5.3.1. To 1 g of the sample (Note 9) add 25 mL of cold water. Disperse the cement in the water and while swirling the mixture, quickly add 5 mL of HCl. If necessary, warm the solution gently, and grind the material with the flattened end of a glass rod for a few minutes until it is evident that decomposition of the cement is complete (Note 10). Dilute the solution to 50 mL with hot water (nearly boiling) and heat the covered mixture rapidly to near boiling by means of a high-temperature hot plate. Then digest the covered mixture for 15 minutes at a temperature just below boiling (Note 11). Filter the solution through a medium-textured paper into a 400-mL beaker, wash the beaker, paper, and residue thoroughly with hot water, and reserve the filtrate for the sulfur trioxide determination, if desired (Note 12). Transfer the filter paper and contents to the original beaker, add 100 mL of hot (near boiling) NaOH solution (10 g/L), and digest at a temperature just below boiling for 15 minutes. During the digestion, occasionally stir the mixture and macerate the filter paper. Acidify the solution with HCl using methyl red as the indicator and add an excess of four or five drops of HCl. Filter through medium-textured paper and wash the residue at least 14 times with hot NH_4NO_3 solution (20 g/L) making certain to wash the entire filter paper and contents during each washing. Ignite the residue in a tared platinum crucible at 900 to 1000°C, cool in a desiccator, and determine the mass.

Note 9—If sulfur trioxide is to be determined by turbidimetry it is permissible to determine the insoluble residue on a 0.5-g sample. In this event, the percentage of insoluble residue should be calculated to the nearest 0.01 by multiplying the mass of residue obtained by 200. However, the cement should not be rejected for failure to meet the insoluble residue requirement unless a 1-g sample has been used.

Note 10—If a sample of portland cement contains an appreciable amount of manganic oxide, there may be brown compounds of manganese which dissolve slowly in cold diluted HCl but rapidly in hot HCl in the specified strength. In all cases, dilute the solution as soon as decomposition is complete.

Note 11—In order to keep the solutions closer to the boiling temperature, it is recommended that these digestions be carried out on an electric hot plate rather than in a steam bath.

Note 12—Continue with the sulfur trioxide determination (Sections 15.1.2.1 through 15.1.3) by diluting to 250 or 200 mL as required by the appropriate section.

5.3.2. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

5.4. *Calculation*—Calculate the percentage of the insoluble residue to the nearest 0.01 by multiplying the mass in grams of the residue (corrected for the blank) by 100.

6. SILICON DIOXIDE (REFERENCE TEST METHOD)

6.1. *Selection of Test Method*—For cements other than portland and for which the insoluble residue is unknown, determine the insoluble residue in accordance with Section 5 of these test methods. For portland cements and other cements having an insoluble residue less than 1 percent, proceed in accordance with Section 6.2. For cements having an insoluble residue greater than 1 percent proceed in accordance with Section 6.3.

6.2. *Silicon Dioxide in Portland Cements and Cements with Low Insoluble Residue*:

6.2.1. *Summary of Test Method*—In this test method silicon dioxide (SiO_2) is determined gravimetrically. Ammonium chloride is added and the solution is not evaporated to dryness. This test method was developed primarily for hydraulic cements that are almost completely decomposed by hydrochloric acid and should not be used for hydraulic cements that contain large amounts of acid-insoluble material and require a preliminary sodium carbonate fusion. For such cements or if prescribed in the standard specification for the cement being analyzed, the more lengthy procedure in Section 6.3 shall be used.

6.2.2. *Reagent*—Ammonium chloride (NH_4Cl).

6.2.3. *Procedure*:

6.2.3.1. Mix thoroughly 0.5 g of the sample and about 0.5 g of NH_4Cl in a 50-mL beaker, cover the beaker with a watch glass, and add cautiously 5 mL of HCl, allowing the acid to run down the lip of the covered beaker. After the chemical action has subsided, lift the cover, add 1 or 2 drops of HNO_3, stir the mixture with a glass rod, replace the cover, and set the beaker on a steam bath for 30 minutes (Note 13). During this time of digestion, stir the contents occasionally and break up any remaining lumps to facilitate the complete decomposition of the cement. Fit a medium-textured filter paper to a funnel, transfer the jelly-like mass of silicic acid to the filter as completely as possible without dilution, and allow the solution to drain through. Scrub the beaker with a policeman and rinse the beaker and policeman with hot HCl (1 + 99). Wash the filter two or three times with hot HC1 (1 + 99) and then with ten or twelve small portions of hot water, allowing each portion to drain through completely. Reserve the filtrate and washings for the determination of the ammonium hydroxide group (Note 14).

Note 13—A hot plate may be used instead of a steam bath if the heat is so regulated as to approximate that of a steam bath. Under conditions where water boils at a lower temperature than at sea level, such as at higher elevations, 30 minutes may not be sufficient to recover all of the silica. In such cases, increase the time of digestion as necessary to get complete recovery of the silica. In no case should this time exceed 60 minutes.

Note 14—Determine the ammonium hydroxide group in accordance with the procedure described in Sections 7.1 through 7.3.

6.2.3.2. Transfer the filter paper and residue to a tared platinum crucible, dry, and ignite, at first slowly until the carbon of the paper is completely consumed without inflaming and finally at 1100° to 1200°C for one hour. Cool in a desiccator and determine the mass. Re-ignite to constant mass. Treat the SiO_2 thus obtained, which will contain small amounts of impurities, in the crucible with 1 or 2 mL of water, 2 drops of H_2SO_4 (1 + 1), and about 10 mL of HF, and evaporate cautiously to dryness. Finally, heat the small residue at 1050° to 1100°C for five minutes, cool in a desiccator, and determine the mass. The difference between this mass and the mass previously obtained represents the mass of SiO_2. Consider the mass of the residue remaining after the volatilization of SiO_2 as combined aluminum and ferric oxides and add it to the result obtained in the determination of the ammonium hydroxide group.

6.2.3.3. If the HF residue exceeds 2 mg, the silica determination shall be repeated, steps should be taken to ensure complete decomposition of the sample before a silica separation is attempted, and the balance of the analysis (ammonium hydroxide group, CaO, and MgO) determined on the new silica filtrate provided the new silica determination has an HF residue of 2 mg or less except as provided in Sections 6.2.3.4 and 6.2.3.5.

6.2.3.4. If two or three repeated determinations of a sample of portland cement consistently show HF residues higher than 2 mg, this is evidence that contamination has occurred in sampling or the cement has not been burned properly during manufacture. In such a case, do not fuse the large HF residue with pyrosulfate for subsequent addition to the filtrate from the silica separation. Instead, report the value obtained for the HF residue. Do not ignite the ammonium hydroxide group in the crucible containing this abnormally large HF residue.

6.2.3.5. In the analysis of cements other than portland, it may not always be possible to obtain HF residues under 2 mg. In such cases, add 0.5 g of sodium or potassium pyrosulfate ($Na_2S_2O_7$ or $K_2S_2O_7$) to the crucible and heat below red heat until the small residue of impurities is dissolved in the melt (Note 15). Cool, dissolve the fused mass in water, and add it to the filtrate and washings reserved for the determination of the ammonium hydroxide group.

Note 15—A supply of non-spattering pyrosulfate may be prepared by heating some pyrosulfate in a platinum vessel below red heat until the foaming and spattering cease, cooling, and crushing the fused mass.

6.2.3.6. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

6.2.4. *Calculation*—Calculate the percentage of SiO_2 by multiplying the mass in grams of SiO_2 by 200 (100 divided by the mass (See Section 6.2.3.1) or equivalent mass (See Section 6.3.2.1) of the sample used (0.5 g). Round off in accordance with Table 3.

6.3. *Silicon Dioxide in Cements with Insoluble Residue Greater Than One Percent:*

6.3.1. *Summary of Test Method*—This test method is based on the sodium carbonate fusion followed by double evaporation to dryness of the hydrochloric acid solution of the fusion product to convert silicon dioxide (SiO_2) to the insoluble form. The solution is filtered and the insoluble siliceous residue is ignited and the mass determined. Silicon dioxide is volatilized by hydrofluoric acid and the loss of mass is reported as pure SiO_2.

6.3.2. *Procedure*:

6.3.2.1. Determine the mass of a quantity of the ignited sample equivalent to 0.5 g of the as-received sample calculated as follows:

$$W = \left[0.5\left(100.00 - I\right)/100\right] \qquad (1)$$

where:

W = mass of ignited sample, g; and

I = loss on ignition, percent.

The ignited material from the loss on ignition determination may be used for the sample. Thoroughly mix the sample with 4 to 6 g of Na_2CO_3 by grinding in an agate mortar. Place a thin layer of Na_2CO_3 on the bottom of a platinum crucible of 20- to 30-mL capacity, add the cement-Na_2CO_3 mixture, and cover the mixture with a thin layer of Na_2CO_3. Place the covered crucible over a moderately low flame and increase the flame gradually to a maximum (approximately 1100°C) and maintain this temperature until the mass is quiescent (about 45 minutes). Remove the burner, lay aside the cover of the crucible, grasp the crucible with tongs, and slowly rotate the crucible so that the molten contents spread over the sides and solidify as a thin shell on the interior. Set the crucible and cover aside to cool. Rinse off the outside of the crucible and place the crucible on its side in a 300-mL casserole about one-third full of water. Warm the casserole and stir until the cake in the crucible disintegrates and can be removed easily. By means of a glass rod, lift the crucible out of the liquid, rinsing it thoroughly with water. Rinse the cover and crucible with HCl (1 + 3); then add the rinse to the casserole. Very slowly and cautiously add 20 mL of HCl (sp gr 1.19) to the covered casserole. Remove the cover and rinse. If any gritty particles are present, the fusion is incomplete and the test must be repeated, using a new sample.

Warning—Subsequent steps of the test methods must be followed exactly for accurate results.

6.3.2.2. Evaporate the solution to dryness on a steam bath (there is no longer a gelatinous appearance). Without heating the residue any further, treat it with 5 to 10 mL of HCl, wait at least two minutes, and then add an equal amount of water. Cover the dish and digest for 10 minutes on the steam bath or a hot plate. Dilute the solution with an equal volume of hot water, immediately filter through medium-textured paper, and wash the separated SiO_2 thoroughly with hot HCl (1 + 99), then with hot water. Reserve the residue.

6.3.2.3. Again evaporate the filtrate to dryness, and bake the residue in an oven for one hour at 105° to 110°C. Cool, add 10 to 15 mL of HCl (1 + 1), and digest on the steam bath or hot plate for 10 minutes. Dilute with an equal volume of water, filter immediately on a fresh filter paper, and wash the small SiO_2 residue thoroughly as described in Section 6.3.2.2. Stir the filtrate and washings and reserve for the determination of the ammonium hydroxide group in accordance with Sections 7.1 through 7.3.

6.3.2.4. Continue the determination of silicon dioxide in accordance with Section 6.2.3.2.

7. AMMONIUM HYDROXIDE GROUP (REFERENCE TEST METHOD)

7.1. *Summary of Test Method*—In this test method aluminum, iron, titanium, and phosphorus are precipitated from the filtrate, after SiO_2 removal, by means of ammonium hydroxide. With care, little if any manganese will be precipitated. The precipitate is ignited and the mass determined as the oxides.

7.2. *Procedure*:

7.2.1. To the filtrate reserved in accordance with Section 6.2.3.1 (Note 16) which should have a volume of about 200 mL, add HCl if necessary to ensure a total of 10 to 15 mL of the acid. Add a few drops of methyl red indicator and heat to boiling. Then treat with NH_4OH (1 + 1) (Note 17), dropwise until the color of the solution becomes distinctly yellow, and add one drop in excess (Note 18). Heat the solution containing the precipitate to boiling and boil for 50 to 60 seconds. In the event difficulty from bumping is experienced while boiling the ammoniacal solution, a digestion period of 10 minutes on a steam bath, or on a hot plate having the approximate temperature of a steam bath, may be substituted for the 50 to 60 seconds boiling period. Allow the precipitate to settle (not more than five minutes) and filter using medium-textured paper (Note 19). Wash with hot ammonium nitrate (NH_4NO_3, 20 g/L) (Note 20) twice for a small precipitate to about four times for a large one.

Note 16—If a platinum evaporating dish has been used for the dehydration of SiO_2, iron may have been partially reduced. At this stage, add about 3 mL of saturated bromine water to the filtrate and boil the filtrate to eliminate the excess bromine before adding the methyl red indicator. If difficulty from bumping is experienced during the boiling, the following alternate techniques may be helpful: (1) a piece of filter paper, approximately 1 cm^2 in area, positioned where the bottom and side of the beaker merge and held down by the end of a stirring rod may solve the difficulty, and (2) use of 400-mL beakers supported inside a cast aluminum cup has also been found effective.

Note 17—The NH_4OH used to precipitate the hydroxides must be free of contamination with carbon dioxide (CO_2).

Note 18—It usually takes one drop of NH_4OH (1 + 1) to change the color of the solution from red to orange and another drop to change the color from orange to yellow. If desired, the addition of the indicator may be delayed until ferric hydroxide ($Fe(OH)_3$) is precipitated without aluminum hydroxide ($Al(OH)_3$) being completely precipitated. In such a case, the color changes may be better observed. However, if the content of Fe_2O_3 is unusually great, it may be necessary to occasionally let the precipitate settle slightly so that the color of the supernatant liquid can be observed. If the color fades during the precipitation, add more of the indicator. Observation of the color where a drop of the indicator strikes the solution may be an aid in the control of the acidity. The boiling should not be prolonged as the color may reverse and the precipitate may be difficult to retain on the filter. The solution should be distinctly yellow when it is ready to filter. If it is not, restore the yellow color with more NH_4OH (1 + 1) or repeat the precipitation.

Note 19—To avoid drying of the precipitate with resultant slow filtration, channeling, or poor washing, the filter paper should be kept nearly full during the filtration and should be washed without delay.

Note 20—Two drops of methyl red indicator solution should be added to the NH_4NO_3 solution in the wash bottle, followed by NH_4OH (1 + 1) added dropwise until the color just changes to yellow. If the color reverts to red at any time due to heating, it should be brought back to yellow by the addition of a drop of NH_4OH (1 + 1).

7.2.2. Set aside the filtrate and transfer the precipitate and filter paper to the same beaker in which the first precipitation was effected. Dissolve the precipitate with hot HCl (1 + 2). Stir to thoroughly macerate the paper and then dilute the solution to about 100 mL. Reprecipitate the hydroxides as described in Section 7.2.1. If difficulty from bumping is experienced while boiling the acid solution containing the filter paper, it may be obviated by diluting the hot 1 + 2 solution of the mixed oxides with 100 mL of boiling water and thus eliminate the need for boiling. Filter the solution and wash the precipitate with about four 10-mL portions of hot NH_4NO_3 solution (20 g/L) (Note 20). Combine the filtrate and washings with the filtrate set aside and reserve for the determination of CaO in accordance with Section 13.3.1.

7.2.3. Place the precipitate in a tared platinum crucible, heat slowly until the papers are charred, and finally ignite to constant mass at 1050° to 1100°C with care to prevent reduction, and determine the mass as the ammonium hydroxide group.

7.2.4. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

7.3. *Calculation*—Calculate the percentage of ammonium hydroxide group to the nearest 0.01 by multiplying the mass in grams of ammonium hydroxide group by 200 (100 divided by the mass of sample used (0.5 g)).

8. FERRIC OXIDE (REFERENCE TEST METHOD)

8.1. *Summary of Test Method*—In this test method, the Fe_2O_3 content of the cement is determined on a separate portion of the cement by reducing the iron to the ferrous state with stannous chloride ($SnCl_2$) and titrating with a standard solution of potassium dichromate ($K_2Cr_2O_7$). This determination is not affected by any titanium or vanadium that may be present in the cement.

8.2. *Reagents*:

8.2.1. *Barium Diphenylamine Sulfonate Indicator Solution*—Dissolve 0.3 g of barium diphenylamine sulfonate in 100 mL of water.

8.2.2. *Potassium Dichromate, Standard Solution* (1 mL = 4 mg Fe_2O_3)—Pulverize and dry primary standard potassium dichromate ($K_2Cr_2O_7$) reagent, the current lot of NIST 136, at 180° to 200°C to constant mass. Accurately determine the mass of an amount of dried reagent equal to 2.45700 g times the number of liters of solution to be prepared. Dissolve in water and dilute to exactly the required volume in a single volumetric flask of the proper size. This solution is a primary standard and requires no further standardization (Note 21).

Note 21—Where large quantities of standard solution are required, it may be desirable for certain laboratories to use commercially produced primary standard potassium dichromate for most determinations. Such a material may be used provided that the first solution made from the container is checked, as follows: Using a standard solution of NIST 136, prepared as described in Section 8.2.2, analyze, in duplicate, samples of a NIST CRM cement (Note 1), by the procedure given in Sections 8.3.1.3 and 8.3.1.4. Repeat using a similar solution prepared from the commercial primary standard dichromate. The average percentages of Fe_2O_3 found by each test method should not differ by more than 0.06 percent.

8.2.3. *Stannous Chloride Solution*—Dissolve 5 g of stannous chloride ($SnCl_2 \cdot 2H_2O$) in 10 mL of HCl and dilute to 100 mL. Add scraps of iron-free granulated tin and boil until the solution is clear. Keep the solution in a closed dropping bottle containing metallic tin.

8.3. *Procedure*—For cements other than portland and for which the insoluble residue is unknown, determine the insoluble residue in accordance with the appropriate sections of these test methods. When insoluble residue is known, proceed in accordance with Section 8.3.1 or 8.3.2 as is appropriate for the cement being analyzed.

8.3.1. For portland cements and cements having insoluble residue lower than 1 percent, weigh 1 g of the sample into a 500-mL Phillips beaker or other suitable container. Add 40 mL of cold water and, while the beaker is being swirled, add 10 mL of HCl. If necessary, heat the solution and grind the cement with the flattened end of a glass rod until it is evident that the cement is completely decomposed. Continue the analysis in accordance with Section 8.3.3.

8.3.2. For cements with insoluble residue greater than 1 percent, weigh a 0.500 g sample, blend with 1 g $LiBO_2$ using a mortar and pestle, and transfer to a previously fired 8-mL carbon crucible that has 0.1 g $LiBO_2$ sprinkled in the bottom (Note 22). Cover with 0.1 g $LiBO_2$ that was used to chemically wash the mortar and pestle (Note 23). Place the uncovered crucible in a furnace set at 1100°C for 15 minutes. Remove the crucible from the furnace and check for complete fusion (Note 24). If the fusion is incomplete, return the crucible to the furnace for another 30 minutes. Again, check for complete fusion. If the fusion is still incomplete, discard the sample and repeat the fusion procedure using 0.250 g sample or a smaller quantity with the same amount of $LiBO_2$. When the fusion is complete, gently swirl the melt and pour into a 150-mL glass beaker containing 10 mL concentrated HCl and 50 mL water. Stir continuously until the fusion product is dissolved, usually 10 minutes or less (Note 25). If a stirring bar is used, remove and rinse the bar. Continue the analysis in accordance with Section 8.3.3.

Note 22—The firing loosens the carbon on the surface, reducing the possibility of the fusion product sticking to the crucible.

Note 23—A chemical wash is a dry rinse of the equipment in which the blending was done so that any sample adhering to this equipment will be loosened and transferred to the crucible.

Note 24—When fusion is incomplete, the sample may not be completely melted or there may be particles on top of the bead. Usually, if the bead forms a small smooth spherical ball when taken from the furnace and before it is swirled, the sample is completely fused.

Note 25—There are usually some carbon particles that are in suspension, undissolved in the solution, but they will not interfere with the completion of the analysis.

8.3.3. Heat the solution to boiling and treat it with the $SnCl_2$ solution, added dropwise while stirring and boiling, until the solution is decolorized. Add one drop in excess and cool the solution to room temperature by placing the beaker in a pan of cool water. After cooling and without delay, rinse the inside of the vessel with water, and add all at once 10 mL of a cool, saturated mercuric chloride ($HgCl_2$) solution. Stir the solution vigorously for one minute by swirling the beaker and add 10 mL of H_3PO_4 (1 + 1) and two drops of barium diphenylamine sulfonate indicator. Add sufficient water so that the volume after titration will be between 75 and 100 mL. Titrate with the standard $K_2Cr_2O_7$ solution. The end point shall be taken as the point at which a single drop causes an intense purple coloration that remains unchanged on further addition of standard $K_2Cr_2O_7$ solution.

8.3.4. *Blank*—Make a blank determination following the same procedure and using the same amounts of reagents. Record the volume of $K_2Cr_2O_7$ solution required to establish the end point as described in Section 8.3.3. As some iron must be present to obtain the normal end point, if no definite purple color is obtained after the addition of four drops of the standard $K_2Cr_2O_7$ solution, record the blank as zero.

8.4. *Calculation*:

8.4.1. Calculate the percentage of Fe_2O_3 as follows:

$$\mathrm{Fe_2O_3}, \% = E\left(V - B\right) \times 100 / W \qquad (2)$$

where:

E = Fe_2O_3 equivalent of the $K_2Cr_2O_7$ solution, g/mL;
V = milliliters of $K_2Cr_2O_7$ solution required by the sample determination;
B = milliliters of $K_2Cr_2O_7$ solution required by the blank determination; and
W = mass of sample within 0.1 mg.

Round in accordance with Table 3.

9. PHOSPHORUS PENTOXIDE (REFERENCE TEST METHOD)

9.1. *Summary of Test Method*—This colorimetric test method is applicable to the determination of P_2O_5 in portland cement. Under the conditions of the test, no constituent normally present in portland cement will interfere.

9.2. *Apparatus*:

9.2.1. *Spectrophotometer* (Note 26):

9.2.1.1. The instrument shall be equipped to measure absorbency of solutions at a spectral wavelength of 725 nm.

9.2.1.2. Wavelength measurements shall be repeatable within ±1 nm or less.

9.2.1.3. In the absorbance range from 0.1 to 1.0, the absorbance measurements shall be repeatable within ±1 percent or less.

9.2.1.4. To establish that the spectrophotometer will permit a satisfactory degree of accuracy, qualify the instrument in accordance with Section 3.3.2 using the procedure in Sections 9.4.1 through 9.4.9.

Note 26—For the measurement of the performance of the spectrophotometer, refer to ASTM E 275.

9.3. *Reagents*:

9.3.1. *Ammonium Molybdate Solution*—Into a 1-L volumetric flask introduce 500.0 mL of 10.6 normal H_2SO_4 (Section 9.3.7). Dissolve 25.0 g of ammonium molybdate ($(NH_4)_6\ MO_7O_{24}\cdot 4H_2O$) in about 250 mL of warm water and transfer to the flask containing the H_2SO_4, while swirling the flask. Cool, dilute to 1 L with water, and store in a plastic bottle.

9.3.2. *Ascorbic Acid Powder*—For ease in dissolving, the finest mesh available should be used.

9.3.3. *Hydrochloric Acid, Standard* (6.5 ± 0.1 *N*)—Dilute 540 mL of concentrated HCl (sp gr 1.19) to 1 L with water. Standardize against standard NaOH solution (Section 9.3.6) using phenolphthalein as indicator. Determine the exact normality and adjust to 6.5 ± 0.1 *N* by dilution with water. Restandardize to ensure that the proper normality has been achieved.

9.3.4. *Phosphate, Standard Solution A*—Dissolve 0.1917 g of oven-dried potassium dihydrogen phosphate (KH_2PO_4) in water and dilute to 1 L in a volumetric flask.

9.3.5. *Phosphate, Standard Solution B*—Dilute 50.0 mL of phosphate solution A to 500 mL with water.

9.3.6. *Sodium Hydroxide, Standard Solution* (1 *N*)—Dissolve 40.0 g of sodium hydroxide (NaOH) in water, add 10 mL of a freshly filtered saturated solution of barium hydroxide ($Ba(OH)_2$), and dilute to 1 L with water that has been recently boiled and cooled. Shake the solution from time to time during a several-hour period, and filter into a plastic bottle. Keep the bottle tightly closed to protect the solution from CO_2 in the air. Standardize against acid potassium phthalate or benzoic acid acidimetric standards furnished by NIST (standard samples 84f and 350), using the test methods in the certificates accompanying the standard samples. Determine the exact normality of the solution.

9.3.7. *Sulfuric Acid, Standard* (10.6 ± 0.1 *N*)—To a 1-L volumetric flask cooled in water add about 600 mL of water and then, slowly, with caution, 300 mL of concentrated H_2SO_4 (sp gr 1.84). After cooling to room temperature, dilute to 1 L with water. Standardize against the standard NaOH solution (Section 9.3.6) using the phenolphthalein as indicator. Determine the normality and adjust to 10.6 ± 0.1 *N* by dilution with water. Restandardize to ensure that the proper normality has been achieved.

9.4. *Procedure*:

9.4.1. Prepare a series of phosphate solutions to cover the range from 0 to 0.5 percent P_2O_5. Prepare each solution by adding a suitable volume of standard phosphate solution B and 25.0 mL of the 6.5 *N* hydrochloric acid to a 250-mL volumetric flask (Note 27). Dilute to the mark with water.

Note 27—One milliliter of standard phosphate solution B 250 mL of solution is equivalent to 0.004 percent P_2O_5 for a 0.25-g cement sample. Aliquots of 0, 12.5, 25, 50, 75, 100, and 125 mL are equivalent to P_2O_5 contents in the sample of 0, 0.05, 0.10, 0.20, 0.30, 0.40, and 0.50 percent.

9.4.2. Prepare a blank by adding 25.0 mL of the standard HCl to a 250-mL volumetric flask and diluting to 250 mL with water.

9.4.3. Develop colors in the series of phosphate solutions, and in the blank, in accordance with Sections 9.4.6 through 9.4.8.

9.4.4. Plot the net absorbance (absorbance of standard minus that of the blank) values obtained as ordinates and the corresponding P_2O_5 concentrations as abscissas. Draw a smooth curve through the points (Note 28).

Note 28—A suitable paper for plotting the calibration curve is a 254 by 381-mm (10 by 15-in.) linear cross section paper having 8 by 8 divisions to 10 mm (20 by 20 divisions to 1 in.). The percentage of P_2O_5 can then be plotted on the long dimension using five divisions equal to 0.01 percent P_2O_5. A scale of one division equal to 0.005 absorbance units is suitable as the ordinate (short dimension of the paper). Scales other than this may be used but under no circumstances should a scale division less than 1.3 mm ($^1/_{20}$ in.) be used for 0.005 units of absorbance or for 0.005 percent P_2O_5. A separate calibration curve should be made for each spectrophotometer used, and the calibration curve checked against standard phosphate solution whenever a new batch of ammonium molybdate reagent is used.

9.4.5. Transfer 0.250 g of the sample to a 250-mL beaker and moisten with 10 mL of cold water to prevent lumping. Add 25.0 mL of the standard HCl and digest with the aid of gentle heat and agitation until solution is complete. Filter into a 250-mL volumetric flask and wash the paper and the separated silica thoroughly with hot water. Allow the solution to cool and then dilute with water to 250 mL.

9.4.6. Transfer a 50.0-mL aliquot (Note 29) of the sample solution to a 250-mL beaker, add 5.0 mL of ammonium molybdate solution and 0.1 g of ascorbic acid powder. Mix the contents of the beaker by swirling until the ascorbic acid has dissolved completely. Heat the solution to vigorous boiling and then boil, uncovered, for 90 ± 30 seconds. Cool to room temperature and transfer to a 50-mL volumetric flask. Rinse the beaker with one small portion of water and add the rinse water to the flask. Dilute to 50 mL with water.

Note 29—The range of the test can be extended by taking a smaller aliquot of the sample solution. In such instances the decrease in the aliquot volume must be made up by the blank solution (Section 9.4.5) to maintain the proper acidity of the final solution. Thus, if a 25-mL aliquot of the sample solution is taken (instead of the usual 50 mL), a 25-mL aliquot of the blank solution should be added before proceeding with the test. The result of the test must then be calculated accordingly.

9.4.7. Measure the absorbance of the solution against water as the reference at 725.0 nm.

9.4.8. Develop a 50.0-mL aliquot of the blank solution prepared in Section 9.4.2 in the same manner as was used in Section 9.4.6 for the sample solution. Measure the absorbance in accordance with Section 9.4.7 and subtract this absorbance value from that obtained for the sample solution in Section 9.4.6 in order to obtain the net absorbance for the sample solution.

9.4.9. Using the net absorbance value found in Section 9.4.8, record the percentage of P_2O_5 in the cement sample as indicated by the calibration curve. Report the percentage of P_2O_5 rounded in accordance with Table 3.

---

10. TITANIUM DIOXIDE (REFEREE TEST METHOD)

10.1. *Summary of Test Method*—In this test method titanium dioxide (TiO_2) in portland cement is determined colorimetrically using Tiron reagent. Under the conditions of the test iron is the only constituent of portland cement causing a very slight interference equivalent to 0.01 percent for each 1 percent of Fe_2O_3 present in the sample.

10.2. *Apparatus*:

10.2.1. *Spectrophotometer* (Note 30):

10.2.1.1. The instrument shall be equipped to measure absorbance of solutions at a spectral wavelength of 410 nm.

10.2.1.2. Wavelength measurements shall be repeatable within ±1 nm or less.

10.2.1.3. In the absorbance range from 0.1 to 1.0, the absorbance measurements shall be repeatable within ±1 percent or less.

10.2.1.4. To establish that the spectrophotometer will permit a satisfactory degree of accuracy, qualify the instrument in accordance with Section 3.3.2 using the procedure in Sections 10.4.1 through 10.4.6 of this test method.

Note 30—For the measurement of the performance of the spectrophotometer, refer to ASTM E 275.

10.3. *Reagents*:

10.3.1. *Buffer* (pH 4.7)—68 g of $NaC_2H_3O_2{\cdot}3H_2O$ (sodium acetate trihydrate), plus 380 mL of water, plus 100 mL of 5.0 *N* CH_3COOH (acetic acid).

10.3.2. *Ethylenedinitrilo Tetraacetic Acid Disodium Salt, Dihydrate* (0.2 *M* EDTA)—Dissolve 37.5 g of EDTA in 350 mL of warm water, and filter. Add 0.25 g of $FeCl_3{\cdot}6H_2O$ (ferric chloride hexahydrate) and dilute to 500 mL.

10.3.3. *Hydrochloric Acid* (1 + 6).

10.3.4. *Hydrochloric Acid, Standard* (6.5 *N*)—Dilute 540 mL of concentrated HCl (sp gr 1.19) to 1 L with water.

10.3.5. *Ammonium Hydroxide* (NH_4OH, 1 + 1).

10.3.6. *Potassium Pyrosulfate* ($K_2S_2O_7$).

10.3.7. *Titanium Dioxide, Stock Solution A*—Fuse slowly in a platinum crucible over a very small flame 0.0314 g of NIST CRM 154b (TiO_2 = 99.74 percent) or its replacements with about 2 or 3 g of $K_2S_2O_7$. Allow to cool, and place the crucible in a beaker containing 125 mL of H_2SO_4 (1 + 1). Heat and stir until the melt is completely dissolved. Cool, transfer to a 250-mL volumetric flask, and dilute the solution to volume.

10.3.7.1. *Titanium Dioxide, Dilute Standard Solution B* (1 mL = 0.0125 mg TiO_2)—Pipet 50 mL of stock TiO_2 solution into a 500-mL volumetric flask, and dilute to volume. One milliliter of this solution is equal to 0.0125 mg of TiO_2, which is equivalent to 0.05 percent TiO_2 when used as outlined in Sections 10.4.4 through 10.4.6.

10.3.8. *Sulfuric Acid* (1 + 1).

10.3.9. *Tiron* (disodium-1, 2-dihydroxybenzene-3, 5 disulfonate).

10.4. *Procedure*:

10.4.1. Prepare a series of TiO_2 solutions to cover the range from 0 to 1.0 percent TiO_2. Prepare each solution in a 50-mL volumetric flask (Note 31).

Note 31—One milliliter of dilute TiO_2 standard solution B per 50 mL (Section 10.3.7.1) is equivalent to 0.05 percent TiO_2 for a 0.2500-g cement sample. Aliquots of 0, 5, 10, 15, and 20 mL of dilute TiO_2 standard solution are equivalent to TiO_2 contents in the sample of 0, 0.25, 0.50, 0.75, and 1.0 percent. Dilute each to 25 mL with water.

10.4.2. Develop color in accordance with Section 10.4.4 starting with second sentence. Measure absorbance in accordance with Section 10.4.5.

10.4.3. Plot absorbance values obtained as ordinates and the corresponding TiO_2 concentrations as abscissas. Draw a smooth curve through the points (Note 32).

Note 32—A suitable paper for plotting the calibration curve is a linear cross-section paper having 10 × 10 divisions to 10 mm. A scale division equivalent to 0.002 absorbance and 0.002 percent TiO_2 should be used. A separate calibration curve should be made for each spectrophotometer used.

10.4.4. Transfer a 25.0-mL aliquot of the sample solution prepared in Section 9.4.5 into a 50-mL volumetric flask (Note 33). Add 5 mL tiron and 5 mL EDTA, mix, and then add NH_4OH (1 + 1) dropwise, mixing thoroughly after each drop, until the color changes through yellow to green, blue, or ruby red. Then, *just restore* the yellow color with HCl (1 + 6) *added dropwise and mixing after each drop*. Add 5 mL buffer, dilute to volume and mix.

10.4.5. Measure the absorbance of the solution against water as the reference at 410 nm.

Note 33—The range of the test can be extended by taking a smaller aliquot. The results of the test must then be calculated accordingly.

10.4.6. Using the absorbance value determined in Section 10.4.5, record the percentage of TiO_2 in the cement sample as indicated by the calibration curve to the nearest 0.01. Correct for the iron present in the sample to obtain the true TiO_2 as follows: True TiO_2 = measured % TiO_2 – (0.01 × % Fe_2O_3). Report the percent of TiO_2 rounded in accordance with Table 3.

11. ZINC OXIDE (REFERENCE TEST METHOD)[5]

11.1. Any test method may be used that meets the requirements of Section 3.3 and Table 1.

11.2. Report the result rounded in accordance with Table 3.

12. ALUMINUM OXIDE (REFERENCE TEST METHOD)

Note 34—In the referee test method, Al_2O_3 is calculated from the ammonium hydroxide group by subtracting the separately determined constituents that usually are present in significant amounts in the ammonium hydroxide precipitate. These are Fe_2O_3, TiO_2 and P_2O_5. Most instrumental test methods for Al_2O_3 analysis give Al_2O_3 alone if standardized and calibrated properly.

12.1. *Calculation*:

12.1.1. Calculate the percentage of Al_2O_3 by deducting the percentage of the sum of the Fe_2O_3, TiO_2, and P_2O_5 from the percentage of ammonium hydroxide group, using un-rounded values of all four quantities. All determinations shall be by referee test methods described in the appropriate sections herein. All percentages shall be calculated to the nearest 0.01 percent. Report the Al_2O_3 rounded in accordance with Table 3. For nonreferee analyses, the percentages of Fe_2O_3 TiO_2, and P_2O_5 can be determined by any procedure for which qualification has been shown.

13. CALCIUM OXIDE (REFERENCE TEST METHOD)

13.1. *Summary of Test Method*:

13.1.1. In this test method, manganese is removed from the filtrate after the determination of SiO_2 and the ammonium hydroxide group. Calcium is then precipitated as the oxalate. After filtering, the oxalate is redissolved and titrated with potassium permanganate ($KMnO_4$).

Note 35—For referee analysis or for the most accurate determinations, removal of manganese in accordance with Section 13.3.2 must be made. For less accurate determinations and when only insignificant amounts of manganese oxides are believed present, Section 13.3.2 may be omitted.

13.1.2. Strontium, usually present in portland cement as a minor constituent, is precipitated with calcium as the oxalate and is subsequently titrated and calculated as CaO. If the SrO content is known and correction of CaO for SrO is desired as, for example, for research purposes or to compare results with CRM certificate values, the CaO obtained by this test method may be corrected for SrO. In determining conformance of a cement to specifications, the correction of CaO for SrO should not be made.

13.2. *Reagents*:

13.2.1. *Ammonium Oxalate Solution* (50 g/L).

13.2.2. *Potassium Permanganate, Standard Solution* (0.18 *normal*)—Prepare a solution of potassium permanganate ($KMnO_4$) containing 5.69 g/L. Let this solution stand at room temperature for at least one week or boil and cool to room temperature. Siphon off the clear solution without disturbing the sediment on the bottom of the bottle; then filter the siphoned solution through a bed of glass wool in a funnel or through a suitable sintered glass filter. Do not filter through materials containing organic matter. Store in a dark bottle, preferably one that has been painted black on the outside. Standardize the solution against 0.7000 to 0.8000 g of primary standard sodium oxalate, according to the directions furnished with the sodium oxalate and record the temperature at which the standardization was made (Note 36).

13.2.2.1. Calculate the CaO equivalent of the solution as follows:

1 mL of 1*N* $KMnO_4$ solution is equivalent to 0.6701 g of pure sodium oxalate.

$$\text{Normality of } KMnO_4 = \frac{\text{mass of sodium oxalate} \times \text{fraction of its purity}}{\text{mL of } KMnO_4 \text{ solution} \times 0.06701} \qquad (3)$$

1 mL of 1 *N* $KMnO_4$ solution is equivalent to 28.04 mg of CaO.

$$F = \frac{\text{normality of } KMnO_4 \text{ solution} \times 0.02804 \times 100}{0.5}$$

where:

F = CaO equivalent of the $KMnO_4$ solution in percent CaO/mL based on a 0.5-g sample of cement.

Note 36—Because of the instability of the $KMnO_4$ solution, it is recommended that it be restandardized at least bimonthly.

13.3. *Procedure*:

13.3.1. Acidify the combined filtrates obtained in the precipitations of the ammonium hydroxide group (Section 7.2.2). Neutralize with HCl to the methyl red end point, make just acid, and add six drops of HCl in excess.

13.3.2. *Removal of Manganese*—Evaporate to a volume of about 100 mL. Add 40 mL of saturated bromine water to the hot solution and immediately add NH_4OH until the solution is distinctly alkaline. Addition of 10 mL of NH_4OH is generally sufficient. A piece of filter paper, about 1 cm^2 in area, placed in the heel of the beaker and held down by the end of a stirring rod aids in preventing bumping and initiating precipitation of hydrated manganese oxides (MnO). Boil the solution for five minutes or more, making certain that the solution is distinctly alkaline at all times. Allow the precipitate to settle, filter using medium-textured paper, and wash with hot water. If a precipitate does not appear immediately, allow a settling period of up to one hour before filtration. Discard any manganese dioxide that may have been precipitated. Acidify the filtrate with HCl using litmus paper as an indicator, and boil until all the bromine is expelled (Note 37).

13.3.3. Add 5 mL of HCl, dilute to 200 mL, and add a few drops of methyl red indicator and 30 mL of warm ammonium oxalate solution (50 g/L) (Note 38). Heat the solution to 70° to 80°C, and add NH_4OH (1 + 1) dropwise, while stirring until the color changes from red to yellow (Note 39). Allow the solution to stand without further heating for 60 ± 5 minutes (no longer), with occasional stirring during the first 30 minutes.

13.3.4. Filter, using retentive paper, and wash the precipitate 8 to 10 times with hot water, the total amount of water used in rinsing the beaker and washing not to exceed 75 mL. During this washing, water from the wash bottle should be directed around the inside of the filter paper to wash the precipitate down, then a jet of water should be gently directed towards the center of the paper in order to agitate and thoroughly wash the precipitate. Acidify the filtrate with HCl and reserve for the determination of MgO.

13.3.5. Place the beaker in which the precipitation was made under the funnel, pierce the apex of the filter paper with the stirring rod, place the rod in the beaker, and wash the precipitate into the beaker by using a jet of hot water. Drop about 10 drops of H_2SO_4 (1 + 1) around the top edge of the filter paper. Wash the paper five more times with hot water. Dilute to 200 mL, and add 10 mL of H_2SO_4 (1 + 1). Heat the solution to a temperature just below boiling, and titrate it immediately with the 0.18 *N* $KMnO_4$ solution (Note 40). Continue the titration slowly until the pink color persists for at least 10 seconds. Add the filter paper that contained the original precipitate and macerate it. If the pink color disappears, continue the titration until it again persists for at least 10 seconds.

Note 37—Potassium iodide starch paper may be used to indicate the complete volatilization of the excess bromine. Expose a strip of moistened paper to the fumes from the boiling solution. The paper should remain colorless. If it turns blue, bromine is still present.

Note 38—If the ammonium oxalate solution is not perfectly clear, it should be filtered before use.

Note 39—This neutralization must be made slowly, otherwise precipitated calcium oxalate may have a tendency to run through the filter paper. When a number of these determinations are being made simultaneously, the following technique will assist in ensuring slow neutralization. Add two or three drops of NH_4OH to the first beaker while stirring, then two or three drops to the second, and so on, returning to the first beaker to add two or three more drops, etc., until the indicator color has changed in each beaker.

Note 40—The temperature of the 0.18 *N* $KMnO_4$ solution at time of use should not vary from its standardization temperature by more than 5.5°C (10°F). Larger deviations could cause serious error in the determination of CaO.

13.3.6. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents (Note 41), and record the milliliters of $KMnO_4$ solution required to establish the end point.

Note 41—When the amount of calcium oxalate is very small, its oxidation by $KMnO_4$ is slow to start. Before the titration, add a little $MnSO_4$ to the solution to catalyze the reaction.

