than CT scanning for the detection of hepatic metastases. For rectal cancer, pelvic MRI or endorectal ultrasonography provides important accurate information about the depth of penetration of the cancer through the rectal wall and pararectal lymph nodes that may guide preoperative (neoadjuvant) chemoradiotherapy and operative management. A chest CT scan should also be obtained because the systemic blood supply of the distal rectum may promote distal tumor metastasis outside the abdomen. PET is useful to determine recurrent colorectal cancer but currently is not used for staging of primary tumors.

► Staging

The TNM system is the commonly used classification to stage colorectal cancer. Staging is important not only because it correlates with the patient's long-term survival but also because it is used to determine which patients should receive adjuvant therapy.

► Differential Diagnosis

The nonspecific symptoms of colon cancer may be confused with those of irritable bowel syndrome, diverticular disease, ischemic colitis, inflammatory bowel disease, infectious colitis, and hemorrhoids. Neoplasm must be excluded in any patient over age 40 years who reports a change in bowel habits or hematochezia or who has an unexplained iron deficiency anemia or occult blood in the stools.

► Treatment

Resection of the primary colonic or rectal cancer is the treatment of choice for almost all patients who have resectable lesions and can tolerate general anesthesia. Multiple studies demonstrate that minimally invasive, laparoscopically assisted colectomy results in similar outcomes and rates of recurrence to open colectomy. Regional dissection of at least 12 lymph nodes should be performed to determine staging, which guides decisions about adjuvant therapy. Even patients with extensive metastatic disease may benefit from resection of the colonic tumor to reduce the likelihood of intestinal obstruction or serious bleeding.

For rectal carcinoma, the operative approach depends on the level of the tumor above the anal verge, the size and depth of penetration, and the patient's overall condition. Clinical staging by endorectal ultrasound or MRI with endorectal coil is important in guiding the clinical approach. In carefully selected patients with small, mobile (< 4 cm), well-differentiated T1 or T2 rectal tumors that are less than 8 cm from the anal verge and that appear on endosonography to be localized to the rectal wall, transanal excision may be performed. This approach avoids laparotomy and spares the rectum and anal sphincter, preserving normal bowel continence. All other patients will require either a low anterior resection with a colorectal anastomosis or an abdominoperineal resection with a colostomy, depending on how far above the anal verge the tumor is located and the extent of local tumor spread. Careful dissection of the entire mesorectum at the time of surgery

has been shown to reduce local recurrence to 8%. With improvements in surgical stapling techniques, it is possible to perform low anterior resection provided there is a margin of at least 2 cm of normal tissue below the tumor. Although low resections obviate a colostomy, they are associated with increased immediate postsurgical complications (leak, dehiscence, stricture) and defecatory complaints (increased stool frequency, defecatory problems, and incontinence). With unresectable rectal cancer, the patient may be palliated with a diverting colostomy, laser fulguration, or placement of an expandable wire stent.

A. Adjuvant Therapy for Colon Cancer

Adjuvant chemotherapy and radiotherapy have been demonstrated to improve overall and tumor-free survival in selected patients with colon cancer.

1. Stage I—Because of the excellent 5-year survival rate (90–100%), no adjuvant therapy is recommended.

2. Stage II (node-negative disease)—The expected 5-year survival rate is 80%. A benefit from adjuvant chemotherapy has not been demonstrated in most controlled trials for stage II colon cancer (see discussion for stage III disease). However, otherwise healthy patients with stage II disease that is at higher risk for recurrence (perforation, T4, poor differentiation on histology) may benefit from adjuvant chemotherapy.

3. Stage III (node-positive disease)—With surgical resection alone, the expected 5-year survival rate is 30–50%. Postoperative adjuvant chemotherapy significantly increases disease-free survival as well as overall survival by up to 30% and is recommended for all patients. In stage III colorectal cancer, patients treated for 6 months with intravenous 5-FU and leucovorin (folinic acid) who have one to three involved nodes have a 5-year survival of 65%, and those with more than three involved nodes have a 5-year survival of up to 40%. Capecitabine is an oral 5-FU analog that obviates the need for intravenous infusions. Monotherapy with capecitabine yields a similar rate of disease-free survival with a lower rate of serious side effects (except for hand-foot syndrome) compared with intravenous 5-FU and leucovorin. Oxaliplatin is an important addition to combination adjuvant therapy. Large, well-designed studies of adjuvant therapy for stage III colon cancer reported a higher rate of disease-free survival at 5 years for patients treated with a combination of oxaliplatin, fluorouracil, and leucovorin (FOLFOX) (66%) than with fluorouracil and leucovorin (FL) alone (59%). The addition of oxaliplatin is associated with an increased incidence of diarrhea and sensory neuropathy, which generally is reversible. Based on these studies, FOLFOX currently is the preferred adjuvant therapy for most patients with Stage III disease. Current studies are evaluating oral capecitabine in combination with oxaliplatin. The role of combination adjuvant therapy of FOLFOX plus a biologic agent (bevacizumab, cetuximab, or panitumumab) also is under investigation.

4. Stage IV (metastatic disease)—Approximately 20% of patients have metastatic disease at the time of initial

diagnosis, and another 30% eventually develop metastasis. A subset of these patients have limited disease that is potentially curable with surgical resection. Resection of isolated (one to three) liver or lung metastases may result in long-term (over 5 years) survival in 35–55% of cases. For those with unresectable hepatic metastases, local ablative techniques (cryosurgery, radiofrequency or microwave coagulation, embolization, hepatic intra-arterial chemotherapy) may provide long-term tumor control. The majority of patients with metastatic disease do not have resectable (curable) disease. In the absence of other treatment, the median survival is only 6 months. The goals of therapy are to slow tumor progression while maintaining a reasonable quality of life for as long as possible. Currently, either FOLFOX (the addition of oxaliplatin to 5-FU and folinic acid) or FOLFIRI (the addition of irinotecan to 5-FU and folinic acid) is the preferred first-line treatment regimens for most patients with metastatic colorectal cancer, increasing median survival to 15–20 months. For convenience, oral capecitabine (instead of intravenous 5-FU and leucovorin) can be used in combination with oxaliplatin; however, combination with irinotecan should not be used due to increased toxicity (diarrhea). The role of combination therapy with both oxaliplatin and irinotecan is under investigation. The role of biologic agents (cetuximab, panitumumab, and bevacizumab) is rapidly evolving. Cetuximab and panitumumab are monoclonal antibodies to EGFR; bevacizumab is a monoclonal antibody to VEGF. Combination therapy with bevacizumab and FOLFOX or FOLFIRI prolong mean survival 2–5 months compared with either regimen alone. Therefore, many oncologists are now using one of these combinations for initial therapy of metastatic disease. Bevacizumab may cause serious side effects, including arterial thromboembolic events, bowel perforation, or serious bleeding, in up to 5% of patients.

When disease progresses with FOLFOX or FOLFIRI (often in conjunction with bevacizumab), it is reasonable to switch to the alternative regimen. Patients progressing with one regimen may respond to the alternative regimen, prolonging mean survival to > 20 months. The anti-EGFR agents cetuximab and panitumumab may be used in patients whose disease has progressed despite first-line or second-line therapy. Both agents have modest efficacy when used as single agents for second-line therapy; however, a 2008 study reported that patients whose tumors had *K-ras* mutations did not benefit from anti-EGFR therapy, whereas patients with wild-type *K-ras* had 5 months median improved survival. Patients being considered for anti-EGFR therapy should therefore undergo *K-ras* testing. Cetuximab in combination with FOLFOX or FOLFIRI appears to provide a modest increase in median survival; however, the efficacy of these regimens versus bevacizumab-containing regimens is under investigation. The role of combination therapy of bevacizumab plus cetuximab or panitumumab with or without other agents requires further study.

B. Adjuvant Therapy for Rectal Cancer

Compared with colon cancer, rectal cancer has lower long-term survival rates and significantly higher rates of local

tumor recurrence (25%) due to the difficulty of achieving adequate surgical resection margins. When initial imaging studies suggest stage I disease, surgery may be performed first. Combination therapy with fluorouracil (a radiation sensitizing agent) and radiation has been shown to improve the disease-free survival rate and to decrease pelvic recurrence and is recommended for all patients with stage II and stage III rectal cancers. It has long been controversial whether chemoradiation should be administered preoperatively (“neoadjuvant”) or postoperatively (“adjuvant”). In 2004, a large, randomized controlled trial reported that preoperative therapy led to better patient treatment compliance, reduced local recurrence and toxicity, and a higher number of sphincter-preserving resections. Therefore, preoperative chemoradiation is recommended for patients with distal rectal cancers that are determined to be stage II or III by endorectal ultrasound or MRI. Following surgical resection with total mesorectal excision, fluorouracil-based therapy may be administered for an additional 4 months.

► Follow-Up after Surgery

Patients who have undergone resections for cure are followed closely to look for evidence of symptomatic or asymptomatic tumor recurrence that may be amenable to curative resection in a small number of patients. The optimal cost-effective strategy is not clear. Two randomized trials reported that intense follow-up with yearly colonoscopy, abdominal CT, and chest radiography did not improve overall outcome compared with most standard follow-up protocols. Patients should be evaluated every 3–6 months for 3–5 years with history, physical examination, and CEA determinations. Patients who had a complete preoperative colonoscopy should undergo another colonoscopy 1 year after surgical resection. Patients who did not undergo full colonoscopy preoperatively should undergo colonoscopy within 3–6 months postoperatively to exclude other synchronous colorectal neoplasms and 1 year thereafter. Thereafter, surveillance colonoscopy should be performed every 3–5 years to look for metachronous polyps or cancer. Because of the high incidence of local tumor recurrence in patients with rectal cancer, sigmoidoscopy should be performed every 3–6 months for 3 years. New onset of symptoms or a rising CEA warrants investigation with chest and abdominal CT to look for recurrent or metastatic disease that may be amenable to therapy. For patients with a rising CEA with unrevealing CT imaging, a PET scan is more sensitive for the detection of occult metastatic disease.

► Prognosis

The stage of disease at presentation is the most important determinant of long-term survival: stage I, > 90%; stage II, 70–85%; stage III with fewer than four positive lymph nodes, 67%; stage III with more than four positive lymph nodes, 33%; and stage IV, 5–7%. For each stage, rectal cancers have a worse prognosis. For those patients whose disease progresses despite therapy, meticulous efforts at palliative care are essential (see Chapter 5).

► Screening for Colorectal Neoplasms

Colorectal cancer is ideal for screening because it is a common disease that is fatal in almost 50% of cases yet is curable if detected at an earlier stage. Furthermore, most cases arise from benign adenomatous polyps that progress over many years to cancer, and removal of these polyps has been shown to prevent the majority of cancers. Colorectal cancer screening is endorsed by the US Preventive Services Task Force, the Agency for Health Care Policy and Research, the American Cancer Society, and every professional gastroenterology and colorectal surgery society. Although there is continued debate about the optimal cost-effective means of providing population screening, there is unanimous consent that screening of *some kind* should be offered to every patient over the age of 50 years. Several analyses suggest that screening is cost effective.

It is important for primary care providers to understand the relative merits of various options and to discuss them with their patients. Despite growing awareness of the importance of screening on the part of medical professionals and the public, less than 50% of patients have undergone screening of any kind. Discussion and encouragement by the primary care provider are the most important factors in achieving patient compliance with screening programs. The potential for harm from screening must be weighed against the likelihood of benefit, especially in elderly patients with comorbid illnesses and shorter life expectancy.

Recommendations for screening from the US Multisociety Task Force are listed in Table 39–5. Patients with first-degree relatives with colorectal neoplasms (cancer or

Table 39–5. Recommendations for colorectal cancer screening.¹

Average-risk individuals ≥ 50 years old²

- Annual fecal occult blood testing
- Flexible sigmoidoscopy every 5 years
- Annual fecal occult blood testing and flexible sigmoidoscopy every 5 years
- Colonoscopy every 10 years
- Barium enema every 5 years

Individuals with a family history of a first-degree member with colorectal neoplasia³

Single first-degree relative with colorectal cancer diagnosed at age ≥ 60 years: Begin screening at age 40. Screening guidelines same as average-risk individual; however, preferred method is colonoscopy every 10 years.

Single first-degree relative with colorectal cancer diagnosed at age < 60 years, or multiple first-degree relatives: Begin screening at age 40 or at age 10 years younger than age at diagnosis of the youngest affected relative, whichever is first in time. Recommended screening: colonoscopy every 5 years.

¹For recommendations for families with inherited polyposis syndromes or hereditary nonpolyposis colon cancer, see Chapter 15.

²Colorectal cancer screening and surveillance: clinical guidelines and rationale. Gastroenterology. 2003 Feb;124(2):544–60.

³Screening Recommendations of American College of Gastroenterology. Am J Gastroenterol. 2000 Apr;95(4):868–77.

adenomatous polyps) are at increased risk; earlier and more frequent screening is recommended (preferably with colonoscopy) for these individuals. Recommendations for screening in families with inherited cancer syndromes or inflammatory bowel disease are provided in Chapter 15. For patients at average risk for colorectal cancer, the recommendations of the Task Force are discussed below. Screening tests may be classified into two broad categories: stool-based tests and exams that visualize the structure of the colon by direct endoscopic inspection or radiographic imaging.

A. Stool-based Tests

1. Fecal occult blood test—Most colorectal cancers and some large adenomas result in increased chronic blood loss. A variety of tests for fecal occult blood are commercially available that have varying sensitivities and specificities for colorectal neoplasia. These include guaiac-based tests (Hemoccult I and II and Hemeoccult SENSAs) that detect the pseudoperoxidase activity of heme or hemoglobin and fecal immunochemical tests (FITs) that detect human globin.

Guaiac-based tests have undergone the most extensive testing and currently have the greatest clinical use. For optimal detection, one specimen card must be prepared from three consecutive bowel movements. To reduce the likelihood of false-positive tests, patients should abstain from aspirin (in doses greater than 325 mg/d), NSAIDs, red meat, poultry, fish, and vegetables with peroxide activity (turnips, horseradish) for 72 hours. Vitamin C may cause a false-negative test. Slides should be developed within 7 days after preparation. The reported sensitivities of a single guaiac-based test for detection of colorectal cancer vary widely, but are lower for Hemeoccult II (35%) than Hemeoccult SENSAs (65%). When fecal occult blood test is administered to the general population as part of a screening program, 2–6% of tests are positive. Of those with positive tests, 5–18% have colorectal cancer that is more likely to be at an earlier stage (stage I or II).

Several FITs are commercially available. These tests are highly specific for detecting human globin and therefore eliminate the need for pretest dietary restrictions. As with guaiac-based tests, sampling of three consecutive bowel movements is recommended. In clinical trials that compare FIT with guaiac-based tests, FIT had at least comparable sensitivity to Hemeoccult SENSAs for detection of cancers (60–85%) with higher specificity. Because FITs are not affected by diet or medications and have superior accuracy, they are increasingly being substituted for guaiac-based tests despite a higher cost per test (\$10–20).

The US Multi-Society Task Force emphasizes that colon cancer prevention should be the primary goal of screening. For that reason, the lower sensitivity of fecal occult blood tests for advanced neoplasia (cancer and advanced adenomatous polyps) makes them a less attractive choice for population-based screening than endoscopic or radiographic tests. Currently, fecal occult blood tests are most suitable in settings where health care resources are limited or in patients who desire a noninvasive method of screen-

ing. The Task Force recommends that tests with higher sensitivity for colorectal cancer (Hemeoccult SENSAs or FIT) be used rather than less sensitive tests (Hemeoccult II). Regardless of which stool-based test is used, patients should understand that annual testing is required to achieve the maximum screening benefit and that a positive test will require evaluation by colonoscopy accompanied by removal of any polyps identified. If colonoscopy reveals no colorectal neoplasm, further screening for colorectal cancer can be deferred for 10 years. In a meta-analysis of four large, prospective, longitudinal studies, annual or biennial screening with Hemeoccult or Hemeoccult II reduced mortality from colorectal cancer by 25% among those who were compliant with regular testing. Long-term studies with more sensitive stool tests (Heme SENSAs or FIT) have not been performed.

2. Multitarget DNA assay—A fecal DNA assay (Pre-Gen Plus) is available for screening for colorectal neoplasia. The test analyzes fecal DNA for 22 gene mutations and DNA integrity. The commercially available first-generation fecal DNA panel detected only one-half of cancers; however, a second-generation assay detected almost 90%. Although the Multisociety Task Force concluded that fecal DNA is an acceptable option for colorectal cancer screening, this test is not yet practical for population-based screening due to its high cost and cumbersome requirements for stool collection and mailing.

B. Endoscopic Examinations of the Colon

1. Flexible sigmoidoscopy—Use of a 60-cm flexible sigmoidoscope permits visualization of the rectosigmoid and descending colon. It requires no sedation and in many centers is performed by a nurse specialist or physician's assistant. Adenomatous polyps are identified in 10–20% and colorectal cancers in 1% of patients. (For management of adenomatous polyps identified at sigmoidoscopy, see Chapter 15.) Case-control studies suggest that screening sigmoidoscopy programs lead to a 60% reduction in colorectal cancer mortality. The risk of serious complications (perforation) associated with flexible sigmoidoscopy is less than 1:10,000 patients.

The chief disadvantage of screening with flexible sigmoidoscopy is that it does not examine the proximal colon. The prevalence of proximal versus distal neoplasia is higher in people over age 65 years of age, African Americans, and women. In men, approximately 50% of advanced neoplasms (cancer, adenomas \geq 1 cm in size, polyps with villous histology, or high-grade dysplasia) are located in the proximal colon, compared with 60–70% in women. The finding at sigmoidoscopy of an adenomatous polyp in the distal colon increases the likelihood at least twofold that an advanced neoplasm is present in the proximal colon. Therefore, patients found on screening sigmoidoscopy to have an adenomatous polyp of any size should subsequently undergo colonoscopy to evaluate the proximal colon. Using this strategy in men, it is estimated that screening sigmoidoscopy programs will detect approximately 65% of advanced colonic neoplasms. In women,

however, sigmoidoscopy screening programs may fail to detect up to 65% of advanced neoplasia.

2. Colonoscopy—Colonoscopy permits examination of the entire colon. In addition to detecting early cancers, colonoscopy allows removal of adenomatous polyps by biopsy or polypectomy, which is believed to reduce the risk of subsequent cancer. Over the past decade, there has been a dramatic increase in screening colonoscopy and a similar decrease in screening sigmoidoscopy due to poor reimbursement and the perceived inferiority of sigmoidoscopy compared with colonoscopy. Colonoscopy requires aggressive bowel cleansing prior to the examination. To alleviate discomfort, intravenous sedation is used for most patients. The incidence of serious complications after colonoscopy (perforation, bleeding, cardiopulmonary events) is 0.1%. In asymptomatic individuals between 50 and 75 years of age undergoing screening colonoscopy, the prevalence of advanced neoplasia is 4–11% and of cancer is 0.1–1%.

Although colonoscopy is believed to be the most sensitive test for detecting adenomas and cancer, it is not infallible. In several studies, the rate of colorectal cancer within 3 years of a screening colonoscopy was 0.7–0.9%, ie, approximately 1 in 110 patients. This may be attributable to adenomatous polyps and early cancers that were overlooked during colonoscopy. Studies of back-to-back colonoscopies confirm that endoscopists overlook 6–12% of polyps > 1 cm and up to 25% of smaller adenomas. Polyps that are small, flat, or located behind folds are easily missed, especially if the bowel preparation is poor. Population-based case-control and cohort studies suggest that colonoscopy is associated with greater reduction in colorectal cancer incidence and mortality in the distal colon than the proximal colon. This may be attributable to incomplete examination of the proximal colon, and differences between the proximal and distal colon that include worse bowel preparation, more aggressive polyp biology, or a higher prevalence of flat polyps. The latter are more common than previously recognized, are more likely to contain advanced pathology, and are more difficult to identify than raised (sessile or pedunculated) polyps. To optimize diagnostic accuracy as well as patient safety and comfort, colonoscopy should be performed after optimal bowel preparation by a well-trained endoscopist who spends sufficient time (at least 7 minutes) carefully examining the colon (especially the proximal colon) while withdrawing the endoscope.

C. Radiographic Examinations of the Colon

1. CT colonography—Using helical CT with computer-assisted image reconstruction, two- and three-dimensional views can be generated of the colon lumen that simulate the view of colonoscopy. CT colonography requires a similar bowel cleansing regimen as colonoscopy as well as insufflation of air into the colon through a rectal tube, which may be associated with discomfort. Nonetheless, this examination is performed rapidly and requires no sedation or intravenous contrast. It has minimal acute risk although there is controversy about potential long-term risks related to radiation exposure from CT examinations. Several large studies have compared the accuracy of virtual colonoscopy with

colonoscopy for colorectal screening. Using current imaging software with multidetector helical scanners, the sensitivity is > 95% for the detection of cancer and > 84–92% for the detection of polyps \geq 10 mm in size. The sensitivity for polyps 6–9 mm in size ranges from 57% to 84%; for polyps 5 mm or less, the sensitivity is extremely poor.

Patients undergoing screening with CT colonography should be managed appropriately. If no polyps are found, the interval for repeat screening examination is uncertain; however, 5 years may be reasonable. All patients with polyps \geq 10 mm in size should be referred for colonoscopy with polypectomy because of the high prevalence (30%) of advanced pathology (cancer, high-grade dysplasia, or villous features) within these polyps. The optimal management of patients with polyps < 10 mm in size is controversial. The likelihood of advanced pathology in polyps 6–9 mm in size is 4–7% and in polyps 1–5 mm is < 2%. Studies are ongoing to determine the natural history of polyps within this size range. Pending this information, the US Multisociety Task Force currently recommends that colonoscopy with polypectomy be offered to patients with one or more 6–9 mm polyps. Patients who refuse or who have increased risk of carcinoma should undergo surveillance CT colonography in 3–5 years. At the present time, there is no consensus on the management of patients with polyps < 6 mm; however, some radiologists choose not even to report these findings.

2. Barium enema—Double-contrast barium enema was previously an attractive screening technique because it was widely available, relatively inexpensive, and safe. However, compared to CT colonography, it is more time consuming and difficult to perform, less comfortable, and less accurate. Although it continues to be included among recommended screening options, it has been supplanted CT colonography, where available. A multicenter trial demonstrated that the sensitivity of barium enema is only 50% for polyps \geq 1 cm and 55–85% for early-stage cancers when compared with colonoscopy. At present, barium enema may be recommended when screening of the entire colon is desired but expertise in CT colonography is unavailable and the patient is unable or unwilling to undergo colonoscopy.

► When to Refer

- Patients with symptoms (change in bowel habits, hematochezia), signs (mass on abdominal examination or digital rectal examination [DRE]), or laboratory tests (iron deficiency anemia) suggestive of colorectal neoplasia should be referred for colonoscopy.
- Patients with suspected cancer or adenomatous polyps of any size should be referred for colonoscopy.
- Virtually all patients with proven colorectal cancer should be referred to a surgeon for resection. Patients with stage III or IV disease should be referred to an oncologist.

► When to Admit

- Patients with complications of colorectal cancer (obstruction, acute bleeding) requiring urgent evaluation and intervention.

- Patients with severe complications of chemotherapy.
- Patients with advanced metastatic disease requiring palliative care.

CARCINOMA OF THE ANUS

The anal canal is lined from its proximal to distal extent by columnar, transitional and non-keratinized squamous epithelium, which merges at the anal verge with the keratinized perianal skin. Tumors arising from the mucosa of the anal canal are relatively rare, comprising only 1–2% of all cancers of the anus and large intestine. Squamous cancers make up the majority of anal cancers. Anal cancer is increased among people practicing receptive anal intercourse and those with a history of anorectal warts. In over 80% of cases, HPV may be detected, suggesting that this virus is a major causal factor. Anal cancer is increased in HIV-infected individuals, possibly due to interaction with HPV. Bleeding, pain, and local tumor are the most common symptoms. The lesion is often confused with hemorrhoids or other common anal disorders. These tumors tend to become annular, invade the sphincter, and spread upward via the lymphatics into the perirectal mesenteric lymphatic nodes. MR scan and endoluminal ultrasound assist in determining the depth of penetration and local spread.

Treatment depends on the tumor location and histologic stage. Small (< 3 cm) superficial lesions of the perianal skin may be treated with wide local excision. Adenocarcinoma of the anal canal is treated in similar fashion to rectal cancer (see above), commonly by abdominoperineal resection with adjuvant or neoadjuvant chemoradiotherapy. Squamous cancer of the anal canal and large perianal tumors invading the sphincter or rectum are treated with combined-modality therapy that includes external radiation with simultaneous chemotherapy (fluorouracil and either mitomycin or cisplatin). Local control is achieved in 80% of patients. Radical surgery (abdominoperineal resection) is reserved for patients who fail chemotherapy and radiation therapy. The 5-year survival rate is 60–70% for localized tumors and over 25% for metastatic (stage IV) disease.

CANCERS OF THE GENITOURINARY TRACT

Maxwell V. Meng, MD, FACS

PROSTATE CANCER

ESSENTIALS OF DIAGNOSIS

- ▶ Prostatic induration on DRE or elevation of PSA.
- ▶ Most often asymptomatic.
- ▶ Rarely: systemic symptoms (weight loss, bone pain).

▶ General Considerations

Prostatic cancer is the most common noncutaneous cancer detected in American men and the second leading cause of cancer-related death. In the United States, over 218,000 new cases of prostate cancer are diagnosed annually, and about 27,000 deaths result. However, the clinical incidence of the disease does not match the prevalence noted at autopsy, where more than 40% of men over 50 years of age are found to have prostatic carcinoma. Most such occult cancers are small and contained within the prostate gland. Few are associated with regional or distant disease. The incidence of prostatic cancer increases with age. Whereas 30% of men aged 60–69 years will have the disease, autopsy incidence increases to 67% in men aged 80–89 years. Although the global prevalence of prostatic cancer at autopsy is relatively consistent, the clinical incidence varies considerably (high in North America and European countries, intermediate in South America, and low in the Far East), suggesting that environmental or dietary differences among populations may be important for prostatic cancer growth. A 50-year-old American man has a lifetime risk of 40% for latent cancer, 16% for developing clinically apparent cancer, and a 2.9% risk of death due to prostatic cancer. Blacks, men with a family history of prostatic cancer, and those with a history of high dietary fat intake are at increased risk for developing prostate cancer.

▶ Clinical Findings

A. Symptoms and Signs

Prostate cancer may manifest as focal nodules or areas of induration within the prostate at the time of DRE. However, currently most prostate cancers are associated with palpably normal prostates and are detected on the basis of elevations in serum PSA.

Patients rarely present with signs of urinary retention or neurologic symptoms as a result of epidural metastases and cord compression. Obstructive voiding symptoms are most often due to benign prostatic hyperplasia, which occurs in the same age group. Nevertheless, large or locally extensive prostatic cancers can cause obstructive voiding symptoms while lymph node metastases can lead to lower extremity lymphedema. As the axial skeleton is the most common site of metastases, patients may present with back pain or pathologic fractures.

B. Laboratory Findings

1. Serum tumor markers—PSA is a glycoprotein produced only by cells, either benign or malignant, of the prostate gland. The serum level is typically low and correlates with the volume of both benign and malignant prostate tissue. Measurement of serum PSA is useful in detecting and staging prostate cancer, monitoring response to treatment, and detecting recurrence before it becomes clinically evident. As a screening test, PSA will be elevated in 10–15% of men. Approximately 18–30% of men with intermediate degrees of elevation (4.1–10 ng/mL) will be found to have prostate cancer. Between 50% and 70% of those with elevations greater than 10 ng/mL will have prostate cancer. (See age-specific PSA reference ranges under Screening for Prostate Cancer, below.) Patients with intermediate levels of PSA usually have localized and therefore potentially curable cancers. It should be remembered that approximately 20% of patients who undergo radical prostatectomy for localized prostate cancer have normal levels of PSA.

In untreated patients with prostate cancer, the level of PSA correlates with the volume and stage of the disease. Whereas most organ-confined cancers are associated with PSA levels less than 10 ng/mL, advanced disease (seminal vesicle invasion, lymph node involvement, or occult distant metastases) is more common in patients with PSA levels in excess of 40 ng/mL. Approximately 98% of patients with metastatic prostate cancer will have elevated PSA. However, there are rare cancers that are localized despite substantial elevations in PSA. Therefore, initial treatment decisions cannot be made on the basis of PSA testing alone. A rising PSA after therapy is usually consistent with progressive disease, either locally recurrent or metastatic.

2. Miscellaneous laboratory testing—Patients in urinary retention or those with ureteral obstruction due to loco-regionally advanced prostate cancers may present with elevations in blood urea nitrogen or creatinine. Patients with bony metastases may have elevations in alkaline phosphatase or hypercalcemia. Laboratory and clinical evidence of disseminated intravascular coagulation can occur in patients with advanced prostate cancers.

3. Prostate biopsy—Transrectal ultrasound-guided biopsy is the standard method for detection of prostate cancer. The use of a spring-loaded, 18-gauge biopsy needle has allowed transrectal biopsy to be performed with little patient discomfort and minimal morbidity. Local anesthesia is routinely used and increases the tolerability of the procedure. The specimen preserves glandular architecture and permits accurate grading. Prostate biopsy specimens are taken from the apex, mid-portion, and base in men who have an abnormal DRE or an elevated serum PSA, or both. Extended-pattern biopsies, including a total of at least ten biopsies, are associated with improved cancer detection and risk stratification of patients with newly diagnosed disease. Patients with abnormalities of the seminal vesicles can have these structures specifically biopsied to identify local tumor invasion.

C. Imaging

Transrectal ultrasonography has been used largely for the staging of prostate carcinomas, where they typically appear as hypoechoic areas. In addition, transrectal ultrasound-guided, rather than digitally guided, biopsy of the prostate is a more accurate way to evaluate suspicious lesions. Use of imaging should be tailored to the likelihood of advanced disease in newly diagnosed cases. Asymptomatic patients with well-differentiated to moderately differentiated cancers, thought to be localized to the prostate on DRE and transurethral ultrasound and associated with modest elevations of PSA (ie, < 10 ng/mL), need no further imaging.

MRI of the prostate allows for evaluation of the prostate lesion as well as regional lymph nodes. The positive predictive value for detection of both capsular penetration and seminal vesicle invasion is similar for transrectal ultrasound and MRI. CT plays little role because of its inability to accurately identify or stage prostate cancers, but it can be used to detect regional lymphatic metastases and intra-abdominal metastases.

Radionuclide bone scan is superior to conventional plain skeletal radiographs in detecting bony metastases. Most prostate cancer metastases are multiple and most commonly localized to the axial skeleton. Those men with more advanced local lesions, symptoms of metastases (eg, bone pain), high-grade disease, or elevations in PSA greater than 20 ng/mL should undergo radionuclide bone scan. Because of the high frequency of abnormal scans in patients in this age group resulting from degenerative joint disease, plain films are often necessary in evaluating patients with indeterminate findings on bone scan. Cross-sectional imaging either by CT or MRI is usually indicated only in those patients in the latter group who have negative bone scans in an attempt to detect lymph node metastases. Patients found to have enlarged pelvic lymph nodes are candidates for FNA.

Intravenous urography and cystoscopy are not routinely needed to evaluate patients with prostate cancer.

Despite application of modern, sophisticated techniques, understaging of prostate cancer occurs in at least 20% of patients.

► Screening for Prostate Cancer

Whether screening for prostate cancer results in a decrease in yearly mortality rates due to the disease is the subject of much debate. The screening tests currently available include DRE, PSA testing, and transrectal ultrasound. Depending on the patient population being evaluated, detection rates using DRE alone vary from 1.5% to 7%. Unfortunately, most cancers detected in this manner are advanced (stage T3 or greater). Transrectal ultrasound should not be used as a first-line screening tool because of its expense, low specificity (and therefore high biopsy rate), and minimal improvement in detection rate when compared with the combined use of DRE and PSA testing.

PSA testing increases the detection rate of prostate cancers compared with DRE. Approximately 2–2.5% of men older than 50 years of age will be found to have prostate cancer using PSA testing compared with a rate of approximately 1.5% using DRE alone. PSA is not specific

Table 39–6. Screening for prostatic cancer: Test performance.

| Test | Sensitivity | Specificity | Positive Predictive Value |
|--------------------------|-------------|-------------|---------------------------|
| Abnormal PSA (> 4 ng/mL) | 0.67 | 0.97 | 0.43 |
| Abnormal DRE | 0.50 | 0.94 | 0.24 |
| Abnormal PSA or DRE | 0.84 | 0.92 | 0.28 |
| Abnormal PSA and DRE | 0.34 | 0.995 | 0.49 |

DRE, digital rectal examination; PSA, prostate-specific antigen. Modified, with permission, from Kramer BS et al. Prostate cancer screening: what we know and what we need to know. *Ann Intern Med.* 1993 Nov 1;119(9):914–23.

for cancer, and there is considerable overlap of values between men with benign prostate hyperplasia and those with prostate cancers. The sensitivity, specificity, and positive predictive value of PSA and DRE are listed in Table 39–6. PSA-detected cancers are more likely to be localized compared with those detected by DRE alone.

To improve the performance of PSA as a screening test, several investigators have developed alternative methods for its use. The serial measurement of PSA over time (PSA velocity) may increase specificity for cancer detection with little loss in sensitivity. A rate of change in PSA greater than 0.75 ng/mL per year is associated with an increased likelihood of cancer detection. In a patient with a normal DRE, an elevated PSA, and a normal transrectal ultrasound, the indications for prostate biopsy may be refined by calculating PSA density (serum PSA/volume of the prostate as measured by ultrasound). Patients with high PSA density are more likely to have disease despite a normal DRE and normal transrectal ultrasound. Some have found measurement of PSA transition zone density (portion of the prostate that enlarges with development of benign prostate hyperplasia) to be more predictive of the presence or absence of cancer than PSA density calculated using the entire prostate volume. As PSA concentration is directly related to patient age, establishment of age-specific reference ranges increases specificity (fewer older men with benign prostate hyperplasia would undergo evaluation) and increases sensitivity (more younger men with cancer would undergo evaluation). Age-specific reference ranges have been established: men 40–49, < 2.5 ng/mL; men 50–59, < 3.5 ng/mL; men 60–69, < 4.5 ng/mL; and men 70–79, < 6.5 ng/mL (based on a previously normal serum PSA of < 4 ng/mL). Black men have lower age-specific reference ranges (age 40–49, < 2 ng/mL; age 50–59, < 4 ng/mL; age 60–69, < 4.5 ng/mL; age 70–79, < 5.5 ng/mL). A more recent attempt at refining PSA has been the measurement of free serum and protein-bound levels (cancer patients have a lower percentage of free serum PSA). Generally, men with free fractions exceeding 25% are unlikely to have prostate cancer, whereas those with free fractions less than 10% have an approximately 50% chance of having prostate

cancer. Early reports using cutoffs of 18–20% of free PSA resulted in 5–10% lost sensitivity for 15–40% gains in specificity. The frequency of PSA testing remains a matter of some debate. In men with a normal DRE and a PSA > 2.5 ng/mL, PSA testing should be performed yearly because approximately 50% of these patients convert to having a PSA > 4 ng/mL. Screening can be performed biennially in those with a normal DRE and serum PSA < 2.5 ng/mL; progression in this group is less likely.

► Staging

The majority of prostate cancers are adenocarcinomas. Most arise in the periphery of the prostate (peripheral zone), though a small percentage arise in the central (5–10%) and transition zones (20%) of the gland. Pathologists utilize the Gleason grading system whereby a “primary” grade is applied to the architectural pattern of malignant glands occupying the largest area of the specimen and a “secondary” pattern is assigned to the next largest area of cancer. Grading is based on architectural rather than histologic criteria, and five “grades” are possible. Adding the score of the primary and secondary patterns gives a Gleason score. Grade correlates with tumor volume, pathologic stage, and prognosis.

► Treatment

A. Localized Disease

The optimal treatment for patients with clinically localized prostate cancers remains controversial. Patients need to be advised of all treatment options, including active surveillance, with the specific benefits, risks, and limitations. Currently, treatment decisions are made based on tumor grade and stage as well as the age and health of the patient. Although selected patients may be candidates for surveillance based on age or health and evidence of small-volume or well-differentiated cancers, most men with an anticipated life expectancy in excess of 10 years should be considered for treatment. Both radiation therapy and radical prostatectomy result in acceptable levels of local control. A large, prospective, randomized trial compared surveillance with radical prostatectomy in 695 men with clinically localized and well-differentiated to moderately differentiated tumors for a median of 8.2 years. Radical prostatectomy reduced disease-specific mortality, overall mortality, and risks of metastasis and local progression. The absolute reduction in the risk of death after 10 years was small yet statistically significant, but the reductions in the risk of metastasis and local tumor progression were substantial. This trial accrued patients in Sweden between 1989 and 1999, thus likely including patients with greater cancer burden compared with that in patients currently diagnosed using PSA screening.

