardinalities can be realized by both explicit and implicit referential linkages. Through implicit referential linkages, a parent element can have child elements of the same type, such as

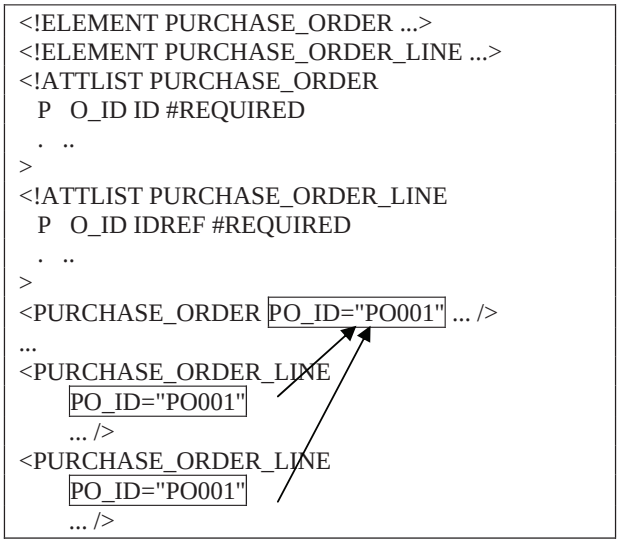
```
<PURCHASE_ORDER>
  <PURCHASE_ORDER_LINE .../>
  <PURCHASE_ORDER_LINE .../>
</PURCHASE_ORDER>.
```

The parent element `PURCHASE_ORDER` and the child elements `PURCHASE_ORDER_LINE` are implicitly in a one-to-many relationship. If the occurrences of child element `PURCHASE_ORDER_LINE` are at most one for all `PURCHASE_ORDER` elements, they are in a one-to-one relationship instead.

If the schema of the XML document is given, it can specify the `ID/IDREF(S)` type attributes. If an XML element defines an `IDREF` attribute and all such elements refer to the same element type, there is a one-to-many relationship between the referred and referring XML elements. For example, sample DTD and XML documents are shown in Figure 3.

For explicit referential linkages, to determine if the cardinality is one to one or one to many, it is necessary to scan the entire XML document. An XML element type may be involved in more than one one-to-many relationship. In other words, all elements of such XML element types define more than one linkage. For example, if an XML element type defines an `IDREF(S)` type attribute,

Figure 3. A many-to-one cardinality implemented by an IDREF type attribute



all elements of such XML element type actually define two linkages: one implicit linkage by the nested structure and one explicit linkage by the `IDREF(S)` type attribute. If the two linkages are both one-to-many relationships, the two referred element types by such a referring element type can be considered to be in a many-to-many relationship. For example, the XML document in Figure 4 illustrates a many-to-many relationship.

For an XML element type that defines two linkages and hence two one-to-many relationships, the two referred XML element types can be considered to be in a many-to-many relationship.

The linkages from the XML elements in an XML document are identified by the referring element name, linkage name, and the referred element name. The algorithm shown in Figure 6 is used to determine the linkages in Table 4.

Figure 5 illustrates the meanings of the four attributes.

There are eight XML elements in the document and there is only one implicit linkage from them. The values of the above four linkage attributes for such implicit linkage are given in Table 5.

According to the combination of the values of the four attributes, it is possible to determine the cardinality data semantics for the involved elements. The rules are shown in Table 6.

The algorithm is composed of two passes of parsing of the same XML document. The first pass assigns a synthetic element identity to each XML element in the document and determines all `ID` type attribute values and their corresponding element types. For the second pass, the XML document is traversed again and the linkages of each XML element are investigated and their attributes are stored. Finally, the stored linkage attributes are consolidated to give the four linkage attributes mentioned above and in Table 4.

The algorithm shown in Figure 6 can determine whether the XML document is valid, in particular,

Figure 4. A many-to-many cardinality implemented by an element type with two IDREF type attributes

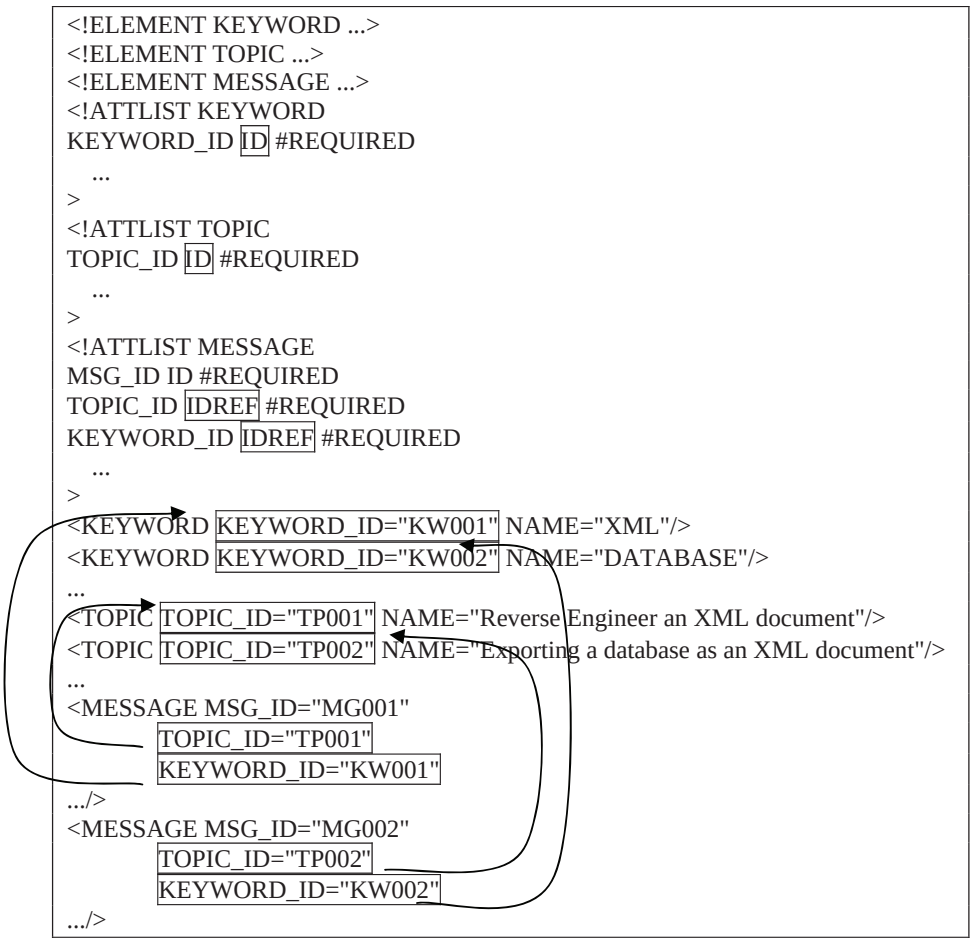


Table 4. The attributes and their sources for determining data semantics

Attribute	Description	Value
MaxReferring	The maximum number of referred elements referred by a single referring element	Get from ReferringInfo with key (RGE, RDE, L)
MaxReferred	The maximum number of referring elements that are referring to the same referred element with the same linkage type	Get from ReferredInfo with key (RGE, RDE, L)
SumReferring	The number of referring elements that possess the linkage	Get from ReferringInfo with key (RGE, RDE, L)
NumberElements	The number of referring elements in the document	Get from ElementNameCount with key RGE

Figure 5. MaxReferring, MaxReferred, SumReferring, and NumberElements example

```
<?xml version="1.0"?>
<message id="ID1" ... >
  <message id="ID2" ... >
    <message id="ID3" ... >
    <message id="ID4" ... >
    <message id="ID5" ... >
  </message>
  <message id="ID6" ... >
    <message id="ID7" ... >
    <message id="ID8" ... >
  </message>
</message>
```

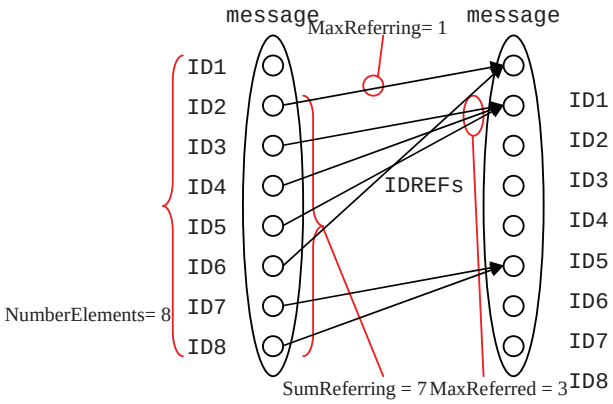

Table 5. Descriptions of variables in reverse-engineering algorithms

Attribute Name	Value	Explanations
MaxReferring	1	All linkages are implicit and each child element has one implicit parent element only.
MaxReferred	3	The root message element with attribute ID value ID1 is referred by two subelements (with attribute ID values ID2 and ID6). The message element with attribute ID value ID2 is referred by three subelements (with attribute ID values ID3, ID4, and ID5). The message element with attribute ID value ID6 is referred by two subelements (with attribute ID values ID7 and ID8). Therefore, the value of MND is 3.
SumReferring	7	Except the root message element with attribute ID value ID1, all other message elements define such linkages. The value of NL is therefore 7.
NumberElements	8	There are eight message elements.

whether a nonexisting ID value is referred by an IDREF(S) type attribute. If the XML document is valid, three tables can be obtained: ReferringInfo, ReferredInfo, and ElementNameCount. The key for the former two tables is the composite key (RGE, RDE, L), that is, the referring element name, the referred element name, and the linkage name, whereas the key for ElementNameCount is

Table 6. Matrix for determining cardinality and participation based on the determined linkage attributes

		Participation	
		Total	Partial
Cardinality	One to one	MaxReferring= 1 MaxReferred = 1 SumReferring= Number-Elements	MaxReferring = 1 MaxReferred= 1 SumReferring < Number-Elements
	One to many	MaxReferring = 1 MaxReferred > 1 SumReferring = Number-Elements	MaxReferring = 1 MaxReferred > 1 SumReferring < Number-Elements
	Many to one	MaxReferring > 1 MaxReferred = 1 SumReferring = Number-Elements	MaxReferring > 1 MaxReferred = 1 SumReferring < Number-Elements
	Many to many	MaxReferring > 1 MaxReferred > 1 SumReferring = Number-Elements	MaxReferring > 1 MaxReferred > 1 SumReferring < Number-Elements

Figure 6. The algorithm for determining linkage information by traversing the XML document

Variable name	Definition
EID	The current element ID. While processing the XML document sequentially, the EID determines the ID to be assigned to individual element encountered.
E	The current element to be handled.
A	An attribute of the current element to be handled.
AV	The attribute value of attribute *A*.
L	A linkage of the current element. It can be an implicit linkage with its parent element or an explicit linkage with an IDREF(S) type attribute. For a non-root element without IDREF(S) attribute, the element has only one implicit linkage to its parent element. Otherwise, the element can have more than one linkage, one implicit linkage and at least one explicit linkages.
L_{value}	The Element ID of the linkage *L* for the current element *E*. For example, if *L* is an implicit linkage, L_{value} is the element ID of the parent element of *E*. Otherwise, L_{value} is the attribute value of IDREF value and the value should be an ID type attribute of an element in the same document.
NG	The number of referring element of the same element name is referring to the same referred element with the same link.
RGE	The referring element of a link.
RDE	The referred element by a link.

continued on following page

Figure 6. continued

```
Pass One:
Let EID = 1;
Repeat until all XML document elements are read
    Let E be the current element to be processed
    If ∃ record in Table_ElementNameCount where ElementName = element name of E
        Get record (ElementName, NumberElement) from Table_ElementNameCount
        Increment NumberElement by 1;
        Update (ElementName, NumberElement) into Table_ElementNameCount;
    Else
        Add (ElementName, 1) into Set_ElementNameCount;
    End If
    Add (EID, ElementName) into Set_ElementIDName;
    If there exists ID type attribute A of element E with attribute value AV
        Add (AV, ElementName) into Set_ElementIDName;
    End If
    Increment EID by 1;
    Navigate to the next element E in the XML document

Pass Two:
Repeat until all XML document elements are read
    Let RGE is the current element to be handled
    For each linkage, L, of RGE
        For each linkage value, L_value of linkage L of RGE
            Get record (EID,ElementName) from Table_ElementIDName
                    where primary key value is L_value
            If no such record exist in Table_ElementIDName
                XML document is invalid
            Else
                Let RDE = ElementName of the record obtained from Table_ElementIDName
            End If

            Get record (RGE, RDE, L, L_value, ND) from Table_RawReferredInfo
                    for primary key (RGE, RDE, L, L_value);
            If record exists
                Increment ND of the record by 1;
                Update the record to Table_RawReferredInfo;
            Else
                Add record (RGE, RDE, L, L_value, 1) to the Table_RawReferredInfo;
            End If

            For each referred element type, RDE
                Let NG = number of RDE referred by this linkage, L;
                Get record (RGE, RDE, L,MaxReferring, SumReferring)
                        from the Table_ReferringInfo for primary key (RGE, RDE, L);
                If record exists
                        If NG > MaxReferring from the record
                            Update MaxReferring of the record to be NG
                        End If
                        Increment SumReferring of the record by 1;
                        Upda    te the record to the Table_ReferringInfo;
                Else
                        Add record (RGE, RDE, L, NG, 1) to the Table_ReferringInfo;
                End If
            End For
        End For
    End For
    Navigator to the next element RGE in the XML document

Consolidate the records with same combination of (RGE, RDE, L) in table RawReferredInfo;

 let MaxReferred = maximum of the ND values of all records;
 Add record (RGE, RDE, L, MaxReferred) to the table ReferredInfo;
```

simply the element name. With three such tables, it is possible to derive the linkage attributes as shown in Table 4.

The complete algorithm is presented in Figure 6, which is followed by a list of definitions for the variables to be used.

The operation in Figure 6 can be represented by the following in SQL (structured query language):

```
SELECT
    RGE, RDE, L,
    ReferringInfo.MaxReferring,
    ReferredInfo.MaxReferred,
    ReferringInfo.SumReferring,
    ElementNameCount.NumberElements
FROM
    ReferringInfo
    INNER JOIN ReferredInfo
    ON ReferringInfo.RGE = ReferredInfo.
    RGE
    AND ReferringInfo.RDE = ReferredInfo.
    RDE
    AND ReferringInfo.L = ReferredInfo.L
    INNER JOIN ElementNameCount
    ON ReferringInfo.RGE = ElementNam-
    eCount.E.
```

Once the four attributes of a linkage are determined, the data semantics can be determined by using the matrix shown in Table 6. According to the determined one-to-one and one-to-many relationships, it is then possible to consolidate the related ones into many-to-many and *n*-ary relationships.

As mentioned above, if an XML element type defines two linkages that are determined to be many-to-one cardinalities, the two referred XML element types are considered to be in a many-to-many relationship. Similarly, if an XML element type defines more than two linkages that are determined to be many-to-one cardinalities, the referred XML element types are considered to be in an *n*-ary relationship. Therefore, based on the one-to-many cardinalities determined by the previous algorithm, the many-to-many and *n*-ary relationships can be determined, and the algorithm is shown in Figure 7.

The many-to-one relationship to be considered should be those implemented by explicit linkages, that is, those defined by `ID/IDREF(S)` linkages. Otherwise, an element type exhibits implicitly a one-to-many relationship due to the nested structure and defines a many-to-one relationship that will be considered to be a many-to-many relationship even though the two referred elements are actually not related at all.

Participation

Participation concerns whether all instances of a particular element type are involved in a relationship with the corresponding element type.

Figure 7. The algorithm for determining many-to-many and n-ary relationships

```
Get referring XML element types from one-to-many cardinalities;
For each referring XML element T_referring type
        Get referred XML element types, S_referred referred by T_referring via explicit linkages;
    If the size of the set S_referred = 2
        XML element types in S_referred = many-to-many relationship with T_referring;
    Else
        If size of S_referred > 2
    XML element types in S_referred = n-ary relationship with T_referring ;
```

For implicit referential linkage by a parent-child relation, such as the following DTD ELEMENT declaration,

```
<!ELEMENT PARENT (CHILD*)>,
```

where there are no other ELEMENT declarations that define CHILD as their child elements, all CHILD element instances must appear as the child element of a PARENT element, and hence the participation can be considered to be total as all instances of CHILD must be involved in the one-to-many cardinality relation with PARENT. If no schema is provided, and if all instances of an element type always appear as the child elements of the same parent element type, the participation is also considered to be total.

For explicit referential linkage by ID/IDREF(S) attributes, if all instances of an element type use the same attribute with values referring instances of the same element type, the relationship is considered to be total participation. Otherwise, the relation is considered to be partial. The DTD of the XML document can only identify the ID/IDREF(S) type attributes and cannot restrict the referring and referred element types. As such, actually parsing the XML document is required to determine the type of participation.

Aggregation

An aggregation means that the creation of a whole part of an element depends on the existence of its component subelements. An aggregation relation is signified by the scenario that elements of different types are considered to be a single entity and all constituting elements must exist together. An XML document by itself does not provide any facility to enforce such a constraint. At best, the schema can hint at the correlations of the existence of the elements in the corresponding XML document.

Implicit referential linkage by an aggregation relationship is shown in the following DTD ELEMENT declaration:

```
<!ELEMENT AGGREGATION (COMPONENT1, COMPONENT2,….COMPONENTN)+>.
```

For example, the following ELEMENT declaration can restrict the existence of the elements enrollment, student, and course:

```
<!ELEMENT enrollment (student, course)+>.
```

Furthermore, no student or course elements exist in the document that are not subelements of an enrollment element. For example, if there is another ELEMENT declaration in the same DTD, such as

```
<!ELEMENT student _ list (student*)>,
```

student elements can exist in the document as the subelements of a student _ list element. As such, the coexistence relationship of enrollment, student, and course elements no longer holds.

Such a coexistence relationship specified in the schema can be extended to more than one nested level. For example, if the existence of a course element must be accompanied by a lecturer element and a tutor element, that is,

```
<!ELEMENT course (lecturer, tutor)+>,
```

then the elements enrollment, student, course, lecturer, and tutor must exist as a whole. All these elements are considered as being in an aggregation relationship. From another perspective, an aggregation relationship is actually composed of two one-to-one cardinality relations (course-lecturer and course-tutor) that are both total participation.

An exceptional case is if the subelements are actually the attribute of the parent element, such

as in the first example, where it is inappropriate to consider that the involved elements are in an aggregation relationship. As a result, user supervision is needed in the process.

Based on the DTD of the XML document, it is possible to determine the aggregation relationships from the elements. As the requirements of an aggregation relationship are the coexistence of the involved elements and the insignificance of the order of the subelements for a parent element, the nested structure of the elements should first be simplified with the algorithm presented in Figure 8, where T is an aggregation tree.

The determination of aggregation relationships is separated into two parts. The first part discovers the pair of parent and child elements that must coexist. Once the pairs are determined, the second part of the algorithm treats each pair as a path from the parent element to the child element in a subtree, and these subtrees are merged to form a bigger tree. Eventually, the nodes in each tree must coexist in an aggregation relationship. The second part is straightforward except for a tricky point: If a child element is found to be a nonroot node of a particular subtree, it implies that such an element can have more than one parent element, and the aggregation relation that includes such element must start with the parent element.

An example is this list of `ELEMENT` declarations in the DTD:

Figure 8. The algorithm for determining aggregation relationships

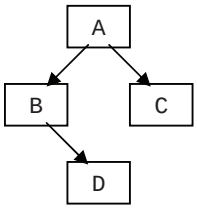
```
Let Set_temporary = empty;
For each ELEMENT declaration for element E_parent
    For each child element, element_child
        If element_child = mandatory and non-repeatable
            Add an aggregation relation (E_parent, E_child) to Set_temporary;

Let Set_aggregation and Set_root = empty;
For each relation R (E_parent, E_child) in Set_temporary
    If (∃ tree, T, in Set_aggregation) ∧ (E_parent is a node in T) ∧ (E_child is not a node in T)
        Add a path E_parent to E_child to T;
    Else
        (∃ tree, T, in Set_aggregation) ∧ (E_child is a node of T) ∧ (E_parent is not a node)
        If (E_child = root node) ∧ (E_child not in Set_root of T)
            A dd the path E_parent to E_child to T;
        Else
            Add E_childto Set_root
            Remove the sub-tree starting with E_child from T;
            If ∃ sub-tree starting with E_child in multiple nodes
                Add sub-tree to Set_aggregation;
            Else
                ∃ tree T_i with a node for E_parent and T_j with E_child as root node;

        Merge trees T_i and T_j with a path from node for E_parent in T_i to root of T_j
    Else
        ¬∃ sub-tree in Set_aggregation with node for either E_parent and E_child;
        Add a new tree with a path E_parent to E_child to Set_aggregation;
```

```
<!ELEMENT A (B, C)>
<!ELEMENT B (D)>
<!ELEMENT C (D)>
<!ELEMENT D (E, F)>.
```

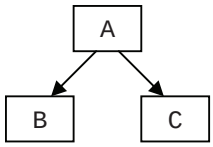
The determined pairs of raw aggregation relations are (A, B), (A, C), (B, D), (C, D), (D, E), and (D, F).