13.4. *Calculation*:

13.4.1. Calculate the percentage of CaO as follows:

$$\text{CaO, \%} = E\left(V - B\right) \tag{4}$$

where:

E = CaO equivalent of the $KMnO_4$ solution in percent CaO/mL based on a 0.5-g sample,

V = milliliters of $KMnO_4$ solution required by the sample, and

B = milliliters of $KMnO_4$ solution required by the blank.

Report the results rounded in accordance with Table 3.

13.4.2. If desired calculate the percentage of CaO corrected for SrO as follows:

$$\text{CaO}_c\,\% = \text{CaO}_i\,\% - 0.54\ \text{SrO}\ \% \tag{5}$$

where:

CaO_c= CaO corrected for SrO,

CaO_i= initial CaO as determined in Section 13.4.1, and

$$0.54 = \frac{56.08}{103.62} = \text{molecular mass ratio, } \frac{\text{CaO}}{\text{SrO}}.$$

---

14. MAGNESIUM OXIDE (REFERENCE TEST METHOD)

14.1. *Summary of Test Method*—In this test method, magnesium is precipitated as magnesium ammonium phosphate from the filtrate after removal of calcium. The precipitate is ignited and the mass is determined as magnesium pyrophosphate ($Mg_2P_2O_7$). The MgO equivalent is then calculated.

14.2. *Reagent*—Ammonium phosphate, dibasic (100 g/L) $(NH_4)_2HPO_4$.

14.3. *Procedure*:

14.3.1. Acidify the filtrate from the determination of CaO (Section 13.3.4) with HCl and evaporate by boiling to about 250 mL. Cool the solution to room temperature, add 10 mL of ammonium phosphate, dibasic, $(NH_4)_2HPO_4$ (100 g/L), and 30 mL of NH_4OH. Stir the solution vigorously during the addition of NH_4OH and then for 10 to 15 minutes longer. Let the solution stand for at least eight hours in a cool atmosphere and filter. Wash the residue five or six times with NH_4OH (1 + 20) and ignite in a tared platinum or porcelain crucible, at first slowly until the filter paper is charred and then burned off (see Section 14.4.1), and finally at 1100°C for 30 to 45 minutes. Determine the mass of the residue as magnesium pyrophosphate ($Mg_2P_2O_7$).

14.3.2. *Blank*—Make a blank determination following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

14.4. *Calculation*:

14.4.1. Calculate the percentage of MgO as follows:

$$\text{MgO, \%} = W \times 72.4 \qquad (6)$$

where:

W = grams of $Mg_2P_2O_7$, and

72.4 = molecular ratio of 2 MgO to $Mg_2P_2O_7$ (0.362) divided by the mass of sample used (0.5 g) and multiplied by 100.

Report the results rounded in accordance with Table 3.

Warning—Extreme caution should be exercised during this ignition. Reduction of the phosphate precipitate can result if carbon is in contact with it at high temperatures. There is also danger of occluding carbon in the precipitate if ignition is too rapid.

---

15. SULFUR (SEE NOTE 42)

15.1. *Sulfur Trioxide (Reference Test Method)*:

15.1.1. *Summary of Test Method*—In this test method, sulfate is precipitated from an acid solution of the cement with barium chloride ($BaCl_2$). The precipitate is ignited and the mass is determined as barium sulfate ($BaSO_4$) and the SO_3 equivalent is calculated.

15.1.2. *Procedure*:

15.1.2.1. To 1 g of the sample add 25 mL of cold water and, while the mixture is stirred vigorously, add 5 mL of HCl (Note 43). If necessary, heat the solution and grind the material with the flattened end of a glass rod until it is evident that decomposition of the cement is complete (Note 44). Dilute the solution to 50 mL and digest for 15 minutes at a temperature just below boiling. Filter through a medium-textured paper and wash the residue thoroughly with hot water. Dilute the filtrate to 250 mL and heat to boiling. Add slowly, dropwise, 10 mL of hot $BaCl_2$ (100 g/L) and continue the boiling until the precipitate is well formed. Digest the solution for 12 to 24 hours at a temperature just below boiling (Note 45). Take care to keep the volume of solution between 225 and 260 mL and add water for this purpose if necessary. Filter through a retentive paper, wash the precipitate thoroughly with hot water, place the paper and contents in a weighed platinum crucible, and slowly char and consume the paper without inflaming. Ignite at 800° to 900°C, cool in a desiccator, and determine the mass.

Note 42—When an instrument test method is used for sulfur or when comparing results of classical wet and instrumental test methods, consult Section 4.1.2 of these test methods.

Note 43—The acid filtrate obtained in the determination of the insoluble residue (Section 5.3.1) may be used for the determination of SO_3 instead of using a separate sample.

Note 44—A brown residue due to compounds of manganese may be disregarded. (See Note 10.)

Note 45—If a rapid determination is desired, immediately after adding the $BaCl_2$, place the beaker with the solution in an ultrasonic bath for 5 minutes, and then continue the determination starting with "Filter through a retentive paper…". Qualify the method in accordance with the Performance Requirements for Rapid Test Methods.

15.1.3. *Blank*—Make a blank determination following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

15.1.4. *Calculation*—Calculate the percentage of SO_3 as follows:

$$\mathrm{SO_3}, \% = W \times 34.3 \qquad (7)$$

where:

W = grams of $BaSO_4$, and

34.3 = molecular ratio of SO_3 to $BaSO_4$ (0.343) multiplied by 100.

Report the results rounded in accordance with Table 3.

15.2. *Sulfide (Reference Test Method)*:

15.2.1. *Summary of Test Method*—In this test method sulfide sulfur is determined by evolution as hydrogen sulfide (H_2S) from an acid solution of the cement into a solution of ammoniacal zinc sulfate ($ZnSO_4$) or cadmium chloride ($CdCl_2$). The sulfide sulfur is then titrated with a standard solution of potassium iodate (KIO_3). Sulfites, thiosulfates, and other compounds intermediate between sulfides and sulfates are assumed to be absent. If such compounds are present, they may cause an error in the determination.

15.2.2. *Apparatus*:

15.2.2.1. *Gas-Generating Flask*—Connect a dry 500-mL boiling flask with a long-stem separatory funnel and a small connecting bulb by means of a rubber stopper. Bend the stem of the funnel so that it will not interfere with the connecting bulb, adjust the stem so that the lower end is close to the bottom of the flask, and connect the opening of the funnel with a source of compressed air. Connect the bulb with an L-shaped glass tube and a straight glass tube about 200 mm in length. Insert the straight glass tube in a tall-form, 400-mL beaker. A three-neck distilling flask with a long glass tubing in the middle opening, placed between the source of compressed air and the funnel, is a convenient aid in the regulation of the airflow. Rubber used in the apparatus shall be pure gum grade, low in sulfur, and shall be cleaned with warm HCl.

15.2.3. *Reagents*:

15.2.3.1. *Ammoniacal Cadmium Chloride Solution*—Dissolve 15 g of cadmium chloride ($CdCl_2 \cdot 2H_2O$) in 150 mL of water and 350 mL of NH_4OH. Filter the solution after allowing it to stand at least 24 hours.

15.2.3.2. *Ammoniacal Zinc Sulfate Solution*—Dissolve 50 g of zinc sulfate ($ZnSO_4 \cdot 7H_2O$) in 150 mL of water and 350 mL of NH_4OH. Filter the solution after allowing it to stand at least 24 hours.

15.2.3.3. *Potassium Iodate, Standard Solution* (0.03 *N*)—Prepare a solution of potassium iodate (KIO_3) and potassium iodide (KI) as follows: Dry KIO_3 at 180°C to constant mass. Dissolve 1.0701 g of the KIO_3 and 12 g of KI and dilute to 1 L in a volumetric flask. This is a primary standard and requires no standardization (Note 46). One milliliter of this solution is equivalent to 480.9 μg of sulfur.

Note 46—The solution is very stable, but may not maintain its titer indefinitely. Whenever such a solution is over one year old it should be discarded or its concentration checked by standardization.

15.2.3.4. *Stannous Chloride Solution*—To 10 g of stannous chloride ($SnCl_2 \cdot 2H_2O$) in a small flask, add 7 mL of HCl (1 + 1), warm the mixture gently until the salt is dissolved, cool the solution, and add 95 mL of water. This solution should be prepared as needed, as the salt tends to hydrolyze.

15.2.3.5. *Starch Solution*—To 100 mL of boiling water, add a cool suspension of 1 g of soluble starch in 5 mL of water and cool. Add a cool solution of 1 g of sodium hydroxide (NaOH) in 10 mL of water, then 3 g of potassium iodide (KI), and mix thoroughly.

15.2.4. *Procedure*:

15.2.4.1. Place 15 mL of the ammoniacal $ZnSO_4$ or $CdCl_2$ solution (Note 47) and 285 mL of water in a beaker. Put 5 g of the sample (Note 48) and 10 mL of water in the flask and shake the flask gently to wet and disperse the cement completely. This step and the addition of $SnCl_2$ should be performed rapidly to prevent the setting of the cement. Connect the flask with the funnel and bulb. Add 25 mL of the $SnCl_2$ solution through the funnel and shake the flask. Add 100 mL of HCl (1 + 3) through the funnel and shake the flask. During these shakings keep the funnel closed and the delivery tube in the ammoniacal $ZnSO_4$ or $CdCl_2$ solution. Connect the funnel with the source of compressed air, open the funnel, start a slow stream of air, and heat the flask and contents slowly to boiling. Continue the boiling gently for five or six minutes. Cut off the heat, and continue the passage of air for three or four minutes. Disconnect the delivery tube and leave it in the solution for use as a stirrer. Cool the solution to 20° to 30°C (Note 49), add 2 mL of the starch solution and 40 mL of HCl (1 + 1), and titrate immediately with the 0.03 *N* KIO_3 solution until a persistent blue color is obtained (Note 50).

Note 47—In general the $ZnSO_4$ is preferable to the $CdCl_2$ solution because $ZnSO_4$ is more soluble in NH_2OH than is $CdCl_2$. The $CdCl_2$ solution may be used when there is doubt as to the presence of a trace of sulfide sulfur, as the yellow cadmium sulfide (CdS) facilitates the detection of a trace.

Note 48—If the content of sulfur exceeds 0.20 or 0.25 percent, a smaller sample should be used so that the titration with the KIO_3 solution will not exceed 25 mL.

Note 49—The cooling is important as the end point is indistinct in a warm solution.

Note 50—If the content of sulfur is appreciable but not approximately known in advance, the result may be low due to the loss of H_2S during a slow titration. In such a case the determination should be repeated with the titration carried out more rapidly.

15.2.4.2. Make a blank determination, following the same procedure and using the same amounts of reagents. Record the volume of KIO_3 solution necessary to establish the end point as described in Section 15.2.4.1.

15.2.5. *Calculation*—Calculate the percentage of sulfide sulfur (Section 15.2.1) as follows:

$$\text{Sulfide, \%} = E\left(V - B\right) \times 20 \qquad (8)$$

where:

E = sulfide equivalent of the KIO_3 solution, g/mL;

V = milliliters of KIO_3 solution required by the sample;

B = milliliters of KIO_3 solution required by the blank; and

20 = 100 divided by the mass of sample used (5 g).

Report the result rounded in accordance with Table 3.

16. LOSS ON IGNITION (REFERENCE TEST METHOD)

16.1. *Portland Cement*:

16.1.1. *Summary of Test Method*—In this test method, the cement is ignited in a muffle furnace at a controlled temperature. The loss is assumed to represent the total moisture and CO_2 in the cement. This procedure is not suitable for the determination of the loss on ignition of portland blast-furnace slag cement and of slag cement. A test method suitable for such cements is described in Sections 16.2.1 through 16.2.3.

16.1.2. *Procedure*—Weigh 1 g of the sample in a tared platinum crucible. Cover and ignite the crucible and its contents to constant mass in a muffle furnace at a temperature of 950° ± 50°C. Allow a minimum of 15 minutes for the initial heating period and at least five minutes for all subsequent periods.

16.1.3. *Calculation*—Calculate the percentage of loss on ignition by multiplying the loss of mass in grams by 100. Report the result rounded in accordance with Table 3.

16.2. *Portland Blast-Furnace Slag Cement and Slag Cement*:

16.2.1. *Summary of Test Method*—Since it is desired that the reported loss on ignition represent moisture and CO_2, this test method provides a correction for the gain in mass due to oxidation of sulfides usually present in portland blast-furnace slag cement and slag cement by determining the increase in SO_3 content during ignition. An optional test method providing for a correction based on the decrease in sulfide sulfur during ignition is given in Sections 24.1.1 through 24.1.3.

16.2.2. *Procedure*:

16.2.2.1. Weigh 1 g of cement into a tared platinum crucible and ignite a muffle furnace at a temperature of 950° ± 50°C for 15 minutes. Cool to room temperature in a desiccator and determine the mass. Without checking for constant mass, carefully transfer the ignited material to a 400-mL beaker. Break up any lumps in the ignited cement with the flattened end of a glass rod.

16.2.2.2. Determine the SO_3 content by the test method given in Sections 15.1.2 through 15.1.4 (Note 51). Also determine the SO_3 content of a portion of the same cement that has not been ignited, using the same procedure.

Note 51—Some of the acid used for dissolving the sample may first be warmed in the platinum crucible to dissolve any adhering material.

16.2.3. *Calculation*—Calculate the percentage loss of mass occurring during ignition and add 0.8 times the difference between the percentages of SO_3 in the ignited sample and the original cement (Note 52). Report the corrected percentage, rounded in accordance with Table 3, as loss on ignition.

Note 52—If a gain in mass is obtained during ignition, subtract the percentage gain from the correction for SO_3.

17. SODIUM AND POTASSIUM OXIDE (REFERENCE TEST METHOD)

17.1. *Total Alkalies*:

17.1.1. *Summary of Test Method*—This test method covers the determination of sodium oxide (Na_2O) and potassium oxide (K_2O) by flame photometry or atomic absorption.[6]

Note 53—This test method is suitable for hydraulic cements that are completely decomposed by hydrochloric acid and should not be used for determination of total alkalies in hydraulic cements that contain large amounts of acid-insoluble material, for example, pozzolan cements. It may be used to determine acid-soluble alkalies for such cements. An alternate test method of sample dissolution for such cements is in preparation.

17.1.2. *Apparatus*:

17.1.2.1. *Instrument*—Any type flame photometer or atomic absorption unit may be used provided it can be demonstrated that the required degree of accuracy and precision is as indicated in Section 17.1.3.

Note 54—After such accuracy is established, for a specific instrument, further tests of instrument accuracy are not required except in cases of dispute when it must be demonstrated that the instrument gives results within the prescribed degree of accuracy by a single series of tests using the designated standard samples.

Note 55—For normal laboratory testing, it is recommended that the accuracy of the instrument be routinely checked by the use of either a National Institute of Standards and Technology cement or cement of known alkali content.

17.1.2.2. The instrument shall consist of an atomizer and burner; suitable pressure-regulating devices and gauges for fuel and oxident gas; an optical system capable of preventing excessive interference from wavelengths of light other than that being measured; and a photosensitive indicating device.

17.1.3. *Initial Qualification of Instrument*— Qualify the instrument in accordance with Section 3.3.2. to establish that an instrument provides the desired degree of precision and accuracy.

17.1.4. *Reagents and Materials*:

17.1.4.1. *Laboratory Containers*—All glassware shall be made of borosilicate glass and all polyethylene shall comply with the requirements of Section 4.2.3.

17.1.4.2. *Calcium Carbonate*—The calcium carbonate ($CaCO_3$) used in the preparation of the calcium chloride stock solution (Section 17.1.5.1) shall contain not more than 0.020 percent total alkalies as sulfate.

Note 56—Materials sold as a primary standard or ACS "low alkali" grade normally meet this requirement. However, the purchaser should assure himself that the actual material used conforms with this requirement.

17.1.4.3. *Potassium Chloride* (KCl).

17.1.4.4. *Sodium Chloride* (NaCl).

17.1.4.5. Commercially available solutions may be used in place of those specified in Section 17.1.5.

17.1.5. *Preparation of Solutions*:

17.1.5.1. *Calcium Chloride Stock Solution*—Add 300 mL of water to 112.5 g of $CaCO_3$ in a 1500-mL beaker. While stirring, slowly add 500 mL of HCl. Cool the solution to room temperature, filter into a 1-L volumetric flask, dilute to 1 L, and mix thoroughly. This solution contains the equivalent of 63,000 mg/L (6.30 percent) CaO.

17.1.5.2. *Sodium-Potassium Chloride Stock Solution*—Dissolve 1.8858 g of sodium chloride (NaCl) and 1.583 g of potassium chloride (KCl) (both dried at 105° to 110°C for several hours prior to the mass determination) in water. Dilute to 1 L in a volumetric flask and mix thoroughly. This solution contains the equivalent of 1000 mg/L (0.10 percent) each of Na_2O and K_2O. Separate solutions of Na_2O and of K_2O may be used provided that the same concentration solutions are used for calibration for cement analysis as were used for the calibration when qualifying the instrument in accordance with Section 17.1.3.

17.1.5.3. *Standard Solutions*—Prepare the standard solutions prescribed for the instrument and method used. Measure the required volume of NaCl-KCl stock solutions in calibrated pipets or burets. The calcium chloride stock solutions, if needed, may be measured in appropriate graduated cylinders. If the instrument being used requires an internal standard, measure the internal standard solution with a pipet or buret. Place each solution in a volumetric flask, dilute to the indicated volume, and mix thoroughly.

17.1.5.4. If more dilute solutions are required by the method in use, pipet the required aliquot to the proper sized volumetric flask, add any necessary internal standard, dilute to the mark, and mix thoroughly.

17.1.6. *Calibration of Apparatus*:

Note 57—No attempt is made in this section to describe in detail the steps for putting the instrument into operation since this will vary considerably with different instruments. The manufacturer's instructions should be consulted for special techniques or precautions to be employed in the operation, maintenance, or cleaning of the apparatus.

17.1.6.1. Turn on the instrument and allow it to warm up in accordance with the manufacturer's instructions. (A minimum of 30 minutes is required for most instruments.) Adjust the fuel and oxidant gas pressures as required by the instrument being used. Light and adjust the burner for optimum operation. Make any other adjustments that may be necessary to establish the proper operating conditions for the instrument.

17.1.7. *Procedure*:

17.1.7.1. *Solution of the Cement*—Prepare the solution of the cement in accordance with the procedure specified by the instrument manufacturer. If no procedure is specified, or if desired, proceed as specified in Section 17.1.7.1.1 or 17.1.7.1.2 (Note 58).

Note 58—The presence of SiO_2 in solution affects the accuracy of some flame photometers. In cases where an instrument fails to provide results within the prescribed degree of accuracy outlined in Sections 3.3.2.1 through 3.3.3, tests should be made on solutions from which the SiO_2 has been removed. For this removal proceed as in Section 17.1.7.1.2.

17.1.7.1.1. Place 1.000 ± 0.001 g of the cement in a 150-mL beaker and disperse with 20 mL of water using a swirling motion of the beaker. While still swirling, add 5.0 mL of HCl all at once. Dilute immediately to 50 mL with water. Break up any lumps of cement remaining undispersed with a flat-end stirring rod. Digest on a steam bath or hot plate for 15 minutes, then filter through a medium-textured filter paper into a 100-mL volumetric flask. Wash beaker and paper thoroughly with hot water, cool contents of the flask to room temperature, dilute to 100 mL, and mix the solution thoroughly. Continue as stated in Section 17.1.7.2.

17.1.7.1.2. Place 1.000 ± 0.001 g of cement into a platinum evaporating dish and disperse with 10 mL of water using a swirling motion. While still swirling, add 5.0 mL of HCl all at once. Break up any lumps with a flat-end stirring rod and evaporate to dryness on a steam bath. Make certain that the gelatinous appearance is no longer evident. Treat the residue with 2.5 mL of HCl and about 20 mL of water. Digest on a steam bath for 5 to 10 minutes and filter immediately through a 9-cm medium-textured filter paper into a 100-mL volumetric flask. Wash thoroughly with repeated small amounts of hot water until the total volume of solution is 80 to 95 mL. Cool to room temperature, dilute to the mark, and mix thoroughly.

When it has been demonstrated that the removal of SiO_2 is necessary to obtain the required accuracy described in Sections 3.3.2.1 through 3.3.3 for a specific flame photometer, SiO_2 must always be removed when making analyses that are used as the basis for rejection of a cement for failure to comply with specifications or where specification compliance may be in question. Where there is no question as to specification compliance, analyses may be made by such instruments without SiO_2 removal provided the deviations from certificate values obtained by the tests prescribed in Sections 3.3.2.1 through 3.3.3 are not more than twice the indicated limits.

17.1.7.2. If the test method in use requires more dilute solutions, an internal standard, or both, carry out the same dilutions as in Section 17.1.5.4 as needed. The standard and the sample solutions to be analyzed must be prepared in the same way and to the same dilution as the solutions of standard cements analyzed for the qualification of the instrument.

17.1.7.3. *Procedure for Na_2O* (Note 60)—Warm up and adjust the instrument for the determination of Na_2O as described in Section 17.1.6.1. Immediately following the adjustment and without changing any instrumental settings, atomize the cement solution and note the scale reading (Note 59). Select the standard solutions which immediately bracket the cement solution in Na_2O content and observe their readings. Their values should agree with the values previously established during calibration of the apparatus. If not, recalibrate the apparatus for that constituent. Finally, alternate the use of the unknown solution and the bracketing standard solutions until readings of the unknown agree within one division on the transmission or meter scale, or within 0.01 mass percent for instruments with digital readout, and readings for the standards similarly agree with the calibration values. Record the average of the last two readings obtained for the unknown solution.

Note 59—The order in determining Na_2O or K_2O is optional. In all cases, however, the determination should immediately follow the adjustment of the instrument for that particular constituent.

17.1.7.4. If the reading exceeds the scale maximum, either transfer a 50-mL aliquot of the solution prepared in Section 17.1.7.1 to a 100-mL volumetric flask or, if desired, prepare a new solution by using 0.500 g of cement and 2.5 mL of HCl (instead of 5.0 mL) in the initial addition of acid. In the event silica has to be removed from the 0.5-g sample of cement, treat the dehydrated material with 1.25 mL of HCl and about 20 mL of water, then digest, filter, and wash. In either case, add 5.0 mL of calcium chloride stock solution (Section 17.1.5.1) before diluting to mark with water. Dilute to the mark. Proceed as in Section 17.1.5.4 if more dilute solutions are required by the test method in use. Determine the alkali content of this solution as described in Section 17.1.7.3 and multiply the percentage of alkali oxide by a factor of 2.

17.1.7.5. *Procedure for K_2O*—Repeat the procedure described in Section 17.1.7.3 except that the instrument shall be adjusted for the determination of K_2O. For instruments that read both Na_2O and K_2O simultaneously, determine K_2O at the same time as determining Na_2O.

17.1.8. *Calculation and Report*—From the recorded averages for Na_2O and K_2O in the unknown sample, report each oxide rounded in accordance with Table 3.

17.2. *Water-Soluble Alkalies*:

Note 60—The determination of water-soluble alkali should not be considered as a substitute for the determination of total alkali according to Sections 17.1.2.1 through 17.1.8. Moreover, it is not to be assumed that in this method all water-soluble alkali in the cement will be dissolved. Strict adherence to the procedure described is essential where there is a specified limit on the content of water-soluble alkali or where several lots of cement are compared on the basis of water-soluble alkali.

17.2.1. *Procedure*:

17.2.1.1. Weigh 25.0 g of sample into a 500-mL Erlenmeyer flask and add 250 mL of water. Stopper the flask with a rubber stopper and shake continuously for 10 minutes at room temperature. Filter through a Büchner funnel that contains a well-seated retentive, dry filter paper into a 500-mL filtering flask, using a weak vacuum. Do not wash.

17.2.1.2. Transfer a 50-mL aliquot (Note 61) of the filtrate to a 100-mL volumetric flask and acidify with 0.5 mL of concentrated HCl (sp gr 1.19). Add 9.0 mL of stock $CaCl_2$ solution (63,000 mg/L CaO), described in Section 17.1.5.1, to the 100-mL flask, and dilute the solution to 100 mL. If the test method in use requires more dilute solutions, an internal standard, or both, carry out the same dilutions as in Section 17.1.5.4. as needed. Determine the Na_2O and K_2O contents of this solution as described in Sections 17.1.7.3 and 17.1.7.5. Record the parts per million of each alkali in the solution in the 100-mL flask.

Note 61—The aliquot of the filtrate taken for the analysis should be based on the expected water-soluble alkali content. If the expected level of either K_2O or Na_2O is more than 0.08 mass percent of cement, or if the water soluble alkali level is unknown, a 50-mL aliquot as given in Section 17.2.1.2 should be used to make up the initial test solution. If either the Na_2O or K_2O exceeds

0.16 percent, place a 50-mL aliquot of the solution from Section 17.2.1.2 in a 100-mL volumetric flask, add 5 mL of $CaCl_2$ stock solution and dilute to 100 mL. When the level of either K_2O or Na_2O is less than 0.08 percent, take a 100-mL aliquot from the original filtrate (obtained by Section 17.2.1.1), add 1 mL of HCl, and evaporate on a hot plate in a 250-mL beaker to about 70 mL. Add 8 mL of stock $CaCl_2$ solution and transfer the sample to a 100-mL volumetric flask, rinsing the beaker with a small portion of distilled water. Cool the solution to room temperature and dilute to 100 mL.

17.2.2. *Calculations*—Calculate the percentage of the water-soluble alkali, expressed as Na_2O, as follows:

$$\text{Total Water-Soluble Alkali, as } Na_2O = A + E \tag{9}$$

$$A = B/(V \times 10)$$

$$C = D/(V \times 10)$$

$$E = C \times 0.658$$

where:

A = percentage of water-soluble sodium oxide (Na_2O),
B = parts per million of Na_2O in the solution in the 100-mL flask,
V = milliliters of original filtrate in the 100-mL flask,
C = percent of water-soluble potassium oxide (K_2O),
D = parts per million of K_2O in the 100-mL flask,
E = percentage Na_2O equivalent to K_2O determined, and
0.658 = molecular ratio of Na_2O to K_2O.

Report the result rounded in accordance with Table 3.

18. MANGANIC OXIDE (REFERENCE TEST METHOD)

18.1. *Summary of Test Method*—In this procedure, manganic oxide is determined volumetrically by titration with sodium arsenite solution after oxidizing the manganese in the cement with sodium metabismuthate ($NaBiO_3$).

18.2. *Reagents*:

18.2.1. *Sodium Arsenite, Standard Solution* (1 mL = 0.3 mg Mn_2O_3)—Dissolve in 100 mL of water 3.0 g of sodium carbonate (Na_2CO_3) and then 0.90 g of arsenic trioxide (As_2O_3), heating the mixture until the solution is as complete as possible. If the solution is not clear or contains a residue, filter the solution. Cool it to room temperature, transfer to a volumetric flask, and dilute to 1 L.

18.2.1.1. Dissolve 0.58 g of potassium permanganate ($KMnO_4$) in 1 L of water and standardize it against about 0.03 g of sodium oxalate ($Na_2C_2O_4$) oxidimetric standard furnished by NIST (Standard Sample No. 40 or its replacement) according to the directions furnished with the sodium oxalate. Put 30.0 mL of the $KMnO_4$ solution in a 250-mL Erlenmeyer flask. Add 60 mL of HNO_3 (1 + 4) and 10 mL of sodium nitrite ($NaNO_2$, 50 g/L) to the flask. Boil the solution until the HNO_2 is completely expelled. Cool the solution, add $NaBiO_3$, and finish by titrating with the standard sodium arsenite ($NaAsO_2$) solution as described in Section 18.3.2. Calculate the manganic oxide (Mn_2O_3) equivalent of the $NaAsO_2$ solution, g/mL, as follows:

$$E = \left(A \times 7.08\right)/BC \tag{10}$$

where:

E = Mn_2O_3 equivalent of the $NaAsO_2$ solution, g/mL;

A = grams of $Na_2C_2O_4$ used;
B = milliliters of $KMnO_4$ solution required by the $Na_2C_2O_4$;
C = milliliters of $NaAsO_2$ solution required by 30.0 mL of $KMnO_4$ solution; and
7.08 = molecular ratio of Mn_2O_3 to 5 $Na_2C_2O_4$ (0.236) multiplied by 30.0 (milliliters of $KMnO_4$ solution).

18.2.2. *Sodium Metabismuthate* ($NaBiO_3$).

18.2.3. *Sodium Nitrite Solution* (50 g $NaNO_2$/L).

18.3. *Procedure*:

18.3.1. Weigh 1.0 to 3.0 g of the sample (Note 62) into a 250-mL beaker and treat it with 5 to 10 mL of water and then with 60 to 75 mL of HNO_3 (1 + 4). Boil the mixture until the solution is as complete as possible. Add 10 mL of $NaNO_2$ solution (50 g/L) to the solution and boil it until the nitrous acid is completely expelled (Note 63), taking care not to allow the volume of the solution to become so small as to cause the precipitation of gelatinous SiO_2. There may be some separated SiO_2, which may be ignored, but if there is still a red or brown residue, use more $NaNO_2$ solution (50 g/L) to effect a complete decomposition, and then boil again to expel the nitrous acid. Filter the solution through a medium-textured paper into a 250-mL Erlenmeyer flask and wash the filter paper with water.

Note 62—The amount of cement taken for analysis depends on the content of manganese, varying from 1 g for about 1 percent of Mn_2O_3 to 3 g for 0.25 percent or less of Mn_2O_3.

Note 63—When $NaNO_2$ is added, the expulsion of HNO2 by boiling must be complete. If any HNO_2 remains in the solution, it will react with the added $NaBiO_3$ and decrease its oxidizing value. If there is any manganese in the cement, the first small quantity of $NaBiO_3$ should bring out a purple color.

18.3.2. The solution should have a volume of 100 to 125 mL. Cool it to room temperature. To the solution add a total of 0.5 g of $NaBiO_3$ in small quantities, while shaking intermittently. After the addition is completed, shake the solution occasionally for five minutes and then add to it 50 mL of cool HNO_3 (1 + 33) which has been previously boiled to expel nitrous acid. Filter the solution through a pad of ignited asbestos in a Gooch crucible or a carbon or fritted-glass filter with the aid of suction. Wash the residue four times with the cool HNO_3 (1 + 33). Titrate the filtrate immediately with the standard solution of $NaAsO_2$. The end point is reached when a yellow color is obtained free of brown or purple tints and does not change upon further addition of $NaAsO_2$ solution.

18.3.3. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

18.4. Calculate the percentage of Mn_2O_3, as follows:

$$\mathrm{Mn_2O_3},\ \% = \left(EV/S\right) \times 100 \qquad (11)$$

where:

E = Mn_2O_3 equivalent of the $NaAsO_2$ solution, g/mL;
V = milliliters of $NaAsO_2$ solution required by the sample; and
S = grams of sample used.

Report the result rounded in accordance with Table 3.

19. CHLORIDE (REFERENCE TEST METHOD)

19.1. *Summary of Test Method*—In this test method, acid-soluble chloride content of cement is determined by the potentiometric titration of chloride with silver nitrate (see Note 64). The procedure is also applicable to clinker and portland cement raw mix. Under the conditions of the test, no constituent normally present in these materials will interfere (see Note 65).

Note 64—In most cases acid-soluble chloride content of a portland cement is total chloride content.

Note 65—Species that form insoluble silver salts or stable silver complexes in acid solution interfere with potentiometric measurements. Thus, iodides and bromides interfere while fluorides will not. Sulfide salts in concentrations typical of these materials should not interfere because they are decomposed by acid treatment.

19.2. *Apparatus*:

19.2.1. *Chloride, Silver/Sulfide Ion Selective Electrode*—or a silver billet electrode coated with silver chloride (Note 66), with an appropriate reference electrode.

19.2.2. *Potentiometer*—with millivolt scale readable to 1 mV or better. A digital read-out is preferred but not required.

19.2.3. *Buret*—Class A, 10-mL capacity with 0.05-mL divisions. A buret of the potentiometric type, having a displaced delivery tip, is convenient, but not required.

Note 66—Suitable electrodes are available from Orion, Beckman Instruments, and Leeds and Northrup. Carefully following the manufacturer's instructions, add filling solution to the electrodes. The silver billet electrodes must be coated electrolytically with a thin, even layer of silver chloride. To coat the electrode, dip the clean silver billet of the electrode into a saturated solution of potassium chloride (about 40 g/L) in water and pass an electric current through the electrode from a 1.5 to 6-V dry cell with the silver billet electrode connected to the positive terminal of the battery. A carbon rod from an all-dry cell or other suitable electrode is connected to the negative terminal and immersed in the solution to complete the electrical circuit. When the silver chloride coating wears off, it is necessary to rejuvenate the electrode by repeating the above procedure. All of the old silver chloride should first be removed from the silver billet by rubbing it gently with fine emery paper followed by water rinsing of the billet.

19.3. *Reagents*:

19.3.1. *Sodium Chloride* (NaCl), primary standard grade.

19.3.2. *Silver Nitrate* ($AgNO_3$), reagent grade.

19.3.3. *Potassium Chloride* (KCl), reagent grade (required for silver billet electrode only).

19.3.4. *Reagent Water* conforming to the requirements of ASTM D 1193 for Type III reagent water.

19.4. *Preparation of Solutions*:

19.4.1. *Sodium Chloride, Standard Solution* (0.05 *N* NaCl)—Dry sodium chloride (NaCl) at 105° to 110°C to a constant mass. Weigh 2.9222 g of dried reagent. Dissolve in water and dilute to exactly

1 L in a volumetric flask and mix thoroughly. This solution is the standard and requires no further standardization.

19.4.2. *Silver Nitrate, Standard Solution* (0.05 *N* $AgNO_3$)—Dissolve 8.4938 g of silver nitrate ($AgNO_3$) in water. Dilute to 1 L in a volumetric flask and mix thoroughly. Standardize against 5.00 mL of standard 0.05 *N* sodium chloride solution diluted to 150 mL with water following the titration test method given in Section 19.5.4 beginning with the second sentence. The exact normality shall be calculated from the average of three determinations as follows:

$$N - 0.25/V \tag{12}$$

where:

N = normality of $AgNO_3$ solution;

0.25 = milliequivalents NaCl (5.0 mL × 0.05 *N*); and

V = volume of $AgNO_3$ solution, mL.

Commercially available standard solutions may be used provided the normality is checked according to the standardization procedure.

19.4.3. *Methyl Orange Indicator*—Prepare a solution containing 2 g of methyl orange per liter of 95 percent ethyl alcohol.

19.5. *Procedure*:

19.5.1. (Note 67). Disperse the sample with 75 mL of water. Without delay slowly add 25 mL of dilute (1 + 1) nitric acid, breaking up any lumps with a glass rod. If the smell of hydrogen sulfide is strongly evident at this point, add 3 mL of hydrogen peroxide (30 percent solution) (Note 68). Add three drops of methyl orange indicator and stir. Cover the beaker with a watch glass and allow to stand for 60 to 120 seconds. If a yellow to yellow-orange color appears on top of the settled solids, the solution is not sufficiently acidic. Add additional dilute nitric acid (1 + 1) dropwise while stirring until a faint pink or red color persists. Then add 10 drops in excess. Heat the covered beaker rapidly to boiling. Do not allow to boil for more than a few seconds. Remove from the hot plate (Note 69).

Note 67—Use a 5-g sample for cement, and other materials having an expected chloride content of less than about 0.15 percent Cl. Use proportionally smaller samples for materials with higher chloride concentrations. Use cement and other powdered materials as is without grinding. Coarse samples require grinding to pass a 0.850-mm (No. 20) sieve. If a sample is too fine, excessive silica gel may form during digestion with nitric acid, thereby slowing subsequent filtration.

Note 68—Slags and slag cements contain sulfide sulfur in concentrations that can interfere with the determination.

Note 69—It is important to keep the beaker covered during heating and digestion to prevent the loss of chloride by volatilization. Excessive amounts of acid should not be used since this results in early removal of the silver chloride coating from the silver billet electrode. A slurry that is only slightly acidic is sufficient.

19.5.2. Wash a 9-cm coarse-textured filter paper with four 25-mL increments of water using suction filtering provided by a 250-mL or 500-mL Büchner funnel and filtration flask. Discard the washings and rinse the flask once with a small portion of water. Reassemble the suction apparatus and filter the sample solution. Rinse the beaker and the filter paper twice with small portions of water. Transfer the filtrate from the flask to a 250-mL beaker and rinse the flask once with water. The original beaker may be used (Note 70). Cool the filtrate to room temperature. The volume should not exceed 175 mL.

Note 70—It is not necessary to clean all the slurry residue from the sides of the beaker nor is it necessary that the filter remove all of the fine material. The titration may take place in a solution containing a small amount of solid matter.

19.5.3. For instruments equipped with dial readout it is necessary to establish an approximate "equivalence point" by immersing the electrodes in a beaker of water and adjusting the instrument to read about 20 mV lower than mid scale. Record the approximate millivoltmeter reading. Remove the beaker and wipe the electrodes with absorbent paper.

19.5.4. To the cooled sample (Note 71) beaker from Section 19.5.2, carefully pipet 2.00 mL of standard 0.05 *N* NaCl solution. Place the beaker on a magnetic stirrer and add a TFE-fluorocarbon-coated magnetic stirring bar. Immerse the electrodes into the solution taking care that the stirring bar does not strike the electrodes; begin stirring gently. Place the delivery tip of the 10-mL buret, filled to the mark with standard 0.05 *N* silver nitrate solution, in (preferably) or above the solution (Note 72).

Note 71—It is advisable to maintain constant temperature during measurement, for the solubility relationship of silver chloride varies markedly with temperature at low concentrations.

Note 72—If the tip of the buret is out of the solution, any adhering droplet should be rinsed onto the beaker with a few milliliters of water following each titration increment.

19.5.5. Gradually titrate, record the amount of standard 0.05 *N* silver nitrate solution required to bring the millivoltmeter reading to –60.0 mV of the equivalence point determined in the water.

19.5.6. Continue the titration with 0.20-mL increments. Record the buret reading and the corresponding millivoltmeter reading in Columns 1 and 2 of a four-column recording form like that shown in Appendix X1. Allow sufficient time between each addition for the electrodes to reach equilibrium with the sample solution. Experience has shown that acceptable readings are obtained when the minimum scale reading does not change within a five-second period (usually within 120 seconds).

19.5.7. As the equivalence point is approached, the equal additions of $AgNO_3$ solution will cause larger and larger changes in the millivoltmeter readings. Past the equivalence point, the change per increment will again decrease. Continue to titrate until three readings past the approximate equivalence point have been recorded.

19.5.8. Calculate the difference in millivolt readings between successive additions of titrant and enter the values in Column 3 of the recording form. Calculate the difference between consecutive values in Column 3 and enter the results in Column 4. The equivalence point of the titration will be within the maximum ΔmV interval recorded in Column 3. The precise equivalence point can be interpolated from the data listed in Column 4 as shown in Appendix X1.

19.5.9. *Blank*—Make a blank determination using 75 mL of water in place of the sample, following the same procedure starting with the third sentence of Section 19.5.1 without delay. Correct the results obtained in the analysis accordingly (Note 73) by subtracting the blank.

19.6. *Calculations*—Calculate the percent chloride as follows:

$$Cl,\% = \frac{3.5453(V_1 - V_2)\,N}{W} \qquad (13)$$

where:

V_1 = milliliters of 0.05 *N* $AgNO_3$ solution used for sample titration (equivalence point),

V_2 = milliliters of 0.05 *N* $AgNO_3$ solution used for blank titration (equivalence point),

N = exact normality of 0.05 *N* $AgNO_3$ solution, and

W = weight of sample, g.

Report the result rounded in accordance with Table 3.

Note 73—For nonreference analysis the blank may be omitted.

20. CHLOROFORM-SOLUBLE ORGANIC SUBSTANCES (REFERENCE TEST METHOD)

20.1. *Summary of Test Method*—This test method was specially designed for the determination of Vinsol resin and tallow in portland cement, although mineral oil, common rosin, calcium stearate, and other fatty acid compounds, and probably some other substances, if present, will be included in the determination.[7] Extreme care is necessary in the entire procedure. The test method may be applied to types of cement other than portland cement, although if the cement contains a large amount of acid-insoluble matter, the emulsions may separate slowly, and less vigorous shaking, more chloroform, and more washing may be necessary.

20.2. *Reagents*:

20.2.1. *Chloroform*—If the blank determination as described in Section 20.3.5 exceeds 1.5 mg, the chloroform should be distilled before use. Chloroform recovered in the procedure may be slightly acid but can be reused for the portions to be shaken with the aqueous acid solution of the sample in the 1-L funnel. Chloroform used for washing the filter and transferring the extract should be fresh or distilled from fresh chloroform.

20.2.2. *Stannous Chloride* ($SnCl_2$).

20.3. *Procedure*:

20.3.1. Place 40 g of cement in a 1-L Squibb separatory funnel (Note 74) and mix it with 520 mL of water added in two approximately equal portions. Shake vigorously immediately after the addition of the first portion to effect complete dispersion. Then add the second portion and shake again. At once add rapidly 185 mL of HCl in which 10 g of $SnCl_2$ (Note75) have been dissolved, rapidly insert the stopper in the funnel, invert, and shake with a swirling motion for a few seconds to loosen and disperse all the cement, taking care to avoid the development of great internal pressure due to unnecessarily violent shaking. Release internal pressure immediately by opening and closing the stopcock. Repeat the shaking and release the pressure until the decomposition of the cement is complete. If necessary, break up persistent lumps with a long glass rod. Cool to room temperature rapidly by allowing tap water to run on the flask.