B. Radical Prostatectomy

During radical prostatectomy, the seminal vesicles, prostate, and ampullae of the vas deferens are removed. Refinements in technique have allowed preservation of urinary

continence in most patients and erectile function in selected patients. Radical prostatectomy can be performed via open retropubic, transperineal, or laparoscopic (with or without robotic assistance) surgery. Local recurrence is uncommon after radical prostatectomy, and the incidence is related to pathologic stage. Organ-confined cancers rarely recur; however, cancers with adverse pathologic features (capsular penetration, seminal vesicle invasion) are associated with higher local (10–25%) and distant (20–50%) relapse rates.

Ideal candidates for prostatectomy include healthy patients with stages T1 and T2 prostate cancers. Patients with advanced local tumors (T4) or lymph node metastases are rarely candidates for prostatectomy alone, although surgery is sometimes used in combination with hormonal therapy and postoperative radiation therapy for select high-risk patients.

Patients with advanced pathologic stage or positive surgical margins are at an increased risk for local and distant tumor relapse. Such patients are candidates for adjuvant therapy (radiation for positive margins or androgen deprivation for lymph node metastases). Although adjuvant radiation appears to reduce local recurrences (0–5% with radiation versus 15–30% without), it has little or no impact on distant failure rates (30–35% with radiation versus 30–45% without). Recent evidence suggests that salvage radiotherapy after radical prostatectomy, within 2 years of PSA relapse, increases prostate cancer-specific survival in men with shorter PSA doubling time (< 6 months).

C. Radiation Therapy

Radiation can be delivered by a variety of techniques including use of external beam radiotherapy and transperineal implantation of radioisotopes. Morbidity is limited, and the survival of patients with localized cancers (T1, T2, and selected T3) approaches 65% at 10 years. As with surgery, the likelihood of local failure correlates with technique and tumor characteristics. The likelihood of a positive prostate biopsy more than 18 months after radiation varies between 20% and 60%. Patients with local recurrence are at an increased risk of cancer progression and cancer death compared with those who have negative biopsies. Ambiguous target definitions, inadequate radiation doses, and understaging of the tumor may be responsible for the failure noted in some series. Newer techniques of radiation (implantation, conformal therapy using three-dimensional reconstruction of CT-based tumor volumes, heavy particle, charged particle, and heavy charged particle) may improve local control rates. Three-dimensional conformal radiation delivers a higher dose because of improved targeting and appears to be associated with greater efficacy as well as lower likelihood of adverse side effects compared with previous techniques. As a result of improvements in imaging, most notably transrectal ultrasound, there has been a resurgence of interest in brachytherapy—the implantation of permanent or temporary radioactive sources (palladium, iodine, or iridium) into the prostate. Brachytherapy can be combined with external beam radiation in patients with higher-grade or higher-volume disease or as monotherapy in those with low-grade

or low-volume malignancies. The PSA may rise after brachytherapy because of prostate inflammation and necrosis. This transient elevation (PSA bounce) should not be mistaken for recurrence and may occur up to 20 months after treatment.

D. Surveillance

A beneficial impact of treating localized prostate cancer with respect to survival has not been conclusively demonstrated. Therefore, surveillance alone may be an appropriate form of management for selected patients with prostate cancer. Patients included in observational series are typically older with small volume, well-differentiated cancers. Currently, many men diagnosed with prostate cancer may be candidates for surveillance due to the significant migration to lower stage, as well lower grade, resulting from screening for prostate cancer using PSA testing. Depending on the age and health of the patient, some of these very low-volume, low-grade cancers may never become clinically relevant and can be monitored with serial PSA levels, rectal examinations, and periodic prostate biopsies to assess grade and extent of tumor. The goal of surveillance is to avoid treatment in men who never experience disease progression while recognizing and effectively treating men with early evidence of progression. End points for intervention in patients on surveillance have not been clearly defined and surveillance regimens remain investigational.

E. Cryosurgery

Cryosurgery is a technique whereby liquid nitrogen is circulated through small hollow-core needles inserted into the prostate under ultrasound guidance. The freezing process results in tissue destruction. There has been a resurgence of interest in less invasive forms of therapy for localized prostate cancer as well as several recent technical innovations, including improved percutaneous techniques, expertise in transrectal ultrasound, improved cryotechnology, and better understanding of cryobiology. The positive biopsy rate after cryoablation ranges between 7% and 23%.

F. Locally and Regionally Advanced Disease

Prostate cancers associated with minimal degrees of capsular penetration are candidates for standard irradiation or surgery. Those with locally extensive cancers, including those with seminal vesicle and bladder neck invasion, are at increased risk for both local and distant relapse despite conventional therapy. Currently, a variety of investigational regimens are being tested in an effort to improve cancer outcomes in such patients. Combination therapy (androgen deprivation combined with surgery or irradiation), newer forms of irradiation, and hormonal therapy alone are being tested, as is neoadjuvant and adjuvant chemotherapy. Neoadjuvant and adjuvant androgen deprivation therapy combined with external beam radiation therapy have demonstrated improved survival compared with external beam radiation therapy alone.

G. Metastatic Disease

Since death due to prostate carcinoma is almost invariably the result of failure to control metastatic disease, research has emphasized efforts to improve control of distant disease. It is well known that most prostate carcinomas are hormone dependent and approximately 70–80% of men with metastatic prostate carcinoma will respond to various forms of androgen deprivation. Androgen deprivation may be affected at several levels along the pituitary–gonadal axis using a variety of methods or agents (Table 39–7). Use of luteinizing hormone-releasing hormone (LHRH) agonists (leuprolide, goserelin) achieves androgen deprivation without orchiectomy or administration of diethylstilbestrol and is currently the most common method of reducing testosterone levels. Because of its rapid onset of action, ketoconazole should be considered in patients with advanced prostate cancer who present with spinal cord compression, bilateral ureteral obstruction, or disseminated intravascular coagulation. Although testosterone is the major circulating androgen, the adrenal gland secretes the androgens dehydroepiandrosterone, dehydroepiandrosterone sulfate, and androstenedione. Some

Table 39–7. Androgen deprivation for prostatic cancer.

| Level | Agent | Dose | Sequelae |
|-------------------------|--------------------|--|---|
| Pituitary, hypothalamus | Diethylstilbestrol | 1–3 mg orally daily | Gynecomastia, hot flushes, thromboembolic disease, erectile dysfunction |
| | LHRH agonists | Monthly or 3-monthly depot injection | Erectile dysfunction, hot flushes, gynecomastia, rarely anemia |
| Adrenal | Ketoconazole | 400 mg three times orally daily | Adrenal insufficiency, nausea, rash, ataxia |
| | Aminoglutethimide | 250 mg four times orally daily | Adrenal insufficiency, nausea, rash, ataxia |
| | Corticosteroids | Prednisone: 20–40 mg orally daily | Gastrointestinal bleeding, fluid retention |
| Testis | Orchiectomy | | Gynecomastia, hot flushes, erectile dysfunction |
| Prostate cell | Antiandrogens | Flutamide: 250 mg three times orally daily Bicalutamide: 50 mg orally daily | No erectile dysfunction when used alone; nausea, diarrhea |

LHRH, luteinizing-hormone-releasing hormone.

investigators believe that suppressing both testicular and adrenal androgens allows for a better initial and longer response than methods that only inhibit production of testicular androgens. Complete androgen blockade can be achieved by combining an antiandrogen with use of an LHRH agonist or orchiectomy. Nonsteroidal antiandrogen agents appear to act by competitively binding the receptor for DHT, the intracellular androgen responsible for prostate cell growth and development. A meta-analysis of trials comparing the use of either an LHRH agonist or orchiectomy alone with the use of either in combination with an antiandrogen agent shows little benefit of combination therapy. However, patients at risk for disease-related symptoms (bone pain, obstructive voiding symptoms) due to the initial elevation of serum testosterone that accompanies the use of an LHRH agonist should receive antiandrogens initially. Bisphosphonates are increasingly being used to prevent osteoporosis associated with androgen deprivation, to decrease bone pain from metastases, and to reduce skeletal related events.

Docetaxel is the first cytotoxic chemotherapy agent to improve survival in patients with hormone-refractory prostate cancer. Current research is underway combining docetaxel with androgen deprivation therapy, radiation therapy, and surgery to determine whether combinations are effective in patients with high-risk prostate cancer. Immune therapies are also under investigation and have shown promise for patients with advanced prostate cancer.

▶ Prognosis

The likelihood of success of surveillance or treatment can be predicted using risk assessment tools that usually combine stage, grade, PSA level, and number and extent of positive prostate biopsies. Several tools are available on the Internet (eg, <http://mskcc.org/mskcc/html/5794.cfm>). One of the most widely used is the Kattan nomogram; it incorporates tumor stage, grade, and PSA level to predict the likelihood that a patient will be disease-free after radical prostatectomy or radiation therapy.

The CAPRA nomogram uses serum PSA, Gleason grade, clinical stage, percent positive biopsies, and patient age in a point system to risk stratify and predict the likelihood of PSA recurrence 3 and 5 years after radical prostatectomy (Tables 39–8 and 39–9). The CAPRA has been validated on large multicenter and international radical prostatectomy cohorts.

The patterns of prostate cancer progression have been well defined. Small and well-differentiated cancers (grades 1 and 2) are usually confined within the prostate, whereas large-volume (> 4 mL) or poorly differentiated (grades 4 and 5) cancers are more often locally extensive or metastatic to regional lymph nodes or bone. Penetration of the prostate capsule by cancer is common and occurs along perineural spaces. Seminal vesicle invasion is associated with a high likelihood of regional or distant disease, and disease recurrence. Lymphatic metastases can be identified in the obturator and internal iliac lymph node chains. The axial skeleton, as mentioned previously, is the most common site of distant metastases.

Table 39–8. The UCSF Cancer of the Prostate Risk Assessment (CAPRA).

| Variable | Level | Points |
|--|------------|--------|
| PSA (ng/mL) | 0-6 | 0 |
| | 6.1-10 | 1 |
| | 10.1-20 | 2 |
| | 20.1-30 | 3 |
| | > 30 | 4 |
| Gleason grade | 1-3/1-3 | 0 |
| | 1-3/4-5 | 1 |
| | 4-5/1-5 | 3 |
| T-stage | T1 or T2 | 0 |
| | T3a | 1 |
| % positive biopsies (biopsy cores positive divided by the number of biopsies obtained) | < 34% | 0 |
| | > 34% | 1 |
| Age | < 50 years | 0 |
| | > 50 years | 1 |

▶ When to Refer

- All patients should be referred to an urologist. PSA remains integral in prostate cancer diagnosis. Low-risk disease may be managed by active surveillance, surgery, or radiation therapy.
- High-risk disease often requires multimodal treatment strategies.

BLADDER CANCER

ESSENTIALS OF DIAGNOSIS

- ▶ Irritative voiding symptoms.
- ▶ Gross or microscopic hematuria.
- ▶ Positive urinary cytology in most patients.
- ▶ Filling defect within bladder noted on imaging.

▶ General Considerations

Bladder cancer is the second most common urologic cancer; it occurs more commonly in men than women (2.7:1), and the mean age of patients at diagnosis is 65 years. Cigarette smoking and exposure to industrial dyes or solvents are risk factors for the disease and account for approximately 60% and 15% of new cases, respectively. Ninety-eight percent of primary bladder cancers are epithelial malignancies, with the majority being urothelial cell carcinomas (90%). Adenocarcinomas and squamous cell cancers account for approximately 2% and 7%, respectively, of all bladder cancers detected in the United States. The latter is often associated with schistosomiasis, vesical calculi, or prolonged catheter use.

▶ Clinical Findings

A. Symptoms and Signs

Hematuria—gross or microscopic, chronic or intermittent—is the presenting symptom in 85–90% of patients with bladder cancer. Irritative voiding symptoms (urinary frequency and urgency) occur in a small percentage of patients as a result of the location or size of the cancer. Most patients with bladder cancer do not have signs of the disease because of its superficial nature. Abdominal masses detected on bimanual examination may be present in patients with large-volume or deeply infiltrating cancers. Hepatomegaly or palpable lymphadenopathy may be present in patients with metastatic disease, and lymph-

edema of the lower extremities may be present as a result of locally advanced cancers or metastases to pelvic lymph nodes.

B. Laboratory Findings

Urinalysis reveals microscopic or gross hematuria in the majority of cases. On occasion, hematuria may be accompanied by pyuria. Azotemia may be present in a small number of cases associated with ureteral obstruction. Anemia may occasionally be due to chronic blood loss or to bone marrow metastases. Exfoliated cells from normal and abnormal urothelium can be readily detected in voided urine specimens. Cytology can be useful in detecting the disease at the time of initial presentation or to detect recurrence. Cytology is sensitive in detecting cancers of higher grade and stage (80–90%) but less so in detecting superficial or well-differentiated lesions (50%). There are numerous urinary tumor markers under investigation for screening, assessing recurrence, progression, prognosis or response to therapy; the NMP22 point-of-care assay for a specific urinary protein has shown utility in detecting recurrent tumors.

C. Imaging

Bladder cancers may be identified using ultrasound, CT, or MRI where filling defects within the bladder are noted. However, the presence of cancer is confirmed by cystoscopy and biopsy, with imaging primarily used to evaluate the upper urinary tract and stage more advanced lesions.

D. Cystourethroscopy and Biopsy

The diagnosis and staging of bladder cancers are made by cystoscopy and transurethral resection. If cystoscopy—performed usually under local anesthesia—confirms the presence of bladder cancer, the patient is scheduled for transurethral resection under general or regional anesthesia. Random bladder and, on occasion, prostate urethral biopsies are performed to detect occult disease elsewhere in the bladder and potentially identify patients at greater risk for tumor recurrence and progression.

▶ Pathology & Staging

Grading is based on cellular features: size, pleomorphism, mitotic rate, and hyperchromatism. Bladder cancer staging is based on the extent of bladder wall penetration and the presence of regional or distant metastases.

The natural history of bladder cancer is based on two separate but related processes: tumor recurrence within the bladder and progression to higher-stage disease. Both are correlated with tumor grade and stage.

▶ Treatment

Patients with superficial cancers (Ta, T1) are treated with complete transurethral resection and selective use of intravesical chemotherapy. In the subset of patients with large, high-grade, recurrent Ta lesions or T1 cancers and those

with carcinoma in situ are good candidates for adjuvant intravesical therapy.

Patients with invasive (T2, T3) but still localized cancers are at risk for both nodal metastases and progression and require radical cystectomy, irradiation, or the combination of chemotherapy and selective surgery or irradiation due to the much higher risk of progression compared with patients with lower-stage lesions.

For patients with muscle invasive (T2 or greater) transitional cell carcinoma, neoadjuvant systemic chemotherapy prior to radical cystectomy is superior to radical cystectomy alone. This is particularly important for higher stage or bulky tumors in order to improve their surgical resectability.

A. Intravesical Chemotherapy

Immunotherapeutic or chemotherapeutic agents delivered directly into the bladder via a urethral catheter can reduce the likelihood of recurrence in those who have undergone complete transurethral resection. Most agents are administered weekly for 6–12 weeks. Efficacy may be increased by prolonging contact time to 2 hours. The use of maintenance therapy after the initial induction regimen is beneficial. Common agents include thiotepa, mitomycin, doxorubicin, and BCG, the last being the most effective agent when compared with the others with respect to reducing disease progression. Side effects of intravesical chemotherapy include irritative voiding symptoms and hemorrhagic cystitis. Patients in whom symptoms or infection develop from BCG may require antituberculous therapy.

B. Surgical Treatment

Although transurethral resection is the initial form of treatment for all bladder tumors since it is diagnostic, allows for proper staging, and controls superficial cancers, muscle-infiltrating cancers require more aggressive treatment. Partial cystectomy is indicated in selected patients with solitary lesions or those with cancers in a bladder diverticulum. Radical cystectomy entails removal of the bladder, prostate, seminal vesicles, and surrounding fat and peritoneal attachments in men and the uterus, cervix, urethra, anterior vaginal vault, and usually the ovaries in women. Bilateral pelvic lymph node dissection is performed in all patients.

Urinary diversion can be performed using a conduit of small or large bowel. However, continent forms of diversion have been developed that avoid the necessity of an external appliance and can be considered in a significant number of patients.

C. Radiotherapy

External beam radiotherapy delivered in fractions over a 6- to 8-week period is generally well tolerated, but approximately 10–15% of patients will develop bladder, bowel, or rectal complications. Local recurrence is common after radiotherapy alone (30–70%) and is therefore combined with systemic chemotherapy in an effort to reduce the need for radical cystectomy or to treat patients who are poor candidates for radical cystectomy.

D. Chemotherapy

Metastatic disease is present in 15% of patients with newly diagnosed bladder cancer, and metastases develop within 2 years in up to 40% of patients who were believed to have localized disease at the time of cystectomy or definitive radiotherapy. Cisplatin-based combination chemotherapy results in partial or complete responses in 15–45% of patients (see Table 39–4).

Combination chemotherapy has been integrated into trials of surgery and radiotherapy. It has been used to decrease recurrence rates with both modalities and to attempt bladder preservation in those treated with radiation. Chemotherapy should be considered before surgery in those with bulky lesions or those suspected of having regional disease, and recent evidence suggests that neoadjuvant chemotherapy may benefit all patients prior to planned cystectomy. Chemoradiation is best suited for those with T2 or limited T3 disease without ureteral obstruction. Alternatively, chemotherapy has been used after cystectomy in patients at high risk for recurrence.

► Prognosis

The frequency of recurrence and progression are correlated with grade. Whereas progression may be noted in few grade I cancers (19–37%), it is common with poorly differentiated lesions (33–67%). Carcinoma in situ is most often found in association with papillary bladder cancers. Its presence identifies patients at increased risk for recurrence and progression.

At initial presentation, approximately 50–80% of bladder cancers are superficial: stage Ta, Tis, or T1. When properly treated, lymph node metastases and progression are uncommon in this population and survival is excellent at 81%. Five-year survival of patients with T2 and T3 disease ranges from 50% to 75% after radical cystectomy. Long-term survival for patients with metastatic disease at presentation is rare.

► When to Refer

- All patients should be referred to an urologist. Hematuria often deserves evaluation with upper urinary tract imaging and cystoscopy.
- Histologic diagnosis and staging require endoscopic resection of tumor.

CANCERS OF THE URETER & RENAL PELVIS

Cancers of the renal pelvis and ureter are rare and occur more commonly in patients with bladder cancer, smokers, those with Balkan nephropathy, those exposed to Thorotrast (a contrast agent with radioactive thorium in use until the 1960s), or those with a long history of analgesic abuse. The majority are urothelial cell carcinomas. Gross or microscopic hematuria is present in most patients, and flank pain secondary to bleeding and obstruction occurs less commonly. Like primary bladder tumors, urinary cytology is often positive. The most common signs identified at the time of IVU or CT include an intraluminal filling defect, unilateral nonvisualization of the collecting system, and hydronephrosis. Ureteral and renal pelvic tumors must be differentiated from calculi, blood clots, papillary necrosis, or inflammatory and infectious lesions. On occasion, upper urinary tract lesions are accessible for biopsy, fulguration, or resection using a ureteroscope. Treatment is based on the site, size, grade, depth of penetration, and number of tumors present. Most are excised with laparoscopic or open nephroureterectomy (renal pelvic and upper ureteral lesions) or segmental excision of the ureter (distal ureteral lesions). Endoscopic resection may be indicated in patients with limited renal function or focal, low-grade, cancers.

RENAL CELL CARCINOMA

ESSENTIALS OF DIAGNOSIS

- ▶ Gross or microscopic hematuria.
- ▶ Flank pain or mass in some patients.
- ▶ Systemic symptoms such as fever, weight loss may be prominent.
- ▶ Solid renal mass on imaging.

▶ General Considerations

Renal cell carcinoma accounts for 2.6% of all adult cancers. In the United States, approximately 52,190 cases of renal cell carcinoma are diagnosed and 12,890 deaths result annually. Renal cell carcinoma has a peak incidence in the sixth decade of life and a male-to-female ratio of 2:1. It may be associated with a number of paraneoplastic syndromes (see below and Table 39–2).

The cause is unknown. Cigarette smoking is the only significant environmental risk factor that has been identified. Familial settings for renal cell carcinoma have been identified (von Hippel–Lindau syndrome) as well as an association with dialysis-related acquired cystic disease and specific genetic aberrations (eg, Xp11.2 translocation), but sporadic tumors are far more common.

Renal cell carcinoma originates from the proximal tubule cells. Various histologic cell types are recognized (clear cell, papillary, chromophobe, collecting duct and sarcomatoid).

▶ Clinical Findings

A. Symptoms and Signs

Historically, 60% of patients presented with gross or microscopic hematuria. Flank pain or an abdominal mass was detected in approximately 30% of cases. The triad of flank pain, hematuria, and mass was found in only 10–15% of patients and is often a sign of advanced disease. Fever may be present as a paraneoplastic symptom (see Table 39–2). Symptoms of metastatic disease (cough, bone pain) occur in 20–30% of patients at presentation. Because of the widespread use of ultrasound and CT scanning, renal tumors are frequently detected incidentally in individuals with no urologic symptoms. There has been profound stage migration toward lower stages of disease over the past 10 years, likely due to the increased use of abdominal imaging. However, population mortality rates remain stable.

B. Laboratory Findings

Hematuria is present in 60% of patients. Erythrocytosis from increased erythropoietin production occurs in 5%, though anemia is more common; hypercalcemia may be present in up to 10% of patients. Stauffer syndrome is a reversible syndrome of hepatic dysfunction in the absence of metastatic disease.

C. Imaging

Renal masses are often first identified by abdominal ultrasonography or CT. CT scanning is the most valuable imaging test for renal cell carcinoma. It confirms the character of the mass and further stages the lesion with respect to regional lymph nodes, renal vein, or hepatic involvement. CT also provides valuable information regarding the contralateral kidney (function, bilaterality of neoplasm). Chest radiographs exclude pulmonary metastases, and bone scans should be performed for large tumors and in patients with bone pain or elevated alkaline phosphatase levels. MRI and duplex Doppler ultrasonography are excellent methods of assessing for the presence and extent of tumor thrombus within the renal vein or vena cava.

▶ Differential Diagnosis

Solid lesions of the kidney are renal cell carcinoma until proved otherwise. Other solid masses include angiomyolipomas (fat density usually visible by CT), urothelial cell cancers of the renal pelvis (more centrally located, involvement of the collecting system, positive urinary cytologic tests), adrenal tumors (superoanterior to the kidney) and oncocytomas (indistinguishable from renal cell carcinoma preoperatively), and renal abscesses.

▶ Treatment

Radical nephrectomy is the primary treatment for localized renal cell carcinoma. Patients with a single kidney, bilateral

lesions, or significant medical renal disease should be considered for partial nephrectomy. Patients with a normal contralateral kidney and good renal function but a small cancer are also candidates for partial nephrectomy. The use of radiofrequency or cryosurgical ablation is being studied.

No effective chemotherapy is available for metastatic renal cell carcinoma. Vinblastine is the single most effective agent, with short-term partial response rates of 15%. Bevacizumab can prolong time to progression in those with metastatic disease (see Table 39–4). Biologic response modifiers have received much attention, including interferon- α and interleukin-2. Partial response rates of 15–20% and 15–35%, respectively, have been reported. Responders tend to have lower tumor burdens, metastatic disease confined to the lung, and a high performance status. Patients with metastatic kidney cancer and good performance status who have resectable primary tumors should undergo cytoreductive nephrectomy. Two randomized trials have shown a survival benefit of surgery followed by the use of systemic therapy—specifically, biologic response modifiers—compared with the use of systemic therapy alone.

Several targeted drugs, specifically VEGF and Raf-kinase inhibitors, are effective (40% response rates) in patients with advanced kidney cancer. The drugs are oral agents, well tolerated, and particularly active for clear cell carcinoma. The appropriate timing and combination of these agents, with and without surgery and cytokine therapy, remains to be determined.

► Prognosis

After radical nephrectomy, tumors confined to the renal capsule (T1–T2) demonstrate 5-year disease-free survivals of 90–100%. Tumors extending beyond the renal capsule (T3 or T4) and node-positive tumors have 50–60% and 0–15% 5-year disease-free survival, respectively. One subgroup of patients with nonlocalized disease has reasonable long-term survival, namely, those with solitary resectable metastases. In this setting, radical nephrectomy with resection of the metastasis results in 5-year disease-free survival rates of 15–30%.

► When to Refer

- Patients with solid renal masses require further evaluation and should be referred to a urologist.
- Surgical excision of renal cell carcinoma remains the gold standard.
- Patients with metastatic disease should be referred to an oncologist.

OTHER PRIMARY TUMORS OF THE KIDNEY

Oncocytomas account for 3–5% of renal tumors, are usually benign, and are indistinguishable from renal cell carcinoma on preoperative imaging. These tumors are seen in other organs, including the adrenals, salivary glands, and thyroid and parathyroid glands.

Angiomyolipomas are rare benign tumors composed of fat, smooth muscle, and blood vessels. They are most commonly seen in patients with tuberous sclerosis (often multiple and bilateral) or in young to middle-aged women. CT scanning may identify the fat component, which is diagnostic for angiomyolipoma. Asymptomatic lesions less than 5 cm in diameter usually do not require intervention; large lesions can spontaneously bleed. Acute bleeding can be treated by angiographic embolization or, in rare cases, nephrectomy. Lesions over 5 cm are often prophylactically treated with angioembolization to reduce the risk of bleeding.

SECONDARY TUMORS OF THE KIDNEY

The kidney is not an infrequent site for metastatic disease. Of the solid tumors, lung cancer is the most common (20%), followed by breast (10%), stomach (10%), and the contralateral kidney (10%). Lymphoma, both Hodgkin and non-Hodgkin, may also involve the kidney, although it tends to appear as a diffusely infiltrative process resulting in renal enlargement rather than a discrete mass.

PRIMARY TUMORS OF THE TESTIS

ESSENTIALS OF DIAGNOSIS

- Commonest neoplasm in men aged 20–35 years.
- Typical presentation as a patient-identified painless nodule.
- Orchiectomy necessary for diagnosis.

► General Considerations

Malignant tumors of the testis are rare, with approximately two to three new cases per 100,000 males reported in the United States each year. Ninety to 95 percent of all primary testicular tumors are germ cell tumors and can be divided into two major categories: **nonseminomas**, including embryonal cell carcinoma (20%), teratoma (5%), choriocarcinoma (< 1%), and mixed cell types (40%); and **seminomas** (35%). The remainder of primary testicular tumors are nongermlinal neoplasms (Leydig cell, Sertoli cell, gona-

doblastoma). The lifetime probability of developing testicular cancer is 0.2% for an American white male. For the purposes of this review, only germ cell tumors will be considered.

Approximately 5% of testicular tumors develop in a patient with a history of cryptorchism, with seminoma being the most common. However, 5–10% of these tumors occur in the contralateral, normally descended testis. The relative risk of development of malignancy is highest for the intra-abdominal testis (1:20) and lower for the inguinal testis (1:80). Placement of the cryptorchid testis into the scrotum (orchidopexy) does not alter the malignant potential of the cryptorchid testis but does facilitate routine examination and tumor detection.

Testicular cancer is slightly more common on the right than the left, paralleling the increased incidence of cryptorchidism on the right side. One to 2 percent of primary testicular tumors are bilateral and up to 50% of these men have a history of unilateral or bilateral cryptorchidism. Primary bilateral testicular tumors may occur synchronously or asynchronously but tend to be of the same histology. Seminoma is the most common histologic finding in bilateral *primary* testicular tumors, while malignant lymphoma is the most common bilateral testicular tumor overall.

In animal models, exogenous estrogen administration during pregnancy has been associated with an increased development of testicular tumors with relative risk ranging from 2.8 to 5.3. Other acquired factors such as trauma and infection-related testicular atrophy have been associated with testicular tumors; however, a causal relationship has not been established.

► Clinical Findings

A. Symptoms and Signs

The most common symptom of testicular cancer is painless enlargement of the testis. Sensations of heaviness are not unusual. Patients are usually the first to recognize an abnormality, yet the typical delay in seeking medical attention ranges from 3 to 6 months. Acute testicular pain resulting from intratesticular hemorrhage occurs in approximately 10% of cases. Ten percent of patients are asymptomatic at presentation, and 10% manifest symptoms relating to metastatic disease such as back pain (retroperitoneal metastases), cough (pulmonary metastases), or lower extremity edema (vena cava obstruction).

A discrete mass or diffuse testicular enlargement is noted in most cases. Secondary hydroceles may be present in 5–10% of cases. In advanced disease, supraclavicular adenopathy may be present, and abdominal examination may reveal a mass. Gynecomastia is seen in 5% of germ cell tumors.

B. Laboratory Findings

Several serum markers are important in the diagnosis and monitoring of testicular carcinoma, including human chorionic gonadotropin (hCG), α -fetoprotein, and LD. α -Fetoprotein is never elevated with pure seminomas, and while hCG is occasionally elevated in seminomas, levels

tend to be lower than those seen with nonseminomas. LD may be elevated with either type of tumor. Liver function tests may be elevated in the presence of hepatic metastases, and anemia may be present in advanced disease.

C. Imaging

Scrotal ultrasound can readily determine whether a mass is intratesticular or extratesticular. Once the diagnosis of testicular cancer has been established by inguinal orchiectomy, clinical staging of the disease is accomplished by chest, abdominal, and pelvic CT scanning.

► Staging

In a commonly used staging system for nonseminoma germ cell tumors, a stage A lesion is confined to the testis; stage B demonstrates regional lymph node involvement in the retroperitoneum; and stage C indicates distant metastasis. For seminoma, the M.D. Anderson system is commonly used. In this system, a stage I lesion is confined to the testis, a stage II lesion has spread to the retroperitoneal lymph nodes, and a stage III lesion has supradiaphragmatic nodal or visceral involvement.

► Differential Diagnosis

An incorrect diagnosis is made at the initial examination in up to 25% of patients with testicular tumors. Scrotal ultrasonography should be performed if any uncertainty exists with respect to the diagnosis. Although most intratesticular masses are malignant, a benign lesion—epidermoid cyst—may rarely be seen. Epidermoid cysts are usually very small benign nodules located just underneath the tunica albuginea; occasionally, however, they can be large.

► Treatment

Inguinal exploration with early vascular control of the spermatic cord structures is the initial intervention. If cancer cannot be excluded by examination of the testis, radical orchiectomy is warranted. Scrotal approaches and open testicular biopsies should be avoided. Further therapy depends on the histology of the tumor as well as the clinical stage.

Stage I and IIa **seminomas** (retroperitoneal disease < 10 cm in diameter) are treated by radical orchiectomy and retroperitoneal irradiation. Patients with clinical stage I disease may be candidates for surveillance or single-agent carboplatin. Seminomas of stage IIb (> 10 cm retroperitoneal involvement) and stage III receive primary chemotherapy (etoposide and cisplatin or cisplatin, etoposide, and bleomycin). Surgical resection of residual retroperitoneal masses is warranted if the mass is larger than 3 cm in diameter, under which circumstances 40% will harbor residual carcinoma.

Up to 75% of clinical stage I **nonseminomas** are cured by orchiectomy alone. Selected patients who meet specific criteria may be offered surveillance after orchiectomy. These criteria are as follows: (1) tumor is confined within the tunica albuginea; (2) tumor does not demonstrate vascular invasion; (3) tumor markers normalize after orchiectomy;

(4) radiographic imaging of the chest and abdomen shows no evidence of disease; and (5) the patient is reliable. Patients most likely to experience relapse on a surveillance regimen include those with predominantly embryonal cancer and those with vascular or lymphatic invasion identified in the orchiectomy specimen. Surveillance needs to be considered an active process both by the clinician and by the patient. Patients are followed monthly for the first 2 years and bimonthly in the third year. Tumor markers are obtained at each visit, and chest radiographs and CT scans are obtained every 3 months. Follow-up continues beyond the initial 3 years; however, the 80% of relapses will occur within the first 2 years. With rare exceptions, patients who relapse can be cured by chemotherapy or surgery. Alternatives to surveillance include adjuvant chemotherapy (bleomycin, etoposide, cisplatin) and retroperitoneal lymph nodes dissection.

Patients with bulky retroperitoneal disease (> 3 cm nodes) or metastatic nonseminomas are treated with primary cisplatin-based combination chemotherapy following orchiectomy (etoposide and cisplatin or cisplatin, etoposide, and bleomycin) (see Table 39–4). If tumor markers normalize and a residual mass greater than 1 cm persists on imaging studies, the mass is resected because 20% of the time it will harbor viable cancer and 40% of the time it will harbor teratoma. Even if patients have a complete response to chemotherapy, some clinicians advocate retroperitoneal lymphadenectomy since 10% of patients may harbor residual carcinoma and 10% may have teratoma in the retroperitoneum. If tumor markers fail to normalize following primary chemotherapy, salvage chemotherapy is required (cisplatin, etoposide, ifosfamide).

► Prognosis

The 5-year disease-free survival rates for stage I and IIa **seminomas** (retroperitoneal disease < 10 cm in diameter) treated by radical orchiectomy and retroperitoneal irradiation are 98% and 92–94%, respectively. Ninety-five percent of patients with stage III disease attain a complete response following orchiectomy and chemotherapy. Patients with bulky retroperitoneal or disseminated disease treated with primary chemotherapy followed by surgery have a 5-year disease-free survival rate of 55–80%. The 5-year disease-free survival rate for patients with stage A **nonseminomas** (includes all treatments, orchiectomy and subsequently) ranges from 96% to 100%. For low-volume stage B disease, 90% 5-year disease-free survival is expected.

► When to Refer

Patients with solid masses of the testis should be referred to a urologist.

Pettersson A et al. Age at surgery for undescended testis and risk of testicular cancer. *N Engl J Med.* 2007 May 3;356(18):1835–41. [PMID: 17476009]

SECONDARY TUMORS OF THE TESTIS

Secondary tumors of the testis are rare. In men over the age of 50 years, lymphoma is the most common testis tumor, and overall it is the most common secondary neoplasm of the testis, accounting for 5% of all testicular tumors. It may be seen in three clinical settings: (1) late manifestation of widespread lymphoma, (2) the initial presentation of clinically occult disease, and (3) primary extranodal disease. Radical orchiectomy is indicated to make the diagnosis. Prognosis is related to the stage of disease.

Metastasis to the testis is rare. The most common primary site of origin is the prostate, followed by the lung, gastrointestinal tract, melanoma, and kidney.

CANCER COMPLICATIONS & EMERGENCIES

Cancer is a chronic disease, but acute emergency complications (eg, spinal cord compression, superior vena cava syndrome, malignant effusions) or generalized systemic effects (eg, hypercalcemia, opportunistic infections, disseminated intravascular coagulation, hyperuricemia) may occur as a consequence of local invasion of the cancer. Superior vena cava syndrome is discussed in Chapter 12 and disseminated intravascular coagulation is discussed in Chapter 13.

SPINAL CORD COMPRESSION

ESSENTIALS OF DIAGNOSIS

- Occurs as a complication of metastatic solid tumor lymphoma or multiple myeloma.
- Back pain is presenting symptom in most patients.
- Prompt diagnosis is essential because once a severe neurologic deficit develops, it is generally irreversible.
- Emergent treatment may prevent or potentially reverse paresis and urinary and bowel incontinence.

► General Considerations

Cancers that cause spinal cord compression most commonly metastasize to the vertebral bodies, resulting in physical damage to the spinal cord from edema, hemor-

rhage, and ischemia. Persistent compression can result in irreversible changes to the myelin sheaths resulting in permanent neurologic impairment.

Prompt diagnosis and therapeutic intervention are essential, since the probability of reversing neurologic symptoms largely depends on the duration of symptoms. Patients who are treated promptly after symptoms appear may have partial or complete return of function and, depending on tumor sensitivity to specific treatment, may respond favorably to subsequent anticancer therapy.

► Clinical Findings

A. Symptoms and Signs

Back pain at the level of the tumor mass occurs in over 80% of cases and may be aggravated by lying down, weight bearing, sneezing, or coughing; it usually precedes the development of neurologic symptoms or signs. Since involvement is usually epidural, a mixture of nerve root and spinal cord symptoms often develops. Progressive weakness and sensory changes commonly occur. Bowel and bladder symptoms progressing to incontinence are late findings.

The initial findings of impending cord compression may be quite subtle, and there should be a high index of suspicion when back pain or weakness of the lower extremities develops in cancer patients.

B. Imaging

MRI is usually the initial imaging procedure of choice in a cancer patient with new-onset back pain. When there are neurologic findings suggesting spinal cord compression, an emergent MRI should be obtained. It is important to obtain a survey of the entire spine to define all areas of tumor involvement for treatment planning purposes.

Bone radiographs, if done, may show evidence of vertebral body or pedicle destruction by the cancer. However, bone radiographs are neither sensitive nor specific and therefore are not helpful in diagnosis or treatment planning. If the back pain symptoms are nonspecific, bone scan imaging may be useful as a screening procedure.

► Treatment

Patients found to have epidural impingement of the spinal cord should be given corticosteroids immediately. The initial dose is 10–100 mg intravenously followed by 4–6 mg every 6 hours intravenously or orally. Patients without a known diagnosis of cancer should have emergent surgery to relieve the impingement and obtain a pathologic specimen. Patients with a single area of compression due to solid tumors are best treated with surgical decompression followed by radiation therapy. A randomized trial comparing surgery followed by radiation therapy with radiation therapy alone showed better outcomes (ie, improved ability to ambulate and improved bladder and bowel functions) in persons who had surgery followed by radiation therapy. If multiple vertebral body levels are involved with cancer, radiation therapy is the preferred treatment option. Corticosteroids are generally tapered toward the end of radiation therapy.