Relations to be added

(C, D), (D, E) and (D, F)

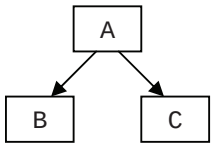
When adding the path (C, D) to the subtree, as D is not a root node, D should be removed from the subtree and is considered to be an individual subtree with D as the single node.

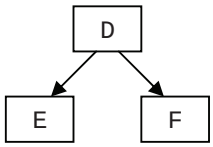


Relations to be added

(D, E) and (D, F)

After the path (D, E) and (D, F) is added to the subtree with node D as the root node, two subtrees are obtained.





As such, the elements A, B, and C and the elements D, E, and F are considered as being two individual aggregation relationships.

```

CASE STUDY AND PROTOTYPE

To illustrate the applicability and correctness of the algorithms mentioned in this article, a prototype was built that implements the algorithms proposed. For actually drawing the DTD graph, the algorithm proposed by Shiren, Xiujun, Zhongshi, and Bing (2001) is used to define the layout of the vertexes on the graph. With such a prototype, a sample XML document with its DTD file as shown in Figure 9 is provided for the prototype.

For this case study, both `ID/IDREF` type attributes are considered and the minimum number of common attributes is one. All elements with at least one attribute are sorted in ascending order of the lengths of their attribute lists. Therefore, the order of the elements to be processed is element1, element2, and element3.

According to the DTD of the XML document, only one `ELEMENT` declaration is used for constructing the extended DTD graph as the contents of other element types are `EMPTY`.

Figure 10. The determined data semantics

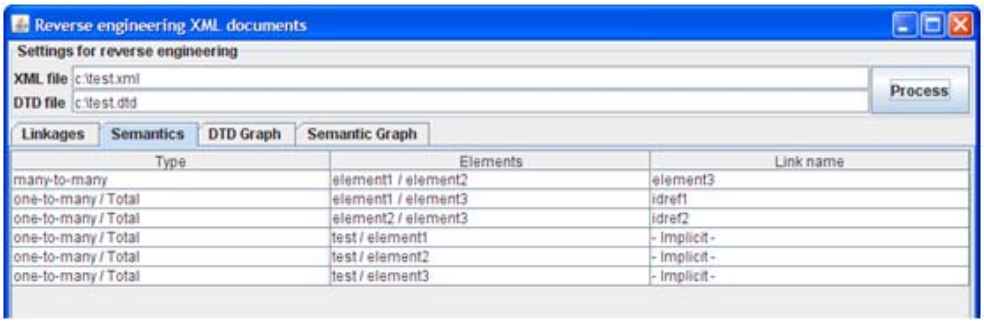

Figure 11. Extended DTD graph based on the DTD and the determined cardinality references

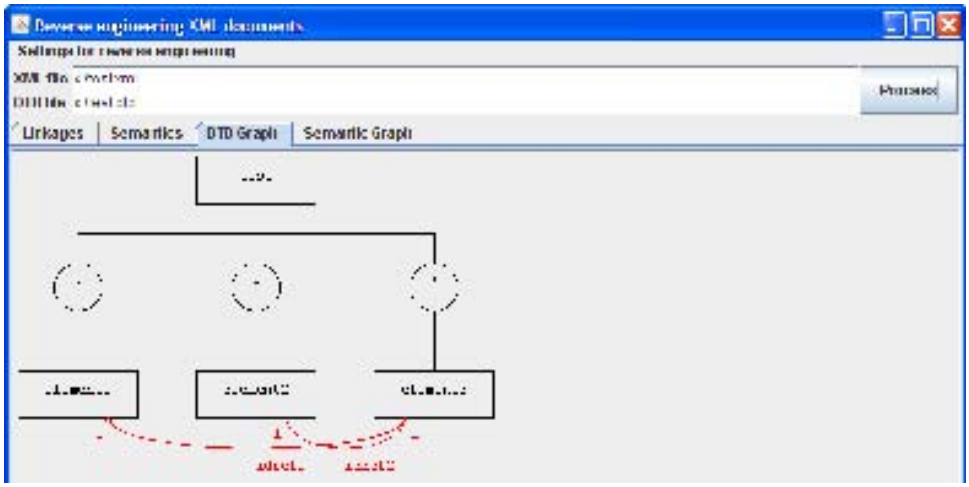