Note 74—The use of grease to lubricate the stopcocks and glass stoppers of the separatory funnels should be avoided. Wetting the stopcocks with water before using will assist in their easy operation.

Note 75—The purpose of the $SnCl_2$ is to prevent the oxidation of sulfide sulfur to elemental sulfur, which is soluble in chloroform.

20.3.2. Add 75 mL of chloroform to the solution, stopper the funnel, shake it vigorously for five minutes, and allow the water and chloroform to stand 15 minutes to separate. Draw off the lower chloroform layer into a 125-mL Squibb separatory funnel, including the scum (Note 76) and a few milliliters of the aqueous layer, making certain that all the scum is transferred. Keep the amount of the aqueous layer transferred to an absolute minimum, since excessive water in the 125-mL funnel may result in incomplete extraction of the scum and may cause an emulsion which does not separate readily. Shake the funnel vigorously to ensure the complete extraction of the scum. Allow the chloroform to separate, and draw it into a 250-mL Squibb separatory funnel which contains 50 mL of water and a few drops of HCl, making sure to keep the scum behind in the 125-mL funnel. Shake the 250-mL funnel, and draw the chloroform into another 250-mL funnel that contains 50 mL of water and a few drops of HCl. Shake this funnel as in the case of the first 250-mL funnel. When the chloroform separates, draw it into a standard-taper flat-bottom boiling flask (Note 77), taking care not to allow any water to enter the flask.

Note 76—There is usually a dark-colored scum at the liquid interface. It may contain chloroform-soluble organic substance after shaking in the funnel, where the proportion of water to chloroform is great. It may be concentrated and confined to a small volume by gently twirling the funnel after the scum has been drawn into the narrower part of the funnel.

Note 77—The liquid is later distilled. No cork or rubber stoppers should be used. A 250- or 300-mL soil analysis flask, fitted with a condenser tube by means of a ground joint, is satisfactory. The tube may be bent near the neck and the remaining part fitted with a water-cooling jacket. Chloroform thus recovered may be reused as described in Section 20.2.1.

20.3.3. Add 25 mL of chloroform to the solution in the original 1-L separatory funnel, and carry out the operations as described in Section 20.3.2, retaining the original wash water in the 250-mL funnels. Repeat, using another 25-mL portion of chloroform.

20.3.4. Distill the combined chloroform extracts in the boiling flask until their volume is reduced to 10 to 15 mL. Filter the remaining liquid into a tared 100-mL glass beaker or platinum dish (Note 78) through a small medium-textured filter paper that has been washed with fresh chloroform. Rinse the flask and wash the paper with several small portions of fresh chloroform. Evaporate the extracts at a low temperature (not over 63°C) to dryness (Note 79) and heat it in an oven at 57° to 63°C for three minutes. Pass dry air into the vessel for 15 seconds, cool, and determine the mass. Repeat the heating and mass determinations until two successive mass determinations do not differ by more than 1 mg. The higher of the last two mass determinations shall be taken as the true mass.

Note 78—A platinum dish is preferable, as it quickly attains the temperature of the balance. If a glass beaker is used, it should be allowed to stand in the case of the balance for at least 20 minutes before determining the mass.

Note 79—Care should be taken in drying the extract, as many of the chloroform-soluble organic substances are somewhat volatile when heated for a long time at even moderate temperatures. With protection from the accumulation of dust, the solution may be evaporated on room temperature overnight.

When a quick evaporation is desired, the solution may be evaporated on a hot plate at low heat under a stream of dry air through a glass tube (about 10 mm in inside diameter) until it is about 3 mm in depth. Then remove the vessel from the hot plate and continue a slow stream of dry air until the residue appears dry. Then continue with a more rapid stream of dry air for five minutes at room temperature before placing the vessel in the oven at 57° to 63°C. After each three-minute heating period in the oven, pass dry air into the vessel for about 15 seconds before determining the mass. The air may be dried by passing it through a cheap desiccant, such as calcium chloride or sulfuric acid, followed by a desiccant of high efficiency, such as magnesium perchlorate or anhydrous calcium sulfate, with care taken to avoid the carrying of dust from the desiccant by the air. Instead of using compressed air, which is often contaminated with oil, dirt, and moisture, one can place the chloroform solution under a bell glass and induce a stream of air through the desiccants by means of an aspirator or vacuum pump.

When Vinsol resin is known to be the only substance present, the residue is more stable and may be heated at 100° to 105°C, instead of 57° to 63°C, in order to expel all possible traces of chloroform.

20.3.5. *Blank*—Make a blank determination. Ignite a 40-g sample of the cement at 950 to 1000°C for one hour (Note 80) and regrind. Treat this ignited sample by the same procedure and using the same reagents as in the analysis and correct the results accordingly.

Note 80—Care should be taken to completely burn off the organic substance. A 100-mL flat platinum dish, in which the sample is well spread out, and a muffle furnace are advised for this purpose. If such a furnace is not available, a large high-temperature burner of the Meker type may be used. Thorough stirring of the sample should be done frequently—every five minutes when a burner is used.

20.4. *Calculation*—Calculate the percentage of chloroform-soluble organic substances to the nearest 0.001 by multiplying the mass in grams of residue (Note 81) by 2.5 (100 divided by the mass of the sample used (40 g)). Report the result rounded in accordance with Table 3.

Note 81—If the organic substance in the cement is tallow, the residue is the fatty acids resulting from the hydrolysis of the tallow in the hot acid solution, and its mass should be multiplied by 1.05 to give the mass of the original glycerides in the tallow. If the original substance is calcium stearate, the residue is stearic acid, and its mass multiplied by 1.07 gives the mass of calcium stearate.

ALTERNATIVE TEST METHODS

21. CALCIUM OXIDE (ALTERNATIVE TEST METHOD)

21.1. *Summary of Test Method*:

21.1.1. This test method covers the gravimetric determination of CaO after removal of SiO_2 and the ammonium hydroxide groups and double precipitation of calcium as the oxalate. The precipitate is converted to CaO by ignition and the mass is determined.

21.1.2. Strontium, usually present in portland cement as a minor constituent, is precipitated with calcium as the oxalate and is subsequently calculated as CaO. If the SrO content is known and correction of CaO for SrO is desired, as, for example, for research purposes or to compare results with CRM certificate values, the CaO obtained by this test method may be corrected by subtracting percent SrO. In determining conformance of a cement to specifications, the correction of CaO for SrO should not be made.

21.2. *Procedure* (Note 82):

21.2.1. Acidify the combined filtrates obtained in the determination of the ammonium hydroxide group (Sections 7.1 through 7.3) and, if necessary, evaporate to a volume of about 200 mL. Add 5 mL of HCl, a few drops of methyl red indicator solution, and 30 mL of warm ammonium oxalate solution (50 g/L) (Note 38). Heat the solution to 70° to 80°C and add NH_4OH (1 + 1) dropwise while stirring until the color changes from red to yellow. (See Note 39.) Allow the solution to stand without further heating for 1 hour (not longer), with occasional stirring during the first 30 minutes. Filter using a retentive paper and wash moderately with cold ammonium oxalate solution (1 g/L). Reserve the filtrate and washings.

Note 82—When analyses are being made for determining conformity to specifications and there is a possibility that sufficient manganese will be present to cause the percentage of magnesium determined by optional test methods to exceed the specification limit, manganese may be removed as directed in Section 13.3.2 before CaO is determined by this alternative test method.

21.2.2. Transfer the precipitate and filter paper to the beaker in which the precipitation was made. Dissolve the oxalate in 50 mL of hot HCl (1 + 4) and macerate the filter paper. Dilute to 200 mL with water, add a few drops of methyl red indicator and 20 mL of ammonium oxalate solution, heat the solution nearly to boiling, and precipitate calcium oxalate again by neutralizing the acid solution with NH_4OH as described in Section 21.2.1. Allow the solution to stand one to two hours (standing for two hours at this point does no harm), filter, and wash as before. Combine the filtrate with that already obtained and reserve for the determination of MgO (Section 14.3.1).

21.2.3. Dry the precipitate in a tared covered platinum crucible. Char the paper without inflaming, burn the carbon at as low a temperature as possible, and, finally, heat with the crucible tightly covered in an electric furnace or over a blast lamp at a temperature of 1100° to 1200°C. Cool in a desiccator and determine the mass as CaO. Repeat the ignition to constant mass.

21.2.4. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

21.3. *Calculation*:

21.3.1. Calculate the percentage of CaO to the nearest 0.1 by multiplying the mass in grams of CaO by 200 (100 divided by the mass of sample used (0.5 g)).

21.3.2. Correct the percent CaO for SrO, if desired, by subtracting the percent SrO.

---

22. CARBON DIOXIDE (REFERENCE TEST METHOD)

22.1. Any test method may be used, provided that acceptable performance has been demonstrated in accordance with Section 22.2. See Appendix X2 for guidance on methods.

22.2. Demonstrate performance by analysis, in duplicate, of at least on portland cement. Prepare three standards, each in duplicate: Standard A shall be the selected portland cement; Standard B shall be Standard A containing 2.00 percent Certified $CaCO_3$ (such as NIST 915a); Standard C shall be Standard A containing 5.00 percent Certified $CaCO_3$. Prepare duplicate specimens of each standard. Assign the CO_2 content of Standard A as the average of the two values determined, provided they agree within the required limit of Table 1, Column 2. Assign CO_2 values to Standards B and C as follows: multiply the Certified $CaCO_3$ value (Y) for CO_2 (from the certificate value) by the mass fraction of Certified $CaCO_3$ added to that standard (percentage added divided by 100); multiply the value determined for Standard A by the mass fraction of Standard A in each of the other standards (that is, 0.98 and 0.95 for Standards B and C, respectively); add the two values for Standard A and for Standard B, respectively; call these values B and C. Example:

$$B = 0.98A + 0.02Y$$
$$C = 0.95A + 0.05Y$$

where for Certified $CaCO_3$, if Y = 44.01%

$$B = 0.98A + 0.88\% \text{ by mass}$$
$$C = 0.95A + 2.20\% \text{ by mass}$$

The difference between the duplicate CO_2 values for Standards B and C, respectively, shall not exceed 0.17 and 0.24 percent by mass. The difference between the average of the duplicate values for Standards B and C and their assigned values (B and C) shall not exceed 0.13 and 0.26 percent by mass respectively.

22.3. Report the results rounded in accordance Table 3.

23. MAGNESIUM OXIDE (ALTERNATIVE TEST METHOD)

23.1. *Summary of Test Method*—This alternative test method is a volumetric procedure suitable for use when the determination of silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), ferric oxide (Fe_2O_3), and calcium oxide (CaO) are omitted.

23.2. *Rapid Volumetric Test Method (Titration of Magnesium Oxyquinolate)*:

23.3. *Reagents*:

23.3.1. *Ammonium Nitrate Solution* (20 g NH_4NO_3/L).

23.3.2. *Ammonium Oxalate Solution* (50 g/L).

23.3.3. *Hydroxyquinoline Solution*—Dissolve 25 g of 8-hydroxyquinoline in 60 mL of acetic acid. When the solution is complete, dilute to 2 L with cold water. One milliliter of this solution is equivalent to 1.6 mg of MgO.

23.3.4. *Potassium Bromate-Potassium Bromide, Standard Solution* (0.2 *normal*)—Dissolve 20 g of potassium bromide (KBr) and 5.57 g of potassium bromate ($KBrO_3$) in 200 mL of water and dilute to 1 L. Obtain the ratio of the strength of this solution to that of the 0.1 *N* $Na_2S_2O_3$ solution (Section 23.3.6) as follows: To 200 mL of water in a 500-mL Erlenmeyer flask add 25.0 mL of the 0.2 *N* $KBrO_3$-KBr solution, measured from a pipet or buret. Add 20 mL of HCl, stir, and add immediately 10 mL of potassium iodide (KI) (250 g/L). Mix well and titrate at once with the $Na_2S_2O_3$ solution until nearly colorless. Add 2 mL of starch solution and titrate to the disappearance of the blue color. Calculate the ratio in strength of the $KBrO_3$-KBr solution to the $Na_2S_2O_3$ solution by dividing the volume of $Na_2S_2O_3$ solution by the volume of $KBrO_3$-KBr solution used in the titration.

23.3.5. *Potassium Iodide Solution* (250 g KI/L).

23.3.6. *Sodium Thiosulfate, Standard Solution* (0.1 *N*)—Dissolve 25 g of sodium thiosulfate ($Na_2S_2O_3 \cdot 5H_2O$) in 200 mL of water, add 0.1 g of sodium carbonate (Na_2CO_3), and dilute to 1 L. Let stand at least seven days. Standardize this solution directly against primary standard potassium dichromate ($K_2Cr_2O_7$). One milliliter of 0.10 N $Na_2S_2O_3$ solution is equivalent to 504 µg of MgO.

23.3.7. *Starch Solution*—To 500 mL of boiling water add a cold suspension of 5 g of soluble starch in 25 mL of water, cool to room temperature, add a cool solution of 5 g of sodium hydroxide (NaOH) in 50 mL of water, add 15 g of KI, and mix thoroughly.

23.4. *Procedure*:

23.4.1. Disperse 0.5 g (Note 83) of the sample of cement in a 400-mL beaker with 10 mL of water, using a swirling motion. While still swirling, add 10 mL of HCl all at once. Dilute immediately to 100 mL. Heat gently and grind any coarse particles with the flattened end of a glass rod until decomposition is complete, add two or three drops of HNO_3 and heat to boiling (Note 84).

Note 83—If SiO_2, ammonium hydroxide group, and CaO are separated and determined in accordance with the appropriate sections for either the reference or alternative test methods, the remaining filtrate may be used for the determination of MgO as described in Section 23.4.1, starting with the third from the last sentence of Section 23.4.2. "Add 5 mL of HCl…".

Note 84—In the case of cements containing blast-furnace slag or a significant quantity of sulfide sulfur, add 12 drops of HNO_3 and boil for 20 minutes to oxidize iron and remove sulfide.

23.4.2. Add three drops of methyl red indicator to the solution and then add NH_4OH until the solution is distinctly yellow. Heat this solution to boiling and boil for 50 to 60 seconds. In the event difficulty from bumping is experienced while boiling the ammoniacal solution, a digestion period of 10 minutes on a steam bath, or a hot plate having the approximate temperature of a steam bath, may be substituted for the 50- to 60-second boiling period. Remove from the burner, steam bath, or hot plate and allow to stand until the precipitate has settled. Using medium-textured paper, filter the solution without delay, wash the precipitate twice with hot NH_4NO_3 (20 g/L), and reserve the filtrate. Transfer the precipitate with the filter paper to the beaker and dissolve in 10 mL of HCl (1 + 1). Macerate the filter paper. Dilute to about 100 mL and heat to boiling. Reprecipitate, filter, and wash the hydroxides as above. Combine this filtrate and washings with those from the first precipitation taking care that the volume does not exceed 300 mL (Note 85). Add 5 mL of HCl, a few drops of methyl red indicator solution and 30 mL of warm ammonium oxalate solution (50 g/L). Heat the solution to 70° to 80°C and add NH_4OH (1 + 1) dropwise, while stirring, until the color changes from red to yellow. (See Note 39.) Allow the solution to stand without further heating for 15 minutes on a steam bath.

Note 85—In the case of cements containing blast-furnace slag, or which are believed to contain a significant quantity of manganese, acidify with HCl, evaporate to about 100 mL, and remove the manganese, using the procedure described in Section 13.3.1.

23.4.3. Add 10 to 25 mL of the 8-hydroxyquinoline reagent (Note 86) and then 4 mL of NH_4OH/100 mL of solution. Stir the solution on a mechanical stirring machine for 15 minutes and set aside until the precipitate has settled (Note 87). Filter the solution using medium-textured paper and wash the precipitate with hot NH_4OH (1 + 40). Dissolve the precipitate in 50 to 75 mL of hot HCl (1 + 9) in a 500-mL Erlenmeyer flask. Dilute the resulting solution to 200 mL and add 15 mL of HCl. Cool the solution to 25°C and add 10 to 35 mL of the 0.2 *N* $KBrO_3$-KBr solution (Note 88) from a pipet or buret. Stir the solution and allow to stand for about 30 seconds to ensure complete bromination. Add 10 mL of KI (250 g/L). Stir the resulting solution well and then titrate with the 0.1 *N* $Na_2S_2O_3$ solution until the color of the iodine becomes faintly yellow. At this point add 2 mL of the starch solution and titrate the solution to the disappearance of the blue color.

Note 86—An excess of the 8-hydroxyquinoline reagent is needed to avoid a low result for MgO, but too great an excess will yield high results. The following guide should be used to determine the amount of reagent added.

Appropriate Content of MgO, percent	Appropriate Amount of Reagent Required, mL
0 to 1.5	10
1.5 to 3.0	15
3.0 to 4.5	20
4.5 to 6.0	25

Note 87—The precipitate should be filtered within an hour. Prolonged standing may cause high results.

Note 88—The amount of the standard $KBrO_3$-KBr solution used should be as follows:

Appropriate Content of MgO, Percent	Amount of Standard $KBrO_3$-KBr Solution, mL
0 to 1	10
1 to 2	15
2 to 3	20
3 to 4	25
4 to 5	30
5 to 6	35

23.4.4. *Blank*—Make a blank determination following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

23.5. *Calculation*—Calculate the percentage of MgO as follows (Note 89):

$$\text{MgO, \%} = E\left(V_1 R - V_2\right) \times 200 \qquad (14)$$

where:

E = MgO equivalent of the $Na_2S_2O_3$ solution, g/mL;
V_1 = milliliters of $KBrO_3$-KBr solution used;
R = ratio in strength of the $KBrO_3$-KBr solution, to the $Na_2S_2O_3$;
V_2 = milliliters of $Na_2S_2O_3$ solution used; and
200 = 100 divided by the mass of sample used (0.5 g).

Report the result rounded in accordance with Table 3.

Note 89—V_1R represents the volume of $Na_2S_2O_3$ solution equivalent to the volume of $KBrO_3$-KBr solution used. V_2 represents the amount of $Na_2S_2O_3$ required by the excess $KBrO_3$-KBr which is not reduced by magnesium oxyquinolate.

24. LOSS ON IGNITION ALTERNATIVE TEST METHOD

24.1. *Portland Blast Furnace Slag Cement and Slag Cement*:

24.1.1. *Summary of Test Method*—This test method covers a correction for the gain in mass due to oxidation of sulfides usually present in such cement by determining the decrease in the sulfide sulfur content during ignition. It gives essentially the same result as the reference test method (Sections 16.2.1 through 16.2.3) which provides for applying a correction based on the increase in SO_3 content.

24.1.2. *Procedure*:

24.1.2.1. Weigh 1 g of cement in a tared platinum crucible, cover, and ignite in a muffle furnace at a temperature of 950° ± 50°C for 15 minutes. Cool to room temperature in a desiccator and determine the mass. After determining the mass, carefully transfer the ignited material to a 500-mL boiling flask. Break up any lumps in the ignited cement with the flattened end of a glass rod.

24.1.2.2. Determine the sulfide sulfur content of the ignited sample using the procedure described in Sections 15.2.1 through 15.2.5. Using the same procedure also determines the sulfide sulfur content of a portion of the cement that has not been ignited.

24.1.3. Calculate the percentage loss of mass occurring during ignition (Section 24.1.2.1) and add twice the difference between the percentages of sulfide sulfur in the original sample and ignited sample as determined in Section 24.1.2.2. Report this value as the loss on ignition, rounded in accordance with Table 3 (Note 90).

Note 90—If a gain in mass is obtained during the ignition, subtract the percentage of gain from the correction for sulfide oxidation.

25. TITANIUM DIOXIDE (ALTERNATIVE TEST METHOD)

25.1. *Summary of Test Method*—In this test method, titanium dioxide (TiO_2) is determined colorimetrically by comparing the color intensity of the peroxidized solution of the titanium in the sample with the color intensity of a peroxidized standard solution of titanic sulfate.

25.2. *Interferences*—Interfering elements in the peroxide test method for TiO_2 are vanadium, molybdenum, and chromium. In very small quantities the interference of the last two is negligible. However, vanadium in very small quantities causes interference and, as some cements contain this element, the Na_2CO_3 fusion (Section 25.5.4) and extraction with water are necessary.

25.3. *Apparatus*:

25.3.1. *Colorimeter*—The apparatus shall consist of a colorimeter of the Kennicott or Duboscq type, or other colorimeter or spectrophotometer designed to measure light transmittancy, and suitable for measurements at wavelengths between 400 and 450 nm.

25.4. *Reagents*:

25.4.1. *Ammonium Chloride* (NH_4Cl).

25.4.2. *Ammonium Nitrate* (20 g NH_4NO_3/L).

25.4.3. *Ferrous Sulfate Solution* (1 mL = 5 mg Fe_2O_3)—Dissolve 17.4 g of ferrous sulfate ($FeSO_47H_2O$) in water containing 50 mL of H_2SO_4 and dilute to 1 L. One milliliter is equivalent to 1 percent of Fe_2O_3 in 0.5 g of sample.

25.4.4. *Hydrogen Peroxide* (30 percent)—Concentrated hydrogen peroxide (H_2O_2).

25.4.5. *Sodium Carbonate* (20 g Na_2CO_3/L).

25.4.6. *Sodium or Potassium Pyrosulfate* ($Na_2S_2O_7$ or $K_2S_2O_7$).

25.4.7. *Titanic Sulfate, Standard Solution* (1 mL = 0.2 mg TiO_2)—Use standard TiO_2 furnished by NIST (Standard Sample 154 or its replacements). Dry for two hours at 105° to 110°C. Transfer a weighed amount, from 0.20 to 0.21 g of the TiO_2 to a 125-mL Phillips beaker. Add 5 g of ammonium sulfate ($(NH_4)_2SO_4$) and 10 mL of H_2SO_4 to the beaker and insert a short-stem glass funnel in the mouth of the beaker. Heat the mixture cautiously to incipient boiling while rotating the flask over a free flame. Continue the heating until complete solution has been effected and no unattached material remains on the wall of the flask (Note 91). Cool and rapidly pour the solution into 200 mL of cold water while stirring vigorously. Rinse the flask and funnel with H_2SO_4 (1 + 19), stir, and let the solution and washings stand for at least 24 hours. Filter into a 1-L volumetric flask, wash the filter thoroughly with H_2SO_4 (1 + 19), dilute to the mark with H_2SO_4 (1 + 19), and mix.

Note 91—There may be a small residue, but it should not contain more than a trace of TiO_2 if the operations have been properly performed.

25.4.8. Calculate the TiO_2 equivalent of the titanic sulfate solution, g/mL, as follows:

$$E = AB/1000 \qquad (15)$$

where:

E = TiO_2 equivalent of the $Ti(SO_4)_2$ solution, g/mL;

A = grams of standard TiO_2 used (corrected for loss on drying);

B = percentage of TiO_2 in the standard TiO_2 as certified by the National Institute of Standards and Technology, divided by 100; and

1000 = number of milliliters in the volumetric flask.

25.5. *Procedure*:

25.5.1. Mix thoroughly 0.5 g of the sample of cement and about 0.5 g of NH_4Cl in a 50-mL beaker, cover the beaker with a watch glass, and add cautiously 5 mL of HCl, allowing the acid to run down the lip of the covered beaker. After the chemical action has subsided, lift the cover, stir the mixture with a glass rod, replace the cover, and set the beaker on a steam bath for 30 minutes (Note 92). During this time of digestion, stir the contents occasionally and break up any remaining lumps to facilitate the complete decomposition of the cement. Fit a medium-textured filter paper to a funnel and transfer the precipitate to the filter. Scrub the beaker with a rubber policeman and rinse the beaker and policeman. Wash the filter two or three times with hot HCl (1 + 99) and then with 10 or 12 small portions of hot water, allowing each portion to drain through completely.

Note 92—A hot plate may be used instead of a steam bath if the heat is so regulated as to approximate that of a steam bath.

25.5.2. Transfer the filter and residue to a platinum crucible (Note 93), dry, and ignite slowly until the carbon of the paper is completely consumed without inflaming. Treat the SiO_2 thus obtained with 0.5 to 1 mL of water, about 10 mL of HF, and 1 drop of H_2SO_4, and evaporate cautiously to dryness (Note 94).

Note 93—When it is desired to shorten the procedure for purposes other than referee analysis, usually with little sacrifice of accuracy, the procedure given in Section 24.5.2 may be omitted.

Note 94—When a determination of SiO_2 is desired in addition to one of TiO_2, the SiO_2 may be obtained and treated with HF as directed in Sections 6.2.3.1 through 6.2.4.

25.5.3. Heat the filtrate to boiling and add NH_4OH until the solution becomes distinctly alkaline as indicated by an ammoniacal odor. Add a small amount of filter paper pulp to the solution and boil for 50 to 60 seconds. Allow the precipitate to settle, filter through a medium-textured paper, and wash twice with hot NH_4NO_3 solution (20 g/L). Place the precipitate in the platinum crucible in which the SiO_2 has been treated with HF and ignite slowly until the carbon of the paper is consumed.

Note 95—When a determination of ammonium hydroxide group is desired in addition to one of TiO_2, the precipitation and ignition may be made as described in Sections 7.2.1 through 7.2.4. However, the crucible must contain the residue from the treatment of the SiO_2 with HF unless circumstances permit its omission as indicated in Note 94.

25.5.4. Add 5 g of Na_2CO_3 to the crucible and fuse for 10 to 15 minutes. (See Section 24.2.1) Cool, separate the melt from the crucible, and transfer to a small beaker. Wash the crucible with hot water, using a policeman. Digest the melt and washings until the metal is completely disintegrated, then filter through a 90-mm medium-textured filter paper and wash a few times with Na_2CO_3

(20 g/L). Discard the filtrate. Place the precipitate in the platinum crucible and ignite slowly until the carbon of the paper is consumed.

25.5.5. Add 3 g of $Na_2S_2O_7$ or $K_2S_2O_7$ to the crucible and heat below red heat until the residue is dissolved in the melt (Note 96). Cool and dissolve the fused mass in water containing 2.5 mL of H_2SO_4. If necessary, reduce the volume of the solution (Note 97), filter into a 100-mL volumetric flask through a 7-cm medium-textured filter paper, and wash with hot water. Add 5 mL of H_3PO_4, and cool the solution to room temperature. Add H_2O_2 (1.0 mL of 30 percent strength or its equivalent) (Note 98), dilute to the mark with water, and mix thoroughly.

Note 96—Start the heating with caution because pyrosulfates (also known as fused bisulfates) as received often foam and spatter in the beginning due to an excess of H_2SO_4. Avoid an unnecessarily high temperature or unnecessarily prolonged heating, as fused pyrosulfates may attack platinum. A supply of nonspattering pyrosulfates may be prepared by heating some pyrosulfate in a platinum vessel to eliminate the excess H_2SO_4 and crushing the cool fused mass.

Note 97—If the solution is evaporated to too small a volume and allowed to cool, there may be a precipitate of sulfates difficult to redissolve. In case of over-evaporation, do not permit the contents to cool, but add hot water and digest on a steam bath or hot plate until the precipitate is redissolved, with the possible exception of a small amount of SiO_2.

Note 98—Hydrogen peroxide deteriorates on standing. Its strength may be determined by adding a measured volume of the solution to 200 mL of cold water and 10 mL of H_2SO_4 (1 + 1) and titrating with a standard solution of potassium permanganate ($KMnO_4$) prepared in accordance with Section 13.2.2. If the standard solution contains 5.6357 mg of $KMnO_4$/mL, 49.5 mL of it will be required by 0.50 mL of H_2O_2 (30 percent).

25.5.6. Prepare from the standard $Ti(SO_4)_2$ solution a suitable reference standard solution or a series of reference standard solutions in 100-mL volumetric flasks, depending upon the type of colorimeter to be used. To each solution add 3 g of $Na_2S_2O_7$ or $K_2S_2O_7$ dissolved in water, an amount of $FeSO_4$ solution equivalent to the Fe_2O_3 content in 0.5 g of the cement under test, 2.5 mL of H_2SO_4, and 5 mL of H_3PO_4 (Note 99). When the solution is at room temperature, add H_2O_2 (1.0 mL of 30 percent strength or its equivalent), dilute to the mark with water, and mix thoroughly (Note 100).

Note 99—The color imparted to the solution by $Fe_2(SO_4)_2$ is partly offset by the bleaching effect of H_2SO_4, H_3PO_4, and alkali salts on ferric and peritanic ions. The directions should be followed closely for the highest degree of precision. However, when it is desired to shorten this procedure for purposes other than referee analysis, the addition of pyrosulfate, $FeSO_4$ solution and H_3PO_4 to the color comparison solutions may be omitted provided the Fe_2O_3 of the sample cement is less than 5 percent. This usually leads to little sacrifice to accuracy.

Note 100—The color develops rapidly and is stable for a sufficient period of time, but if the peroxidized solution is allowed to stand a long time, bubbles of oxygen may appear and interfere with color comparison. When the contents of a tube are first mixed, there may be fine bubbles which should be allowed to clear up before the comparison is made. Comparison between the standard and unknown solution should be made not less than 30 minutes after addition of H_2O_2.

25.5.7. Compare the color, light transmittancy, or absorbance of the unknown solution with the reference standard solution. The technique of comparing colored solutions or measuring transmittancy or absorbance depends on the type of apparatus (see Sections 25.5.8 through 25.5.10) and should be in accordance with standard practice appropriate to the particular type used or with instructions supplied by the manufacturer of the equipment. If the peroxidized solution of cement is compared with a single standard peroxidized solution, bear in mind that a single peroxidized solution cannot be used for the whole range in TiO_2 content that may be encountered. The difference in volume or depth for the two liquids should not exceed 50 percent of the smaller value. All solutions should contain the prescribed concentrations of H_2SO_4, H_3PO_4, $Fe_2(SO_4)_3$, and persulfate except under the circumstances indicated in Note 100.

25.5.8. *Colorimeter of the Kennicott Type*—By means of a plunger in a reservoir of standard peroxidized solution, adjust the amount of solution through which light passes until it gives the same color intensity as the peroxidized solution of the sample.

25.5.9. *Colorimeter of the Duboscq Type*—Lower or raise the plungers in the cups until the two solutions give the same color intensity when viewed vertically. The color matching may be done either visually or photoelectrically.

25.5.10. *Colorimeter Designed to Measure Light Transmittancy*—The measurement should be made between 400 to 450 nm and may be made either visually or photoelectrically. In most colorimeters of this type, the instrument is calibrated with standard solutions and a calibration curve showing the relation of light transmittancy or absorbance to TiO_2 content is prepared in advance of the analysis of the sample for TiO_2.

25.5.11. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagent, and correct the results obtained in the analysis accordingly.

25.6. *Calculation*—Calculate the percentage of TiO_2, rounded in accordance with Table 3. When a colorimeter designed to measure light transmittancy is used, read the percentage of TiO_2 from a calibration curve showing the relation of light intensity to TiO_2 content. When the peroxidized solution of the sample is compared with a single reference standard solution, calculate the percentage of TiO_2 as follows (Note 101):

25.6.1. *For Colorimeters of the* Kennicott *Type*:

$$\mathrm{TiO_2}, \% = \left(100\,VE/S\right) \times \left(D/C\right) \qquad (16)$$

25.6.2. *For* Colorimeters *of the Duboscq Type*:

$$\mathrm{TiO_2}, \% = \left(100\,VE/S\right) \times \left(F/G\right) \qquad (17)$$

where:

V = milliliters of standard $Ti(SO_4)_2$ solution in the peroxidized standard solution;

E = TiO_2 equivalent of the standard $Ti(SO_4)_2$ solution, g/mL;

S = grams of sample used;

C = total volume of the peroxidized reference standard solution, mL;

D = volume of peroxidized reference standard solution that matches the peroxidized solution of the sample, mL;

F = depth of peroxidized reference standard solution through which light passes; and

G = depth of peroxidized solution of the sample through which light passes.

Note 101—The difference between D and C or between F and G should not exceed 50 percent of the smaller value.

26. PHOSPHORUS PENTOXIDE (ALTERNATIVE TEST METHOD)

26.1. *Summary of Test Method*—In this test method, phosphorus is determined volumetrically by precipitation of the phosphorus as ammonium phosphomolybdate and titration with NaOH and H_2SO_4.

26.2. *Reagents*:

26.2.1. *Ammonium Molybdate Solution*—Prepare the solution in accordance with Section 9.3.1.

26.2.2. *Ammonium Nitrate* (NH_4NO_3).

26.2.3. *Potassium Nitrate Solution* (10 g/L)—Dissolve 10 g of potassium nitrate (KNO_3) in water freshly boiled to expel CO_2 and cooled, and dilute to 1 L.

26.2.4. *Sodium Hydroxide, Standard Solution* (0.3 *N*)—Dissolve 12 g of sodium hydroxide (NaOH) in 1 L of water that has been freshly boiled to expel CO_2, and cooled. Add 10 mL of a freshly filtered, saturated solution of barium hydroxide ($Ba(OH)_2$). Shake the solution frequently for several hours, and filter it. Protect it from contamination by CO_2 in the air. Standardize the solution against standard acid potassium phthalate (Standard Sample No. 84) or benzoic acid (Standard Sample No. 39) furnished by the National Institute of Standards and Technology, according to the directions furnished with the standard. Calculate the phosphorus pentoxide (P_2O_5) equivalent (Note 102) of the solution, g/mL, as follows:

$$E = N \times 0.003086 \tag{18}$$

where:

E = P_2O_5 equivalent of the NaOH solution, g/mL;

N = normality of the NaOH solution; and

0.003086 = P_2O_5 equivalent of 1 N NaOH solution, g/mL.

Note 102—The value of the solution is based on the assumption that the phosphorus in cement is precipitated as ammonium phosphomolybdate $2(NH_4)_3PO_4 \cdot 12MoO_3$) and that the precipitate reacts with the NaOH solution thus:

$$\begin{aligned} &2(NH_4)_3PO_4 \cdot 12MoO_3 + 46NaOH = \\ &\qquad 2(NH_4)_2HPO_4 + (NH_4)_2MoO_4 + 23Na_2MoO_4 + 22H_2O \end{aligned} \tag{19}$$

The number of 0.003086 is obtained by dividing the molecular weight of P_2O_5 (141.96) by 46 (for 46 NaOH in the equation) and by 1000 (number of milliliters in 1 L).

As the actual composition of the precipitate is influenced by the conditions under which the precipitation is made, it is essential that all the details of the procedure are followed closely as prescribed.

26.2.5. *Sodium Nitrite* (50 g $NaNO_2$/L).

26.2.6. *Sulfuric Acid, Standard Solution* (0.15 *N*)—Dilute 4.0 mL of H_2SO_4 to 1 L with water that has been freshly boiled and cooled. Standardize against the standard NaOH solution. Determine the ratio in strength of the standard H_2SO_4 solution to the standard NaOH solution by dividing the volume of NaOH solution by the volume of H_2SO_4 solution used in the titration.

26.3. *Procedure*:

26.3.1. Weigh 1 to 3 g of the sample (Note 103) and 10 g of NH_4NO_3 into a 150-mL beaker. Mix the contents, add 10 mL of HNO_3, and stir quickly, using the flattened end of a glass rod to crush lumps of cement, until the cement is completely decomposed and the thick gel of silica (SiO_2) is broken up. Cover the beaker with a watch glass, place it on a water bath or a hot plate at approximately 100°C for 15 to 20 minutes, and stir the contents occasionally during the heating.

Add 20 mL of hot water to the beaker and stir the contents. If the cement contains an appreciable amount of manganese as shown by the presence of a red or brown residue, add a few milliliters of $NaNO_2$ (50 g/L) to dissolve this residue. Boil the contents of the beaker until all nitrous fumes are completely expelled. This procedure should not take more than five minutes, and water should be added to replace any lost by evaporation. Filter, using medium-textured paper, into a 400-mL beaker under suction and with a platinum cone to support the filter paper. Wash the residue of SiO_2 with hot water until the volume of filtrate and washings is about 150 mL.

Note 103—The amounts of sample and reagents used depend on the content of phosphorus in the cement. The minimum requirements are sufficient if the cement contains 0.5 percent P_2O_5 or more. The maximum amounts are required if the content of P_2O_5 is 0.1 percent or less.

26.3.2. Heat the solution to 69° to 71°C, remove it from the heat source, and immediately add 50 to 100 mL of the ammonium molybdate solution. Stir the solution vigorously for five minutes, wash down the sides of the beaker with cool KNO_3 solution (10 g/L), cover the beaker with a watch glass, and allow to stand two hours. Using suction, filter the precipitate (Note 104), decanting the solution with as little disturbance to the precipitate as possible. Stir the precipitate in the beaker with a stream of the cool KNO_3 solution, decant the liquid, then wash the precipitate onto the filter. Scrub the stirring rod and beaker with a policeman and wash the contents onto the filter. Wash and precipitate until it is acid-free (Note 105), allowing each portion of wash solution to be sucked completely through before adding the next.

Note 104—The filter may be a small medium-textured filter paper supported by a platinum cone, or a small Hirsch funnel may be used with filter paper cut to fit and a thin mat of paper pulp or acid-washed asbestos pulp. The filtration should be carried out with care to avoid any loss of the precipitate. The filter should fit well, and the suction should be started before filtration and maintained until the end of the washing.

Note 105—About 10 washings are usually required. Test the 10th washing with one drop of neutral phenolphthalein indicator and half a drop of the standard NaOH solution. If a definite pink color lasts at least five minutes, the precipitate is considered to be acid-free; otherwise, continue the washing.

26.3.3. Transfer the filter and precipitate to the beaker in which the precipitation took place, using small damp pieces of paper to wipe out the funnel and to pick up portions of the precipitate that may remain on it. Add 20 mL of cool CO_2-free water to the beaker, and break up the filter by stirring rapidly with the policeman that was used to scrub the beaker. Add an excess of the 0.3 normal NaOH solution, stir the contents until all trace of yellow has disappeared, wash down the policeman and sides of the beaker with 50 mL of cool, CO_2-free water, and add two drops of neutral phenolphthalein indicator solution. Treat the solution with a measured quantity of the 0.15 N H_2SO_4 solution, sufficient to destroy completely the pink color. Complete the titration with the NaOH solution until there is a definite faint pink color that lasts at least five minutes.

26.3.4. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

26.4. *Calculation*—Calculate the percentage of P_2O_5 as follows:

$$P_2O_5,\ \% = \left[E\left(V_1 - V_2R\right)/S\right] \times 100 \qquad (20)$$

where:

E = P_2O_5 equivalent of the NaOH solution, g/mL;

V_1 = milliliters of NaOH solution used;

V_2 = milliliters of H_2SO_4 solution used;

R = ratio in strength of the H_2SO_4 solution to the NaOH solution; and

S = grams of sample used.

Report the result rounded in accordance with Table 3.

27. MANGANIC OXIDE (ALTERNATIVE TEST METHOD)

27.1. *Summary of Test Method*—In this test method manganic oxide is determined volumetrically by titration with potassium permanganate solution.

27.2. *Reagents*:

27.2.1. *Potassium Permanganate, Standard Solution* (0.18 *normal*)—Prepare a solution of potassium permanganate ($KMnO_4$) and standardize as described in Section 13.2.2, except that the manganic oxide (Mn_2O_3) equivalent of the solution is calculated instead of the calcium oxide (CaO) equivalent. Calculate the Mn_2O_3 equivalent of the solution as follows:

$$E = \left(B \times 0.3534\right)/A \tag{21}$$

where:

E = Mn_2O_3 equivalent of the $KMnO_4$ solution, g/mL;

B = grams of $Na_2C_2O_4$ used,

A = milliliters of $KMnO_4$ solution required by the $Na_2C_2O_4$; and

0.3534 = mole ratio of 3 Mn_2O_3 to 10 $Na_2C_2O_4$.

27.2.2. *Zinc Oxide* (ZnO), powder.

27.3. *Procedure*:

27.3.1. Place 2 g of the sample in a 250-mL beaker and add about 50 mL of water to the cement. Stir the mixture until it is in suspension and then add about 15 mL of HCl. Heat the mixture gently until the solution is as complete as possible. Add 5 mL of HNO_3 and 50 mL of water to the solution and boil it until most of the chlorine has been expelled. If necessary, add hot water to maintain the solution at a volume of about 100 mL. Stop the boiling and add ZnO powder to the solution until the acid is neutralized. Add an excess of 3 to 5 g of ZnO powder to the solution and boil it for a few minutes.

27.3.2. Without filtering, and while keeping the solution hot (90° to 100°C) by intermittent or continuous heating, titrate the solution with the 0.18 *N* $KMnO_4$ solution until a drop of it gives a permanent pink color (Note 106). When the end point is approached, add the standard solution dropwise. After each drop, stir the solution, allow the precipitate to settle a little, and observe the color of the stratum of the solution by looking through the side of the beaker.

Note 106—In the case of a cement in which the approximate content of Mn_2O_3 is unknown, a preliminary determination may be made with rapid titration, 0.5 to 1 mL of the standard solution being added at a time, and without an attempt to keep the solution close to the boiling point.

27.3.3. *Blank*—Make a blank determination, following the same procedure and using the same amounts of reagents, and correct the results obtained in the analysis accordingly.