MALIGNANT EFFUSIONS

ESSENTIALS OF DIAGNOSIS

- Occur in pleural, pericardial, and peritoneal spaces.
- Caused by direct neoplastic involvement of serous surface or obstruction of lymphatic drainage.
- Half of undiagnosed effusions in patients not known to have cancer are malignant.

► General Considerations

The development of an effusion in the pleural, pericardial, or peritoneal space may be the initial finding in a patient with cancer, or an effusion may appear during the course of disease progression. Direct involvement of the serous surface with tumor is the most frequent initiating cause of the accumulation of fluid. The most common malignancies causing pleural and pericardial effusions are lung and breast cancers; the most common malignancies associated with malignant ascites are ovarian, colorectal, stomach, and pancreatic cancers.

► Clinical Findings

A. Symptoms and Signs

Patients with pleural and pericardial effusions complain of shortness of breath and orthopnea. Patients with ascites complain of abdominal distention and discomfort. Cardiac tamponade causing pressure equalization in the chambers impairing both filling and cardiac output can be a life-threatening event. Signs of tamponade include tachycardia, pulsus paradoxus, and hypotension. Signs of pleural effusions include decreased breath sounds, egophony, and percussion dullness.

B. Laboratory Findings

Malignancy is confirmed as the cause of an effusion when analysis of the fluid specimen shows malignant cells in either the cytology or cell block specimen.

C. Imaging

The presence of effusions can be confirmed with radiographic studies or ultrasonography.

► Differential Diagnosis

The differential diagnosis of a malignant pleural or pericardial effusion includes benign processes, such as congestive heart failure, pulmonary embolism, trauma, and infection.

The differential diagnosis of malignant ascites includes similar benign processes, such as congestive heart failure and infections; cirrhosis and pancreatic disease also cause ascites.

Bloody effusions are usually due to cancer, but a bloody pleural effusion can also be due to pulmonary embolism or trauma. Chylous pleural or ascitic fluid is generally associated with obstruction of lymphatic drainage as might occur in lymphomas.

► Treatment

In some cases, treatment of the underlying cancer with chemotherapy can cause regression of the effusions; however, not uncommonly, the presence of an effusion is an end-stage manifestation of the disease. In this situation, decisions regarding management are in large part dictated by the patient's symptoms and goals of care.

A. Pleural Effusion

A pleural effusion that is symptomatic may be managed initially with a **large volume thoracentesis**. With some patients, the effusion slowly reaccumulates, which allows for periodic thoracentesis when the patient becomes symptomatic. However, in most patients, the effusion reaccumulates quickly, causing rapid return of symptoms of shortness of breath. For those patients, several options exist for management. **Chest tube drainage followed by pleurodesis** is the preferred option for patients with a reasonable life expectancy. Patients are generally hospitalized for 3–7 days. The procedure involves placement of a chest tube that is connected to closed water seal drainage. Fluid is allowed to drain over several days. After lung expansion is confirmed on a chest radiograph, a sclerosing agent (such as talc slurry) is injected into the catheter. Other agents that can be used include doxycycline or bleomycin. Patients should be premedicated with analgesics and placed in a variety of positions in order to distribute the drug through the pleural spaces. Pleurodesis will not be successful if the lung cannot be reexpanded; these patients may be treated with the placement of a shunt or continued use of catheter drainage. Until recently, standard management had been to hold sclerosis until the chest tube drainage had decreased to less than 100 mL/d; a recent randomized trial comparing immediate pleurodesis after initial drainage with waiting until drainage had decreased to 100 mL/d showed no difference in pleurodesis efficacy between the two groups.

B. Pericardial Effusion

Fluid may be removed by a needle aspiration or by placement of a catheter for more thorough drainage. As with pleural effusions, most pericardial effusions will reaccumulate. Management options for recurrent, symptomatic effusions include catheter drainage followed by sclerosis with such agents as doxycycline or bleomycin or by pericardiectomy.

C. Malignant Ascites

Patients with malignant ascites not responsive to chemotherapy are generally treated with repeated large volume

paracenteses. As the frequency of drainage to maintain comfort can compromise the patient's quality of life, other alternatives include placement of a catheter or port so that the patient, family member, or visiting nurse can drain fluid as needed at home. Another option is placement of a peritoneovenous shunt; this can be considered for a select group of patients with life expectancy greater than 3 months and fluid that is nonviscous, nonbloody, and nonoculated.

HYPERCALCEMIA

ESSENTIALS OF DIAGNOSIS

- Usually symptomatic and severe (≥ 15 mg/dL).
- Most common paraneoplastic endocrine syndrome, accounting for most cases of hypercalcemia among inpatients.
- The neoplasm is clinically apparent in nearly all cases when hypercalcemia is detected.

► General Considerations

Hypercalcemia affects 20–30% of cancer patients at some point during their illness. The most common cancers causing hypercalcemia are myeloma, breast carcinoma, and non–small cell lung cancer. The presence of bone metastasis is not an essential feature of the syndrome, since hypercalcemia can be caused by systemic effects of tumor-released proteins (see The Paraneoplastic Syndromes above).

► Clinical Findings

A. Symptoms and Signs

Symptoms and signs of hypercalcemia can be subtle; the severity of symptoms not only depends on the degree of hypercalcemia but also the rate at which the calcium level rises. Early symptoms typically include anorexia, nausea, fatigue, constipation, and polyuria; later findings may include muscular weakness and hyporeflexia, confusion, psychosis, tremor, and lethargy.

B. Laboratory Findings

Symptoms and signs are caused by free calcium; as calcium is bound by protein in the serum, the measured serum calcium will underestimate the free or ionized calcium in

patients with low albumin levels. In the setting of hypocalcemia, the corrected serum calcium should be calculated by one of several available formulas (eg, corrected calcium = measured calcium – measured albumin + 4). Alternatively, the free calcium can be measured. When the corrected serum calcium rises above 12 mg/dL, sudden death due to cardiac arrhythmia or asystole may occur. The presence of hypercalcemia does not invariably indicate a dismal prognosis, especially in patients with breast cancer, myeloma, or lymphoma.

In the absence of signs or symptoms of hypercalcemia, a laboratory finding of elevated serum calcium should be retested immediately to exclude the possibility of error.

C. ECG

Electrocardiography often shows a shortening of the QT interval.

▶ Treatment

Emergency management should begin with the initiation of intravenous fluids with 0.9% saline at 100–200 mL/h to ensure rehydration with brisk urinary output of the often volume-depleted patient. If kidney function is normal or only marginally impaired, a bisphosphonate should be given. Choices include pamidronate, 60–90 mg intravenously over 2–4 hours, or zoledronic acid, 4 mg intravenously over several minutes. Zoledronic acid is more potent than pamidronate and has the advantage of a shorter administration time as well as a longer duration of effect but is more associated with the uncommon but serious side effect of osteonecrosis of the jaw. Once hypercalcemia is controlled, treatment directed at the cancer should be initiated if possible. Commonly, though, hypercalcemia occurs in patients with cancers that are unresponsive to treatment. In the event that the hypercalcemia becomes refractory to repeated doses of bisphosphonates, other agents that can help control hypercalcemia (at least temporarily) include gallium nitrate, calcitonin, and mithramycin; corticosteroids can be useful in patients with myeloma and lymphoma. Salmon calcitonin, 4–8 international units/kg given subcutaneously or intramuscularly every 12 hours, can be useful in patients with kidney disease; its onset of action is within hours but its hypocalcemic effect will wane in 2–3 days.

HYPERURICEMIA & TUMOR LYSIS SYNDROME

ESSENTIALS OF DIAGNOSIS

- ▶ Complication of treatment-associated tumor lysis of hematologic malignancies as well as rapidly proliferating malignancies.
- ▶ May be worsened by thiazide diuretic use.
- ▶ Rapid increase in serum uric acid can result in acute urate nephropathy caused by uric acid crystallization.
- ▶ Reducing pre-chemotherapy serum uric acid is fundamental to preventing urate nephropathy.

▶ General Considerations

Tumor lysis syndrome (TLS) is seen most commonly following treatment of hematologic malignancies, such as acute lymphoblastic leukemia and Burkitt lymphoma. However, TLS can develop from any tumor highly sensitive to chemotherapy. TLS is caused by the massive release of cellular material including nucleic acids, proteins, phosphorus, and potassium. If both the metabolism and excretion of these breakdown products are overwhelmed, hyperuremia, hyperphosphatemia, and hyperkalemia will develop abruptly. Acute kidney injury may develop from the hyperuremia, further exacerbating the hyperphosphatemia and hyperkalemia.

▶ Clinical Findings

Symptoms of hyperphosphatemia include nausea and vomiting as well as seizures. Also, with high levels of phosphorus, co-precipitation with calcium can cause renal tubule blockage further exacerbating the kidney injury. Hyperkalemia, due to release of intracellular potassium and with excretion impaired by the kidney disease, can cause arrhythmias and sudden death.

▶ Treatment

Prevention is the most important factor in the management of TLS. Guidelines for management of TLS have been developed by the American Society of Clinical Oncology and include aggressive hydration prior to initiation of chemotherapy as well as during and after completion of the chemotherapy. Administration of fluid helps keep urine flowing and facilitate excretion of uric acid and phosphorus. For the patients with moderate risk of developing TLS, allopurinol (which blocks the enzyme xanthine oxidase and therefore the formation of uric acid from purine breakdown) should be given before starting chemotherapy at an oral dose of 100 mg/m² every 8 hours (maximum 800 mg/d) with dose adjustments for kidney disease. For patients at high risk for developing TLS or in whom hyperuricemia develops despite treatment with allopurinol, rasburicase 0.1–0.2 mg/kg/d is given intravenously for 1–7 days. Rasburicase is a recombinant urate oxidase that converts uric acid into the more soluble form resulting in rapid decline in uric

acid levels. Rasburicase cannot be given to patients with known glucose 6-phosphate dehydrogenase (G6PD) deficiency nor can it be given to pregnant or lactating women. One of the mainstays of TLS management, systemic bicarbonate infusions to alkalinize the urine, is no longer recommended. Laboratory values should be monitored following initiation of chemotherapy; elevated potassium or phosphorus levels need to be promptly managed.

▶ When to Refer

Should urinary output drop or creatinine level rise, a nephrologist should be consulted to evaluate the need for dialysis.

INFECTIONS

Chapter 30 provides a more detailed discussion of infections in the immunocompromised patient.

ESSENTIALS OF DIAGNOSIS

- ▶ In patients with neutropenia, infection is a medical emergency.
- ▶ The presence of fever, although sometimes attributable to other causes, must be assumed to be due to an infection.

▶ General Considerations

Many patients with disseminated neoplasms have increased susceptibility to infection. In some patients, this results from impaired defense mechanisms (eg, acute leukemia, Hodgkin disease, multiple myeloma, chronic lymphocytic leukemia); in others, it results from the myelosuppressive and immunosuppressive effects of cancer chemotherapy or a combination of these factors. Complicating impaired defense mechanisms are the frequent presence of indwelling catheters, impaired mucosal surfaces, and colonization with more virulent hospital-acquired pathogens.

The source of a neutropenic febrile episode is determined in about 30% of cases through blood, urine, or sputum cultures. The bacterial organisms accounting for the majority of infections in cancer patients include gram-negative bacteria (*Escherichia coli*, *Klebsiella*, *Pseudomonas*, *Enterobacter*) and gram-positive bacteria (coagulase-negative *Staphylococcus*, *Staphylococcus aureus*, *Streptococcus pneumoniae*, *Corynebacterium*, and streptococci). There has been a trend over the last decade of an increasing percentage of gram-positive organisms. The risk of bacterial infections rises when the granulocyte count is below 1000/mcL; the risk dramatically increases when the count falls below 100/mcL.

▶ Clinical Findings

Appropriate cultures (eg, blood, sputum, urine, cerebrospinal fluid) should always be obtained before starting therapy. Two sets of blood cultures should be drawn; if the patient has an indwelling catheter, one of the cultures should be drawn from the line. A chest radiograph should also be obtained.

▶ Treatment

Empiric antibiotic therapy needs to be initiated immediately in the febrile, neutropenic patient. The choice of antibiotics depends on a number of different factors including the patient's clinical status and any localizing source of infection. If the patient is clinically well, monotherapy with an intravenous β -lactam with anti-*Pseudomonas* activity (cefepime, ceftazidime, imipenem/cilastatin, piperacillin/tazabactam) should be started. If the patient is clinically ill with hypotension or hypoxia, an aminoglycoside or fluoroquinolone should be added for "double" gram-negative bacteria coverage. If there is a strong suspicion of a gram-positive organism, such as from *S aureus* catheter infection, vancomycin can be given empirically. In some instances, patients may be treated with oral antibiotics and potentially in the outpatient setting. The Infectious Disease Society of America (IDSA) has published recommendations for antibiotic use in these low-risk patients. These patients must have an expected neutropenic timeframe of 7 days or less and not have comorbidities or signs of hemodynamic instability, gastrointestinal symptoms, altered mental status, pulmonary issues (an infiltrate, hypoxia, or underlying chronic obstructive pulmonary disease) and their liver and kidney function must not be impaired. If a patient is to be treated as an outpatient, he or she must also have good support at home and easy access to returning to the hospital if the clinical status worsens.

Antibiotics should be continued until the neutrophil count is rising and greater than 500/mcL for at least 1 day and the patient has been afebrile for 2 days. If an organism is identified through the cultures, the antibiotics should be adjusted to the antibiotic sensitivities of the isolate; treatment should be continued for the appropriate period of time and at least until the neutrophil count recovers.

For the neutropenic patient who is persistently febrile despite broad-spectrum antibiotics, an empiric antifungal drug should be added (amphotericin B, caspofungin, itraconazole, voriconazole, or liposomal amphotericin B).

Segal BH et al. Prevention and treatment of cancer-related infections. *J Natl Compr Canc Netw*. 2008 Feb;6(2):122–74. [PMID: 18319048]

PRIMARY CANCER TREATMENT

SYSTEMIC CANCER THERAPY

Detailed guidelines from the NCCN for cancer treatment can be found at www.nccn.org.

Use of cytotoxic drugs, hormones, antihormones, and biologic agents has become a highly specialized and increasingly effective means of treating cancer, with therapy usually administered by a medical oncologist. Selection of specific drugs or protocols for various types of cancer has traditionally been based on results of prior clinical trials; however, many patients have drug-resistant tumors. Molecular mechanisms of drug resistance continue to be the subject of intense study. Described mechanisms of drug resistance include impaired membrane transport of drugs, enhanced drug metabolism, mutated target proteins, and blockage of apoptosis due to mutations in cell cycle proteins. Cancer cells may initially be resistant to chemotherapy or acquire resistance when exposed to drugs.

TOXICITY & DOSE MODIFICATION OF CHEMOTHERAPEUTIC AGENTS

Use of chemotherapy to treat cancer is generally guided by results from clinical trials in individual tumor types. The complexity of treating cancer has increased over the last decade as more drugs, including those with novel mechanisms of action, have been approved by the Food and Drug Administration and introduced into general practice. Drug side effects and toxicities must be anticipated and carefully monitored. The short- and long-term toxicities of individual drugs are listed in Tables 39–10 and 39–11. Decisions on dose modifications for toxicities should be guided by the intent of therapy. In the palliative setting where the aim of therapy is to improve symptoms and quality of life, lowering doses to minimize toxicity is commonly done. However, when the goal of treatment is cure, dosing frequency and intensity should be maintained whenever possible. Cancer chemotherapy should be given and monitored by a medical oncologist or hematologist.

A complete blood count consisting of a differential count with particular attention to the absolute neutrophil count and platelet count as well as tests of liver and kidney function should be obtained before the initiation of chemotherapy. In patients with normal blood counts as well as normal liver and kidney function, drugs are started at their full dose. When the intent of chemotherapy is cure, including treatment in the adjuvant setting, every attempt should be made to schedule chemotherapy on time and at full dose. A complete blood count with differential should be checked at mid cycle to determine the nadir of the absolute neutrophil and platelet counts as well as immediately before the next cycle of chemotherapy is due.

Dose reductions may be necessary for patients with impaired kidney or liver function depending on the clearance mechanism of the drug. For patients receiving chemotherapy for palliation, bone marrow toxicity can be managed with dose reductions or delaying the next treatment cycle. A schema for dose modification is shown in Table 39–12.

1. Bone Marrow Toxicity

Depression of the bone marrow and the ability to produce adequate numbers of white cells, red cells, and platelets is

usually the most significant limiting toxicity with cancer chemotherapy. Drugs to ameliorate bone marrow suppression have become standard tools in the armamentarium of medical oncologists.

A. Neutropenia

Granulocyte colony-stimulating factor (G-CSF), given as either daily subcutaneous injections (filgrastim, 300 mcg or 480 mcg) or as a one-time dose (pegfilgrastim, 6 mg) beginning 24–72 hours after cytotoxic chemotherapy is completed, has been shown to markedly reduce the duration and severity of granulocytopenia following cytotoxic chemotherapy (Table 39–11). The American Society of Clinical Oncology and NCCN guidelines recommend primary prophylaxis with a G-CSF when there is 20% risk of febrile neutropenia or when the patient's age, medical history, and disease characteristics makes the patient at high risk for complications related to myelosuppression.

B. Anemia

Erythropoiesis-stimulating agents (ESAs) have been shown to ameliorate the anemia and associated symptoms caused by cancer chemotherapy. However, the evidence suggests that these drugs have untoward effects, including an increased risk of thromboembolism, and even more concerning, decreased survival due to cancer-related deaths. These findings have prompted the US Food and Drug Administration and other organizations (American Society of Hematology, American Society of Clinical Oncology, and NCCN) to issue advisories and guidelines limiting their use. The recommendation that these drugs should not be used when the intent of chemotherapy is curative is controversial, although the evidence is mounting that survival is indeed adversely affected by the administration of ESAs. Studies done in patients with potentially curable head and neck, breast, and cervical cancers have shown inferior outcomes when ESAs were used, though the target hemoglobin for patients in these studies was higher than what is currently recommended. The alternative to managing symptomatic anemia in these patients receiving curative chemotherapy is administration of red blood cell transfusions.

Although the details of these recommendations vary, all agree that oncologists should use ESAs in anemic patients receiving chemotherapy and generally should not be given until the hemoglobin is less than 10 g/dL with the medication held when the hemoglobin is greater than 12 g/dL. Epoetin alfa can be given subcutaneously as a weekly dose of 30,000–40,000 units with a target hemoglobin of 11–12 g/dL (see Table 39–11). Darbepoetin alfa is given subcutaneously every 2–3 weeks at a dose of 200–300 mcg with the same target hemoglobin. Patients need to be iron replete to have maximum therapeutic effect. Uncontrolled hypertension is a contraindication to the use of ESAs; blood pressure must be controlled prior to initiation of this therapy.

C. Thrombocytopenia

Drug management of chemotherapy-induced thrombocytopenia is more limited. The only available drug, oprelvekin or

Table 39–10. Chemotherapeutic agents: Dosage and toxicity.

| Chemotherapeutic Agent | Usual Adult Dosage | Acute Toxicity | Delayed Toxicity |
|---|---|---|---|
| Alkylating Agents—Nitrogen Mustards | | | |
| Bendamustine (Treanda) | 100–120 mg/m ² intravenously every 3–4 weeks | Hypersensitivity reaction, nausea, vomiting, skin reaction | Myelosuppression, pyrexia, fatigue |
| Cyclophosphamide (Cytosan) | 500–1000 mg/m ² intravenously every 3 weeks; 100 mg/m ² /d orally for 14 days every 4 weeks | Nausea and vomiting | Myelosuppression, hemorrhagic cystitis, alopecia, cardiotoxicity with high-dose therapy, SIADH |
| Estramustine (Emcyt) | 14 mg/kg/d orally in three or four divided doses | Nausea, vomiting, diarrhea | Gynecomastia, thromboembolism, edema |
| Ifosfamide (Ifex) | 1200 mg/m ² daily for 5 days intravenously every 3 weeks | Nausea and vomiting | Myelosuppression, hemorrhagic cystitis, neurotoxicity, alopecia, SIADH |
| Mechlorethamine (nitrogen mustard, Mustargen) | 0.4 mg/kg intravenously every 3–6 weeks; or 6 mg/m ² intravenously on days 1 and 8 every 4 weeks | Severe nausea and vomiting, severe vesicant | Myelosuppression, increased risk of secondary malignancies |
| Melphalan (Alkeran) | 0.25 mg/kg/d or 8–10 mg/m ² /d orally for 4 days every 4–6 weeks; 16 mg/m ² intravenously every 2–4 weeks; 200 mg/m ² intravenously for bone marrow transplant | Nausea, vomiting, diarrhea, hypersensitivity (IV), mucositis (IV) | Myelosuppression, increased risk of secondary malignancies |
| Alkylating Agents—Platinum Analogs | | | |
| Carboplatin (Paraplatin) | Area under the curve (AUC)-based dosing use Calvert equation [Dose (mg) = AUC × (GFR + 25)] AUC = 2–7 mg/mL/min every 2–4 weeks; or 200–400 mg/m ² intravenously every 4 weeks | Nausea, vomiting, hypersensitivity reaction | Myelosuppression, electrolyte disturbances, peripheral neuropathy, nephrotoxicity (less common than with cisplatin) |
| Cisplatin (Platinol) | 50–100 mg/m ² intravenously every 3–4 weeks; 20 mg/m ² /d intravenously for 5 days every 3 weeks | Severe nausea and vomiting | Nephrotoxicity, ototoxicity, peripheral neuropathy, myelosuppression, electrolyte disturbances |
| Oxaliplatin (Eloxatin) | 85–130 mg/m ² intravenously every 2–3 weeks | Peripheral neuropathy triggered or exacerbated by cold, nausea, vomiting, diarrhea, rare anaphylactic reactions | Peripheral neuropathy, myelosuppression |
| Alkylating Agents—Triazines | | | |
| Dacarbazine (DTIC-Dome) | 375 mg/m ² intravenously on day 1 and 15 every 4 weeks, 250 mg/m ² intravenously for 5 days | Severe nausea and vomiting, anorexia | Myelosuppression, photosensitivity, hepatotoxicity, flu-like syndrome |
| Procarbazine (Matulane) | 60–100 mg/m ² orally for 14 days every 4 weeks | Nausea and vomiting | Myelosuppression; disulfiram-like reaction with alcohol; caution with tyramine-containing foods, tricyclic antidepressants, and sympathomimetic agents – MAO inhibition; increased risk of secondary malignancies |
| Temozolomide (Temodar) | 75 mg/m ² orally daily during radiation for 42 days 150–200 mg/m ² orally for 5 days every 4 weeks | Nausea, vomiting, headache, constipation | Myelosuppression |
| Alkylating Agents—Miscellaneous | | | |
| Busulfan (Myleran) | 1–8 mg daily orally | Nausea and vomiting | Myelosuppression, mucositis, hyperpigmentation of skin, rare pulmonary fibrosis, hepatic veno-occlusive disease with high doses (> 16 mg/d in transplant patients) |

(continued)

Table 39–10. Chemotherapeutic agents: Dosage and toxicity. (continued)

| Chemotherapeutic Agent | Usual Adult Dosage | Acute Toxicity | Delayed Toxicity |
|---|---|---|--|
| Chlorambucil (Leukeran) | 0.1–0.2 mg/kg/d orally for 3–6 weeks; or 0.4 mg/kg pulse every 4 weeks | None | Myelosuppression, rare pulmonary toxicity, skin reaction, increased risk of secondary malignancies with prolonged use |
| Lomustine (CCNU) | 100–130 mg/m ² orally every 6 weeks | Nausea and vomiting | Myelosuppression, pulmonary toxicity |
| Antimetabolites—Folate Antagonists | | | |
| Methotrexate (MTX; Trexall) | Intrathecal: 12 mg High dose: 1000–12,000 mg/m ² intravenously every 2–3 weeks | Nausea, vomiting, mucositis | Myelosuppression, nephrotoxicity, hepatotoxicity, neurotoxicity (with intrathecal administration and high-dose therapy), photosensitivity, pulmonary toxicity, caution multiple drug interactions which may enhance toxicities (avoid aspirin, penicillins, NSAIDs, omeprazole, TMP-SMZ) |
| Pemetrexed (Alimta) | 500 mg/m ² intravenously every 3 weeks | Fatigue, nausea, vomiting, diarrhea, rash | Myelosuppression, mucositis Avoid NSAIDs which may decrease pemetrexed clearance and enhance toxicities |
| Antimetabolites—Purine Analogs | | | |
| Cladribine (Leustatin) | 0.14 mg/kg/d intravenously or subcutaneously daily for 5 days or 0.09 mg/kg/d intravenously via continuous infusion for 7 days | Mild nausea, fatigue, injection site reaction, rash | Myelosuppression, immunosuppression, fever |
| Clofarabine (Clolar) | 52 mg/m ² intravenously daily for 5 days every 2–6 weeks (for patients < 21 years of age) | Nausea, vomiting, diarrhea, dermatitis, pruritus, headache, rigor | Myelosuppression, hepatotoxicity, nephrotoxicity, capillary leak syndrome, immunosuppression |
| Fludarabine (Fludara) | 25 mg/m ² intravenously for 5 days every 4 weeks | Asthenia, fever, myalgias, rare hypersensitivity reaction | Myelosuppression, immunosuppression, neurotoxicity, visual disturbances |
| Mercaptopurine (6-MP; Purinethol) | Induction: 2.5–5 mg/kg/d orally Maintenance: 1.5–2.5 mg/kg/d orally | Diarrhea, hyperpigmentation of skin, rash | Myelosuppression, immunosuppression, hepatotoxicity, mucositis |
| Pentostatin (Nipent) | 4 mg/m ² intravenously every other week | Nausea, vomiting, rash | Myelosuppression, immunosuppression, hepatotoxicity |
| Antimetabolites—Pyrimidine Analogs | | | |
| Azacitidine (Vidaza) | 75 mg/m ² subcutaneously or intravenously for 7 days every 4 weeks, may increase to 100 mg/m ² after two cycles if no response | Injection site reaction, nausea, constipation, fever | Myelosuppression, hepatotoxicity, and nephrotoxicity (rare) |
| Capecitabine (Xeloda) | 625–1250 mg/m ² orally twice a day for 14 days every 3 weeks | Nausea, vomiting, diarrhea | Hand-foot syndrome, mucositis, hyperbilirubinemia, myelosuppression |
| Cytarabine (Ara-C, Cytosar U) | Standard dose: 100 mg/m ² /d intravenously via continuous infusion for 7 days High dose: 1000–3000 mg/m ² intravenously every 12 hours on days 1, 3, 5 | Nausea, vomiting, rash, flu-like syndrome | Myelosuppression High-dose therapy: neurotoxicity (cerebellar ataxia, lethargy, confusion), ocular toxicities (conjunctivitis and keratitis), hepatotoxicity, pancreatitis, pulmonary toxicity |
| Cytarabine Liposome (DepoCyt) | 50 mg intrathecally every 14 or 28 days | | Chemical arachnoiditis |
| Decitabine (Dacogen) | 15 mg/m ² intravenously every 8 hours for 3 days, repeat every 8 weeks | Nausea, fatigue, hyperglycemia | Myelosuppression |

(continued)

Table 39–10. Chemotherapeutic agents: Dosage and toxicity. (continued)

| Chemotherapeutic Agent | Usual Adult Dosage | Acute Toxicity | Delayed Toxicity |
|---|---|---|--|
| Fluorouracil (5-FU; Adrucil) | 500–600 mg/m ² intravenous bolus weekly for 6 weeks, repeat every 8 weeks; in combination with oxaliplatin: 400 mg/m ² intravenous bolus followed immediately by 600 mg/m ² intravenously over 22 hours on days 1 and 2 or 400 mg/m ² intravenous bolus followed immediately by 2400 mg/m ² intravenously over 46 hours; 1000 mg/m ² intravenously via continuous infusion for 4–5 days every 3–4 weeks | Nausea, diarrhea | Myelosuppression (intravenous bolus), hand-foot syndrome, mucositis, neurotoxicity, ocular toxicity, photosensitivity, cardiotoxicity (rare) |
| Gemcitabine (Gemzar) | 1000–1250 mg/m ² intravenously on days 1, 8, 15 every 4 weeks | Nausea, rash, flu-like symptoms, fever, diarrhea | Myelosuppression, edema, hepatotoxicity (rare), hemolytic uremic syndrome (rare), pulmonary toxicity (rare) |
| Antimicrotubules—Vinca Alkaloids | | | |
| Vinblastine (Velban) | 6 mg/m ² intravenously on days 1 and 15 every 4 weeks; 0.11 mg/kg on days 1 and 2 | Vesicant, bronchospasm and dyspnea (rare) | Myelosuppression, peripheral neuropathy, constipation, mucositis, alopecia, SIADH (rare) |
| Vincristine (Oncovin) | 0.5–1.4 mg/m ² intravenously every 3 weeks; 0.4 mg/m ² intravenously via continuous infusion for 4 days; maximum single dose usually limited to 2 mg | Vesicant | Peripheral neuropathy, constipation, alopecia, SIADH (rare) |
| Vinorelbine (Navelbine) | 30 mg/m ² intravenously on days 1 and 8 every 3 weeks | Vesicant, nausea, vomiting, bronchospasm and dyspnea (rare) | Myelosuppression, peripheral neuropathy, constipation, alopecia, SIADH (rare) |
| Antimicrotubules—Taxanes | | | |
| Docetaxel (Taxotere) | 60–100 mg/m ² intravenously every 3 weeks; 35–40 mg/m ² intravenously weekly for 3 weeks with 1 week rest | Hypersensitivity reaction, nausea, vomiting | Myelosuppression, peripheral neuropathy, alopecia, edema, fatigue, mucositis, diarrhea |
| Paclitaxel (Taxol) | 135–175 mg/m ² intravenously every 3 weeks; 50–80 mg/m ² intravenously weekly | Hypersensitivity reaction, nausea, vomiting, bradycardia and hypotension during infusion | Myelosuppression, peripheral neuropathy, alopecia, mucositis, diarrhea, arthralgias/myalgias |
| Paclitaxel protein-bound (Abraxane) | 260 mg/m ² intravenously every 3 weeks | Nausea, vomiting, diarrhea, hypersensitivity reaction (less than paclitaxel) | Myelosuppression, peripheral neuropathy, alopecia, mucositis, arthralgias/myalgias |
| Antimicrotubules—Epothilone | | | |
| Ixabepilone (Ixempra) | 40 mg/m ² intravenously every 3 weeks | Hypersensitivity reaction, nausea, vomiting | Peripheral neuropathy, myelosuppression, alopecia, fatigue, mucositis, diarrhea, arthralgias/myalgias |
| Enzyme Inhibitors—Anthracyclines | | | |
| Daunorubicin (Cerubidine) | 30–60 mg/m ² intravenously for 3 days | Nausea, vomiting, mucositis, diarrhea, red/orange discoloration of urine, cardiotoxicity (ECG changes). - All anthracyclines except for liposomal doxorubicin are potent vesicants. - Liposomal daunorubicin and liposomal doxorubicin may cause infusion-related reactions | Myelosuppression, cardiotoxicity (cardiomyopathy with congestive heart failure—dose related), alopecia. - Liposomal Doxorubicin can also cause hand-foot syndrome |
| Liposomal Daunorubicin (Daunoxome) | 40 mg/m ² intravenously every 2 weeks | | |
| Doxorubicin (Adriamycin) | 15–20 mg/m ² intravenously weekly; 45–60 mg/m ² intravenously every 3 weeks | | |
| Liposomal Doxorubicin (Doxil) | 20–50 mg/m ² intravenously every 3–4 weeks | | |
| Epirubicin (Ellence) | 35 mg/m ² intravenously every 2 weeks; 60–120 mg/m ² intravenously every 3–4 weeks | | |
| Idarubicin (Idamycin) | 12 mg/m ² intravenously for 3 days | | |

(continued)

Table 39–10. Chemotherapeutic agents: Dosage and toxicity. (continued)

| Chemotherapeutic Agent | Usual Adult Dosage | Acute Toxicity | Delayed Toxicity |
|--|--|---|--|
| Enzyme Inhibitors—Topoisomerase Inhibitors | | | |
| Etoposide (Vepesid) | 50–100 mg/m ² intravenously for 3–5 days every 3 weeks, oral dose is twice the intravenous dose | Nausea, vomiting, hypersensitivity reaction, fever, hypotension | Myelosuppression, alopecia, fatigue |
| Etoposide Phosphate (Etopophos) | 100 mg/m ² intravenously for 3–5 days every 3 weeks | | |
| Irinotecan (Camptosar) | 60 mg/m ² intravenously on days 1, 8, and 15 every 4 weeks; 125 mg/m ² intravenously weekly for 4 weeks every 6 weeks; 180 mg/m ² intravenously every other week; 350 mg/m ² intravenously every 3 weeks | Diarrhea and cholinergic syndrome, nausea, vomiting | Myelosuppression, alopecia |
| Topotecan (Hycamtin) | 1.5 mg/m ² intravenously for 5 days every 3 weeks; 2.3 mg/m ² orally for 5 days every 3 weeks | Nausea, vomiting, diarrhea | Myelosuppression, alopecia, asthenia |
| Targeted Therapy—Monoclonal Antibodies | | | |
| Alemtuzumab (Campath) | 30 mg/m ² intravenously three times weekly | Infusion-related reaction, nausea, vomiting, hypotension | Myelosuppression, immunosuppression |
| Bevacizumab (Avastin) | 5–15 mg/kg intravenously every 2–3 weeks | Infusion-related reaction | Arterial thromboembolism, wound healing complications, gastrointestinal perforation or fistula, hemorrhage, hypertension, proteinuria |
| Cetuximab (Erbix) | Loading dose 400 mg/m ² intravenously followed by maintenance dose 250 mg/m ² intravenously weekly | Infusion-related reaction | Acneiform skin rash, hypomagnesemia, asthenia, paronychia inflammation, pulmonary toxicity (rare) |
| Gemtuzumab ozogamicin (Mylotarg) | 9 mg/m ² intravenously | Infusion-related reaction, nausea, vomiting | Myelosuppression, hepatotoxicity, veno-occlusive disease (rare) |
| Ibritumomab tiuxetan (Zevalin) | 0.4 mCi/kg intravenously on day 8 | Infusion-related reaction | Myelosuppression, asthenia, infections, increased risk of secondary malignancies |
| ¹³¹ I Tositumomab (Bexxar) | 450 mg intravenously | Infusion-related reaction | Myelosuppression, asthenia, infections, hypothyroidism, increased risk of secondary malignancies |
| Panitumumab (Vectibix) | 6 mg/kg intravenously every 2 weeks | Infusion-related reaction | Acneiform skin rash, hypomagnesemia, asthenia, paronychia inflammation, pulmonary toxicity (rare) |
| Rituximab (Rituxan) | 375 mg/m ² intravenously weekly for 4 weeks, or every 3 weeks | Infusion-related reaction | Rare reactions: Hepatitis B reactivation, pulmonary toxicity, tumor lysis syndrome, Stevens-Johnson syndrome, progressive multifocal leukoencephalopathy, cardiac arrhythmias, bowel obstruction |
| Trastuzumab (Herceptin) | Loading dose 4 mg/kg intravenously followed by 2 mg/kg intravenously weekly; or loading dose 8 mg/kg followed by 6 mg/kg intravenously every 3 weekly | Infusion-related reaction, headache, diarrhea | Cardiotoxicity, pulmonary toxicity, myelosuppression in combination with chemotherapy |
| Targeted Therapy—Tyrosine Kinase Inhibitors | | | |
| Dasatinib (Sprycel) | 70 mg orally twice daily; 100–140 mg orally once daily | Diarrhea, nausea, vomiting | Myelosuppression, fluid retention, fatigue, musculoskeletal pain, rash, cardiac dysfunction/congestive heart failure (rare), hemorrhage (rare) |

(continued)