```
<!ELEMENT test (element1*,
    element2*,element3*)>
```

Therefore, only those explicit one-to-many relationships are to be added to the graph, and the graph will become the one shown in Figures 10 and 11. The detailed derivation of the reverse engineering can be referred to in Shiu (2006).

CONCLUSION

In order to make use of an XML document, software developers and end users must have a thorough understanding of the contents in the document, especially in historical and large XML documents. Sometimes, the schemas of XML documents are missing and the documents cannot be opened to be inspected on the screen due to their huge size. Therefore, it is necessary to determine as much information as possible regarding the relationships from the elements in the document.

By reverse engineering the XML document with DTD, all explicit linkages can be determined, and the resultant DTD graph can be used to verify the correctness of `ID/IDREF(S)` linkages as any incorrect `IDREF(S)` linkage will be indicated as an extra cardinality and shown in the extended DTD graph. This article provides algorithms to help the users to understand the relationships from the elements by reverse engineering data semantics from the XML document, including the following.

1. Cardinality relationships
2. Participation relationships
3. *n*-ary relationships
4. Aggregation relationships
5. Many-to-many relationships (a special case of cardinality relationships)

In summary, to visualize the determined data semantics, a new extended DTD graph is proposed. XML documents natively support one-to-one, one-to-many, and participation data semantics. With a corresponding schema such as DTD, the `ID` and `IDREFS` attributes of the elements can be identified, and many-to-many, *n*-ary, and aggregation relationships can also be determined.

Chapter 3.12
LOGIC–Minimiser:
A Software Tool to Enhance Teaching and Learning Minimization of Boolean Expressions

Nurul I. Sarkar
Auckland University of Technology, New Zealand

Khaleel I. Petrus
University of Southern Queensland, Australia

ABSTRACT

Boolean algebra, minimization of Boolean expressions, and logic gates are often included as subjects in electronics, computer science, information technology, and engineering courses as computer hardware and digital systems are a fundamental component of IT systems today. We believe that students learn minimization of Boolean expressions better if they are given interactive practical learning activities that illustrate theoretical concepts. This chapter describes the development and use of a software tool (named LOGIC-Minimiser) as an aid to enhance teaching and learning minimization of Boolean expressions.

LEARNING OBJECTIVES

After completing this chapter, you will be able to:

- List and describe three main features of LOGIC-Minimiser.
- Explain how LOGIC-Minimiser can be used in the classroom to enhance teaching and learning Boolean expression minimization.
- Describe the Q-M algorithm for the minimization of Boolean expressions.
- Define the following key terms: Boolean expression, SOP, logic gate, logic minimization, and K-maps.

INTRODUCTION

It is often difficult to motivate students to learn minimization of Boolean expressions because students find the subject rather abstract and technical. A software tool (named LOGIC-Minimiser) has been developed that gives students a hands-on learning experience in minimizing Boolean expressions. LOGIC-Minimiser was developed in C language under MS Windows and is suitable for classroom use in introductory Boolean algebra courses. Based on user input (i.e., logic expression), the system displays the sum of product (SOP) functions as well as minimized logic gate diagrams. Test results demonstrate the successful implementation of LOGIC-Minimiser, and the simplicity of the user interface makes it a useful teaching and learning tool for both students and instructors.

This chapter describes the development of LOGIC-Minimiser and its usefulness as an aid to teaching and learning minimization of Boolean expressions. The chapter concludes with a discussion of the strengths and weaknesses of LOGIC-Minimiser and its future development.

BACKGROUND AND MOTIVATION

Boolean algebra, minimization of Boolean expressions, and logic gates are essential concepts included in electronics, computer science, information technology, and engineering. These concepts play a fundamental role in computer hardware and digital systems design. We believe that it is extremely important to incorporate practical demonstrations into these courses to illustrate theoretical concepts and therefore provide an opportunity for hands-on experience. These demonstrations will significantly enhance student learning about Boolean expression minimization.

In fact, very little material has been designed and made available for public access to supplement the teaching of Boolean expression minimization. This is revealed by searches of the Computer Science Teaching Center Web site (http://www.cstc.org/) and the SIGCSE Education Links page (http://sigcse.org/topics/) on the Special Interest Group on Computer Science Education Web site. We strongly believe, as do many others (Bem & Petelczyc, 2003; Hacker & Sitte, 2004; Ibbett, 2002; Leva, 2003; Shelburne, 2003; Williams, Klenke, & Aylor, 2003), that students learn more effectively from courses that provide for active involvement in hands-on learning activities.

Boolean expression minimization is one of the most challenging subjects to teach and learn in a meaningful way because students find the topic full of technical jargon, dry in delivery, and quite boring. Sarkar, Petrus, and Hossain (2001) have developed LOGIC-Minimiser in C under MS Windows to give students an interactive, hands-on learning experience in minimization of Boolean expressions. LOGIC-Minimiser can be used by a teacher in the classroom as a demonstration to enhance the traditional lecture environment at an introductory level. Also, students can use the system in completing tutorials on Boolean expression minimization and to verify (interactively and visually) the results of in-class tasks and exercises on Boolean expression minimization. LOGIC-Minimiser can be used either in the classroom or at home as an aid to enhance teaching and learning Boolean expression minimization.

Minimization of Boolean expressions using traditional methods such as truth tables, Boolean algebra, and K-maps can be very tedious and is not well-suited for expressions involving more than six variables. A more useful approach, the Quine-McCluskey (Q-M) algorithm, also called tabular method, is an attractive solution for minimizing complex Boolean expressions involving variables of any length. Moreover, the algorithm lends itself to a fast and easy machine implementation.

The remainder of the chapter is organized as follows. First we examine various open source software tools suitable for logic-gate design and minimization. We then describe LOGIC-Mini-

miser in teaching and learning contexts. Then, software implementation of LOGIC-Minimiser is discussed, and the educational benefits of the software are highlighted. An example of a classroom plan and LOGIC-Minimiser in practice is discussed. Test results which verify the successful implementation of LOGIC-Minimiser are presented, followed by a conclusion and future research directions.

RELATED WORK

A detailed discussion of digital systems design and minimization of Boolean expressions in general can be found in Green (1985), Greenfield (1977), Mano (1984), and Tanenbaum (1999). The Quine-McCluskey algorithm is described extensively in the computer hardware and digital logic design literature (Carothers, 2003; Costa, 2004; Hideout, 2003; Hintz, 2003). Grimsey (2000) examined the strengths and weaknesses of various methods of minimizing Boolean expressions, including truth tables, Boolean algebra, and Karnaugh maps (K-maps).

A variety of open source and commercial software tools exist for modelling and simulation of logic circuit design and Boolean expression minimization. These powerful tools can have steep learning curves; while they may be good for doing in-depth performance modelling of computer hardware and logic design, they often simulate a hardware environment in far more detail than is necessary for a simple introduction to the subject.

Lockwood (2003) presented a program for the implementation of the Q-M algorithm. However, it is of limited use as a teaching and learning tool because of its text-based interface that is not user-friendly. Leathrum (2003) described another text-based menu-driven program for the Q-M algorithm, but the user interface is rather difficult to use. Costa (2004) developed a package called "bfunc" for Boolean functions minimization. It is an MS-DOS-based program and is considered an alternative to the K-map method of simplifying Boolean functions. Burch (2002) proposed a tool named Logisim, a graphical system for logic circuit design and simulation which is suitable for classroom use. Logisim is a Java application and can be run on both Windows and Unix workstations. While Logisim is an excellent tool for building a variety of complex combinational circuits, but it is not suitable for logic gate minimization. Other tools such as Digital Works 3.0 (2001) and LogicWorks (1999) are similar to Logisim in that they provide a graphical toolbox interface for composing and simulating logic circuits. LOGIC-Minimiser, which we describe in the next section, has its own unique features, including simplicity and ease of use either in the classroom or at home, to enhance teaching and learning Boolean expression minimization.

ARCHITECTURE OF LOGIC-MINIMISER

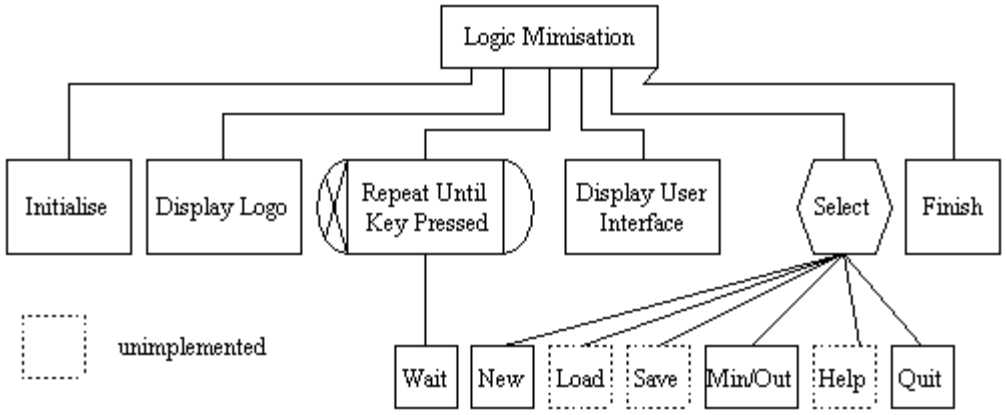
Figure 1 shows the structured diagram of LOGIC-Minimiser. The main features of LOGIC-Minimiser are briefly described.

- **New**: This feature allows users to enter a new set of variables for minimization.
- **Min/Out**: This feature allows users to view a minimized sum of product (SOP) expression and logic circuit diagram.
- **Quit**: This feature allows users to exit from the program at any time.

The following three features have not been implemented yet and are considered as future work.

- **Load**: This feature will allow users to view existing data (i.e., minimized minterms) for further analysis and modifications.

Figure 1. Structured diagram of LOGIC-Minimiser



- **Save**: This feature will allow users to store outputs on disk for later use and further modifications.
- **Help**: This feature will provide help on various topic related to minimization of Boolean expressions.

SOFTWARE IMPLEMENTATION

The Q-M algorithm is used to reduce a Boolean expression to its simplest form. It is designed particularly for use with problems containing six variables or more but can be used equally well for a smaller number of variables. The algorithm is based on repeated applications of the distributed law and the fact that XOR (NOT X) is always true. The Q-M method is a systematic way of selecting the pairs to be used for simplification. The main steps in the Q-M algorithm are summarized below:

1. Representing all addends as sums of minterms
2. Grouping the minterms that have the same number of ones
3. Merging the terms that differ in only one bit (this is done in several steps)
4. In order to find the irredundant cover we use the min-cover algorithm:
   a. Find all distinct minterms.
   b. Find all essential prime implicants.
   c. Find all the minterms that are covered by the essential prime implicants.
   d. Remove all minterms and prime implicants found in (a)-(c).
   e. Choose that prime implicant that covers most of the remaining minterms.
   f. Repeat (d) until all minterms have been covered.

A structured analysis and design has been employed to design the package. C programming language under MS Windows has been used in the implementation.

USEFULNESS AND BENEFITS OF LOGIC-MINIMISER

For simplicity and ease of use, it has been decided to implement LOGIC-Minimiser with a menu-driven, keyboard-based interface with a few menu options. The interface is self-explanatory, which makes the package well-suited for both students and teachers for classroom use. Therefore, the package can be an integral part of a 2-hour session for teaching and learning the Q-M method for logic gate minimization. An in-class task will be given to the students to produce a minimized logic diagram on paper. After a prescribed period of time (for example, 20 minutes), LOGIC-Minimiser will be introduced to the students on a step-by-step basis to verify their solution and learn more about minimization of Boolean expressions.

LOGIC-Minimiser provides the following main benefits:

- **Hands-on**: It facilitates an interactive, hands-on introduction to minimization of Boolean expressions.
- **Modelling**: It provides a simple and easy way to develop a variety of SOP functions and models. Students can experiment with minterms of various sizes and develop a sound knowledge and understanding of Boolean expression minimization.
- **Ease of use**: The use of a menu-driven interface makes LOGIC-Minimiser easy to use and a user-friendly tool. The software can be easily installed and run on any PC operating under MS Windows.
- **Economical/usefulness**: It enhances face-to-face teaching with online learning and can be used either in the classroom or at home to provide hands-on experience.
- **Robustness**: It was tested on various PCs across campuses and was found to be robust.
- **Challenging**: It provides an environment for students to test their knowledge on Boolean expression minimization.

EXAMPLE OF CLASSROOM PLAN

In this section we present a detailed lesson plan (2-hour session) which can be used in teaching and learning minimization of Boolean expressions using LOGIC-Minimiser. The learning outcomes focus on learning the Q-M algorithm as well as use of the software tool for verifying results of Boolean expression minimization. The lesson plan incorporates a number of resources and classroom activities, including revision of Boolean expressions, brainstorming, teaching, example, worksheet, demonstration of software package, and use of the package to verify the worksheet exercises.

Lesson Plan

Table 1 lists the learning outcomes, resources, and various activities that can be conducted in the classroom in teaching minimization of Boolean expressions effectively. It can be used for a 2-hour lecture session on the minimization of Boolean expressions. The lesson plan includes a guided worksheet (see Table 2) suitable for classroom use.

HOW TO USE THE SYSTEM

LOGIC-Minimiser is easy to use and can be run from any PC operating under MS-DOS/Windows. To run the package, the user can either double-click on “newqm.exe” or type “newqm” at the DOS prompt. The main steps of using this package (from Windows) are summarized below:

Table 1. Lesson plan (2-hour session with 10-minute break)

<table>
<tr><td colspan="2">By the end of this session students will be able to:
• Outline steps in minimization of Boolean expressions using Q-M algorithm.
• Use LOGIC-Minimiser to verify the minimization of Boolean expressions.</td></tr>
<tr><td>Resources required</td><td>• LOGIC-Minimiser
• Data Show
• Computer Laboratory
• Whiteboard
• Worksheets</td></tr>
<tr><td>Time (minutes)</td><td>Activity</td></tr>
<tr><td>10</td><td>Quickly review of Boolean expressions</td></tr>
<tr><td>5</td><td>Brain storming (ask the class what they know about Boolean expression minimization)</td></tr>
<tr><td>15</td><td>Explain Q-M algorithm</td></tr>
<tr><td>5</td><td>LOGIC-Minimiser demonstration</td></tr>
<tr><td>15</td><td>Solve workout/example problems</td></tr>
<tr><td>10</td><td>Break</td></tr>
<tr><td>20</td><td>Worksheet Exercises (ask the class to work in pairs and solve worksheet exercises)</td></tr>
<tr><td>20</td><td>Use LOGIC-Minimiser and verify results of minimization (worksheet exercises)</td></tr>
<tr><td>10</td><td>Conclusion and checking learning outcomes</td></tr>
<tr><td colspan="2">Review:
What went well:

What could be improved:</td></tr>
</table>

- **Run**: Double-click on "newqm.exe."
- **Entering minterms**: Select the New option to enter a new set of minterms. The user will be prompted for the number of variables to be used. After entering the appropriate number of variables, a matrix of cells with index numbers will appear on the screen. At this point the user can enter each minterm by selecting a cell by pressing the Enter key on the keyboard.
- **Accepting data**: When a set of minterms has been entered, press the F8 key to accept.
- **Display diagram**: The minimized logic-gate diagram can be seen on the screen in graphics mode. The user can zoom the diagram using the F1, F2, and F3 keys for 100%, 50%, and 20% scaling, respectively. To go back to main menu, press the F10 key.
- **Display minterms and output**: Select the Min/Out option from the main menu to see

Table 2. Boolean expression minimization worksheet

Consider the minimization of following logical function:

$F = A.B.C.D + A.B.C.\overline{D} + A.B.\overline{C}.D + A.\overline{B}.C.D + \overline{A}.B.C.D + \overline{A}.B.C.\overline{D}$

The above function can be written as:

$F(A,B,C,D) = \sum(0,1,2,4,8,9)$

Where 0, 1, 2, 4, 8, 9 are the decimal values of the minterms.
It is required to apply the minimization on this Boolean function with the use of Quine-McCluckey's algorithm, firstly by hand and then verify the solution using LOGIC-Minimiser.

Solution:

1. Write the first list as:

	A	B	C	D
0	0	0	0	0
1	0	0	0	1
2	0	0	1	0
4	0	1	0	0
8	1	0	0	0
9	1	0	0	1

2. Deduce the second list (You have to complete this list)

	A	B	C	D
0,1	0	0	0	-
0,2				
0,4				
0,8				
1,9				
8,9	1	0	0	-

3. Third list (You have to do it all yourself)

	A	B	C	D
0,8,1,9				

4. Now build the chart which relates minterms with the prime implicates as shown:

	0	2	4	8	9
$\overline{A}.\overline{B}.\overline{C}$	X	X			

5. Now use the LOGIC-Minimiser to cross check your solution.

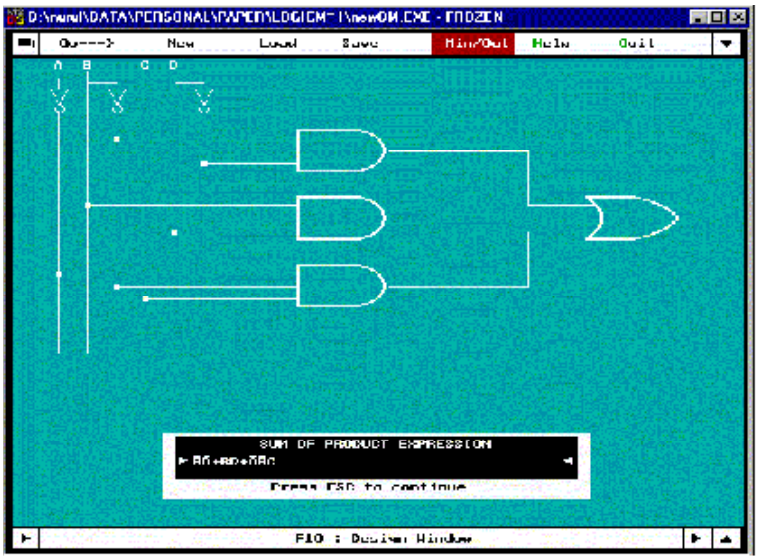
the list of minterms (that have been entered) and the minimized output expression.

- **Exit from the program**: Select the Quit option from the main menu to exit from the program at any time.

TEST RESULTS

To evaluate the performance of LOGIC-Minimiser, the software has been installed on various PCs and tested with various Boolean expres-

Figure 2. Example of four-variable minimization with minimized output expression and logic gate diagram



sions, each involving a different number of input variables. Then the test results were validated manually. Figure 2 shows a sample test result for four-variable (A, B, C, and D) Boolean expression minimization. The following minterms were entered from the keyboard: [0,2,3, 5,7,8,10,13,15], and the software produced the simplified logic-gate diagram as well as the output expression, as shown in Figure 2.

EVALUATION

An earlier version of LOGIC-Minimiser had been presented at the National Advisory Committee on Computing Qualifications conference in Napier, New Zealand (Sarkar & Petrus, 2001). The discussion during the conference presentation was quite encouraging, and many staff members from various polytechnic institutions expressed their interest in using the package in their classes.

To assess the educational value of LOGIC-Minimiser, we administered a survey to the students of the introductory digital logic subject. The survey was repeated for two consecutive years. Overall results revealed that the majority of students found the package useful and user-friendly, with an overall rating of 4 out of 5.

The questionnaire also posed five open-ended questions: (1) How well did you understand minimization of Boolean expressions before entering this course? (2) How easy did you find the software package to use? (3) How well did the package help in understanding the minimization of Boolean expressions? (4) Would you like to have more software tools of this kind as part of your course? (5) Would you prefer to learn minimization of Boolean expressions in a hybrid mode (i.e.,

minimization by hand and verification of results by software tool)?

CONCLUDING REMARKS

A software tool (LOGIC-Minimiser) has been developed that can be used in the classroom to enhance the teaching and learning of various aspects of Boolean expression minimization. LOGIC-Minimiser is easy to use and can be run from any computer operating under MS-DOS and MS Windows. It was tested on various PCs and was found to be robust. Many staff members from various polytechnic institutions expressed their interest in using the software in the classroom.

Currently, the system minimizes Boolean expressions involving variables of size 8, which is adequate for demonstration purposes. LOGIC-Minimiser can easily be upgraded to accommodate variables of any length. User options such as New, Min/Out, and Quit have been implemented. More options such as Save, Load, and Help are still under development, and incorporation of a mouse-based user interface is also suggested for future work.

LOGIC-Minimiser is available free of cost to faculty interested in using it to supplement their teaching. More information about LOGIC-Minimiser can be obtained by contacting the first author.

SUMMARY

Boolean algebra, minimization of Boolean expressions, and logic gates are essential concepts included in electronics, computer science, information technology, and engineering. These concepts play a fundamental role in computer hardware and digital systems design. We believe that it is extremely important to incorporate practical demonstrations into these courses to illustrate theoretical concepts and therefore provide an opportunity for hands-on experience. These demonstrations will significantly enhance student learning about Boolean expression minimization. This chapter described the development and use of LOGIC-Minimiser as an aid to enhance teaching and learning Boolean expression minimization. It was tested on various PCs and was found to be robust.

REVIEW QUESTIONS

1. List and describe three main features of LOGIC-Minimiser.
2. Discuss the usefulness of LOGIC-Minimiser in teaching and learning contexts.
3. Describe the main steps in the Q-M algorithm for the minimization of Boolean expressions.
4. Define the following key terms: Boolean expression, logic gate, logic, minterms, and K-maps.
5. Explain how LOGIC-Minimiser can be used in the classroom for demonstration.
6. List and describe further enhancements to LOGIC-Minimiser.

KEY TERMS AND DEFINITIONS

Boolean Expression: An expression which results in a Boolean (binary or TRUE/FALSE) value. For example 4 > 3 is a Boolean expression. All expressions that contain relational operators like >, <, and so forth are Boolean. Logical gates and their combinations are used to implement physical representations of Boolean expressions.

K-Maps: This term refers to Karnaugh maps, a logical minimization method based on graphical representation of Boolean functions in which each row in the truth table of the Boolean function is represented as a box. Unlike the truth table, K- map values of input must be ordered such that the values of adjacent columns vary by one single bit.

Logic Gate: An electronic device (based on transistors) used for implementing logical functions. The inputs and outputs of the gate are Boolean (i.e., binary) values. Gates can be used to implement various Boolean functions. NOT gates take one input and have one output. The AND, NAND, OR, and NOR gates may take two or more inputs and have one output. XOR gates take two inputs and have one output. Logical functions are all combinational functions, that is, their output depends on the input. Gates can also be used to implement latches and flip-flops which have an internal state and are used to implement sequential logical systems.

Logic Minimization: Simplification of Boolean expressions with the aim of reducing the number of logical gates. This is done by reducing the number of minterms into a number of prime implicants in which as many variables as possible are eliminated. The tabular method makes repeated use of the rule $\bar{A} + A = 1$.

LOGIC-Minimiser: Software package developed at the Auckland University of Technology to enhance teaching and learning minimization of Boolean expressions. The package was implemented in C programming language.

Minterms: This term refers to the product of Boolean variables. These variables can appear either as themselves or their inverses. A minterm corresponds to exactly one row in the truth table of the Boolean function. If we have four variables A, B, C, and D, then a minterm can be something like A.B.C.D or .B.C.D, and so forth.

Quine-McCluskey Algorithm: Table-based reduction method for simplification of Boolean expressions. This method is quite versatile as compared with other algorithms. It can handle any number of inputs and can easily be implemented on machines. The method starts from the truth table of the Boolean function.