27.4. *Calculation*—Calculate the percentage of Mn_2O_3 as follows:

$$\mathrm{Mn_2O_3}, \% = EV \times 50 \tag{22}$$

where:

E = Mn_2O_3 equivalent of the $KMnO_4$ solution, g/mL;

V = milliliters of $KMnO_4$ solution used; and

50 = 100 divided by the mass of sample used (2 g).

Report the result rounded in accordance with Table 3.

28. FREE CALCIUM OXIDE (ALTERNATIVE TEST METHOD)

28.1. *Summary of Test Methods*—These are rapid test methods for the determination of free calcium oxide in fresh clinker. When applied to cement or aged clinker, the possibility of the presence of calcium hydroxide should be kept in mind since these test methods do not distinguish before free CaO and free $Ca(OH)_2$. Two test methods are provided. Alternate Test Method A is a modified Franke procedure in which uncombined lime is titrated with dilute perchloric acid after solution in an ethylacetoacetate-isobutyl alcohol solvent. Alternate Test Method B is an ammonium acetate titration of the alcohol-glycerin solution of uncombined lime with $Sr(NO_3)_2$ as an accelerator.

28.2. *Modified Franke Test Method (Alternative Method A)*:

28.2.1. *Apparatus*:

28.2.1.1. *Refluxing Assembly*—consisting of a flask with flat-bottom short neck Erlenmeyer flask with 250-mL capacity. The water-cooled refluxing condenser should have a minimum length of 300 mm. The flask and reflux condenser shall be connected with standard tapered ground glass joints. The reflux condenser shall be fitted with an absorption tube containing a desiccant such as indicating silica gel and a material for the removal of CO_2 such as Ascarite. The absorption tube shall be inserted with a rubber stopper in the upper end of the reflux column.

28.2.1.2. *Buret*—having a 10-mL capacity and graduated in units not more than 0.05 mL.

28.2.1.3. *Vacuum Filtration Assembly*—consisting of a Gooch crucible size No. 3, 25-mL capacity in which is placed a suitable filter paper, 21-mm size, a Walter crucible holder, a 500-mL vacuum flask, and vacuum source. The crucible is half filled with compressed filter pulp.

28.2.1.4. *Glass Boiling Beads*:

28.2.2. *Solutions Required*:

28.2.2.1. *Ethyl Acetoacetate-Isobutyl Alcohol Solvent*—three parts of volume of ethyl acetoacetate and 20 parts by volume of isobutyl alcohol.

28.2.2.2. *Thymol Blue Indicator*—Dissolve 0.1 g of thymol blue indicator powder in 100 mL of isobutyl alcohol.

28.2.2.3. *Perchloric Acid, Standard Solution* (0.2 *normal*)—Dilute 22 mL of 70 to 72 percent perchloric acid to 1 L with isobutyl alcohol. Standardize this solution as follows: Ignite 0.1000 g of primary standard calcium carbonate in a platinum crucible at 900° to 1000°C. Cool the crucible and contents in a desiccator and determine the mass to the nearest 0.0001 g to constant mass. Perform the mass determinations quickly to prevent absorption of water and CO_2. Immediately transfer the CaO without grinding to a clean, dry Erlenmeyer flask and again determine the mass of the empty crucible to the nearest 0.0001 g to determine the amount of CaO added. Then follow procedure beginning with "Add 70 mL of the prepared ethyl acetoacetate isobutyl alcohol . . ." in Section 28.2.3.1. Calculate the CaO equivalents of the standard perchloric acid solution in grams per milliliter by dividing the mass of CaO used by the volume of perchloric acid required for the titration.

28.2.3. *Procedure*:

28.2.3.1. Transfer 1.0000 g of ground sample (Note 107) into a clean, dry 250-mL Erlenmeyer flask. Add four to five glass boiling beads. Add 70 mL of the prepared ethyl acetoacetate-isobutyl alcohol solvent. Agitate the flask to disperse the sample.

Note 107—Thorough grinding of the sample is essential for proper exposure of the free lime grains that often are occluded in crystals of tricalcium silicate in the cement. However, exposure of the sample to the air must be kept at a minimum to prevent carbonation of the free lime. In particular, direct breathing into the sample must be avoided. The sample should be sufficiently fine to easily pass a No. 200 (75-µm) sieve but actual sieving is not recommended. If the sample is not to be immediately tested, it must be kept in an airtight container to avoid unnecessary exposure to the atmosphere.

28.2.3.2. Attach the flask to a reflux condenser and bring the material to a boil. Reflux for 15 minutes.

28.2.3.3. Remove flask from condenser, stopper, and cool rapidly to room temperature.

28.2.3.4. Filter the sample and solution using the vacuum assembly. Wash the flask and residue with small increments (10 to 15 mL) of isobutyl alcohol until a total of 50 mL has been used for wash solution.

28.2.3.5. Add 12 drops of the thymol blue indicator to the filtrate and immediately titrate with 0.2 normal perchloride acid to the first distinct color change.

28.2.4. *Calculations*—Calculate the percent free calcium oxide as follows:

$$\text{free CaO, \%} = \frac{EV \times 100}{W} \qquad (23)$$

where:

E = CaO equivalent of the perchloric acid, g/mL;

V = milliliters of perchloric acid solution required by sample; and

W = mass of the sample, g.

Report the result rounded in accordance with Table 3.

28.3. *Rapid $Sr(NO_3)_2$ Test Method (Alternative Test Method B)*:

28.3.1. *Reagents*:

28.3.1.1. *Ammonium Acetate, Standard Solution* (1 mL = 5 mg CaO)—Prepare a standard solution of ammonium acetate ($NH_4C_2H_3O_2$) by dissolving 16 g of desiccated ammonium acetate in 1 L of ethanol in a dry, clean, stoppered bottle. Standardize this solution by the same procedure as described in Section 28.3.2.1, except use the following in place of the sample: ignite to constant mass approximately 0.1 g of calcium carbonate ($CaCO_3$) in a platinum crucible at 900 to 1000°C, cool the contents in a desiccator, and determine the mass to the nearest 0.0001 g. Perform the mass determinations quickly to prevent absorption of water and CO_2. Immediately transfer the CaO without grinding to a 250-mL boiling flask (containing glycerin-ethanol solvent and $Sr(NO_3)_2$), and again determine the mass of the empty crucible to determine the mass of CaO to the nearest

0.1 mg. Continue as described in Sections 28.3.2.1 and 28.3.2.2. Calculate the CaO equivalent of the ammonium acetate in grams per milliliter by dividing the mass of CaO used by the volume of solution required.

28.3.1.2. *Phenolphthalein Indicator*—Dissolve 1.0 g of phenolphthalein in 100 mL of ethanol (Formula 2B) (Note 108).

28.3.1.3. *Glycerin-Ethanol Solvent* (1 + 2)—Mix 1 volume of glycerin with two volumes of ethanol (Formula 2B). To each liter of this solution, add 2.0 mL of phenolphthalein indicator solution.

Note 108—Ethanol denatured in accordance with Formula 2B (99.5 percent ethanol and 0.5 percent benzol) is preferred but may be replaced by isopropyl alcohol, A.R.

28.3.1.4. *Strontium Nitrate* ($Sr(NO_3)_2$), reagent grade.

28.3.2. *Procedure*:

28.3.2.1. Transfer 60 mL of the glycerin-ethanol solvent into a clean, dry, 250-mL standard-taper flat-bottom boiling flask. Add 2 g of anhydrous strontium nitrate ($Sr(NO_3)_2$), and adjust the solvent to slightly alkaline with a dropwise addition of a freshly prepared dilute solution of NaOH in ethanol until a faint pink color is formed. Weigh 1.000 g of the finely ground sample (Note 108) into the flask, add encapsulated stirring bar, and immediately attach a water-cooled condenser (with a standard 24/40 glass joint). Boil the solution in the flask on a magnetic stirrer hot plate for 20 minutes with mild stirring.

28.3.2.2. Remove the condenser and filter the contents of the flask on a small polypropylene Büchner funnel under vacuum, using a 250-mL filtering flask with side tube. Bring the filtrate to a boil and immediately titrate with standard ammonium acetate solution to a colorless end point.

28.3.3. *Calculation*—Calculate the percent free CaO as follows:

$$\text{free CaO, \%} = EV \times 100 \qquad (24)$$

where:

E = CaO equivalent of the ammonium acetate solution, g/mL; and

V = milliliters of ammonium acetate solution required by the sample.

Report the result rounded in accordance with Table 3.

The equivalence point is in the maximum ΔmV interval (Column 3) and thus between 2.20 and 2.40 mL. The exact equivalence point in this 0.20 increment is calculated from the Δ^2mV (Column 4) data as follows:

$$E = 2.20 + (1.3/(1.3 + 0.6)) \times 0.20 = 2.337 \text{ mL. Round to } 2.34.$$

[a] Differences between successive readings in Column 2.

[b] Differences between successive Δ readings in Column 3 "second differentials."

X2. CO_2 DETERMINATIONS IN HYDRAULIC CEMENTS

X2.1. *Scope*:

X2.1.1. This appendix contains information about methods for determination of carbon dioxide (CO_2) in hydraulic cement. The methods listed received a favorable evaluation by ASTM Task Group C01.23.04.

X2.1.2. Section X2.2 lists the analytical methods that received a favorable evaluation, briefly describes each method, suggests analytical techniques or cautions that may be useful, and indicates limitations to some of the methods.

X2.1.3. The methods listed in Sections X2.2.1, X2.2.4, X2.2.5, and X2.2.6 determine total carbon calculated as CO_2. For that reason, they are not appropriate for determination of carbon dioxide in fly ash, limestones containing carbon in the form of graphite or kerogen, in other carbon-bearing materials, or in blended cements produced from these materials.

X2.1.4. The methods listed in Sections X2.2.2 and X2.2.3 can determine actual CO_2 directly rather than by calculation from total carbon. They are suggested for analysis of blended cement ingredients that are likely to contain non-carbonate carbon.

X2.1.5. The split loss on ignition method in Section X2.2.1 can give misleading results when used with materials containing $CaOH_2$ (calcium hydroxide). This can occur with aged cement, cement made from aged clinker, or high free lime clinker, in addition to cements with a lime or hydrated lime ingredient.

X2.2. *Analytical Methods*:

X2.2.1. *Split Loss on Ignition*—This procedure is comparable to the analytical method described in ASTM C 114, Section 16.1.2, with the following modifications:

1. A crucible of known mass and containing a sample of known mass is initially heated at 550°C for two hours.
2. After being cooled to room temperature in a desiccator, and its mass determined, the crucible with sample is then heated at 950°C for two hours.
3. Finally, the crucible with sample is cooled and its mass is determined as per step No. 2.
4. The difference in residue masses after the respective heat treatments is assumed to be carbon dioxide.

TGA results indicated that $Ca(OH)_2$ can lose a significant portion of its mass above 500°C. Thus the Split on Loss of Ignition procedure should not be used when situations described in Section X2.1.5 exist.

X2.2.2. *Thermogravimetric Analysis (TGA)*—This method involves the determination of sample mass at various temperatures. The heating of a sample through a temperature range allows for mass loss differentiation based on mineral form (for example, $CaCO_3$, $MgCO_3$, $CaOH_2$, etc.). Specific operational information is provided by the equipment manufacturers. If free carbon is present, an inert atmosphere (for example, nitrogen) should be used for sample analysis.

X2.2.3. *ASTM C 25, Section 22*—"Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime." This method involves decomposition of the sample with HCl. The liberated CO_2 is then passed through a series of scrubbers to remove water and sulfides. The CO_2 is absorbed with special Sodium Hydroxide Absorbent (Ascarite). The gain in mass of the absorption tube is determined and calculated as percent CO_2. Calcium carbonate, for instance, can be calculated by multiplying the determined CO_2 content by a conversion factor (for example, $CO_2 \times 2.2742 = CaCO_3$).

X2.2.4. *X-ray Fluorescence Spectroscopy*—In this method the sample is ground to a fine particle size, pressed into a flat pellet and irradiated with the chosen instrument. Carbon content is determined by comparing the collected carbon emissions to calibration standards.

X2.2.5. *Combustion by Induction Furnace/IR*—This method involves volatilization by induction furnace and detection by infrared absorption. Suitable calibration standards (for example, calcium carbonate and synthetic carbon) are available from some instrument manufacturers. NIST cement CRMs with known additions of NIST argillaceous limestone (or other suitable standards) should also be considered to check instrument calibration.

X2.2.6. *ASTM E 350*—This method, "Total Carbon by the Combustion Gravimetric" from "Test Methods for Chemical Analysis of Carbon Steel, Low-Alloy Steel, Silicon Electrical Steel, Ingot Iron, and Wrought Iron," is suitable for the determination of carbon in concentrations from 0.05 to 1.80 percent (as carbon dioxide 0.18 to 6.60 percent). The test method involves burning the sample in a stream of oxygen; the carbon dioxide in the evolved gases is then collected in a suitable absorbent and its mass determined. Time of analysis is less than 10 minutes.

X2.3. *Cooperative Test Results:*

X2.3.1. Tables X2.1 and X2.2 list results from two series of cooperative tests using several of the analytical methods evaluated by the Task Force Group. In all, five of the six methods receiving favorable ratings were included. The sixth method, ASTM C 25, was specifically not tested in these cooperative series, but was rated favorably because of long history of use with related materials.

X2.3.2. Table X2.1 includes results of single determinations using three of the different analytical methods. The methods used were Split Loss on Ignition, ASTM E 350, and Combustion by Induction Furnace with Infrared Detection.

Table X2.1—Cooperative Test Series No. 1

	Single Determinations			
	Carbon Dioxide Unknown[a]	Determinations Base Cement[b]	Added CO_2, c% Determined[c]	Added CO_2, % Known[d]
Split LOI	2.40	0.45	1.97	2.00
	2.52	0.56	1.99	
	2.41	0.36	2.07	
	2.39	0.32	2.09	
	2.41	0.36	2.07	
	2.28	0.27	2.02	
ASTM E 350	2.00	0.02	1.98	
	2.00	0.02	1.98	
Induction Furnace/IR	2.46	0.40	2.07	
	2.53	0.48	2.08	
	2.38	0.40	2.00	
	2.42	0.48	1.97	
			2.02	
Average Standard Deviation			0.05	

[a] The Unknown was prepared by blending/grinding a mixture of 5.00% NIST CRM 1C Argillaceous Limestone and 95.00% CCRL Portland Cement Reference Sample No. 85. According to the Certificate of Analysis, CRM 1C had a loss on ignition of 39.9%. For the purpose of the cooperative test series, the loss on ignition was assumed to be CO_2 only.

[b] The Base Cement was CCRL Portland Cement Reference Sample No. 85.

[c] The Determined % Added CO_2 was obtained by subtracting the Base Cement % CO_2 from the Unknown % CO_2.

[d] The addition of 5.00% NIST CRM 1C (with a loss on ignition value of 39.9%) would provide 2.00% Added CO_2. (Again, it was assumed that the CRM 1C loss on ignition was only carbon dioxide.)

X2.3.3. Table X2.2 includes results based on average of three determinations. Results from four of the different analytical methods are included. Methods used were Split Loss on Ignition, X-Ray Fluorescence Analysis, Induction Furnace with Infrared Detection, and Thermo-Gravimetric Analysis. ASTM E 350 was not used in this series of tests.

Table X2.2—Cooperative Test Series No. 2

	Average from Three Determinations			
	Carbon Dioxide Unknown[a]	Determinations Base Cement[b]	Added CO_2, c% Determined[c]	Added CO_2, % Known[d]
Split LOI	2.00	0.41	1.59	1.60
	1.65	0.32	1.33	
	2.02	0.46	1.56	
	1.91	0.35	1.56	
	2.10	0.43	1.67	
	1.91	0.41	1.50	
	1.98	0.46	1.52	
XRFA	1.68[e]	0.00[e]	1.68[e]	
Induction Furnace/IR	2.23	0.28	1.95	
	1.96	0.28	1.68	
	1.95	0.40	1.55	
TGA	1.77	0.20	1.57	
	1.87	0.25	1.62	
			1.60	
Average Standard Deviation			0.14	

[a] The Unknown was prepared by blending/grinding a mixture of 4.00% NIST CRM 1C Argillaceous Limestone and 96.00% CCRL Portland Cement Reference Sample No. 85. According to the Certificate of Analysis, CRM 1C had a loss on ignition of 39.9%. For the purpose of the cooperative test series, the loss of ignition was assumed to be CO_2 only.

[b] The Base Cement was CCRL Portland Cement Reference Sample No. 85.

[c] The Determined % Added CO_2 was obtained by subtracting the Base Cement % CO_2 from the Unknown % CO_2.

[d] The addition of 4.00% NIST CRM 1C (with a loss on ignition value of 39.9%) would provide 1.60% Added CO_2. (Again, it was assumed that the CRM 1C loss on ignition was only carbon dioxide.)

[e] The XRF instrument was calibrated using standards composed of the Base Cement (that is, CCRL No. 85) and NIST CRM 1C. It was assumed that the Base Cement contained 0% CO_2.

---

[5] The 1988 revision of these test methods deleted the colorimetric method for determination of ZnO using an extraction with CCl_4. Those interested in this test method should refer to the 1987 *Annual Book of ASTM Standards*, Volume 4.01.

[6] The 1963 revision of these test methods deleted the classical (J. L. Smith) gravimetric method for the determination of Na_2O and K_2O in cements. Those interested in this method should refer to the 1961 *Annual Book of ASTM Standards*, Part 4. The 1983 revision of these test methods deleted the details of the flame photometric procedure for the determination of Na_2O and K_2O. Those interested in this method should refer to the 1987 *Annual Book of ASTM Standards*, Part 13.

[7] The 1965 revision of these test methods deleted the methoxyl test method for determining vinsol resin. Those interested in this test method should refer to the 1966 *Annual Book of ASTM Standards*, Part 9.

Standard Method of Test for

Compressive Strength of Hydraulic Cement Mortar (Using 50-mm or 2-in. Cube Specimens)

AASHTO Designation: T 106M/T 106-09
ASTM Designation: C 109/C 109M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Compressive Strength of Hydraulic Cement Mortar (Using 50-mm or 2-in. Cube Specimens)

AASHTO Designation: T 106M/T 106-09
ASTM Designation: C 109/C 109M-07

1. SCOPE

1.1. This test method covers determination of the compressive strength of hydraulic cement mortar using 50-mm (or 2-in.) cube specimens.

Note 1—ASTM C 349 provides an alternative procedure for this determination (not to be used for acceptance tests).

1.2. This test method covers the application of the test using either inch-pound or SI units. The values stated in either system shall be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

1.3. Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rebounding given in Standard IEEE/ASTM SI 10, of measurements made in other units.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)

- SI 10, American National Standard for Use of the International System of Units (SI): The Modern Metric System

3. SUMMARY OF TEST METHOD

3.1. The mortar used consists of one part cement and 2.75 parts of sand proportioned by mass. Portland or air-entraining portland cements are mixed at specified water/cement ratios. Water content for other cements is that sufficient to obtain a flow of 110 ± 5 in 25 drops of the flow table. Fifty-millimeter [or 2-in.] test cubes are compacted by tamping in two layers. The cubes are cured 24 hours in the molds and stripped and immersed in lime water until tested.

4. SIGNIFICANCE AND USE

4.1. This test method provides a means of determining the compressive strength of hydraulic cement and other mortars and results may be used to determine compliance with specifications. Further, this test method is referenced by numerous other specifications and test methods. Caution must be exercised in using the results of this test method to predict the strength of concretes.

5. APPARATUS

5.1. *Weights and Weighing Devices*—Shall conform to the requirements of ASTM C 1005. The weighing device shall be evaluated for precision and bias at a total load of 2000 g.

5.2. *Glass Graduates*—Of suitable capacities (preferably large enough to measure the mixing water in a single operation) to deliver the indicated volume at 20ºC. The permissible variation shall be ±2 mL. These graduates shall be subdivided to at least 5 mL, except that the graduation lines may be omitted for the lowest 10 mL for a 250-mL graduate and for the lowest 25 mL for a 500-mL graduate. The main graduation lines shall be circles and shall be numbered. The least graduations shall extend at least one-seventh of the way around, and intermediate graduations shall extend at least one-fifth of the way around.

5.3. *Specimen Molds*—For the 50-mm [or 2-in.] cube specimens shall be tight fitting. The molds shall have no more than three cube compartments and shall be separable into no more than two parts. The parts of the molds when assembled shall be positively held together. The molds shall be made of hard metal not attacked by the cement mortar. For new molds the Rockwell hardness number of the metal shall be not less than 55 HRB. The sides of the molds shall be sufficiently rigid to prevent spreading or warping. The interior faces of the molds shall be plane surfaces and shall conform to the tolerances of Table 1.

Table 1—Permissible Variations of Specimen Molds

Parameter	50-mm Cube Molds		2-in. Cube Molds	
	New	In Use	New	In Use
Planeness of sides	<0.025 mm	<0.05 mm	<0.001 in.	<0.002 in.
Distance between opposite sides	50 mm ± 0.13 mm	50 mm ± 0.50 mm	2 in. ± 0.005	2 in. ± 0.02
Height of each compartment	50 mm + 0.25 mm to – 0. 13 mm	50 mm + 0.25 mm to – 0.38 mm	2 in. + 0.01 in. to – 0.005 in.	2 in. + 0.01 in. to – 0.015 in.
Angle between adjacent faces[a]	90 ± 0.5°	90 ± 0.5°	90 ± 0.5°	90 ± 0.5°

[a] Measured at points slightly removed from the intersection. Measured separately for each compartment between all the interior faces and the adjacent face and between interior faces and top and bottom planes of the mold.

5.4. *Mixer, Bowl, and Paddle*—An electrically driven mechanical mixer of the type equipped with paddle and mixing bowl, as specified in T 162.

5.5. *Flow Table and Flow Mold*—Conforming to the requirements of M 152M/M 152.

5.6. *Tamper*—A nonabsorptive, nonabrasive, nonbrittle material such as a rubber compound having a Shore A durometer hardness of 80 ± 10 or seasoned oak wood rendered nonabsorptive by immersion for 15 minutes in paraffin at approximately 200ºC [392ºF], shall have a cross section of 13 by 25 mm [$^1/_2$ by 1 in.] and a convenient length of about 120 to 150 mm [5 to 6 in.]. The tamping face shall be flat and at right angles to the length of the tamper.

5.7. *Trowel*—Having a steel blade 100 to 150 mm [4 to 6 in.] in length, with straight edges.

5.8. *Moist Cabinet or Room*—Conforming to the requirements of M 201.

5.9. *Testing Machine*—Either the hydraulic or the screw type, with sufficient opening between the upper bearing surface and the lower bearing surface of the machine to permit the use of verifying apparatus. The load applied to the test specimen shall be indicated with an accuracy of ±1.0 percent. If the load applied by the compression machine is registered on a dial, the dial shall be provided with a graduated scale that can be read to at least the nearest 0.1 percent of the full scale load (Note 2). The dial shall be readable within one percent of the indicated load at any given load level within the loading range. In no case shall the loading range of a dial be considered to include loads below the value that is 100 times the smallest change of load that can be read on the scale. The scale shall be provided with a graduation line equal to zero and so numbered. The dial pointer shall be of sufficient length to reach the graduation marks; the width of the end of the pointer shall not exceed the clear distance between the smallest graduations. Each dial shall be equipped with a zero adjustment that is easily accessible from the outside of the dial case, and with a suitable device that at all times until reset will indicate to within 1 percent accuracy the maximum load applied to the specimen.

5.9.1. If the testing machine load is indicated in digital form, the numerical display must be large enough to be easily read. The numerical increment must be equal to or less than 0.10 percent of the full scale load of a given loading range. In no case shall the verified loading range include loads less than the minimum numerical increment multiplied by 100. The accuracy of the indicated load must be within 1.0 percent for any value displayed within the verified loading range. Provision must be made for adjusting to indicate true zero at zero load. There shall be provided a maximum load indicator that at all times until reset will indicate within 1 percent system accuracy the maximum load applied to the specimen.

Note 2—As close as can be read is considered 0.5 mm [$^1/_{50}$ in.] along the arc described by the end of the pointer. Also, one-half of the scale interval is about as close as can reasonably be read when the spacing on the load indicating mechanism is between 1 mm [$^1/_{25}$ in.] and 1.6 mm [$^1/_{16}$ in.]. When the spacing is between 1.6 mm [$^1/_{16}$ in.] and 3.2 mm [$^1/_8$ in.], one-third of the scale interval can be read with reasonable certainty. When the spacing is 3.2 mm [$^1/_8$ in.] or more, one-fourth of the scale interval can be read with reasonable certainty.

5.9.2. The upper bearing shall be a spherically seated, hardened metal block firmly attached at the center of the upper head of the machine. The center of the sphere shall lie at the center of the surface of the block in contact with the specimen. The block shall be closely held in its spherical seat, but shall be free to tilt in any direction. A hardened metal bearing block shall be used beneath the specimen to minimize wear of the lower platen of the machine. To facilitate accurate centering of the test specimen in the compression machine, one of the two surfaces of the bearing blocks shall have a diameter or diagonal of between 70.7 mm [2.83 in.] (see Note 3) and 73.7 mm [2.9 in.]. When the upper block bearing surface meets this requirement, the lower block bearing surface shall be greater than 70.7 mm [2.83 in]. When the lower block bearing surface meets this requirement, the diameter or diagonal of upper block bearing surface shall be between 70.7 and 79.4 mm [2.83 and $3^1/_8$ in.]. When the lower block is the only block with a diameter or diagonal between 70.7 and 73.7 mm [2.83 and 2.9 in.], the lower block shall be used to center the test specimen. In that case, the lower block shall be centered with respect to the upper bearing block and held in position by suitable means. The bearing block surfaces intended for contact with the specimen shall have a Rockwell hardness number not less than 60 HRC. These surfaces shall not depart from plane surfaces by more than 0.013 mm [0.0005 in.] when the blocks are new and shall be maintained within a permissible variation of 0.025 mm [0.001 in.].

Note 3—The diagonal of the 50-mm [2-in.] cube is 70.7 mm [2.83 in.].

6. MATERIALS

6.1. *Graded Standard Sand*:

6.1.1. The sand (Note 4) used for making test specimens shall be natural silica sand conforming to the requirements for graded standard sand in ASTM C 778.

Note 4—*Segregation of Graded Sand*—The graded standard sand should be handled in such a manner as to prevent segregation, because variations in the grading of the sand cause variation in the consistency of the mortar. In emptying bins or sacks, care should be exercised to prevent the formation of mounds of sand or craters in the sand, down the slopes of which the coarser particles will roll. Bins should be of sufficient size to permit these precautions. Devices for drawing the sand from bins by gravity should not be used.

7. TEMPERATURE AND HUMIDITY

7.1. *Temperature*—The temperature of the air in the vicinity of the mixing slab, the dry materials, molds, base plates, and mixing bowl shall be maintained between 23.0 ± 3.0°C [73.5 ± 5.5°F]. The temperature of the mixing water, moist closet, or moist room and water in the storage tank shall be set at 23 ± 2ºC [73.5 ± 3.5ºF].

7.2. *Humidity*—The relative humidity of the laboratory shall be not less than 50 percent. The moist closet or moist room shall conform to the requirements of M 201.

---

8. TEST SPECIMENS

8.1. Make two or three specimens from a batch of mortar for each period of test or test age.

---

9. PREPARATION OF SPECIMEN MOLDS

9.1. Apply a thin coating of release agent to the interior faces of the mold and non-absorptive base plates. Apply oils and greases using an impregnated cloth or other suitable means. Wipe the mold faces and the base plate with a cloth as necessary to remove any excess release agent and to achieve a thin, even coating on the interior surfaces. When using an aerosol lubricant, spray the release agent directly onto the mold faces and base plate from a distance of 150 to 200 mm [6 to 8 in.] to achieve complete coverage. After spraying, wipe the surface with a cloth as necessary to remove any excess aerosol lubricant. The residue coating should be just sufficient to allow a distinct fingerprint to remain following light finger pressure (Note 5).

9.2. Seal the surfaces where the halves of the mold join by applying a coating of light cup grease such as petrolatum. The amount should be sufficient to extrude slightly when the two halves are tightened together. Remove any excess grease with a cloth.

9.3. After placing the mold on its base plate (and attaching, if clamp-type) carefully remove with a dry cloth any excess oil or grease from the surface of the mold and the base plate to which watertight sealant is to be applied. As a sealant, use paraffin, microcrystalline wax, or a mixture of three parts paraffin to five parts rosin by mass. Liquefy the sealant by heating between 110 and 120ºC [230 and 248ºF]. Effect a watertight seal by applying the liquefied sealant at the outside contact lines between the mold and its base plate.

Note 5—Because aerosol lubricants evaporate, molds should be checked for a sufficient coating of lubricant immediately prior to use. If an extended period of time has elapsed since treatment, retreatment may be necessary.

Note 6—*Watertight Molds*—The mixture of paraffin and rosin specified for sealing the joints between molds and base plates may be found difficult to remove when molds are being cleaned. Use of straight paraffin is permissible if a watertight joint is secured; but due to the low strength of paraffin, it should be used only when the mold is not held to the base plate by paraffin alone. A watertight joint may be secured with paraffin alone by slightly warming the mold and base plate before brushing the joint. Molds so treated should be allowed to return to the specified temperature before use.

---

10. PROCEDURE

10.1. *Composition of Mortars*:

10.1.1. The proportions of materials for the standard mortar shall be one part of cement to 2.75 parts of graded standard sand by mass. Use a water-cement ratio of 0.485 for all portland cements and 0.460 for all air-entraining portland cements. The amount of mixing water for other than portland and air-entraining portland cements shall be such as to produce a flow of 110 ± 5 as determined in accordance with Section 10.3 and shall be expressed as mass percent of cement.

10.1.2. The quantities of materials to be mixed at one time in the batch of mortar for making six and nine test specimens shall be as follows in Table 2:

Table 2—Mixing Proportions for 2-in. Cubes

	No. of Specimens	
	6	9
Cement, g	500	740
Sand, g	1375	2035
Water, mL: portland (0.485)	242	359
Air-entraining portland (0.460)	230	340
Other (to flow of 110 ± 5)	—	—

10.2. *Preparation of Mortar*:

10.2.1. Mechanically mix in accordance with the procedure given in T 162.

10.3. *Determination of Flow*:

10.3.1. Carefully wipe the flow-table top clean and dry, and place the flow mold at the center. Place a layer of mortar about 25 mm [1 in.] in thickness in the mold and tamp 20 times with the tamper. The tamping pressure shall be just sufficient to ensure uniform filling of the mold. Then fill the mold with mortar and tamp as specified for the first layer. Cut off the mortar to a plane surface, flush with the top of the mold, by drawing the straight edge of a trowel (held nearly perpendicular to the mold) with a sawing motion across the top of the mold. Wipe the table top clean and dry, being especially careful to remove any water from around the edge of the flow mold. Lift the mold away from the mortar 60 seconds after completing the mixing operation. Immediately, drop the table through a height of 13 mm [$^1/_2$ in.], 25 times in 15 seconds. Using the calipers, determine the flow by measuring the diameters of the mortar along the four lines scribed in the table top, recording each diameter as the number of caliper divisions, estimated to one tenth of a division. If some other caliper is being used, measure the diameter of the mortar along the four lines scribed in the table top, recording each diameter to the nearest millimeter.

10.3.2. For portland and air-entraining portland cements, merely record the flow.

10.3.3. In the case of cements other than portland or air-entraining portland cements, make trial mortars with varying percentages of water until the specified flow is obtained. Make each trial with fresh mortar.

10.3.4. Immediately following completion of the flow test, return the mortar from the flow table to the mixing bowl. Quickly scrape the bowl sides and transfer into the batch the mortar that may have collected on the side of the bowl and then remix the entire batch 15 seconds at medium speed. Upon completion of mixing, the mixing paddle shall be shaken to remove excess mortar into the mixing bowl.

10.3.5. When a duplicate batch is to be made immediately for additional specimens, the flow test may be omitted and the mortar allowed to stand in the mixing bowl 90 seconds without covering. During the last 15 seconds of this interval, quickly scrape the bowl sides and transfer into the batch the mortar that may have collected on the side of the bowl. Then remix for 15 seconds at medium speed.

10.4. *Molding Test Specimens*:

10.4.1. Complete the consolidation of the mortar in the molds either by hand tamping or by a qualified alternative method. Alternative methods include but are not limited to the use of a vibrating table or mechanical devices.

10.4.2. *Hand Tamping*—Start molding the specimens within a total elapsed time of not more than 2 minutes and 30 seconds after completion of the original mixing of the mortar batch. Place a layer of mortar about 25 mm [1 in.] (approximately one-half of the depth of the mold) in all of the cube compartments. Tamp the mortar in each cube compartment 32 times in about 10 seconds in four rounds, each round to be at right angles to the other and consisting of eight adjoining strokes over the surface of the specimen, as illustrated in Figure 1. The tamping pressure shall be just sufficient to ensure uniform filling of the molds. The four rounds of tamping (32 strokes) of the mortar shall be completed in one cube before going to the next. When the tamping of the first layer in all of the cube compartments is completed, fill the compartments with the remaining mortar and then tamp as specified for the first layer. During tamping of the second layer, bring in the mortar forced out onto the tops of the molds after each round of tamping by means of the gloved fingers and the tamper upon completion of each round and before starting the next round of tamping. On completion of the tamping the tops of all cubes should extend slightly above the tops of the molds. Bring in the mortar that has been forced out onto the tops of the molds with a trowel and smooth off the cubes by drawing the flat side of the trowel (with the leading edge slightly raised) once across the top of each cube at right angles to the length of the mold. Then, for the purpose of leveling the mortar and making the mortar that protrudes above the top of the mold of more uniform thickness, draw the flat side of the trowel (with the leading edge slightly raised) lightly once along the length of the mold. Cut off the mortar to a plane surface flush with the top of the mold by drawing the straightedge of the trowel (held nearly perpendicular to the mold) with a sawing motion over the length of the mold.

10.4.3. *Alternative Methods*—Any consolidation method may be used that meets the qualification requirements of this section. The consolidation method consists of a specific procedure, equipment and consolidation device, as selected and used in a consistent manner by a specific laboratory. The mortar batch size of the method may be modified to accommodate the apparatus, provided the proportions maintain the same ratios as given in Section 10.1.2.

10.4.3.1. Separate qualifications are required for the following classifications:

10.4.3.2. *Class A, Non-Air Entrained Cements*—For use in concrete. Refer to M 85, M 240, and ASTM C 1157.

10.4.3.3. *Class B, Air-Entrained Cements*—For use in concrete. Refer to M 85, M 240, and ASTM C 1157.

10.4.3.4. *Class C, Masonry, Mortar, and Stucco Cements*—Refer to ASTM C 91, ASTM C 1328, and ASTM C 1329.

10.4.3.5. An alternative method may only be used to test the cement types as given in Section 10.4.3.1 above, for which it has been qualified.

10.4.3.6. It can also be used for Strength Activity Index determinations for fly ash and slag, refer to M 295 and M 302, provided the alternative method has qualified for both Class A and Class C cements.

10.4.4. *Qualification Procedure*—Contact Cement and Concrete Reference Laboratory (CCRL) to purchase cement samples that have been used in the Proficiency Sample Program (PSP). Four samples (5 kg each) of the class to be qualified will be required to complete a single qualification (see Note 7).

10.4.4.1. In one day, prepare replicate six-cube or nine-cube batches using one of the cements and cast a minimum of 36 cubes. Complete one round of tests on each cement on different days. Store and test all specimens as prescribed in the sections below. Test all cubes at the age of 7 days.

10.4.4.2. Tabulate the compressive strength data and complete the mathematical analyses as instructed in Annex A1.

10.4.5. *Re-qualification of the Alternate Compaction Method*:

10.4.5.1. Re-qualification of the method shall be required if any of the following occur:

- Evidence that the method may not be providing data in accordance with the requirements of Table 2.
- Results that differ from the reported final average of a CCRL-PSP sample with a rating of three or less.
- Results that differ from the accepted value of a known reference sample with established strength values by more than twice the multi-laboratory 1s percent values of Table 2. Before starting the re-qualification procedure, evaluate all aspects of cube fabrication and testing process to determine if the offending result is due to some systematic error or just an occasional random event.

10.4.5.2. If the compaction equipment is replaced, significantly modified, repaired, or has been recalibrated, re-qualify the equipment in accordance with Section 10.4.4.

Note 7—It is recommended that a large homogenous sample of cement be prepared at the time of qualification for use as a secondary standard and for method evaluation. Frequent testing of this sample will give early warning of any changes in the performance of the apparatus.

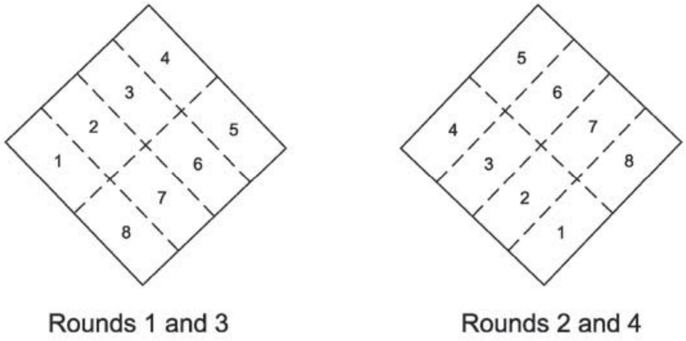

Figure 1—Order of Tamping in Molding of Test Specimens

10.5. *Storage of Test Specimens*—Immediately upon completion of molding, place the test specimens in the moist closet or moist room. Keep all test specimens, immediately after molding, in the molds on the base plates in the moist closet or moist room from 20 to 72 hours with their upper surfaces exposed to the moist air but protected from dripping water. If the specimens are removed from the molds before 24 hours, keep them on the shelves of the moist closet or moist room until they are 24 hours old. Then immerse the specimens, except those for the 24-hour test, in saturated lime water in storage tanks constructed of non-corroding materials. Keep the storage water clean by changing as required.

10.6. *Determination of Compressive Strength*:

10.6.1. Test the specimens immediately after their removal from the moist closet in the case of 24-hour specimens, and from storage water in the case of all other specimens. All test specimens for a given test age shall be broken within the permissible tolerance prescribed as follows in Table 3:

Table 3—Testing Time Tolerances

Test Age	Permissible Tolerance
24 hours	± $^1/_2$ hour
3 days	± 1 hour
7 days	± 3 hours
28 days	± 12 hours
56 days	± 24 hours

If more than one specimen at a time is removed from the moist closet for the 24-hour tests, keep these specimens covered with a damp cloth until time of testing. If more than one specimen at a time is removed from the storage water for testing, keep these specimens in water at a temperature of 23 ± 2°C [73.5 ± 3.5°F] and of sufficient depth to completely immerse each specimen until time of testing.

10.6.2. Wipe each specimen to a surface-dry condition, and remove any loose sand grains or incrustations from the faces that will be in contact with the bearing blocks of the testing machine.

Check these faces by applying a straightedge (Note 8). If there is appreciable curvature, grind the face or faces to plane surfaces or discard the specimen. A periodic check of the cross-sectional area of the specimen should be made.

Note 8—*Specimen Faces*: Results much lower than the true strength will be obtained by loading faces of the cube specimen that are not truly plane surfaces. Therefore, it is essential that the specimen molds be kept scrupulously clean, as otherwise large irregularities in the surface will occur. Instruments for cleaning molds should always be softer than the metal in the molds to prevent wear. In case grinding specimen faces is necessary, it can be accomplished best by rubbing the specimen on a sheet of fine emery paper or cloth glued to a plane surface, using only a moderate pressure. Such grinding is tedious for more than a few hundredths of a millimeter (thousandths of an inch); where more than this is found necessary, it is recommended that the specimen be discarded.

10.6.3. Apply the load to specimen faces that were in contact with the true plane surfaces of the mold. Carefully place the specimen in the testing machine below the center of the upper bearing block. Prior to the testing of each cube, it shall be ascertained that the spherically seated block is free to tilt. Use no cushioning or bedding materials. Bring the spherically seated block into uniform contact with the surface of the specimen. Apply the load rate at a relative rate of movement between the upper and lower platens corresponding to a loading on the specimen with the range of 900 to 1800 N/s [200 to 400 lb/s]. Obtain this designated rate of movement of the platen during the first half of the anticipated maximum load and make no adjustment in the rate of movement of the platen in the latter half of the loading, especially while the cube is yielding before failure.

Note 9—It is advisable to apply only a very light coating of a good quality, light mineral oil to the spherical seat of the upper platen.

11. CALCULATION

11.1. Record the total maximum load indicated by the testing machine, and calculate the compressive strength as follows:

$$fm = P/A \qquad (1)$$

where:

fm = compressive strength in MPa [psi],

P = total maximum load in N [lbf], and

A = area of loaded surface in mm^2 [$in.^2$].

Either 50-mm [2-in.] cube specimens may be used for the determination of compressive strength, whether SI or inch-pound units are used. However, consistent units for load and area must be used to calculate strength in the units selected. If the cross-sectional area of the specimen varies more than 1.5 percent from the nominal, use the actual area for the calculation of the compressive strength. The compressive strength of all acceptable test specimens (Section 13) made from the same sample and tested at the same period shall be averaged and reported to the nearest 0.1 MPa [10 psi].