Table 39–10. Chemotherapeutic agents: Dosage and toxicity. (continued)

| Chemotherapeutic Agent | Usual Adult Dosage | Acute Toxicity | Delayed Toxicity |
|-----------------------------|--|--|--|
| Erlotinib (Tarceva) | 100–150 mg orally once daily | Diarrhea | Acneiform skin rash, fatigue, anorexia, conjunctivitis, gastrointestinal hemorrhage (rare), pulmonary toxicity (rare) |
| Gefitinib (Iressa) | 250 mg orally once daily | Diarrhea | Acneiform skin rash, asthenia, ocular toxicity, myelosuppression, hepatotoxicity (rare), pulmonary toxicity (rare) |
| Imatinib (Gleevec) | 100–800 mg orally once daily | Nausea, vomiting, diarrhea | Myelosuppression, edema, myalgias, rash, congestive heart failure, left ventricular dysfunction (rare), hemorrhage (rare), hepatotoxicity (rare) |
| Lapatinib (Tykerb) | 1250 mg orally once daily in combination with capecitabine | Diarrhea, nausea, vomiting | Hand-foot syndrome, fatigue, hepatotoxicity (rare), left ventricular dysfunction (rare), prolonged QT interval (rare), interstitial lung disease (rare) |
| Nilotinib (Tasigna) | 400 mg orally twice daily | Nausea, vomiting, headache, diarrhea | Edema, rash, arthralgia, fatigue, myelosuppression, electrolyte abnormalities, elevated serum lipase (rare), hepatotoxicity (rare), prolonged QT interval (rare) |
| Sorafenib (Nexavar) | 400 mg orally twice daily | Diarrhea and nausea | Hypertension, hand-foot syndrome, rash, fatigue, gastrointestinal perforation (rare), hemorrhage (rare), cardiac ischemia/infarction (rare) |
| Sunitinib (Sutent) | 50 mg orally once daily for 4 weeks followed by 2 weeks rest. | Diarrhea and nausea | Hypertension, hand-foot syndrome, rash, yellow discoloration of skin, fatigue, hypothyroidism, mucositis, myelosuppression, left ventricular dysfunction (rare), prolonged QT interval (rare), hemorrhage (rare) |
| Miscellaneous Agents | | | |
| Altretamine (Hexalen) | 260 mg/m ² orally in 4 divided doses for 14–21 days every 4 weeks | Nausea, vomiting, diarrhea | Neurotoxicity, myelosuppression, flu-like syndrome |
| Arsenic Trioxide (Trisenox) | 0.15 mg/kg intravenously daily | Nausea, dizziness | Edema, acute promyelocytic leukemia differentiation syndrome (fever, dyspnea, skin rash, fluid retention, pleural effusions), prolonged QT interval and complete atrioventricular block |
| Asparaginase (Elspar) | 6000–10,000 units/m ² intravenously daily on days 17–28; 6000–10,000 units/m ² intramuscularly every 3 days for a total of 9 doses | Hypersensitivity reaction (requires test dose), nausea, vomiting | Coagulation abnormalities (hemorrhagic and/or thrombotic events), hepatotoxicity, pancreatitis, neurotoxicity |
| Bleomycin (Blenoxane) | 10 units/m ² intravenously on days 1 and 15 every 4 weeks; 30 units on day 2, 9, and 16 every 3 weeks | Hypersensitivity reaction | Skin reaction (rash, hyperpigmentation of skin, striae), pulmonary fibrosis |
| Bortezomib (Velcade) | 1.3 mg/m ² intravenous bolus on days 1, 4, 8, 11 followed by a 10 day rest every 3 weeks | Orthostatic hypotension, fever | Peripheral neuropathy, fatigue, myelosuppression, hemorrhage (rare), left ventricular dysfunction (rare), pulmonary toxicity (rare), reversible posterior leukoencephalopathy syndrome (rare), hepatotoxicity (rare) |

(continued)

Table 39–10. Chemotherapeutic agents: Dosage and toxicity. (continued)

| Chemotherapeutic Agent | Usual Adult Dosage | Acute Toxicity | Delayed Toxicity |
|---|---|---|--|
| Dactinomycin (Cosmegen) | 15 mcg/kg intravenously daily for 5 days; 12 mcg/kg intravenously daily for 5 days; 1000 mcg/m ² intravenously | Vesicant, nausea, vomiting | Myelosuppression, mucositis, diarrhea, alopecia, hyperpigmentation of skin, hepatotoxicity, hepatovenous-occlusive disease (rare) |
| Denileukin diftitox (Ontak) | 9 or 18 mcg/kg intravenously daily for 5 days every 3 weeks | Flu-like syndrome, hypersensitivity reaction, nausea, vomiting | Diarrhea, decreased visual acuity, fever, increased risk for infection, hypoalbuminemia, capillary leak syndrome (rare) |
| Hydroxyurea (Hydrea) | 20–30 mg/kg orally once daily | Nausea | Myelosuppression, dermatopathy |
| Lenalidomide (Revlimid) | 5–25 mg orally once daily for 21 days every 4 weeks | Diarrhea, itching, rash | Myelosuppression, potential for birth defects, thromboembolic events, fatigue |
| Mitomycin (Mutamycin) | 20 mg/m ² intravenously every 6–8 weeks; 20–40 mg intravesically weekly | Vesicant, local irritation (cystitis when given intravesically) | Myelosuppression, mucositis, hemolytic uremic syndrome (rare), pulmonary toxicity (rare) |
| Mitoxantrone (Novantrone) | 12–14 mg/m ² intravenously every 3 weeks; induction chemotherapy for leukemia 12 mg/m ² intravenously for 2–3 days | Blue-green discoloration of urine, nausea, vomiting, diarrhea, intravenous irritant | Myelosuppression, cardiotoxicity, alopecia, mucositis, increased risk of secondary malignancies (rare) |
| Temsirolimus (Torisel) | 25 mg intravenously weekly | Hypersensitivity reaction, rash | Myelosuppression, edema, fatigue, mucositis, hyperglycemia, hyperlipemia, immunosuppression, nephrotoxicity, interstitial lung disease (rare), bowel perforation (rare), abnormal wound healing |
| Thalidomide (Thalomid) | 50–800 mg orally once daily | Sedation, constipation, fatigue | Potential for birth defects, thromboembolic events, peripheral neuropathy, edema |
| Tretinoin (All-Trans-Retinoic Acid, ATRA, Vesanoid) | 45 mg/m ² orally divided twice daily for 45–90 days or 30 days past complete remission | | Headache, vitamin A toxicity, retinoic acid-acute promyelocytic leukemia syndrome, ototoxicity |
| Antiandrogens | | | |
| Bicalutamide (Casodex) | 50 mg orally once daily | None | Hot flashes, decreased libido, impotence, gynecomastia, breast tenderness, fatigue |
| Flutamide (Eulexin) | 250 mg orally every 8 hours | Diarrhea, yellow-green discoloration of urine | Hot flashes, decreased libido, impotence, gynecomastia, breast tenderness, hepatotoxicity (rare) |
| Nilutamide (Nilandron) | 300 mg orally for 30 days then 150 mg orally once daily | Nausea | Visual disturbances (impaired adaptation to dark), hot flashes, decreased libido, impotence, gynecomastia, breast tenderness, disulfiram reaction with alcohol, interstitial pneumonitis (rare), hepatotoxicity (rare) |
| Selective Estrogen Receptor Modulators | | | |
| Tamoxifen (Nolvadex) | 20–40 mg orally once daily | None | Hot flashes, vaginal discharge or bleeding, menstrual irregularities, thromboembolic events (rare), endometrial hyperplasia, cataracts, hepatotoxicity, tumor flare |
| Toremifene (Fareston) | 60 mg orally once daily | Nausea | Hot flashes, vaginal discharge, thromboembolic events (rare), tumor flare, endometrial hyperplasia, cataracts, hepatotoxicity |

| Aromatase Inhibitors | | | |
| Anastrozole (Arimidex) | 1 mg orally once daily | Nausea | Hot flashes, peripheral edema, hypercholesterolemia, arthralgia/myalgia, headache, osteoporosis |
| Exemestane (Aromasin) | 25 mg orally once daily | | |
| Letrozole (Femara) | 2.5 mg orally once daily | | |
| Pure Estrogen Receptor Antagonist | | | |
| Fulvestrant (Faslodex) | 250 mg intramuscularly once a month | Injection site reactions, nausea, diarrhea, constipation | Hot flashes, backache, headache |
| Progestins | | | |
| Megestrol acetate (Megace) | 40–320 mg orally once daily or in divided doses (four times a day) | Nausea | Hot flashes, tumor flare, weight gain, hyperglycemia, thrombotic events (rare), adrenal insufficiency (rare) |
| LHRH Analogs | | | |
| Goserelin acetate (Zoladex) | 3.6 mg subcutaneously once every month; 10.8 mg subcutaneously once every 3 months | Injection site discomfort | Hot flashes, tumor flare, decreased libido, impotence, vaginal bleeding, thromboembolic events (rare), osteoporosis (rare) |
| Leuprolide (Lupron) | 7.5 mg intramuscularly once every month; 22.5 mg intramuscularly once every 3 months; 30 mg intramuscularly once every 4 months | Injection site reaction | Hot flashes, tumor flare, edema, impotence, thromboembolic events (rare), osteoporosis |
| Triptorelin pamoate (Trelstar) | 3.75 mg intramuscularly once every month; 11.25 mg intramuscularly once every 3 months | None | Hot flashes, tumor flare, skeletal pain, impotence |
| Adrenocorticosteroids | | | |
| Dexamethasone | 40 mg orally once weekly or 40 mg orally on days 1–4, 9–12, 17–20 | None | Hyperglycemia, weight gain, fluid retention, psychiatric symptoms |
| Ketoconazole | 400 mg orally three times daily | Nausea and vomiting | Hepatotoxicity (rare) |
| Prednisone | 5 mg orally twice a day; 100 mg orally daily for 5 days | None | Hyperglycemia, weight gain, gastritis, fluid retention, psychiatric symptoms |
| Biologic Response Modifiers | | | |
| Interferon- α -2b (Intron A) | 5 million international units subcutaneously 3 times a week; 2 million international units/m ² intramuscularly/subcutaneously three times a week; 20 million international units/m ² 5 days a week for 4 weeks then 10 million international units/m ² three times a week | Hypersensitivity reaction, injection site reaction, flu-like syndrome, nausea, vomiting, diarrhea | Myelosuppression, fatigue, anorexia, alopecia, depression, hyperthyroidism or hypothyroidism (rare), hepatotoxicity (rare), visual disturbances |
| Aldesleukin (IL-2, Proleukin) | 600,000 international units/kg intravenously every 8 hours for 14 doses, repeat after 9 days rest | Hypotension, nausea, vomiting, diarrhea | Capillary leak syndrome (rare), impaired neutrophil function and increased risk of infection, lethargy or somnolence that may result in coma if therapy is not held |

GFR, glomerular filtration rate; LHRH, luteinizing hormone–releasing hormone; MAO, monoamine oxidase; NSAIDs, nonsteroidal anti-inflammatory drugs; SIADH, syndrome of inappropriate antidiuretic hormone; TMP-SMZ, trimethoprim-sulfamethoxazole.

recombinant interleukin-11, has modest activity in improving thrombocytopenia associated with chemotherapy; however, the side effects of fluid retention, congestive heart failure, and arrhythmias have limited its use. Thrombopoietin, the protein that stimulates megakaryopoiesis in vivo,

was isolated in 1994. Despite much work attempting to produce a clinically effective thrombopoietin drug for therapeutic use, no such drug is commercially available for this indication. Two drugs approved for use in idiopathic thrombocytopenia romiplostim and eltrombopag have not

Table 39–11. Supportive care agents: Dosage and toxicity.

| Agent | Indication | Usual Dose | Acute Toxicity | Delayed Toxicity |
|--------------------------|---|---|---|--|
| Allopurinol (Xyloprim) | Prevent hyperuricemia from tumor lysis syndrome | 300 mg orally once daily | None | Rash, Stevens-Johnson syndrome (rare), myelosuppression (rare) |
| Rasburicase (Elitek) | Prevent hyperuricemia from tumor lysis syndrome | 0.17–0.17 mg/kg intravenously for pediatric patients; 3–6 mg intravenously once | Hypersensitivity reaction in patients with G6PD deficiency, nausea, vomiting, diarrhea, fever, headache | Rash |
| Mesna (Mesnex) | Prevent ifosfamide-induced hemorrhagic cystitis | 20% of ifosfamide dose intravenously immediately before ifosfamide and at 4 hours and 8 hours after (total dose is 60% of ifosfamide dose); 100% of ifosfamide dose mixed with ifosfamide in same intravenous bag | Nausea and vomiting | Fatigue, hypotension |
| Leucovorin | Rescue after high-dose methotrexate; in combination with fluorouracil for colon cancer | 10 mg/m ² intravenously or orally every 6 hours until serum methotrexate level is below 0.01 micromolar; 20 mg/m ² or 200–500 mg/m ² intravenously before fluorouracil | Nausea | None |
| Amifostine (Ethylol) | Prevent cisplatin nephropathy; prevent radiation-induced xerostomia | 910 mg/m ² intravenously before cisplatin; 200 mg/m ² intravenously before radiation | Nausea, vomiting, hypotension, infusion-related reaction | Hypocalcemia |
| Dexrazoxane (Zinecard) | Prevent cardiomyopathy secondary to doxorubicin; anthracycline-induced injection site extravasation | 10 times the doxorubicin dose intravenously before doxorubicin | Nausea | Myelosuppression |
| Palifermin (Kepivance) | Prevent mucositis following chemotherapy | 60 mcg/kg/d intravenously for 3 days before and 3 days after chemotherapy | None | Edema, rash, pruritus, erythema, fever, enlargement or discoloration of tongue, altered taste sensation |
| Pilocarpine (Salagen) | Radiation-induced xerostomia | 5 mg orally 1 hour before chemotherapy, then 5 mg once daily for 7 days; 5–10 mg orally three times a day | Flushing, sweating, nausea, dizziness, increased urinary frequency, rhinitis | None |
| Samarium (Quadramet) | Pain from bone metastasis | 1 milliCurie/kg intravenously | Pain flare, diarrhea, hematuria | Myelosuppression, spinal cord compression |
| Strontium (Metastron) | Pain from bone metastasis | 148 megabecquerels (4 milliCuries) intravenously; or 1.5–2.2 megabecquerels/kg (40–60 microcuries/kg) | Flushing, pain flare | Myelosuppression |
| Pamidronate (Aredia) | Osteolytic bone metastasis, hypercalcemia of malignancy | 90 mg intravenously every 3–4 weeks; 60–90 mg intravenously, may repeat after 7 days | Injection site reaction | Electrolyte disturbances (hypocalcemia), anemia, arthralgia, bone pain, osteonecrosis of the jaw, nephrotoxicity |
| Zoledronic acid (Zometa) | Osteolytic bone metastasis, hypercalcemia of malignancy | 4 mg intravenously every 3–4 weeks | Injection site reaction | Electrolyte disturbances (hypocalcemia), anemia, arthralgia, bone pain, osteonecrosis of the jaw, nephrotoxicity |

(continued)

| Agent | Indication | Usual Dose | Acute Toxicity | Delayed Toxicity |
|---------------------------------|--|--|---|--|
| Growth Factors | | | | |
| Epoetin alfa (Epo-gen, Procrit) | Chemotherapy-induced anemia | 40,000 units subcutaneously once weekly; 150 units/kg subcutaneously 3 times a week | Injection site reaction | Hypertension, thrombotic events, increased risk of tumor progression or recurrence, seizures, rash |
| Darbepoetin alfa (Aranesp) | Chemotherapy-induced anemia | 2.25 mcg/kg subcutaneously weekly; 500 mcg subcutaneously every 3 weeks Alternative dosing: 200 mcg subcutaneously every 2 weeks or 300 mcg subcutaneously every 3 weeks | Injection site reaction | Hypertension, thrombotic events, increased risk of tumor progression or recurrence, seizures, rash |
| Filgrastim (Neupogen) | Febrile neutropenia prophylaxis | 5-10 mcg/kg/d subcutaneously or intravenously once daily, treat past nadir | Injection site reaction | Bone pain, enlarged spleen, leukocytosis |
| Pegfilgrastim (Neulasta) | Febrile neutropenia prophylaxis | 6 mg subcutaneously once per chemotherapy cycle | Injection site reaction | Bone pain, enlarged spleen, leukocytosis |
| Sargramostim (Leukine) | Myeloid reconstitution following bone marrow transplant, febrile neutropenia prophylaxis | 250 mcg/m ² intravenously daily until the absolute neutrophil count is greater than 1500 cells/mcl for 3 consecutive days | Rash, pruritus, injection site reaction, dyspnea, fever | Bone pain, myalgia, fluid retention, supraventricular tachycardia, capillary leak syndrome (rare) |
| Oprelvekin (Neumega) | Chemotherapy-induced thrombocytopenia | 50 mcg/kg subcutaneously every day for 14-21 days or until post-nadir platelet count is greater than 50,000/mcl | Nausea, vomiting, headache, dizziness, blurred vision, dyspnea, injection site reaction | Candidiasis, rash, fluid retention, arrhythmias, febrile neutropenia |

G6PD, glucose 6-phosphate dehydrogenase.

been shown to benefit patients with chemotherapy-associated thrombocytopenia.

2. Chemotherapy-Induced Nausea & Vomiting

A number of cytotoxic anticancer drugs can induce nausea and vomiting, which can be the most anticipated and stressful side effects for patients. Chemotherapy-induced nausea and vomiting is mediated in part by the stimulation of at least two central nervous system receptors, 5-hydroxytryptamine subtype 3 (5HT₃) and neurokinin subtype 1

(NK₁). Chemotherapy-induced nausea and vomiting can be acute, occurring within minutes to hours of chemotherapy administration, or delayed until the second day and lasting up to 7 days. Anticipatory nausea and vomiting may even occur before the administration of chemotherapy. Chemotherapy drugs or drug regimens are classified into high, moderate, low, and minimal likelihoods of causing emesis (90%, 30-90%, 10-30%, < 10%, respectively). Highly emetogenic chemotherapy drugs include cisplatin, carmustine, cyclophosphamide at doses over 1.5 g/m², dacarbazine, mechlorethamine, and streptozocin. Chemotherapy drugs that are moderately emetogenic include doxorubicin, daunomycin, idarubicin, epirubicin, cyclophosphamide, irinotecan, oxaliplatin, ifosfamide, cytarabine, and carboplatin. Drugs with low emetic potential include bortezomib, docetaxel, etoposide, fluorouracil, gemcitabine, methotrexate, mitomycin, mitoxantrone, paclitaxel, pemetrexed, temsirolimus, and topotecan. Drugs with minimal risk of emesis include bevacizumab, bleomycin, cladribine, fludarabine, vinblastine, vincristine, and vinorelbine.

By understanding the physiology of chemotherapy-induced nausea and vomiting, major advances have occurred with the development of new, highly effective antiemetic drugs. Antagonists to the 5HT₃-receptor include ondansetron, granisetron, dolasetron, tropisetron, and palonosetron. Each of these drugs have similar efficacy. Ondansetron can be

Table 39-12. A common scheme for dose modification of cancer chemotherapeutic agents.

| Granulocyte Count (cells/mcl) | Platelet Count (/mcl) | Suggested Drug Dosage (% of Full Dose) |
|-------------------------------|-----------------------|--|
| > 2000 | > 100,000 | 100% |
| 1000-2000 | 75,000-100,000 | 50% |
| < 2000 | < 50,000 | 0% |

given either intravenously (8 or 0.15 mg/kg) or orally (24 mg for highly emetogenic chemotherapy, 8 mg twice daily for moderately emetogenic chemotherapy). Doses of 8 mg can be repeated parenterally or orally every 8 hours. Dosing of granisetron is 1 mg or 0.01 mg/kg intravenously or 1–2 mg orally. Dolasetron is given 1.8 mg/kg or a fixed dose of 100 mg intravenously or 100 mg can be given orally. Tropisetron is given at a dose of 5 mg either orally or intravenously. Palonosetron, a long-acting 5HT₃ with high affinity for the 5HT₃-receptor given at a dose of 0.25 mg intravenously, is effective for not only acute but also delayed emesis. The efficacy of the 5HT₃-blockers is improved by adding 6–10 mg of either oral or intravenous dexamethasone.

Aprepitant is an antagonist to the NK₁ receptor. When given as a 125-mg oral dose followed by 80 mg on the second and third day with a 5HT₃-receptor antagonist (such as ondansetron or granisetron), the immediate and delayed protective effect for highly emetogenic chemotherapy is increased.

Standard therapy for highly emetogenic chemotherapy includes a 5HT₃-antagonist given on the first day and both dexamethasone and aprepitant given on the first day as well as the second and third days. Moderately emetogenic chemotherapy regimens are best managed with a two-drug regimen of a 5HT₃-antagonist and dexamethasone. Doses of the 5HT₃ may be given on days 2 and 3 to prevent delayed emesis.

Other adjunctive medications that may be helpful include lorazepam, 0.5–1.0 mg given orally every 6–8 hours, and prochlorperazine, 5–10 mg orally or intravenously every 8 hours. Lorazepam, in addition to antianxiety effects, has an anti-nausea effect. Prochlorperazine is generally sufficient to treat patients receiving low emetogenic chemotherapy. A suppository form of prochlorperazine, 25 mg, may be used for patients who are unable to swallow oral medications.

The importance of treating chemotherapy-induced nausea and vomiting expectantly and aggressively beginning with the first course of chemotherapy cannot be understated. Patients being treated in the clinic setting should always be given antiemetics for home use with written instructions as well as contact numbers to call for advice.

3. Gastrointestinal Toxicity

Untoward effects of cancer chemotherapy include damage to the more rapidly growing cells of the body such as the mucosal lining from the mouth through the gastrointestinal tract. Oral symptoms range from mild mouth soreness to frank ulcerations in the mouth. Not uncommonly, mouth ulcerations will have superimposed candida or herpes simplex infections. In addition to receiving cytotoxic chemotherapy, a significant risk factor for development of oral mucositis is poor oral hygiene and existing caries or periodontal disease. Toxicity in the gastrointestinal tract usually manifests as diarrhea. Gastrointestinal symptoms can range from mild symptoms of loose stools to life-threatening diarrhea due to dehydration and electrolyte imbalances. Drugs most commonly associated with causing mucositis in the mouth and the gastrointestinal tract are cytarabine, 5-fluorouracil, and methotrexate.

Patients undergoing treatment for head and neck cancer with concurrent chemotherapy and radiation therapy have a very high risk of developing severe mucositis.

Preventive strategies for managing oral mucositis includes a pretreatment dental examination, particularly for all head and neck cancer patients and any cancer patient with poor dental hygiene who will be receiving chemotherapy. For patients receiving fluorouracil, simple measures such as ice chips in the mouth for 30 minutes during infusion can reduce the incidence and severity of mucositis. Once mucositis is encountered, superimposed fungal infections should be treated with topical antifungal medications (oral nystatin mouth suspensions, or clotrimazole troches) or systemic therapy (fluconazole 100–400 mg orally daily). Suspected herpetic infections can be treated with acyclovir (up to 800 mg orally five times daily) or valacyclovir (1 g orally twice daily). Mucositis may also be managed with mouthwashes; it is also important to provide adequate pain medication.

Newer strategies for prevention of oral mucositis includes the recombinant keratinocyte growth factor inhibitor palifermin. Practice guidelines recommend its use in patients undergoing high-dose chemotherapy because when intravenous palifermin (60 mcg/kg/d) is given prophylactically to patients undergoing high-dose chemotherapy for hematologic diseases, both the incidence and length of mucositis is decreased.

Diarrhea is most associated with fluorouracil, capecitabine, and irinotecan as well as the tyrosine kinase inhibitors (sorafenib, sunitinib, imatinib, dasatinib) and epithelial growth factor inhibitors (cetuximab, panitumumab, and erlotinib). Mild to moderate diarrhea can be managed with oral antidiarrheal medication (loperamide, 4 mg initially followed by 2 mg every 2–4 hours until bowel movements are formed). Occasionally, the diarrhea will be overwhelming causing dehydration, electrolyte imbalances, and acute kidney injury. These patients require inpatient management with aggressive intravenous hydration and replacement of electrolytes.

4. Skin Toxicity

Dermatologic complications from cancer chemotherapy can include hyperpigmentation (liposomal doxorubicin, busulfan, hydroxyurea) alopecia, photosensitivity, nail changes, acral erythema, and generalized rashes. Acral erythema, otherwise known as hand-foot syndrome and most commonly associated with administration of fluorouracil, capecitabine, and liposomal doxorubicin, manifests as painful palms or soles accompanied by erythema, progressing to blistering desquamation and ulceration in its worst forms. Management can include attempts at prevention with oral pyridoxine, 200 mg daily, and applying cold packs to the extremities while the chemotherapy is being administered. The newer agents targeting the epidermal growth factor pathway can cause an acne like rash; interestingly, the development of the rash may identify those who will respond to the drug. Inhibitors of the tyrosine kinase pathway are also associated with a high incidence of dermatologic complications, such as rash and acral erythema.

5. Miscellaneous Drug-Specific Toxicities

The toxicities of individual drugs have been summarized in Tables 39–10 and 39–11; however, several of these warrant additional mention, since they occur with frequently administered agents, and special measures are often indicated.

A. Hemorrhagic Cystitis Induced by Cyclophosphamide or Ifosfamide

Metabolic products of cyclophosphamide that retain cytotoxic activity are excreted into the urine. Some patients appear to metabolize more of the drug to these active excretory products; if their urine is concentrated, severe bladder damage may result. Patients receiving cyclophosphamide must maintain a high fluid intake prior to and following the administration of the drug and be counseled to empty their bladders frequently. Early symptoms suggesting bladder toxicity include dysuria and increased frequency or urination. Should microscopic hematuria develop, it is advisable to stop the drug temporarily or switch to a different alkylating agent, to increase fluid intake, and to administer a urinary analgesic such as phenazopyridine. With severe cystitis, large segments of bladder mucosa may be shed, resulting in prolonged gross hematuria. Such patients should be observed for signs of urinary obstruction and may require cystoscopy for removal of obstructing blood clots. The cyclophosphamide analog ifosfamide can cause severe hemorrhagic cystitis when used alone. However, when its use is followed by a series of doses of the neutralizing agent mesna, bladder toxicity can be prevented. Mesna can also be used for patients taking cyclophosphamide in whom cystitis develops.

B. Neuropathy Due to Vinca Alkaloids and Other Chemotherapy Drugs

Neuropathy is caused by a number of different chemotherapy drugs, the most common being vincristine. The peripheral neuropathy can be sensory, motor, autonomic, or a combination of these effects. In its mildest form, it consists of paresthesias of the fingers and toes. Occasionally, acute jaw or throat pain can develop after vincristine therapy. This may be a form of trigeminal neuralgia. With continued vincristine therapy, the paresthesias extend to the proximal interphalangeal joints, hyporeflexia appears in the lower extremities, and significant weakness can develop. Other drugs in the vinca alkaloid class as well as the taxane drugs (paclitaxel and docetaxel) and the newer agents to treat myeloma (thalidomide and bortezomib) cause similar toxicity. The presence of neurologic symptoms is not in itself a reason to stop therapy; the severity of the symptoms must be balanced against the goals of therapy. Usually though, the presence of moderate to severe paresthesias or the detection of motor impairment would result in the decision to discontinue the drug.

Constipation is the most common symptom of autonomic neuropathy associated with the vinca alkaloids. Patients receiving these drugs should be started on stool softeners and mild cathartics when therapy is begun; otherwise, severe impaction may result from an atonic bowel.

More serious autonomic involvement can lead to acute intestinal obstruction with signs indistinguishable from those of an acute abdomen. Bladder neuropathies are uncommon but may be severe. These two complications are absolute contraindications to continued vincristine therapy.

C. Methotrexate Toxicity

Methotrexate, a folate antagonist, is a commonly used drug and a key component of regimens to treat patients with leptomeningeal disease, acute lymphoblastic leukemia, and sarcomas. The dose used in intrathecal therapy is 12 mg. Methotrexate is almost entirely eliminated by the kidney. The methotrexate toxicity affects cells with rapid turnover, including the bone marrow and mucosa resulting in myelosuppression and mucositis. Methotrexate can also damage the liver and kidney manifesting as elevated liver enzymes and creatinine. High-dose methotrexate, usually defined as a dose of 500 mg/m² or more given over 4–36 hours, would be lethal without “rescue” of the normal tissues. Leucovorin, a form of folate, will reverse the toxic effects of methotrexate and is given until serum methotrexate levels are in the safe range (less than 0.05 mmol/L). It is crucial that high-dose methotrexate and leucovorin are given precisely according to protocol as deviations of the timing of methotrexate delivery or delay in rescue can result in patient death. Lower doses of methotrexate can be problematic in patients with kidney disease who cannot clear the drug normally or with patients who have effusions. In the latter instance, methotrexate distributes itself in effusions and will leak out continuously, exposing normal tissue to small but cumulatively toxic amounts of the drug. If methotrexate is given to a patient who either has or develops kidney disease or to a patient with an effusion, prolonged rescue with leucovorin will be necessary.

Vigorous hydration and bicarbonate loading also appear to be important in preventing crystallization of high-dose methotrexate in the renal tubular epithelium and minimizing the possibility of nephrotoxicity. Daily monitoring of the serum creatinine is mandatory. Drugs impairing methotrexate excretion include aspirin, nonsteroidal anti-inflammatory drugs, amiodarone, omeprazole, penicillin, phenytoin, and sulfa compounds; these drugs should be stopped if possible before methotrexate administration.

D. Bleomycin Toxicity

Bleomycin is used for the treatment of testicular cancer, Hodgkin disease, and non-Hodgkin lymphoma. Bleomycin produces edema of the interphalangeal joints and hardening of the palmar and plantar skin. The more serious toxicities include an anaphylactic or serum sickness-like reaction and a serious or fatal pulmonary fibrotic reaction (seen especially in elderly patients receiving a total dose of over 300 units). If nonproductive cough, dyspnea, and pulmonary infiltrates develop, the drug is discontinued, and high-dose corticosteroids are instituted as well as empiric antibiotics pending cultures. Fever alone or with chills is an occasional complication of bleomycin treatment and is not an absolute contraindication to continued treatment. The fever may be avoided by intravenous premedication with hydrocortisone

administration. Moreover, fever alone is not predictive of pulmonary toxicity. About 1% of patients (especially those with lymphoma) may have a severe or even fatal hypotensive reaction after the initial dose of bleomycin. In order to identify such patients, a test dose of 5 units of bleomycin is administered first with adequate monitoring and emergency facilities available should they be needed. Patients exhibiting a hypotensive reaction should not receive further bleomycin therapy.

E. Anthracycline Cardiotoxicity

A number of cancer chemotherapy drugs can cause cardiotoxicity. The most common class of drugs associated with cardiotoxicity is the anthracycline antibiotics, including doxorubicin, daunomycin, idarubicin, and epirubicin. They can produce acute (during administration), subacute (days to months following administration), and delayed (years following administration) cardiac toxicity. The most feared complication is the delayed development of congestive heart failure. Risk factors for this debilitating toxicity include the anthracycline cumulative dose, age over 70, previous or concurrent irradiation of the chest, preexisting cardiac disease, and concurrent administration of chemotherapy drugs such as trastuzumab. The problem is greatest with doxorubicin because this drug is the most commonly administered anthracycline due to its major role in the treatment of lymphomas, sarcomas, breast cancer, and certain other solid tumors. Patients receiving anthracyclines should have a baseline multiple-gated radionuclide cardiac scan (MUGA) to calculate the left ventricular ejection fraction (LVEF). If the LVEF is greater than 50%, anthracyclines can be administered; if the LVEF is less than 30%, these drugs should not be given. For patients with intermediate cardiac function, anthracycline dosing, if necessary, should be cautiously done with LVEF monitoring between doses. Studies of left ventricular function and endomyocardial biopsies indicate that some changes in cardiac dynamics occur in most patients by the time they have received 300 mg/m² of doxorubicin. In general, patients should not receive a total dose of doxorubicin in excess of 450 mg/m²; the dose should be lower if prior chest radiotherapy has been given. The appearance of a high resting pulse may herald the appearance of overt cardiac toxicity. Unfortunately, toxicity may be irreversible and frequently fatal at dosage levels above 550 mg/m². At lower doses (eg, 350 mg/m² of doxorubicin), the symptoms and signs of cardiac failure generally respond well to medical therapy as well as the discontinuation of anthracycline. Laboratory studies suggest that cardiac toxicity may be due to a mechanism involving the formation of intracellular free radicals in cardiac muscle. The iron chelator dexrazoxane has been approved for use as a cardioprotectant for patients

receiving anthracyclines; however, some evidence suggests that the anthracycline anticancer effect may be compromised by the coadministration of dexrazoxane. In general, dexrazoxane should not be used when the goal of chemotherapy is for curative intent either in the settings of adjuvant or definitive treatment. Doxorubicin and daunomycin have been formulated as liposomal products; these drugs, approved for use in patients with Kaposi sarcoma and sometimes used in certain cancers as a substitute for conventional anthracyclines, appear to have minimal potential for cardiac toxicity.

F. Cisplatin Nephrotoxicity and Neurotoxicity

Cisplatin is effective in treating a wide range of malignancies, including testicular, bladder, lung, and ovarian cancers. Although nausea and vomiting are the side effects most commonly associated with cisplatin, the more serious side effects of nephrotoxicity and neurotoxicity must also be anticipated and aggressively managed. Patients must be vigorously hydrated prior, during, and after cisplatin administration. Both kidney function and electrolytes must be monitored. Low magnesium and potassium levels as well as hyponatremia can develop. The neurotoxicity is usually manifested as a peripheral neuropathy of mixed sensorimotor type and may be associated with painful paresthesias. Development of neuropathy typically occurs after cumulative doses of 300 mg/m². Ototoxicity is a potentially serious manifestation of neurotoxicity and can progress to deafness. Amifostine, developed initially as a radioprotective agent and given intravenously at a dose of 910 mg/m² over 15 minutes prior to cisplatin, is used to protect against nephrotoxicity and neuropathy. Use of amifostine does not appear to compromise the antineoplastic effect of cisplatin. The second-generation platinum analog carboplatin is non-nephrotoxic, although it is myelosuppressive. In the setting of preexisting kidney disease or neuropathy, carboplatin is occasionally substituted for cisplatin.

PROGNOSIS

A valuable sign of clinical improvement is the general well-being of the patient. Although this finding is a combination of subjective and objective factors and may be partly a placebo effect, it nonetheless serves as a sign of clinical improvement in assessing some of the objective observations listed above. Factors included in the assessment of general well-being are improved appetite and weight gain and increased "performance status" (eg, ambulatory versus bedridden). Evaluation of factors such as activity status enables the clinician to judge whether the net effect of chemotherapy is worthwhile palliation (see Chapter 5).

Clinical Genetic Disorders

Reed E. Pyeritz, MD, PhD

ACUTE INTERMITTENT PORPHYRIA

ESSENTIALS OF DIAGNOSIS

- ▶ Unexplained abdominal crisis, generally in young women.
- ▶ Acute peripheral or central nervous system dysfunction.
- ▶ Recurrent psychiatric illnesses.
- ▶ Hyponatremia.
- ▶ Porphobilinogen in the urine during an attack.

▶ General Considerations

Though there are several different types of porphyrias, the one with the most serious consequences and the one that usually presents in adulthood is acute intermittent porphyria (AIP), which is inherited as an autosomal dominant, though it remains clinically silent in most patients who carry the trait. Clinical illness usually develops in women. Symptoms begin in the teens or 20s, but onset can begin after menopause in rare cases. The disorder is caused by partial deficiency of porphobilinogen deaminase activity, leading to increased excretion of aminolevulinic acid and porphobilinogen in the urine. The diagnosis may be elusive if not specifically considered. The characteristic abdominal pain may be due to abnormalities in autonomic innervation in the gut. In contrast to other forms of porphyria, cutaneous photosensitivity is absent in AIP. Attacks are precipitated by numerous factors, including drugs and intercurrent infections. Harmful and relatively safe drugs for use in treatment are listed in Table 40–1. Hyponatremia may be seen, due in part to inappropriate release of antidiuretic hormone, although gastrointestinal loss of sodium in some patients may be a contributing factor.

▶ Clinical Findings

A. Symptoms and Signs

Patients show intermittent abdominal pain of varying severity, and in some instances it may so simulate acute abdomen

as to lead to exploratory laparotomy. Because the origin of the abdominal pain is neurologic, there is an absence of fever and leukocytosis. Complete recovery between attacks is usual. Any part of the nervous system may be involved, with evidence for autonomic and peripheral neuropathy. Peripheral neuropathy may be symmetric or asymmetric and mild or profound; in the latter instance, it can even lead to quadriplegia with respiratory paralysis. Other central nervous system manifestations include seizures, psychosis, and abnormalities of the basal ganglia. Hyponatremia may further cause or exacerbate central nervous system manifestations.

B. Laboratory Findings

Often there is profound hyponatremia. The diagnosis can be confirmed by demonstrating an increased amount of porphobilinogen in the urine during an acute attack. Freshly voided urine is of normal color but may turn dark upon standing in light and air.

Most families have a different mutation in the porphobilinogen deaminase gene causing AIP. Mutations can be detected and used for presymptomatic and prenatal diagnosis.

▶ Prevention

Avoidance of factors known to precipitate attacks of AIP—especially drugs—can reduce morbidity. Sulfonamides and barbiturates are the most common culprits; others are listed in Table 40–1 and on the Internet (www.drugs-porphyrria.org). Starvation diets or prolonged fasting also cause attacks and so must be avoided. Hormonal changes during pregnancy can precipitate crises.