Sum of Product (SOP): A two-level expression which represents a sum of minterms of a logical function. It is two-level because it is implemented by two layers of logic gates. The first level represents the product of Boolean variables of the logical function and the second level represents summing the products with OR operator.

Igor Hawrysiewycz
University of Technology, Sydney, Australia

ABSTRACT

To make online learning more productive, software agent technology has been applied to provide services for learners in order to assist them to construct knowledge in constructivist ways. This paper is focused on the application of software agents in assisting learners to dynamically adjust learning processes. Unlike pedagogical agents, the agents in this application do not hold domain knowledge but simply assist learners to get through learning processes by a variety of supportive services. They assist learners to develop personalized preferred learning plans and to guide them to dynamically adjust learning toward their goals. In this article, the online learning process is first investigated, and an approach to assisting learners to dynamically adjust learning is outlined. Then, the structure of the UOL (unit of learning) database that provides links between a practical learning scenario and the required services is explored. A multi-agent architecture for realizing the services is configured, and the roles of the involved agents are described. After that, the related agent algorithms for guiding learners to dynamically adjust learning are described.

INTRODUCTION

Constructivist learning is being recognized by more and more people as a productive learning method. Although there are diverse constructivist paradigms, they share commonly epistemologi-

cal assumptions for learning (Fosnot, 1996). The fundamental epistemological assumption is that knowledge cannot be transmitted to learners but must be individually constructed and socially co-constructed by learners (Jonassen, 1999). Because constructivist learning focuses on actively constructing meaningful understandings of the study theme, it can generate more significant outcomes than other methods such as the objectivist ones (Wilson, Teslow, & Osman-Jourchoux, 1995).

According to constructivist theories for learning, learners are *active* knowledge-constructors, whereas teachers are cognitive guides who provide guidance and scaffolds to support the construction (Mayer, 1999). Unfortunately, most current online instructional systems have not really taken such roles. Mostly, they just simply deliver online course materials over the Internet without providing effective guidance on how to use these materials to construct knowledge. As a result, learners only passively receive information from the presented materials. They have not been engaged in *actively* constructing meaningful understandings of the study theme. This research is aimed by applying software agents into online learning to *actively* assist learners to construct knowledge by using constructivist methods.

The research into software agents has been a rapidly developing area of research. Already a lot of agent-based systems have been proposed, ranging from comparatively small systems such as e-mail filters to large, complex, mission-critical systems such as air-traffic control (Jennings, Sycara, & Wooldridge, 1998). In particular, pedagogical agents have been developed to take the role of a virtual tutor, a virtual learning partner, and so forth. The agents we are developing facilitate online learning through comprehensive applications of the properties agents exhibit (e.g., autonomy, learning, cooperation, reactivity, goal-driven, etc.). They work together cooperatively in order to facilitate effective knowledge construction for individual learners. They assist learners to construct knowledge not through understanding the academic content of subjects but rather through providing a wide range of services. These services include (1) providing access to appropriate learning resources and learning strategies; (2) fostering meaningful interactions with content, teachers, and fellow learners; (3) supporting personalized learning for individual learners; (4) promoting collaborative learning among learners in groups; and (5) aiding to evaluate learning achievements in a timely and accurate manner (Pan & Hawryszkiewycz, 2004a).

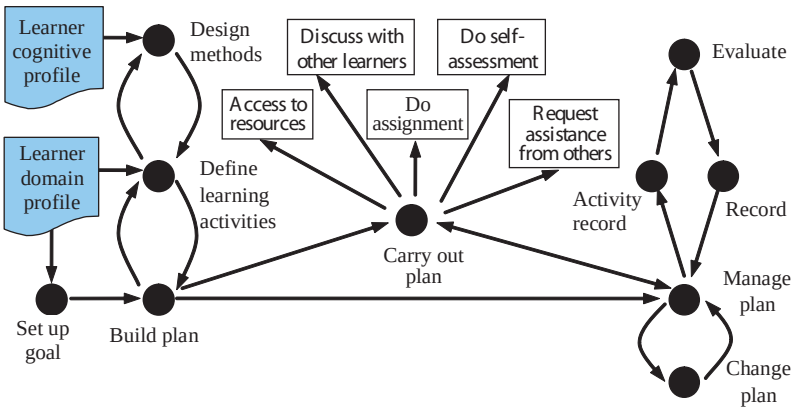
This article is focused on showing how software agents are applied to assist learners to dynamically adjust learning processes. This includes (1) guiding them to develop personalized preferred learning plans that satisfy their learning needs and that match their particular learning styles; and (2) assisting them in the alignment of learning plans according to the real progress in learning. The purpose of such services is to engage learners in knowledge construction and to promote its success through providing guidance for learners to solve the problems pertaining to learning strategies that they often encounter in online learning.

DYNAMICALLY ADJUSTING THE LEARNING PROCESSES

Online Learning and Learning Plans

Online learning takes place in many environments rather than just at educational institutions. Learners in education institutions usually follow a particular instruction program. Other learners, however, build their knowledge through a continuous and guided process of identifying learning project goals, discussing and trying ideas, and evaluating learning outputs. Such a process, as shown in Figure 1, is initiated and driven by a learning goal. After a goal is constituted based

Figure 1. An online learning process



on a project or a case study, learners go through a guided process in order to reach it. The first step is to *build a plan* in order to achieve the goal. This includes defining the learning activities to be taken and designing the methods to conduct these activities based on their particular cognitive features and learning history. Then, learners *carry out the plan* to construct their own understanding of the study theme. They follow the learning steps in sequence, as defined in the plan. Each learning step is a particular learning activity (e.g., accessing learning resources, discussing with others, doing assignments, doing self-assessments, requesting assistance from others, etc.). As the learning proceeds, learners *manage the plan* in order to align learning toward their goal. They record the learning activities that they conducted, evaluate their outcomes, and then revise the current plan based on the evaluation. The updated plan immediately will affect the learning process; the relevant activities or sequences will be aligned. The learning, based on the updated plan, will be evaluated again that further results in a plan revision. An online learning process evolves in this way, until the evaluation shows that the learning goal has been achieved.

General Framework for Supporting Online Learning

As previously described, the major challenges for learners to take part in online learning include (1) building an appropriate learning plan to achieve their learning goal; and (2) timely and accurately adjusting the learning plan toward the goal, based on the practical learning progress. It will significantly benefit learners to continue their pursuits for the goal, if the online instructional system can provide assistance for them to tackle these challenges. This is because *not* all learners are equally capable of adequately addressing these challenges on their own (Large, 1996). Some may lack the necessary *prior* knowledge or abilities to determine independently the needed learning activities and to choose a proper method to conduct them. Some may have no idea how to evaluate the outcomes of learning and to vary plans according to learning progress.

What degree of assistance is suitable for helping learners to deal with these problems? Is it suitable to take full control of the learning by the online instructional system? Most intelligent tutoring systems (ITS) adopt this mode. They *predesign* all learning routes for learners based on a variety of learner models, expert models, and tutorial models. Learners only can *follow* these routes precisely. The problem is that these models cannot possibly specify all possible ways in which learners may go about trying to solve a problem (Jonassen, 2000). This is because learners never learn in the same way due to their different backgrounds, interests, styles, motivations, capabilities, and so forth. It is even truer for online learning, because most online learners are adults. As a result, learners in those systems often are forced down the *preset* learning routes that do not suit them or even limit the development of their cognitive abilities.

In order to provide personalized learning experiences for individual learners and to make the learning process optimal, learners must assume responsibility for some decisions in the process (Kay, 2001). *Active learning* must be encouraged, because learners construct knowledge only by active learning (Akhras & Self, 2000). Therefore, an innovative strategy have been applied in our work where learners are encouraged to actively construct knowledge, and meanwhile, the system provides them with services to shape and to scaffold the learning process. Those services are aimed directly at solving the problems that emerge in the learning process. They are customized to the personalized needs of learners according to their unique learning characteristics.

In the proposed instructional system, learners are not imposed to take any learning activities. They thus can independently develop and explore their own learning plans for the study themes and actively construct meaningful understandings of the themes. Their autonomy in learning has been sufficiently supported and encouraged. Meanwhile, the system offers suggestions or advice for directing them to develop learning plans and to revise learning plans while they have trouble with these things. This contrasts with most current online instructional systems that just present course materials and leave learners to determine how to achieve their learning goals. This also contrasts with those ITS where learners only can *passively* follow a preset learning plan chosen by the system.

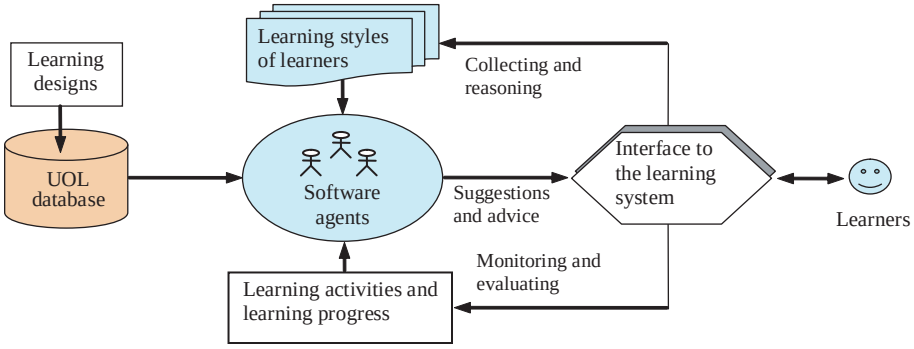
Approach for Dynamically Adjusting Learning

In order for the online instructional system to provide services to meet an individual learner's *just-in-time* needs or even *just-for-me* needs in online learning, knowledge about the learning activities being conducted, the practical learning progress, and the learner's learning styles is necessary. It thus requires combining learning content and learning evaluation with the service components together. A UOL (unit of learning) database is being used to provide the connection.

A UOL is a learning unit that satisfies one or more learning objectives. It may correspond to a course, a module, or even a single learning activity such as a discussion to elaborate on some topic. The UOL database contains a collection of UOLs, each of which is a carefully designed learning scenario where not only the learning content and evaluation methods are specified, but also the relevant learning activities, conduct sequences, and supportive services for various types of learners are defined, as well. The structure of the UOL database will be explored in detail in the next section.

Furthermore, the customized services suggest the requirements for the dynamic interaction and communication between different components in the system. Those require communications between distributed components, sensing and monitoring of the environment, and autonomous operations. The application of software agents is quite appropriate to realize these services, since

Figure 2. The overall architecture of the online learning system



software agents can act as human agents on behalf of humans. They can easily perform sequences of complex operations based on the messages they receive, their own internal beliefs, and the overall goals and objectives (Garro & Palopoli, 2002). Therefore, software agents have been developed to implement the service components. They are responsible for providing suggestions or advice according to the real learning progress and learner styles.

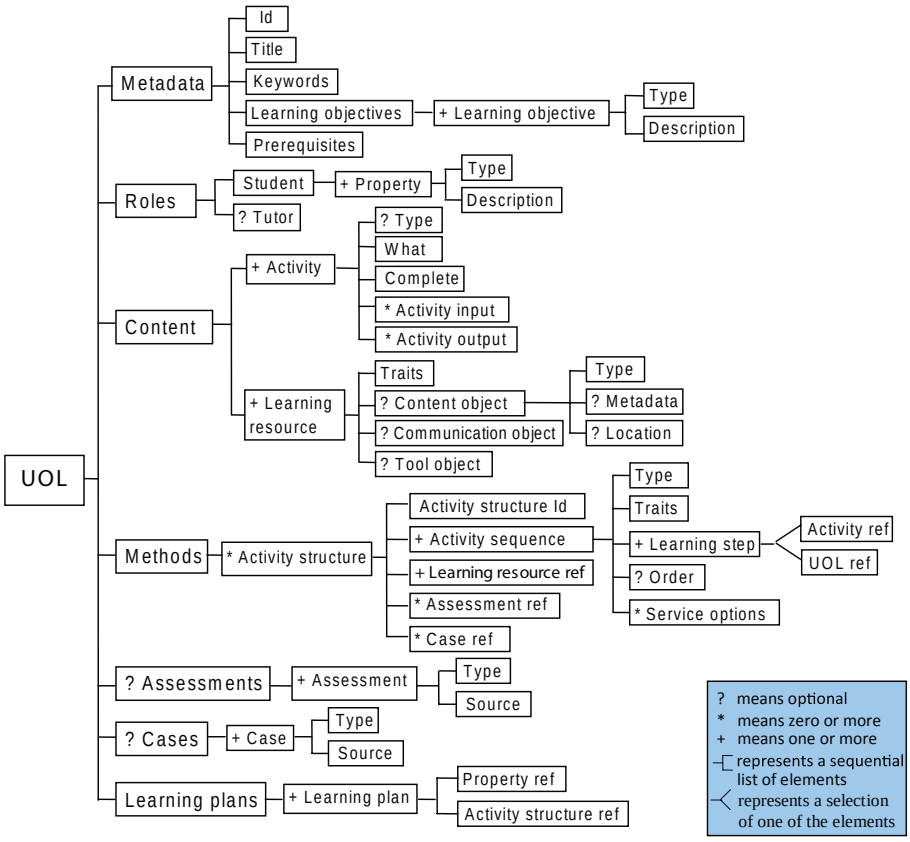
Figure 2 depicts the overall system architecture. The agents work independently of learners, observe and monitor the learning of individual learners, and make suggestions and advise them, when necessary. Any change taking place in the learning environment made by the learner is detected by the agents. The learning progress is evaluated through evaluating the detected events. The learner profiles are built and updated timely through collecting the detected events and inducing from them. The multi-agent architecture takes a practical learning scenario and the learner styles as input and generates a suggestion or advice for individual learners. The suggestion is about what the learner should do next, which mainly is based on the knowledge extracted from the UOL database by matching the input to the learning scenario in the UOL database.

THE UOL DATABASE

The purpose of developing a UOL database is to link the practical learning scenarios with the corresponding services for different learners so that agents can, based on the links, determine an appropriate service to assist individual learners to learn while a scenario appears. Building upon the earlier work in the descriptions of learning activities, particularly the educational modeling language (EML) (Koper, 2001), we are developing mechanisms to describe and specify learning processes so that individual learning can be promoted by the services provided by the agents. The primary means is to extend and to adapt the object parameters of the EML in ways that they can be combined flexibly to describe the arrangements of learning activities and the services to support personalized learning (Pan & Hawryszkiewycz, 2004b).

As shown in Figure 3, a UOL describes the learning activities for a particular objective and

Figure 3. The major components of a UOL



the corresponding supportive services using seven composite fields. Every field contains more elementary fields, constructing a complex architecture. The major fields and their roles in implementing the services to facilitate knowledge construction of learners are outlined below.

The *metadata* field is for providing the meta-information of the UOL, including the title, the prerequisites, the learning objectives, and so forth. Each objective has a brief description and a corresponding category (e.g., skill, knowledge, etc.). The *keywords* field is to store the keywords extracted from the objective descriptions that are used to match the learning goals of the learner.

The *roles* field is for specifying the intended users of the UOL. Its *property* field contains the description of the learning characteristics of every class of the intended learners, which enables the software agents to provide services according to the unique learning characteristics of individual learners.

The *content* field is for storing the description of all the learning resources and all the learning activities relating to the UOL. Every *activity* field describes a learning activity. Its *complete* field specifies the progress status of learning while the activity is completed. Its *activity output* field specifies the artifact files that the activity

will produce, which is used for evaluating the outcomes of learning. Every *learning resource* field describes a resource available for the UOL. Its *traits* field specifies the specific features of the learning resource; *content object* indicates the medium type of the resource and its exact location; *communication object* represents the requirements for the communication facilities; and *tool object* specifies the prerequisite tools and facilities for using the resource.

The *methods* field is for defining all the dynamics of the learning process in order to achieve the objectives of the UOL. They are categorized based on the learning characteristics of their targeted learners and divided into different groups accordingly. Each group is put into an *activity structure* field. This implies that an *activity structure* field stores all of the possible methods suitable for a particular category of learners to achieve the learning objectives defined in the UOL. Within an *activity structure*, there are multiple *activity sequence* fields, each of which defines a particular *learning flow* in which a sequence of learning activities is performed during the learning process. This enables the software agents to assist a learner with optional activity sequences that suit his or her learning characteristics. Each activity sequence can be associated with more than one learning resource, ensuring that an activity sequence can be conducted by using different learning resources. Each activity sequence can be associated with multiple assessment approaches and multiple related case materials, ensuring an activity sequence can be evaluated through alternative methods and be scaffolded by alternative case materials, respectively.

Within the description of a particular activity sequence, a learning step can be a reference to a learning activity defined in the UOL or a reference to another UOL. In the latter case, another UOL is referenced in order to implement a learning step of the UOL, constructing a hierarchical architecture of a module or a subject. The *type* field is to specify the pedagogical methodology category of the activity sequence (e.g., knowledge acquisition, problem-based, project-based, learning by designing, discovery learning, etc.). *Service options* declare the computer-supported collaborative tools that are required in the learning activities (e.g., learning spaces, discussion forums, etc.). *Traits* indicate the particular features of the sequence.

The *assessments* field and the *cases* field are respectively for describing the assessment approaches and the case materials, related to the UOL. The *type* specifies the category, and *source* indicates where to find it.

The *learning plans* field provides the link between a learning method and its targeted learner category. It is composed of a number of *learning plan* fields, each of which contains a pair of *property ref* and *activity structure ref*. The former is an ID of the property defined in the *roles* field, whereas the latter is an ID of the activity structure defined in the *methods* field. This enables the software agents to specify the learning methods based on the category of the learner. This field is crucial to determine dynamically a specific learning mode for individual learners and to provide associated supportive services for different learning needs.

THE MULTI-AGENT ARCHITECTURE

Agents and Their Roles

The agents that we have developed to realize the services to facilitate knowledge construction of learners are a series of individual agents with specific expertise, which forms a multi-agent architecture. In this article, we only concentrate on the agents that are involved in assisting learners to dynamically adjust their learning processes. The agents responsible for this task are described briefly as follows:

- **Personal Assistant Agent:** Helps individual learners with their learning activities. It continuously observes the behaviors of its owner learner in order to maintain a profile. The profile covers many facets that can be relevant in the learning process. The assistant agent updates the profile as the learning proceeds and provides this information to other agents when being requested.
- **Planning Agent:** An agent responsible for assisting learners to develop personalized preferred learning plans for a particular goal. Its tasks include designing learning activities and their sequences, determining evaluation methods, and so forth. All of these are accomplished based on the practical learning scenarios and the unique learning characteristics of individual learners.
- **Managing Agent:** Responsible for managing the learning for a particular UOL. Each UOL has an agent, whose task is to provide personal assistance for individual learners to learn the unit and to manage the learning based on the plan being adopted. It delegates work to learning activities according to the plan. The managing agent keeps track of the progress in the learning activity for the UOL and provides assistance to learners in revising the learning plan accordingly. It includes monitoring the submission of the artifact file for the UOL, evaluating the artifact file or asking a field expert to evaluate it and then receiving the evaluation result from the expert.

Working Modes of the Agents

The agents use a hybrid architecture that combines a reactive reasoning and a BDI-based proactive reasoning (Wooldridge, 2002). They autonomously monitor the learning environment, observe and react to the events in the environment. When a learner sets up a learning goal, the personal assistant agent for the learner perceives the event. It requests the planning agent for a learning plan for that goal. The planning agent, based on the goal and the learning characteristics of the learner provided by the assistant agent, designs learning plans for that goal and provides them to the learner for making decisions. While the learner starts learning a unit, a managing agent is created for assisting the completion of the learning activities in that unit. The managing agent manages the learning of the unit by following the plan being adopted. Based on the sequence of the learning activities scheduled in the plan, it delegates a learning activity and creates a learning space for the learning activity and an agent for it, as well. The activity agent further creates action agents to assist in conducting related actions in the activity and reports the progress to the managing agent. The managing agent delegates another learning activity after it receives the report from the activity agent on the completion of the activity with which it is associated. It reports the progress of the plan to the planning agent, and the latter revises the plan accordingly.

IMPLEMENTATION APPROACHES FOR ADJUSTING LEARNING PROCESSES

Developing Personalized Preferred Learning Plans

Assisting learners to develop personalized preferred learning plans is realized through advising them on several plans that they can follow to achieve their goals. These plans are the methods to conduct learning, including relevant learning activities to be taken and their sequence. They are extracted from the UOL database, based on the practical learning scenario and the specific learning characteristics of the learner. As shown in Figure 4, the agent first determines a UOL by matching an individual learner's goals to the objectives of a UOL in the UOL database. Then,

Figure 4. Assisting learners to develop personalized preferred learning plans

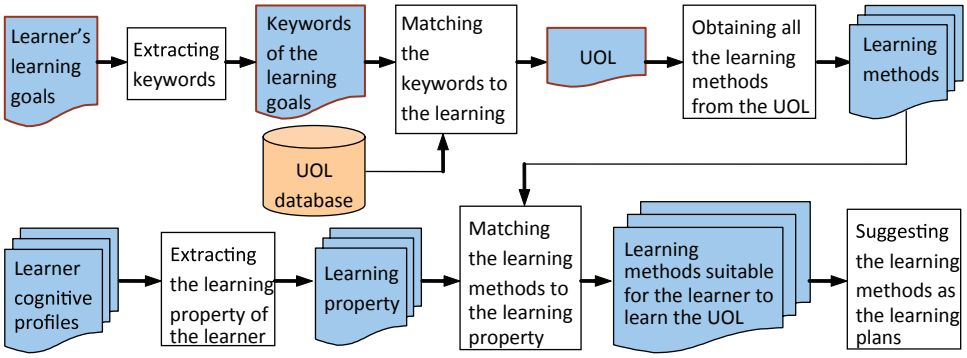


Figure 5. Presenting learners with appropriate learning plans

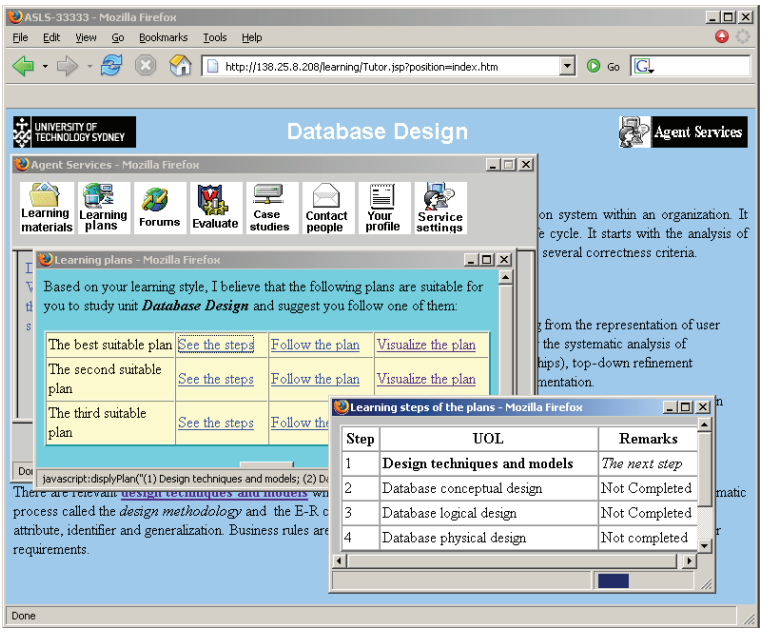


it captures the learning methods for the UOL from the database. Next, it further determines the ones from them that are suitable for the learner according to the fit degree of the method for him. Finally, it presents these methods as the recommended learning plans.

The following technique is used by the agent to identify if a particular learning method is suitable for a learner and to measure the fit degree. The learning property of a learner, stored in his or her cognitive profile, is characterized by a set $P = \{p_1, p_2, \ldots, p_n\}$, where p_i is one of his or her preferred styles in learning (e.g., like to study together with other learners, like to work through concrete experiences, etc.). Every learning method for a UOL stored in the UOL database has a set $M = \{m_1, m_2, \ldots, m_m\}$ to describe its traits, where m_i is a style that the method can accommodate.

The agent recognizes if a method is suitable for a learner by comparing set *M* with *P*. The fit degree is calculated by summing the numbers where the learner's favored styles are met by a method; namely, $V_{fit} = \sum (p_i \text{ in } M)$. A method is recognized as an appropriate one for a learner, if its V_{fit} is larger than a designated threshold value. A method is considered as the optimal one, if it has a larger V_{fit} than other methods.