12. REPORT

12.1. Report the flow to the nearest 1 percent and the water used to the nearest 0.1 percent. Average compressive strength of all specimens from the same sample shall be reported to the nearest 0.1 MPa [10 psi].

13. FAULTY SPECIMENS AND RETESTS

13.1. In determining the compressive strength, do not consider specimens that are manifestly faulty.

13.2. The maximum permissible range between specimens from the same mortar batch, at the same test age, is 8.7 percent of the average when three cubes represent a test age and 7.6 percent when two cubes represent a test age (Note 10).

Note 10—The probability of exceeding these ranges is 1 in 100 when the within-batch coefficient of variation is 2.1 percent. The 2.1 percent is an average for laboratories participating in the portland cement and masonry cement reference sample programs of the Cement and Concrete Reference Laboratory (CCRL).

13.3. If the range of three specimens exceeds the maximum in Section 13.2, discard the result that differs most from the average and check the range of the remaining two specimens. Make a retest of the sample if fewer than two specimens remain after discarding faulty specimens or discarding tests that fail to comply with the maximum permissible range of two specimens.

Note 11—Reliable strength results depend upon careful observance of all the specified requirements and procedures. Erratic results at a given test period indicate that some of the requirements and procedures have not been carefully observed; for example, those covering the testing of the specimens as prescribed in Sections 10.6.2 and 10.6.3. Improper centering of specimens resulting in oblique fractures or lateral movement of one of the heads of the testing machine during loading will often cause lower strength results.

14. PRECISION AND BIAS

14.1. *Precision*—The precision statements for this test method are listed in Table 4 and are based on results from the Cement and Concrete Reference Laboratory (CCRL) Reference Sample Program. They are developed from data where a test result is the average of compressive strength tests of three cubes molded from a single batch of mortar and tested at the same age. A significant change in precision will not be noted when a test result is the average of two cubes rather than three.

Table 4—Precision

		Test Age, Days	Coefficient of Variation 1s, Percent[a]	Acceptable Range of Test Results d2s, Percent[a]
Portland cements:				
Constant water-cement ratio:				
Single-laboratory		3	4.0	11.3
		7	3.6	10.2
	Av		3.8	10.7
Multilaboratory		3	6.8	19.2
		7	6.4	18.1
	Av		6.6	18.7
Blended cements:				
Constant flow mortar:				
Single-laboratory		3	4.0	11.3
		7	3.8	10.7
		28	3.4	9.6
	Av		3.8	10.7
Multilaboratory		3	7.8	22.1
		7	7.6	21.5
		28	7.4	20.9
	Av		7.6	21.5
Masonry cements:				
Constant flow mortar:				
Single-laboratory		7	7.9	22.3
		28	7.5	21.2
	Av		7.7	21.8
Multilaboratory		7	11.8	33.4
		28	12.0	33.9
	Av		11.9	33.7

[a] These numbers represent, respectively, the (1s percent) and (ds2 percent) limits as described in ASTM C 670. Precision data for tests at ages of 24 hours and 56 days are not available.

14.2. These precision statements are applicable to mortars made with cements mixed and tested at the ages as noted. The appropriate limits are likely somewhat larger for tests at younger ages and slightly smaller for tests at older ages.

14.3. *Bias*—The procedure in this test method has no bias because the value of compressive strength is defined in terms of the test method.

15. KEYWORDS

15.1. Compressive strength; hydraulic cement mortar; hydraulic cement strength; mortar strength; strength.

ANNEX

(Mandatory Information)

A1. ANALYSES OF TEST RESULTS FOR QUALIFICATION OF ALTERNATE COMPACTION METHODS

A1.1. *Calculation of Average Within-Batch Standard Deviation and Elimination of Outliers*—Tabulate the results for each cement sample (or round) in separate spreadsheets. In the spreadsheet, list results of each batch in columns and complete the calculations as shown in Table A1.1.

A1.1.1. Eliminate any outliers from the test data and repeat the calculations until none of the values lie outside the normal range.

A1.1.2. Tabulate the cube strengths with all the outliers eliminated and complete the calculations as shown in Table A1.2.

A1.2. *Summary of Results*—Compile the results of the four rounds and complete the calculations as shown in Table A1.3. The number of outliers shall not exceed 5 percent of the total number of test when rounded to the nearest whole number (for example, 4 rounds by 4 batches by 9 cubes = 144 tests by 5% (5/100) = 7.2 or 7.

A1.3. *Precision Qualification*—Calculate the relative within batch error (*RWBE*%) as shown in Table A1.3. This value must be less than 2.1percent to comply with the limit established in Note 10 of this specification.

A1.4. *Bias Qualification*—The test results compiled in Table A1.3 are evaluated against three limits to demonstrate an acceptable qualification. The limits have been established statistically from analyses of historical CCRL data and are given in Table A1.4.

A1.5. *Rationale for the Limits Given in Section A1.4*:

A1.5.1. The multilaboratory precision (1s%) for the average of *n* batches is given by:

Table A1.1—Example Using 9-Cube Batch

Round—2

CCRL Sample #140 Industry Average Strength, $X_i = 32.923$
Cast Date—00/00/00

7-Day Strengths, MPa

A	B	C	D	E
Batch Number	1	2	3	4
Cube 1	33.0	34.3	34.4	33.2
Cube 2	33.9	32.5	34.0	34.0
Cube 3	33.4	34.0	34.1	33.8
Cube 4	33.1	33.8	34.0	33.8
Cube 5	33.0	33.4	34.2	34.0
Cube 6	32.8	33.7	31.8	33.1
Cube 7	33.6	32.6	33.9	32.8
Cube 8	31.5	32.1	33.0	33.3
Cube 9	33.6	34.3	33.4	34.4
Average, X_b	33.10	33.42	33.65	33.60
SD_b	0.70	0.82	0.81	0.52
N_b	9	9	9	9
$(N_b–1)SD_b^2$	3.936	5.432	5.265	2.145
			N_r	36
			X_r	33.44
			SD_r	0.692
			MND	1.703
Normal Range				
Maximum	34.81	35.12	35.35	35.30
Minimum	31.40	31.71	32.95	31.89
Outliers	None	None	Cube 6	None

where:

X_i = industry average strength (CCRL);
X_b = average of test values in a single batch;
SD_b = Standard deviation of a single batch =

$$\sqrt{\frac{\sum_{\text{cube}}\left(x - x_b\right)^2}{N_b - 1}}$$

N_b = number of tests per batch;
$(N_b - 1)SD_b^2$ = an intermediate calculation;
N_r = total number of tests per round;
X_r = grand average of tests values obtained per round, MPa;
SD_r = mean standard deviation of round =

$$\sqrt{\frac{\sum_{\text{Batch}}\left(N_b - 1\right)SD_b^2}{N_r - 1}}$$

MND = Maximum normal deviation: use Excel™ function "=nominv (1–0.25/Nr,0,SDr)" or equivalent, or use statistical tables to find the inverse integrated nominal distribution for an integral value (1–0.25/N_r) in a normal distribution with $\sigma = SD_r$.

Normal Range:
Maximum = $(X_b + MND)$
Minimum = $(X_b - MND)$
Outlier = Any test value falling outside the calculated normal range

$$s\%_{ML,n} = \sqrt{s\%_{ML}^2 - \left(1 - \frac{1}{n}\right) s\%_{SO}^2}$$

A1.5.2. The limit for deviation of the individual rounds (no failures being allowed when four rounds are performed) is 1.2 $s\%_{ML,n}$, as used in T 105.

A1.5.3. The multilaboratory precision (1s%) for the mean of four rounds is 0.5 $s\%_{ML,n}$.

A1.5.4. The limit for deviation of the mean of four rounds (95 percent confidence) is 1.96 times this, or 0.98 $s\%_{ML,n}$.

Table A1.2—Test Data after the Elimination of Outlines (Example Using 9-Cube Batch)

Round—2

CCRL Sample #140 Industry Average Strength, X_i = 32.923
Cast Date—00/00/00

7-Day Strengths, MPa

A	B	C	D	E
Batch Number	1	2	3	4
Cube 1	33.0	34.3	34.4	33.2
Cube 2	33.9	32.5	34.0	34.0
Cube 3	33.4	34.0	34.1	33.8
Cube 4	33.1	33.8	34.0	33.8
Cube 5	33.0	33.4	34.2	34.0
Cube 6	32.8	33.7		33.1
Cube 7	33.6	32.6	33.9	32.8
Cube 8		32.1	33.0	33.3
Cube 9	33.6	34.3	33.4	34.4
Average, X_{bv}	33.29	33.42	33.89	33.60
SD_{bv}	0.39	0.82	0.46	0.52
N_{bv}	8	9	8	9
$(N_{bv} - 1)SD_{bv}^2$	1.092	5.348	1.462	2.159
			N_{rv}	34
			X_{rv}	33.55
			X_i	32.92
			SD_{rv}	0.55
			E_r, MPa	0.63
			RE_r,%	1.91

where:

X_{bv} = average of valid test values obtained per batch, MPa;
X_i = Industry average strength (CCRL), MPa;
SD_{bv} = $\sqrt{\dfrac{\sum_{\text{Valid cube}} \left(x - x_{bv}\right)^2}{N_{bv} - 1}}$

N_{bv} = number of tests per batch;
$(N_{vb} - 1)SD_{bv}^2$ = an intermediate calculation;
N_{rv} = total number of tests per round;
X_{rv} = grand average of tests values obtained per round, MPa;
SD_{rv} = mean standard deviation of round =

$$\sqrt{\frac{\sum_{\text{Batch}} \left(N_{bv} - 1\right) SD_{bv}^2}{N_{rv} - 1}}$$

E_r = error = $(X_i - X_{rv})$, MPa; and
R_{er} = relative error for the round, % = $100(E_r/X_{rv})$.

A1.5.5. The values for $s\%_{ml}$ and $s\%_{xo}$ for Cement Classes A and C (non-air-entrained cements for mortar respectively) are the 7-day values in the current precision statement of T 106M/T 106. There appear to be no data for Cement Class B (air-entrained cements for concrete). Working on the assumption that the value of this quantity is related to the air content, the values adopted for Class B are the mean of the A and C-values.

For the applicable conditions, the equations above give the following:

Deviations of Limits for Table A1.4

Cement Class	A	B	C	A	B	C
Batches per round (*n*)	6	6	6	4	4	4
Single Operator s% (single batch)	3.6	5.75	7.9	3.6	5.75	7.9
Multilaboratory s% (single batch)	6.4	9.1	11.8	6.4	9.1	11.8
Multilaboratory s% (n batches)	5.5	7.4	9.3	5.6	7.6	9.6
Limit for deviation of a single round %	6.6	8.9	11.2	6.7	9.1	11.5
Limit of deviation of mean of four rounds %	5.4	7.3	9.2	5.5	7.5	9.4

Table A1.3—Summary of Results

A	B	C	D	E	F	G	H	I

						Max, RE_r,%		6.85
						Mean, RE_r,%		3.17
						GMWBE, MPa		0.65
						RWBE, %		2.01
						Max, *RWBE*, %[a]		2.1
						Precision Test		Pass

[a] = See Note 10.

where:

X_r = industry average strength, MPa;
X_{rv} = grand mean value of the valid tests of a round;
RE_{rv}, % = relative error = $100(X_i - X_{rv})$;
N_{rv} = total number of valid tests of the round;

SD_{rv} = mean standard deviation of a round = $\sqrt{\dfrac{\sum_{\text{Batch}} \left(N_{bv} - 1\right) SD_{rv}^{2}}{N_{rv} - 1}}$

$(N_r - 1)SD_r^2$ = intermediate calculation;
X_g = grand mean value of the valid tests (4 rounds);
N_g = total number of valid tests in 4 rounds;
$GMWBE$ = grand mean within-batch error, MPa = $\sqrt{\dfrac{\sum_{\text{Round}} \left(N_{rv} - 1\right) SD_{rv}^{2}}{N_{g} - 1}}$

$RWBE$ = relative within batch error, % = $100\left(\dfrac{GMWBE}{X_g}\right)$; and

Max, $RWBE$ = maximum allowed $RWBE$ = 2.10% (see Note 10).

Table A1.4—Bias Qualification Requirements

	6-Cube Batches (Minimum 6 Batches per Round)			9-Cube Batches (Minimum 4 Batches per Round)		
Cement classification (see Section 10.4.3.1)	A	B	C	A	B	C
Maximum allowable relative error any 4 or 6 batches, $MARE_r$%	6.6	8.9	11.2	6.7	9.1	11.5
Maximum allowable relative error mean of 4 rounds of 4 batches or 6 batches <5% failures, *GRE*%	5.4	7.3	9.2	5.5	7.5	9.4
Minimum allowable confidence limit, % *MACL* %	95	95	95	95	95	95

Table A1.5—Bias Tests (Example Using 9-Cube Batches, Class A Cement)

MRE_r %, the maximum relative error value of the four rounds	6.85
$MARE_r$ %, max allowable MRE_r from Table A1.4	6.7—Fails
GRE, the average RE_r % of the 4 rounds	3.13
Maximum limit of $MGRE_g$ % from Table A1.4	5.5—Pass
Bias confidence limit, *CL* %	96.99
Minimum allowable confidence limit, *MACL* % (from Table A1.4)	95—Pass

The above results indicate the data fails to show compliance.

where:

MRE_r, % = the maximum relative error, % obtained for any round (from values in column F, Table A1.3),
$MARE_r$, % = the maximum allowable relative error, % of any Round (Table A1.4),
GRE, % = the grand average of the RE_r, % values of the 4 rounds,
$MARE_g$, % = maximum allowed *GRE*, % value (average of column F, Table A1.3), and
CL, % = bias confidence limit, %, the confidence with which it can be stated that the error of the mean of 4 rounds is non-zero. Calculate this by use of ExcelT function "=ttest(<range of industry means>,<range of values obtained>,1,1)" or equivalent, or use statistical tables to find the confidence in a one-tailed, paired-value t-test on the set of round errors.

Note A1—The qualification method fails for bias if (1) the MRE_r exceeds the $MARE_r$, percentage limit; or if (2) the GRE, percentage exceeds the $MGRE_g$ limit and the CL, percentage exceeds 95 percent.

Standard Method of Test for

Autoclave Expansion of Hydraulic Cement

AASHTO Designation: T 107-07
ASTM Designation: C 151-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Autoclave Expansion of Hydraulic Cement

AASHTO Designation: T 107-07
ASTM Designation: C 151-05

1. SCOPE

1.1. This test method covers determination of the autoclave expansion of hydraulic cement by means of a test on a neat cement specimen.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. For specific precaution statements, see the section on Safety Precautions.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 201, Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes
- M 210, Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete
- T 129, Normal Consistency of Hydraulic Cement
- T 162, Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

2.2. *ASTM Standard*:

- C 856, Standard Practice for Petrographic Examination of Hardened Concrete
- C 1005, Standard Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements
- C 1157, Standard Performance Specification for Hydraulic Cement
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. SIGNIFICANCE AND USE

3.1. The autoclave expansion test provides an index of potential delayed expansion caused by the hydration of CaO or MgO or both, when present in hydraulic cement.[1]

4. INTERFERENCES

4.1. Pozzolans containing fine-grained quartz have been reported to cause excessive expansion under autoclave test conditions due to alkali-silica reaction that will not occur under normal service conditions.[2] When excessive expansion of paste containing pozzolans occurs, it is recommended that the specimens be examined (See ASTM C 856) for evidence of alkali-silica reaction (Note 1).

Note 1—If the excessive expansion has resulted from alkali-silica reaction under autoclave conditions, the pozzolan can be evaluated for alkali reactivity using the procedure described in ASTM C 1157.

5. APPARATUS

5.1. *Weighing Devices and Weights*—for determining the mass of materials conforming to the requirements of ASTM C 1005.

5.2. *Glass Graduates*—200- or 250-mL capacity, and conforming to the requirements of M 210.

5.3. *Molds*—25 by 25-mm or 1 by 1-in. cross section, conforming to the requirements of M 210.

5.4. *Flat Trowel*—having a straightedged steel blade 100 to 150 mm (4 to 6 in.) in length.

5.5. *Autoclave*—consisting of a high-pressure steam vessel provided with a thermometer well. The autoclave shall be equipped with automatic controls and a rupture disk with a bursting pressure of 2.41 MPa (350 psi) ±5 percent. In locations where the use of a rupture disk is not permitted, the autoclave shall be equipped with a safety valve. In addition, the autoclave shall be equipped with a vent valve to allow the escape of air during the early part of the heating period and to release any steam pressure remaining at the end of the cooling period. The pressure gauge shall have a nominal capacity of 4.14 MPa (600 psi), a dial with a nominal diameter of 114 mm ($4^1/_2$ in.) and shall be graduated from 0 to 4.14 MPa (0 to 600 psi) with scale divisions not exceeding 0.03 MPa (5 psi). The error in the gauge shall not exceed ±0.02 MPa (±3 psi) at the operating pressure of 2.03 MPa (295 psi). The capacity of the heating unit shall be such that with maximum load (water plus specimens) the pressure of the saturated steam in the autoclave may be raised to a gauge pressure of 2.03 MPa (295 psi) in 45 to 75 minutes from the time the heat is turned on. The automatic control shall be capable of maintaining the gauge pressure of 2.03 ± 0.07 MPa (295 ± 10 psi) for at least three hours. A gauge pressure of 2.03 ± 0.07 MPa (295 ± 10 psi) corresponds to a temperature of (420 ± 3ºF) 216 ± 2ºC. The autoclave shall be designed to permit the gauge pressure to drop from 2.03 MPa (295 psi) to less than 0.07 MPa (10 psi) in 1.5 hours after the heat supply has been shut off.

5.5.1. *Rupture Disk*—The rupture disk shall be made of a material having a tensile strength that is relatively insensitive to temperature in the range 20 to 216ºC (68 to 420ºF) and that is electrochemically compatible with the pipe leading to it and to its holder.

5.6. *Length Comparator*—The comparator used for measuring length change of specimens shall conform to the requirements of M 210.

6. TEMPERATURE AND HUMIDITY

6.1. *Molding Room*—Maintain the temperature of the molding room, dry materials, and mixing water, and the relative humidity of the molding room within the limits of M 210.

6.2. *Moist Storage Facilities*—Maintain the temperature and humidity of the moist storage facilities to the requirements of M 201.

7. SAFETY PRECAUTIONS

7.1. The pressure gauge should have a maximum capacity of 4.14 MPa (600 psi). A gauge with too small or too large a capacity may be a hazard, since for pressure above the specified maximum working pressure, with a smaller capacity gauge, the pressure may be off scale, and with a larger capacity gauge, the arc of movement may be too small to invite attention. The operator shall be sure the gauge hand has not passed the maximum graduation on the scale.

7.2. Test the pressure gauge for proper operation. Always use a thermometer together with the pressure gauge, so as to provide a means of detecting any failure of the pressure gauge to operate properly, and to indicate any unusual condition.

7.3. Maintain the automatic control in proper working order at all times.

7.4. Set the safety valve to relieve the pressure at about 6 to 10 percent above the maximum of 2.10 MPa (305 psi) specified in this test method, that is, at about 2.28 MPa (330 psi). Unless the manufacturer has given specific instructions as to maintenance of the safety valve, test the valve twice each year. Test with a gauge testing device, or by adjusting the automatic controls to allow the autoclave to reach a pressure of about 2.28 MPa (330 psi), at which pressure the safety valve will either open or be adjusted to open. Direct the safety valve discharge away from the operator.

Note 2—Unexpected combinations of conditions may occur. For example, in one case the automatic control had failed, the safety valve had become stuck, and the gauge hand, which at first glance appeared to be at about zero, had passed the maximum graduation and had come to stop on the wrong side of the pin. This condition of the gauge was finally detected and the pressure, then of an unknown magnitude, was released before failure could occur in the apparatus.

7.5. Wear heavy leather work gloves to prevent burning of the hands when removing the top of the autoclave at the end of the test. Direct the vent valve away from the operator. When removing the autoclave lid, tilt it so that any steam escaping from beneath the lid may be discharged away from the operator. Care shall be taken to avoid scalding by any liquid that may have been used in the autoclave well.

7.6. The operator shall be made aware that for many autoclave pressure gages the return of the gauge hand to the initial rest or starting point does not necessarily indicate zero pressure within the autoclave; there may then still remain an appreciable dangerous pressure.

8. NUMBER OF TEST SPECIMENS

8.1. Make at least one test specimen.

9. PREPARATION OF SPECIMEN MOLDS

9.1. Prepare the specimen molds in accordance with the requirements of M 210 except that molds need not be sealed.

10. PREPARATION OF TEST SPECIMENS

10.1. *Mixing Cement Paste*—Prepare the standard batch consisting of 650 g of cement and sufficient water to give a paste of normal consistency in accordance with the procedure described in T 129. Mix this batch in accordance with the procedure described in T 162. Both a time of setting specimen and an autoclave bar may be made from the same batch. If the paste to be used for time of setting is the paste sample already used to determine normal consistency, then the autoclave bar may be prepared immediately from the remainder of the batch.

10.2. *Molding Specimens*—Immediately following preparation of the time of setting specimen or completion of mixing, mold the test specimen in two approximately equal layers, each layer being compacted with the thumbs or forefingers by pressing the paste into the corners, around the gauge studs, and along the surface of the mold until a homogeneous specimen is obtained. Compact the top layer, cut off the paste flush with the top of the mold with a thin-edged trowel, and smooth the surface with a few strokes of the flat trowel. During the operations of mixing and molding, protect the hands with rubber gloves.

10.3. *Storage of Test Specimens*—After filling the mold, place it in the moist closet or moist room. Store the specimens in the molds in the moist enclosure for at least 20 hours; if removed from the molds before 24 hours, they shall be kept in the moist closet or moist room until time of test.

11. PROCEDURE

11.1. At 24 hours ± 30 minutes after molding, remove the specimens from the moist atmosphere, immediately obtain a length comparator reading for each specimen, and place in the autoclave at room temperature in a rack so that all sides of the specimen will be exposed to saturated steam. The autoclave shall contain enough water, at an initial temperature of 68 to 82ºF (20 to 28ºC), to maintain an atmosphere of saturated steam vapor during the entire test. Ordinarily 7 to 10 percent of the volume of the autoclave should be occupied by the water.

11.2. To permit air to escape from the autoclave during the early portion of the heating period, leave the vent valve open until steam begins to escape. (**Warning**—See Section 7 on Safety Precautions.) Close the valve and raise the temperature of the autoclave at a rate that will bring the gauge pressure of the steam to 2.03 MPa (295 psi) in 45 to 75 minutes from the time the heat is turned on. Maintain 2.03 ± 0.07 MPa (295 ± 10 psi) pressure for three hours. At the end of the three-hour period, shut off the heat supply and cool the autoclave at such a rate that the pressure will be less than 0.07 MPa (10 psi) at the end of the 1.5-hour period, and slowly release any remaining pressure by partially opening the vent valve until atmospheric pressure is attained. Then open the autoclave and place the test specimen in water at a temperature above 90ºC (194ºF). Cool the water surrounding the bars at a uniform rate by adding cold water so that the temperature of the water will be lowered to 23ºC (74ºF) in 15 minutes. Maintain the water surrounding the specimens at 23ºC for an additional 15 minutes; then, remove one specimen at a time from the water, blot the pins, but not the specimen, and obtain a length comparator reading for each specimen.

12. CALCULATION

12.1. Calculate the change in length of the test specimen by subtracting the length comparator reading before autoclaving from that after autoclaving, and report as percent of the effective gauge length to the nearest 0.01 percent. Report the percentage of increase in length as the autoclave expansion. Indicate a decrease in length by a minus sign prefixed to the percent value.

13. PRECISION AND BIAS

13.1. *Precision*—The single-operator (within-laboratory) standard deviation has been found to be 0.024 percent throughout the range of 0.11 percent to 0.94 percent expansions. Therefore, results of two properly conducted tests by the same operator for expansions of similar batches should not differ from each other by more than 0.07 percent expansion. The multilaboratory (between laboratory) standard deviation has been found to be 0.030 percent throughout the range of 0.11 percent to 0.94 percent expansions. Therefore, results of two properly conducted tests from two different laboratories for expansions of similar batches should not differ from each other by more than 0.09 percent expansion.

13.2. *Bias*—Because there is no accepted reference material suitable for determining bias, bias has not been determined.

For additional useful information on details of cement test methods, reference may be made to the "Manual of Cement Testing," which appears in the *Annual Book of ASTM Standards*, Volume 04.01.

14. KEYWORDS

14.1. Autoclave; autoclave expansion; expansion; hydraulic cement; soundness.

Standard Method of Test for

Sampling and Amount of Testing of Hydraulic Cement

AASHTO Designation: T 127-04 (2008)
ASTM Designation: C 183-02

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling and Amount of Testing of Hydraulic Cement

AASHTO Designation: T 127-04 (2008)
ASTM Designation: C 183-02

1. SCOPE

1.1. This practice covers procedures for sampling and for the amount of testing of hydraulic cement after it has been manufactured and is ready to be offered for sale.

1.2. The values stated in SI units are to be regarded as the standard. The inch–pound units in parentheses are for information purposes only.

1.2.1. A ton as used in this practice is 907 kg (2000 lb).

1.2.2. Values in SI units shall be obtained by measurement in SI units or by appropriate conversion using the rules for conversion and rounding given in standard IEEE/ASTM SI 10, of measurements made in other units.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions of Terms Specific to This Standard*:

3.1.1. *lot (of cement)*—specific quantity of cement offered for inspection at any one time. A lot may be one or more storage bins filled consecutively. A lot may also be the contents of one or more transport units representing cement drawn from the same storage bin.

3.1.2. *reduced testing rate*—test program that provides for the testing of only two samples from any given lot of samples obtained and prepared for testing at the normal rate as described herein. The program utilizes probability factors and is so designed that when results from the two samples fulfill the requirements of the program, it may be said with 95 percent confidence that fewer than 5 percent of the samples would be outside the specification limits.

4. SIGNIFICANCE AND USE

4.1. The sampling procedures described are intended for use in the procurement of samples of hydraulic cement after it has been manufactured and is ready to be offered for sale. They are not intended as sampling procedures for quality control purposes during manufacturing. The testing procedures outlined cover the amount of testing to be done and provide guidance for reporting on conformance or non-conformance of cements with requirements of purchase specifications.

4.2. This practice is referenced as the procedure for sampling masonry cement (ASTM C 91), portland cement (M 85), blended hydraulic cement (M 240), expansive hydraulic cement (ASTM C 845), plastic stucco cement (ASTM C 1328), mortar cement (ASTM C 1329), and hydraulic cement based on a performance specification (ASTM C 1157).

4.3. Most building codes and construction specifications require that hydraulic cement to be used in the work meet the applicable requirements of the relevant purchase specifications, such as Specifications M 85, M 240, ASTM C 91, ASTM C 845, ASTM C 1157, ASTM C 1328 and ASTM C 1329. If the code or specification requires sampling of the manufactured cement, the provisions given in Section 4.4 are applicable. Not much cement is sold on the basis of such sampling and testing. A useful discussion of sampling and testing cement is contained in ACI 225.1R.

4.4. The procedures covered in this practice should be done by or for purchasers of hydraulic cement who are using a code or specification that requires sampling and testing to determine if the samples conform to the relevant acceptance specifications. The testing is done using specified methods to determine whether the samples yield test results that conform to the specification, and the tests serve as a basis for acceptance or rejection of the lot of material sampled.

4.5. It is neither intended nor required that all cements be tested using all the test methods referenced in Section 2.

5. KINDS AND SIZE OF SAMPLES AND BY WHOM TAKEN

5.1. A cement sample secured from a conveyor, from bulk storage, or from a bulk shipment in one operation shall be termed a “grab sample.” A sample obtained during a 10-minute interval using an automatic sampling device that continuously samples a cement stream may also be termed a grab sample. Grab samples taken at prescribed intervals over a period of time may be combined to form a “composite sample” representative of the cement produced during that period of time.

5.2. All samples, whether grab or composite, shall have a mass of at least 5 kg (10 lb).

5.3. The purchaser may designate a representative to supervise the sampling, packing, and shipping of samples when it is so specified in the purchase contract.

5.4. Package the samples in moisture-proof, airtight containers numbered consecutively in the order in which the samples are taken. The purchase contract shall state who will pay for the costs of sampling, packaging, shipping, and testing the samples.

Note 1—Polyvinyl chloride sample containers, upon occasion, have been found to affect the air-entraining potential of a cement sample. The same problem might be experienced with containers made from other plastics.

6. TESTING-TIME REQUIREMENTS FOR THE COMPLETION OF TESTS

6.1. When tests of hydraulic cement are made at a laboratory other than that of the cement manufacturer, the cement sampling schedule, sample transportation time, and sample testing schedule must be coordinated among the purchaser, the manufacturer, and the testing laboratory so that the tests results will be available when required.

6.2. The manufacturer of the cement shall make the cement available to be sampled for testing early enough before the time the test results are needed so that at least the applicable time intervals listed in Section 6.3 exist.

6.3. When this has been done, the testing laboratory shall provide test results not later than the indicated number of days after sampling:

Tests	Time Interval, Days
T 106 (1-day results), T 98,T 105, T 107, T 131, T 137, T 153, T 154, T 186; ASTM C 265, C 563	8
T 106 (3-day results)	10
T 106 (7-day results); ASTM C 186	14
ASTM C 227, C 452, and C 1012 (14-day results)	21
T 106 (28-day results); ASTM C 186	35
T 160 (34-day results); ASTM C 157	41
ASTM C 227 (56-day results)	63
ASTM C 227 (91-day results)	98

7. SAMPLING

7.1. The cement may be sampled by any of the applicable methods described in this section.

7.1.1. *From the Conveyor Delivering to Bulk Storage*—Take one grab sample, having a mass of at least 5 kg (10 lb), at approximately six-hour intervals.

7.1.2. *Transfer Sampling*—Sample cement in storage while the cement is being transferred from one bin to another. Take one grab sample from the transfer stream for each 360 Mg (400 tons) of cement, or fraction thereof, but take no less than two grab samples and combine them to produce a composite sample.

7.1.3. *Other Sampling Methods*—When neither of the above sampling methods is applicable, samples may, when authorized by the purchaser, be taken by one of the following methods:

7.1.3.1. *From Bulk Storage at Points of Discharge*—Withdraw cement from the discharge openings in a steady stream until sampling is completed. Estimate the quantity of cement in Mg to be withdrawn from one discharge opening as $0.055\ d^3 \times 0.2$, where d is the depth in meters of cement above the discharge opening. If a high circular silo is being sampled, take all samples from one opening. If the quantity of the cement in the bin exceeds 1100 Mg (1200 tons) when low rectangular bins are being sampled, discharge openings employed in the sampling shall be such that for no opening shall the number of samples represent more than one-half the contents of the bin or more than 1800 Mg (2000 tons). In sampling bulk storage at points of discharge, while the cement is flowing through the openings, take samples at such intervals so that at least two grab samples shall be secured for each 360 Mg (400 tons) in the bin or silo.

7.1.3.2. *From Bulk Storage and Bulk Shipment by Means of a Slotted Tube Sampler*—When the depth of the cement to be sampled does not exceed 2.1 m (7 ft), obtain samples using a slotted tube sampler similar to that shown in Figure 1. It shall be between 1.5 and 1.8 m (5 and 6 ft) long and approximately 35 mm ($1^3/_8$ in.) in outside diameter and consist of two polished brass telescopic tubes with registering slots that are opened or closed by rotation of the inner tube, the outer tube being provided with a sharp point to facilitate penetration. Take samples from well-distributed points and various depths of the cement so that the samples taken will represent the cement involved.

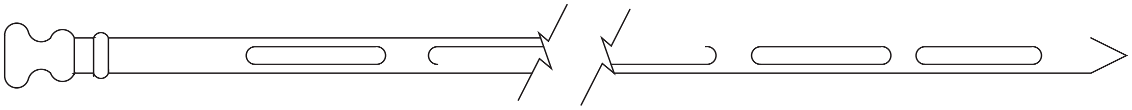

Figure 1—Slotted Tube Sampler for Bulk Cement

7.1.3.3. *From Packaged Cement by Means of Tube Sampler*—Insert the sampler, shown in Figure 2, diagonally into the valve of the bag and place the thumb over the air hole. Then withdraw the sampler. Take one sample from a bag in each 4.5 Mg (5 tons) or fraction thereof.

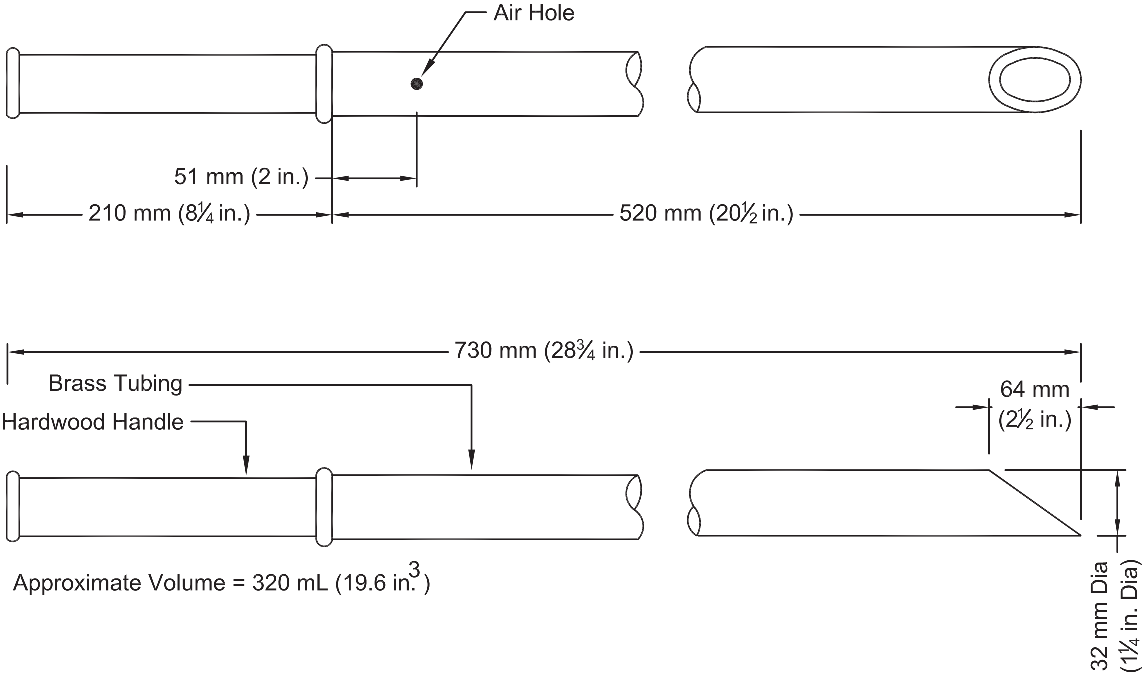

Figure 2—Tube Sampler for Packaged Cement

7.1.3.4. *From Bulk Shipment of Car or Truck*:

1. *Single Shipment*—If only one car or truck is being loaded and the loading is continuous and all from the same source, take a 5-kg (10-lb) sample. If not continuous or unknown, combine five or more portions from different points in the load to form the test sample.
2. *Multiple Shipments*—When the shipment consists of several cars or trucks loaded from the same source and on the same day, sample the shipment at the rate of one sample for each 90 Mg (100 tons) of cement or fraction thereof, but take not less than two samples. Consider cement represented by such samples as a lot, and test the samples in accordance with the procedure outlined in Section 9, Amount of Testing.

7.2. *Protection of Samples*—As samples are taken, place them directly in moisture-proof airtight containers to avoid moisture absorption and aeration of the sample. If the samples are placed in cans, fill the can completely and immediately seal. Use moisture-proof, multiple-wall paper bags or plastic bags if they are strong enough to avoid breakage, and if they can be sealed immediately after filling in such a manner as to eliminate excess air in the sample and avoid moisture absorption and aeration of the sample. Samples shall be treated as described in Section 8, Preparation of Sample.

8. PREPARATION OF SAMPLE

8.1. Before testing, pass each sample through an 850-µm (No. 20) sieve, or any other sieve having approximately the same size openings, in order to mix the sample, break up lumps, and remove foreign material. Discard the foreign materials and hardened lumps that do not break up on sieving or brushing. Store the cement in airtight moisture-proof containers to prevent aeration or absorption of moisture prior to test.

9. AMOUNT OF TESTING

9.1. *General*—When required, the purchaser shall specify the amount of testing for heat of hydration (ASTM C 186), alkali reactivity (ASTM C 227), and sulfate resistance (ASTM C 1012). Make all other tests on individual grab or composite samples chosen as specified herein under Section 9.2.6, Selection of Samples for Testing. Do only those tests required by the applicable specification.

9.2. *Normal Testing*—Determine the number of samples to be tested in accordance with Table 1. The normal testing rate shall be used under the following conditions:

9.2.1. Before the quality history has been established,

9.2.2. When no samples from a particular mill have been tested within a year,

9.2.3. When the quality history is based entirely on data more than two years old, and

9.2.4. When it is deemed necessary to recalculate the critical limit because of indicated lack of control as shown by the control chart of the range.

Table 1—Number of Samples for Test

Lot Size—Number of Samples	Number of Tests	
	Normal Rate	Reduced Rate
2	2	2
3	3	2
4 to 10	4	2
11 to 20	6	2
Over 20	8	2

Note 2—Random grab samples taken at inappropriate times, such as immediately following the repair or adjustment of manufacturing equipment, or from inappropriate places, such as from the top surface of the material in a car, will not suitably reflect the properties of a cement, and therefore should not be used as the basis for acceptance or rejection of a lot of cement.

9.2.5. *Reduced Testing*—After the quality history has been established, test at the reduced testing rate. If the results of these tests are within the critical range, make additional tests (total equal to the number of tests at the normal rate as shown in Table 1).

Note 3—When the quality history indicates that the results for a given requirement will probably be within the critical range, and substantial delay in completion of the tests would result from making additional tests (for example, compressive strength), it may be desirable to make the tests at the normal rate, rather than the reduced testing rate.

9.2.6. *Selection of Samples for Testing*—Take samples to be tested from each lot by some random method. The following method is suggested: Place a group of consecutively numbered markers equal to the number of samples in a container and mix, then draw one marker at a time from the container until the number drawn is equal to the number of samples to be tested at the normal rate. If the testing is to be done at the reduced rate, mix the drawn markers and draw two to select the numbers of the samples to be tested.

9.3. *Establishing a Quality History and Control Charts*:

9.3.1. *Quality History*—The quality history shall represent cement from the same source as the cement to be tested, and shall be based on data not more than two years old. There shall be available test results for not less than 40 test samples representing not less than seven lots of cement. The test samples shall conform to the applicable provisions of this practice. A pair shall be two test samples from the same lot, in numerical sequence. Several pairs from the same lot may be used where available. The number of paired samples representing a large lot may be reduced as follows: From the consecutively numbered group of tested samples representing the entire lot, select a subgroup by some random method. List the numbers identifying the subgroup in numerical sequence, and pair in the order of listing. Compute the range (difference between the test results of a pair) for each pair of test results. Total the ranges and divide their sum by the total number of ranges used to obtain the average range, $\bar{r}$. Compute the average range, $\bar{r}$, for each included physical and chemical property limited by specification requirements.

9.3.2. *Critical Limit*—Calculate the critical limit, *C*, for each included physical and chemical property limited by a specification requirement. First, multiply the average range, $\bar{r}$, by the probability factor, 2.49; this will yield a number that for convenience is called *d*. If the requirement has a maximum specification limit, obtain *C* by subtracting *d* from the specification limit and, if a minimum, add *d* to the specification limit. Maintain quality history charts.

Note 4—Improved estimates of the range $\bar{r}$, and consequently of *C*, will result if the test results are not rounded. For example, the test result of 21.78 percent for SiO_2 is preferred to the rounded value of 21.8 percent. For the fineness, the calculated value of 3,243 is preferred to the rounded value of 3,240.

9.3.3. *Control Chart of the Range*—Maintain a control chart of the range to indicate when the critical limit needs to be recomputed. Multiply the average range, $\bar{r}$, as obtained in Section 9.5.2, by the probability factor 3.267 to obtain the upper control limit for the range between each consecutive pair of test results. The horizontal scale of the chart will be successive groups of two, and the vertical scale will be the range. Where the range chart indicates lack of control (points beyond the upper control limit), the critical limit, *C*, may need to be recalculated. Consider the occurrence of two consecutive points beyond the upper control limit for the range, or the occurrence of three points beyond the upper control limit in any series of five consecutive points cause to recalculate the critical limit. Where it becomes necessary to recalculate the critical limit, discontinue reduced testing until a new quality history has been established.

Note 5—Examples of the calculation of $\bar{r}$, *d*, and quality history and control charts are shown in Table 2 and Figures 3 and 4. The specification limits used in these examples are hypothetical.