▶ Treatment

Treatment with a high-carbohydrate diet diminishes the number of attacks in some patients and is a reasonable empiric gesture considering its benignity. Acute attacks may be life-threatening and require prompt diagnosis, withdrawal of the inciting agent (if possible), and treatment with analgesics and intravenous glucose and hemein. A minimum of 300 g of carbohydrate per day should be provided orally or intravenously. Electrolyte balance requires close attention. Hemein therapy is still evolving and should be undertaken with full

Table 40–1. Some of the “unsafe” and “probably safe” drugs used in the treatment of acute porphyrias.

| Unsafe | Probably Safe |
|----------------------|----------------------------|
| Alcohol | Acetaminophen |
| Alkylating agents | β-Adrenergic blockers |
| Barbiturates | Amitriptyline |
| Carbamazepine | Aspirin |
| Chloroquine | Atropine |
| Chlorpropamide | Chloral hydrate |
| Clonidine | Chlordiazepoxide |
| Dapsone | Corticosteroids |
| Ergots | Diazepam |
| Erythromycin | Digoxin |
| Estrogens, synthetic | Diphenhydramine |
| Food additives | Guanethidine |
| Glutethimide | Hyoscyne |
| Griseofulvin | Ibuprofen |
| Hydralazine | Imipramine |
| Ketamine | Insulin |
| Meprobamate | Lithium |
| Methyldopa | Naproxen |
| Metoclopramide | Nitrofurantoin |
| Nortriptyline | Opioid analgesics |
| Pentazocine | Penicillamine |
| Phenytoin | Penicillin and derivatives |
| Progestins | Phenothiazines |
| Pyrazinamide | Procaine |
| Rifampin | Streptomycin |
| Spirolactone | Succinylcholine |
| Succinimides | Tetracycline |
| Sulfonamides | Thiouracil |
| Theophylline | |
| Tolazamide | |
| Tolbutamide | |
| Valproic acid | |

recognition of adverse consequences, especially phlebitis and coagulopathy. The intravenous dosage is up to 4 mg/kg once or twice daily. Liver transplantation may provide an option for patients with disease poorly controlled by medical therapy.

▶ When to Refer

- For management of severe abdominal pain, seizures, or psychosis.
- For preventive management when a patient with porphyria contemplates pregnancy.
- For genetic counseling and molecular diagnosis.

▶ When to Admit

The patient should be hospitalized when he or she has an acute attack accompanied by mental status changes, seizure, or hyponatremia.

ALKAPTONURIA

ESSENTIALS OF DIAGNOSIS

- ▶ Ochronosis (gray-black discoloration of connective tissue, including the sclerae, ears, and cartilage).
- ▶ Characteristic radiologic changes in the spine, with radiodense intervertebral discs.
- ▶ Arthropathy.
- ▶ Urine darkens on standing.

▶ Clinical Findings

A. Symptoms and Signs

Alkaptonuria is caused by a recessively inherited deficiency of the enzyme homogentisic acid oxidase. This acid derives from metabolism of both phenylalanine and tyrosine and is present in large amounts in the urine throughout the patient's life. An oxidation product accumulates slowly in cartilage throughout the body, leading to degenerative joint disease of the spine and peripheral joints. Indeed, examination of patients in the third and fourth decades shows a slight darkish blue color below the skin in areas overlying cartilage, such as in the ears, a phenomenon called **ochronosis**. In some patients, a more severe hyperpigmentation can be seen in the sclera, conjunctiva, and cornea. Accumulation of metabolites in heart valves can lead to aortic or mitral stenosis. A predisposition to coronary artery disease may also be present. Although the syndrome causes considerable morbidity, life expectancy is reduced only modestly. Symptoms are more often attributable to spondylitis with back pain, leading to a clinical picture difficult to distinguish from that of ankylosing spondylitis, though on radiographic assessment the sacroiliac joints are not fused in alkaptonuria.

B. Laboratory Findings

The diagnosis is established by demonstrating homogentisic acid in the urine, which turns black spontaneously on exposure to the air; this reaction is particularly noteworthy if the urine is alkaline or when alkali is added to a specimen. Molecular analysis of the homogentisic acid oxidase gene, recently mapped to chromosome 3, is available but not necessary for diagnosis.

▶ Prevention

Carrier screening and prenatal diagnosis are possible by testing for genetic mutations.

▶ Treatment

Treatment of the arthritis is similar to that for other arthropathies. Though, in theory, rigid dietary restriction might reduce accumulation of the pigment, this has not proved to be of practical benefit.

DOWN SYNDROME

ESSENTIALS OF DIAGNOSIS

- ▶ Typical craniofacial features (flat occiput, epicanthal folds, large tongue).
- ▶ Mental retardation.
- ▶ Congenital heart disease (eg, atrioventricular canal defects) in 50% of patients.
- ▶ Three copies of chromosome 21 (trisomy 21) or a chromosome rearrangement that results in three copies of a region of the long arm of chromosome 21.

▶ Clinical Findings

A. Symptoms and Signs

Down syndrome is usually diagnosed at birth on the basis of the typical craniofacial features, hypotonia, and single palmar crease. Several serious problems that may be evident at birth or may develop early in childhood include duodenal atresia, congenital heart disease (especially atrioventricular canal defects), and hematologic malignancy. The intestinal and cardiac anomalies usually respond to surgery. A transient neonatal leukemia generally responds to conservative management. The incidences of both acute lymphoblastic and myeloid leukemias are increased in childhood. Intelligence varies across a wide spectrum. Many people with Down syndrome do well in sheltered workshops and group homes, but few achieve full independence in adulthood. Other frequent complications include atlanto-axial instability, celiac disease, and hypothyroidism. An Alzheimer-like dementia usually becomes evident in the fourth or fifth decade and, for those who survive childhood, accounts for a reduced life expectancy.

B. Laboratory Findings

Cytogenetic analysis should always be performed—even though most patients will have simple trisomy for chromosome 21—to detect unbalanced translocations; such

patients may have a parent with a balanced translocation, and there will be a substantial recurrence risk of Down syndrome in future offspring of that parent and potentially that parent's relatives.

▶ Prevention

The presence of a fetus with Down syndrome can be detected in many pregnancies in the first or early second trimester through screening maternal serum for α -fetoprotein and other biomarkers (“multiple marker screening”) and by detecting increased nuchal thickness and underdevelopment of the nasal bone on fetal ultrasound. The risk of bearing a child with Down syndrome increases exponentially with the age of the mother at conception and begins a marked rise after age 35. By age 45 years, a mother has one chance in 40 of having an affected child. The risk of other conditions associated with trisomy also increases, because of the predisposition of older oocytes to nondisjunction during meiosis. There is little risk of trisomy associated with increased paternal age. However, older men do have an increased risk of fathering a child with a new autosomal dominant condition. But because there are so many distinct conditions, the chance of fathering an offspring with any given one is extremely small.

▶ Treatment

Duodenal atresia should be treated surgically. Congenital heart disease should be treated as in any other patient. No medical treatment has been proven to affect the intellectual capacity.

▶ When to Refer

- For comprehensive evaluation of infants to investigate congenital heart disease, hematologic malignancy, and duodenal atresia.
- For genetic counseling of the parents.
- For signs of dementia in an adult patient.

▶ When to Admit

An affected young patient should be hospitalized when he or she has failure to thrive, regurgitation, breathlessness, or easy bruising.

FRAGILE X MENTAL RETARDATION

ESSENTIALS OF DIAGNOSIS

- ▶ Expanded trinucleotide repeat in the *FMR1* gene.
- ▶ Mental retardation and autism in males.
- ▶ Large testes after puberty.
- ▶ Learning disabilities or mental retardation in females.
- ▶ Premature ovarian failure.
- ▶ Late-onset tremor and ataxia in males and females with moderate trinucleotide repeat expansion (premutation carriers).

▶ Clinical Findings

A. Symptoms and Signs

This X-linked condition accounts for more cases of mental retardation in males than any condition except Down syndrome; about 1 in 4000 to 1 in 6000 males is affected; the condition also affects intellectual function in females, although less severely and about 50% less frequently than in males.

B. Laboratory Findings

The first marker for this condition was a small gap, or fragile site, evident near the tip of the long arm of the X chromosome. Subsequently, the condition was found to be due to expansion of a trinucleotide repeat (CGG) near a gene called *FMR1*. All individuals have some CGG repeats in this location, but as the number increases beyond 52, the chances of further expansion during spermatogenesis or oogenesis increase.

Being born with one *FMR1* allele with 200 or more repeats results in mental retardation in most men, and in about 60% of women. The more repeats, the greater the likelihood that further expansion will occur during gametogenesis; this results in anticipation, in which the disorder can worsen from one generation to the next. Affected (heterozygous) young women show no physical signs other than early menopause, but they may have learning difficulties or frank retardation. Affected males show macroorchidism (enlarged testes) after puberty, large ears and a prominent jaw, a high-pitched voice, autistic characteristics, and mental retardation. Some males show evidence of a mild connective tissue defect, with joint hypermobility and mitral valve prolapse.

Women who are premutation carriers (55–200 CGG repeats) are at increased risk for premature ovarian failure

and mild cognitive or behavioral abnormalities. Male and female premutation carriers are at risk for the development of tremor and ataxia beyond middle age (fragile-X tremor-ataxia syndrome, FXTAS). Changes in the cerebellar white matter on MRI may be evident before symptoms appear. Because of the relatively high prevalence of premutation carriers in the general population, older people in whom any of these behavioral or neurologic problems develop should undergo testing of the *FMR1* locus.

▶ Prevention

DNA diagnosis for the number of repeats has supplanted cytogenetic analysis for both clinical and prenatal diagnosis. This should be done on any male or female who has unexplained mental retardation.

▶ Treatment

No specific treatments have been developed. Attention-deficit and hyperactivity symptoms can respond to standard therapy, and a recent trial of L-acetylcarnitine showed promise.

▶ When to Refer

- For otherwise unexplained mental retardation or learning difficulties in boys and girls.
- For otherwise unexplained tremor or ataxia in middle-aged individuals.
- For premature ovarian failure.
- For genetic counseling.

GAUCHER DISEASE

ESSENTIALS OF DIAGNOSIS

- ▶ Deficiency of β -glucocerebrosidase.
- ▶ Anemia and thrombocytopenia.
- ▶ Hypersplenism.
- ▶ Pathologic fractures.

► Clinical Findings

A. Symptoms and Signs

Gaucher disease has an autosomal recessive pattern of inheritance. A deficiency of β -glucocerebrosidase causes an accumulation of sphingolipid within phagocytic cells throughout the body. Anemia and thrombocytopenia are common and may be symptomatic; both are due primarily to hypersplenism, but marrow infiltration with Gaucher cells may be a contributing factor. Cortical erosions of bones, especially the vertebrae and femur, are due to local infarctions, but the mechanism is unclear. Episodes of bone pain (termed “crises”) are reminiscent of those in sickle cell disease. A hip fracture in a patient with a palpable spleen—especially in a Jewish person of Eastern European origin—suggests the possibility of Gaucher disease.

Two uncommon forms of Gaucher disease, called type II and type III, involve neurologic accumulation of sphingolipid and a variety of neurologic problems. Type II is of infantile onset and has a poor prognosis. Heterozygotes for Gaucher disease may be at increased risk for developing Parkinson disease.

B. Laboratory Findings

Bone marrow aspirates reveal typical Gaucher cells, which have an eccentric nucleus and periodic acid–Schiff (PAS)-positive inclusions, along with wrinkled cytoplasm and inclusion bodies of a fibrillar type. In addition, the serum acid phosphatase is elevated. Definitive diagnosis requires the demonstration of deficient glucocerebrosidase activity in leukocytes. Over 200 mutations have been found to cause Gaucher disease and some are highly predictive of the neuronopathic forms. Thus, mutation detection, especially in a young person, is of potential value. Only four mutations in glucocerebrosidase account for more than 90% of the disease among Ashkenazi Jews, in whom the carrier frequency is 1:15.

► Prevention

Most clinical complications can be prevented by early institution of enzyme replacement therapy. Carrier screening, especially among Ashkenazi Jews, detects those couples at 25% risk of having an affected child. Prenatal diagnosis through mutation analysis is feasible.

► Treatment

For many years, treatment was supportive and included splenectomy for thrombocytopenia secondary to platelet sequestration. A recombinant form of the enzyme glucocerebrosidase (imiglucerase) for intravenous administration on a regular basis now permits a reduction in total body stores of glycolipid and improvement in orthopedic and hematologic manifestations. Unfortunately, the neurologic manifestations of types II and III have not improved with enzyme replacement therapy. The major drawback is the exceptional cost of imiglucerase, which can exceed \$350,000 per year for a severely affected patient. Administration of less enzyme (30 units/kg per month) is effective for most adults and

reduces the cost to about \$100,000–150,000 annually. Alternative or complementary therapies, including methods to reduce substrate and to provide a chaperone for a defective enzyme, are being developed.

DISORDERS OF HOMOCYSTEINE METABOLISM

ESSENTIALS OF DIAGNOSIS

- For homocystinuria, dislocated ocular lenses.
- Elevated homocysteine in the urine or plasma.

► General Considerations

Considerable evidence has accumulated to support the 20-year-old observation that patients with clinical and angiographic evidence of coronary artery disease tend to have higher levels of plasma homocysteine than persons without coronary artery disease. The relationship has been extended to cerebrovascular and peripheral vascular diseases. Although this effect was initially thought to be due at least in part to heterozygotes for cystathionine β -synthase deficiency (see below), there is little supporting evidence. Rather, the major factor leading to hyperhomocystinemia is folate deficiency. Pyridoxine (vitamin B_6) and vitamin B_{12} are also important in the metabolism of methionine, and deficiency of any of these vitamins can lead to accumulation of homocysteine. A number of genes influence utilization of these vitamins and can predispose to deficiency. For example, having one—and especially two—copies of an allele that causes thermolability of methylene tetrahydrofolate reductase predisposes people to elevated fasting homocysteine levels. However, both nutritional and most genetic deficiencies of these vitamins can be corrected by dietary supplementation of folic acid and, if serum levels are low, vitamins B_6 and B_{12} . In the United States, cereal grains are now fortified with folic acid. Studies are ongoing to determine the long-term utility of routine vitamin supplementation in people at risk for arterial occlusive disease, but many workers in this field recommend, at a minimum, taking 1 mg of folic acid per day. Recent studies showed

that therapy with B vitamins lowered homocysteine levels significantly, but did not reduce the risk of either venous thromboembolism or complications of coronary artery disease. The role of lowering homocysteine as primary prevention for sequelae of atherosclerosis is still undetermined. Hyperhomocysteinemia occurs with end-stage chronic kidney disease.

► Clinical Findings

A. Symptoms and Signs

Homocystinuria in its classic form is caused by cystathionine β -synthase deficiency and exhibits an autosomal recessive pattern of inheritance. This results in extreme elevations of plasma and urinary homocystine levels, a basis for diagnosis of this disorder. Homocystinuria is similar in certain superficial aspects to Marfan syndrome, since patients may have a similar body habitus and ectopia lentis is almost always present. However, mental retardation is often present in homocystinuria, and the cardiovascular events are those of repeated venous and arterial thromboses whose precise cause remains obscure. Life expectancy is reduced, especially in untreated and pyridoxine-unresponsive patients; myocardial infarction, stroke, and pulmonary embolism are the most common causes of death. This condition is diagnosed by newborn screening for hypermethioninemia; however, pyridoxine-responsive infants may not be detected. The diagnosis should be suspected in patients in the second and third decades of life who show evidence of arterial or venous thromboses and have no other risk factors.

B. Laboratory Findings

Although many mutations have been identified in the cystathionine β -synthase gene, amino acid analysis of plasma remains the most appropriate diagnostic test. Patients should be studied after they have been off folate or pyridoxine supplementation for at least 1 week. Relatively few laboratories currently provide highly reliable assays for homocysteine. Processing of the specimen is crucial to obtain accurate results. The plasma must be separated within 30 minutes; otherwise, blood cells release the amino acid and the measurement will then be artificially elevated.

► Prevention

About 50% of patients have a form of cystathionine β -synthase deficiency that improves biochemically and clinically through pharmacologic doses of pyridoxine and folate. For these patients, treatment from infancy can prevent retardation and the other clinical problems. Patients who are pyridoxine nonresponders must be treated with a dietary reduction in methionine and supplementation of cysteine, also from infancy. The vitamin betaine is also useful in reducing plasma methionine levels by facilitating a metabolic pathway that bypasses the defective enzyme.

► Treatment

Patients with classic homocystinuria who have suffered venous thrombosis receive anticoagulation therapy, but

there are no studies to support prophylactic use of warfarin or antiplatelet agents.

KLINFELTER SYNDROME

ESSENTIALS OF DIAGNOSIS

- Males with hypogonadism and small testes.
- 47,XXY karyotype.

► Clinical Findings

A. Symptoms and Signs

Boys with an extra X chromosome are normal in appearance before puberty; thereafter, they have disproportionately long legs and arms, a female escutcheon, gynecomastia, and small testes. Infertility is due to azoospermia; the seminiferous tubules are hyalinized. The diagnosis is often not made until a couple is evaluated for inability to conceive. Mental retardation is somewhat more common than in the general population. Many men with Klinefelter syndrome have learning problems. However, their intelligence usually tests within the broad range of normal. As adults, detailed psychometric testing may reveal a deficiency in executive skills. The risk of breast cancer and diabetes mellitus is much higher in men with Klinefelter syndrome than in 46,XY men.

B. Laboratory Findings

Low serum testosterone is common. The karyotype is typically 47,XXY.

► Prevention

Screening for cancer, especially of the breast, and for glucose intolerance are indicated.

► Treatment

Treatment with testosterone after puberty is advisable but will not restore fertility. However, men with Klinefelter

syndrome have had mature sperm aspirated from their testes and injected into oocytes, resulting in fertilization. After the blastocysts have been implanted into the uterus of a partner, conception has resulted. However, men with Klinefelter syndrome do have an increased risk for aneuploidy in sperm, and therefore chromosome analysis of a blastocyst should be considered before implantation.

MARFAN SYNDROME

ESSENTIALS OF DIAGNOSIS

- ▶ Disproportionately tall stature, thoracic deformity, and joint laxity or contractures.
- ▶ Ectopia lentis and myopia.
- ▶ Aortic dilation and dissection.
- ▶ Mitral valve prolapse.

▶ General Considerations

Marfan syndrome, a systemic connective tissue disease, has an autosomal dominant pattern of inheritance. It is characterized by abnormalities of the skeletal, ocular, and cardiovascular systems; spontaneous pneumothorax; dural ectasia; and striae atrophicae. Of most concern is disease of the ascending aorta, which begins as a dilated aortic root. Histology of the aorta shows diffuse medial degeneration. Mitral valve leaflets are also abnormal and mitral prolapse and regurgitation may be present, often with elongated chordae tendineae, which on occasion may rupture.

▶ Clinical Findings

A. Symptoms and Signs

Affected patients are typically tall, with particularly long arms, legs, and digits (arachnodactyly). However, there can be wide variability in the clinical presentation. Commonly, scoliosis and anterior chest deformity, such as pectus excavatum, are found. Ectopia lentis may lead to severe

myopia and retinal detachment. Mitral valve prolapse is seen in about 85% of patients. Aortic root dilation is common and leads to aortic regurgitation or dissection with rupture. To diagnose Marfan syndrome, people with an affected relative need features in at least two systems. People with no family history need features in the skeletal system, two other systems, and one of the major criteria of ectopia lentis, dilation of the aortic root, or aortic dissection. Patients with homocystinuria due to cystathionine synthase deficiency also have dislocated lenses; tall, disproportionate stature; and thoracic deformity. They tend to have below normal intelligence, stiff joints, and a predisposition to arterial and venous occlusive disease. Males with Klinefelter syndrome do not show the typical ocular or cardiovascular features of Marfan syndrome and are generally sporadic occurrences in the family.

B. Laboratory Findings

Mutations in the fibrillin gene (*FBN1*) on chromosome 15 cause Marfan syndrome. Nonetheless, no simple laboratory test is available to support the diagnosis in questionable cases because related conditions may also be due to defects in fibrillin. The nature of the *FBN1* mutation has little predictive value in terms of prognosis. The pathogenesis of Marfan syndrome involves aberrant regulation of transforming growth factor (TGF) β activity. Mutations in either of two receptors for TGF β (TGFBR1 and TGFBR2) can cause conditions that resemble Marfan syndrome in terms of aortic aneurysm and dissection and autosomal dominant inheritance.

▶ Prevention

There is prenatal and presymptomatic diagnosis for patients in whom the molecular defect in fibrillin has been found and for large enough families in whom linkage analysis using polymorphic markers around *FBN1* can be performed.

▶ Treatment

Children with Marfan syndrome require regular ophthalmologic surveillance to correct visual acuity and thus prevent amblyopia, and annual orthopedic consultation for diagnosis of scoliosis at an early enough stage so that bracing might delay progression. Patients of all ages require echocardiography at least annually to monitor aortic diameter and mitral valve function. All patients should use standard endocarditis prophylaxis. Long-term β -adrenergic blockade, titrated to individual tolerance but enough to produce a negative inotropic effect (atenolol, 1–2 mg/kg), retards the rate of aortic dilation. A clinical trial comparing the effectiveness of atenolol and losartan, a drug that reduces activity of TGF β , is underway. Restriction from vigorous physical exertion protects from aortic dissection. Prophylactic replacement of the aortic root with a composite graft when the diameter reaches 45–50 mm in an adult (normal: < 40 mm) prolongs life. A procedure to reimplant the patient's native aortic valve and replace just the aneurysmal sinuses of Valsalva shows promise and also avoids the need for lifelong anticoagulation.

► Prognosis

People with Marfan syndrome who are untreated commonly die in the fourth or fifth decade from aortic dissection or congestive heart failure secondary to aortic regurgitation. However, because of earlier diagnosis, lifestyle modifications, β -adrenergic blockade, and prophylactic aortic surgery, life expectancy has increased by several decades in the past 25 years.

► When to Refer

- For detailed ophthalmologic examination.
- For at least annual cardiologic evaluation.
- For moderate scoliosis.
- For pregnancy in a woman with Marfan syndrome.
- For genetic counseling.

► When to Admit

Any patient with Marfan syndrome in whom severe or unusual chest pain develops should be hospitalized to exclude pneumothorax and aortic dissection.

HEREDITARY HEMORRHAGIC TELANGIECTASIA

ESSENTIALS OF DIAGNOSIS

- Recurrent epistaxis.
- Mucocutaneous telangiectases.
- Visceral arteriovenous malformations (especially lung, liver, brain, bowel).

► Clinical Findings

A. Symptoms and Signs

Hereditary hemorrhagic telangiectasia (HHT), formerly termed “Osler-Weber-Rendu syndrome,” is an autosomal dominant disorder of development of the vasculature. Epistaxis may begin in childhood or later in adolescence. Punctate telangiectases of the lips, tongue, fingers, and skin generally appear in later childhood and adolescence. Arteriovenous malformations (AVMs) can occur at any age in the brain, lungs, and liver. Bleeding from the gastrointestinal tract is due to mucosal vascular malformations and usually is not a problem until mid-adult years or later. Pulmonary AVMs can cause hypoxemia (with peripheral cyanosis, dyspnea, and clubbing) and right-to-left shunting (with embolic stroke or brain abscess). The criteria for diagnosis require presence of three of the following four features: (1) recurrent epistaxis, (2) visceral AVMs, (3) mucocutaneous telangiectases, and (4) being the near relative of a clearly affected individual. Mutation analysis can be used for pre-symptomatic diagnosis or exclusion of the worry of HHT.

MR or CT arteriography detects AVMs. Mutations in at least five genes can cause HHT. Three have been identified and molecular analysis to identify them is available; these mutations in *ENG*, *ALK1*, and *SMAD4* account for about 70% of families with HHT.

B. Laboratory Findings

MR or CT arteriography detects AVMs. Mutations in at least five genes can cause HHT. Three have been identified and molecular analysis to identify them is available; these mutations in *ENG*, *ALK1*, and *SMAD4* account for about 70% of families with HHT.

► Prevention

Embolization of pulmonary AVMs reduces the risk of stroke and brain abscess. Treatment of brain AVMs reduces the risk of hemorrhagic stroke. All patients with HHT should practice routine endocarditis prophylaxis. All intravenous lines should have an air-filter to prevent embolization of an air bubble. Prenatal diagnosis through mutation detection is possible.

► Treatment

All patients in whom the diagnosis of HHT is considered should have an MRI of the brain with contrast. A contrast echocardiogram will detect most pulmonary AVMs when “bubbles” appear on the left side of the heart after 3–6 cardiac cycles. A positive contrast echocardiogram should be followed by a high-resolution CT angiogram for localization of pulmonary AVMs. Patients who have AVMs with a feeding artery of 1 mm diameter or greater should undergo embolization. After successful embolization of all treatable pulmonary AVMs, the CT angiogram should be repeated in 3 years. A person with a negative contrast echocardiogram should have the test repeated every 5 years.

Complementary & Alternative Medicine

Ellen F. Hughes, MD, PhD
Kevin Barrows, MD

The use of complementary and alternative medicine (CAM) has become common in the United States. To maintain effective clinician-patient communication and ensure responsible clinical practice, it is important that clinicians learn the theory, practice, and scientific evidence associated with these therapies. This chapter provides an overview of four alternative medicine therapies: herbal medicine, nonherbal dietary supplements, acupuncture, and mind-body medicine.

► General Considerations

CAM is defined by the National Institutes of Health (NIH) as a group of diverse health care systems, practices, and products that are not presently considered to be part of conventional medicine. CAM therapies may be used alone as an alternative to conventional therapies or in addition to conventional, mainstream medicine to treat conditions and promote well being.

CAM modalities have been classified by NIH into five major categories:

1. **Biologically based practices** use substances found in nature, such as herbs, special diets, or vitamins (in doses outside those used in conventional medicine).
2. **Energy medicine** involves the use of energy fields, such as magnetic fields or biofields (energy fields that some believe surround and penetrate the human body). Examples include Reiki, external qigong, and therapeutic touch.
3. **Manipulative and body-based practices** use manipulation or movement of one or more body parts (massage, chiropractic, Feldenkrais method and other “body work” systems).
4. **Mind-body medicine** uses a variety of techniques designed to enhance the mind’s ability to affect bodily function and symptoms, such as biofeedback, meditation, prayer, art and music therapy, hypnosis, and guided imagery.
5. **Whole medical systems** are built on complete systems of theory and practice that have evolved apart from—and often earlier than—the conventional medical approach used in the United States. Systems such as

traditional Oriental medicine, acupuncture, homeopathy, naturopathy, Ayurveda, and Tibetan medicine often use one or more of the methods listed above.

The Centers for Disease Control and Prevention conducted National Health Interview Surveys (NHIS) in 2002 and 2007. Overall, 23,300 American adults from diverse populations were asked about their use of CAM in the 2007 survey. Thirty-eight percent reported using some form of CAM in the previous 12 months, essentially unchanged from 36% in 2002. The most commonly used CAM therapies were nonvitamin, nonmineral natural products (17.7%), with fish oil, glucosamine, echinacea, flaxseed and ginseng being the most common; deep breathing exercises (12.7%); meditation (9.4%); chiropractic or osteopathic manipulation (8.6%); massage (8.3%); and yoga (6.1%). CAM use was higher among women, adults aged 30–69 years, those with higher levels of education, who were not poor, who live in the West and who have quit cigarette smoking. The most common conditions for which adults used CAM were similar to those seen in most primary care offices: musculoskeletal complaints, such as back, neck, and joint pain. Similar to 2002, CAM usage in 2007 was positively associated with the number of health conditions and number of doctor visits in the past 12 months. Most people who use CAM combine it with conventional medicine because they perceive the combination to be superior to either alone. Dissatisfaction with conventional medicine has not previously been found to predict greater CAM use, but more than 25% of US adults in the 2002 survey said they used CAM because they believed conventional medicine could not help them. No questions on health care spending were asked during NHIS interviews, but a smaller national phone survey conducted in 1997 estimated that the US public paid \$36 billion on CAM therapies, much of it out-of-pocket.

In January 2005, the Institute of Medicine of the National Academies released a report on the use of CAM in the United States. They recommended “health profession schools incorporate sufficient information about complementary and alternative medicine (CAM) into the standard curriculum at all levels to enable licensed professionals to competently advise their patients about CAM.” Indeed, despite the grow-

ing numbers of patients seeking CAM, less than 40% of alternative therapies used are disclosed to physicians. In one survey of 1559 patients age 50 or older, 70% who used CAM did not tell their physician. A lack of communication may be dangerous because some CAM therapies can interact adversely with conventional treatments.

Funding for biomedical research in this field increased when the NIH established the Office of Alternative Medicine in 1992 with an annual budget of \$2 million. In 1998, its role was expanded as the National Center for Complementary and Alternative Medicine (NCCAM). NCCAM's budget for fiscal year 2008 was \$122 million. Although some CAM modalities are not easily evaluated using randomized control trial methodology, the 2005 Institute of Medicine report recommends that conventional and CAM treatments both be held to similar standards of safety and efficacy.

HERBAL MEDICINES

▶ Epidemiology

For thousands of years, plants have been used worldwide for medicinal purposes, dispensed by traditional herbalists who have been involved with their cultivation and preparation as well as assessment of their potency. At present, most herbal products are commercially cultivated, processed in unregulated environments, and purchased over-the-counter without the counseling of a qualified health practitioner.

The use of herbs in the United States has increased dramatically over the past decade, although sales have leveled off over the past several years. Herbal products are used by one of five Americans at an annual total cost of more than \$4 billion, but fewer than half of those individuals discuss the matter with a conventional health care provider. Consumers hold strong views about the efficacy of the supplements they take. Seventy percent state that they would continue to take their favorite supplement even if a government study claimed it was not effective.

▶ Regulatory Issues

In 1994, the United States Congress unanimously passed the Dietary Supplement and Health Education Act. This legislative act classifies vitamins, minerals, herbs, and amino acids as nutritional or dietary supplements. Under this law, supplements can be marketed without proof of safety or efficacy as long as no claim is made for their use in the diagnosis, treatment or cure, or prevention of disease. Manufacturers can, however, make “structure and func-

tion” claims that a product enhances a normal body function or state such as thinking, mood, or immune function. For example, saw palmetto can be marketed to support urinary tract health but not to treat benign prostatic hyperplasia. In contrast to prescription drugs, the US Food and Drug Administration (FDA) must first prove that an herbal preparation is *unsafe* before it can order that a product be taken off the market.

▶ Quality Assurance

In the past, consumers had no guarantee of the quality of the products they purchased. They could not be certain that the plant was accurately identified; that the product was free of microbial, pesticide, and heavy metal contamination; or that all batches contained the same ingredients in the same strengths.

Such lack of consistency prompted the Institute of Medicine to call on the government to implement improved quality-control manufacturing standards for supplements, more accurate labeling requirements, and greater consumer protections. In June 2007, the FDA announced that dietary supplement manufacturers must now evaluate the identity, purity, strength, and composition of their products and report all serious adverse events. These new good manufacturing practices must be phased in by June 2010.

Patients should be advised to follow certain guidelines when considering whether to use herbal medicines (Table 41-1).

▶ Product Formulations & Standardization

Herbal formulations include liquids (extracts, tinctures, infusions, and decoctions) and fresh, dried, and powdered preparations. The potency of herbs varies widely depending on which part of the plant is used, where it is cultivated, and what variations there may be in growing conditions and methods of preparation.

To ensure a consistent percentage of the primary active ingredients across batches and brand names, standardized extracts have been developed. Since multiple constituents may have pharmacologic activity, determining the active ingredients for standardization purposes can be a difficult task. In addition, ensuring stability of these active ingredients can be challenging. In a recent study of St John's wort for attention deficit/hyperactivity disorder in children, the product used in the trial was retested at the end of the trial and found to deliver only 50% of the intended dose. The European scientific community has played a significant role in producing and investigating high-quality standardized extracts that contain consistent quantities of marker compounds (ideally, the active ingredients). This work has laid the foundation for conducting phase 2 and phase 3 clinical trials. The quality of research in the field is improving, but most herbal remedies have not been evaluated in controlled clinical trials.

▶ Safety of Herbal Medicines

Although many medicinal herbs are relatively safe, some have significant toxicity. Herbs themselves can have unan-

Table 41-1. Advice to patients using herbal medicines.

| |
|---|
| Communication |
| Discuss use of all therapies with your health care provider. |
| Product Quality |
| Manufacturers are not required to submit evidence to the FDA or any regulatory body to demonstrate product safety, effectiveness, or product quality but must begin to do so (at least for adverse events) by 2010. |
| Ask your primary care provider, a pharmacist, or a trained herbalist regarding the specific herbs you are using. |
| Use herbs that are standardized to contain a specific quantity of the active ingredients. |
| Select formulations that have been studied in clinical trials. |
| Select formulations that have been independently tested for quality. |
| Labeling |
| Look for a seal of approval from an independent testing agency such as National Products Association (formerly National Nutritional Food Association), NSF International (formerly National Sanitation Foundation), or ConsumerLab. |
| It should state the common and scientific names of herb(s). |
| It should state the concentration or dose of the herb(s) and provide instructions on dose and frequency. |
| It should state that the product is "standardized" to contain a certain amount of the active ingredient(s). |
| It should state the methods used to ensure product quality. |
| It should state the name and address of the manufacturer. |
| It should state the batch or lot number and the expiration date. |
| It should list potential side effects and interactions. |
| Pregnancy |
| Few herbs have been studied for safety during pregnancy. |
| Seek advice from your primary care provider before using herbs during pregnancy. |
| Interactions |
| Discuss with your health care provider the safety profile and interactions that may occur when combining herbs and when taking herbs plus drugs. |
| Reporting |
| Report any adverse reactions to your state poison control program or the FDA. |

FDA, Food and Drug Administration.

anticipated effects such as hepatotoxicity as seen with chaparral and germander. Ten of twenty patients with fulminant hepatic failure referred to a liver transplant service over a 21-month period were recent or active users of potentially hepatotoxic supplements. Ma-huang contains ephedrine and was sold as a component of many weight loss products and in a banned euphoriant called "herbal ecstasy." Over 800 adverse events associated with ma-huang have been reported, including the widely publicized death of a US major league baseball player in 2003, causing the FDA to ban ephedra-containing products from the market. Herbal products may also be intentionally adulterated with prescription drugs or contaminated with harmful substances such as pesticides or heavy metals. Prescription drugs such as prednisone, nonsteroidal anti-inflammatory drugs (NSAIDs), antibiotics, and testosterone have been detected in imported Chinese patent medicines. In December 2008, the FDA issued a warning that 25 weight loss products available over the counter and on the Internet contained

undeclared, active pharmaceutical ingredients, such as sibutramine, that could put consumers' health at risk.

Twenty-five percent of patients who take prescription medications also take at least one nonvitamin dietary supplement, creating a potential risk for adverse drug-herb or drug-supplement interactions. This figure increases to 50% in older US adults who take prescription medications, putting 1/25 of them at risk for developing a major drug-supplement interaction. Proving that a side effect experienced by a patient taking a dietary supplement is caused by that supplement is often difficult. Practitioners should take a detailed history from the patient and, if possible, obtain a sample of the product to facilitate further analysis, if needed. All suspected adverse events should be reported to the FDA's Medwatch Program (<http://www.fda.gov/medwatch>), although it is estimated that less than 1% are actually reported.

▶ Review of the Evidence for Selected Herbal Medicines

Table 41-2 provides an overview of selected herbal medicines.

A. St. John's Wort (*Hypericum perforatum*)

Over the past two decades, St. John's wort has been studied in thousands of patients for the treatment of mild to moderate depression. Most preparations are standardized to hypericin or hyperforin. The precise mechanisms of action are not known but are postulated to include selective inhibition of serotonin, γ -aminobutyrate, norepinephrine, and dopamine reuptake in the central nervous system.

Most of the 60-plus randomized controlled clinical trials, systematic reviews, and meta-analyses, including a 2008 Cochrane review, have shown that St. John's wort is more effective than placebo and as effective as prescription antidepressants for the treatment of mild to moderate depression. In addition, a standardized European hypericum extract helped prevent relapse of depression in patients who responded initially to the extract. Pooled analyses of six recent, large trials restricted to patients with major depression, however, showed only minimal effects of St. John's wort compared with placebo. A 4-year NIH study of 300 patients with mild symptoms of depression began in 2003. Patients are being randomized to St. John's wort, placebo, or citalopram for 12 weeks.

St. John's wort is generally well tolerated. Side effects are not common but include mild headache, photosensitivity, gastrointestinal upset, and restlessness. Data from 35 double-blind randomized trials show that drop out and adverse event rates in patients receiving *Hypericum* extracts

Table 41–2. Overview of selected herbal medicines.

| | Leading Indications | Dosage | Level of Evidence ¹ | Safety ² | Interaction; Side Effects | Comments |
|---|---|--|--|---|---|---|
| Echinacea (purple coneflower) | 1. Treatment of URIs 2. Prevention of URIs | 300 mg, or 3 mL q3-4h | 1. B 2. C | I | None known: rash, pruritus, nausea | Avoid in immunocompromised patients; avoid use > 4 weeks |
| Black cohosh | Menopausal symptoms (hot flashes) | Depends on formulation (Remifemin = 20 mg twice daily) | B | I | | Case reports of hepatitis, so avoid in liver disease |
| Garlic (<i>Allium sativum</i>) | 1. Cholesterol 2. Hypertension 3. Coronary artery disease | 600–900 mg once daily | 1. B 2. C 3. C | I | 1. Odor, flatulence 2. May have antiplatelet activity | |
| <i>Ginkgo biloba</i> (Egb 761, GBE) | 1. Dementia 2. Claudication | 60 mg three times daily | 1. A 2. A | II | May have anticoagulant effect | Do not use in patients taking anticoagulants and use caution if allergic to urushiols (mango rind, sumac-poison ivy, cashew nuts) |
| Asian ginseng (<i>Panax ginseng</i>) | Stamina, aphrodisiac, fertility, “tonic,” “energy-booster,” “adaptogen” | 200–600 mg once daily extract; 1–2 g crude drug | C: multiple studies but few for any given indication | I | Previous reports of toxicity have been attributed to adulterants | |
| St. John’s wort (<i>Hypericum perforatum</i>) | 1. Depression: mild to moderate 2. Depression: major | 300 mg three times daily | 1. A 2. B | I (but significant drug-herb interaction) | Induces cytochrome P450, leading to lower serum levels of certain drugs | Cyclosporine, protease inhibitors, oral contraceptives, warfarin, digoxin levels reduced |
| Saw palmetto (<i>Serenoa repens</i>) | Benign prostatic hyperplasia | 160 mg twice daily | B: small or none | I | Mild GI upset and headaches (rare) | Does not effect PSA levels or prostate size |

¹Level of evidence: A, high quality: consistent evidence from randomized trials or overwhelming evidence from other sources; B, moderate quality: evidence from randomized trials with important limitations or very strong evidence of some other form; C, low quality: evidence from observational studies or randomized trials with serious methodologic flaws.