In order to promote active learning, the agents do not force a learner to accept any of the learning plans that they have designed for him or her. Instead, they present these plans as a suggestion for the learner to make his or her own decisions. Figure 5 shows a typical scene, where the planning agent, based on the cognitive profile and domain profile of a learner, already has generated three plans for the learner to learn the *database design* unit and is presenting the three plans for the learner in a popup window. The learner is free to accept any one of them or to reject them, building his or her own plan. If the learner wants to accept a plan recommended by the agent, he or she only needs to click on *Follow the plan* in the plan line. The learner then is forwarded to the learning step defined in the plan. The learner also may want to look at the detailed learning steps of a plan before making a decision. If so, he or she can click *See the steps* in the plan line. If the learner wants to inspect and to analyze a plan in depth, he or she can click on *Visualize the plan* in the plan line. The learner will be presented with an interactive visual interface, where he or she can inspect the learning steps and view their hierarchical architecture.

Dynamically Revising Learning Plans

Guiding learners to align the learning toward their goals is implemented through managing individual learning plans. The agents perform this work with the aid of two lists; namely, activity list and checklist. The activity list stores the UOLs that a learner has started learning but has not completed yet; whereas the checklist stores the UOLs that a learner has completed. The major components of these lists are shown in Table 1 and Table 2. When a learner initiates the learning for a UOL, the UOL, its learning goal (i.e. the goal UOL), and the adopted learning plan for achieving the goal are added to the activity list. When the learner has completed the learning for a UOL, the UOL will be moved to the checklist. The two lists are updated dynamically by the agents as the learning proceeds.

The requirements for aligning learning recognized by the agents take place mainly in two scenarios: (1) when a learner starts learning a new UOL but has not completed all the UOLs planned to learn prior to the one he or she is going to study; and (2) when a learner is not able to achieve the objectives of the UOL. Figure 6 depicts the recognition of the first scenario. The agent first retrieves the learning plan from the activity list that the learner is adopting for the UOL goal. It then compares the checklist against the learning tasks scheduled in the plan to see if the checklist contains all of the UOLs planned to be learned prior to the one to be studied. If it does not, then the agent will suggest adjusting the learning plan. The second scenario is recognized by keeping track of the execution of the UOLs in the activity list and by evaluating the artifacts submitted by the learner for those UOLs. If a learner fails to submit the desired artifacts for a long time after starting a UOL, the agent will suggest adjusting the learning plan. If the evaluation of an artifact indicates that a learner is not able to achieve the objectives of a UOL, the agent also will suggest adjusting.

As to the approaches for adjusting learning, the agent usually suggests two kinds of adjustments: (1) keep the learning plans being carried out unchanged and select another UOL to learn; or (2) revise one of the plans being carried out. The agent can generate a suggestion for the first kind of adjustment by examining the current plan and the

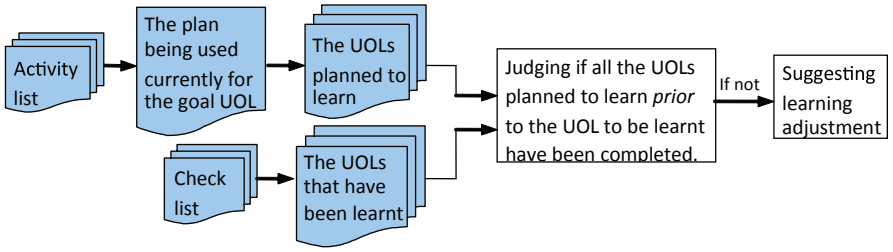
Table 1. The major components of the activity list

Field	Meaning
username	the user name of a learner
uol	the ID of a UOL the learner has started learning
goal_uol	the ID of the goal UOL for the UOL
plan	the ID of the plan for achieve the goal UOL
status	the status of learning for the UOL by using the plan, e.g. proceed or suspended
remarks	the plan is selected by agent or designed by learner

Table 2. The major components of the check list

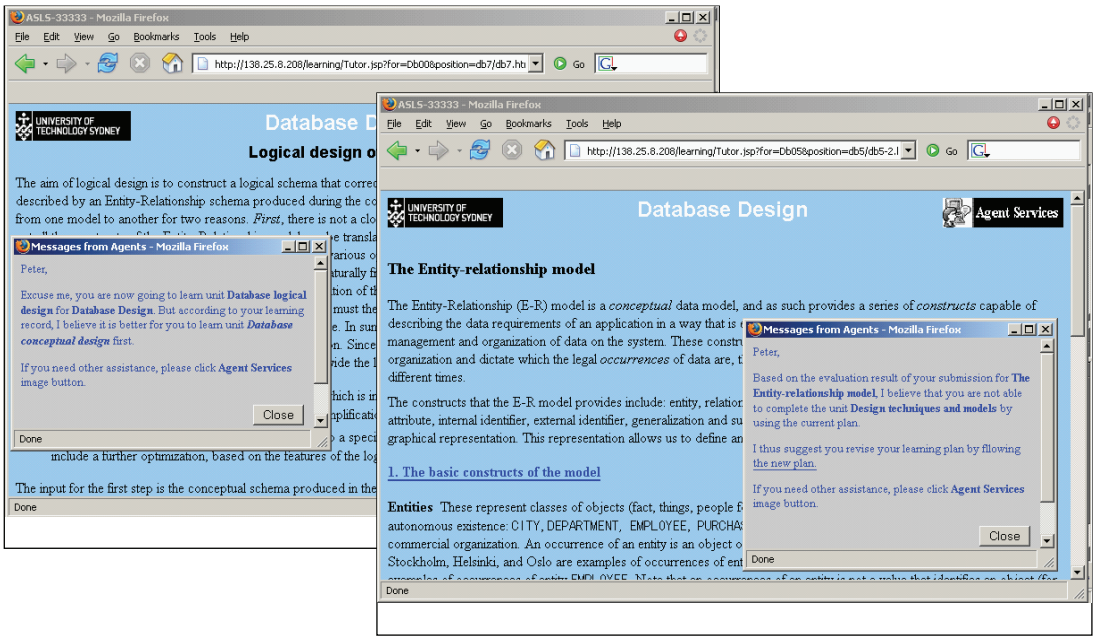
Field	Meaning
username	the user name of a learner
uol	the ID of a UOL that the learner has completed
goal_uol	the ID of the goal UOL for the UOL
remarks	the plan is selected by agent or designed by learner

Figure 6. Recognizing the requirement for learning adjustment



checklist, since it can identify the UOL that should be learned next by comparing the learning tasks scheduled in the current plan against the ones in the checklist. It is a challenging task to generate a suggestion for the second kind of adjustment, as it needs a complicated search procedure. As can be seen, a UOL with a larger grain (e.g., a subject or a chapter) may have a lot of learning paths with a complicated hierarchical structure. Accordingly, there are very complicated relationships between the plans being carried out and the ones that can be adopted after some alignment. To search for a suitable plan in the hierarchical architecture, the agent has to examine the plans from the current

Figure 7. Example suggestions by agents for learning alignment



UOL to higher level UOLs level by level. That is, the agent first checks if there is any other plan to reach the current UOL's goal, and, if not, it will further check to see if there is any possible plan suitable for the goal of the higher level UOLs. In this way, the agent checks the plans for the UOLs level by level, until it finds a suitable plan or attains another reasonable result.

Figure 7 shows two examples of the suggestions generated by the agents for learning alignment. The one on the left shows the agent suggesting that the learner study another UOL first, because it is scheduled to be learned prior to the one that the learner is going to study, based on the plan being adopted. The one on the right corresponds to changing the current learning plan, because the evaluation illustrates that the learner is not able to achieve the objectives of the UOL.

SUMMARY AND FURTHER WORK

A prototype of the multi-agent architecture for facilitating knowledge construction of learners has been developed, and the services related to assisting learners to dynamically adjust learning processes have been implemented. This research has illustrated that software agents are effective in assisting learners to dynamically adjust learning processes. They can efficiently solve the problems that learners face in online learning and can promote deeper cognitive engagement for them. Our future work involves further refining and extending of the UOL database and the agent services so that they can assist learners in adjusting learning process in different ways. An empirical validation of the system also would be carried out in order to demonstrate the usefulness of the system to a wide audience.

Chapter 3.14
Integrating Software Engineering and Costing Aspects within Project Management Tools

INTRODUCTION

Currently, there is no integration among CASE tools (computer aided software engineering, also named AMD tools, analysis modeling and design), costing tools, and project management (PM) tools. Not only are there no integrated tools, but there is also no conceptual integration among software engineering (SE) aspects and accounting-costing aspects of software projects within PM tools. PM tools, as well as costing tools are used not only for tracking and controlling an ongoing software project, but also at the very beginning stages of the project, in which critical estimations concerning budget and time frame are made. In order to have a firm, robust, and accurate planning, project planning should be based directly upon raw SE components-objects, that is, upon analysis and design components-objects.

According to the Standish Group CHAOS Report 2003, each year in the USA there are approximately 175,000 projects in IT Application Development which spends $250 billion. Among these, 31.1% of projects will be cancelled, 52.7% of projects will cost 189% of their original estimates, only 52% of required features and functions make

it to the released product, and Time overruns 82%. In financial terms $55 Billion dollars is wasted in these projects (Madpat, 2005).

Budget overrun indicates cost management problems, although this area is defined by the project management integration (PMI), as one of the nine core activities of projects management. Costing difficulties result from both implementation limitations of costing solutions in complex and changing requirements as well as the technological environment. Risk management is also defined by the PMI as one of the nine core areas of project management; but there is also no integration between PM tools and SE tools in light of the need for risk management.

According to Maciaszek and Liong (2005), success of a software project depends on five software engineering areas that are related to each other: the development of the life cycle of the software, processes management, the model's configuration and language, and SE tools and project planning. The combining between formal tools of SE and PM processes in the different stages has been proved by research as holding a positive contribution to the efficacy of the project and as an improver of the adherence to costs, technical requirements, and the schedules that were allocated to the project (Barker & Verma, 2003).

This study proposes and prototypes a model that integrates these three aspects of software projects by automatically mapping SE objects and accounting–costing objects into PM objects. To validate the feasibility of the model and without loss of generality, it is demonstrated using former research platform focused on conversion of data flow diagrams (DFD), which are actually full enterprise set of use cases diagrams reflecting entire system-software project into Gantt charts.

BACKGROUND

CASE and PM Tools

CASE/AMD tools support the analysis, design, construction, and implementation stages of the information system life cycle (ISLC) (Barker & Longman, 1992; Pendharkar, Subramanian, & Rodger, 2005; Sommerville, 2004). Commercial tools, such as IBM–Rational XDE, are covering main stages of ISLC; the "Requisite-Pro" module, for instance, is designated to the stage of requirement definition, "Rose" module to the analysis and design stage, and "Test-Studio" module to the testing stage.

Although PM tools support management and control along the ISLC, there is hardly any integration between CASE tools and PM tools. Thus, ISLC modeling approaches, such as the functional approach (e.g., DFD, ERD, STD), as well the object-oriented approach (e.g., use cases, activity diagrams, STD), even when automated, are used mainly in the early analysis stage primarily for visual documentation. The "database of specifications," laboriously elicited and gathered during the creation of modeling diagrams, is hardly ever applied again for project management purposes, even though this information is valuable for project managers who are involved in the construction and implementation stages. In fact, due to lack of integration along the ISLC, the specifications database is often either overlooked altogether or collected again as if their creation earlier never took place. Moreover, standard methods for system analysis and development usually make no reference to methods for project management. Accounting and costing parameters, which are reviewed at the next chapter, are not represented not at SE tools or at PM tools, and handled in totally separated systems.

One conclusion that emerges from a thorough review of software engineering and project management areas is that SE tools are much more heterogeneous than PM tools. Gantt and Pert charts have become dominant project management modeling tools (Fox & Spence, 1998; Hughes & Cotterell, 2002) and are currently included in standard PM software such as Microsoft Project, PS-Next, and others. A survey of 1,000 project managers has found that 48.4% use MS Project, 8.5% use MS Excel, and the rest use Gantt/Pert-based tools from other vendors. The average satisfaction from PM tools in this survey was 3.7 on a scale of 1 to 5. Another survey reveals that only 10% of 240 project managers do not use PM tools at all, down from 33% in 1996. Moreover, more than 50% use Gantt/Pert-based project management software to manage every project, independently of its application domain and characteristics.

In contrast, the following two commercial CASE software packages demonstrate the heterogeneity of tools in the area of software engineering. Oracle's *Designer* supports functional hierarchy analysis based on Barker and Longman (1992) methodology, and IBM-Rational offers XDE-*Rose*, a modeling tool based on the unified modeling language (UML) only. PM tools thus seem more standardized and mature than CASE tools. This could be the reason why 71% of 397 software engineers surveyed in 20 European countries employ PM tools while only about 26% utilize CASE tools, despite similar levels of training (Domges & Pohl, 1998).

Although CASE tools, including those mentioned above, support teamwork, none contain elements that take into consideration teamwork planning, time planning, dependencies, resources allocation, cost estimation, or risk management. Moreover, none include Gantt or Pert models or offer built-in interfaces to PM tools. Methodologies and models for managing software projects have yet to make it from the idea to the product phase, despite persistent improvements in automated tools for requirement definition, systems modeling, and software engineering. The failure to transform project management theory to practice in the context of software development is especially troubling since more than 50% of such projects do not succeed (Madpat, 2005; Reel, 1999). In addition to the lack of integration between SE tools and PM tools managers in charge of software projects usually refrain from basing managerial judgement on data about requirements and functional characteristics of the specific development project (Reel, 1999).

With decades of systems development behind us, there is quite a consensus today with respect to the critical success factors (CSF) of system development projects and agile methodologies, there is still a need to introduce effective concepts, methods, measures, and tools for better control of software projects. All these observations lead one to conclude that assembling a repository of system requirements and system components, complete as it might be, does not guarantee effective planning of teamwork, scheduling of tasks, and controlling deviations between planned milestones and actual progress.

Against this background, the questions to consider are:

I. Is the gap between SE tools, costing methods, and PM tools is bridgeable?
II. Can SE components, collected by CASE tools, become directly available for the use of cost estimation, risk management, and directly integrated within PM without being subjectively interpreted or biased?
III. Is there a way to improve software modeling and engineering by introducing a managerial perspective in addition to the technical perspectives?

Our preliminary answers to those questions are "yes." This study proposes and prototypes a model that integrates these three aspects of software projects by automatically mapping SE objects and accounting–costing objects into PM objects. We have engaged in symmetry–isomorphism research with respect to distinct methodologies for software engineering and project management. Since Gantt chart is a technique for visual description of networks, the ability to convert DFD model or hierarchical use-case model to a network format is at the basis of our symmetry–isomorphism research. It is our intention in this article to demonstrate, based on this research, a possible integration scheme and provide more robust answers to the above questions. Given the wealth of CASE and PM tools, this work refrains from developing yet another one, but prototyping an integrated platform built-up of common CASE tool, costing models, and common PM tools. We show that combining these sets of capabilities can create the desired synergy where the whole is greater than the sum of its parts.

Costing Aspects and Methods

Detailed costing information is expected to include all types of costs that are required for manufacturing a product-software or providing a service. Data based on financial systems, which contain costs, derived from the income statement and the estimation of the company's capital and assets, enclosed the historical execution data and future estimations and forecasts (Roztocki & Needy, 1999). Williams (2004) supports the integration approach according to the conception that a modern accounting system is supposed to supply a framework for strategic management of the company's resources. In order to realize this conception, Williams proposes a multidimensional construct that clusters information from the company's systems on customers base, activity areas, and more for the purpose of forming an accounting system that facilitates planning, improvement and control, analysis and regulation of resources, and enhancement of profitability. Such a system is based on integrative information from a number of systems or from the arrays DW (data warehouse), BI (business intelligent) in five areas: costs, assets, quality/service, time, and outputs. The pioneers of the combining of financial and operational information are Cooper and Kaplan who developed the method of activity based costing (ABC) at the end of the 1980s. Cooper and Kaplan (1998) suggest in light of the technological development of information systems to define the integration between operational and financial systems for the purpose of building an accurate costing model.

In light of the above, establishment of integration conception required the definition not only of an enterprise costing model but also the definition of interfacing between the different areas and systems, that is, interface between SE aspects tools, financial aspects tools, and PM tools. Cost management is a term used for a wide description of short-term and long-term managerial activities involved in planning and controlling of costs (Horngren, Foster, & Datar, 2000). Table 1 presents variety aspects of costing model in a technological projects environment.

Costs analysis within the framework of technological environment must be carried out with the understanding of the project life cycle. Kerzner (2000) portrays the distribution of the project's cost over the project's life cycle:

- 5% - Conceptualization
- 10% - Feasibility study
- 15% - Preliminary planning
- 20% - Detail planning
- 40% - Execution
- 10% - Testing and commissioning

Tasks in each of these stages are described under the work breakdown structure (WBS). The WBS represents the required activities for the project's management in a hierarchical structure.

For each component of the WBS, an evaluation of direct and indirect (overhead) costs must be included. Direct costs are divided to work's cost (usually work hours multiple hourly rate) and direct costs that are not work payment such as travel, materials, and so forth. It is recommended that these costs will include managerial reserve as well (Jurison, 1999).

A reinforcement of the need to include the project's tasks (or the WBS components) in a costing model is intensified in the light of the cost estimations that are founded on work hours' evaluation. It has been argued (Ooi & Soh, 2003) that according to traditional approaches of software costing (time-based estimations), there may be a bending towards time planning without linking it to the specific task and the role player that performs it. Therefore, it is suggested to include the detailing of the tasks (Ooi & Soh, 2003) and/or an elaborate planning of the various project's resources as part of the costing model. The advantages of the resources' cost analysis throughout activities/tasks are more detailed information for managers, monitoring abilities, analysis of resources' cost and allocation, and a more accurate ability of overhead allocation (Jahangir, 2003; Kinsella, 2002; Ooi & Soh, 2003; Raz & Elnathan, 1999).

Indirect costs (overhead costs) include all types of costs that cannot be attributed directly to a specific task in the project marketing and sales expenses, office supplies, buildings' cost, professional services, information systems, computerization infrastructure, and the like. These costs are only occasionally incorporated in the project planning, but they carry great influence on the profitability of the portfolio and the projects' pricing decisions (Horngren et al., 2000). These costs are described as one of the "major headaches" (Kerzner, 2000). However,

Table 1. Aspects of costing model in a technological projects environment

	Aspect	Description	Difficulties
1.	**Planning**	Costs estimation of the project and for each resource in the projects portfolio	Defining direct and indirect resources and their costs
2.	**Controlling**	Costs analysis for each project and executed task	Attributing in-reality-costs to each project's task
3.	**Timeline**	Costs analysis over different time periods in planning and execution	Evaluating capacities of resources consumption over specified time periods
4.	**Tasks**	Identification and costing of project's tasks (WBS items)	Matching the costs to each of the project's components
5.	**Overhead Allocation**	A precise allocation of indirect costs	Determining the indirect cost generators in project's tasks
6.	**Risk management**	The inclusion of risk element and its value as part of the costing	Estimating risk on the basis of risk factors in the different tasks
7.	**Scenarios**	The ability to analyze alternative modes of action and costs	Defining assumptions and alternatives to the mode of cost's calculation
8.	**Profitability Analysis**	The understanding of the profit that derives from each of the projects and the whole projects portfolio	The inclusion of all the cost factors in the model

in this context, it has been argued that the ability to control costs is largely dependent on the monitoring of these costs.

Table 2 summarizes costing methods according to financial and engineering literature. The table also presents the common evaluation of model compatibility in light of entire costing aspects.

- **Analogy:** Cost estimation based on previous experience, using case-based reasoning (CBR) techniques. The accuracy of this method ranges from –10% to +25% (Kerzner, 2000).
- **Parametric:** Cost estimation based on heuristics and thumb's rules (Jahangir, 2003). Similar to the analogy estimation method, a parametrical model is also based on accumulation of historical data of project costs. On the basis of these data, a mathematical model is defined for the prediction of costs (Kinsella, 2002). The level of accuracy of a parametrical model ranges on a wide scope of –25% to +75% (Kerzner, 2000).
- **Function points:** A method that was first introduced in 1979 by Albrecht. Its objective is to assess the software system's size while using the user's requirements without direct dependence on the technological realization (Hale & Smith, 2001). The function points method is calculated in three steps using the quantity and complexity of the functional components and the system attributes (Kemerer, 1993).
- **COCOMO (constructive cost model):** The model was first introduced in 1981 and since then several modifications were made in order to suit fourth generation languages, decrease in hardware costs, increase in quality assurance (QA) levels, advanced and agile development methods. The current version, COCOMO 2.0 (Boehm, Clark,

Table 2. Costing methods according to financial and engineering literature

		COCOMO II	√	P	X	√	P*	√	√	X
Costing		Target Costing	√	P	P	P*	P	X	P	√
		Standard Costing	√	P	√*	√*	P	X	√	P
		ABC	√	P	P*	X	√	X	√	√

*√ - Good compatibility; X - No compatibility; P - Partial compatibility; * - Adjustments are required*

Horowitz, Madachy, Sclby, & Westland, 1995), is not based upon line of codes but on four submodels that match a spiral approach of software system development that are applied according to the stage of the life cycle (the application-composition model, early design model, reuse model, and post-architecture model).

- **Target costing:** Suits engineering framework in which there are several engineering activities simultaneously and is utilized as a means for costs strategic management. The idea behind the method is that a product's cost must be based on the sum that can be received for it in the market, and in other words, the development cost should be the basis for the quantity and mode of investment in the development rather than the development's outcome.
- **Standard costing:** Ascertains the cost framework while employing the amount of direct cost components and a standard price that was set for this unit. We shall formulate it concisely as:

$$TotalCost = \sum_{i-1}^{n} Qty_i * StdP_i \cdot$$

It should be accentuated that the standard price does not solely include the direct price of the component (price per working hour) and is intended to contain the meaning of the cost or the consumption of indirect resources (rent, computerization, etc.). In the calculation of the standard price, it is customary to rely on known performance data from the past (Horngren et al., 2000).