Table 2—Test Data, Type I Low-Alkali Cement

Lot No.	Sample No.	Alkalies, %	Range, %	Seven-Day Strength (Average of Three Specimens) MPa	(psi)	Range MPa	(psi)
88	1	0.58		35.5	(5150)		
	13	0.61	0.03	37.0	(5358)	1.44	(208)
	17	0.57		32.2	(4675)		
	21	0.55	0.02	33.1	(4800)	0.86	(125)
91	1	0.55		32.0	(4633)		
	5	0.55	0.00	33.9	(4917)	1.95	(283)
	13	0.57		34.3	(4975)		
	21	0.54	0.03	35.2	(5108)	0.92	(133)
98	5	0.55		33.8	(4896)		
	13	0.56	0.01	34.2	(4957)	0.42	(61)
	17	0.56		35.4	(5133)

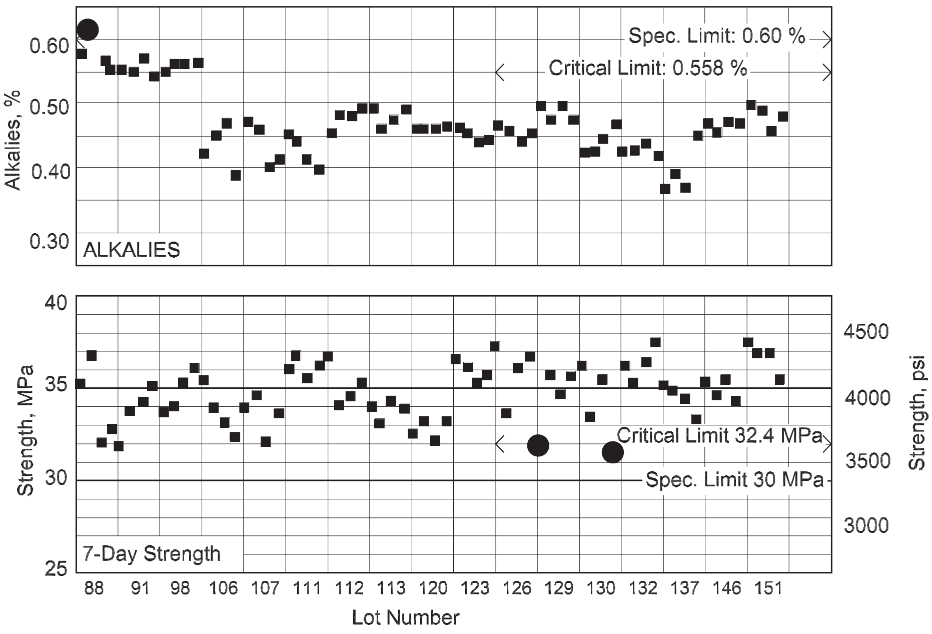

Figure 3—Quality History Chart

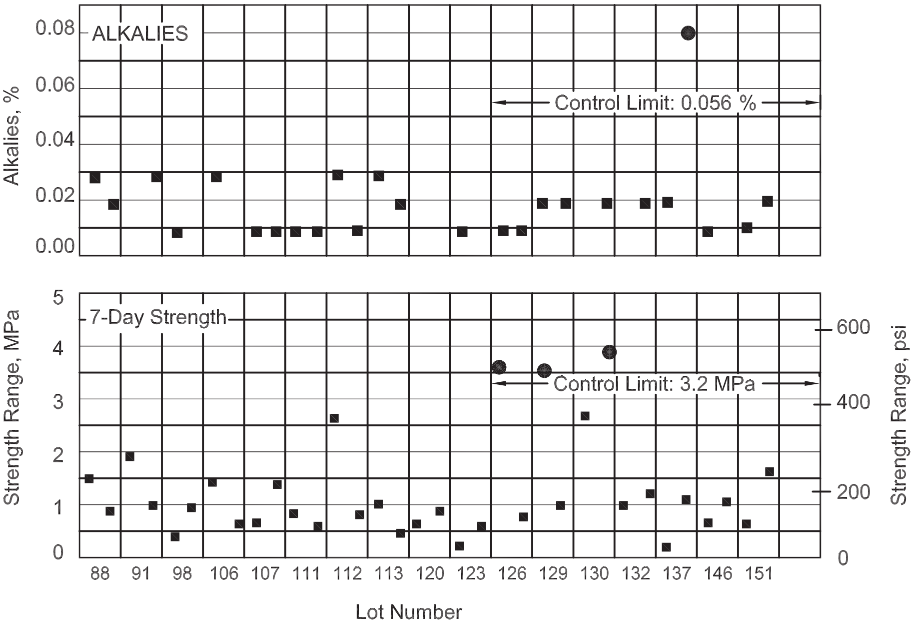

Figure 4—Control Chart for Range

9.4. *Reporting for Normal Testing*—When the testing is done at the normal testing rate, report the cement as complying with the specification if it meets the specification requirements, and report it as failing to meet the specification requirements if it does not meet each of the requirements as specified.

9.5. *Reporting for Reduced Testing*—When the testing is done at the reduced testing rate, report the cement as complying with the specification if the average of the test results is further from the specified limit than the critical limit. If the average of the results for one or more requirements is between the critical limit and the specification limit, test additional samples (total equal to the number of tests at the normal rate) for that requirement, and if on completion of the additional tests, all of the results meet the specified requirements, report the cement as complying with the specification. Report the cement as failing to meet the specification requirements if any test result does not conform to the respective requirements.

9.6. When a cement is reported as failing to meet the specification requirements, state in the report which requirement the cement failed and the applicable limit.

10. NONCOMPLIANCE AND RETEST

10.1. If any test result fails to meet the specification requirement, the lot of cement shall not be reported as not complying with the specification unless noncompliance is confirmed by retest as described in Section 10.2.

10.2. A retest is considered to be an additional test of a certain property that is made when the initial test of that property produces a result not complying with the specification requirements. A retest may consist of either a single determination or a set of replicate determinations.

10.3. Retests shall be conducted in accordance with the provisions, if given, of the applicable specification. If no provisions are given, the following procedure shall be used:

10.3.1. Make the retest on a portion of the same sample as was used for the initial test. Use referee methods whenever they are provided for determination of the property requiring retest and in such case use only the results obtained by referee methods. The retest shall consist of the same number of determinations required for the initial test, or, if a within-laboratory precision statement is given which is based on a specified number of replicates (that is, duplicate or triplicate determinations), the number of replicates used as the basis of such precision statement. If two or more determinations are required, the value reported shall be the average of all results that are within the limits of precision of the method at the 95 percent confidence level, as stated in the applicable specification or as generally recognized.

Standard Method of Test for

Normal Consistency of Hydraulic Cement

AASHTO Designation: T 129-06
ASTM Designation: C 187-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Normal Consistency of Hydraulic Cement

AASHTO Designation: T 129-06
ASTM Designation: C 187-04

1. SCOPE

1.1. This method covers determination of the normal consistency of hydraulic cement.

1.2. The values stated in SI units are to be regarded as the standard. The values in parentheses are for information only.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. See Section 1.4 for a specific warning statement.

1.4. **Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 min. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 210, Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete
- T 162, Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

2.2. *ASTM Standards*:

- C 1005, Standard Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements
- D 1193, Standard Guide for Use of Joint Sealants
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 177, Standard Practice for Use of the Terms Precision and Bias in ASTM Test Methods

3. SIGNIFICANCE AND USE

3.1. This method is intended to be used to determine the amount of water required to prepare hydraulic cement pastes for testing.

4. APPARATUS

4.1. *Reference Masses and Devices for Determining Mass* conforming to the requirements of ASTM C 1005. The devices for determining mass shall be evaluated for precision and bias at a total load of 1000 g.

4.2. *Glass Graduates*—200- or 250-mL capacity and conforming to the requirements of M 210.

4.3. *Vicat Apparatus*—shall consist of a frame (A) bearing a movable rod (B), weighing 300 g, with one end (C), the plunger end, being 10 mm in diameter for a distance of at least 50 mm, and the other end having a removable needle (D), 1 mm in diameter and 50 mm in length. The rod (B) is reversible, and can be held in any desired position by a set screw (E), and has an adjustable indicator (F) that moves over a scale (graduated in millimeters) attached to the frame (A). The paste is held in a rigid conical ring (G), resting on a plane non-absorptive square base plate (H) about 100 mm on each side. The rod (B) shall be made of stainless steel having a hardness of not less than 35 HRC (see Note 1) and shall be straight with the plunger end, which is perpendicular to the rod axis. The ring shall be made of a noncorroding, nonabsorbent material; shall have an inside diameter of 70 mm at the base and 60 mm at the top; and shall have a height of 40 mm. (See Figure 1.) In addition to the above, the Vicat apparatus shall conform to the requirements as indicated in Table 1.

4.4. *Flat Trowel*, having a sharpened straightedged steel blade 100 to 150 mm in length.

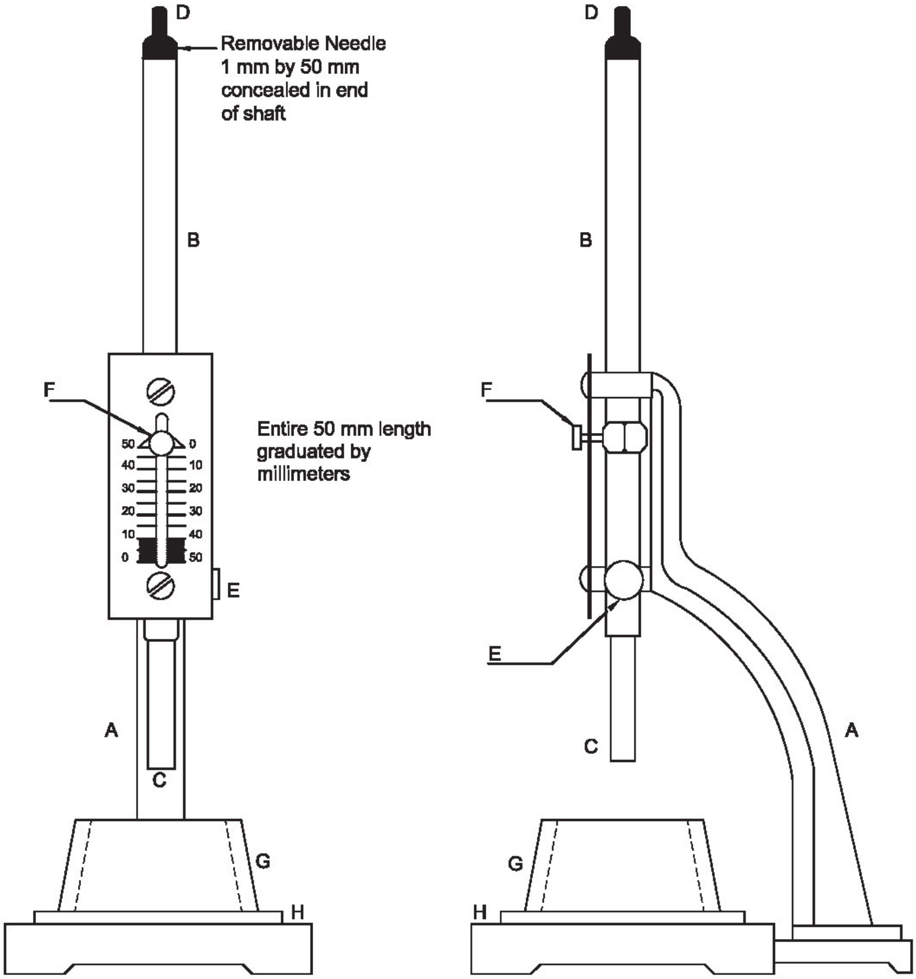

Figure 1—Vicat Apparatus

Table 1—Vicat Apparatus

Vicat Apparatus	
Weight of movable rod	300 ± 0.5 g (0.661 lb ± 8 grains)
Diameter of plunger end of rod	10 ± 0.05 mm (0.394 ± 0.002 in.)
Diameter of needle	1 ± 0.05 mm (0.039 ± 0.002 in.)
Inside diameter of ring at bottom	70 ± 3 mm (2.75 ± 0.12 in.)
Inside diameter of ring at top	60 ± 3 mm (2.36 ± 0.12 in.)
Height of ring	40 ± 1 mm (1.57 ± 0.04 in.)
Graduated scale	The graduated scale, when compared with a standard scale accurate to within 0.1 mm at all points, shall not show a deviation at any point greater than 0.25 mm.

Note 1—The requirement that the rod be made of stainless steel shall apply only to new Vicat apparatus or replacement rods and not to equipment in use that meets the other requirements of T 129.

5. TEMPERATURE AND HUMIDITY

5.1. The temperature of the air in the vicinity of the mixing slab, the dry cement, molds, and base plates shall be maintained between 20 and 27.5ºC (68 and 81.5ºF). The temperature of the mixing water shall not vary from 23ºC (73.4ºF) by more than ±1.7ºC (3ºF).

5.2. The relative humidity of the laboratory shall be not less than 50 percent.

6. PROCEDURE

6.1. *Preparation of Cement Paste*—Mix 650 g of cement with a measured quantity of clean water following the procedure prescribed in Section 6 of T 162. The water shall conform to the numerical limits of ASTM D 1193 for Type III or Type II grade of reagent water.

6.2. *Molding Test Specimen*—Quickly form the cement paste, prepared as described in Section 6.1, into the approximate shape of a ball with gloved hands. Then toss six times through a free path of about 150 mm (6 in.) from one hand to another so as to produce a nearly spherical mass that may be easily inserted into the Vicat ring with a minimum amount of additional manipulation. Press the ball, resting in the palm of one hand, into the larger end of the conical ring (G), held in the other hand, completely filling the ring with paste. (See Figure 1.) Remove the excess at the larger end by a single movement of the palm of the hand. Place the ring on its larger end on the base plate (H), and slice off the excess paste at the smaller end at the top of the ring by a single oblique stroke of a sharp-edged trowel held at a slight angle with the top of the ring; smooth the top, if necessary, with a few light touches of the pointed end of the trowel. During these operations of cutting and smoothing, take care not to compress the paste.

6.3. *Consistency Determination*—Center the paste confined in the ring, resting on the plate, under the rod (B) (see Figure 1), the plunger end C of which shall be brought in contact with the surface of the paste, and tighten the setscrew (E). Then set the movable indicator (F) to the upper zero mark of the scale, or take an initial reading and release the rod immediately. This must not exceed 30 seconds after completion of mixing. The apparatus shall be free of all vibrations during the test. The paste shall be of normal consistency when the rod settles to a point 10 ± 1 mm below the original surface in 30 seconds after being released. Make trial pastes with varying percentages of water until the normal consistency is obtained. Make each trial with fresh cement.

7. CALCULATION

7.1. Calculate the amount of water required for normal consistency to the nearest 0.1 percent and report it to the nearest 0.5 percent of the weight of the dry cement.

8. PRECISION AND BIAS

8.1. The single operator-instrument precision has been found to be 0.25(1s), and the multilaboratory precision has been found to be 0.35(1s) as defined in ASTM E 177; therefore, the results of two properly conducted tests by the same operator in a laboratory should agree within 0.7 percentage point, and test results between two laboratories should agree within 1.0 percentage point 95 percent of the time.

9. KEYWORDS

9.1. Consistency; normal consistency; Vicat needles.

Standard Method of Test for

Time of Setting of Hydraulic Cement by Vicat Needle

AASHTO Designation: T 131-10
ASTM Designation: C 191-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Time of Setting of Hydraulic Cement by Vicat Needle

AASHTO Designation: T 131-10
ASTM Designation: C 191-08

1. SCOPE

1.1. These test methods determine the time of setting of hydraulic cement by means of the Vicat needle. Two test methods are given; Method A is the Reference Test Method using the manually operated standard Vicat apparatus, while Method B permits the use of an automatic Vicat machine that has, in accordance with the qualification requirements of this method, demonstrated acceptable performance.

1.2. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. See Section 1.4 for a specific warning statement.

1.4. **Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 minutes. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.

Note 1—For the method for determining the time of setting by Gillmore needles, see T 154.

3. TERMINOLOGY

3.1. *Definitions*—The terms used in this test method are defined in accordance with ASTM C 219.

4. SUMMARY OF TEST METHOD

4.1. A paste that is proportioned and mixed to normal consistency, as described in the test method T 129, is molded and placed in a moist cabinet and allowed to start setting. Periodic penetration tests are performed on this paste by allowing a 1-mm Vicat needle to settle into this paste. The Vicat initial time of setting is calculated as the time elapsed between the initial contact of cement and water and the time when the penetration is at 25 mm. The Vicat final time of setting is calculated as the time when the needle does not sink visibly into the paste.

5. SIGNIFICANCE AND USE

5.1. This test method provides a means of determining compliance with a specification limit for Vicat time of setting. Refer to the appropriate specification for the cement to determine if this test method is used for specification compliance.

5.2. The measured time of setting is affected by the percentage and temperature of the water used, the amount of kneading the paste received, and by the temperature and humidity of the mixing room air and the moist cabinet or moist room air.

5.3. The measured time of setting of hydraulic cement is test-method specific. Time of setting as measured by this method will not necessarily be similar to other methods used for determining the time of setting of hydraulic cements.

6. APPARATUS

6.1. *Vicat Apparatus*—See Annex A1.1 and Figure A1.1. The Vicat apparatus for this test method shall have a movable rod, B, of mass 300 ± 0.5 g.

6.1.1. The end of the rod used for measuring penetration shall have a removable needle, D, with a diameter of 1.00 ± 0.05 mm and length no less than 50 mm.

6.1.2. The needle end that contacts the specimen shall be flat, plane, and at right angles to the axis of the rod.

6.2. *Reference Masses and Devices for Determining Mass,* conforming to the requirements of ASTM C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1 kg.

6.3. *Glass Graduates*, 200- or 250-mL capacity, and conforming to the requirements of ASTM C 1005.

6.4. Plane non-adsorptive plate, 100 ± 5 mm square of similar planeness, corrosivity, and absorptivity to that of glass (see Annex A1.1, Figure A1.1, H).

6.5. *Flat trowel*, having a sharpened straightedged steel blade 100 to 150 mm in length. The edges, when placed on a plane surface, shall not depart from straightness by more than 1 mm.

6.6. Conical ring, made of a rigid non-corroding, nonabsorbent material that shall have a height of 40 ± 1 mm, an inside diameter at the bottom of 70 ± 3 mm, and an inside diameter at the top of 60 ± 3 mm (see Annex A1.1, Figure A1.1, G).

6.7. *Mixer, bowl, and paddle*, conforming to T 162.

6.8. *Automatic Vicat Needle Apparatus for Method B*—The apparatus shall be equipped essentially with a standard Vicat needle. The needle shall have a 1.0 ± 0.05 mm diameter and have a length of at least 50 mm. The total mass supported by the needle tip at the time of measurement shall be 300 ± 0.5 g. The instrument shall be capable of automatically completing and recording penetration measurements of a test specimen at predetermined time intervals not exceeding 10 minutes and make each penetration test at least 5 mm away from any previous penetration and at least 10 mm away from the inner side of the mold.

6.9. *Specimen Mold for Method B*—The cement paste is held in a conical ring with a height of 40 ± 1 mm and a removable base plate. The test surface shall have a minimum diameter of 60 ± 3 mm as described in Section 6.6.

6.10. Inspect and document Section 6 apparatus for conformance to the requirements of this test method at least every $2^1/_2$ years.

7. REAGENTS AND MATERIALS

7.1. *Mixing Water*—Potable water is satisfactory for routine tests. Use water conforming to the requirements of ASTM D 1193 for Type III or Type IV grade reagent water for all referee and cooperative tests.

8. SAMPLING

8.1. When the test is required for acceptance testing, sample cement in accordance with ASTM C 183.

9. CONDITIONING

9.1. Maintain the temperature of the air in the vicinity of the mixing slab, the dry cement, molds, and base plates at 23.0 ± 3.0°C.

9.2. Maintain the temperature of the mixing water at 23.0 ± 3.0°C.

9.3. The relative humidity of the mixing room shall not be less than 50 percent.

9.4. The moist closet or moist room shall be in accordance with M 201.

10. PREPARATION OF CEMENT PASTE

10.1. The cement paste used for the determination of the time of setting is obtained from one of the following methods:

10.1.1. Prepare a new batch of paste by mixing 650 g of cement with the percentage of mixing water required for normal consistency (T 129), following the procedure described in T 162.

10.1.2. For Method A, at the option of the tester, use the test specimen used for determining normal consistency (Note 2).

10.1.3. At the option of the tester, use the paste remaining from the batch used for the autoclave specimen (ASTM C 151) or from the normal consistency determination (T 129).

Note 2—The specimen used for the determination of the normal consistency will have an irregular surface, making it unsuitable for Method B.

11. METHOD A—MANUAL VICAT NEEDLE

11.1. *Apparatus*—Refer to Sections 6.1, 6.4, 6.6, and 11.1.1, and Annex A1 for a description of the Vicat apparatus.

12. METHOD A—PROCEDURE

12.1. *Molding Test Specimen*—With gloved hands, quickly form the cement paste, prepared as described in Section 10, into a ball and toss six times from one hand to the other, maintaining the hands about 150 mm (6 in.) apart. Press the ball, resting in the palm of the hand, into the larger end of the conical ring (G), held in the other hand, completely filling the ring with paste. (See Figure A1.1.) Remove the excess at the larger end by a single movement of the palm of the hand. Place the ring on its larger end onto a non-absorptive plate (H), and slice off the excess paste at the smaller end at the top of the ring by a single oblique stroke of the trowel held at a slight angle with the top of the ring. Smooth the top of the specimen, if necessary, with one or two light touches of the pointed end of the trowel. During the operation of cutting and smoothing, take care not to compress the paste. Immediately after molding, place the test specimen in the moist closet or moist room and allow it to remain there except when penetration measurements are being made. The specimen shall remain in the conical mold, supported by the non-absorptive plate throughout the test period.

12.2. *Time of Setting Determination*—Allow the time of setting specimen to remain in the moist cabinet for 30 minutes after molding without being disturbed. Determine the penetration of the 1-mm needle at this time and every 15 minutes thereafter (every 10 minutes for Type III cements) until a penetration of 25 mm or less is obtained. Perform the penetration test by lowering the needle (D), of the rod (B) until it rests on the surface of the cement paste. Tighten the set screw, E, and set the indicator (F), at the upper end of the scale, or take an initial reading. Release the rod quickly by releasing the set screw (E), and allow the needle to settle for 30 seconds; then take the reading to determine the penetration. At the option of the tester, if the paste is obviously quite soft on the early readings, retard the fall of the rod to avoid bending the 1-mm needle, but when actual penetration measurements to determine the time of setting are made, release the rod only by the set screw. Make each penetration test at least 5 mm away from any previous penetration and at least 10 mm away from the inner side of the mold. Record the results of all penetration tests and, by interpolation, determine the time when a penetration of 25 mm is obtained. The elapsed time between the initial contact of cement and water and the penetration of 25 mm is the Vicat time of setting or Vicat initial time of setting.

12.3. Determine the Vicat final time of setting end point to be the first penetration measure that does not mark the specimen surface with a complete circular impression. Verify final set by performing two additional penetration measurements on different areas of the specimen surface. Obtain verification measurements within 90 s of the first "final set" measurement. The elapsed time between the initial contact of cement and water and the end point determination above is the Vicat final time of setting.

12.4. *Precautions*—Keep all the apparatus free from vibration during the penetration test. Keep the 1-mm needle straight and clean. The needle must be kept clean to prevent cement from adhering to the sides of the needle and decreasing penetration, and to prevent cement from adhering to the point and increasing penetration.

13. METHOD A—PRECISION AND BIAS

13.1. *Precision*:

13.1.1. The single-operator (within-laboratory) standard deviation has been found to be 12 minutes for the initial time of setting, throughout the range of 49 to 202 minutes, and 20 minutes for the final time of settings throughout the range of 185 to 312 minutes. Therefore, results of two properly conducted tests by the same operator on Vicat initial time of setting of similar paste should not differ from each other by more than 34 minutes and on Vicat final time of setting of similar pastes should not differ from each other by more than 56 minutes.

13.1.2. The multilaboratory (between-laboratory) standard deviation has been found to be 16 minutes for the initial time of setting throughout the range of 49 to 207 minutes, and 43 minutes for the final time of setting throughout the range of 185 to 312 minutes. Therefore, results of two properly conducted tests from two different laboratories on Vicat initial time of setting of similar pastes should not differ from each other by more than 45 minutes, and on Vicat final time of setting of similar pastes should not differ from each other by more than 122 minutes.

13.2. *Bias*—Since there are no accepted reference materials suitable for determining the bias for the procedure in this test method, no statement on bias is presented.

14. METHOD B—AUTOMATIC VICAT APPARATUS

14.1.1. *Automatic Vicat Needle Apparatus*—Refer to Sections 6.8 and 6.9 for a description of the Automatic Vicat needle apparatus.

15. METHOD B—PROCEDURE

15.1. *Molding Test Specimen*—With gloved hands, quickly form the cement paste, prepared as described in Section 10, into a ball and toss six times from one hand to the other, maintaining the hands about 150 mm (6 in.) apart. Press the ball, resting in the palm of the hand, into the larger end of the conical ring, held in the other hand, completely filling the ring with paste. Remove the excess at the larger end by a single movement of the palm of the hand. Place the ring on its larger end on to the base plate. Use a trowel to remove the excess paste at the top of the mold. Holding the trowel at about a 30 degrees incline with the leading edge raised and starting near the center of the mold, level the paste by drawing the trowel across the top of the mold using a sawing motion; repeat the procedure for the other half of the surface. Then smooth the surface level to the top of the mold making steady and complete strokes across the entire surface with the trailing edge of the trowel. Repeat the cutting and smoothing steps but at 90 degrees from the previous cut. Repeat the steps as required to produce a surface level with the top of the mold. Usually the paste is level within two cycles, but occasionally three will be required. Avoid excessive strokes and compaction. Since the automatic Vicat device references to the top edge of the mold, it is imperative that the top surface of the paste be uniform and level with the top of the mold.

15.2. *Time of Setting Determination*—Follow the manufacturer's instructions and complete the required instrument calibration and zero procedures. Set the instrument to measure no less frequently than every 10 minutes (Note 3). Position the molded specimen in the automatic Vicat apparatus and initiate measurements (Note 4).

Note 3—Automatic devices are usually capable of measurement more frequently than once every 10 minutes and more frequent measurement minimizes interpolation.

Note 4—The initial time of setting according to Method A is determined as the elapsed time required to achieve a penetration of 25 mm and the final time of setting as the total time elapsed until the needle does not sink visibly into the paste. The end points established by a qualified automatic Vicat test method may deviate significantly from end points specified in Method A, and require standardization to correct bias.

15.3. Determine the range of applicability of the method from the range of the average time of setting of the cements used for qualification and standardization, and limit that range to 30 minutes greater than the maximum, and 30 minutes less than the minimum.

15.4. *Performance Requirement (Qualification) for Automatic Vicat Instrument*:

15.4.1. When time of setting results from automatic Vicat apparatus are to be used for acceptance or rejection of cement, the method used shall comply with the qualification requirements covered in Annex A2.

---

16. METHOD B—PERFORMANCE REQUIREMENT (QUALIFICATION) FOR AUTOMATIC VICAT INSTRUMENT

16.1. *Scope*—When time of setting results from the automatic Vicat apparatus are to be used for acceptance or rejection of cement, the method used shall comply with the qualification requirements of this section. A method is considered to consist of the specific instrument and the molding procedure meeting the requirements of this standard, and used in a consistent manner by a given laboratory.

16.2. *Hydraulic Cement Samples Required*—Select three cements that comply with requirements of M 85, M 240, or ASTM C 1157, and that when tested in accordance with Method A, shall include the following:

16.2.1. One cement that has an initial time of setting of less than 110 minutes,

16.2.2. One cement with an initial time of setting of greater than 150 minutes,

16.2.3. One cement with a final time of setting of less than 180 minutes, and

16.2.4. One cement with a final time of setting of greater than 210 minutes (Note 5).

Note 5—Laboratories are advised to reserve sufficient cement for future qualification and standardization.

16.3. *Tests*—Using the method to be qualified and including the standardization formula described in the section on standardization, make single determinations of the times of initial and final setting on each of the three cements. On the same day, conduct companion time of setting determinations according to Method A. Make single determinations of the normal consistency on each cement, and use that amount of water for all replicate batches. Complete three rounds of tests on different days, repeating all the steps of the methods. Conduct the qualification tests on specimens prepared separately from the standardization testing.

16.4. *Calculations*—Calculate the three-round averages for initial and final time of setting for each cement and method. A method complies with the initial time of setting qualification requirements if the difference between the initial time of setting average values for Method A and the corresponding average values of Method B is not greater than 25 minutes for any sample, and the range for any three replicate tests by Method B does not exceed 30 minutes. Likewise, a method complies with the final time of setting qualification requirements if the difference between the final time of setting average values for Method B is not greater than 45 minutes for any sample, and the range for any three replicate tests by Method B does not exceed 30 minutes. Example qualification data are given in Annex A1.

16.5. *Standardization*—When standardization is required in order to achieve agreement between Method A and Method B, it can be applied to either the initial time of setting, final time of setting, or both. A standardization formula shall be based on a comparison of test results obtained using Method A and the chosen method using the automatic instrument (Method B). Results of tests from at least five different hydraulic cements shall be required for standardization. The cements shall have a minimum range of 60 minutes initial time of setting, and a minimum range of 90 minutes final time of setting when tested in accordance with Method A. If desired, the three cements used for instrument qualification may be used, but make new determinations. Use the same method as used for instrument qualification, including all the same steps. Valid standardization formulas shall be mathematically derived and applied to all samples (Note 6).

Note 6—Generally, the automatic instruments are computer operated and easily adapted to standardization calculations.

17. METHOD B—PRECISION AND BIAS

17.1. *Precision*—No precision data are available at this time. A laboratory is advised to develop its own precision data for the method and instrument used. Based on qualification requirements, the precision of the method should not be greater than that of Method A.

17.2. *Bias*—Since there are no accepted reference materials suitable for determining the bias for the procedure in this test method, no statement on bias is presented.

18. CALCULATION

18.1. Calculate the Vicat time of setting to the nearest one minute as follows:

$$\left(\left(\frac{(H-E)}{(C-D)}\right)\times(C-25)\right)+E \qquad (1)$$

where:

H = time in minutes of first penetration less than 25 mm,
E = time in minutes of last penetration greater than 25 mm,
C = penetration reading at time E, and
D = penetration reading time at time H.

18.2. Calculate the Vicat final time of setting by determining the elapsed time between the time of the initial contact between cement and water and the time when the needle does not sink visibly into the paste, rounded to the nearest 5 minutes.

19. REPORT

19.1. Report the time of setting and the method used as follows:

Vicat time of setting (A or B) ______ minutes
Vicat final time of setting (A or B) ______ minutes

20. KEYWORDS

20.1. Automatic Vicat; hydraulic-cement paste; time of setting; Vicat; Vicat needle.

ANNEX

(Mandatory Information)

A1. VICAT APPARATUS

A1.1. The Vicat apparatus shall consist of a frame (A), bearing a movable rod (B), having a mass as specified by the method referencing this apparatus, with one end (C), the plunger end, with a diameter as specified by the method referencing this apparatus, and the other end having a mass or removable steel needle (D), as specified by the method referencing this apparatus. The rod (B) is reversible, and can be held in any desired position by a set screw (E), and has an adjustable indicator (F), which moves over a scale graduated in millimeters and attached to the frame (A). The gradations on the graduated scale, when compared to a scale accurate to within 0.1 mm at all points, shall not show a variance from the reference scale greater than 0.25 mm. (See Figure A1.1.)

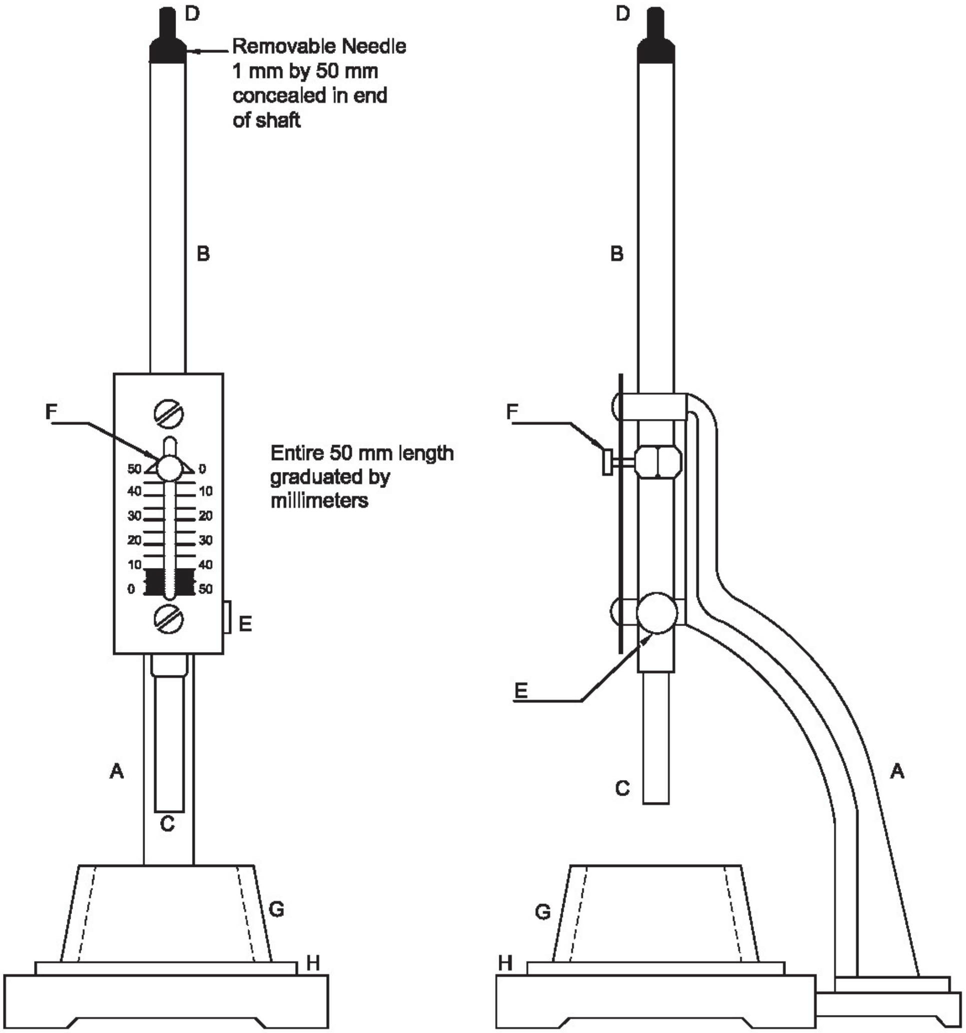

Figure A1.1—Vicat Apparatus

A2. PERFORMANCE REQUIREMENT (QUALIFICATION) FOR AUTOMATIC VICAT INSTRUMENT

A2.1. When time of setting results from the automatic Vicat apparatus are to be used for acceptance or rejection of cement, the method used shall comply with the qualification requirements covered in this section. A method is considered to consist of the specific instrument and the molding procedure meeting the requirements of this test method, and used in a consistent manner by a given laboratory.

A2.2. *Hydraulic Cement Samples Required*—Select three cements that comply with requirements of M 85 or M 240, and that when tested in accordance with Method A, shall include the following:

A2.2.1. One cement that has an initial time of setting of less than 110 min,

A2.2.2. One cement with an initial time of setting of greater than 150 min,

A2.2.3. One cement with a final time of setting of less than 180 min, and

A2.2.4. One cement with a final time of setting of greater than 210 min (see Note A1).

Note A1—Laboratories are advised to reserve sufficient cement for future qualification and standardization.

A2.3. *Tests*—Using the method to be qualified and including the standardization formula described in the section of standardization, make single determinations of the times of initial and final setting on each of the three cements. On the same day, conduct companion time of setting determinations according to Method A. Make single determinations of the normal consistency on each cement, and use that amount of water for replicate batches. Complete three rounds of tests on different days, repeating all the steps of the methods. Conduct the qualification tests on specimens prepared separately from the standardization testing.

A2.4. *Calculations*—Calculate the three-round averages for initial and final time of setting for each cement and method. A method complies with the initial time of setting qualifications requirements if the difference between the initial time of setting average values for Method A and the corresponding average values of Method B is not greater then 25 min for any sample, and the range for any three replicate tests by Method B does not exceed 30 min. Likewise, a method complies with the final time of setting averages values for Method A and corresponding average values for Method B is not greater than 45 min for any sample, and the range for any three replicate tests by Method B does not exceed 30 min. Example qualification data are given in Appendix X1.

A2.5. *Standardization*—When standardization is required in order to achieve agreement between Method A and Method B, it can be applied to either the initial time of setting, final time of setting, or both. A standardization formula shall be based on a comparison of test results obtained using Method A and chosen method using the automatic instrument (Method B). Results of tests from at least five different hydraulic cements shall be required for standardization. The cements shall have a minimum range of 60 min initial time of setting, and a minimum range of 90 min final time of setting when tested in accordance with Method A. If desired, the three cements used for instrument qualification may be used, but make new determinations. Use the same method as used for instrument qualification, including all the same steps. Valid standardization formulas shall be mathematically derived and applied to all samples (see Note A2).

Note A2—Generally, the automatic instruments are computer operated and easily adapted to standardization calculations.

A3. REQUALIFICATION OF A METHOD

A3.1. Requalify the method at least once per year and when any of the following conditions occur:

A3.1.1. The instrument has been significantly modified.

A3.1.2. The instrument has been substantially repaired.

A3.1.3. Substantial evidence indicates that the method is not providing data meeting the performance requirements.

A3.1.4. The average of a Cement and Concrete Reference Laboratory (CCRL) sample differs from the value obtained by the method by more than 45 min for either the initial of final time of setting.

Standard Method of Test for

Tensile Strength of Hydraulic Cement Mortars

AASHTO Designation: T 132-87 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Tensile Strength of Hydraulic Cement Mortars

AASHTO Designation: T 132-87 (2009)

1. SCOPE

1.1. This method covers determination of the tensile strength of hydraulic cement mortars employing the briquet specimen. It is primarily for use by those interested in research on methods for determining tensile strength of hydraulic cement.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 85, Portland Cement
- M 92, Wire-Cloth Sieves for Testing Purposes
- T 129, Normal Consistency of Hydraulic Cement

2.2. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- C 778, Standard Specification for Standard Sand
- C 1005, Standard Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- *Manual of Cement Testing*

3. SIGNIFICANCE AND USE

3.1. Researchers in the field of hydraulic cement have recognized the need for improved tensile strength. This method allows for the determination of tensile strength of a hydraulic cement mortar by casting and testing briquet specimens. It is recommended that the tester be familiar with this method in order to obtain the best possible accuracy and precision.

3.2. Table 1 contains minimum tensile strength values, which are stated limits in M 85 for portland cement. The user of this method may be interested in comparing research results with these values when briquets composed of one part cement to three parts standard sand have been made. These values may not be appropriate for comparison when different proportions or proportions involving other than standard sand have been used.

Table 1—Tensile Strength[a]

	Cement Type				
	I	II	III	IV	V
1 day in moist air, psi (kPa)	—	—	275 (1,896)	—	—
1 day in moist air, 2 days in water, psi (kPa)	150 (1,034)	125 (862)	375 (2,586)	—	—
1 day in moist air, 6 days in water, psi (kPa)	275 (1,896)	250 (1,724)	—	175 (1,207)	250 (1,724)
1 day in moist air, 27 days in water, psi (kPa)	350 (2,413)	325 (2,241)	—	300 (2,068)	325 (2,241)

[a] Taken from M 85-70 without change.

4. APPARATUS

4.1. *Weights and Weighing Devices*—The weights and weighing devices shall conform to the requirements of ASTM C 1005. The weighing devices shall be evaluated for precision and accuracy at a total load of 1,000 g or at 2,000 g, as applicable.

4.2. *Sieves*—Square-hole, woven wire cloth, No. 20 (850-µm) and No. 30 (600-µm) sieves conforming to M 92.

4.3. *Glass Graduates*—Glass graduates of suitable capacities (preferably large enough to measure the mixing water in a single operation) shall be made to deliver the indicated volume at 68°F (20°C). The permissible variation shall be ±1.0 mL. These graduates shall be subdivided to at least 1 mL, except that the graduation lines may be omitted for the lowest 5 mL for 100- and 150-mL graduates and for the lowest 10 mL for a 200-mL graduate. The main graduation lines shall be circles and shall be numbered. The least graduations shall extend at least one-seventh of the way around the cylinder, and intermediate graduations shall extend at least one-fifth of the way around.

4.4. *Briquet Molds*—The molds for making test specimens shall be made of metal not attacked by the cement mortar, and shall have sufficient material in the sides to prevent spreading during molding. Gang molds, when used, shall be of the type shown in Figure 1. The dimensions of the briquet molds shall conform to the following requirements: width of mold, between inside faces, at waist line of briquet, 25 mm (1 in.) with permissible variations of ±0.25 mm (0.01 in.) for molds in use and ±0.13 mm (0.005 in.) for new molds; thickness of molds measured at the point of greatest thickness on either side of the mold at the waist line, 25 mm (1 in.) with permissible variations of +0.10 mm (0.004 in.) and –0.05 mm (0.002 in.) for new molds and –0.5 mm (0.02 in.) for molds in use. The briquet test specimens shall conform to the dimensional requirements shown in Figure 2.