²Safety: I, generally safe; II, relatively safe; III, insufficient evidence; IV, may be harmful; V, clear evidence of harm. GI, gastrointestinal; PSA, prostate-specific antigen; URI, upper respiratory infection.

were similar to placebo, lower than with older antidepressants, and slightly lower than with selective serotonin reuptake inhibitors (SSRIs). Patients are advised to avoid taking St. John’s wort in combination with prescription antidepressants, as there have been case reports of the serotonin syndrome. St. John’s wort also induces the cytochrome P450 system (isozyme CYP3A4), which may lower the blood levels of nearly 50% of prescription medications that are metabolized by this system (eg, ethinyl estradiol, warfarin, cyclosporine, statins, and indinavir). St. John’s wort can also lower the serum level of other medications by affecting the p-glycoprotein transporter system. Several cases of cardiac and renal organ rejection have been reported in patients whose previously stable level of cyclosporine was lowered after initiation of St. John’s wort. Of further concern is that this herb-drug interaction may persist even after St. John’s wort is discontinued. A 40%

decrease in serum levels of the chemotherapeutic agent irinotecan noted in five patients taking concurrent St. John’s wort persisted for 3 weeks after St. John’s wort was discontinued.

B. Garlic

Garlic is one of the top-selling herbs in Europe and the United States. It has been used since antiquity for the treatment of cardiovascular and infectious diseases. The German Federal Health Agency Commission E and the European Scientific Cooperative on Phytotherapy have approved its use for the treatment of hyperlipidemia and atherosclerosis. Garlic is available in multiple over-the-counter formulations (dried, powdered, oils). Many products are standardized to yield 0.6% allicin, the ingredient believed responsible for its odor and therapeutic benefit. Allicin is formed by the action of allinase enzymes when garlic is crushed. Both heat and acid destroy these enzymes, so some experts recommend that garlic is best ingested raw. The best-studied form is an enteric-coated capsule of dehydrated garlic. Freeze-drying helps retain most of the active ingredients found in raw garlic. Enteric coating permits allicin to be released in the small intestine, thereby enhancing absorption and reducing the breath odor. Allicin yield among powdered preparations varies as much as 230-fold in brands used in trials. This lack of standardization may contribute to inconsistent results in dozens of clinical trials.

Several mechanisms for garlic's beneficial effects on cardiovascular disease have been proposed: decreased low-density lipoprotein cholesterol (LDL-C) synthesis and oxidation, decreased platelet aggregation, decreased inflammation, lowered blood pressure, and antibacterial activity.

Doses of 600–900 mg of freeze-dried garlic (equivalent to one-half to one clove) taken for 4–6 weeks lower total cholesterol and LDL-C levels by 4–12%, have minimal effect on blood pressure (< 10 mm Hg, with greater decreases in subjects with hypertension), and no effect on glucose levels. In a well-designed 2007 trial, 192 adults with moderate hypercholesterolemia were randomized to one of four treatment arms for 6 months: raw garlic, two popular garlic supplements, or placebo. None of the three forms of garlic given at approximate doses of a 4-g clove garlic/d, 6 days/week for 6 months had statistically or clinically significant effects on plasma lipids in adults with initial LDL-C levels of 130–160 mg/dL. In addition, a double-blind randomized study in which 90 overweight smokers were randomized to 2.1 g/d garlic powder, 40 mg/d atorvastatin, or placebo for 3 months, showed no significant effect of garlic on inflammatory biomarkers, endothelial function, or lipid profile compared with placebo. Numerous observational studies have suggested that regular consumption of garlic might reduce the risk of developing certain malignancies, but no prospective controlled trials have been performed.

Garlic is well tolerated and apparently safe for long-term use. In addition to the well-known breath and body odor, common side effects include gastrointestinal upset, nausea, and flatulence.

A more than 50% reduction in blood levels of saquinavir after garlic supplementation has been reported. Although the induction of the cytochrome P450 system was hypothe-

sized as the mechanism of action of this significant herb-drug interaction, a recent study of healthy volunteers did not reveal an effect of garlic on isozymes CYP2D6 or CYP3A4. Garlic has been shown to have some antiplatelet activation activity, so there is a theoretical risk of increased bleeding, especially if taken with aspirin, anticoagulants, or NSAIDs. However, a 2006 study of 48 patients taking warfarin randomized to aged garlic extract or placebo for 12 weeks did not report any increased bleeding in those taking garlic. In addition, a 2008 study showed no effect of garlic on warfarin pharmacokinetics in healthy volunteers. No changes in platelet function were noted in healthy volunteers after ingesting raw garlic and garlic oil, but some clinicians recommend stopping garlic 1–2 weeks prior to undergoing elective surgery.

C. Ginkgo

The dried leaf of the ginkgo tree has been used medicinally for thousands of years. More than 400 studies over the past 30 years have investigated ginkgo's ability to improve blood flow in a variety of conditions, including memory impairment, dementia, peripheral vascular disease, vertigo, tinnitus, asthma, SSRI-induced sexual dysfunction, anxiety and acute mountain sickness. It is the sixth best selling herb in the United States with greater than \$250 million in sales per year. The German Commission E has approved a standardized form of ginkgo leaf extract (EGb 761) for the treatment of cognitive impairment and intermittent claudication. Multiple pharmacologically active compounds have been isolated from ginkgo. Flavonoids have antioxidant and free radical scavenging ability and terpene lactones have platelet-activating factor antagonist activity. In addition, ginkgo extracts increase the production of nitric oxide and activate certain central neurotransmitters, including the cholinergic system, which may contribute to their beneficial effects on memory and cognition. EGb 761—the formulation that has been studied most extensively—is standardized to contain 24% flavonoid glycosides and 6% terpene lactones.

Early studies that assessed ginkgo's efficacy on cognitive function in the elderly showed a modest improvement when

compared with placebo. The longest of these studies (1 year) showed stabilization of cognitive and functional abilities in 309 demented patients treated with EGb 761 compared with placebo, with no differences in adverse outcomes. A 2007 systematic review, however, concluded that ginkgo did not have predictable and clinically significant benefits in patients with dementia. A well-designed NIH-funded study also showed that ginkgo (120 mg EGb721 twice a day) did not prevent dementia in more than 3000 elderly subjects with normal or mildly impaired cognitive function who were monitored for a mean of 6 years. A smaller study also failed to show any reduction in progression to dementia in 118 subjects 85 years of age or older who were randomized to 80 mg of a different formulation of ginkgo three times a day or placebo for 42 months. When researchers took into account participant's adherence, however, the group that actually took their ginkgo had a smaller decline in memory compared with those taking a placebo. There is conflicting evidence about ginkgo's ability to enhance memory in healthy individuals. In general, ginkgo is well tolerated in healthy adults at recommended doses for up to 6 months. Allergic skin reactions, gastrointestinal disturbances, and headache occur in less than 2% of patients. There are theoretical concerns about a risk of increased bleeding because antiplatelet activating factor activity has been demonstrated in vitro. Nearly 20 cases of increased bleeding in patients taking ginkgo have been reported, but establishing a causal relationship is challenging because many of these patients had other risk factors including age and use of medications, such as warfarin, aspirin, or NSAIDs. Of note, no excess bleeding complications have been reported in clinical trials and no differences in coagulation, platelet function, or pharmacokinetics of warfarin have been reported in healthy volunteers. Caution should still be exercised in patients with bleeding disorders or who are taking anticoagulants, aspirin, or other herbs that may increase the risk of bleeding. In one study, ginkgo (90 mg/d) did not show any adverse effects on the pharmacokinetics of donepezil (5 mg/d) when administered together, but potential interactions with other medications used to treat dementia are not known.

Ginkgo has also been evaluated for its effect on intermittent claudication. A meta-analysis of nine randomized, placebo-controlled, double-blinded trials of patients treated with EGb761 showed a modest treatment effect in the increase of pain-free walking distance in favor of ginkgo over placebo. There is insufficient evidence to support ginkgo's efficacy in treating tinnitus, acute mountain sickness, vertigo, or SSRI-associated sexual dysfunction.

D. Echinacea

Echinacea ranks third among the top-selling herbs in the United States, accounting for more than \$300 million in sales annually. Three of nine *Echinacea* species are currently used for the treatment and prevention of upper respiratory infections. Preparations are made from roots (*Echinacea pallida* and *Echinacea angustifolia*), above-ground parts (stems, leaves, and flowers of *Echinacea purpurea*), or a combination of both. Multiple forms are available over-the-counter, including capsules, fresh pressed juice, tinctures, and teas. Differences in species, growing conditions, plant parts used, and extraction procedures can result in differences in chemical composition and biologic activity. Several active ingredients have been identified, including polysaccharides, glycoproteins, alkaloids, and flavonoids. In vitro, animal, and human studies suggest that these ingredients cause stimulation of the immune system and that they possess anti-inflammatory, free radical-scavenging, and antiviral activity.

The quality of most clinical trials has been limited by use of multiple products and doses (including formulations containing multiple herbs) and the lack of rigorous methodology.

The majority of early trials reported that echinacea is effective in reducing the duration and severity of colds if started within several days of the onset of symptoms but no more effective than placebo when taken to prevent infection. A well-designed, 2005 trial studied three different *E angustifolia* root preparations for the prevention and treatment of laboratory-induced rhinovirus infections. Four hundred thirty-seven volunteers were randomized to receive either prophylaxis (beginning 7 days before a challenge with rhinovirus) or treatment (beginning at the time of viral challenge), with one of the three different echinacea preparations. No statistically significant effects were seen on rates of infection or severity of symptoms in patients taking the herb. The echinacea used in this trial was well characterized and of high quality, but some clinicians feel that the dose used was lower than that used in routine practice. In contrast, an updated meta-analysis of echinacea monopreparations found that 10 of 16 trials showed the herb to be more effective than placebo for the treatment of colds, particularly preparations made from above-the-ground parts of *E purpurea*. Authors of a 2007 meta-analysis of 14 clinical trials also conclude that echinacea is beneficial in decreasing both the incidence and duration of the common cold. The herb decreased the odds of developing an upper respiratory tract infection by 58% and the duration of a cold by 1.4 days. In contrast, *E pallida* was no more effective than placebo in decreasing the risk of ear

infections in children prone to otitis media. In general, echinacea is well tolerated, with few reported adverse events. Rare allergic reactions including rash have been reported (especially in patients with ragweed allergies), and there was a single case of recurrent erythema nodosum. The German Commission E recommends that patients who are pregnant, have autoimmune disease, or who are immunocompromised not take echinacea because of its immune-stimulating effects. The Commission also recommends that its use be limited in others to less than 4 weeks. The data supporting these recommendations are not clear.

E. Ginseng

Ginseng root has been used for medicinal purposes in Asia for over 2000 years and is consumed by up to 5% of the population in Western countries. Two major forms of ginseng are in use today: Asian ginseng (*Panax ginseng*) and American ginseng (*Panax quinquefolius*). *Eleutherococcus senticosus* (previously known as Siberian ginseng), is not a member of the *Panax* genus and does not contain ginsenosides that are thought to be the active ingredients in true ginseng. The German Commission E monograph on ginseng root approves its use as “a tonic to counteract weakness and fatigue, as a restorative for declining stamina and impaired concentration, and as an aid to convalescence.” Extracts are made from dried roots and contain more than 25 ginsenosides, each with unique and sometimes oppositional effects on the cardiovascular, central nervous, and immune systems. The mechanisms of action have not been clearly delineated.

Multiple indications have been studied using different ginseng species, often with poor methodologic rigor. One European study identified 57 randomized controlled trials of ginseng in the world’s literature, but only 16 studies were of good enough quality to be included in their systematic review. Insufficient evidence was available to support or refute the use of ginseng for any of the purported indications, including improvement of physical performance, cognitive functioning, and quality of life. In contrast, a small open label 2008 trial suggests that Korean red ginseng (unskinned *Panax ginseng* before it is steamed and dried) may improve cognitive function in patients with Alzheimer disease. Some early studies suggest that ginseng causes small reductions in blood pressure, but there was no effect on 24-hour blood pressure or kidney function in 52 hypertensive

patients who took North American ginseng for 12 weeks. A 2006 systematic review of 34 studies also did not support the use of ginseng to treat cardiovascular risk factors, although at least 7 human studies since 2000 report that American and Asian ginseng may lower blood glucose in both healthy and diabetic patients. Ginseng is believed by many to enhance sexual function. A systematic review of 7 randomized clinical trials of Korean red ginseng concluded there was suggestive evidence for effectiveness in treating erectile dysfunction, although the quality of these studies was low.

Ginseng is well tolerated at recommended doses, with few adverse effects. A recent systematic review of adverse reactions reports that the incidence is similar in ginseng monopreparations and placebo. Possible drug interactions have been reported between *P. ginseng* and warfarin, phenelzine, calcium channel blockers, digoxin, and alcohol. A potential risk of hypoglycemia exists in diabetic patients taking medications. Earlier reports of “ginseng abuse syndrome” and other toxicities are now attributed to adulterants found in earlier unregulated over-the-counter ginseng products. Indeed, 13 of 21 ginseng products recently evaluated for quality and purity failed because they contained unacceptable levels of pesticides or heavy metals or inadequate concentrations of ginsenosides.

F. Saw Palmetto

Saw palmetto is used by over 2 million men in the United States to treat benign prostatic hyperplasia (BPH), and in Europe, it is often the first-line therapy for lower urinary tract symptoms. Lipophilic extracts are prepared from the berries of the dwarf palm tree (*Serenoa repens*) and are standardized to sterols and free fatty acids. Several mechanisms of action have been proposed, including inhibition of 5 α -reductase activity, as well as antiandrogenic, anti-inflammatory, and antiproliferative activity. More than 350 saw palmetto products are marketed in the United

States; however, the most studied brand of saw palmetto (Permixon) is not available.

Early studies showed that saw palmetto was more effective than placebo and only slightly less effective than α -blockers for the treatment of BPH. In a 2008 trial of 92 Chinese men with lower urinary tract symptoms associated with BPH, those treated with saw palmetto for 3 months had significantly greater urine flow rates and improved symptoms relative to those taking the placebo. In contrast, a well-designed 2006 trial showed no difference in symptom scores, flow rates, prostate size, postvoid residual volume, quality of life, or prostate-specific antigen in 225 men with moderate to severe BPH treated with saw palmetto (160 mg twice daily) or placebo for 1 year. An even larger (3000 patient), 4–6 year long, multicenter, three-arm randomized, controlled trial of saw palmetto, the herb *Pygeum africanum*, and placebo is being sponsored by the NIH.

Saw palmetto is very well tolerated by most patients, with only mild and rare gastrointestinal symptoms being reported. It has not been shown to reduce prostate size or lower the serum level of prostate-specific antigen. No herb-drug interactions have been reported.

G. Black Cohosh

Black cohosh, a member of the buttercup family, is a plant native to North America that has gained popularity as a nonhormonal treatment for menopause-related symptoms. Preparations made from its roots and rhizomes were used by Native Americans to treat malaise, genitourinary complaints, colds, and rheumatism. Its mechanism of action remains unclear, but it does not appear to have significant estrogenic effects in vitro or in vivo. A recent report suggests that it acts on the human opioid mu receptor, which may play a role in regulating body temperature.

Black cohosh has been studied in more than 3000 women. The most widely used formulations are two German-manufactured preparations. Fifteen clinical trials have shown efficacy for Remifemin, an isopropanoic extract available since the mid-1950s, and six trials have studied a different product, marketed as Klimadynon. Many clinical trials published since 2003 demonstrate efficacy of black cohosh for reducing menopausal symptoms such as hot flashes, including a 2007 study in which it was as effective as tibolone (a synthetic steroid only available in Europe). In contrast, a year-long trial published in late 2006 did not

show that black cohosh alone or in combination with other herbs was any more effective than placebo in reducing hot flashes or night sweats. In this five-arm trial, 351 women, age 45–55 with at least two hot flashes per day, were randomized to receive black cohosh, a combination of black cohosh and nine other herbs, the combination product along with counseling to increase soy consumption, placebo, and conventional hormone replacement therapy (HRT). (The HRT arm was terminated when the Women's Health Initiative trials were prematurely halted in 2002.) A smaller 2008 trial of a preparation containing black cohosh and Chinese herbs also showed no reduction in hot flashes compared with placebo.

Black cohosh is generally well tolerated at recommended doses. Rare case reports of hepatitis have been reported (some severe enough to require liver transplantation), causing the Medicines and Healthcare Registry Agency in Britain to join Australia in requiring that products be labeled with a safety warning. The NIH held a workshop on the safety of black cohosh in 2004 and concluded that there was inadequate evidence of a causal relationship between black cohosh and hepatotoxicity, although they did recommend that liver enzymes be monitored in all participants in NIH-sponsored trials of black cohosh. No significant drug-herb interactions have been reported.

A 2006 analysis of 11 black cohosh products available in the United States revealed that 4 contained a cheaper Asian species, which has different chemical properties, either as the sole ingredient or in combination with North American black cohosh.

DIETARY SUPPLEMENTS

Sales of dietary supplements have increased dramatically over the past decade. The Dietary Supplement Health

Education Act of 1994 has made it possible for manufacturers to sell dietary supplements directly to the public without FDA approval or oversight. Reports of adulteration and contamination are available, but the magnitude of this problem remains unknown. Furthermore, there have been several reports of the dose printed on the label being different from the actual dose provided. (See section on herbal medicines, above, for further details on regulatory and quality assurance issues and advice for patients to follow when purchasing these products.) Table 41–3 provides an overview of selected dietary supplements commonly used in the United States today.

▶ Dehydroepiandrosterone

Dehydroepiandrosterone (DHEA) and its metabolite, DHEAS, are secreted by the adrenal cortex and serve as precursors for the synthesis of more than 40 different hormones, including male and female sex hormones. In healthy individuals, DHEA levels fall 10–15% per decade from age 20 until age 70, when they are at 30% of lifetime peak levels. Normal circulating levels vary widely by age, sex, and ethnicity and are affected by body mass index, medications (insulin, corticosteroids, opioids), and thy-

roid function. Reduced levels of DHEA have been reported in people who suffer from a wide variety of chronic illness, including depression, cancer, type 2 diabetes, HIV infection, Alzheimer disease, lupus erythematosus, chronic kidney disease, anorexia, and atherosclerosis. Low levels of DHEA associated with aging and medical illness have been cited in the popular press as evidence that DHEA supplementation might be beneficial.

The mechanism of action of DHEA remains unknown. Animal studies suggest that DHEA and DHEAS have excitatory effects on the central nervous system, which may account for their influence on mood and sense of well-being. A 6-week clinical trial randomized 52 persons with major or minor depression to monotherapy with DHEA or placebo and found DHEA to be superior as measured by multiple well-validated depression scales.

Low DHEA levels in men and women with systemic lupus erythematosus (SLE) and reduction in interleukin-10 levels after supplementation compared with placebo suggest that DHEA may play a causative role. A 2007 systematic review of seven clinical trials of DHEA in SLE patients concluded that it had modest but clinically significant impact on health-related quality of life measures in the short term. Several studies suggest that DHEA supplementation

Table 41–3. Overview of selected dietary supplements.

| | Leading Indications | Dosage | Level of Evidence ¹ | Safety ² | Interactions; Side Effects | Comments |
|--|---|---|--------------------------------|-------------------------|--|--|
| Melatonin | 1. Insomnia 2. Jet lag | 0.1–5 mg | 1. B 2. B | I | None | |
| Dehydroepiandrosterone (DHEA, DHEAS) | 1. Depression, dysthymia 2. Lupus 3. Adrenal insufficiency | 50 mg once daily | 1. C 2. B 3. C | IV (with long-term use) | None reported; androgenic effects | Theoretical concerns that long-term use may result in hormone-dependent malignancies |
| Omega-3 fatty acids (fish oil) | 1. High triglycerides 2. Coronary heart disease 3. Inflammatory conditions | Fish twice weekly for general health (300–500 EPA plus DHA) 1 g/d for heart disease | 1. A 2. B 3. C | I I I | Theoretical risk of bleeding at high doses | |
| Glucosamine sulfate and chondroitin | Osteoarthritis (knee) | Glucosamine 500 mg three times daily; chondroitin 400 mg three times daily | B | I | None reported; rare reports of constipation, diarrhea, drowsiness | Insulin resistance not seen in clinical trials |
| Coenzyme Q ₁₀ (ubiquinone, ubiquinone, Co-Q ₁₀) | Congestive heart failure, cardiac arrest, angina, acute myocardial infarction, migraine prophylaxis | 50 mg once daily–150 mg three times daily; goal is to achieve serum level of 2.1 mcg/mL | C | I | Patients taking statins noted to have lower serum levels of Co-Q ₁₀ | Fat-soluble, so absorption improved when taken with meals |

¹Level of evidence: A, high quality: consistent evidence from randomized trials or overwhelming evidence from other sources; B, moderate quality: evidence from randomized trials with important limitations or very strong evidence of some other form; C, low quality: evidence from observational studies or randomized trials with serious methodologic flaws.

²Safety: I, generally safe; II, relatively safe; III, insufficient evidence; IV, may be harmful; V, clear evidence of harm. DHA, docosahexaenoic acid; EPA, eicosapentaenoic acid.

improves physical and psychological well being in healthy persons, but several well-designed trials have shown that DHEA supplementation has no effect on cognitive performance, body composition, physical performance, or well-being in healthy older adults.

DHEA modestly increases testosterone levels in women, but not in men, unless they have hypogonadism. Side effects include acne, deepening of the voice, and facial hair growth. No serious adverse events have been reported. The long-term effects of DHEA supplementation remain unknown. The safety issue of most concern is that DHEA—as a potent precursor of sex steroids—may increase the risk of estrogen- and androgen-dependent malignancies. Therefore, if supplementation is used, patients should be screened carefully and monitored closely. Furthermore, patients at high risk for prostate, ovarian, breast, or uterine cancer should be counseled against DHEA supplementation.

▶ Glucosamine & Chondroitin

Glucosamine and chondroitin have been used in Europe alone and in combination to treat osteoarthritis since the 1980s. Glucosamine is an amino sugar synthesized by chondrocytes that serves as a substrate for the synthesis of cartilage. In addition to providing structural support, it may also have anti-inflammatory activity. Chondroitin is a glycosaminoglycan normally present in the cartilage matrix that helps maintain articular fluid viscosity, inhibit enzymes that break down cartilage, and stimulate cartilage repair. Glucosamine is prepared commercially from crustacean shells. Chondroitin is extracted from bovine tissues such as cow trachea.

A 2007 meta-analysis concluded that use of chondroitin by itself to treat knee or hip osteoarthritis was not warranted in routine clinical practice.

Two meta-analyses and a 2005 Cochrane Review of 20 randomized, double-blind, placebo-controlled trials involving more than 2570 patients with osteoarthritis support the use of glucosamine (or glucosamine and chondroitin) in the treatment of osteoarthritis of the knee. The Cochrane Review identified efficacy only for trials using a once daily proprietary formulation manufactured by Rotta Pharmaceuticals. In the longest trial using the Rotta formulation, glucosamine not only reduced the symptoms of osteoarthritis of the knee but also slowed the progression of the disease. Reginster and coworkers randomized 212 patients to receive 1500 mg/d of glucosamine or placebo. After 3 years, patients taking glucosamine reported a 24% reduction in symptoms versus a

10% increase in the placebo group. Radiographs revealed that the treatment patients experienced a loss of only 0.06 mm joint space versus 0.31 mm in the placebo group after 3 years. A 2006 randomized controlled trial that examined the efficacy of a non-Rotta glucosamine preparation, however, came to a different conclusion. The Glucosamine/chondroitin Arthritis Intervention Trial (GAIT) was a multicenter randomized double-blind placebo-controlled clinical trial in which 1583 persons were randomized to glucosamine hydrochloride, chondroitin sulfate, glucosamine hydrochloride plus chondroitin sulfate, celecoxib, or placebo. Investigators found no difference overall between the supplements alone or in combination and the placebo at 24 weeks. In a predefined subgroup of patients with moderate to severe pain, however, combined therapy with glucosamine and chondroitin did provide greater pain relief than placebo. When joint-space narrowing was evaluated in a subset of patients who continued in the study for a total of 2 years, glucosamine and chondroitin, alone or in combination, were no better than placebo in slowing the loss of knee cartilage. The generalizability of these results may be limited by the fact that glucosamine hydrochloride was used and patients in the placebo group had less cartilage loss than predicted. In contrast, the 2007 European GUIDE Trial (Glucosamine Unum in Die Efficacy Trial) studied the once daily proprietary formulation of crystalline glucosamine sulfate and found that after 6 months it was more effective than placebo in relieving the symptoms of knee osteoarthritis.

Fewer clinical data are available for patients with osteoarthritis of other joints. In a well-designed 2008 study, 222 patients with mild to moderate osteoarthritis of the hip were randomized to 1500 mg/d of glucosamine sulfate or placebo. Glucosamine had no clinically significant effect on pain, function, or joint space narrowing after 2 years.

Oral glucosamine is generally well tolerated and does not elevate serum glucose levels in humans. No significant drug-herb interactions have been reported, except a possible increase in INR in patients taking glucosamine and warfarin together. In contrast to NSAIDs, glucosamine may take weeks to months before improvement in symptoms is noticed. In summary, clinical trial literature suggests that glucosamine with or without chondroitin is well tolerated and safe with fewer side effects than NSAIDs. However, the efficacy of formulations other than a proprietary European product in the treatment of osteoarthritis remains in question.

▶ Coenzyme Q₁₀

Coenzyme Q₁₀ (also known as ubiquinone-10) is a fat-soluble provitamin that resides in the lipid layer of the mitochondria. It plays a crucial role in electron and proton transfer during oxidative phosphorylation and production of adenosine triphosphate (ATP), so it is necessary for the basic functioning of all cells. It also has antioxidant, free radical scavenging, and membrane stabilizing activities. Coenzyme Q₁₀ levels decrease with age. Deficiencies have been observed among patients with certain chronic medical conditions, including cardiovascular disease (hypertension, acute coronary syndromes, congestive heart failure), renal failure, male infertility, periodontal disease, cancer, HIV/AIDS, muscular dystrophies, Parkinson disease, and Alzheimer disease. Certain prescription medications may also lower coenzyme Q₁₀ levels, including HMG-CoA reductase inhibitors, diabetes medications, β -blockers, diuretics, and antidepressants. Serum levels of coenzyme Q₁₀ are increased by taking supplements, but there are conflicting data about whether this results in clinical benefit.

In parts of Russia, Europe, and Japan, coenzyme Q₁₀ is part of standard therapy for congestive heart failure, although it is not recommended for treatment of congestive heart failure by the American College of Cardiology or the American Heart Association. Other studies have evaluated coenzyme Q₁₀ for acute myocardial infarction, angina, diabetes mellitus, hypertension, migraine prophylaxis, muscular dystrophy, Parkinson disease and periodontal disease with mixed results. A 2006 Cochrane systematic review of treatments for mitochondrial disorders describe two trials of coenzyme Q₁₀, one reporting subjective improvement and significant increase in a scale of muscle strength but the other showing no benefit. Although other medical conditions are also associated with low levels of coenzyme Q₁₀, additional randomized controlled clinical trials are needed before supplementation with coenzyme Q₁₀ can be routinely recommended to improve outcomes for any particular condition.

Because coenzyme Q₁₀ is lipophilic, it is often formulated with vegetable oil or vitamin E to enhance its absorption. Its bioavailability is also enhanced when it is taken with meals, especially fat-rich foods. No serious adverse events have been noted with coenzyme Q₁₀ use, and it is generally well tolerated. Insomnia, elevated liver enzymes, rash, and abdominal complaints are among the mild adverse reactions reported in clinical trials. No significant drug-herb interactions have been reported, but coenzyme Q₁₀ is chemically similar to vitamin K and so theoretically may reduce the effectiveness of warfarin.

▶ Omega-3 Fatty Acids

Interest in omega-3 fatty acids began 30 years ago, when it was discovered that the Inuit population of Greenland had low rates of cardiovascular disease, despite consuming a high protein and high fat diet (mostly in form of fish). Evidence from multiple large-scale observational studies and randomized controlled trials indicates that intake of fish or fish oil supplements (or both) containing the omega-3 fatty acids eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) is associated with many health benefits. A recent review concluded that modest consumption of fish (1–2 servings per week), especially species higher in the omega-3 fatty acids EPA and DHA, reduces the risk of coronary death by 36% and total mortality by 17%. Multiple mechanisms have been proposed for the beneficial effects of omega-3 fatty acids for both primary and secondary prevention of cardiac disease. These include reductions in triglyceride levels, inflammation, blood pressure (2–5 mm Hg), blood clotting, arrhythmias, atherosclerotic plaque formation, and improvements in arterial and endothelial function. The reduction in triglyceride levels appear to be dose-dependent, with effects at doses as low as 2 g/d. Higher doses have greater effects, and 4 g/d can lower triglyceride levels by 25–40%.

Several well-conducted, randomized controlled trials report that in individuals with a history of heart attack, regular consumption of oily or fish oil/omega-3 supplements reduces the risk of nonfatal heart attack, fatal heart attack, sudden death, and all-cause mortality. Benefits have been reported beginning after 3 months of use, and for as long as 3.5 years of follow-up. Recent data suggest that omega-3 fatty acids may be more effective than statins in treating congestive heart failure. Although fish oils have been studied primarily in patients at risk for cardiovascular disease as well as those with established cardiovascular disease, they are also being investigated in treatment of other conditions such as diabetes, dementia, depression, obesity, inflammatory bowel disease, and attention deficit/hyperactivity disorder.

Animal sources of omega-3 fatty acids (EPA and DHA) include fish, especially cold-water fatty fish such as salmon, mackerel, halibut, anchovies, and sardines. A proprietary plant-based source of DHA is manufactured from algae. Vegetable sources of the omega-3 fatty acid alpha-linolenic acid (ALA) include English walnuts; flaxseeds; tofu/soy and some vegetable oils, such as canola, soy, flaxseed, and

olive oil. Dietary intake of omega-3 fatty acids has declined by 80% over the past century, while intake of omega-6 fatty acids has greatly increased. Omega-6 fatty acids come from the common use of other vegetable oils (corn, safflower, and sunflower oils) containing linoleic acid; these compete with omega-3 fatty acids to be converted to active pro-inflammatory metabolites in the body.

In 2003, the American Heart Association recommended that healthy people eat fish at least twice a week as well as consume plant-derived sources of omega-3 fatty acids, such as tofu/soybeans, walnuts, flaxseed oil, and canola oil. People with known coronary heart disease should take in approximately 1 g/d of EPA and DHA (combined). The FDA regards intake of up to 3 g/d of omega-3 fatty acids from fish as safe. Fish oil supplements are widely available over the counter and should be dosed based on their content of EPA and DHA. Omega-3 fatty acid 1 g prescription capsules, containing 465 mg of EFA and 375 mg of DHA, are also FDA-approved for the treatment of hypertriglyceridemia. In a 2007 trial, addition of 4 g/d of prescription omega-3 acids to 40 mg/d simvastatin improved lipid parameters to a greater extent than simvastatin alone.

The most common side effects of fish oil supplementation are gastrointestinal upset, burping, fishy taste, loose stools, and nausea. High doses may also have harmful effects, such as an increased risk of bleeding, so the FDA recommends no more than 3 g of EPA plus DHA per day and no more than 2 g from the diet. The potential for harm from mercury, dioxins, and polychlorinated biphenyls (PCBs) present in some fish was addressed in a recent review which concluded that, in general, the benefits of fish intake exceed the potential risks.

▶ Melatonin

Melatonin (N-acetyl-5-methoxytryptamine) is a hormone synthesized by the pineal gland from the amino acid tryptophan that is released into the circulation in response to environmental light-and-dark signals. Serum levels in humans vary 10- to 20-fold over 24 hours from a low of 2–10 pg/mL during daylight hours to a high of 100–200 pg/mL at night.

Melatonin is used to treat a variety of medical conditions, particularly insomnia and jet lag, given its role in regulating

the body's circadian rhythm. Although available as an over-the-counter sleep aid in this country, it is available only by prescription in much of the rest of the world (European Union, Australia, and New Zealand).

A 2005 meta-analysis of 17 clinical trials involving 284 subjects concluded that melatonin was effective in reducing the time it took them to fall asleep and increasing the amount of time they remained asleep. The authors concluded that exogenous melatonin was helpful in treating insomnia, particularly in older individuals and those with low nocturnal levels of melatonin. An NIH State-of-the-Science Panel Report that same year also concluded that melatonin was effective in the management of chronic insomnia in subsets of the adult population.

In contrast, a 2006 meta-analysis, which included patients of all age-groups, failed to document clinically meaningful effects of exogenous melatonin on sleep quality, time to fall asleep, and hours slept per night. Nightly melatonin (2.5 mg) combined with daytime bright light was shown to modestly improve cognitive and noncognitive function in 189 elderly Dutch residents of 12 group care facilities. Melatonin was noted to have adverse effects on mood when used alone in these elderly subjects, but these effects were not observed when melatonin was used in combination with bright light.

Melatonin is believed to have antioxidant, antineoplastic, and immunomodulatory activity, but there are insufficient clinical trial data to support its use for conditions other than insomnia and jet lag. Of interest, melatonin receptors have recently been demonstrated on pancreatic islet cells, which may help explain a link between disturbed sleep and glucose intolerance.

Three melatonin receptors have been identified in mammals: MT1, MT2, and MT3. MT1 and MT2 appear to regulate the circadian sleep-wake cycle. Ramelteon, a selective MT1 and MT2 receptor agonist, was approved by the FDA in 2005 to treat insomnia.

Considerable person-to-person variability in serum levels after taking the same dose of melatonin has been reported. Physiologic doses (0.1–0.3 mg) have been shown to decrease time until sleep, increase duration of sleep, and decrease daytime fatigue. Commonly available over-the-counter doses (1–10 mg) have been reported to raise plasma concentrations to levels 3–60 times greater than normal peak levels.

Melatonin is generally considered safe at recommended oral doses of 5 mg or less for up to 2 years. No hangover effect has been noted, even after 1 month of taking high doses.

Side effects of fatigue, sleepiness, headache, dizziness, and irritability are no more commonly reported than with placebo. Caution is advised in patients taking immunosuppressants or those with vascular disorders or infertility problems.

ACUPUNCTURE

In acupuncture, anatomic points on the surface of the body are stimulated by a variety of techniques, often with needles, to treat illness and promote health. Many styles exist and are practiced as part of the thousands of years old medical traditions of China, Japan, Korea and other countries. Practitioners trained in Oriental medicine believe that a vital energy called chi (pronounced “chee”) circulates in the body through 12 virtual pathways called meridians. Disease occurs when the flow of chi in the body is not in balance. Each meridian is named after a particular organ or “official.” In addition to describing the structure and function of the organ itself, the naming of each meridian also reflects a broader energetic function in Traditional Chinese Medicine.

► Mechanism of Action

The mechanism of action of acupuncture is not well understood, but physiologic effects can be measured when acupuncture points are stimulated, such as the release of endorphins and enkephalins. Functional MRI studies reveal that different areas of the brain are activated and deactivated during needling.

Stux G, Berman B, Pomeranz B (editors). *Basics of Acupuncture.* 5th ed. Springer, 2003.

► Training, Licensure, & Regulation

Typical acupuncture training for nonphysicians in the United States involves completion of a 4-year (2500 hours) master’s degree training program accredited by the Accreditation Commission for Acupuncture and Oriental Medicine (ACAOM). In order to become a licensed acupuncturist (LAc), a national and, frequently, state board examination must be passed. Although many states do not require physicians to obtain additional training, many encourage a minimum of 200 hours of training in an accredited program. There are currently approximately 18,000 licensed acupuncture practitioners and more than 3000 physician acupuncturists in the United States. In 22 of the 43 states that license, register, or certify acupuncturists, these practitioners are permitted to work independently.