- **Activity based costing (ABC):** Considered one of the advanced models for predicting costs while incorporating managerial decisions. The model was developed in the 1980s and its main innovation is in the addition of nonfinancial elements to the costing model. The model is widely used in a variety of industries such as agronomy, banking (Kao & Lee, 2001), and medicine. In the projects area, there is not much literature that discusses the application of ABC; however, there are a few studies that help to understand the method. These studies include the description of the method for software developing and assimilation (Ooi & Soh, 2003), the portrayal of the mode in which ABC can be taken on in projects (Raz & Elnathan, 1999), the implementation of ABC in favor of IT cost analysis in the organization, and a recommendation to include this model in the project management body of knowledge, or PMBOK (Kinsella, 2002).

THE INTEGRATED MODEL

The integrated model is based upon former research (Gelbard, Pliskin, & Spiegler, 2002) that has mapped data flow diagrams, which are actually comprehensive enterprise sets of use cases diagrams reflecting entire system-software project into Gantt charts. Current research is focused on the following extensions:

- Extending the database schema, used as the integrated system repository, in a flexible way enabling the addition of any costing parameter to each of the DFD/use case/SE components.
- Adding specific manipulations and outputs in order to support presentation of costing aspects.

Mapping DFD/Use Case Objects into Gantt Objects

As suggested in former research (Gelbard et al., 2002), data flow diagrams as well as use case diagrams can be mapped into Gantt charts based on the following conversions:

1. Each of the external entities are represented once only for input (if they produce input) and once only for output (if they produce output).
2. Each read only (RO) data store and each read/write (R/W) data store are represented once only for input and once only for output.
3. Each basic flow appears once only in every Gantt diagram.
4. Each basic process appears once only in every Gantt diagram.
5. OR connections between flows are not represented in the absence of parallels in Gantt diagrams. Logical connection traits between flows can, however, be included within basic process characteristics, thus maintaining mapping completeness.
6. A general process is represented by means of a summary task, that is, a grouping of activities and flows under a general name.
7. General flows are those that connect between summary tasks.

Example: Mapping of Hierarchical DFD

DFD as well as use case methodology enable hierarchical analysis of systems. The hierarchical description is achieved by "blowing up" general processes-usages into dedicated diagrams. Those dedicated diagrams represent lower level descriptions and can be composed of basic pro-

Figure 1. DFD-0

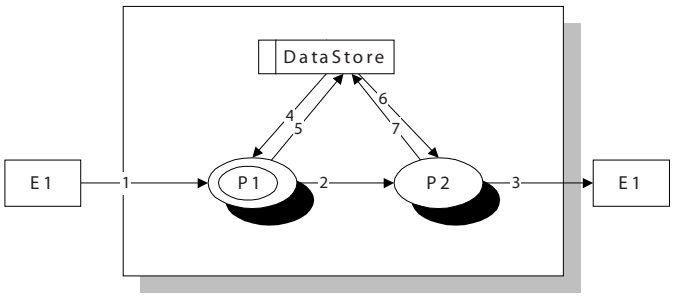

Figure 2. DFD-1 ("Blow-up" of General Process P1)

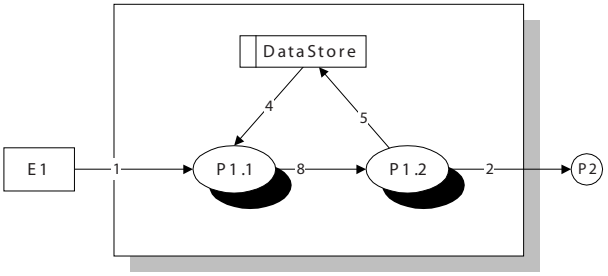

cesses, general processes, and of "includes" and "extends" use cases. The hierarchical description can be halted when there are no more general processes at the lowest-level diagrams. Except for the root level, identified as "DFD-0," each diagram in the DFD hierarchy is identified by the respective general function, and the same can be defined for use case diagrams. For the sake of simplicity, the DFD used in the examples below contains only the following objects: basic and general processes, flows, external entities, and data stores. Processes are symbolized by ellipses and denoted by **P#**, entities by rectangles and **E#**, and flows by arrows and **#**.

Figures 1 and 2 demonstrate a hierarchical DFD. Figure 1 describes the root level with Basic Process P2 and General Process P1 (a general process is depicted by concentric ellipses). Figure 2 describes a lower level description of the General Process P1.

A composite DFD, made up from both DFD-0 (Figure 1) and DFD-1 (Figure 2), is shown in Figure 3. A composite DFD, not a typical or common representation of a hierarchical DFD, is included here because of its similarity to Gantt diagram representation, where summary tasks and subtasks can be displayed on the same diagram. A summary task represents, in the mapping model, a general process, while each subtask represents a component at the respective hierarchical DFD level. As can be seen in the fourth section, Figure 6 depicts the Gantt diagram corresponding to DFD-0 in Figure 1, and Figure 7 depicts the mapping of the composite DFD in Figure 3 into a Gantt diagram.

Adding Costing Aspects

In order to enable location of any costing parameter to each of the DFD/use case models, we have used predefined symbols for each costing aspect. Noting a symbol with a numerical parameter beside it, in the "Label" input box at any "engineering" object dialog box, as shown in Figure 4, inserts relevant costing value (in light of the relevant costing aspect) to the relevant software component. A parser, running over the CASE repository, recognizes those predefined symbols and allocates the costing data in the integrated repository for further manipulation and interchanges. Overheads (indirect costs) inputs are made as labels of the entire project (the DFD-0 object itself).

Figure 3. A composite DFD representing both DFD-0 and DFD-1

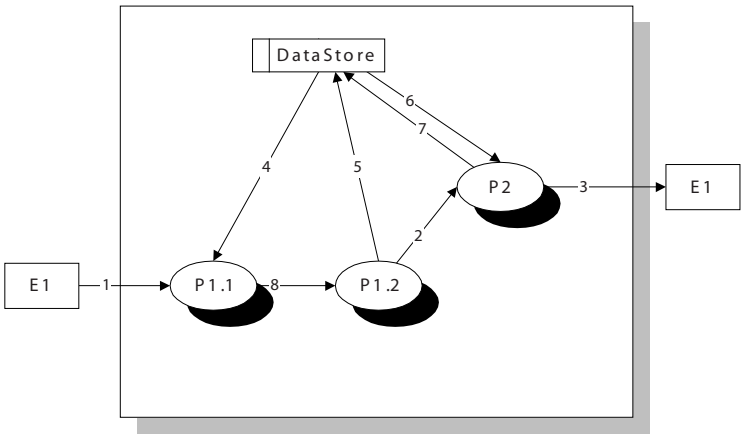

Figure 4. The "Label" input box used to insert costing aspects and values

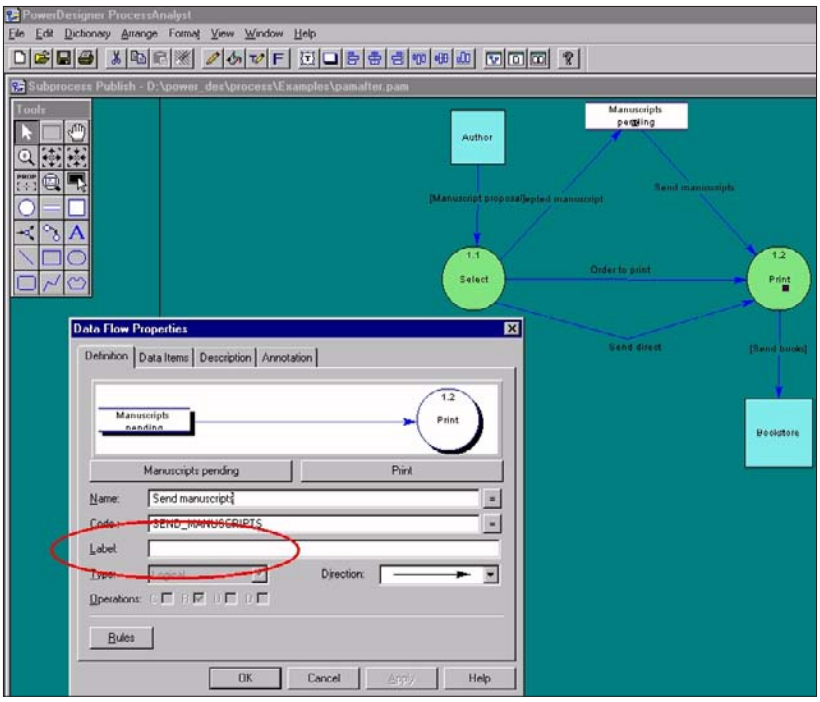


The Integrated Repository

As mentioned above, the database schema, used as the integrated system repository, was extended in a flexible way so it is possible to add any costing parameter to each of the DFD/use case/SE components. Figure 5 illustrates the integrated database schema, which supports engineering objects (DFD/use cases), PM objects (WBS and ascription of dependencies), and costing objects (costing aspects and values). The integrated repository contains three main components: SE components, PM components, and costing components.

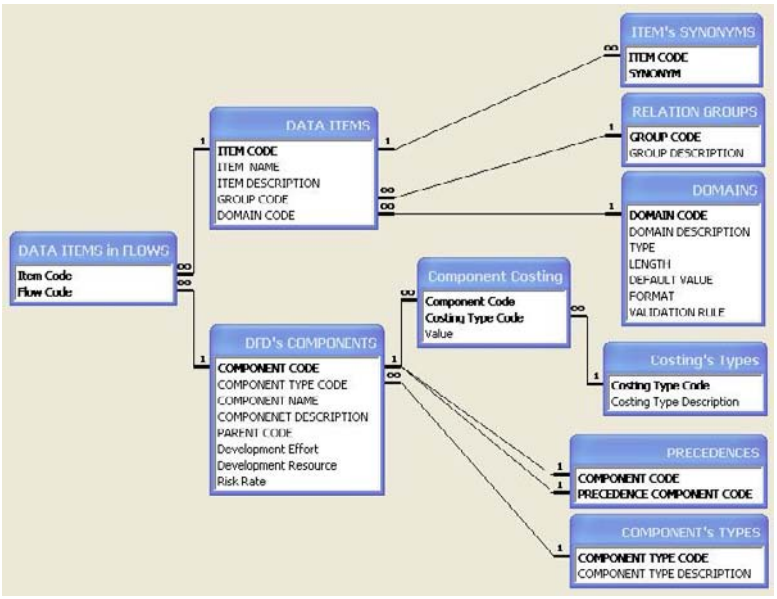
The SE component is based upon the following tables:

- Objects Dictionary = Tables: [DFD's COMPONENTS], and [COMPONENT's TYPES].
- Data Items Dictionary = Tables: [DATA ITEMS], [ITEM SYNONYMS], [DOMAINS], and [RELATION GROUPS].
- Ascription of Data Items to Basic Flows = Table: [DATA ITEMS in FLOWS].

The PM component is based upon the following tables:

- Ascription of dependencies between SE objects = Tables: [DFD's COMPONENTS], and [PRECEDENCES].

Figure 5. Database schema of the integrated repository



The costing component is based upon the following tables:

- Ascription of costing aspects and values to each SE object = Tables: [DFD's COMPONENTS], [Component Costing], and [Costing's Types]

In this way, those components enable representing and manipulating of DFD objects, costing aspects, and Gantt objects. The [PRECEDENCES] table stands for many-to-many network relationships as required for a Gantt representation.

In Figure 5, rectangles represent database tables, with the table name contained in the blue header and the primary key bolded. Lines between rectangles represent the database constraints (foreign key) and indicate the cardinality (one-to-many) of the relation. To distinguish between the various DFD/use case components, each component, in the [DFD's COMPONENTS] table, is attributed to a component type, defined in the [COMPONENT TYPES] table. The [Cocting's Types] table stands for the variety of costing aspects, while the [Component Costing] represents many-to-many relations between SE component-object and costing aspects. The specific value of costing aspect of the relevant SE component-object is stored in this table (in the [Value] field).

THE PROTOTYPE

Data flow diagrams where constructed by using the CASE tool "Power Designer; Process Analyst," and it is worth mentioning that the same can be done for use cases using the same tool. Costing aspects and values were referenced to each SE

component (see Figure 4). A parser while running over the CASE repository inserts accordingly the relevant records to the integrated database schema, as described in the third section and illustrated in Figure 5. Then, the prototype activates MS Projects and MS Excel, creating project Gantt charts (by MS Project), and project summation (by MS Excel). The following figures illustrate two kinds of outputs: "classic" PM outputs and costing outputs. "Classic" PM outputs relate to Gantt chart, while costing outputs relate to project summations.

"Classic" PM Outputs

DFD models shown in Figures 1, 2, and 3 were mapped into MS Project Gantt charts. Figure 6 displays the Gantt chart corresponding to DFD-0 in Figure 1, and Figure 7 displays the mapping of the composite DFD in Figure 3 into a Gantt chart. The Summary Task P1 in Figures 6 and 7 (line 10) corresponds to General Process P1, while subtasks of P1 are represented only in Figure 7. The P1 Summary Task has a distinct symbol with emphases at the edges.

Double clicking on line 10 "blows up" the summary task and displays its subtasks. Lines 11, 12, and 13 in the Gantt chart of Figure 6 are hidden because they are related to a lower level in the DFD hierarchy, DFD-1 (Figure 2). Lines 11, 12, and 13 in Figure 7 represent the DFD objects that are shown in DFD-1 (Figure 2).

Figure 6. Ms Project Gantt chart representation of Figure 1 DFD's objects

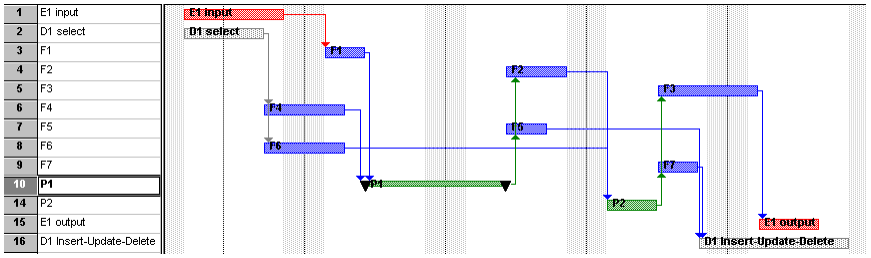


Figure 7. Ms Project Gantt chart representation of Figure 3 DFD's objects

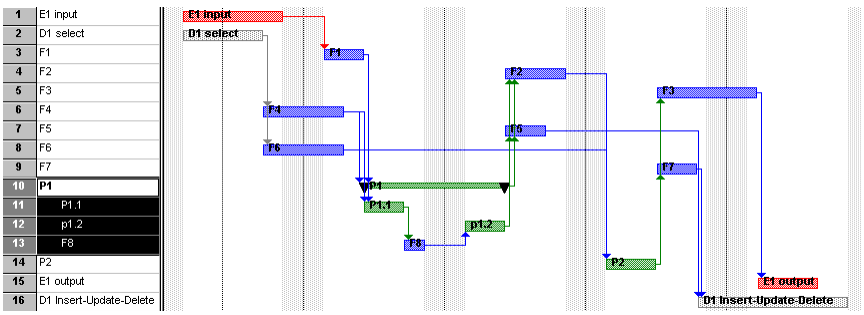

Costing Outputs

Costing aspects of risk and direct costs where constructed by using the "Label" input box (see Figure 4). A parser, while running over the CASE repository, inserts accordingly the relevant records to the integrated database schema and then activates the Visual Basic Excel module, which

WBS / Costing

has created a project summation accordingly. Hierarchical presentations were applied using built-in features of MS Excel.

Figures 8 and 9 illustrate hierarchical presentations of the same DFD models shown in Figures 1, 2, and 3. Figure 8 displays the summation corresponding to DFD-0 in Figure 1, and Figure 9 displays the summation of the composite DFD in Figure 3. The Summary Task P1 in Figures 8 and 9 (line 13) corresponds to General Process P1, while subtasks of P1 are represented only in Figure 9. The P1 Summary Task has a distinct background with "+" sign beside it.

Risk was assigned separately to time, budget, and functional aspects of each SE component-object. Direct costs are presented in units of months. Further calculation can be made according to parameters of salary rates and overheads, presented in the "costing" sheet.

Double clicking on the "+" sign beside line 13 "blows up" the summary task and displays its subtasks. Lines 14 and 15, in the Excel spreadsheet of Figure 8, are hidden because they are related to a lower level in the DFD hierarchy, DFD-1 (Figure 2). Lines 14 and 15 in Figure 9 represent the DFD objects that are shown in DFD-1 (Figure 2).

DISCUSSION AND CONCLUSION

Current research demonstrates the derivation of PM objects and project risk and costing evaluation, directly on the basis of raw SE components-objects. By this, we provide an integrating layer, which combines standard PM tools with common system analysis and design tools and costing aspects and models. Applying such an integrating layer in software development projects enables improved risk and cost estimations at the very beginning stages of a software project, as well as better monitoring and control over various topics uniquely related to software projects.

The integration model presented in this study has the following advantages:

1. The integrated model enables risk, effort, direct, and indirect cost estimation for software development to be an integral part of conventional analysis and design methodologies. This is due to the possibility of deriving assessments *directly from raw data stored at the repository of a CASE tool*, as opposed to relying on aggregates or other secondary sources.
2. The integrated model enables extension of the basic development time assessment beyond the mere aspects of time and direct cost *to include also risk, overheads, and any accounting-costing parameter.*
3. The integrated model bases the estimation process on the *very common management tools*, for example, MS Project and MS Gantt.
4. Use of Gantt charts enables *dynamic* control of the estimation, based on reports regarding *actual* progress. This provides for *projected-to-actual* comparisons of cost and *moment-to-moment* updates of CPM calculations, as opposed to the *static* control methods customary in the field of software development.
5. Use of Gantt charts allows *"drilling down,"* into the *system code design,* including master routines and system major service routines. This differs from current methods used for software development, which are limited primarily to the area of *functionality.*
6. The potential of a detailed drill-down concerning system code design provides for engaging and *integrating* the technical team (development managers) as early as the analysis stage. This results in a more *reliable* and *accurate* estimation base for the entire system development project.

It is noteworthy that conversion of a DFD model as well as of a use-case model into a Gantt chart is actually a representation of a knowledge model as a semantic network. We have reason to believe that

the integration of SE aspects and costing aspects within PM tools, modeled and prototyped in this study, is not limited to the DFD/use-case approach or to the described costing methods, but can be applied to any "network-based" software engineering modeling, as well as to any additional costing method. The fact that DFD conversion into Gantt chart is actually a representation of a knowledge model as a semantic network opens opportunities for commercialization for practitioners.

In sum, this study showed the feasibility and validity of converting SE objects and the risk and the cost we ascribe to those software components into PM objects. The integration of common CASE tools with costing models and standard PM tools can potentially improve estimation, planning, and control of software development projects in terms of cost, time, and risk management. In software projects, where so many things may go out of control, any theoretical as well as practical novelty is required in order to gain additional progress.

KEY TERMS

Activity Based Costing (ABC): A cost prediction model that has greatly improved the ability to predict a proper allocation of indirect costs among several activities and thereafter between many products. Before using this model, one has to appreciate and understand the overall business (including its production and marketing). The model is not always applicable: a cost-benefit analysis is necessary before a final decision is made.

CASE/AMD Tools: Software tools (Computer Aided Software Engineering), also named AMD tools (Analysis Modeling and Design), to assist entire System Life Cycle (SLC), including analysis phase, design phase, testing phase, and even

maintenance phase. CASE/AMD tools support the fuctional analysis phase using visual modeling notations, which can automatically convert into code.

COCOMO (Constructive Cost Model): An estimation method used to assess the human effort required for software development, which was first introduced in 1981, and since then several modifications were made in order to suit fourth generation languages, decrease in hardware costs, increase in QA levels, and advanced and agile development methods. The current version, COCOMO 2.0 (Boehm et al., 1995), is not based upon line of codes but on four submodels that match a spiral approach of software system development that are applied according to the stage of system life cycle.

Function Points: An estimation method used to assess the human effort required for software development, which was first introduced in 1979. Method objective is to assess the software system's size while using the user's requirements without direct dependence on the technological realization. It is calculated in three steps using the quantity and complexity of the functional components and the system attributes.

Gantt Chart: A popular type of bar chart that illustrates a project schedule. Gantt charts illustrate the start and finish dates (ES, EF, LS, LF) of entire project elements. Project elements comprise the work breakdown structure (WBS) of the project. Gantt charts also show the dependency (i.e., precedence network) relationships between activities. Gantt charts can be used to show current schedule status using percent-complete shadings and a vertical "Today" line.

Modeling Languages: Visual-graphical notations used to express functionality, processes, structures, behavior, as well as technical aspects of a system. Modeling languages are defined by a consistent set of rules, which are used for interpretation of those graphical symbols. Among modeling languages, in the software domain, there are data flow diagrams, used for hierarchical functionality decomposing; process diagrams, used for business processes modeling; entity relation diagrams, used for data structure modeling; and state transition diagrams, used for behavior modeling.

Target Costing: A cost prediction model that suits an engineering framework in which there are several engineering activities which take place simultaneously. It is utilized as a means for costs strategic management. The idea behind the method is that a product's cost must be based on the sum that can be received for it in the market. It is therefore the development costs which should be the basis for the quantity and mode of investment in the development rather then the development's outcome.

UML (Unified Modeling Language): A standardized visual-graphical notation gathering together diverse modeling diagrams, which are required in order to define entire software system aspects. UML is officially defined at the Object Management Group (OMG) by the UML metamodel, a meta-object facility metamodel (MOF).

Chapter 3.15
Developing Enjoyable Second Language Learning Software Tools:
A Computer Game Paradigm

City University, UK

ABSTRACT

This chapter attempts to examine computer game theories—ludology and narratology—that explain computer games as play activities and storytelling media. Founded on this theoretical explanation, a game model that incorporates gameplay and narratives is presented. From the model, two aspects of learning in the game environment are identified: gameplay-oriented and narrative-oriented. It is believed that playing computer games involves at least one of these types of learning; thus, this game's nature can be used in designing engaging educational software. In addition, based on Malone's theoretical framework on motivational heuristics, there are two methods of applying computer games in language learning: extrinsic and intrinsic, depending on the integration of game designs and learning materials. Then, two cases of language-learning games are scrutinized, using the game model, in order to demonstrate the use of computer games in language learning.

INTRODUCTION

In one of his most influential texts about computer games, *The Art of Computer Game Design*, Chris Crawford (1982) states that schools, but not games, are the untested fad and violator of tradition in education. Game playing is a vital educational function for any creature capable of learning. Hence, games are the most ancient and time-honored vehicle for education. Crawford

explores the reasons for people playing games and asserts that the fundamental motivation of game playing is to learn. He also cites an example to support his view by observing the behavior of lion cubs near their mother: the cubs crouch in the grass, creeping slowly toward a butterfly and pouncing on it. The beasts are apparently playing some sort of game and having fun. However, the game is also how lions learn to hunt their prey without being injured. They are learning by doing, with minimum risks. This observation is true not only for animals. Since the dawn of human history, games have been used in the teaching and learning process. Board games, for example, are believed to be the earliest games, and they were battle simulations designed to instruct the young (Murray, 1978).

The ability of computer games to spark interest among players can hardly be denied, and some educators have started to see the capability of these highly engaging games. People play games voluntarily, without asking for external rewards. Besides, the use of computer games in learning is parallel with Piaget's constructivism, in which knowledge is constructed instead of being transmitted. A lot of game-based learning projects have been carried out with an emphasis on this pedagogical epistemology. Nevertheless, most of these projects are centered in science education and mathematics. Not much theoretical work has been done on language learning, although computer games have long been used in this area. This is due to the fact that computer games are too varied and intricate to indicate a clear function in language education. Furthermore, what counts as a game is rather loosely defined. Therefore, a proper study of computer game theories would throw light upon this issue.

This chapter is structured as follows: First, we review the theoretical parts of computer games, which include ludology and narratology. Then, a theoretical model of game is proposed. The next section explains two kinds of learning that occur when playing computer games based on the model. We outline two methods of integrating game designs with language learning. Next, an analysis of two cases of language-learning games is presented. Then, we discuss the future direction of this study; and the final section concludes the chapter.

THEORETICAL REVIEW ON GAMING

Although the use of computer games in learning is gaining attention among educators, there is still a lack of theoretical understanding of the game itself in most studies. Recent literature reveals that the research of computer games falls into two major principles: ludology and narratology. Ludology focuses on the study of computer games as play and game activities, while narratology focuses on the study of computer games as stories. The views between ludologists and narratologists are generally contradictory; the former argues that the pleasure of playing games lies in the gameplay, while the latter treats narrative as the fundamental enjoyment players are experiencing during the play session. In computer games, gameplay is referred to as activities conducted within a framework of agreed rules that directly or indirectly contribute to achieving goals (Lindley, 2002). A narrative is an account of something that happens to someone (Barrett, 1997). It consists of a series of events, from the background setting to the completion of the game. In other words, gameplay is the actions taken by the players, while narratives are an account of these actions. In this section, several kinds of game rules are explicated to better comprehend gameplay. The narrative mechanisms of the game are also scrutinized.

Gameplay and Ludology

The term ludology first appeared in the text of computer game research in 1999. Gonzalo Frasca (1999) points out in his paper, *Ludology Meets*

Narratology: Similitude and Differences Between (Video) Games and Narrative, that another dimension has been almost ignored when studying computer games: to analyze them as games. He proposes the term "ludology" to refer to the discipline that studies game and play activities as opposed to narratives, and asserts that ludology should be independent from the medium that supports the activity. Frasca (2001) identifies two kinds of game: ludus and paidea. Ludus refers to the games whose result defines a winner and a loser, while paidea refers to the games whose result does not (Frasca, 2001). Based on this difference, Frasca introduces two types of game rules: paidea rules and ludus rules. Paidea rules are established to play the game as paidea, while ludus rules are established to win or lose the game. In chess, for example, paidea rules describe how each token moves, while ludus rules state a condition to end the match. It is noticed that we can easily switch from paidea to ludus and vice versa. In SimCity (see Figure 1) — a paidea game in which no explicit ludus rules are defined — players can engage in paidea by playing with the buildings. Once they establish a goal, say, to build a city with a population of 10,000, they immediately switch to a ludus activity. Not only can we have several paidea rules, we can also have several ludus rules. In chess, we can define the winner by counting the amount and value of each player's remaining tokens. Table 1 shows some examples of paidea and ludus rules in computer games.