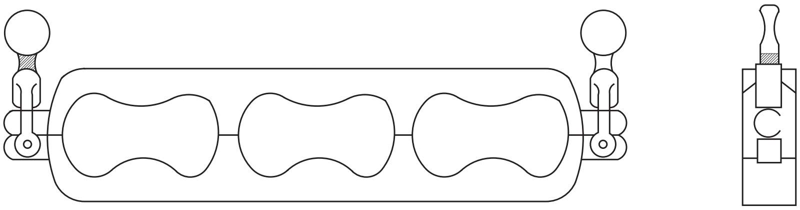

Figure 1—Briquet Gang Mold

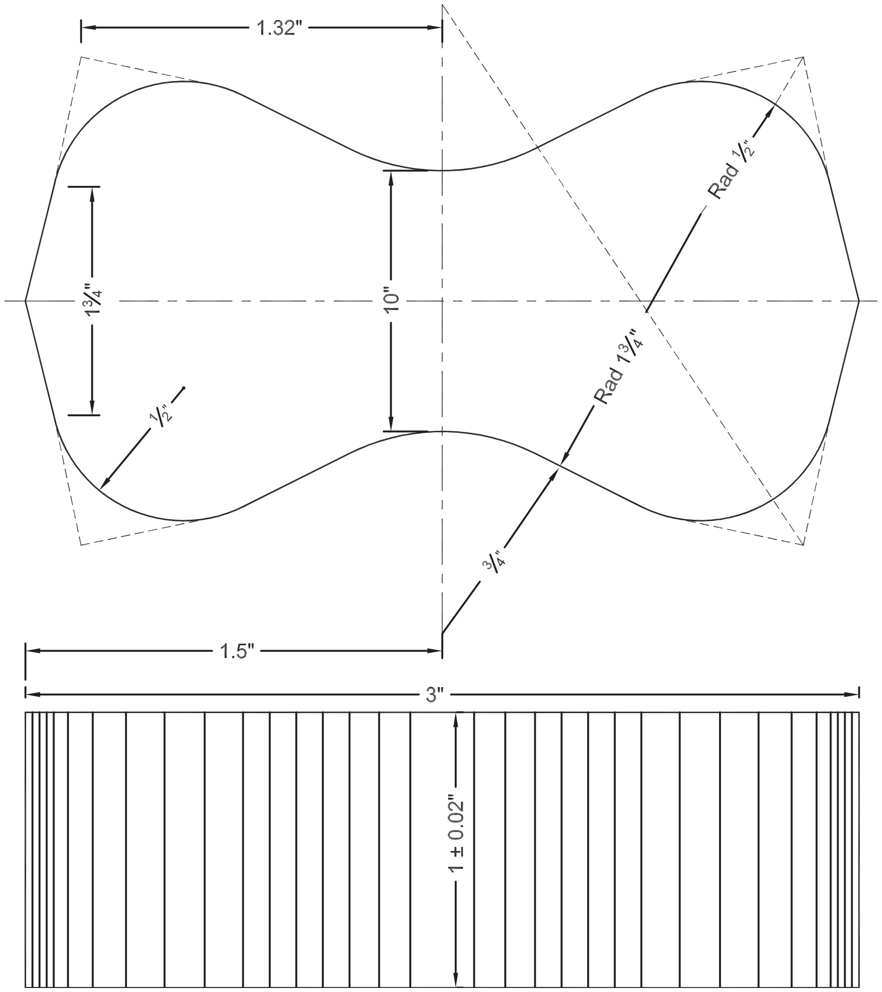


Note: 1 in. = 25.4 mm

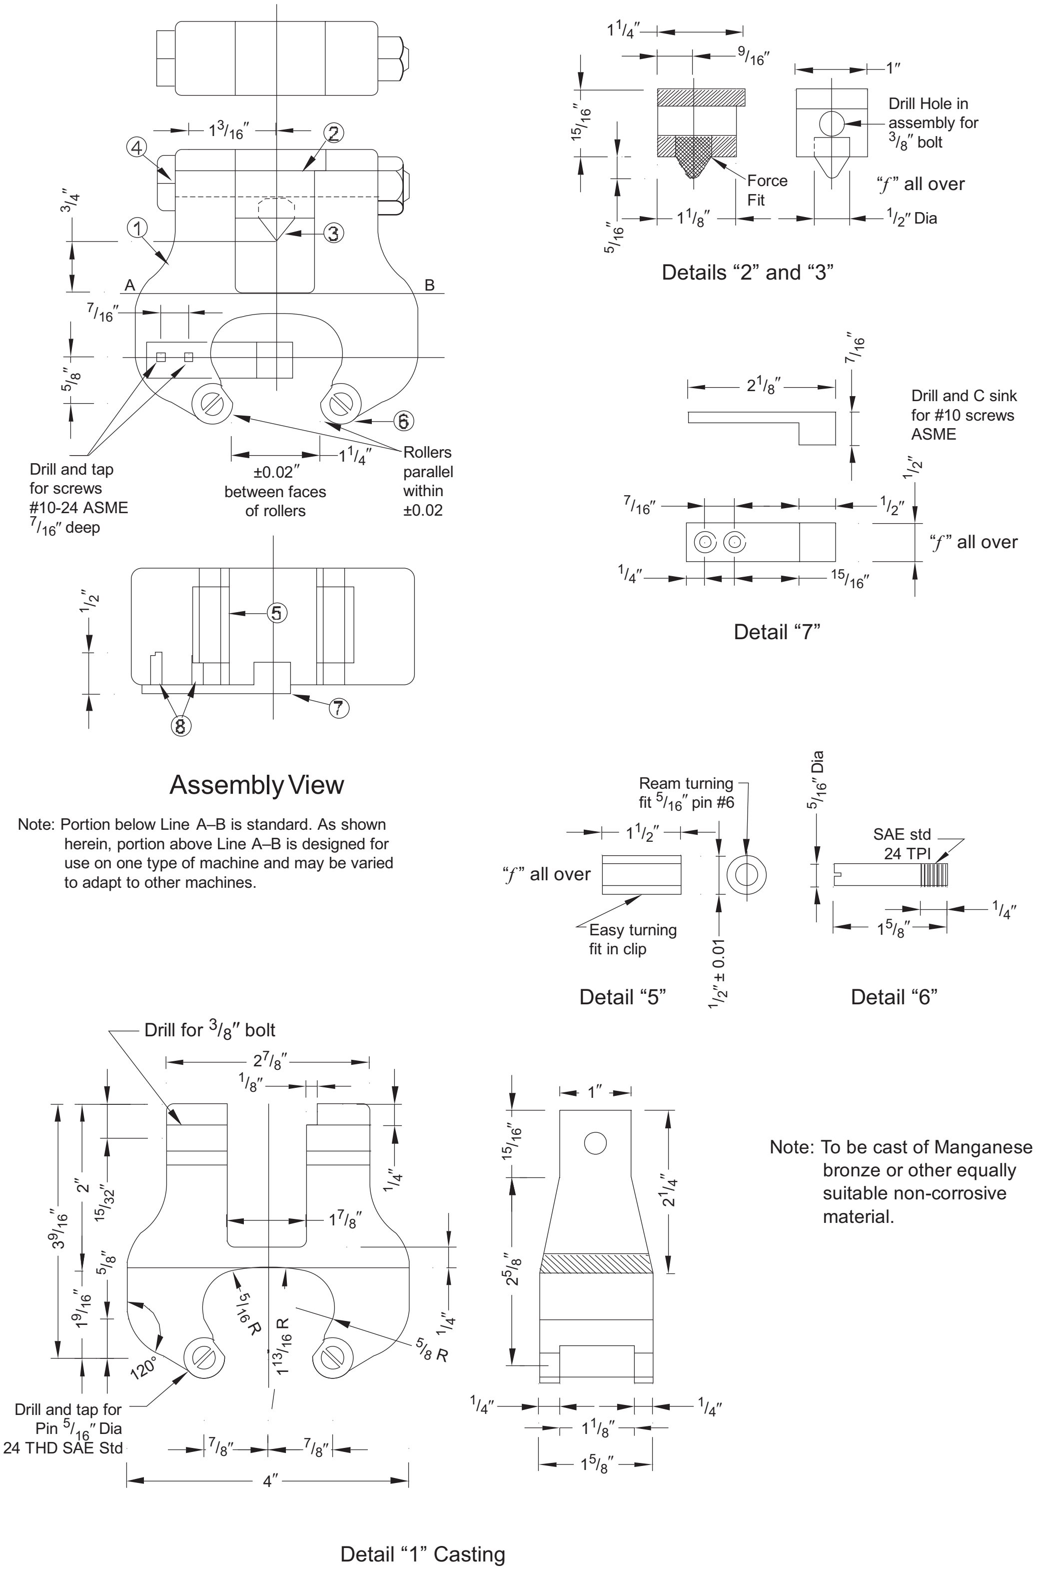
Figure 2—Briquet Specimen for Tensile Strength Test

4.5. *Trowel*—The trowel shall be of a convenient size and have a steel blade 100 to 150 mm (4 to 6 in.) long.

4.6. *Testing Machine*—The testing machine shall be capable of applying the load continuously at a rate of 600 ± 25 lbf (2.67 ± 0.11 kN) min, with provision for adjustments of the rate of loading. The requirements for accuracy of the testing machine shall be as follows: The error for loads of not less than 100 lbf (445 N) shall not exceed ± 1.0 percent for a new machine, or ± 1.5 percent for a used machine. The testing machine shall be calibrated frequently in order to determine its accuracy.

Note 1—For instructions relating to the manner and frequency of calibration of the testing machine, see Section 40 of the *Manual of Cement Testing*.

4.7. *Clips*—The clips for holding the tension test specimens shall be in accordance with Figure 3 and Table 2.



Note: Portion below Line A–B is standard. As shown herein, portion above Line A–B is designed for use on one type of machine and may be varied to adapt to other machines.

Note: To be cast of Manganese bronze or other equally suitable non-corrosive material.

Note: 1 in. = 25.4 mm

Figure 3—Clips for Briquet Testing Machine

Table 2—Clip for Briquet Testing Machine

No.	Name	Req'd	Mat'l	Remarks
1	Clip	2	*	* See Detail
2	Pivot Block	2	*	* Manganese Bronze
3	Pivot	2	Steel	Case-Hardened
4	Sq. H'd. Bolt, Hex. Nut	2	M.S.	$^3/_8$ in. St'd. – $3^1/_2$ in. long
5	Roller	4	**	** Stainless Steel
6	Pin	4	**	**Stainless Steel
7	Guide	2	**	**Stainless Steel
8	Flat Head Mach. Scr.	4	Brass	#10-24 TH'D ASME

5. STANDARD SAND

5.1. The sand used for making test specimens (see Section 8.1) shall be natural silica sand conforming to the requirements for 20–30 standard sand as described in ASTM C 778.

6. TEMPERATURE AND HUMIDITY

6.1. The temperature of the air in the vicinity of the mixing slab, the dry materials, molds, and base plates shall be maintained between 68 and 81.5°F (20 and 27.5°C). The temperature of the mixing water, moist closet or moist room, and water in the briquet storage tank shall not vary from 73.4°F (23°C) by more than ± 3°F (1.7°C).

6.2. The relative humidity of the laboratory shall be not less than 50 percent. The moist closet or moist room shall be so constructed as to provide storage facilities for test specimens at a relative humidity of not less than 95 percent.

7. NUMBER OF BRIQUETS

7.1. Three or more briquets shall be made for each period of test specified.

8. PROCEDURE

8.1. *Proportioning, Consistency, and Mixing of Mortars*:

8.1.1. The proportions of the standard mortar shall be one part cement to three parts standard sand by weight. The quantities of dry materials to be mixed at one time in the batch of mortar shall be no less than 1,000 nor more than 1,200 g for making six briquets and no less than 1,500 nor more than 1,800 g for making nine briquets. The percentage of water used in the standard mortar shall depend upon the percentage of water required to produce a neat cement paste of normal consistency from the same sample of cement and shall be as indicated in Table 3, the values being in percentage of the combined dry weights of the cement and standard sand. Determine the percentage of water required to produce a neat cement paste of normal consistency in accordance with T 129.

Table 3—Percentage of Water for Standard Mortars

Water for Neat Cement Paste of Normal Consistency, Percent	Water for Mortar of One Part Cement to Three Parts Standard Sand, Percent[a]
15	9.0
16	9.2
17	9.3
18	9.5
19	9.7
20	9.8
21	10.0
22	10.2
23	10.3
24	10.5
25	10.7
26	10.8
27	11.0
28	11.2
29	11.3
30	11.5

[a] When the proportions of cement to sand are other than one to three by weight, the amount of mixing water shall be calculated from the following formula upon which Table 3 is based:

$$y = \frac{2}{3}\left(\frac{P}{n+1}\right) + K$$

where:

y = water required for the sand mortar, percent;

P = water required for neat cement paste of normal consistency, percent;

n = number of parts of sand to one of cement by weight; and

K = a constant which for the standard sand has the value 6.5.

Note 2—Other proportions involving the use of graded sand, silica flour, or other similar materials may also be used to develop meaningful research information.

8.1.2. Weigh the dry materials, place them upon a smooth nonabsorbent surface, thoroughly mix dry, and form a crater in the center. Pour the proper percentage of clean water into the crater, and turn the material on the outer edge into the crater within 30 seconds by the aid of a trowel. After an additional interval of 30 seconds for the absorption of the water, during which interval lightly trowel the dry mortar around the outside of the cone over the remaining mortar to reduce the evaporation losses and to promote absorption, complete the operation by continuous, vigorous mixing, squeezing, and kneading with the hands for $1^1/_2$ minutes. During the operation of mixing, protect the hands with snug-fitting rubber gloves.

8.2. *Molding Test Specimens*:

8.2.1. Before being filled, thinly cover the molds with a film of mineral oil. Immediately following completion of mixing the mortar, and with the molds resting on unoiled glass or metal plates, fill the molds heaping full without compacting. Then press the mortar in firmly with the thumbs, applying the force 12 times to each briquet, at points to include the entire surface. The force shall be such that the simultaneous application of both thumbs will register a force of 15 to 20 lbf (67 to 89 N). Maintain each application of the thumbs not longer than sufficient to attain the specified force. Heap the mortar above the mold and smooth it off with a trowel. Draw the trowel over the mold in such a manner as to exert a force of not more than 4 lbf (17.8 N). Cover the mold with a plane glass or metal plate oiled with mineral oil, and turn over the mold and plates (held together with the hands) rotating the mold about its longitudinal axis. Remove the top plate and repeat the operation of heaping, thumbing, and smoothing off. Use no ramming or tamping, nor any troweling in excess of that required to smooth off the specimen.

8.3. *Storage of Test Specimens*:

8.3.1. Keep all test specimens, immediately after molding, in the molds on the base plates in the moist closet or moist room for from 20 to 24 hours with their upper surfaces exposed to the moist air but protected from dripping water. If removed from the molds before 24 hours, keep them on the shelves of the moist closet or moist room until they are 24 hours old, then immerse the specimens, except for those for the 24-hour test, in saturated lime water in storage tanks constructed of noncorroding materials. Keep the storage water clean by changing as required.

8.4. *Determination of Tensile Strength*:

8.4.1. Test the briquet specimens immediately after their removal from the moist closet for 24-hour specimens, and from storage water for all other specimens. Break all test specimens for a given test age within the permissible tolerance prescribed in the following table:

Test Age	Permissible Tolerance
24 h	± $^1/_2$ h
3 days	± 1 h
7 days	± 3 h
28 days	± 12 h

If more than one specimen at a time is removed from the moist closet for the 24-hour tests, cover these briquets with a damp cloth until time of testing. If more than one specimen at a time is removed from the storage water for testing, place these briquets in a pan of water at a temperature of 73.4 ± 3°F (23 ± 1.7°C) and of sufficient depth to completely immerse each briquet until time of testing.

8.4.2. Wipe each briquet to a surface-dry condition, and remove any loose sand grains or incrustations from the surfaces that will be in contact with the clips of the testing machine. The bearing surfaces of the clips shall be clean and free of sand, and the roller bearings shall be well oiled and maintained so as to ensure freedom of turning. Keep the stirrups supporting the clips free of accumulations, and keep the pivots in proper adjustment so that the clips may swing freely on the pivots without binding in the stirrups. Carefully center the briquets in the clips and apply the load continuously at the rate of 600 ± 25 lbf (2.67 ± 0.11 kN)/min.

9. FAULTY BRIQUETS AND RETESTS

9.1. Briquets that are manifestly faulty, or that give strengths differing by more than 15 percent from the average value of all test briquets made from the same sample and tested at the same period, shall not be considered in determining the tensile strength (Note 3). After discarding briquets or strength values, if less than two strength values are left for determining the tensile strength at any given period, a retest shall be performed.

Note 3—Reliable strength results depend upon careful observance of all of the specified requirements and procedures. Erratic results at a given test period indicate that some of the requirements and procedures have not been carefully observed; for example, those covering the testing of the briquets, as prescribed in Section 8.4.2.

10. CALCULATION

10.1. Record the total maximum load indicated by the testing machine and calculate the tensile strength in pounds-force per square inch or kilopascals. If the cross-sectional area of a briquet varies more than 2.0 percent from the nominal, use the actual area for the calculation of the tensile strength. The tensile strength of all acceptable test briquets (see Section 9) made from the same sample and tested at the same period shall be averaged and reported to the nearest 5 psi (34.5 kPa).

11. PRECISION AND BIAS

11.1. The following precision statements are applicable when a test result is the average of tensile strength tests of three briquets molded from a single batch of mortar tested at the same age. It is applicable to mortar made with Type I, IA, II, or III cement tested at 3 or 7 days (1 and 3 days for Type III cement) (Note 4).

Note 4—The appropriate limits are likely somewhat smaller at 1 day and larger at ages greater than 7 days.

11.1.1. *Multilaboratory Precision*—The multilaboratory standard deviation has been found to be 32 psi. Therefore, the results of properly conducted tests of a single batch by two different laboratories should not differ from each other by more than 90 psi (Note 5).

Note 5—These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670.

11.1.2. *Single-Laboratory Precision*—The single-laboratory standard deviation has been found to be 21 psi. Therefore, the results of two properly conducted tests of single batches of mortar made with the same materials either on the same day or within the same week should not differ from each other by more than 59 psi (Note 4).

Standard Method of Test for

Density of Hydraulic Cement

AASHTO Designation: T 133-98 (2006)
ASTM Designation: C 188-95e

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Density of Hydraulic Cement

AASHTO Designation: T 133-98 (2006)
ASTM Designation: C 188-95e

1. SCOPE

1.1. This method covers determination of the density of hydraulic cement. Its particular usefulness is in connection with the design and control of concrete mixtures.

1.2. The density of hydraulic cement is defined as the mass of a unit volume of the solids.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

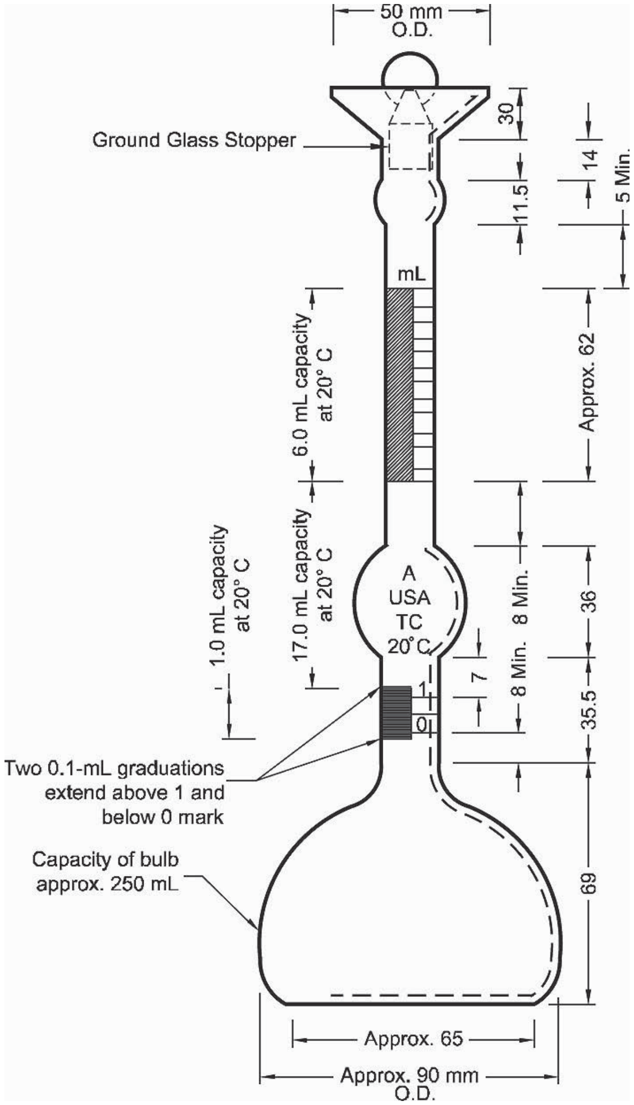
- T 105, Chemical Analysis of Hydraulic Cement

2.2. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. APPARATUS

3.1. *Le Chatelier Flask*—the standard flask—is circular in cross section with shape and dimensions conforming essentially to Figure 1 (Note 1). The requirements in regard to tolerance, inscription and length, spacing, and uniformity of graduation will be rigidly observed. There shall be a space of at least 10 mm between the highest graduation mark and the lowest point of grinding for the glass stopper.



Notes: 1. All dimensions shown in millimeters unless otherwise noted.

2. Variations of a few millimeters in such dimensions as total height of flask, diameter of base, etc., are to be expected and will not be considered sufficient cause for rejection. The dimensions of the flask shown in Figure 1 apply only to new flasks and not to flasks in use which meet the other requirements of this test method.

Figure 1—Le Chatelier Flask for Density Test

3.1.1. The material of construction shall be best quality glass, transparent and free of striae. The glass shall be chemically resistant and shall have small thermal hysteresis. The flasks shall be thoroughly annealed before being graduated. They shall be of sufficient thickness to ensure reasonable resistance to breakage.

3.1.2. The neck shall be graduated from 0 to 1 mL and from 18 to 24 mL in 0.1 mL graduations. The error of any indicated capacity shall not be greater than 0.05 mL.

3.1.3. Each flask shall bear a permanent identification number and the stopper, if not interchangeably ground, shall bear the same number. Interchangeable ground-glass parts shall be marked on both members with the standard-taper symbol, $\overline{\$}$, followed by the size designation. The standard temperature shall be indicated, and the unit of capacity shall be shown by the letters “mL” placed above the highest graduation mark.

3.2. Kerosine, free of water, or naphtha, having a density greater than 0.7391 mL at 23 ± 2ºC shall be used in the density determination.

3.3. The use of alternative equipment or methods for determining density is permitted provided that a single operator can obtain results with ±0.03 Mg/m^3 of the results obtained using the flask method.

Note 1—The design is intended to ensure complete drainage of the flask when emptied and stability of standing on a level surface as well as accuracy and precision of reading.

4. PROCEDURE

4.1. Determine the density of cement on the material as received, unless otherwise specified. If the density determination on a loss-free sample is required, first ignite the sample as described in the test for loss on ignition in Section 16.1 of T 105.

4.2. Fill the flask (Note 2) with either of the liquids specified in Section 3.2 to a point on the stem between the 0 and the 1-mL mark. Dry the inside of the flask above the level of the liquid, if necessary, after pouring. Record the first reading after the flask has been immersed in the water bath (Note 3) in accordance with Section 4.4.

Note 2—It is advisable to use a rubber pad on the table top when filling or rolling the flask.

Note 3—Before the cement has been added to the flask, a loose-fitting, lead-ring weight around the stem of the flask will be helpful in holding the flask in an upright position in the water bath, or the flask may be held in the water bath by a buret clamp.

4.3. Introduce a quantity of cement, weighed to the nearest 0.05 g (about 64 g for portland cement) in small increments at the same temperature as the liquid (Note 2). Take care to avoid splashing and see that the cement does not adhere to the inside of the flask above the liquid. A vibrating apparatus may be used to accelerate the introduction of the cement into the flask and to prevent the cement from sticking to the neck. After all the cement has been introduced, place the stopper in the flask and roll the flask in an inclined position (Note 2), or gently whirl it in a horizontal circle, so as to free the cement from air until no further air bubbles rise to the surface of the liquid. If a proper amount of cement has been added, the level of the liquid will be in its final position at some point of the upper series of graduations. Take the final reading after the flask has been immersed in the water bath in accordance with Section 4.4.

4.4. Immerse the flask in a constant-temperature water bath for sufficient periods of time in order to avoid flask-temperature variations greater then 0.2ºC between the initial and the final readings.

5. CALCULATION

5.1. The difference between the first and the final readings represents the volume of liquid displaced by the mass of cement used in the test.

5.2. Calculate the cement density, p, as follows:

$$p(\mathrm{Mg/m^3}) = p(g/\mathrm{cm^3}) = \text{mass of cement, g/displaced volume, cm}^3$$

Note 4—The displaced volume in milliliters is numerically equal to the displaced volume in cubic centimeters.

Note 5—Density in megagrams per cubic meter (Mg/m^3) is numerically equal to grams per cubic centimeter (g/cm^3). Calculate the cement density, *p*, to three decimal places and round to the nearest 0.01 Mg/m^3.

Note 6—In connection with proportioning and control of concrete mixtures, density may be more usefully expressed as specific gravity, the latter being a dimensionless number. Calculate the specific gravity as follows: Sp gr = cement density/water density at 4ºC (at 4ºC the density of water is 1 Mg/m^3(1 g/cm^3)).

6. PRECISION AND BIAS

6.1. The single-operator standard deviation for portland cements has been found to be 0.012.[1] Therefore, the results of two properly conducted tests by the same operator on the same material should not differ by more than 0.03.[1]

6.2. The multilaboratory standard deviation for portland cements has been found to be 0.037.[1] Therefore, the results of two properly conducted tests from two different laboratories on samples of the same cement should not differ by more than 0.10.[1]

6.3. Since there is no accepted reference material suitable for determining any bias that may be associated with T 133, no statement on bias is being made.

7. KEYWORDS

7.1. Density; hydraulic cement; specific gravity.

Standard Method of Test for

Air Content of Hydraulic Cement Mortar

AASHTO Designation: T 137-04 (2008)
ASTM Designation: C 185-02

1. SCOPE

1.1. This test method covers the determination of the air content of hydraulic cement mortar under the conditions hereinafter specified.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. Values in SI shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding in IEEE/ASTM SI 10, of measurements made in other units.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

---

3. SUMMARY OF TEST METHOD

3.1. Prepare a mortar with standard sand and the cement to be tested, using a water content sufficient to give a required flow. Compact the mortar into a measure of known volume and determine mass. Calculate the air content from the measured density of the mortar, the known densities of the constituents, and the mixture proportions.

---

4. SIGNIFICANCE AND USE

4.1. The purpose of this test method is to determine whether or not the hydraulic cement under test meets the air-entraining or non-air-entraining requirements of the applicable hydraulic cement specification for which the test is being made. The air content of concrete is influenced by many factors other than the potential of the cement for air entrainment.

---

5. APPARATUS

5.1. *Flow Table, Flow Mold, and Caliper*—conforming to the requirements of M 152M/M 152.

5.2. *Measure*—A cylindrical measure having an inside diameter of 76 ± 2 mm and a depth (approximately 88 mm) adjusted by standardization with water to contain 400 ± 1 mL at 23.0 ± 2.0ºC (Note 2). For the purposes of this test, the capacity of the measure in milliliters is the mass of the water content of the measure, in grams, divided by 0.9976, no correction in mass being made for the buoyant effect of air. The measure shall have a uniform wall thickness. The thickness of the wall and bottom shall not be less than 2.9 mm. The total mass of the empty measure shall not be more than 900 g. The measure shall be made of a metal not attacked by the cement mortar.

Note 1—The 400-mL measure can be calibrated readily by filling with distilled water at 23.0 ± 2.0ºC to a point where the meniscus extends appreciably above the top of the measure, placing a clean piece of plate glass on the top of the measure, and allowing the excess water to be squeezed out. The absence of air bubbles as seen through the glass ensures that the measure is completely full. Care shall be taken that the excess water is wiped from the sides of the container before determining the mass.

5.3. *Mixer, Bowl, and Paddle*—conforming to the apparatus section of T 162.

5.4. *Straightedge*—A steel straightedge not less than 200 mm long and not less than 1.5 mm nor more than 3.5 mm in thickness.

5.5. *Standard Masses and Balances*—conforming to the requirements of ASTM C 1005. The balance device shall be evaluated for precision and accuracy at a total load of 2 kg.

5.6. *Glass Graduates*—Glass graduates of 250-mL capacity, conforming to the requirements of ASTM E 438 and E 694.

5.7. *Tamper*—in accordance with T 106. The tamping face of the tamper shall be flat and at right angles to the length of the tamper.

5.8. *Tapping Stick*—a piece of hard wood having a diameter of approximately 16 mm and a length of approximately 152 mm.

5.9. *Spoon*—A metal restaurant-type serving spoon not less than 230 mm in length and with a bowl approximately 100 mm in length.

6. TEMPERATURE AND HUMIDITY

6.1. Maintain the temperature of the room and dry materials at 23.0 ± 4.0ºC.

6.2. Condition the mixing water and the measure, if it is being calibrated at 23.0 ± 2.0ºC.

6.3. The relative humidity of the laboratory shall not be less than 50 percent.

7. STANDARD SAND

7.1. Use sand conforming to the requirements of ASTM C 778 for 20–30 sand.

8. SAMPLING

8.1. Sample the cement in accordance with T 127.

9. PROCEDURE

9.1. *Batch*—Proportion the standard mortar using 350 g of cement to 1400 g of 20–30 standard sand and sufficient water to give a flow of 87.5 ± 7.5 percent when determined in accordance with Section 9.3.

Note 2—Masonry cements require different sand, sample mass, and flow. Refer to ASTM C 91.

9.2. *Mixing of Mortar*—Mix the mortar in accordance with T 162.

9.3. *Flow Determination*—Carefully wipe dry the flow-table top and place the flow mold at the center of it. Using the spoon, place a layer of mortar about 25 mm in thickness in the mold and tamp 20 times with the tamper. The tamping pressure shall be just sufficient to ensure uniform filling of the mold. Over fill the mold approximately 20 mm with mortar and tamp as specified for the first layer. Then cut off the mortar to a plane surface, flush with the top of the mold, by drawing the straightedge with a sawing motion across the top of the mold. Wipe the flow-table top clean and dry, being especially careful to remove any water from around the edge of the mold. Lift the mold away from the mortar 60 seconds after completing the mixing operation. Immediately drop the table 10 times in accordance with M 152. The flow is the resulting increase in average diameter of the mortar mass, as determined with the calipers, measured on at least four diameters at approximately equispaced intervals, expressed as a percentage of the original diameter. Make trial mortars with varying percentages of water until the specified flow is obtained. Make each trial with fresh mortar.

9.4. *Mass per 400 mL of Mortar*—When the quantity of mixing water has been found that produces a flow of 87.5 ± 7.5 percent, immediately determine the mass per 400 mL of mortar, using the mortar remaining in the mixing bowl after the flow has been determined. In the determination of the mass per 400 mL, do not use the portion of the mortar used in the flow determination.

Using the spoon, place the mortar gently into the 400-mL measure in three equal layers, tamping each layer 20 times with the tamper around the inner surface of the measure. The position of the tamper shall be that: the broad side of the tamper is parallel to the radius and is perpendicular to the inner surface of the measure. Each layer is tamped in on complete revolution (rotation) with only sufficient pressure to adequately fill the measure and eliminate voids within the mortar. After the measure has been filled and tamped in the above prescribed manner, tap the sides of the measure lightly with the side of the tapping stick, one each at five different points at approximately equal spacing around the outside of the measure, in order to preclude entrapment of extraneous air (Note 3).

No obvious space shall be left between the mortar and the inner surface of the measure as a result of the tamping operation. Then cut the mortar off to a plane surface, flush with the top of the measure, by drawing the straightedge with a sawing motion across the top of the measure, making two passes over the entire surface, the second pass being made at right angles to the first. If, in the striking-off operation, loose sand grains cause the straightedge to ride above the top surface of the measure, these grains shall be removed, and the operation repeated. Complete the entire operation of filling and striking off the measure within 90 seconds. Wipe off all mortar and water adhering to the outside of the measure. Determine the mass of the measure and its contents. Subtract the mass of the container, and record the mass of the mortar in grams.

Note 3—This operation may be facilitated by placing the measure on a steady flat-surfaced support of lesser diameter than the measure while filling and wiping.

10. CALCULATION

10.1. Calculate the air content of the mortar from the following formula, which is based on batch proportions given in Section 9.1, taking the specific gravity of portland cement as 3.15 and of 20–30 standard sand as 2.65. When the hydraulic cement is other than portland, the appropriate value for its specific gravity shall be substituted for the value of 3.15 and the formula rederived accordingly:

$$\text{Air Content, Volume, Percent} = 100 - W\,[(182.7 + P)/(2000 + 4P)] \qquad (1)$$

where:

W = mass of 400 mL of mortar, g; and

P = percentage of mixing water, based on mass of cement used.

Note 4—This formula can be derived as follows:

$$\text{Air Content, Volume, Percent} = 100[1 - (W_a/W_c)] \qquad (2)$$

where:

W_a = actual mass per unit of volume as determined by this test method;

= W/400 g/mL, where W is the mass in grams of the specified 400 mL of mortar (Section 9.4);

W_c = theoretical mass per unit of volume, calculated on an air-free basis as follows and using the values for quantities of materials and specific gravities as given in Sections 9.1 and 10.1:

$$= \frac{350 + 1400 + 350 \times P \times 0.01}{\frac{350}{3.15} + \frac{1400}{2.65} + \frac{350 \times P \times 0.01}{1}}$$

$$= \frac{(5 + 0.01P)}{(1.827 + 0.01P)}$$

P = percentage of mixing water, based on mass of cement.

Substituting for W_a and W_c, we have:

Air Content, Volume, Percent:

$$= 100\left(1 - \frac{W}{400} \times \frac{1.827 + 0.01P}{5 + 0.01P}\right)$$

$$= 100 - \frac{W}{4} \times \frac{(1.827 + 0.01P)}{(5 + 0.01P)}$$

$$= 100 - 2.5W\,\frac{(182.7 + P)}{(5000 + 10P)}$$

$$= 100 - W\,\frac{(182.7 + P)}{(2000 + 4P)}$$

10.2. Make only one determination of air content on a batch.

Note 5—Difficulty has occasionally been experienced with this test by some persons. These difficulties usually have taken the form of values for air content that are abnormally high and that may be greater than the specified maxima in specifications for hydraulic cement. The air-entraining potential of the sand may be reduced by washing in the laboratory with potable water by decantation until a clear, colorless supernatant liquid is obtained. In case of dispute, such freshly washed sand shall be used.

11. REPORT

11.1. When this test method is used for specific action in compliance testing, the value for air content shall be reported to the nearest 1 percent.

12. PRECISION AND BIAS

12.1. The single operator, within-laboratory, standard deviation has been found to be 0.56 percent air content throughout the range of 8 to 19 percent air. Therefore, results of two properly conducted tests by the same operator on similar batches should not differ by more than 1.6 percent air.

12.2. The multilaboratory standard deviation has been found to be 1.0 percent air content throughout the range from 8 to 19 percent air. Therefore, results of two different laboratories on similar batches should not differ from each other by more than 2.8 percent air.

13. KEYWORDS

13.1. Air content; hydraulic cement; mortar.

Standard Method of Test for

Fineness of Hydraulic Cement by Air Permeability Apparatus

AASHTO Designation: T 153-09
ASTM Designation: C 204-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Fineness of Hydraulic Cement by Air Permeability Apparatus

AASHTO Designation: T 153-09
ASTM Designation: C 204-07

1. SCOPE

1.1. This test method covers determination of the fineness of hydraulic cement, using the Blaine air permeability apparatus, in terms of the specific surface expressed as total surface area in square centimeters per gram, or square meters per kilogram of cement. Two test methods are given: Test Method A is the Reference Test Method using the manually operated standard Blaine apparatus, while Test Method B permits the use of an automated apparatus that is in accordance with the qualification requirements of this test method's demonstrated acceptable performance. Although the test method may be, and has been, used for the determination of the measures of fineness of various other materials, it should be understood that, in general, relative rather than absolute fineness values are obtained.

1.1.1. This test method is known to work well for portland cements. However, the user should exercise judgment in determining its suitability with regard to fineness measurements of cements with densities or porosities that differ from those assigned to Standard Reference Material No. 114.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 832, Standard Specification for Laboratory Filter Papers

2.2. *Other Documents*:

- No. 114, National Institute of Standards and Technology Standard Reference Material[1]
- BS 4359: 1971 British Standard Method for the Determination of Specific Surface of Powders: Part 2: Air Permeability Methods[2]

TEST METHOD A: REFERENCE METHOD

3. APPARATUS

3.1. *Nature of Apparatus*—The Blaine air permeability apparatus consists essentially of a means of drawing a definite quantity of air through a prepared bed of cement of definite porosity. The number and size of the pores in a prepared bed of definite porosity is a function of the size of the particles and determines the rate of airflow through the bed. The apparatus, illustrated in Figure 1, shall consist specifically of the parts described in Sections 3.2 to 3.8.

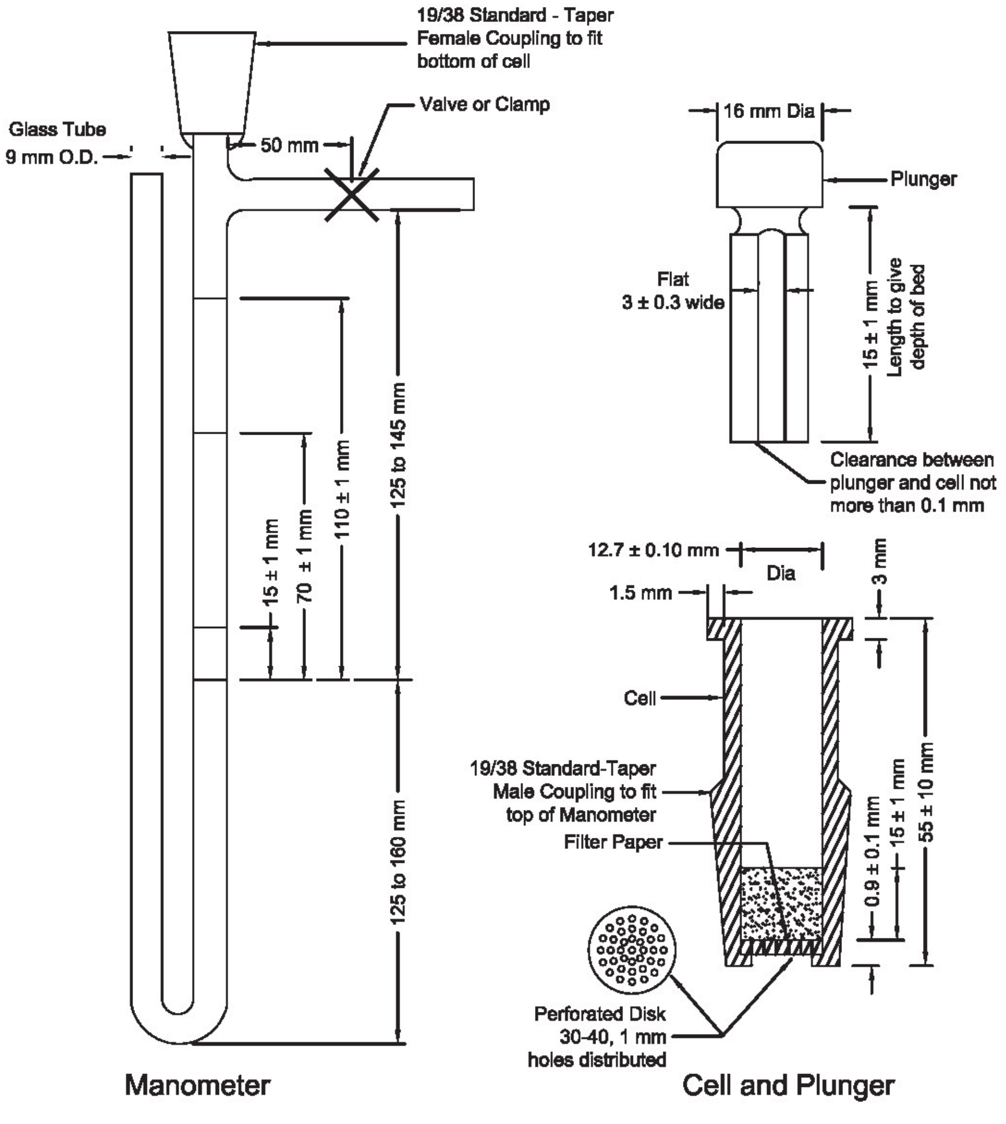

Figure 1—Blaine Air Permeability Apparatus

3.2. *Permeability Cell*—The permeability cell shall consist of a rigid cylinder 12.70 ± 0.10 mm in inside diameter, constructed of austenitic stainless steel. The interior of the cell shall have a finish of 0.81 µm (32 µin.). The top of the cell shall be at right angles to the principal axis of the cell. The lower portion of the cell must be able to form an airtight fit with the upper end of the manometer, so there is no air leakage between the contacting surfaces. A ledge 0.5 to 1 mm in width shall be an integral part of the cell or be firmly fixed in the cell 55 ± 10 mm from the top of the cell for support of the perforated metal disk. The top of the permeability cell shall be fitted with a protruding collar to facilitate the removal of the cell from the manometer.

Note 1—ASTM A 582/A 582M Type 303 stainless steel (UNS designation S30300) has been found to be suitable for the construction of the permeability cell and the plunger.