► Clinical Practice

In the United States and Europe, Oriental medicine-trained practitioners conduct a comprehensive multisystem history, observation, and physical examination during the initial consultation. Examination consists of palpation of the abdomen and selected acupuncture points; examination of the tongue to assess color, shape, and coating; and palpation of the pulse along the wrist at three locations on both arms to assess its quality, rhythm, and strength. In classic acupunc-

ture, each patient is viewed as having a unique constellation of symptoms and signs. What this means is that ten patients presenting with migraine headaches might receive ten unique Chinese medical diagnoses and ten different treatments. Because acupuncture is just one part of a comprehensive system, patients are also often prescribed Chinese herbal therapy, diet, and exercise. Western-style practitioners will conduct a conventional examination and include variable components of the Oriental medicine approach depending on the individual’s depth of training. Treatment typically utilizes a fixed combination of acupuncture points for a given medical diagnosis, such that a cohort of migraine sufferers will be treated in a similar way.

Treatment typically involves inserting four to fifteen needles at selected acupuncture points for 10–30 minutes—though certain schools leave the needles in place for only a few seconds to minutes. Virtually all acupuncture is performed with thin, solid, stainless steel, sterile disposable needles that are stimulated manually or with electricity or heat. Follow-up consultations last from 20 minutes to 45 minutes. A course of treatment usually consists of weekly or biweekly visits for 4–10 weeks, followed by less frequent visits as the condition improves.

► Adverse Events

The current practice of acupuncture in the United States and Europe is associated with a very low incidence of adverse events (as low as 1 in 10,000 to 1 in 100,000 needle insertions). Reactions such as presyncope, syncope, and drowsiness can be easily prevented by having the patient lie flat on the table, monitoring them during their initial visit, and permitting them to remain in the office until a normal state of awareness is achieved. Serious complications in the literature over the past 30 years are very rare but include spread of infection and pneumothorax from needling patients with emphysema.

► Clinical Uses of Acupuncture

More than 1000 English-language reviews of the clinical use of acupuncture in humans have been published in the last 20 years, many pointing out the challenge of designing high-quality trials with effective placebo controls. Several types of placebos have been tried: needling at nonacupuncture points, using a retractable sham needle that does not penetrate the skin, and needling at true acupuncture points that are inappropriate for the condition being treated. Data analysis is complicated by the fact that sham treatments can have physiologic effects in and of themselves. Acupuncture has been shown to be most effective in treating pain and nausea. A 2009 systematic review, however, concluded that “whether needling at acupuncture points or at any site reduces pain independent of the psychological impact of the ritual is unclear.” Recent reviews have also concluded that acupuncture is not effective (or that data were inconclusive for) treating hypertension, hot flashes, epilepsy, insomnia, allergic rhinitis, Parkinson disease, restless leg syndrome, and dyspnea. What follows is a selection of some conditions for which patients commonly seek acupuncture care.

Park J et al. The status and future of acupuncture clinical research. *J Altern Complement Med.* 2008 Sep;14(7):871–81. [PMID: 18803496]

A. Low Back Pain

More than 50 clinical trials of acupuncture for the treatment of low back pain were reviewed by the American Pain Society and American College of Physicians as part of clinical practice guidelines that were published in 2007. They concluded that there was a fair level of evidence supporting a moderate benefit of acupuncture in treating subacute (4–8 weeks) or chronic low back pain. In most studies, acupuncture has not been shown to be more effective when compared with other active treatments, but provides additional benefit when added to conventional therapies. A 2008 systematic review of 23 randomized controlled trials involving more than 6000 patients concluded that acupuncture versus no treatment and as an adjunct to conventional care should be advocated in the European Guidelines for the treatment of chronic low back pain.

B. Osteoarthritis

A 2006 systematic review and meta-analysis of 18 randomized controlled trials concluded that “sham-controlled trials suggest specific efficacy of acupuncture for pain control in patients with osteoarthritis of peripheral joints. The favorable safety profile makes acupuncture a worthy option of consideration, particularly for knee osteoarthritis.” Acupuncture plus routine care was associated with marked clinical improvement in a German trial in which 632 patients with osteoarthritis of the hip or knee were randomized to up to 15 sessions of physician-delivered acupuncture or wait-list control for 3 months. The treatment protocol was individualized for each patient at the discretion of the physician, more closely reflecting how acupuncture is practiced clinically. One-third (34.5%) of the acupuncture-treated group had a good response after 3 months, compared with 6.5% of the wait-list control group. The improvement in pain and quality of life was maintained at 6-month follow-up.

A 2007 meta-analysis of nine clinical trials revealed clinically relevant short-term (but not long-term) improvements in pain and function compared with those in wait-list control groups. Authors concluded that some of acupuncture’s clinically relevant benefits might be due to placebo and expectation effects.

A 2007 cost effectiveness trial involving almost 500 German patients who were randomized to routine care or routine care plus acupuncture concluded that acupuncture was a cost-effective treatment for osteoarthritis.

C. Postoperative Pain

Acupuncture was helpful in reducing pain intensity, opioid consumption, and opioid-associated side effects in a 2008 systematic review of 15 randomized clinical trials comparing acupuncture with sham control for acute postoperative pain. In contrast, a systematic review of 9 trials of auricular acupuncture concluded that the evidence was “promising but not compelling” in its reducing postoperative pain.

Usichenko TI et al. Auricular acupuncture for postoperative pain control: a systematic review of randomized clinical trials. *Anesthesia.* 2008 Dec;63(12):1343–8. [PMID: 19032304]

D. Headache

Mixed results were reported early on about acupuncture’s efficacy in the treatment of headaches, but more recent reviews conclude that it is a safe and effective option for treating both tension and migraine headaches. A 2008 study also concluded that acupuncture was cost effective when compared with routine care in patients with primary headache.

E. Nausea & Vomiting

Based on multiple randomized controlled trials involving more than 6000 patients, there is strong evidence that acupuncture is effective in the treatment of pregnancy-induced, chemotherapy-induced, and postoperative nausea and vomiting. A 2006 systematic review identified 43 trials using a particular acupuncture point (P6) for treatment of nausea and vomiting. P6 is located on the anterior surface of the forearm, several inches proximal to the wrist between the tendons of palmaris longus and flexor carpi radialis. Results across trials were the most consistent for postoperative nausea and vomiting. Compared with sham procedures, P6 stimulation was more effective than comparison in preventing nausea (RR 0.72, 95% CI 0.59–0.89) and vomiting (RR 0.71, 95% CI 0.56–0.91). For example, in the 9 trials that compared P6 stimulation to antiemetic medication, P6 was superior in preventing nausea and equivalent in preventing vomiting. Electroacupuncture was reported to be effective for first-day vomiting after chemotherapy. Trials using noninvasive electrostimulation (primarily with wristwatch type devices) showed no benefit above and beyond control treatment with antiemetic medications.

Streitberger K et al. Acupuncture for nausea and vomiting: an update of clinical and experimental studies. *Auton Neurosci*. 2006 Oct 30;129(1–2):107–17. [PMID: 16950659]

F. Nicotine, Heroin, Cocaine, & Alcohol Addiction

There is good evidence suggesting that acupuncture is not effective in maintaining abstinence from nicotine addiction. A 2006 Cochrane systematic review of 24 trials concluded “there is no consistent evidence that acupuncture or acupressure, laser therapy or electrostimulation are effective for smoking cessation.”

Despite insufficient evidence to support its use, auricular acupuncture is in widespread use throughout American drug treatment facilities. Although heroin, alcohol, and cocaine addiction studies have frequently reported positive outcomes, serious methodologic flaws have been found in these studies. A 2006 Cochrane systematic review of seven studies in which 1433 patients were treated with ear acupuncture for cocaine dependence concluded that there is currently no evidence to support its use.

G. Infertility

Conflicting results have been reported about the efficacy of acupuncture in improving the outcomes of women undergoing in vitro fertilization. A systematic review of seven clinical studies of acupuncture given with embryo transfer suggested that it may improve rates of pregnancy and live births. In contrast, a review of eight trials published later in 2008 concluded there were insufficient data that adjunctive acupuncture improved in vitro fertilization–related pregnancy rates.

MIND-BODY MEDICINE

► Definition

Mind-body medicine is commonly described as the field of medicine that uses processes of the mind to influence the health of the body. While this is a useful initial concept, it still can perpetuate the notion that mind and body are separate, and it fails to acknowledge the bidirectional relationship of mind and body (eg, exercise improves mood). It may be more accurate to think of *mind/body* as a single entity, with the health of one part necessarily influencing the health of the other. The NIH has defined mind-body medicine as “behavioral, psychological, social, and spiritual approaches to medicine not commonly used.” This definition distinguishes mind-body medicine therapies from therapies that are more established or mainstream but that may have similar mechanisms of action (eg, psychotherapies, behavioral training, support groups, education). Traditionally defined mind-body therapies include biofeedback, hypnosis, meditation, guided imagery, relaxation techniques, yoga, tai chi, and chi gung.

► History

The relationship between mind and body and its importance to health has been recognized for thousands of years by all major healing traditions, including the ancient Greek system that gave rise to modern Western medicine. With the ascendancy in the West of the scientific method and the biomedical model of illness, however, the relationship between mind and body has often been neglected. In the 19th

century, interest in hypnosis began and later Freud championed the theory of the unconscious mind, which helped establish the paradigm that processes of the mind profoundly affect health. In the early 20th century, the American physiologist Walter Cannon began exploring the physiologic effects of emotional stimuli. In the 1930s, Dr. Clark Hull began studies of hypnosis, and research into hypnosis greatly expanded in the 1950s. The first biofeedback experiments also occurred in the 1950s. Since then, there has been considerable research evaluating mind-body phenomena and therapies. It has been established, for example, that certain emotions such as anger, anxiety, and depression affect clinical outcomes (including mortality) for conditions such as cardiovascular disease, cancer, and HIV infection. The new field of psychoneuroimmunology has documented, at the physiologic level, the powerful effect of the mind on the nervous, endocrine, and immune systems, and vice versa. Studies have demonstrated that certain forms of mental training, in addition to affecting health, can affect brain function and even structure, leading to a reevaluation of previously held beliefs about neuroplasticity.

► Clinical Applications of Mind-Body Medicine

Mind-body medicine is popular. Over 20% of the US adult population has used one or more mind-body therapies in the past year. Data from the 2007 National Health Interview Survey show that use of most mind-body therapies has increased since 2002. The more conventional mind-body therapies already are established, supported by evidence, and widely available. For example, multimodal mind-body interventions that use some combination of cognitive behavioral therapies, support groups, education, relaxation and skills training have been proven effective for coronary artery disease, cancer, and chronic pain conditions. Mind-body therapies also work well as adjunctive treatments, for example with surgery, cancer treatment, and stress-exacerbated conditions (Table 41–4). They also offer the psychological benefit of increasing sense of control for the patient. Finally, mind-body therapies can be recommended because they have a very favorable safety profile.

BIOFEEDBACK

► Definition

Biofeedback is a behavioral therapy method that teaches a patient to gain greater awareness and control over physiologic functions, including some not normally under conscious control. This is achieved by using technology that presents to the patient in visual or auditory form the level of activity of a physiologic parameter, such as muscle tension,

skin temperature, sweat gland activity, respiratory muscle activity, PCO_2 , heart rate variability, or brain wave pattern.

► History

Biofeedback began in the 1950s with the work of the experimental psychologist Dr. Neil Miller. He demonstrated that rats could learn to regulate autonomic functions when motivated by painful or pleasurable stimuli. The idea that autonomic function could be volitionally controlled was contrary to the scientific dogma of the time. In the 1960s, other researchers began to examine the human ability to consciously alter physiologic function.

► Training & Certification

Certification is obtained through the Biofeedback Certification Institute of America (BCIA) and is open to professionals from clinical health care areas including, but not limited to, psychology, nursing, and counseling. Requirements for certification are: (1) 48 hours of didactic education, (2) 20 hours of contact spent with a BCIA approved mentor, 50 patient/client sessions, and case conference presentations, and (3) successful completion of a written certification examination. There is also a continuing education requirement.

When treating a medical or psychological disorder, biofeedback practitioners are required to hold a current state license in a BCIA-approved health care field or, if without this license, work under the supervision of an appropriately credentialed health care professional. Separate, additional certificates are required for electroencephalographic (EEG) biofeedback (neurofeedback) and pelvic muscle dysfunction work.

► Clinical Practice

Since biofeedback is a taught, self-regulatory skill, the patient should be motivated; prepared to take an active role in their treatment; respond well to visible, quantifiable information; or have aptitude or familiarity with technology. Typical biofeedback sessions last 50 minutes, with half or more of that time in active monitoring. To begin a biofeedback session, the therapist applies sensors to the patient that monitor the physiologic parameters of interest. For example, in a case of chronic tension headache, an electromyographic (EMG) sensor may be applied to the skin of the forehead. Information from the sensor feeds back to the patient as sound or as an image on a computer screen in real time, so he or she can begin to learn to reduce tension in the forehead muscle. Multiple sessions are usually required and the patient is asked to practice the learned skills between sessions. The goal of biofeedback is to help the patient train himself to produce the desired response at other times. Some biofeedback software programs and sensors are available for use on a home computer or with portable electronic devices.

► Adverse Events & Contraindications

There are no reported adverse effects of biofeedback therapy. Benzodiazepines, opioids, other sedating medicines,

Table 41–4. Overview of mind-body therapies for various clinical conditions.

| Condition | Mind-Body Therapy | Level of Evidence ¹ | Comment |
|--|--|--------------------------------|---|
| Surgery/Procedure: Pain | Hypnosis Guided imagery | A B | Guided imagery may reduce length of hospital stay |
| Surgery/Procedure: Anxiety | Hypnosis Guided imagery | B B | |
| Cancer: Pain | Hypnosis Guided imagery | A B | Guided imagery “B” when combined with other therapies |
| Cancer: nausea and vomiting (chemotherapy) | Guided imagery Hypnosis | A B | Guided imagery “A” when combined with other therapies |
| Cancer: Psychological symptoms (eg, mood, anxiety, stress) | Guided imagery Mindfulness meditation | A A | |
| Chronic pain (various etiologies) | Guided imagery Mindfulness meditation Hypnosis | B B B | |
| Fibromyalgia | Mindfulness meditation Guided imagery | B C | |
| Migraine headache | Biofeedback Guided imagery | A C | EMG biofeedback or thermal biofeedback plus relaxation |
| Tension headache (recurrent) | Biofeedback Guided imagery | B C | |
| Irritable bowel syndrome | Hypnosis Guided imagery | A C | |
| Hypertension | Biofeedback | B | Thermal or electrodermal biofeedback best, add relaxation or cognitive therapy to biofeedback |
| Raynaud phenomenon (primary) | Biofeedback | B | |
| Anxiety disorders | Mindfulness meditation | B | |
| Depression | Mindfulness meditation | A | MBCT or MBSR |
| Insomnia | Mindfulness meditation Biofeedback Hypnosis | B C C | Progressive muscle relaxation and combination of mind-body therapies also shown effective |
| Urinary incontinence | Biofeedback | B | Stress, urge, mixed or post-prostatectomy |
| Fecal incontinence | Biofeedback | B | First-line therapy |
| Chronic constipation (pelvic floor dyssynergia) | Biofeedback | A | First-line therapy |
| Asthma | Biofeedback Hypnosis | C C | |
| Smoking cessation | Hypnosis Mindfulness meditation | C C | |

¹Level of evidence: A, high quality: consistent evidence from randomized trials or overwhelming evidence from other sources; B, moderate quality: evidence from randomized trials with important limitations or very strong evidence of some other form; C, low quality: evidence from observational studies or randomized trials with serious methodologic flaws.

EMG, electromyographic; MBCT, mindfulness-based cognitive therapy; MBSR, mindfulness-based stress reduction.

and even caffeine can sometimes impair the efficacy of biofeedback training.

► Clinical Uses of Biofeedback

A. Hypertension

Studies on the blood pressure lowering effect of biofeedback have been published for over 40 years. Meta-analyses

consistently show that compared with wait-list or other inactive control groups, biofeedback can significantly lower patients' systolic and diastolic blood pressures (approximately 5–8 mm Hg systolic and 3–5 mm Hg diastolic pressure). However, when biofeedback is compared with active control group (eg, sham biofeedback or nonspecific behavioral control), it is usually not statistically superior in its effect on blood pressure except when coupled with

relaxation training or cognitive therapy. One exception is a randomized controlled trial that compared active biofeedback to sham biofeedback and found significant reductions in systolic and mean blood pressure at 12-week follow-up. This study used direct blood pressure biofeedback, although the literature taken as a whole favors thermal and electrodermal (galvanic skin response) biofeedback methods over EMG or direct blood pressure biofeedback methods. In general, the degree of blood pressure reduction with biofeedback strongly correlates with pretest blood pressure. Persons with higher baseline blood pressures show larger beneficial effects from biofeedback.

Because most patients in studies of nonpharmacologic treatment of hypertension have only mild hypertension, the effect of treatments like biofeedback may be more difficult to detect. Also, it is worth noting that, as is the case for all antihypertensive therapies, small reductions in blood pressure yield important clinical benefits.

Also noteworthy in recent years is research on respiratory biofeedback training, in contrast to traditional thermal or electrodermal biofeedback methods for blood pressure reduction. A particular pattern of device-assisted respiration practiced for 15 minutes daily has been shown in seven of eight small studies to lower ambulatory blood pressure. In 2002, the FDA approved a simple device (RESPERATE) to enable respiratory training for home use.

B. Coronary Artery Disease

There have been clinical studies of the effect of biofeedback on heart rate variability. Heart rate variability is considered to be an indicator of autonomic tone and has been postulated to be the mediator of the effects of cognitive and mind-body therapies on cardiovascular conditions. Cardiac electrophysiology studies have shown that poor heart rate variability is predictive of both short-term and long-term mortality after myocardial infarction. One randomized controlled trial of 63 patients with established coronary artery disease showed that biofeedback significantly increases heart rate variability. Another randomized controlled trial showed an 86% reduction in post-myocardial infarction mortality at 2 years from a psychosocial intervention that included biofeedback training of heart rate variability. However, this study did not show a significant change in heart rate variability with the intervention unless individuals with high heart rate variability at baseline were excluded. Thus, it remains unanswered whether improved heart rate variability from biofeedback training indeed affects important cardiovascular outcomes.

C. Raynaud Phenomenon

There have been seven randomized controlled trials of the efficacy of biofeedback on Raynaud phenomenon. Two show biofeedback to be superior to active control (eg, autogenic training), and four show benefit from biofeedback but equal to active control. One large study showed thermal biofeedback to be equivalent to EMG biofeedback treatment and to treatment with sustained-release nifedipine. However, there was a nonsignificant trend showing superiority of nifedipine over thermal biofeedback.

D. Headache

Biofeedback and other behavioral techniques have been extensively studied in prevention of recurrent migraine and tension headaches, with more than 50 studies including many randomized controlled trials. Several meta-analyses concur there is a significant reduction (30–55%) in headache frequency with biofeedback and other behavioral interventions. Other outcomes with significant improvement in several studies are anxiety, depression, self-efficacy and medication usage. The American Academy of Neurology practice guidelines state that there is grade “A” evidence for the use of thermal biofeedback with relaxation or EMG biofeedback for prevention of migraine. Biofeedback compares favorably with pharmaceutical treatments in several studies. There are also studies showing enhanced efficacy from adding medications to biofeedback therapy. The American Academy of Neurology practice guidelines state that there is grade “B” evidence for behavioral therapy (eg, biofeedback and relaxation techniques) when combined with prophylactic drug therapy (eg, propranolol and amitriptyline) to achieve additional clinical improvement for migraine relief.

E. Urinary Incontinence

There are at least 20 randomized controlled trials of biofeedback for stress, urge, and mixed types of incontinence in mostly postmenopausal women. In all of these trials, biofeedback produced improvement in symptoms; however, when compared with other treatment methods (eg, assisted or unassisted pelvic floor muscle training, use of vaginal cones), biofeedback was superior in less than half of these trials. It could be argued, however, that methods such as assisted pelvic floor muscle training or the use of vaginal cones are themselves forms of biofeedback. Therefore, while it is clear that training of the pelvic muscles is beneficial for reducing incontinence, it is less clear whether biofeedback-enhanced pelvic floor muscle training offers a significant advantage. The same conclusion can be drawn from the 11 randomized controlled trials of urinary incontinence in post-prostatectomy men, which show a benefit for pelvic floor muscle training whether assisted by biofeedback or not. Also noteworthy is a recent secondary analysis of an ongoing study of biofeedback for urinary incontinence, which importantly showed not only improvement in continence but also significant reduction of depression.

F. Fecal Incontinence

There are more than 40 experimental trials of biofeedback for fecal incontinence in adults and all but 2 of these report moderate to large benefit. However, the methodologic quality of many of these publications is low. A 2006 Cochrane review of biofeedback and sphincter exercises for fecal incontinence included 11 randomized controlled trials and concluded that the efficacy of biofeedback for fecal incontinence remained in question. Nonetheless, many authors and clinicians in this field consider it a first-line therapy. A report of 513 consecutive patients seen at a tertiary colorectal referral clinic showed that more than

70% of patients received benefit. American College of Gastroenterology Practice Guidelines consider biofeedback safe and effective and recommend it for treatment of fecal incontinence.

G. Chronic Constipation

About 30–50% of cases of chronic constipation are due to pelvic floor dyssynergia, a failure of the pelvic floor and anal muscles to relax during straining. Pelvic floor dyssynergia may be less amenable to laxative and fiber treatment but appears to be successfully treated with biofeedback. This indication has been studied in adults in at least nine randomized controlled trials. In three trials, biofeedback was superior to sham biofeedback, polyethylene glycol, diazepam, and placebo. Because of its success rate (70–80%) and safety, biofeedback is widely recommended as first-line therapy alone or in combination with other measures.

H. Stroke Rehabilitation

Biofeedback for stroke rehabilitation has been difficult to evaluate for several reasons, including nonstandardized outcome measures and variability in the time post-stroke at which biofeedback is offered. There are over 20 randomized controlled trials, all with small sample sizes. Some individual studies show benefit in motor strength, gait quality, and functional recovery with EMG biofeedback. A Cochrane review concludes EMG biofeedback cannot be recommended as a routine treatment but due to its safety and possible efficacy its use can be reasonably considered.

I. Psychiatric Disorders

EEG biofeedback, also known as neurofeedback, was first used to reduce seizure frequency in epilepsy in the 1970s. Since then, it has been applied to attention-deficit hyperactivity disorders, anxiety disorders, affective disorders, substance use disorders, other psychiatric conditions, and traumatic brain injury. However, there are still few methodologically rigorous trials investigating this form of biofeedback. A recent pilot study suggests that a portable heart-rate variability biofeedback device produces additive benefit when combined with cognitive behavioral therapy (CBT) for patients with anxiety disorders.

J. Asthma

Evidence for the efficacy of biofeedback in asthma is tentatively favorable. Of the 11 small, randomized controlled trials, 5 show clear and significant benefit for clinical (eg, frequency of attacks, medication use) and physiologic (eg, peak expiratory flow, respiratory resistance) parameters, 3 fail to show benefit, and 3 have mixed results. EMG, P_{CO₂}, heart rate variability, and trachea noise methods have all been used.

HYPNOSIS

▶ Definition

Hypnosis is a procedure that induces an altered state of consciousness in which the patient's mind is more accepting of suggestion. It is believed that during hypnosis the usual evaluative, critical function of the conscious mind is bypassed and more direct communication with the subconscious mind occurs.

▶ History

Hypnotic phenomena, including trancelike states for medical purposes, have been practiced around the world throughout human history. It was the Scottish surgeon, James Braid, in 1843, however, who coined the term “hypnosis” and laid the foundation for the use of hypnosis in modern medicine. Braid believed the effects of hypnosis were mediated by the mind of the patient. Important early research was conducted in the 1930s by Dr. Clark Hull and his student, Dr. Milton Erickson. In the mid-1950s, the British and American Medical Associations suggested that hypnosis be incorporated into the medical curriculum. In 1960, the American Psychological Association endorsed hypnosis as a branch of psychology. In 1996, an NIH Technology Assessment Panel judged hypnosis to be an effective intervention for alleviating pain.

▶ Mechanism of Action

The mechanism of action of hypnosis has not been fully elucidated, but its effects are seen at multiple levels, including somatosensory cortex, anterior cingulate cortex (modulation of pain affect via limbic system), spinal cord and autonomic nervous system (eg, hypnosis can reduce colonic motility in irritable bowel syndrome). Additional recent evidence of mechanism includes upregulation of immune-related gene expression (eg, effects on tumor necrosis factor [TNF]- α) and reduction of mucosal inflammatory response in ulcerative colitis. Hypnotic trance is a state distinct from sleep or relaxation, and hypnotic analgesia is distinct from placebo analgesia.

▶ Training & Certification

Certification for hypnosis, granted through the American Society of Clinical Hypnosis, has the following requirements: (1) health professional degree, (2) 40 hours of

workshop training, (3) 20 hours of supervised clinical training, and (4) 2 years of independent practice using clinical hypnosis.

Other certification programs exist. Patients and clinicians should inquire about the training and certification of any practitioner of hypnosis because there are no restrictions limiting its use to licensed health care practitioners.

► Clinical Practice

The procedure of hypnosis can be divided into three phases: induction (or pre-suggestion), suggestion, and post-suggestion. The induction of a trance is accomplished in a variety of ways with the intention of developing relaxation and focused attention. Once the trance is induced, therapeutic suggestions are offered. In the post-suggestion phase, the patient returns to their usual state of consciousness and the suggestions may be discussed and reinforced. Self-hypnosis may be taught to further reinforce the therapeutic suggestions between sessions.

Although most people can respond to hypnosis, there is great variability in hypnotic susceptibility (“suggestibility”) in the population. This can be measured with standard instruments such as the Harvard Group Scale of Hypnotic Susceptibility and the Stanford Hypnotic Susceptibility Scale. Studies have shown a positive correlation between hypnotic susceptibility and its efficacy.

The ideal candidate for hypnosis is a patient with high suggestibility and motivation, with a condition for which hypnosis has proven benefit. Course of treatment can vary from a single session to several. Sessions are usually 45–60 minutes, with the first session typically lasting 90–120 minutes. It is helpful when referring patients to dispel common myths about hypnosis. For example, it is not true that one loses consciousness in trance nor that one cedes control to the hypnotist. Trance state may best be described as a voluntary state of mind not unlike the one experienced when absorbed in reading a book or when daydreaming. It may be useful to explain to patients that the purpose of referral to hypnosis is to learn skills to use the mind-body connection.

► Adverse Events

Adverse events from hypnosis have not been well studied. As with any psychological therapy, distressing emotions or thoughts may occur. These can manifest as somatic symptoms, such as dizziness, headache, or nausea. Occasionally, uncovering repressed psychic content can evoke strong emotional response, known as abreaction. A minority of hypnosis practitioners believe abreaction is therapeutic. Also, as with other mind-body medicine modalities that include deliberate relaxation, paradoxical anxiety reactions can rarely occur.

► Contraindications

There is no consensus on contraindications to hypnosis; however, the use of hypnosis in patients with severe psychiatric disease is controversial. Also, patients who have very low scores on hypnotic susceptibility scales are less likely to derive therapeutic benefit.

► Clinical Uses of Hypnosis

A. Pain

There are at least 40 controlled studies of variable methodologic quality on the use of hypnosis for treating acute pain in adult and pediatric populations. All but 3 studies show superiority of hypnosis over a control condition (usual care, no treatment, or attentional control). Hypnosis has been shown effective for peri-procedural and perioperative pain in patients undergoing breast lumpectomy, excisional and core breast biopsy, bone marrow aspiration, pectus excavatum repair (Nuss procedure), percutaneous transluminal coronary angioplasty and other percutaneous vascular and renal procedures, burn wound care, and plastic surgery. Many studies also report less procedure-related anxiety and lower analgesic medication requirement.

For chronic pain, individual studies have shown efficacy for headache, orofacial pain, dyspepsia, vulvodynia, pain from sickle cell disease, fibromyalgia, and low back pain.

B. Cancer-related Symptoms

There are at least four randomized controlled trials specifically evaluating the efficacy of hypnosis for cancer-related pain and anxiety in adults. All four trials show benefit compared with no treatment or usual care. In addition, two of three randomized controlled trials show significant benefit of hypnosis for reducing anticipatory nausea and vomiting from chemotherapy. Other recent randomized controlled trials concluded (1) hypnosis decreased hot flash scores by 68% in breast cancer survivors; (2) self-hypnosis plus empathic attention was superior to empathic attention alone (for reducing pain, anxiety and medication usage) in 201 patients undergoing percutaneous tumor treatment; and (3) hypnosis preoperatively reduced institutional costs for breast cancer patients.

C. Irritable Bowel Syndrome

There are 14 studies of hypnosis for irritable bowel syndrome, 6 of which are controlled (placebo pill, CBT, or wait-list control). All 6 controlled studies show reduction in pain and bowel symptoms and some show improved quality of life and reduced anxiety. There are also 3 follow-up studies showing maintenance of benefits for 1 to 5 years in duration. The American College of Gastroenterology recommends behavioral therapies including hypnosis for the treatment of irritable bowel syndrome.

D. Smoking Cessation

A Cochrane review of 9 trials, distilled from a literature of over 50 studies, concluded that hypnosis is ineffective for smoking cessation. However, a more recent randomized controlled trial comparing hypnosis plus nicotine patch with behavioral counseling plus nicotine patch showed superiority of hypnosis, especially in those with a history of depression.

MINDFULNESS MEDITATION

► Definition

Meditation is broadly defined as the self-regulation of attention. There are two general types of meditation: mindfulness meditation and concentration meditation. In health care settings, the most widely available form of meditation is the mindfulness-based stress reduction (MBSR) program. This program was specifically designed for medical populations.

The essential exercise of meditation is focusing one's full attention on a designated object of meditation, such as one's breath. When it is noticed that the mind has wandered from this object, attention is returned to the object. Training the mind, beginning with this basic exercise, has many effects including relaxation, metacognition, and revelation of previously subconscious content. In mindfulness meditation, after initial training with the breath, the objects of meditation can include other aspects of human experience, such as physical sensations (eg, pain) or mental and emotional states (eg, anxiety).

► History

Mindfulness meditation originated 2500 years ago in northern India from the tradition of Buddhism. It is a deliberate, sustained, nonjudgmental way of paying attention to one's experience that is said to enhance self-awareness, change maladaptive thinking, increase the capacity for skillful response to challenges, and reduce suffering. In 1979, mindfulness meditation practice was first introduced into American medical settings with the development of the MBSR program by Dr. Jon Kabat-Zinn. MBSR is an intensive 8-week program that introduces mindfulness practice in a secular, practical form to participants in the context of their life circumstances. There are now over 250 MBSR programs throughout the United States and many in other countries throughout the world. More recently, a close derivative of MBSR, mindfulness-based cognitive therapy (MBCT), has been developed exclusively for people with recurrent major depression. Mindfulness has also been adapted for use in programs for borderline personality disorder (Dialectical Behavior Therapy), eating disorders, substance abuse, and childbirth preparation.

► Mechanism of Action

There have been extensive cardiac, respiratory, metabolic, endocrine, and functional central nervous system studies of individuals during meditation. Though much remains unknown, it is clear that meditation works in part through

modulation of the autonomic nervous system, and that its effects are different from and more complex than simple relaxation. From a psychological perspective, it is thought that meditation enables the mind to establish a stable platform from which all events in the field of awareness can be viewed (eg, emotions, thoughts, physical sensations) without reactivity. At the psychological level, proposed mechanisms of mindfulness meditation include metacognition, exposure, uncoupling of maladaptive thoughts from physical stimuli (eg, pain), enhancing cognitive flexibility, relaxation, self-regulation, and re-perceiving. At the physiologic level, studies of mindfulness meditation have found effects on the immune system (increased antibody response to vaccination, reduction in proinflammatory cytokines, possible slowed decline of CD4+ lymphocytes in HIV disease), nervous system (enhanced cortical thickness in specific brain regions, enhanced left prefrontal activation on EEG, characteristic functional MRI findings), and endocrine system (reduced cortisol, increased melatonin levels). There is evidence of a dose-response relationship with mindfulness meditation.

► Training & Certification

Certification is not required to teach MBSR, but in 2005 the Center for Mindfulness at the University of Massachusetts Medical School, where MBSR began, established a professional certification program. Ideally, an MBSR teacher should have a long-standing daily mindfulness meditation practice, a history of silent meditation retreats, experience leading groups, and a health professional degree.

► Clinical Practice

The best candidate for an MBSR program is someone who is motivated and has a medical, surgical, or psychiatric condition with a significant component of psychological distress. Motivation is essential for two reasons. First, participation in an MBSR program requires as much as 28 hours of classroom time over 8 weeks (including an all-day silent retreat) and 30–45 minutes of formal guided mindfulness practice each day. Second, an important part of mindfulness practice is to directly explore any unpleasant physical or mental experiences as they arise. Often, MBSR programs offer free informational sessions that precede the 8-week series so patients can evaluate the program before they decide to enroll.

► Adverse Events

There are no adverse effects of mindfulness meditation specifically reported in experimental trials, but meditation can allow previously subconscious, distressing psychic content to come into consciousness. Patients with psychiatric disorders should consult with a mental health care professional before starting a program of meditation.

► Contraindications

Untreated psychosis, mania and intoxication from active substance abuse are relative contraindications because these conditions may impair the fundamental exercise required

for mindfulness training (ie, repeatedly returning one's attention to a desired object of awareness).

► Clinical Uses of Mindfulness Meditation

There are over 60 experimental trials assessing mindfulness-based interventions, approximately half of which are controlled trials. Most of the research examines the efficacy of MBSR programs, but there are also studies of MBCT, shorter mindfulness interventions and vipassana residential retreats. Two meta-analyses of MBSR show average effect sizes of 0.5–0.6.

A. Cancer-related Symptoms

There are 15 studies of mindfulness meditation in patients with cancer, including 4 randomized controlled trials. All 11 studies that measured psychological variables showed significant improvement (mood disturbance, anxiety, symptoms of stress, quality of life). Two studies assessed sleep problems and both found improvement. In a nonrandomized comparison of MBSR and a healing-through-creative-arts program, the mindfulness intervention was superior in reducing symptoms of stress, anxiety, mood disturbance, and increasing sense of spirituality. The two groups were equal in increasing a measure of posttraumatic growth. Two other cancer studies showed that psychological benefits from MBSR were sustained at 6-month and 12-month follow-up, respectively. Interestingly, the first inpatient study of a mindfulness intervention, an uncontrolled pilot study of 20 adults undergoing hematopoietic stem cell transplantation, showed reduced pain, anxiety, and physiological arousal from pre- to post-intervention.

B. Depression

Four studies, two of which are randomized controlled trials, specifically examined the effect of MBCT on patients with major depression and demonstrated relapse reduction of almost 50% in patients who have a history of more than two relapses. One uncontrolled study of MBCT showed that the measured level of mindfulness attained after the intervention successfully predicted depression relapse. An additional randomized controlled trial of MBCT showed improvement in depression and anxiety for bipolar patients with suicidal ideation or behavior. A pilot study using MBCT for 51 patients with treatment-resistant depression (defined as two or more adequate trials of antidepressants) found significantly decreased depression and anxiety levels. A randomized controlled trial of MBSR for women with fibromyalgia showed improvement in depression maintained at 2-month follow-up. Multiple other MBSR studies show improvement in mood in various populations; however, two studies found mindfulness interventions to be equal to comparison groups (CBT and relaxation therapy) and a 2007 review of 15 of these studies concludes overall evidence of benefit is equivocal.

C. Anxiety Disorders

Two early uncontrolled studies specifically examined the effect of MBSR on patients with anxiety disorders and

found significant benefits that were maintained at 3 year follow-up. Two uncontrolled studies examined MBCT for generalized anxiety disorder and found pre-to-post changes in anxiety but in one study the effect size was less than that commonly found in CBT studies. A randomized controlled trial of MBSR versus cognitive behavioral group therapy for social anxiety disorder showed cognitive behavioral group therapy was more effective at reducing symptoms of social anxiety; however, the CBT intervention was 50% longer in duration and results for functionality, quality of life, and mood were equal in the two groups. A randomized controlled trial of 31 pregnant women showed reduction of anxiety, perceived stress, and an improvement in mood. A small controlled study showed a significant reduction of symptoms in patients with obsessive-compulsive disorder. An uncontrolled study of adults and adolescents with attention deficit hyperactivity disorder showed significant benefit with MBSR; however, an intensive 10-day mindfulness (vipassana) retreat did not improve symptoms of posttraumatic stress disorder in an incarcerated population.

D. Fibromyalgia

There are four studies of mindfulness interventions for fibromyalgia, including two randomized controlled trials. All four studies show improvement in psychological measures; three showed improvement in pain, although one of the randomized controlled trials did not find MBSR to be superior to an education and support comparison group. One study showed maintenance of most benefits (pain, quality of life, anxiety, depression) at 3-year follow-up.