Besides rules, ludologists are also keen on understanding gameplay. Jesper Juul (2002) proposes two types of gameplay based on the relationship between the rules of a game and the actual game sessions played. First is emergent gameplay, where a number of simple rules are combined to form an interesting variation of gameplay. In a game of emergence, the game structure is primitive and defined by a set of simple paidea rules with usually only one ludus rule. Chess, for instance, is a game of emergence. It has a set of paidea rules that define how each piece moves, and one ludus rule, which is to take the opponent's King. Driven towards this explicitly stated ludus rule, players might construct more ludus rules (such as to take the Knight) and plan for complicated strategies to achieve the goal. Second is progressive gameplay,

Figure 1. SimCity 4000 (courtesy Electronic Arts, 2003)

Table 1. Paidea rules and ludus rules

	Paidea rules	Ludus rules
SimCity (Paidea game)	If the crime rate is high, the population becomes low	Nil
Tetris (Ludus game)	If the blocks fill a layer, the layer is cleared	To keep the level of block as low as possible

Figure 2. Myst III (courtesy UbiSoft Entertainment, 2001)

where separate challenges are introduced serially for the player to solve. Most adventure games, like Myst (see Figure 2), fall into this category. Players are introduced, one after another, to ludus rules of goals to be achieved that lead to the attainment of the ultimate game goal.

Narratives and Narratology

For narratologists, the advent of the computer signifies the birth of a new medium for storytelling. The capability of computers is not limited to performing calculations; computers are a new medium to represent human activities and present narratives in an unprecedented way. In most modern computer games, players can naturalize their actions as the solving of a familiar type of problem (Ryan, 1994). In Myst III, the player needs to track down the villain; in Super Mario Bros. 3 (see Figure 3), the player is trying to save Princess Toadstool; and in SimCity, the player plays the role of the mayor and plans for city development.

Marie Ryan (2001) tries to understand narratives in computer games, and she proposes a definition of narrative based on mental images: A narrative is defined as a mental image, or cognitive construct, that can be activated by various types of signs. This image consists of a world (setting) populated by intelligent agents (characters). These agents participate in actions and happenings (events, plot) that cause global changes in the narrative world. Several useful terms are recognized in this definition: world, character and action, and we would like to know to what extent these exist in computer games. First, a game has a spatial representation, whether real or abstract. Espen Aarseth (1998) has claimed in the article *Allegories of Space* that computer games are essentially concerned with spatial representation and negotiation. Myst, for example, has a rich description of space represented with high-quality pre-rendered 3D images. The player recognizes the space immediately after entering the game world, and knows what and how they should act because it resembles a real social setting. Pong, on the other hand, represents an abstract space, which might not have a referent in the real world. Players might construct their own mental image about the game, though most players would probably relate Pong with table tennis. The space in Pong is symbolic, while in Myst it is narrative.

Figure 3. Super Mario Bros. 3 (courtesy Nintendo, 1988)

One thing in common is that these two worlds operate within a strict set of rules that define the mechanism of the worlds. Second, most computer games feature explicit characters who will interact with the world or the player. In Myst, the characters are descriptive, and players can interact with them as if they are real humans, although the interaction is limited to several chosen aspects. In Pong, even though it does not have an explicit character, the player is apparently playing against an opponent or intelligent agent. The character is not depicted graphically in the game world, but the existence cannot be overlooked. Third, all games involve active actions and reactions of the players. Games are usually discerned from linear narratives by the existence of interaction: the reciprocal actions between players and games. These actions include not only the action of the player, but also the autonomous actions of the characters in the game world.

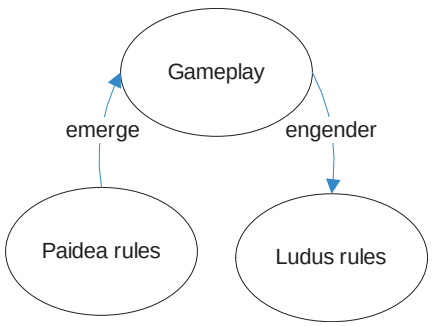
A GAME MODEL OF GAMEPLAY AND NARRATIVES

In this section, we propose a game model of gameplay and narratives that attempts to unify the view of ludologists and narratologists, thus advocating the study of computer games that comprises both gameplay and narratives. From the ludological perspective, we know that game rules are significant in understanding the semantics and structure of the game. Though they constitute a very important part of computer games, rules are not always the only thing one needs to learn in order to play. Game playing is more than simply memorizing the rules. Having learned the rules merely establishes the ability to play, and successful play does not necessarily require learning all the rules (Lindley, 2002). We need to understand something more complex that can arise from the rules: the gameplay. Examining the two types of rules and gameplay closely, it has been found that gameplay emerges from and must conform to the paidea rules that describe the semantic of the game. In addition, gameplay is oriented towards the ludus rules that describe the structure of the game. This relation is described in Figure 4.

Usually, paidea rules are fixed and predefined by the game designer. The player cannot breach paidea rules and their planning of strategies should conform to these rules. If the paidea rules state that the game character can only move forward and backward, the player can never move it upward or downward. Ludus rules are more flexible compared to paidea rules. The player may change the ludus rules and get involved in a different gameplay the game designer has intended, although the player might not be able to win the game. Gameplay emerges from paidea rules; but without ludus rules, there is hardly any gameplay. Paidea rules can be simple, but ludus rules can lead to complex gameplay. If players do not set the ludus rules while playing SimCity, the gameplay does not exist in the play session, because the players' actions are not oriented toward achieving a goal. In Super Mario Bros. 3, if players are only playing around with the world without having the intention to solve the level, gameplay does not exist, although the ludus rules are explicitly defined by the game designer.

If we view from the prism of narratology, it

Figure 4. A game model of gameplay and rules

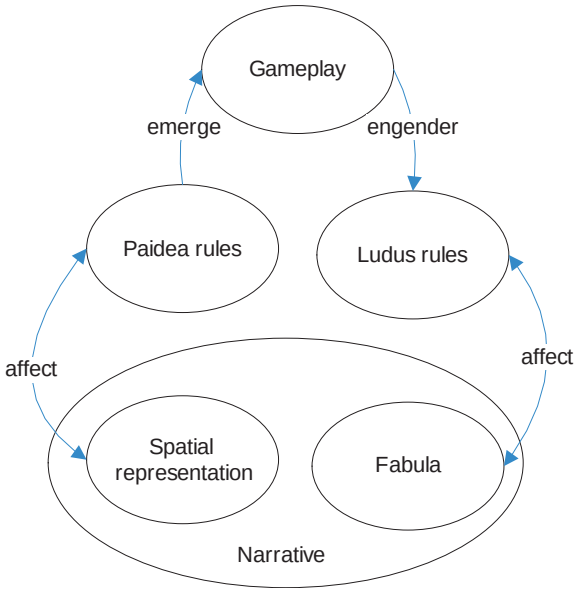


appears that games and narratives are quite similar, as computer games use narrative structures to organize their worlds. Nevertheless, games are not a mental image; they are a system defined by a set of concrete rules. Within this context, players can act freely as long as their actions conform to the rules. The chain of these actions can then be recounted in narrative discourse. In brief, the difference between narratives in computer games and linear narratives is that a linear narrative presents the facts in an immutable sequence, while a game presents a branching tree of sequences and allows the players to create their own story by making choices at each branch point (Crawford, 1982). However, there are sequences of events in games that do not become or form stories (like in Tetris). Therefore, not all games are interactive narratives; rather, some games can be interactive narratives, and these games can be used as a medium for storytelling. In fact, Frasca (1999) has attempted to relate paidea and ludus with narrative elements:

If ludus can be related to narrative plot, paidea can be related to the narrative settings. The ability to perform paidea activities is determined by the environment and the actions.

This statement is quite valuable in analyzing the relationship between rules and narratives in computer games. To perceive this subtle relationship, we would like to derive two narrative components from the narratological framework: spatiality, the space of the narrative; and fabula, the actions and events that might happen in the space. By applying these to the previous model, we have a more descriptive one (see Figure 5). The game space usually consists of compound worlds (Gingold, 2003). In most games, players travel through many locations, and enjoy the exploration of these multiple worlds and the movement between them. Compound worlds are collections

Figure 5. A game model of gameplay and narratives



of micro-worlds, which are governed by their own sets of paidea rules. These rules influence how the narrative world operates, while the movement of each world is marked by the changes in description and organization. Music, environment and, most importantly, rules change as the player moves between worlds. Ludus rules, on the other hand, are closely related to the narrative events in the narrative world. The player's actions are directly or indirectly affected by the ludus rules which, in turn, are changed according to the players' actions.

The relationship between narratives and gameplay is two-way. As narratives change, the rules become different. Evolving fabula can create new ludus rules, new sources of conflict and even new forms of gameplay. In fact, the best evolving stories can effectively change the rules of the game, something that probably would not be tolerated by a player lacking a story-driven reason. Rules in games need not be static. Narratives provide an explanation and meaning of the change of rules so that the virtual world is more believable. To exemplify this relationship, let us presume that Mario eats the mushroom and grows up in Super Mario Bros. 3. This event immediately triggers the creation of a ludus rule: to avoid being touched by monsters. It is very likely that in a certain point of the game, a monster will touch Mario and Mario will shrink. This event then again activates new ludus rules: to eat the mushroom.

THE GAME MODEL AND LEARNING IN COMPUTER GAMES

The game model that binds both gameplay and narratives reveals something about learning activities when players are engaged in game playing. In most modern computer games, the successfully playing of a game involves at least two types of learning: gameplay and the narrative. In this section, we look into these two aspects of learning in games and how we could use them in designing engaging learning software tools.

Gameplay-Oriented Learning

This relationship between rules and gameplay has a significant implication on designing pleasurable activities, such as learning. In the article *E-Learning as Computer Games: Designing Immersive and Experiential Learning*, e-learning software is interpreted as computer games, and several principles in designing interesting learning environments are outlined (Ang & Rao, 2004). If we look into the definition of paidea and ludus, it is not difficult to conclude that most conventional educational software is actually a loose type of game. It has paidea rules: Click the menu buttons and scroll the text with the mouse button, and so forth. Ludus rules are usually stated as the learning objective: to understand the concept of metamorphosis. Although the definition of game is much more intricate than just having these rules, this software could be seen as paidea or ludus games depending on the existence of an explicit goal. We are interested in investigating why it is not as engaging as commercial games with game rules.

The internal structure of a game can be characterized by its paidea rules, which can further be classified into two types: symbolic and semantic. Briefly, symbolic paidea rules explain the first layer of game interface — the input and output device interactions; while semantic paidea rules describe the narrative layer of interface. Obviously, the paidea rules of most learning software are symbolic, and do not impel learners to search for semantic meaning. The enjoyment of users should not be limited to symbolic paidea rules that define how users interact with computer devices. Learners should engage in gameplay by observing, hypothesizing, testing and updating the semantic paidea rules of the narrative environment. The pleasure of paidea should lie in the exploration of the virtual world and the discovery of paidea rules. Some learners find

some educational software interesting when they first play with it. They might have fun interacting with the mouse or keyboard. However, they soon will see through the mechanisms of the system: There is nothing more to explore. Besides, understanding the paidea rules does not let them plan for strategies to achieve the goal. Unlike Super Mario Bros. 3, where players play and observe the causality of their actions and the behavior of the spatial system, most learning software does not contain such qualities. The major "gameplay" of this software revolves around the reading of texts, since the paidea rules are oversimplified: Click and read.

The game designer not only has to design the paidea rules that define how games work, but also must define the goal of the game (ludus rules). We can further derive two kinds of ludus rules: micro and macro. Micro ludus rules contribute indirectly to winning a game, while macro ludus rules contribute directly. Computer games usually have macro ludus rules, which define the ultimate goal; while most micro ludus rules are either predefined by the game designers or created by the players during the play session. Oriented towards macro ludus rules, the player devises individual micro ludus rules in order to achieve the goal. For a game-based learning system, explicitly stated micro ludus rules can be important to scaffold learning. Micro ludus rules also function as guidance in the virtual world that steers players toward the learning objective. Learning objectives are presented as part of the narrative context. Instead of "to understand genetic configuration of animals," we can intrigue the learners "to defeat the monsters by breaking the genetic codes." Besides, this matches task-based learning, while each task is introduced as ludus rules.

Narrative-Oriented Learning

Narrative interfaces have been used in the game industry since its infancy and have successfully enticed a large portion of computer users for decades. Unfortunately, most educational software fails to take advantage of this highly effective design. Spatial design is obviously lacking, as most interfaces of conventional learning software adopt the metaphor of a book. The computer screen should not be a representation of a page of book, but a window to a new world. Learners look through the screen like through a window to a new spatial world of knowledge in which the images of real objects act coherently with virtual models (Morozov & Markov, 2000).

Like paidea rules, the interface of a game is doubled in an interesting way. First is the interface of the computer: the keyboard and the mouse. An additional interface is the narrative metaphor, which illuminates the narrative space in a new dynamic and interactive medium. The spatial design makes the first interface "disappear." Learners are not interacting with the keyboard or mouse, but with the story presented from the computer screen (Jaron & Biocca, 1992). Another issue pertaining to the spatiality of the software is that most educational software structures learning contents linearly, offers textual explanations and gives a particular spatial organization that does not reflect physical experiences. Learners should not regurgitate the context-free facts; rather, they expect to use knowledge in a contextually rich situation.

Apart from these, educational software does not offer narrativity to its users. There is hardly any action except for the clicking of menu buttons, which is hardly conceivable as stories. As Ryan (2001) has pointed out, players do not want to "gather points by hitting moving targets with a cursor controlled by a joystick"; they want to fight terrorists or save Earth from invasion by evil creatures from outer space. It is the same for learning software, which is also a type of game. Learners do not want to click the button to flip through the pages about genetics; they want to defeat monsters by analyzing and breaking their genetic codes.

LANGUAGE LEARNING AS EXTRINSIC AND INTRINSIC GAMES

We have elucidated two types of learning that might arise when playing a game. But how could these game designs be applied in language-learning software? Malone (1980) has propounded a motivational heuristic of educational games that comprises challenge, curiosity and fantasy. According to his interpretation of fantasy in computer games, two kinds of game design for learning are distinguished: intrinsic and extrinsic games. Intrinsic games rely on the understanding of the subject matter from within the game world, while extrinsic games rely on those external to the game world. Extrinsic games usually consist of a structured series of puzzles or tasks embedded in a game or narrative structure with which they have only the most slender connection. Intrinsic games build in challenges and activities that are more seamlessly integrated, more dependent on the narrative of the game. In brief, extrinsic games are used to attract users to learn a language, while in intrinsic games, the computer game itself becomes the learning activity. Therefore, the game design could be applied in language learning with two methods: the learning of the material as well as the learning of the game itself.

Extrinsic Game Learning

In extrinsic game design, the language learning is superimposed on the paidea rules of an existing game, resulting in new paidea rules. This may and may not engender new gameplay, depending on the quality of the bond between paidea rules and the learning material: Does the game world depend on the learning? In fact, this kind of game design is quite commonly used in language-learning games. Kana Warrior, for example, is a combination of first-person shooter and the learning of Japanese characters (Stubbs, 2003). In this game, the game world is dependent on the language skill. The player must improve in the language to make progress in the game. Often, extrinsic games are regarded as not as good as intrinsic games. They are somewhat the same as conventional e-learning software: Learners are not learning the paidea rules or the narrative of the system, but something external — the textual description of the subject matter. This is rather similar to reading books; we are not learning how the book operates, but the contents in the book. However, an extrinsic game could be effective in making some boring aspects of language learning interesting, such as rote learning of Japanese characters. The key factors that make game-based learning appear more interesting than typical e-learning software are its paidea rules and narratives. It is made enjoyable by binding paidea and ludus rules of computer games and language learning with narratives, creating an imaginary learning space that is engaging and immersive. It is very much like inventing a new form of book, in which every turning of the page yields a more interesting experience to the reader. The paidea is made fun, but it does not help the learning process.

Theoretically, almost every genre of games from the industry — racing games, board games, action games and so forth — could be used for this purpose. Extrinsic game design can be used to develop language-learning games for spelling, character recognition and vocabulary that require memorization and repetitive learning. Extrinsic design can be characterized as drill and practice, in which learning is context-free. Games-based learning has the potential for motivating drill and practice by offering an environment in which learners actually enjoy repetition. To fully utilize this design in learning, the following measures are suggested:

1. Investigate the type of game that target users enjoy. If learners get no delight in the particular genre of the game, it will not be successful in motivating them.
2. Allow learners to switch off the game in the middle of playing. Although the game is used totally as an extrinsic motivation to attract

learners, they might become interested in the subject matter and want to focus only on the learning content.

3. Provide strong narratives to create drama effect. Since the bond between paidea and the subject matter is rather weak, narratives are needed to reinforce the connection apart from creating drama effect.
4. The students must be familiar with the game's paidea rules. If the learner is unfamiliar with the game, the paidea rules must be simple so that the learning of paidea rules does not interfere with the learning of the subject matter.
5. Ludus rules must lead to the learning objective. Ludus rules should be stated distinctly and give guidance to the learner.

Narrative-Oriented Intrinsic Game Learning

Unlike extrinsic games, for intrinsic game design, learning contents are seamlessly integrated into either narrative or gaming mechanisms. Hence, intrinsic games provide two ways of learning as derived from the game model previously: narrative-oriented and gameplay-oriented. In narrative-oriented game design, players need to understand the virtual world, the event, the character and, most importantly, the story, in order to proceed. Like a book, the game mechanisms are trivial compared to the narrative mechanisms. The learning material is woven into the game as a story and, strictly speaking, the learning process is almost the same as for extrinsic games. Although the learning content is woven into a narrative context, the learning is explicit because the learners are shown the learning material in the form of text or graphics. Paidea rules merely define how learners should discover and read the material.

This differs from extrinsic game design in that it serves as a complete learning situation. This is most suitable characterized as a computer-based tutorial, in which information is designed to be presented in an effective and interesting way. Material is presented to the student in a narrative structure. This design is useful for learning the cultural aspects of a language by displaying pictorial or animated narratives of social settings, while reading skills could be fostered by exposing learners to textual narratives. In short, in this game design, the learning content or environment is designed as narrative, while paidea is for navigation. To fully utilize this design in language learning, the following measures are suggested:

1. Investigate what fantasy theme the target user is interested in. Narratives are crucial factors in this design. If the user does not like the fantasy theme the designer has chosen, it is likely that the design will be a failure.
2. The learning material is designed in the narrative context. The learning content is not presented as detached items of words or characters, but is connected to form a narrative.
3. The narrative should be able to stimulate the player to know what happens next. Curiosity is incited through the twist of narrative plots.
4. Goals are divided into several sub-goals to scaffold learning. Generally, the sub-goals are gradually presented to lead learners to the learning objective.
5. The control over the program is not as crucial as the control of the flow of the learning content.

Gameplay-Oriented Intrinsic Game Learning

In gameplay-oriented intrinsic games, players learn in a virtual world by interacting with the characters and events with languages. In this game design, paidea rules do not act as a simple interactivity that allows the player to discover predefined material. The learning material is embedded tactfully into the paidea rules of the

game. This is used as a game design that prevails, as it demands active experimentation rather than observation, of its subject material. It is also a way to explore, to test models and hypotheses, and to construct and acquire new knowledge in a way traditional media never can. At the extreme end of an intrinsic game for language learning, it would be a computerized conversation game. In fact, a project has been undertaken to develop a language training game in a fully 3D virtual world. The character in the game would be able to respond to what the learner speaks via Natural Language Processing Parser (Johnson, Marsella, Mote, Viljhálmsson, Narayanan, & Choi, 2004).

While in extrinsic games, the learning material is read and understood, in intrinsic games, the learning is experienced. In this design, the game designers — rather than implementing the material for the player to experience — implement a system of parts that come together to form the material in the hands of the player. This design can be used for subjects that require logical thinking, where information is not fact-based but rule- or process-based, such as the grammar of a language. It can be attributed to simulation. This simulation, however, is different from scientific simulations. This design is narrative and context-based, rather than simulating a scenario such as the lab experiment that is not relevant to real-life experiences. It provides an enticing problem-solving environment where students play an authentic role, exploring at will, creating their own ideas of its underlying structure and synthesizing strategies, which reflect their understanding of this structure. To fully use this design, the following measures are suggested:

1. The game should have explicit goals. Unlike scientific simulations, which have no goals, this design should provide clear and unambiguous goals.
2. It should have a narrative theme. This is true for three types of design; as, without narratives, the learner will be just manipulating words and alphabets.
3. The games should be able to stimulate the player to know more about the mechanism of the system by giving clear feedback.
4. The control over the program is crucial. The interaction will determine how the learner observes and infers the rules of the system,

Table 2. The summary of extrinsic and intrinsic game design

	Extrinsic	Intrinsic	
		Narrative-oriented	Gameplay-oriented
Paidea rules	Paidea rules are loosely linked with learning contents	Paidea rules define the navigation of learning contents	Paidea rules define the construction of learning contents
Ludus rules	Fictional learning objectives	Fictional learning objectives	Fictional learning objectives
Narrative	Narrative has little or no connection with learning	Narrative provides a context and contents for learning	Narrative provides a context for learning
Learning	Explicit, Context-free	Explicit, Context-based	Tacit, Context-based

which are also the subject matter.

Table 2 is the summary of game-based learning design.

AN ANALYSIS OF GAME-BASED LANGUAGE LEARNING WITH THE GAME MODEL

In this section, a theoretical view of games in computer-based learning is elucidated based on the game model and method of game-learning integration illustrated in the previous section. Two case studies are presented to demonstrate the implementation of "Slime Forest" in learning Japanese language, as well as how "Alien Language" is used for learning English, Spanish, French and German.

Case Study: Slime Forest

Slime Forest is a game similar to a role playing game (RPG) created to teach three sets of kana (Japanese characters). This is a summary of

Figure 6. Screenshots of Slime Forest (courtesy http://lrnj.com/sfa)

(a) the world map

(b) dealing with one Japanese character

(c) dealing with a katakana word

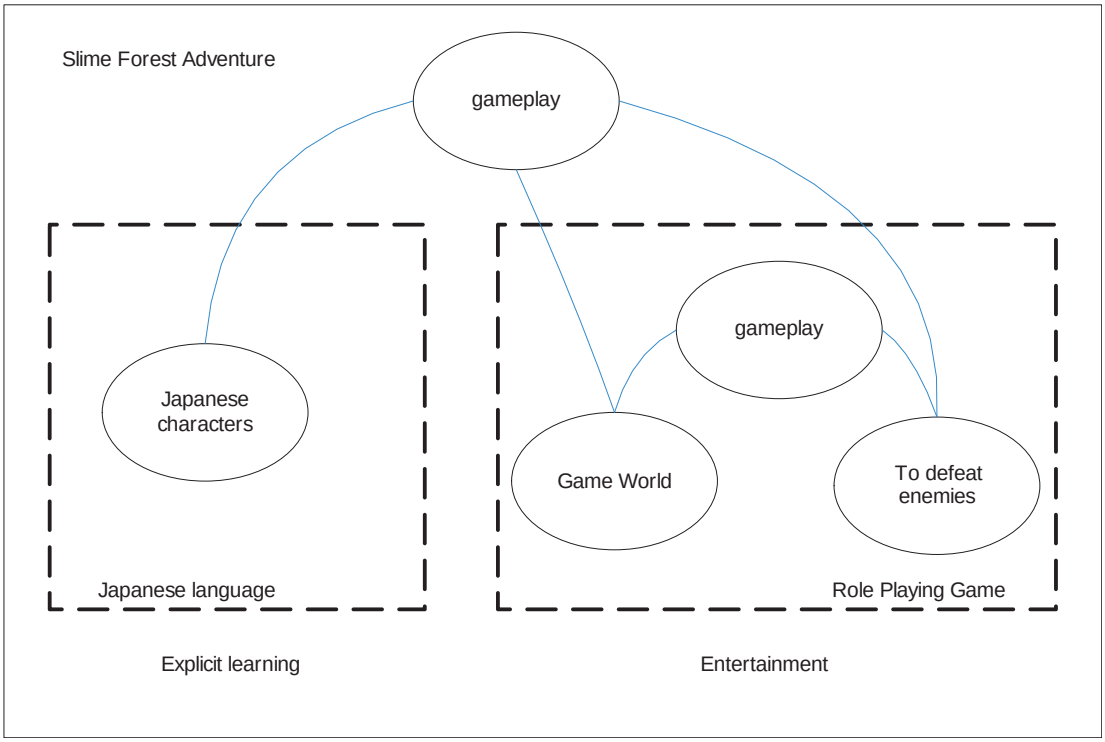
Slime Forest:

The game starts in a cave where the player is required to venture into the world outside to sell potatoes. The player will then be assigned, one by one, several sub-tasks and fight slime monsters in the forest to accomplish the tasks.

The game features two complete sets of hiragana and katakana, and 200 kanji, the Chinese characters. The aim of this game is to create a learning environment that provides a fun way of memorizing these characters, which are usually learned in a classroom via rote learning. In addition, players are also expected to learn some words borrowed from non-Chinese foreign languages, written in katakana. The instruction of the game is in English; therefore, this game aims at English speakers who wish to learn the Japanese language.

Basically, there are two types of activities: the world, and the battle in which the learning takes place. In the world map, the player plays a role of the game protagonist and explores different locations, such as the cave and the castle. The player needs to gather information about various missions by talking to people in the game. In the forest, the player will get involved in battles to fight slime monsters by typing the Romanized pronunciation of a particular kana that appears on top of the monster. If it is answered correctly, the player gains a chance to attack. Actually, the ultimate goal of this project is to design a game for everyone, even for those who are not interested

Figure 7. Theoretical view of Slime Forest



in learning Japanese.

We would like to examine the game and learning using the theoretical model of gameplay. Based on the definition of paidea and ludus, one can make learning Japanese a form of game by simply adding ludus rules; say, "Those who manage to write down 10 kanas the fastest win the game." In Slime Forest, users are more eager to learn the language because they have an interesting goal in mind: to kill the monsters, so they can progress in the game. However, adding ludus rules to a boring activity merely reduces the boredom. This form of game is not fun enough to engage learners for hours. What would have happened if the rules of "Who Wants to be a Millionaire" were reduced to answering the questions and wining $1 million without the "safe havens," "lifelines" and so on? Apparently, extra paidea rules are added to make the game really interesting.

It is noted that without the learning part, the game is a complete RPG game system (see Figure 7). The learning of Japanese characters is integrated, though in a loose manner, with the paidea rules of the battle system, resulting in a new form of gameplay oriented toward the ludus rules of the RPG. Besides, the integration of language learning and entertainment would not have been successful if not for narratives. The narrative in Slime Forest has at least two functions: to introduce fantasy learning goals (to fight monsters and save the princess) and to project the game as a complete virtual space with characters and events that retain the learner's interests. The narrative gives an explanation why players have to perform certain tasks. It is unlike certain educational software, in which the user is rewarded with a game playing session after completing learning tasks. By applying a well-integrated narrative, the learning and the game are bound together. Narratives also increase the urgency that pushes learners to complete the learning tasks.

It is concluded that the RPG game used in Slime Forest serves only as an external motivation. The integration of game and learning is extrinsic. It by no means aids the users in understanding the language. Some educators argue that games should not be used merely as means to motivate students to learn, and that play and learning must be mutually constitutive (Jenson, 2002). Indeed, learning should be made self-motivating, so learners are willing to learn it voluntarily. However, we should realize that not all aspects of language learning are internally motivating. Some are boring and difficult, and we need to help learners learn. In fact, if the learning was motivating, people may have learned them on their own and we probably need not put them in the curriculum (Prensky, 2001).

Case Study: Alien Language

Alien Language is a game distributed over the Internet used to support the teaching of "parts of the body" in four modern languages: English, French, Spanish and German. This is a brief summary of Alien Language:

The aliens are on a mission to collect creatures from around the galaxy for the alien zoo. You need to help them transport the creatures, label the specimens and cure the sick aliens.

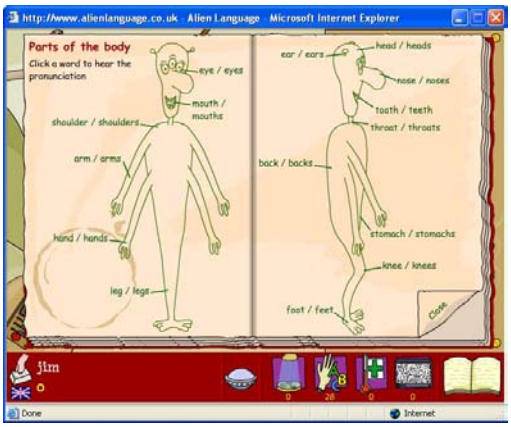
The motivation of this project is to create supplementary material for foreign language education based on a particular topic. The key aspects of language learning — spelling, grammar and sentence construction — are the focus of this project. The game can be used in many different combinations; for example, learning English for German speakers, learning Spanish for French speakers and so forth. It assumes that learners have known the basic vocabulary and sentences on the target language. However, if they need help, they can get a translation of the game instruction in their native language by pressing the control button.

Basically, the learners have three major tasks.

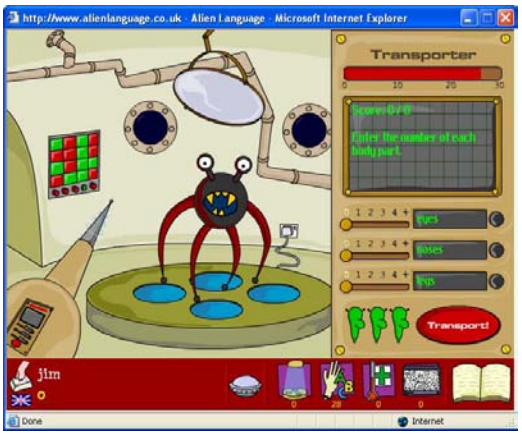
First, they need to record the number of each body part the alien has and transport it to the alien zoo. Second, they will label the specimen in the museum by typing the name of a body part. Third, they need to construct sentences from a set of given words to identify the medical condition of the alien. The game includes a trivia game — resembling the popular "Who Wants to be a Millionaire" game — that tests the understanding of the learners. It also contains a simple dictionary of body parts.

One of the best ways of learning a language is to use it in daily life. When interacting with people, we are actively receiving what people say, reflecting the meaning in our mind and constructing sentences. Different ludus rules could be introduced to create different scenarios to the language learning environment, hence, creating a game-like learning activity. If we examine Alien Language with the game model, we could see that the learning is designed to be part of the paidea rules. Take the hospital activity, for example: It is actually a micro version of a real-life conversation environment, where the player constructs

Figure 8. Screenshots of Alien Language (courtesy www.alienlanguage.co.uk)



(a) the dictionary

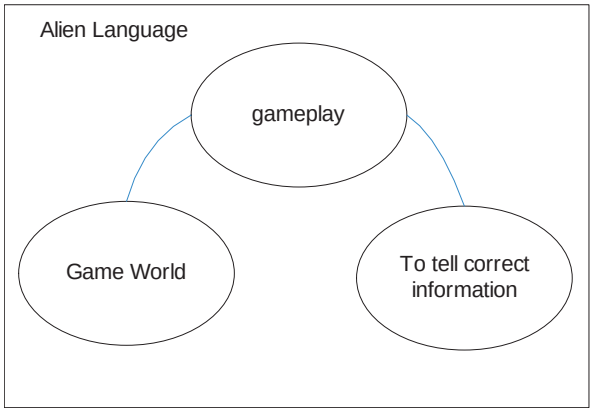


(b) the transporter

(c) the body museum

(d) the hospital

Figure 9. Theoretical view of Alien Language



sentences from words, although the sentence construction activity is far less complex than the real-life conversation.

Figure 9 shows a similar gameplay model as shown in the previous section. No external learning material is imposed to this internal structure of game. The paidea rules of the game are, in fact, the grammar rules that the player needs to learn in order to proceed in the game. Predefined ludus rules exist for each activity: to construct a meaningful sentence based on a given context, to construct the word and to count the number of each body part correctly. The use of narrative is also obvious in this case. The game projects a fantasy space with imaginative characters. This creates a more experiential learning environment, as the learners are put in a role within the narrative space. The design is coupled with narrative so the learners are not just manipulating the words and grammar rules, but are solving context-based problems and overcoming challenges.

Unlike Slime Forest, the learning happens in Alien Language itself. The players learn to play the game, and at the same time, they learn the language. The learning happens internally in the game, as the learning content is an integral part of the game structure. It is a gameplay-oriented intrinsic game design. Instead of learning something external to the game, the learner of Alien Language plays an authentic role and carries out interesting tasks.

Cross-Case Analysis

The two cases are examined together to find out what elements differentiate them and what they have in common. The observation is done from two perspectives: ludology and narratology, to derive something about computer game designs for learning. First, it is noted that even if the language learning part is removed from Slime Forest, the game is still a complete RPG on its own. The language learning is superimposed on the paidea rules and can be easily changed to something else, such as answering mathematics questions. Therefore, paidea rules of the RPG are used to attract learners into the learning environment. For Alien Language, however, this is quite different, since

the paidea rules are actually designed specifically for language learning. The learning contents cannot be swapped without significant modification of the fundamental structure of the game.

Second, both have clear and explicit ludus rules that bring about gameplay. The learning objectives are not stated explicitly as the learning of a language. Although both games use fantasy goals, such as defeating monsters and transporting aliens, the goals will eventually lead to language learning, since without leaning the specific language, the goals can never be achieved. Third, both games make full use of the narrative metaphor in designing the user interface. The games are designed as a fantasy world with narrative events. They also feature explicit characters that interact with learners to provide challenges: a fantasy narrative explanation of ludus rules. Some characters in Alien Language also give guidance to the learners regarding language contents. Actions taken by the learner in the game are conceivable and can be recounted as narratives. The following table summarizes the case studies.

DISCUSSION AND FUTURE DIRECTION

By studying ludology and narratology, we are able to derive something on how these theories are useful in designing language-learning software applications. It is maintained that computer game theories provide a better framework for designing language-learning software tools, making the experience of learning more immersive and engaging. Computer game-based language learning is expected to be better than its traditional counterpart from two perspectives: learning effectiveness and motivation. It is more effective in the sense that knowledge is constructed instead of being transmitted, especially for intrinsic game designs. It is also motivating, where it challenges the learners, intrigues their curiosity and brings about fantasy. However, an empirical study needs to be conducted to verify the advantages, and these results should help guide designers of educational games to consider how to effectively balance the demands of motivation and learning. Moreover, implementing game-based learning in light of language education needs detailed studies on the

Table 3. Summary of cross-case analysis

	Slime Forest	**Alien Language**
Paidea rules	The learning material is loosely incorporated as part of the paidea rules of the RPG	The paidea rules are carefully designed based on the target languages
Ludus rules	Ludus rules are fantasy objectives, which are not related to the learning (killing monster has nothing to do with learning Japanese)	Ludus rules are fantasy objective, which are related to the learning (reporting illnesses is related to languages)
Narrative	Like paidea rules, the narrative serves no purpose in the learning. It merely makes the game appear more interesting.	The narrative presents a context in which learning takes place.

nature of language learning, which could be approached from linguistics, psycholinguistics and sociolinguistics. Each of these fields seems to pose an insightful view of language acquisition from different stands. We believe that the understanding of how a language is acquired and learned, either by an infant or an adult, might open up a new door for a more novel use of computer games in language learning.

SUMMARY

We have analyzed two educational games from the perspective of ludology and narratology that explain two important types of game design in language-learning applications. In Slime Forest, computer games are used to attract the learner to learn a language aspect, while in Alien Language, the computer game itself becomes the learning activity. By analyzing both cases with computer game theories, we are able to understand them more closely, and thus derive a better principle of designing learning software based on computer games. Both extrinsic and intrinsic games are suitable for language-learning designs, although the latter is more desirable. It not only creates an engaging learning environment, but also an experiential one in which learners experience the knowledge first hand instead of being told.

Chapter 3.16
VIPER:
Evaluation of an Integrated Group VoiceIP Software Application for Teaching and Learning in Higher Education

John Beaumont-Kerridge
University of Luton Business School, UK

ABSTRACT

Recent developments producing new Internet conferencing (IC) and multipoint desktop conferencing (MDC) systems have emerged, which may supersede text-based and audio/video conferencing (AVC) software. The newer IC or MDC systems also integrate interactive tools and have the advantage of operating at a fraction of the cost when compared to AVC systems. Communication by face to face methods are important within the learning process, but can online methods that incorporate sound, video, and integrated online tools be as effective? AVC systems within higher education (HE) have been available for some time although the quality of such approaches, however, has been open to question. This chapter evaluates an exploratory study of one MDC application, "Voice Café," in a higher education, business school setting. For commercial distinctiveness, the academic application of this software was called "VIPER" (voice Internet protocol extended reach). Consideration is given to the software itself in terms of its features, pedagogic aspects, and how students and faculty viewed its use.

INTRODUCTION

Recent developments producing new Internet conferencing (IC) and multipoint desktop conferencing (MDC) systems have emerged over and above the text-based discussion and audio/video conferencing (AVC) software. The major differences of the newer IC or MDC systems are the integrated use of interactive tools and their advantage of operating at a fraction of the cost when compared to the AVC systems. Communication

by face-to-face methods is important within the learning process, but can online software that incorporates sound and video and interactive tools be as effective? AVC systems within higher education (HE) have been available for some time. The quality of such approaches, however, has been open to question when compared to face-to-face methods (Knipe & Lee, 2002). Compatibility issues exist between competing AVC commercial providers, which have limited deployment, they are relatively expensive, and disagreement has also been voiced about how AVC should be used (Laurillard, 1993; Mason, 1998).

Easy access to education is not available for everyone. As a result, pressure is upon teaching providers to develop different methods of communication to extend the "reach" from an institution to students. Computer conferencing using text-based systems is widely used within online courses although learners and tutors have noted problems (Cartwright, 2000; Harasim, 1997; Salmon, 2000).

This chapter evaluates an exploratory study of an MDC application, "voice café," in a higher education, business school setting. For commercial distinctiveness, the academic application of this software was called "VIPER" (voice Internet protocol extended reach). Consideration is given to the software itself in terms of its features, pedagogic aspects, and how students and faculty viewed its use.

VOICE CAFÉ AND VIPER

The business school became aware of the voice café software at the beginning of 2004. It was initially evaluated as a useful means of improving communication for staff, students, and between partner institutions. It was initially applied to the overseas MBA program. Because of the "newness" of this software and the alacrity of HE providers to search out new methods of communication, it was decided to call the academic application of this software "VIPER," short for voice Internet protocol extended reach. Figure 1 shows a screen shot of the VIPER, which has the following features:

1. **Voice to voice capability over analogue telephone modem:** For a participant to speak, similar to a "walkie talkie" participants depress the F9 or ctrl button continuously for others to be heard. Either speakers or headphones can be used with a microphone needed for speech. Important, however, was the feature that communications took place over an ordinary telephone line and a broadband connection was not needed, helpful for connections in many parts of the world do not have the advantages of broadband. The minimum requirement for the software was 33kb, which is well below the normal analogue telephone connection speed of about 40- 50kb, although in some countries speeds as low as 26k were recorded.
2. **Up to 25 synchronous connections:** The version used provided up to 25 simultaneous connections, although up to 500+ are possible. One connection could be one person, a group in front of one computer, or a computer in a lecture theatre. Where there was more than one person, a suitable screen or projector was needed, as well as speakers and a "moderator" to control the computer to allow for a full dialogue to take place.
3. **Browser capability with "follow me" functions:** The ability to combine voice and browser capability proved to be a most powerful feature. Not only could Web sites be accessed, but also materials for presentation within discussion could be viewed. The PowerPoint™ "publish and save as Web page" function proved to be most useful because of its ease converting PPT files to HTML files, which also provided an index

within the conversion process.

4. **"Hands Up" functions:** Due to the absence of a video of the student, the tutor is not able to "see" if a student wishes to ask a question. The hands up facility is activated by the student using the right mouse button over the participants icon and the five options of (a) ask a question, (b) make a statement, (c) thumbs up image, (d) thumbs down image, or (e) never mind. The last function enables the user to reset this feature. Activating this provides a small icon for each of the items (a) to (d), which is viewable by all. There is also an overview screen that lists who is waiting to ask a question or make a statement, and a sum total of "thumbs up" or "thumbs down."
5. **Text chat, group and private:** Two text chat facilities are available, group and individual. The former allows all participants to see the posted messages, which can be saved in either a text or HTML format. The individual messaging allows only the participant and tutor to see the message.
6. **Interactive whiteboard:** This tool was interactive for all participants with a standard palette for the variety of drawing tools available. One interesting feature was the ability to "capture" a browser image for interactive use with students. In addition, as would be expected with software such as this, browser compatible images could be loaded from the desktop.
7. **Tutor video out:** Albeit a frame rate of some 24 frames per second, only one image is available of the tutor and this all participants can see. The default size of the image is 150x150 pixels, although this can be enlarged. The minimal video capability was, however, one of the reasons for the very low bandwidth requirement. This was essential for operation in some parts of the world where it was known that only analogue telephone over poor standard lines would be available. In addition, it was noted early on that once the video had been set up, and a tutor's image was available, it could then be paused further decreasing the bandwidth requirement.
8. **Installation and network requirements:** The voice café software operates on the client PC via a "plug in" on Internet Explorer™ v6.0 or later browser software. It requires a PC with at least a Pentium III equivalent, appropriate memory, hard drive, mic, and headphones or speakers. Functionally it worked via servers in the U.S. and Australia. Installation took about three minutes on a broadband connection, but 30 minutes on a dialup. This was, however, a once only operation unless the software was updated, which was automatically sensed by the installed program. Setup in the home environment did not generally meet with problems unless the PC specification was below specification. Setup in an office or college environment, however, was more problematic due to the need for firewall ports required opening (9500 to 9509 outgoing traffic only). The major difficulty under these circumstances was being able to contact the appropriate member of staff. In almost all instances, once the network member of staff was contacted any communications' problems were resolved in a matter of minutes. What often caused the delays, often days or weeks, was the difficulty of contacting the member of the network staff.
9. **256 bit security encryption:** Previous experience by voice café designers were commercial considerations of confidentiality and outsiders "listening in" to conversations and documents under consideration. Although not tested, the software boasts this high level of security. The only drawback with this, however, was the inability to enter and show in the browser Web sites that required

a username and password for access.

10. **Management functions:** The moderator has mute, boot, and banish functions if needed. Userful also was the ability to use multiple usernames and passwords, that is, one cohort could be assigned one username and password. This enabled a much easier management of student and staff access.

Pedagogic Considerations