E. Other Chronic Pain

Seven studies, including almost 700 patients, have been conducted using MBSR in chronic pain populations. All studies showed significant improvement in mental health parameters, such as quality of life, acceptance, pain tolerance, and mood. Six of these studies (three controlled, three uncontrolled) showed pain reduction. One follow-up study showed that improvements were maintained up to 4 years later. A randomized controlled trial of MBSR for patients with rheumatoid arthritis showed improvement in psychological distress and well-being at 6-month follow-up, but no improvement in disease activity. A second randomized controlled study of patients with rheumatoid arthritis compared a mindfulness-based intervention (that was much less intensive than standard MBSR) with a CBT intervention and an education control group. Both experimental groups were significantly superior to the control group, although overall the CBT group showed the greatest reduction in pain and IL-6 levels. In the subset of patients with a history of recurrent depression, however, the mindfulness-based intervention yielded greatest reduction in pain and improvement in mood. Interestingly, a comparison of distant (via videoconferencing) versus on-site mindfulness-based programs for chronic pain showed significant gains for both groups, but the on-site group rated superior in physical quality of life and pain reduction.

F. Other Conditions

Other studies have been conducted on organ transplant recipients, patients suffering from psoriasis, tinnitus, type 2 diabetes, eating disorders, women with sexual arousal disorder, inner city residents, nursing home residents, incarcerated individuals, smokers, nurses and nursing students, college students, and medical students. Nearly all of these studies showed mental health benefit from mindfulness meditation and most showed index symptom reduction. Interestingly, a randomized controlled trial of psychotherapists in training showed improvement in the patients of those therapists who were taught mindfulness.

GUIDED IMAGERY

► Definition

Guided imagery uses the imaginative capacity of the mind to affect one's physical, emotional, or spiritual state. As is the case with psychotherapeutic techniques, guided imagery can be applied in a variety of ways. It may be directive, with the therapist providing specific images, or it may be more receptive, inviting the patient to find their own images. It may be supportive, with the intention to create a relaxed, pleasant or specifically positive feeling (eg, trust or patience) or it may intend to directly work with an area of active challenge (eg, anxiety or pain). Classically, in guided imagery, the therapist is less directive and the patient has a more active role than in hypnosis; however, this distinction is not always true in clinical practice and guided imagery can closely resemble hypnosis, especially when suggestion is used. Guided imagery can be conducted live with a therapist one-on-one, in a group setting (less common), or via audio recording.

► History

Imagery has been used throughout history and can be found in the origins of all ancient healing systems still extant today. In contemporary Western medicine, the psychiatrist Dr. Carl Jung recognized the importance of imagery as an expression of the subconscious and in 1915 developed a psychotherapeutic technique called “active imagination.” With the similar intention to aid psychoanalytic exploration, the French psychotherapist Dr. Robert Desoille in the late 1930s created a method he called “directed daydreaming,”

and in the 1950s Dr. Hanscarl Leuner introduced “guided affective imagery.” Medical research on guided imagery began in the 1970s and increased greatly in the 1980s. In 1989, the physician Dr. Martin Rossman and the psychologist Dr. David Bresler founded the Academy for Guided Imagery which began certifying health professionals. In recent years, some health insurance companies and surgical programs have been providing free guided imagery recordings for patients undergoing surgery.

► Mechanism of Action

The mechanism of action of guided imagery is not well known, but some physiologic effects have been demonstrated. Three of five studies examining cortisol levels in relation to guided imagery have found that serum levels decreased after the intervention. Studies of the effect of guided imagery on immune function have shown mixed results. However, a recent randomized controlled trial of women with breast cancer showed increased NK cell cytotoxicity and increased IL-2-activated NK cell activity. One study documented reduced physiologic arousal around chemotherapy sessions, as measured by heart rate and systolic blood pressure. Some proposed psychological mechanisms postulated to explain the effects of guided imagery include cognitive restructuring, increased sense of control, increased adaptive coping, distraction, and relaxation.

► Training & Certification

The leading certifying organization, the Academy for Guided Imagery, generally limits certification to licensed health care professionals or health professional students, but exceptions are allowed. To obtain the certification known as “interactive guided imagery,” 150 total hours of training is required, including 52 hours of small group supervision. Applicants are also required to adhere to the American Psychological Association code of ethics. Another certifying organization is Beyond Ordinary Nursing, which requires 110 total hours of training, including ten documented imagery sessions.

► Clinical Practice

The length of a typical guided imagery session with a therapist is 50 minutes, with 20–30 minutes spent in active imagery. The imagery portion of the appointment often begins with imagining a place of comfort and safety, then proceeding to the desired area of specific clinical attention. Polysensory recruitment is often used (ie, the patient is asked to imagine visual, auditory, tactile, olfactory cues in imagining the safe place and then in focusing attention). Examples of specific clinical techniques used by the therapist might include dialoging with the symptom (“If your back pain had a voice, what would it say?”), consulting a wisdom figure or inner advisor (“What does your wisdom figure say about how to approach this cancer treatment?”), and visualizing a desired outcome (“Imagine yourself waking up after surgery feeling calm and comfortable.”). Interactive Guided Imagery is a type of imagery that more deliberately aims to enhance awareness of subconscious content.

Predictors of favorable outcome from guided imagery, based on three studies, are previous experience with guided imagery, imaging ability of the patient, perceived credibility of the therapist, and rapport of the patient with the therapist. Age, gender, and education level have not shown significant correlation with outcomes, suggesting that this technique can be applied widely.

▶ Adverse Events

Adverse events have not been reported with guided imagery. However, as is the case with any psychotherapeutic technique, distressing psychological content can arise.

▶ Contraindications

There are no contraindications based on outcomes studies. However, due to the potential risk of reexperiencing original trauma, caution is advised in using guided imagery in patients with posttraumatic stress disorder or history of severe trauma or abuse.

▶ Clinical Uses of Guided Imagery

A. Surgery

There are many studies examining the use of guided imagery on outcomes related to such surgeries and procedures as heart surgery, colorectal surgery, abdominal surgery, laparoscopic gynecologic surgery in adults, bone marrow aspiration, lumbar puncture, burn wound debridement, and administration of immunizations in children. Although many of the studies have methodologic limitations, reviews and meta-analyses have found overall benefit of small to moderate effect sizes for reducing psychological distress and reducing postoperative pain. However, a randomized controlled trial of guided imagery for peri-procedural pain and anxiety conducted with 170 women undergoing colposcopy did not show a significant effect. Two of the three randomized controlled trials assessing its effect on average length of hospital stay found a significant decrease with guided imagery intervention. Other studies have shown significant decreases in total opioid use and average pharmacy costs.

B. Cancer-related Symptoms

Most of the studies in patients with cancer use guided imagery in combination with another modality, such as progressive muscle relaxation, meditation, hypnosis, biofeedback, or music therapy. These studies vary in methodologic quality. There are at least 18 randomized controlled

trials in this category and all show benefit for psychological outcomes, such as quality of life, anxiety, and depression. Studies that assessed the effect of guided imagery in combination with other modalities on nausea and vomiting also showed uniform benefit for this symptom. With respect to nonprocedural, cancer-related pain, there are at least 6 randomized controlled trials using guided imagery as part of a combination intervention. Three studies showed significant pain reduction with guided imagery intervention, 2 showed no pain reduction, and 1 showed significant benefit in patients' self-reported ability to decrease pain but not in measured pain intensity.

There are also several randomized controlled trials of guided imagery as a sole adjunctive treatment for patients with cancer. All of these studies again showed that guided imagery led to improvement in psychological outcomes, and in approximately half of the studies, the improvement was superior to other comparison interventions, such as progressive muscle relaxation or hypnosis. The evidence for guided imagery alone in preventing chemotherapy-related nausea and vomiting is mixed.

A single study has examined the effect of guided imagery directly on cancer disease regression using clinical (UICC criteria) and pathologic (biopsy) measures and found no effect.

C. Chronic Pain

There are several studies of guided imagery for various chronic pain conditions, such as osteoarthritis, headache, low back pain, fibromyalgia, and interstitial cystitis. Some of the studies are controlled and all show benefit in either pain, psychological distress, or both.

D. Stroke Rehabilitation

Four randomized controlled trials report efficacy of motor imagery for rehabilitation post-stroke.

Appendix: Therapeutic Drug Monitoring & Laboratory Reference Intervals

C. Diana Nicoll, MD, PhD, MPA
Chuanyi Mark Lu, MD

Table 1. Therapeutic drug monitoring.¹

| Drug | Effective Concentrations | Half-Life (hours) | Dosage Adjustments | Comments |
|---------------|-------------------------------------|------------------------|---|---|
| Amikacin | Peak: 20-30 mg/L; trough: < 10 mg/L | 2-3; ↑ in uremia | ↓ in renal dysfunction | Concomitant kanamycin or tobramycin therapy may give falsely elevated amikacin results by immunoassay. |
| Amitriptyline | 95-250 ng/mL | 9-46 | | Drug is highly protein-bound. Patient-specific decrease in protein binding may invalidate quoted therapeutic reference interval for effective concentration. |
| Carbamazepine | 4-12 mg/L | 10-15 | | Induces its own metabolism. Metabolite 10,11-epoxide exhibits 13% cross-reactivity by immunoassay. Toxicity: diplopia, drowsiness, nausea, vomiting, and ataxia. |
| Cyclosporine | 100-300 mcg/L (ng/mL) whole blood | 6-12 | Need to know specimen and methodology used | Cyclosporine is lipid-soluble (20% bound to leukocytes; 40% to erythrocytes; 40% in plasma, highly bound to lipoproteins); the binding is temperature-dependent in vitro and concentration-dependent in vivo. Obtain whole blood sample in a lavender (EDTA) tube for monitoring. HPLC and LC-tandem mass spectrometry methods are highly specific for parent drug and considered as the gold standard assays. Monoclonal fluorescence polarization immunoassay (FPIA) also measures cyclosporine reliably; polyclonal FPIAs are less specific due to cross-reaction with drug metabolites. Anticonvulsants and rifampin increase metabolism. Erythromycin, ketoconazole, and calcium channel blockers decrease metabolism. The main adverse reaction is dose-related nephrotoxicity. |
| Desipramine | 100-250 ng/mL | 13-23 | | Drug is highly protein-bound. Patient-specific decrease in protein binding may invalidate quoted therapeutic reference interval for effective concentration. |
| Digoxin | 0.8-2 ng/mL | 42; ↑ in uremia, CHF | ↓ in renal dysfunction, CHF, hypothyroidism ↑ in hyperthyroidism | Bioavailability of digoxin tablets is 50-90%. Specimen must not be drawn within 6 hours of dose. Dialysis does not remove a significant amount. Hypokalemia potentiates toxicity. Digitalis toxicity is a clinical and <i>not</i> a laboratory diagnosis. Digibind (digoxin-specific antibody) therapy of digoxin overdose can interfere with measurement of digoxin levels depending on the digoxin assay. Elimination reduced by quinidine, verapamil, and amiodarone. |
| Ethosuximide | 40-100 mg/L | Child: 30 Adult: 50 | | Levels used primarily to assess compliance. Toxicity is rare and does not correlate well with plasma concentrations. |

(continued)

Table 1. Therapeutic drug monitoring.¹ (continued)

| Drug | Effective Concentrations | Half-Life (hours) | Dosage Adjustments | Comments |
|---------------|--|---------------------------------------|---|--|
| Gentamicin | Peak: 4-8 mg/L; trough: < 2 mg/L | 2-5; ↑ in uremia (7.3 on dialysis) | ↓ in renal dysfunction | Draw peak specimen 30 minutes after end of infusion. Draw trough just before next dose. In uremic patients, carbenicillin may decrease gentamicin half-life from 46 hours to 22 hours. |
| Imipramine | 180-350 ng/mL | 10-16 | | Drug is highly protein-bound. Patient-specific decrease in protein binding may invalidate quoted therapeutic reference interval for effective concentration. |
| Lidocaine | 1-5 mg/L | 1.8; ↔ in uremia, CHF; ↑ in cirrhosis | ↓ in CHF, liver disease | Levels increased with cimetidine therapy. CNS toxicity common in the elderly. |
| Lithium | 0.7-1.5 mmol/L | 22; ↑ in uremia | ↓ in renal dysfunction | Thiazides and loop diuretics may increase serum lithium levels. |
| Methotrexate | | 8.4; ↑ in uremia | ↓ in renal dysfunction | Therapeutic concentrations depend on the treatment protocol (low versus high dose) and time of specimen collection. 7-Hydroxymethotrexate cross-reacts 1.5% in immunoassay. To minimize toxicity, leucovorin should be continued if methotrexate level is > 0.1 mcmol/L at 48 hours after start of therapy. Methotrexate > 1 mcmol/L at > 48 hours requires an increase in leucovorin rescue therapy. |
| Nortriptyline | 50-140 ng/mL | 18-44 | | Drug is highly protein-bound. Patient-specific decrease in protein binding may invalidate quoted therapeutic reference interval for effective concentration. |
| Phenobarbital | 10-40 mg/L | 86; ↑ in cirrhosis | ↓ in liver disease | Metabolized primarily by the hepatic microsomal enzyme system. Many drug-drug interactions. |
| Phenytoin | 10-20 mg/L; 5-10 mg/L in uremia, hypoalbuminemia | Dose/concentration-dependent | | Drug metabolite cross-reacts in immunoassays; the cross-reactivity may be of significance only in the presence of advanced chronic kidney disease. Metabolism is capacity-limited. Increase dose cautiously when level approaches therapeutic reference interval, since new steady-state level may be disproportionately higher. Drug is very highly protein-bound; protein binding is decreased in uremia and hypoalbuminemia. Free drug level may be indicated in certain circumstances. |
| Primidone | 5-10 mg/L | 8 | | Phenobarbital cross-reacts 0.5%. Metabolized to phenobarbital. Primidone/phenobarbital ratio > 1:2 suggests poor compliance. |
| Procainamide | 4-8 mg/L | 3; ↑ in uremia | ↓ in renal dysfunction | 30% of patients with plasma levels of 12-16 mcg/mL have ECG changes; 40% of patients with plasma levels of > 16 mcg/mL have severe toxicity. Metabolite <i>N</i> -acetylprocainamide is active. |
| Quinidine | 1-4 mg/L | 7; × in CHF; ↑ in liver disease | ↓ in liver disease, CHF | Effective concentration is lower in chronic liver disease and nephrosis, where binding is decreased. |
| Salicylate | 150-300 mg/L | Dose-dependent | | |
| Sirolimus | Trough: 4-12 ng/mL when used in combination with cyclosporine A; 12-20 ng/mL if used alone | 62 | ↓ in liver dysfunction and with drugs affecting CYP3A4 activity | Sirolimus is an immunosuppressant used in combination with cyclosporine and corticosteroids for prophylaxis of organ rejection after kidney transplantation. It has also been used in liver and heart transplantation. When used in combination with cyclosporine, careful monitoring of kidney function is required. Once the initial dose titration is complete, monitoring sirolimus trough concentrations weekly for the first month and every 2 weeks for the second month appears to be appropriate. |

(continued)

Table 1. Therapeutic drug monitoring.¹ (continued)

| Drug | Effective Concentrations | Half-Life (hours) | Dosage Adjustments | Comments |
|---------------|--------------------------------------|-------------------|---|---|
| Tacrolimus | Trough: 5-20 ng/mL | 8.7-11.3 | ↓ in liver dysfunction and with drugs affecting CYP3A4 activity | Tacrolimus is used for prophylaxis of organ rejection in adult patients undergoing liver or kidney transplantation and in pediatric patients undergoing liver transplantation. It has also been used to prevent rejection in heart, small bowel, and allogeneic bone marrow transplant patients and to treat autoimmune diseases. Antacid or sucralfate administration should be separated from tacrolimus by at least 2 hr. |
| Theophylline | 5-20 mg/L | 9 | ↓ in CHF, cirrhosis, and with cimetidine | Caffeine cross-reacts 10%. Elimination is increased 1.5-2 times in smokers. 1,3-Dimethyl uric acid metabolite increased in uremia and, because of cross-reactivity, may cause an apparent slight increase in serum theophylline. |
| Tobramycin | Peak: 5-10 mg/L; trough: < 2 mg/L | 2-3; ↑ in uremia | ↓ in renal dysfunction | Tobramycin, kanamycin, and amikacin may cross-react in immunoassay. |
| Valproic acid | 55-100 mg/L | 13-19 | | 95% protein-bound. Decreased binding in uremia and cirrhosis. |
| Vancomycin | Trough: 5-15 mg/L | 6; ↑ in uremia | ↓ in renal dysfunction | Toxicity in uremic patients leads to irreversible deafness. Keep peak level < 30-40 mg/L to avoid toxicity. |

¹Use red-topped tube (not marbled) for therapeutic drug monitoring. In general, the specimen should be drawn just before the next dose (trough).

x, unchanged; ↑, increase(d); ↓, decrease(d); HPLC, high performance liquid chromatography; CHF, congestive heart failure; CNS, central nervous system; ECG, electrocardiogram.

| D-dimer, quantitative | Plasma | < 500 ng/mL | 1.00 | < 500 mcg/L | Blue |
| Eosinophil count | Whole blood | 0.04-0.5 × 10 ³ /mCL | 1.00 | 0.04-0.5 × 10 ⁹ /L | Lavender |
| Erythrocyte count (RBC count) | Whole blood | 4.7-6.1 × 10 ⁶ /mCL | 1.00 | 4.7-6.1 × 10 ¹² /L | Lavender |
| Erythrocyte sedimentation rate | Whole blood | Male: < 10 mm/h Female: < 15 mm/h (laboratory-specific) | | Same | Lavender (test must be run within 2 h) |
| Erythropoietin (EPO) | Serum | 5-30 mU/mL | 1.00 | 5-30 units/L | SST |
| Estradiol | Serum | Early follicular: 30-100 pg/mL Late follicular: 100-400 pg/mL Luteal: 50-150 pg/mL Postmenopausal: 2-21 pg/mL | 3.67 | 110-367 pmol/L 367-1468 pmol/L 183-550 pmol/L 7-77 pmol/L | SST |
| Ethanol | Serum | 0 mg/dL Legal "driving under the influence" in many states is defined as > 80 mg/dL (> 17 mmol/L) blood alcohol level; serum alcohol levels are 10-35% higher than whole blood alcohol levels | 0.217 | 0 mmol/L | SST |
| Factor VIII assay | Plasma | 50-150% of normal (varies with age) | | | Blue (iced) |
| Fecal fat | Stool | Random: < 60 droplets of fat per high-power field 72-hour: < 7 g/24 h | | | Qualitative: Random stool sample Quantitative: 72-hour collection following 2-day dietary fat regimen |
| Ferritin | Serum | Male: 16-300 ng/mL Female: 4-161 ng/mL | 1.00 | Male: 16-300 mcg/L Female: 4-161 mcg/L | SST |
| α-Fetoprotein (AFP) | Serum | 0-15 ng/mL | 1.00 | 0-15 mcg/L | SST |
| Fibrinogen (functional) | Plasma | 175-433 mg/dL Panic: < 75 mg/dL | 0.01 | 1.75-4.3 g/L | Blue |

(continued)

Table 2. Reference intervals for commonly used tests.^{1,2} (continued)

| Current metric units × Conversion factor = SI units SI units ÷ Conversion factor = Current metric units | | | | | |
|--|---------------------------|---|-------------------|---|-------------------------------|
| Test | Specimen | Conventional Units | Conversion Factor | SI Units ² | Collection |
| Folic acid (red cells) | Whole blood | 165–760 ng/mL | 2.27 | 370–1720 nmol/L | Lavender |
| Follicle-stimulating hormone (FSH) | Serum | Female: Follicular phase 4–13 mU/mL Luteal phase 2–13 mU/mL Midcycle 5–22 mU/mL Postmenopausal 30–138 mU/mL Male: 1–10 mU/mL (laboratory-specific) | 1.00 | Female: 4–13 units/L 2–13 units/L 5–22 units/L 30–138 units/L Male: 1–10 units/L (laboratory-specific) | SST |
| Free erythrocyte protoporphyrin (FEP) | Whole blood | < 35 mcg/dL (method-dependent) | | | Lavender |
| Fructosamine | Serum | 190–270 mcmol/L | 1.0 | 190–270 mcmol/L | SST |
| γ-Glutamyl transpeptidase (GGT) | Serum | 9–85 units/L (laboratory-specific) | 0.02 | 0.15–1.42 mckat/L (laboratory-specific) | SST |
| Gastrin | Serum | < 100 pg/mL (laboratory-specific) | 1.00 | < 100 ng/L | SST |
| Glomerular filtration rate, estimated (eGFR) | Serum | > 60 mL/min/1.73 m ² (calculated based on serum creatinine) | | | SST |
| Glucose | Serum | 60–110 mg/dL Panic: < 40 or > 500 mg/dL | 0.055 | 3.3–6.1 mmol/L | (Fasting) SST |
| Glucose-6-phosphate dehydrogenase (G6PD) screen | Whole blood | 5–14 units/g Hb | 0.02 | 0.1–0.28 mckat/L | Lavender |
| Glutamine | Cerebrospinal fluid (CSF) | 6–15 mg/dL Panic: > 40 mg/dL | 68.5 | 411–1028 mcmol/L | Collect CSF in a plastic tube |
| Glycated (glycosylated) hemoglobin (HbA _{1c}) | Serum | 3.9–6.9% (method-dependent) | | | Lavender |
| Growth hormone (GH) | Serum | 0–5 ng/mL | 1.00 | 0–5 mcg/L | SST |
| Haptoglobin | Serum | 46–316 mg/dL | 0.01 | 0.5–3.2 g/L | SST |
| HDL cholesterol | Serum | Male: 27–67 mg/dL Female: 34–88 mg/dL (HDL cholesterol > 60 mg/dL is thought to lower risk of coronary heart disease) | 0.026 | 0.7–1.73 mmol/L 0.88–2.28 mmol/L | SST |
| <i>Helicobacter pylori</i> antibody | Serum | Negative | | | SST |
| Hematocrit (Hct) | Whole blood | Male: 39–49% Female: 35–45% (age-dependent) | 0.01 | Male: 0.39–0.49 Female: 0.35–0.45 | Lavender |
| Hemoglobin A _{1c} (See Glycated Hemoglobin) | Serum | | | | |
| Hemoglobin A ₂ (HbA ₂) | Whole blood | 1.5–3.5% of total hemoglobin | 0.01 | 0.015–0.035 | Lavender |
| Hemoglobin electrophoresis | Whole blood | HbA: > 95% HbA ₂ : 1.5–3.5% HbF: < 2% (age dependent) | | | Lavender |

(continued)

Table 2. Reference intervals for commonly used tests.^{1,2} (continued)

| Current metric units × Conversion factor = SI units SI units ÷ Conversion factor = Current metric units | | | | | |
|--|---------------|--|-------------------|--|--|
| Test | Specimen | Conventional Units | Conversion Factor | SI Units ² | Collection |
| Hemoglobin, total (Hb) | Whole blood | Male: 13.6–17.5 g/dL Female: 12.0–15.5 g/dL (age dependent) Panic: ≤ 7 g/dL | 10.00 | Male: 136–175 g/L Female: 120–155 g/L | Lavender |
| Heparin-associated antibody (heparin-induced thrombocytopenia) | Serum | Negative | | | SST |
| HIV antibody | Serum | EIA: Negative Western blot: Nonreactive | | | SST |
| HIV RNA, quantitative (viral load) | Plasma | Negative (or < 75 copies/mL, assay-specific) | | | Lavender |
| Homocysteine | Plasma | 4–12 μmol/L (method- and age-dependent) | 1.00 | 4–12 μmol/L | Lavender |
| 5-Hydroxyindoleacetic acid (5-HIAA) | Urine | 2–8 mg/24 h | 5.23 | 10–40 μmol/d | Urine bottle containing hydrochloric acid |
| IgG index | Serum and CSF | 0.29–0.59 ratio (CSF serum ratio) | | | SST (for serum) and plastic tube (for CSF) |
| Immunoglobulins (Ig) | Serum | IgA: 78–367 mg/dL IgG: 583–1761 mg/dL IgM: 52–335 mg/dL | 0.01 | IgA: 0.78–3.67 g/L IgG: 5.83–17.6 g/L IgM: 0.52–3.35 g/L | SST |
| Insulin, immunoreactive | Serum | 6–35 mU/mL | 7.18 | 42–243 pmol/L | SST |
| Insulin-like growth factor-1 | Plasma | 123–463 ng/mL (age- and sex-dependent) | 1.0 | 123–463 mcg/L | SST |
| Iron (Fe) | Serum | 50–175 mcg/dL | 0.18 | 9–31 μmol/L | SST |
| Iron-binding capacity, total (TIBC) | Serum | 250–460 mcg/dL | 0.18 | 45–82 μmol/L | SST |
| Kappa and lambda free light chains, quantitative | Serum | Free kappa: 0.57–2.63 mg/dL Free lambda: 0.33–1.94 mg/dL Free kappa/lambda ratio: 0.26–1.65 | 0.01 | 5.7–26.3 × 10 ⁻³ g/L 3.3–19.4 × 10 ⁻³ g/L | SST |
| Lactate dehydrogenase (LDH) | Serum | 88–230 units/L (laboratory-specific) | 0.02 | 1.46–3.82 mkat/L (laboratory-specific) | SST |
| Lactic acid (lactate) | Venous blood | 0.5–2.0 mEq/L | 1.00 | 0.5–2.0 mmol/L | Gray (iced) |
| LDL cholesterol (calculated or direct) | Serum | Desirable: < 130 mg/dL (< 99 mg/dL for patients with CHD); Borderline: 130–159 mg/dL; High risk: ≥ 160 mg/dL | 0.026 | < 3.37 mmol/L (< 2.57 mmol/L); 3.38–4.13 mmol/L; > 4.16 mmol/L | SST |
| Lead (Pb) | Whole blood | Child: < 25 mcg/dL Adult: < 40 mcg/dL | 0.05 | Child: < 1.21 μmol/L Adult: < 1.93 μmol/L | Navy blue (trace metal free) |
| Leukocyte (white blood cell) count, total (WBC count) | Whole blood | 4.8–10.8 × 10 ³ /mCL Panic: < 1.5 × 10 ³ /mCL | 1.00 | 4.8–10.8 × 10 ⁹ /L | Lavender |
| Lipase | Serum | 0–160 units/L (laboratory-specific) | 0.02 | 0–2.66 mkat/L (laboratory-specific) | SST |

(continued)

Table 2. Reference intervals for commonly used tests.^{1,2} (continued)

| Current metric units × Conversion factor = SI units SI units ÷ Conversion factor = Current metric units | | | | | |
|--|-------------|--|-------------------|--|---|
| Test | Specimen | Conventional Units | Conversion Factor | SI Units ² | Collection |
| Luteinizing hormone (LH) | Serum | Female: Follicular phase 1-18 mU/mL Luteal phase 0.4-20 mU/mL Midcycle 24-105 mU/mL Postmenopausal 15-62 mU/mL Male: 1-10 mU/mL (laboratory-specific) | 1.00 | Female: 1-18 units/L 0.4-20 units/L 24-105 units/L 15-62 units/L Male: 1-10 units/L (laboratory-specific) | SST |
| Lymphocyte count | Whole blood | $0.8-3.5 \times 10^3/\text{mCL}$ | 1.00 | $0.8-3.5 \times 10^9/\text{L}$ | Lavender |
| Magnesium (Mg ²⁺) | Serum | 1.8-3.0 mg/dL Panic: < 0.5 or > 4.5 mg/dL | 0.41 | 0.75-1.25 mmol/L | SST |
| Mean corpuscular hemoglobin (MCH) | Whole blood | 26-34 pg | | | Lavender |
| Mean corpuscular hemoglobin concentration (MCHC) | Whole blood | 31-36 g/dL | 10.00 | 310-360 g/L | Lavender |
| Mean corpuscular volume (MCV) | Whole blood | 80-100 fL | | | Lavender |
| Metanephrines, free | Plasma | Normetanephrine: < 0.9 nmol/L Metanephrine: < 0.5 nmol/L | | | Lavender |
| Metanephrines | Urine | 0.3-0.9 mg/24 h | 5.46 | 1.6-4.9 mcmol/24 h | Urine bottle containing hydrochloric acid |
| Methemoglobin (MetHb) | Whole blood | < 1% of total hemoglobin | 0.01 | < 0.01 fraction of total hemoglobin | Blood gas syringe, lavender, or green |
| Methylmalonic acid | Serum | 0-0.05 mg/L | 8.475 | 0-0.4 mcmol/L | SST |
| Monocyte count | Whole blood | $0.2-0.8 \times 10^3/\text{mCL}$ | 1.00 | $0.2-0.8 \times 10^9/\text{L}$ | Lavender |
| Neutrophil count | Whole blood | $2.2-8.6 \times 10^3/\text{mCL}$ | 1.00 | $2.2-8.6 \times 10^9/\text{L}$ | Lavender |
| Osmolality | Serum | 275-293 mosm/kg H ₂ O Panic: < 240 or > 320 mosm/kg H ₂ O | 1.00 | 275-293 mmol/kg H ₂ O | SST |
| | Urine | Random: 100-900 mosm/kg H ₂ O | 1.00 | Random: 100-900 mmol/kg H ₂ O | Urine container |
| Oxygen, partial pressure (Po ₂) | Whole blood | 83-108 mm Hg | 0.13 | 11.04-14.36 kPa | Heparinized syringe (iced) |
| Parathyroid hormone (PTH), intact | Serum | Intact PTH: 11-54 pg/mL (laboratory-specific) | 0.11 | Intact PTH: 1.2-5.7 pmol/L (laboratory-specific) | Red, SST |
| Partial thromboplastin time, activated (PTT) | Plasma | 25-35 seconds (reference interval varies) Panic: ≥ 60 seconds | | | Blue |
| pH | Whole blood | Arterial: 7.35-7.45 Venous: 7.31-7.41 | | | Heparinized syringe (iced) |
| Phosphorus | Serum | 2.5-4.5 mg/dL Panic: < 1.0 mg/dL | 0.32 | 0.8-1.45 mmol/L | SST |
| Plasminogen | Plasma | 70-113% (activity) | 1.00 | 70-113% | Blue |
| Platelet count (Plt) | Whole blood | $150-450 \times 10^3/\text{mCL}$ Panic: < $25 \times 10^3/\text{mCL}$ | 1.0 | $150-450 \times 10^9/\text{L}$ Panic: < $25 \times 10^9/\text{L}$ | Lavender |

(continued)

Table 2. Reference intervals for commonly used tests.^{1,2} (continued)

| Current metric units × Conversion factor = SI units SI units ÷ Conversion factor = Current metric units | | | | | |
|---|-------------|---|-------------------|--|--------------------|
| Test | Specimen | Conventional Units | Conversion Factor | SI Units ² | Collection |
| Platelet-associated IgG | Whole blood | Negative | | | Lavender |
| Platelet function test (PFA-100 closure time) (CEPI: collagen/epinephrine cartridge; CADP: collagen/ADP cartridge) | Whole blood | CEPI: 70–170 seconds (laboratory-specific) CADP: 50–110 seconds (laboratory-specific) | 1.0 | CEPI: 70–170 seconds CADP: 50–110 seconds | Blue |
| Porphobilinogen (PBG) | Urine | Negative | | | Protect from light |
| Potassium (K ⁺) | Serum | 3.5–5.0 mEq/L Panic: < 3.0 or > 6.0 mEq/L | 1.00 | 3.5–5.0 mmol/L | SST |
| Prolactin (PRL) | Serum | < 20 ng/mL | 1.00 | < 20 mcg/L | SST |
| Prostate-specific antigen (PSA) | Serum | 0–4 ng/mL | 1.00 | 0–4 mcg/L | SST |
| Protein C | Plasma | 71–176% (functional) 60–150% (antigenic) | | | Blue |
| Protein electrophoresis | Serum | Adults: Albumin: 3.3–4.7 g/dL α_1 : 0.1–0.4 g/dL α_2 : 0.3–0.9 g/dL β_2 : 0.7–1.5 g/dL γ : 0.5–1.4 g/dL (polyclonal) | 10.00 | 33–47 g/L 1–4 g/L 3–9 g/L 7–15 g/L 5–14 g/L (polyclonal) | SST |
| Protein S (antigen) | Plasma | 76–178% | | | Blue |
| Protein, total | Serum | 6.0–8.0 g/dL | 10.00 | 60–80 g/L | SST |
| Prothrombin time (PT) | Whole blood | 11–15 seconds Panic: ≥ 30 seconds (laboratory-specific) | | | Blue |
| Red blood cell count | Whole blood | 4.7–6.1 × 10 ⁶ /mCL (male) 3.5–5.5 × 10 ⁶ /mCL (female) | 1.00 | 4.7–6.1 × 10 ¹² /L 3.5–5.5 × 10 ¹² /L | Lavender |
| Renin activity | Plasma | High-sodium diet (75–150 mEq Na ⁺ /d): Supine: 0.2–2.3 ng/mL/h Standing: 1.3–4.0 ng/mL/h Low-sodium diet (30–75 mEq Na ⁺ /d): Standing: 4.0–7.7 ng/mL/h | | | Lavender |
| Reptilase clotting time | Plasma | 13–19 seconds | | | Blue |
| Reticulocyte count | Whole blood | 33–137 × 10 ³ /mCL | 1.00 | 33–137 × 10 ⁹ /L | Lavender |
| Russell viper venom clotting time (dilute) (RVVT) | Plasma | 24–37 seconds | | | Blue |
| Salicylate (aspirin) | Serum | 20–30 mg/dL Panic: > 35 mg/dL | 10.00 | 200–300 mg/L | SST |
| Sodium (Na ⁺) | Serum | 135–145 mEq/L Panic: < 125 or > 155 mEq/L | 1.00 | 135–145 mmol/L | SST |
| Testosterone | Serum | Male: 175–781 ng/dL Female: 10–75 ng/dL | 0.0347 | Male: 6–27 nmol/L Female: 0.3–2.6 nmol/L | SST |

(continued)

Table 2. Reference intervals for commonly used tests.^{1,2} (continued)

| Current metric units × Conversion factor = SI units SI units ÷ Conversion factor = Current metric units | | | | | |
|--|-------------|---|-------------------|---|---|
| Test | Specimen | Conventional Units | Conversion Factor | SI Units ² | Collection |
| Thrombin time | Plasma | 8–12 seconds (laboratory-specific) | | | Blue |
| Thyroglobulin | Serum | 3–42 ng/mL | 1.00 | 3–42 mcg/L | SST |
| Thyroid-stimulating hormone (TSH) | Serum | 0.4–6 mIU/mL | 1.00 | 0.4–6 mIU/L | SST |
| Thyroid-stimulating hormone receptor antibody (TSH-R Ab [stim]) | Serum | < 130% of basal activity; based on cAMP generation in thyroid cell tissue culture | | | |
| Thyroxine, free (FT ₄) | Serum | 9–24 pmol/L (varies with method) | | | SST |
| Thyroxine (T ₄), total | Serum | 5–11 mcg/dL | 12.80 | 64–142 nmol/L | SST |
| Transferrin | Serum | 190–375 mg/dL | 0.01 | 1.9–3.75 g/L | SST |
| Transferrin receptor, soluble (sTfR) | Serum | 2.2–5 mg/L (male) 1.9–4.4 mg/L (female) (laboratory-specific) | | | SST |
| Triglycerides | Serum | < 165 mg/dL | 0.01 | < 1.8 mmol/L | SST (fasting) |
| Triiodothyronine (T ₃), total | Serum | 95–190 ng/dL | 0.015 | 1.5–2.9 nmol/L | SST |
| Troponin-I (cTnI) | Serum | < 1.50 ng/mL (method-dependent) | | | SST |
| Uric acid | Serum | Male: 2.4–7.4 mg/dL Female: 1.4–5.8 mg/dL | 59.48 | Male: 140–440 μmol/L Female: 80–350 μmol/L | SST |
| Vanillylmandelic acid (VMA) | Urine | 2–7 mg/24 h | 5.05 | 10–35 μmol/d | Urine bottle containing hydrochloric acid |
| Vitamin B ₁₂ | Serum | 140–820 pg/mL | 0.74 | 100–600 pmol/L | SST |
| Vitamin D, 25-hydroxy (25[OH]D) | Serum | 20–50 ng/mL | 2.5 | 50–125 nmol/L | SST |
| Vitamin D, 1,25-dihydroxy (1,25[OH] ₂ D) | Serum | 20–76 pg/mL | 2.4 | 48–182 pmol/L | SST |
| von Willebrand factor (vWF) | Plasma | 50–180% (activity and antigen) | | | Blue |
| White blood cell count | Whole blood | 4.8–10.8 × 10 ³ /mCL | 1.00 | 4.8–10.8 × 10 ⁹ /L | Lavender |

¹The reference intervals given here in conventional units and in SI units are from several large medical centers. Always use the reference intervals provided by your clinical laboratory, since intervals may be method-dependent.

Table 3. Commonly used specimen collection tubes.

| Tube | Tube Contents | Typical Use |
|----------|---|--|
| Lavender | EDTA | Complete blood count; molecular testing |
| SST | Serum separator | Serum chemistry tests |
| Red | None | Blood banking (serum); therapeutic drug monitoring |
| Blue | Citrate | Coagulation studies |
| Gray | Inhibitor of glycolysis (sodium fluoride) | Lactic acid |
| Green | Heparin | Plasma chemistry tests; chromosome analysis |
| Yellow | Acid citrate | HLA typing; flow cytometry immunophenotyping |
| Navy | Trace metal free | Trace metals (eg, lead, mercury, arsenic) |

EDTA, ethylenediamine tetraacetic acid; SST, serum separator tube.