3.3. *Disk*—The disk shall be constructed of noncorroding metal and shall be 0.9 ± 0.1 mm in thickness, perforated with 30 to 40 holes 1 mm in diameter equally distributed over its area. The disk shall fit the inside of the cell snugly. The center portion of one side of the disk shall be marked or inscribed in a legible manner so as to permit the operator always to place that side downwards when inserting it into the cell. The marking or inscription shall not extend into any of the holes, nor touch their peripheries, nor extend into that area of the disk that rests on the cell ledge.

3.4. *Plunger*—The plunger shall be constructed of austenitic stainless steel and shall fit into the cell with a clearance of not more than 0.1 mm. The bottom of the plunger shall sharply meet the lateral surfaces and shall be at right angles to the principal axis. An air vent shall be provided by means of a flat 3.0 ± 0.3 mm wide on one side of the plunger. The top of the plunger shall be provided with a collar such that when the plunger is placed in the cell and the collar brought in contact with the top of the cell, the distance between the bottom of the plunger and the top of the perforated disk shall be 15 ± 1 mm.

3.5. *Filter Paper*—The filter paper shall be medium retentive, corresponding to Type 1, Grade B, in accordance with ASTM E 832. The filter paper disks shall be circular, with smooth edges, and shall have the same diameter (Note 2) as the inside of the cell.

Note 2—Filter paper disks that are too small may leave part of the sample adhering to the inner wall of the cell above the top disk. When too large in diameter, the disks have a tendency to buckle and cause erratic results.

3.6. *Manometer*—The U-tube manometer shall be constructed according to the design indicated in Figure 1, using nominal 9-mm outside diameter, standard-wall, glass tubing. The top of one arm of the manometer shall form an airtight connection with the permeability cell. The manometer arm connected to the permeability cell shall have a midpoint line etched around the tube at 125 to 145 mm below the top side outlet and also others at distances of 15 ± 1 mm, 70 ± 1 mm, and 110 ± 1 mm above that line. A side outlet shall be provided at 250 to 305 mm above the bottom of the manometer for use in the evacuation of the manometer arm connected to the permeability cell. A positive airtight valve or clamp shall be provided on the side outlet not more than 50 mm from the manometer arm. The manometer shall be mounted firmly and in such a manner that the arms are vertical.

3.7. *Manometer Liquid*—The manometer shall be filled to the midpoint line with a nonvolatile, nonhygroscopic liquid of low viscosity and density, such as dibutyl phthalate (dibutyl 1,2-benzenedicarboxylate) or a light grade of mineral oil. The fluid shall be free of debris.

3.8. *Timer*—The timer shall have a positive starting and stopping mechanism and shall be capable of being read to the nearest 0.5 seconds or less. The timer shall be accurate to 0.5 seconds or less for time intervals up to 60 seconds, and to 1 percent or less for time intervals of 60 to 300 seconds.

4. CALIBRATION OF APPARATUS

4.1. *Sample*—The calibration of the air permeability apparatus shall be made using the current lot of NIST Standard Reference Material No. 114. The sample shall be at room temperature when tested.

4.2. *Bulk Volume of Compacted Bed of Powder*—Determine the bulk volume of the compacted bed of powder by the mercury displacement method as follows:

4.2.1. Place two filter paper disks in the permeability cell, pressing down the edges, using a rod having a diameter slightly smaller than that of the cell, until the filter disks are flat on the perforated metal disk; then fill the cell with mercury, ACS reagent grade or better, removing any air bubbles adhering to the wall of the cell. Use tongs when handling the cell. If the cell is made of material that will amalgamate with mercury, the interior of the cell shall be protected by a very thin film of oil just prior to adding the mercury. Level the mercury with the top of the cell by lightly pressing a small glass plate against the mercury surface until the glass is flush to the surface of the mercury and rim of the cell, being sure that no bubble or void exists between the mercury surface and the glass plate. Remove the mercury from the cell, determine the mass, and record the mass of the mercury. Remove one of the filter disks from the cell. Using a trial quantity of 2.80 g of cement (Note 3) compress the cement (Note 4) in accordance with Section 4.5 with one filter disk above and one below the sample. Into the unfilled space at the top of the cell, add mercury, remove entrapped air, and level off the top as before. Remove the mercury from the cell, determine the mass, and record the mass of the mercury.

4.2.2. Calculate the bulk volume occupied by the cement to the nearest 0.005 cm^3 as follows:

$$V = \frac{W_A - W_B}{D} \tag{1}$$

where:

V = bulk volume of cement, cm^3;

W_A = grams of mercury required to fill the cell, no cement being in the cell;

W_B = grams of mercury required to fill the portion of the cell not occupied by the prepared bed of cement in the cell; and

D = density of mercury at the temperature of test, Mg/m^3. (See Table 1.)

Table 1—Density of Mercury, Viscosity of Air (η), and $\sqrt{n}$ at Given Temperatures

Room Temperature, °C	Density of Mercury, Mg/m^3	Viscosity of Air, η μ Pa·s	$\sqrt{\eta}$
16	13.56	17.88	4.23
18	13.55	17.98	4.24
20	13.55	18.08	4.25
22	13.54	18.18	4.26
24	13.54	18.28	4.28
26	13.53	18.37	4.29
28	13.53	18.47	4.30
30	13.52	18.57	4.31
32	13.52	18.67	4.32
34	13.51	18.76	4.33

4.2.3. Make at least two determinations of bulk volume of cement, using separate compactions for each determination. The bulk volume value used for subsequent calculations shall be the average of two values agreeing within ±0.005 cm^3. Note the temperature in the vicinity of the cell and record at the beginning and end of the determination.

Note 3—It is not necessary to use the standard sample for the bulk volume determination.

Note 4—The prepared bed of cement shall be firm. If too loose or if the cement cannot be compressed to the desired volume, adjust the trial quantity of cement used.

4.3. *Preparation of Sample*—Enclose the contents of a vial of the standard cement sample in a jar, approximately 120 cm^3 (4 oz) and shake vigorously for 2 minutes to fluff the cement and break up lumps or agglomerates. Allow the jar to stand unopened for a further 2 minutes, then remove the lid and stir gently to distribute throughout the sample the fine fraction that has settled on the surface after fluffing.

4.4. *Mass of Sample*—The mass of the standard sample used for the calibration test shall be that required to produce a bed of cement having a porosity of 0.500 ± 0.005, and shall be calculated as follows:

$$W = \rho V \left(1 - \in\right) \tag{2}$$

where:

W = grams of sample required;

ρ = density of test sample (for portland cement a value of 3.15 Mg/m^3 or 3.15 g/cm^3 shall be used);

V = bulk volume of bed cement, cm^3, as determined in accordance with Section 4.2; and

$\in$ = desired porosity of bed of cement (0.500 ± 0.005) (Note 5).

Note 5—The porosity is the ratio of volume of voids in a bed of cement to the total or bulk volume of the bed, *V*.

4.5. *Preparation of Bed of Cement*—Seat the perforated disk on the ledge in the permeability cell, inscribed or marked face down. Place a filter paper disk on the metal disk and press the edges down with a rod having a diameter slightly smaller than that of the cell. Determine the mass to the nearest 0.001 g the quantity of cement determined in accordance with Section 4.4 and place in the cell. Tap the side of the cell lightly in order to level the bed of cement. Place a filter paper disk on top of the cement and compress the cement with the plunger until the plunger collar is in contact with the top of the cell. Slowly withdraw the plunger a short distance, rotate about 90 degrees, repress, and then slowly withdraw. Use of fresh disks is required for each determination.

4.6. *Permeability Test*:

4.6.1. Attach the permeability cell to the manometer tube, making certain that an airtight connection is obtained (Note 6) and taking care not to jar or disturb the prepared bed of cement.

4.6.2. Slowly evacuate the air in the one arm of the manometer U-tube until the liquid reaches the top mark, and then close the valve tightly. Start the timer when the bottom of the meniscus of the manometer liquid reaches the second (next to the top) mark and stop when the bottom of the meniscus of liquid reaches the third (next to the bottom) mark. Note the time interval measured and record in seconds. Note the temperature of test and record in degrees Celsius.

4.6.3. In the calibration of the instrument, make at least three determinations of the time of flow on each of three separately prepared beds of the standard sample (Note 7). The calibration shall be made by the same operator who makes the fineness determination.

Note 6—A little stopcock grease should be applied to the standard taper connection. The efficiency of the connection can be determined by attaching the cell to the manometer, stoppering it, partially evacuating the one arm of the manometer, then closing the valve. Any continuous drop in pressure indicates a leak in the system.

Note 7—The sample may be refluffed and reused for preparation of the test bed, provided that it is kept dry and all tests are made within 4 hours of the opening of the sample.

4.7. *Recalibration*—The apparatus shall be recalibrated (Note 8):

4.7.1. At periodic intervals, the duration of which shall not exceed $2^1/_2$ years to correct for possible wear on the plunger or permeability cell, or upon receipt of evidence that the test is not providing data in accordance with the precision and bias statement in Section 8.

4.7.2. If any loss in the manometer fluid occurs, recalibrate starting with Section 4.5, or

4.7.3. If a change is made in the type or quality of the filter paper used for the tests.

Note 8—It is suggested that a secondary sample be prepared and used as a fineness standard for the check determinations of the instrument between regular calibrations with the standard cement sample.

5. PROCEDURE

5.1. *Temperature of Cement*—The cement sample shall be at room temperature when tested.

5.2. *Size of Test Sample*—The mass of the sample used for the test shall be the same as that used in the calibration test on the standard sample, with these exceptions: When determining the fineness of Type III or other types of fine-ground portland cement whose bulk for this mass is so great that ordinary thumb pressure will not cause the plunger collar to contact the top of the cell, the mass of the sample shall be that required to produce a test bed having a porosity of 0.530 ± 0.005. When determining the fineness of materials other than portland cement, or if for a portland cement sample one of the required porosities cannot be attained, the mass of the sample shall be adjusted so that a firm, hard bed is produced by the compacting process. In no case, however, shall more than thumb pressure be used to secure the proper bed, nor shall such thumb pressure be used that the plunger "rebounds" from the cell top when pressure is removed.

5.3. *Preparation of Bed of Cement*—Prepare the test bed of cement in accordance with the method described in Section 4.5.

5.4. *Permeability Tests*—Make the permeability tests in accordance with the method described in Section 4.6, except that only one time-of-flow determination need be made on each bed.

6. CALCULATION

6.1. Calculate the specific surface values in accordance with the following equations:

$$S = \frac{S_s \sqrt{T}}{\sqrt{T_s}} \tag{3}$$

$$S = \frac{S_S \sqrt{\eta_S} \sqrt{T}}{\sqrt{T_S} \sqrt{\eta}} \tag{4}$$

$$S = \frac{S_s(b - \in_s)\sqrt{\in^3}\sqrt{T}}{\sqrt{\in_s^3}\sqrt{T_s}(b - \in)} \tag{5}$$

$$S = \frac{S_s(b - \in_s)\sqrt{\in^3}\sqrt{\eta_s}\sqrt{T}}{\sqrt{\in_s^3}\sqrt{T_s}\sqrt{\eta}(b - \in)} \tag{6}$$

$$S = \frac{S_s\rho_s(b_s - \in_s)\sqrt{\in^3}\sqrt{T}}{\rho(b - \in)\sqrt{\in_s^3}\sqrt{T_s}} \tag{7}$$

$$S = \frac{S_s\rho_s(b_s - \in_s)\sqrt{\eta_s}\sqrt{\in^3}\sqrt{T}}{\rho(b - \in)\sqrt{\in_s^3}\sqrt{\eta}\sqrt{T_s}} \tag{8}$$

where:

S = specific surface of the test sample, m^2/kg;

S_s = specific surface of the standard sample used in calibration of the apparatus, m^2/kg (Note 9);

T = measured time interval, *s*, of manometer drop for test sample (Note 10);

T_s = measured time interval, *s*, of manometer drop for standard sample used in calibration of the apparatus (Note 10);

η = viscosity of air, micro pascal seconds (μ Pa·s), at the temperature of test of the test sample (Note 10);

η_s = viscosity of air, micro pascal seconds (μ Pa·s), at the temperature of test of the standard sample used in calibration of the apparatus (Note 10);

$\in$ = porosity of prepared bed of test sample (Note 10);

$\in_s$ = porosity of prepared bed of standard sample used in calibration of apparatus (Note 10);

ρ = density of test sample (for portland cement a value of 3.15 Mg/m^3 or 3.15 g/cm^3 shall be used);

ρ_s = density of standard sample used in calibration of apparatus (assumed to be 3.15 Mg/m^3 or 3.15 g/cm^3);

b = a constant specifically appropriate for the test sample (for hydraulic cement a value of 0.9 shall be used); and

b_s = 0.9, the appropriate constant for the standard sample.

Note 9—The proper specific surface value is indicated on the certificate that accompanies the SRM 114 series samples at the time of purchase.

Note 10—Values for $\sqrt{\eta}$, $\sqrt{\in^3}$, and $\sqrt{T}$ may be taken from Tables 1, 2, and 3, respectively.

6.1.1. Equations 3 and 4 shall be used in calculations of fineness of portland cements compacted to the same porosity as the standard fineness sample. Equation 3 is used if the temperature of test of the test sample is within ±3°C of the temperature of calibration test, and Equation 4 is used if the temperature of test of the test sample is outside of this range.

6.1.2. Equations 5 and 6 shall be used in calculation of fineness of portland cements compacted to some porosity other than that of the standard fineness sample used in the calibration test. Equation 5 is used if the temperature of test of the test sample is within ±3ºC of the temperature of calibration test of the standard fineness sample, and Equation 6 is used if the temperature of test of the test sample is outside of this range.

6.1.3. Equations 7 and 8 shall be used in calculation of fineness of materials other than portland cement. Equation 7 shall be used when the temperature of test of the test sample is within ±3°C of the temperature of calibration test, and Equation 8 is used if the temperature of test of the test sample is outside of this range.

6.1.4. It is recommended that values of *b* be determined on no less than three samples of the material in question. Test each sample at a minimum of four different porosities over a porosity range of at least 0.06. Correlation coefficients should exceed 0.9970 for the correlation of

$$\sqrt{\in^3}\,T$$

versus $\in$ on each sample tested. (See Appendix.)

6.2. To calculate the specific surface values in square meters per kilogram, multiply the surface area in cm^2/g by the factor of 0.1.

6.3. Round values in cm^2/g to the nearest 10 units (in m^2/kg to the nearest unit). Example: 3447 cm^2/g is rounded to 3450 cm^2/g or 345 m^2/kg.

T = Time of airflow in seconds; $\sqrt{T}$ = The factor for use in the equations.

7. REPORT

7.1. For portland cements and portland cement-based materials, report results on a single determination on a single bed.

7.2. For very high fineness materials with longtime intervals, report the average fineness value of two permeability tests, provided that the two agree within 2 percent of each other. If they do not agree, discard the values and repeat the test (Note 11) until two values so agreeing are obtained.

Note 11—Lack of agreement indicates a need for checks of procedure and apparatus. See also the ASTM *Manual of Cement Testing*.

8. PRECISION AND BIAS

8.1. *Single-Operator Precision*—The single-operator coefficient of variation for portland cements has been found to be 1.2 percent (Note 12). Therefore, results of two properly conducted tests, by the same operator, on the same sample, should not differ by more than 3.4 percent (Note 12) of their average.

8.2. *Multilaboratory Precision*—The multilaboratory coefficient of variation for portland cements has been found to be 2.1 percent (Note 12). Therefore, results of two different laboratories on identical samples of a material should not differ from each other by more than 6.0 percent (Note 12) of their average.

Note 12—These numbers represent, respectively, the 1s percent and d2s percent limits as described in ASTM C 670.

8.3. Since there is no accepted reference material suitable for determining any bias that may be associated with T 153, no statement is being made.

TEST METHOD B: AUTOMATED APPARATUS

9. APPARATUS

9.1. The automated test method shall employ apparatus designed either on the principles of the Blaine air-permeability method (see Note 13) or apparatus based on the air permeability principles of the Lea and Nurse method (see Note 14).

Note 13—Automated apparatus is generally equipped with a microprocessor capable of operating the measuring devices, and calculating and displaying the test results. Commercially available units may have significantly different dimensions for manometer and cement bed than those specified by standard methods.

Note 14—The Lea and Nurse constant flow rate air permeability method is described in BS 4359: 1971.

10. CALIBRATION OF APPARATUS

10.1. Follow the manufacturer's directions for calibrating the apparatus (see Note 15). If the apparatus is equipped with more than one cell, each cell will require a separate calibration. The manufacturer's procedure shall detail the method for bed preparation and the steps required to initiate the automated measurement. It is essential that the procedure be followed precisely and consistently for all tests.

Note 15—The manufacturer of the apparatus will generally provide standard samples that can be used for calibration.

11. PROCEDURE

11.1. *Temperature of Cement*—The cement sample shall be at room temperature when tested.

11.2. *Size of the Test Sample*—The mass of the sample used for the test shall be the same as used in the calibration test unless cements of different density or porosity are to be tested; then follow the manufacturer's guidelines for adjusting mass.

11.3. *Permeability Tests*—Make permeability tests using the same procedure used for the calibration tests. Only one determination need be made for each bed preparation.

12. PERFORMANCE REQUIREMENT (QUALIFICATION) FOR THE AUTOMATED APPARATUS

12.1. *Scope*—When the specific surface values determined by an automated apparatus are to be used for acceptance or rejection of cement, the method used shall comply with the qualification requirements of this section. A method is considered to consist of the specific instrument and testing procedure meeting the requirements of this standard and used in a consistent manner by a given laboratory.

12.2. *Samples*—Select two cement samples that have surface area and density that bracket the desired test range. The range of the surface area shall not exceed 2000 cm^2/g (200 m^2/kg) and shall have densities that differ no more than 0.06 g/cm^3 (60 Mg/m^3).

12.3. *Tests*—Make triplicate determinations on each cement sample following Test Method A (Reference Method). On the same day, complete a second round of triplicate tests using the method to be qualified (Test Method B) and including the standardization formula described in this section. Prepare a new cell bed and repeat all the steps of the test procedures for each determination. Report values to the nearest 10 cm^2/g (1 m^2/kg).

12.4. *Calculations*—Calculate the range and the mean of the three replicate tests for each method and each cement. A method complies with the qualification requirements if the absolute difference between the average value of Test Method A and the corresponding average value for Test Method B (each with three replicates) is not greater than 2.7 percent of the Test Method A average (see Note 16) and the range for any three replicate tests does not exceed 4.0 percent of the average (see Note 17). The method is qualified only if both cement samples shall meet the above requirements. Example qualification data are given in the Appendix.

Note 16—This value represents the least-significant-difference (*lsd*) for 95 percent confidence as applied to the coefficient of variation of 1.2 percent (Single-Operator-Precision) for Test Method A, given in Section 8.1. The equation is:

$$lsd\left(95\%\right) = t_{0.05,df}\left[\left(2CV^2/n\right)\right]^{1/2} \tag{9}$$

where:

df = 4, degree of freedom, two from each of the two sets of results;

n = 3, the number of replicates;

CV = 1.2 percent, the Single-Operator-Precision; and

$t_{0.05,4}$ = 2.776, Students-*t* statistic for a 5 percent probability with a $df = 4$.

Note 17—This value represents the d2s percentage calculation for 3 replicates in accordance with Table 1 of ASTM C 670 and applied to the coefficient of variation of 1.2 percent (Single-Operator-Precision) for Test Method A, given in Section 8.1.

12.5. *Standardization*:

12.5.1. When standardization is required in order to achieve agreement between Test Method A and Test Method B, standardize the apparatus as follows:

12.5.1.1. Prepare a separate standardization for each type of cement to be tested, using reference samples of density within 0.06 g/cm^3(60 Mg/m^3) of the cement to be tested, and packed to the same bed porosity.

12.5.1.2. For each standardization, obtain five reference samples with a minimum air permeability fineness range of 800 cm^2/g (80 m^2/kg) and a minimum difference between samples of 50 cm^2/g (5 m^2/kg). If cement samples used for qualification are used, make new determinations. Use the same method as used for the instrument qualification and follow all the steps. Valid standardization formulas shall be mathematically derived and applied to all samples.

13. REQUALIFICATION OF A METHOD

13.1. Requalify the method at least once per year and when any of the following conditions occur:

13.1.1. The instrument has been significantly modified.

13.1.2. The instrument has been substantially repaired.

13.1.3. Substantial evidence indicates that the method is not providing data meeting the performance requirements.

13.1.4. The average of a Cement and Concrete Reference Laboratory (CCRL) proficiency test sample differs from the value obtained by the method by more than 6 percent.

14. PRECISION AND BIAS

14.1. *Precision*—No precision data are available at this time. Based on qualification requirements, the precision of the method should not be greater than that of Test Method A.

14.2. *Bias*—Since there are no acceptable reference materials suitable for determining any bias that may be associated with T 153, no statement on bias is presented.

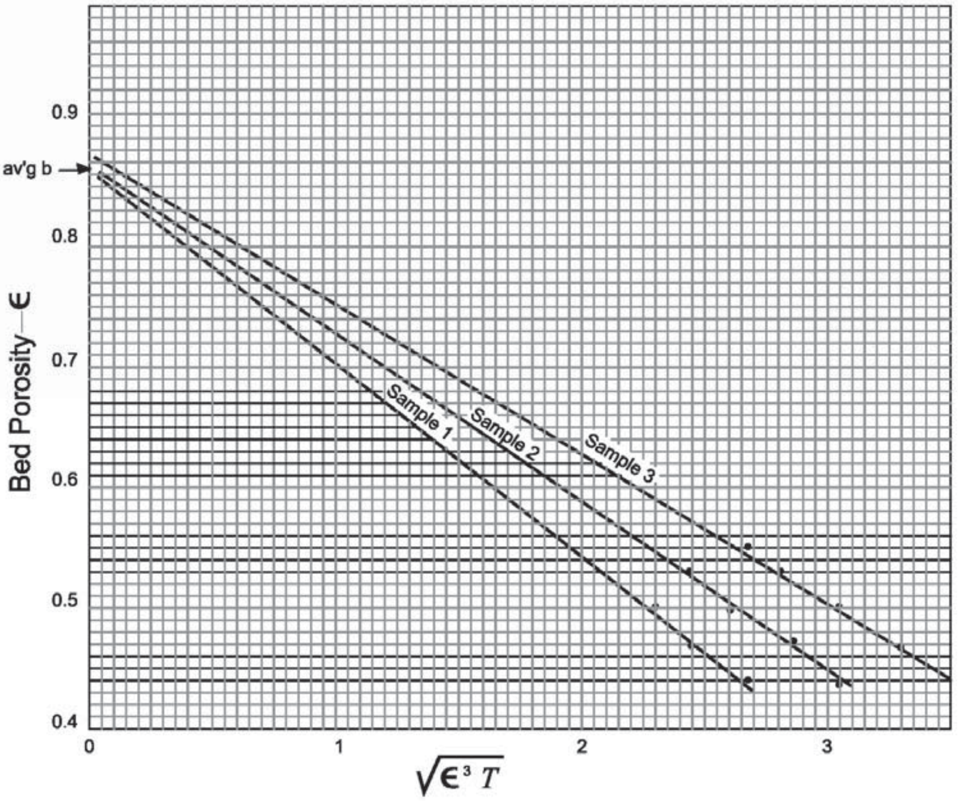
15. KEYWORDS

15.1. Air permeability; apparatus; fineness.

APPENDIX

(Nonmandatory Information)

X1. ILLUSTRATIVE METHOD FOR THE DETERMINATION OF THE VALUE FOR THE CONSTANT *B* (FOR USE IN FINENESS CALCULATIONS OF MATERIALS OTHER THAN PORTLAND CEMENT)



Material: Silica flour:

ρ = density of test sample = 2.65 Mg/m^3;

V = bulk volume of sample bed = 1.887 cm^3;

∈ = desired porosity of test;

W = grams of sample required = ρ*V* (1 – ∈); and

T = measured test time interval, seconds.

Computed values of *b* by linear regression:

Sample 1 *b* = 0.863 (correlation coefficient = 0.9980)

Sample 2 *b* = 0.869 (correlation coefficient = 0.9993)

Sample 3 *b* = 0.879 (correlation coefficient = 0.9973)

Average *b* = 0.870

Figure X1.1—Illustrative Method for the Determination of the Value for the Constant *b* (for use in fineness calculations of materials other than portland cement) (See Table X1.1.)

Table X1.1—Illustrative Method for the Determination of the Value for the Constant *b* (See Figure X1.1.)

$\in$	W	T	$\sqrt{\in^{3} T}$
Sample 1			
0.530	2.350	29.0	2.078
0.500	2.500	42.0	2.291
0.470	2.650	57.5	2.443
0.440	2.800	82.5	2.651
Sample 2

Standard Method of Test for

Time of Setting of Hydraulic Cement Paste by Gillmore Needles

AASHTO Designation: T 154-10
ASTM Designation: C 266-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Time of Setting of Hydraulic Cement Paste by Gillmore Needles

AASHTO Designation: T 154-10
ASTM Designation: C 266-08

1. SCOPE

1.1 This test method covers the determination of the time of setting of hydraulic-cement paste by means of the Gillmore needles.

1.2 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

1.4 **Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 minutes. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.

1.5 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

- M 210, Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete
- T 107, Autoclave Expansion of Hydraulic Cement
- T 127, Sampling and Amount of Testing of Hydraulic Cement
- T 129, Normal Consistency of Hydraulic Cement
- T 162, Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

2.2 *ASTM Standards*:

- C 219, Standard Terminology Relating to Hydraulic Cement
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- C 1005, Standard Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements
- D 1193, Standard Specification for Reagent Water

3. TERMINOLOGY

3.1 Refer to ASTM C 219 for definitions of terms.

4. SUMMARY OF TEST METHOD

4.1 Sufficient water is added to the cement that is being tested to produce a paste of normal consistency. A specimen is molded from this paste and is tested for time of setting by means of the Gillmore initial and final needles. The initial time of setting is the time elapsed between initial contact of cement and water and the time when the Gillmore Initial needle does not leave a complete circular impression in the paste surface. The final time of setting is the time elapsed between initial contact of cement and water and the time when the Gillmore Final needle does not leave a complete circular impression in the paste surface.

5. SIGNIFICANCE AND USE

5.1 The purpose of this test method is to establish whether a cement complies with a specification limit on Gillmore time of setting.

6. APPARATUS

6.1 *Flat Trowel,* having a sharpened straightedged steel blade 100 to 150 mm in length. The edges, when placed on a plane surface, shall not depart from straightness by more than 1 mm.

6.2 *Mixer, Bowl, Paddle, and Scraper*—conforming to the requirements of T 162.

6.3 *Glass Graduates,* 200 or 250 mL capacity, conforming to the requirements of M 210.

6.4 *Mass Determining Devices,* conforming to the requirements of ASTM C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

6.5 *Plane Non-Absorptive Plates,* 100 mm ± 5 mm (4 ± 0.197 in.) square, of similar planeness, corrosivity, and absorptivity to that of glass (see T 129, Figure 1, item H).

6.6 *Gillmore Needles,* conforming to the following requirements:

6.6.1 The initial time of setting needle shall have a mass of 0.250 ± 0.001 lb (113.4 ± 0.5 g) and a tip diameter of 0.084 ± 0.002 in. (2.12 ± 0.05 mm).

6.6.2 The final time of setting needle shall have a mass of 1.000 ± 0.001 lb (453.6 ± 0.5 g) and a tip diameter of 0.042 ± 0.002 in. (1.06 ± 0.05 mm).

6.6.3 The needle tips shall be cylindrical for a distance of 0.189 ± 0.020 in. (4.8 ± 0.5 mm). The needle ends shall be plane and at right angles to the axis of the rod and shall be maintained in a clean condition. (See Note 1.)

Note 1—The Gillmore needles should preferably be mounted as shown in Figure 1(b).

6.7 Inspect and document Section 6 apparatus for conformance to the requirements of this test method at least every $2^1/_2$ years.

7. REAGENTS

7.1 *Mixing Water*—Potable water is satisfactory for routine tests. For all referee and cooperative tests, reagent water conforming to the requirements of ASTM D 1193 for Type III or Type IV grade of reagent water shall be used.

8. SAMPLING

8.1 When the test is part of acceptance testing, sample the cement in accordance with T 127.

9. CONDITIONING

9.1 Maintain the temperature of the room, dry materials, paddle, bowl, and plane non-absorptive plates at 23.0 ± 3.0 ºC (73.4 ± 5.4ºF). Maintain the temperature of the mixing water at 23.0 ± 2.0ºC (73.4 ± 3.5ºF).

9.2 Maintain the relative humidity of the mixing room at not less than 50 percent.

9.3 The moist cabinet or moist room shall conform to the requirements of M 201.

10. PROCEDURE

10.1 *Preparation of Cement Paste*:

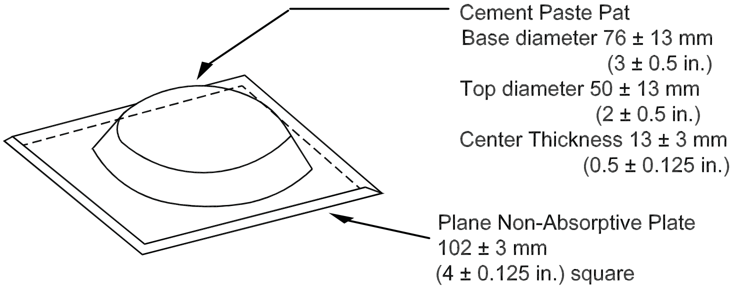
10.1.1 Obtain the cement paste used for determination of the time of setting from one of the following methods:

10.1.2 Prepare a new batch of paste by mixing 650 g of cement with the percentage of mixing water required for normal consistency (T 129), following the procedure described in T 162.

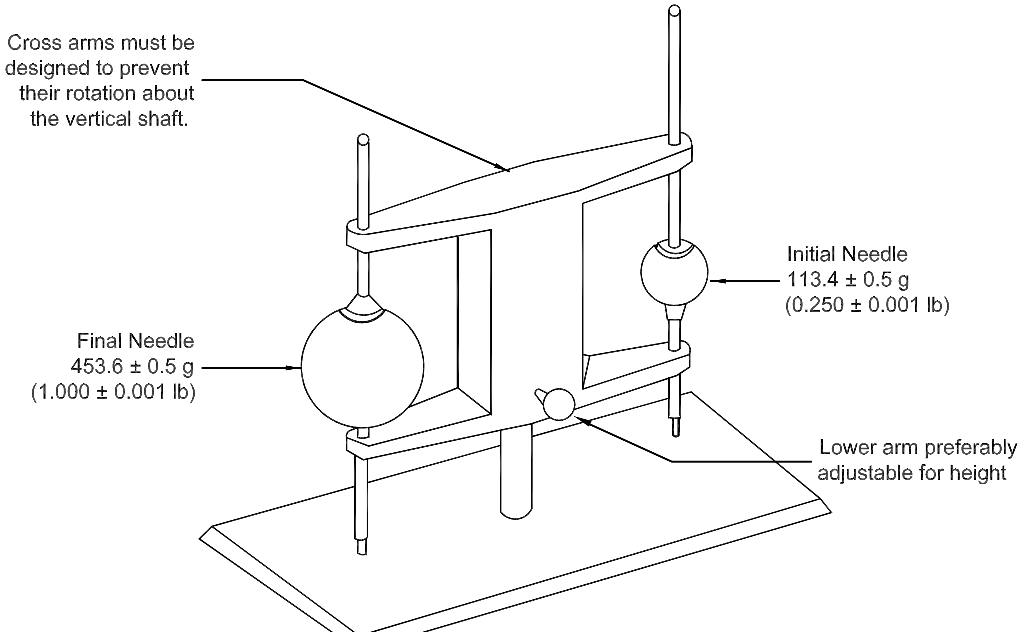
10.1.3 At the option of the tester, use the paste remaining from the batch used for the autoclave expansion specimen (T 107) or from the normal consistency determination (T 129).

10.2 *Molding Test Specimen*—From the cement paste prepared as described in Section 10.1, make a pat approximately 76 mm (3 in.) in diameter and approximately 13 mm (0.5 in.) in thickness at the center with a flat top and tapering to a thin edge (Figure 1(a)) on a clean *plane nonabsorptive plate*. In molding the pat, flatten the cement paste first on the glass and then form the pat by drawing the trowel from the outer edge toward the center, then flattening the top. After making, place the pat in the moist cabinet or moist room and allow it to remain there except when the determinations of time of setting are being made.

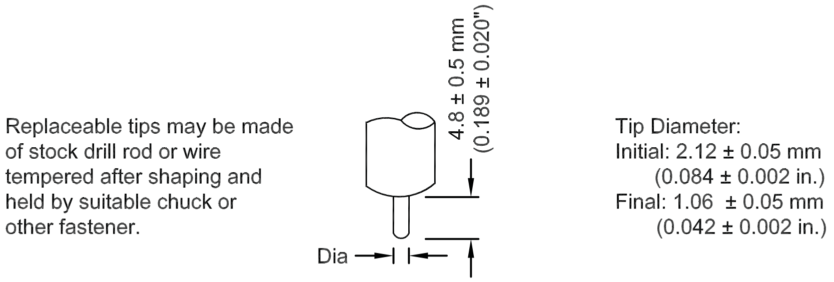
10.3 *Time of Setting Determination*—Determine the time of setting by holding the needle in a vertical position and lightly applying it to the surface of the pat.



(a) Pat with top surface flattened for determining time of setting by Gillmore Method



(b) Gillmore Apparatus



(c) Detail of Gillmore Apparatus Needle Tips

Figure 1—Gillmore Apparatus and Test Specimen

10.3.1 Using the Initial Gillmore needle, determine the Gillmore Initial time of setting end point to be the first penetration measurement that does not mark the specimen surface with a complete circular impression. Verify Initial set by obtaining two additional penetration measurements on different areas of the specimen surface. Verification measurements must be obtained within 90 s of the first "initial set" measurement. The elapsed time, in minutes, between the time of contact of cement and mixing water and the end point determined above is the Gillmore initial time of setting.

10.3.2 Using the Final Gillmore needle, determine the Gillmore Final time of setting end point to be the first penetration measurement that does not mark the specimen surface with a complete circular impression. Verify Final set by obtaining two additional penetration measurements on different areas of the specimen surface. Verification measurements must be obtained within 90 s of the first "final set" measurement. The elapsed time, in minutes, between the time of contact of cement and mixing water and the end point determined above is the Gillmore final time of setting.

11. REPORT

11.1 Report the time of setting, to the nearest 5 minutes, as follows:

- Initial Time of Setting, Gillmore—minutes.
- Final Time of Setting, Gillmore—minutes.

12. PRECISION AND BIAS

12.1 *Precision*—Gillmore Initial Time of Setting on samples testing is between 100 and 341minutes. (See Note 2.)

12.1.1 The single-operator (within laboratory) standard deviation has been found to be 16 minutes (1s); therefore, results of two properly conducted tests by the same operator on samples of the same cement should not differ from each other by more than 44 minutes (d2s) (1s and d2s are defined in ASTM C 670).

12.1.2 The multilaboratory standard deviation has been found to be 28 minutes (1s); therefore, results of two properly conducted tests from two different laboratories should not differ from each other by more than 78 minutes (d2s).

12.2 *Precision*—Gillmore Final Time of Setting on samples testing is between 239 and 561 minutes. (See Note 2.)

12.2.1 The single-operator (within laboratory) standard deviation has been found to be 22 minutes (1s); therefore, results of two properly conducted tests by the same operator on samples of the same cement should not differ from each other by more than 62 minutes (d2s).

12.2.2 The multilaboratory standard deviation has been found to be 46 minutes (1s); therefore, results of two properly conducted tests from two different laboratories on samples of the same cement should not differ by more than 129 minutes (d2s).

12.3 *Bias*:

12.3.1 Since an accepted reference material suitable for determining any bias of this method does not exist, no statement on bias is being made.

Note 2—These data are based upon CCRL Portland Cement round-robin test samples 47 to 138 and CCRL Masonry cement round-robin test samples 1 to 46.

13. KEYWORDS

13.1 Gillmore needles; hydraulic cement paste; time of setting.

Standard Method of Test for

Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

---

AASHTO Designation: T 162-09
ASTM Designation: C 305-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

AASHTO Designation: T 162-09
ASTM Designation: C 305-06

1. SCOPE

1.1. This method covers the mechanical mixing of hydraulic cement pastes and mortars of plastic consistency.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *ASTM Standard*:

- C 778, Standard Specification for Standard Sand

3. SIGNIFICANCE AND USE

3.1. This method is intended for use in the mechanical mixing of pastes and mortars for the testing of hydraulic cements.

4. APPARATUS

4.1. *Mixer*—The mixer shall be an electrically driven mechanical mixer of the epicyclic type, which imparts both a planetary and a revolving motion to the mixer paddle. The mixer shall have a minimum of two speeds, controlled by definite mechanical means. (Rheostat adjustment of speed will not be acceptable.) The first, or slow, speed shall revolve the paddle at a rate of 140 ± 5 r/min, with a planetary motion of approximately 62 r/min. The second speed shall revolve the paddle at a rate of 285 ± 10 r/min, with a planetary motion of approximately 125 r/min. The electric motor shall be at least 124 W ($^1/_6$ hp). The mixer shall be equipped with a screw which is an integral part of the mixer or a clearance adjustment bracket as shown in Figure 1 (Note 1), which shall be used to maintain the clearance between the lower end of the paddle and the bottom of the bowl not greater than 2.5 mm but not less than 0.8 mm (the approximate diameter of a grain of 20 to 30 Ottawa sand) when the bowl is in the mixing position.

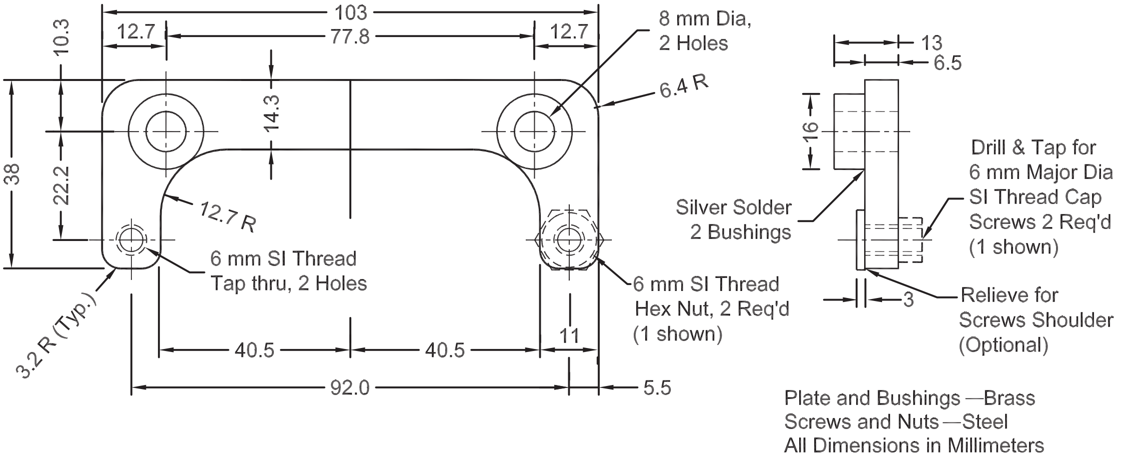


Figure 1—Clearance Adjustment Bracket

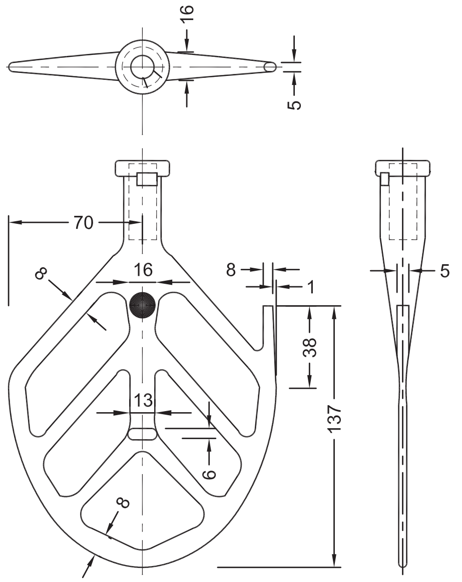
Note 1—When the bracket is in the proper position beneath the motor housing, the lugs are to the front and facing upward and the heads of the adjustment screws are to the rear and facing downward in the path of the sliding frame that holds the bowl. It is intended that the bracket be fastened at the front housing connection by inserting replacement screws of an appropriate size upward through the opening in each lug and into the existing threaded holes in the bottom of the motor housing. The original stops for the sliding frame are to be filed down if they prevent the frame from coming in contact with the adjustment screws.

Note 2—This is the approximate diameter of a grain of 20 to 30 sand as described in ASTM C 778.

4.2. *Paddle*—The paddle shall be readily removable, made of stainless steel, and shall conform to the basic design shown in Figure 2. The dimensions of the paddle shall be such that when in the mixing position, the paddle outline conforms to the contour of the bowl used with the mixer, and the clearance between corresponding points on the edge of the paddle and the side of the bowl in the position of closest approach shall be approximately 4.0 mm, but not less than 0.8 mm.



Note: All dimensions shown in millimeters unless otherwise noted.

Figure 2—Paddle

4.3. *Mixing Bowl*—The removable mixing bowl shall have a nominal capacity of 4.73 L, shall be of the general shape and comply with the limiting dimensions shown in Figure 3, and shall be made of stainless steel. The bowl shall be so equipped that it will be positively held in the mixing apparatus in a fixed position during the mixing procedure. There shall be provided a lid, made of a nonabsorbing material not attacked by cement.

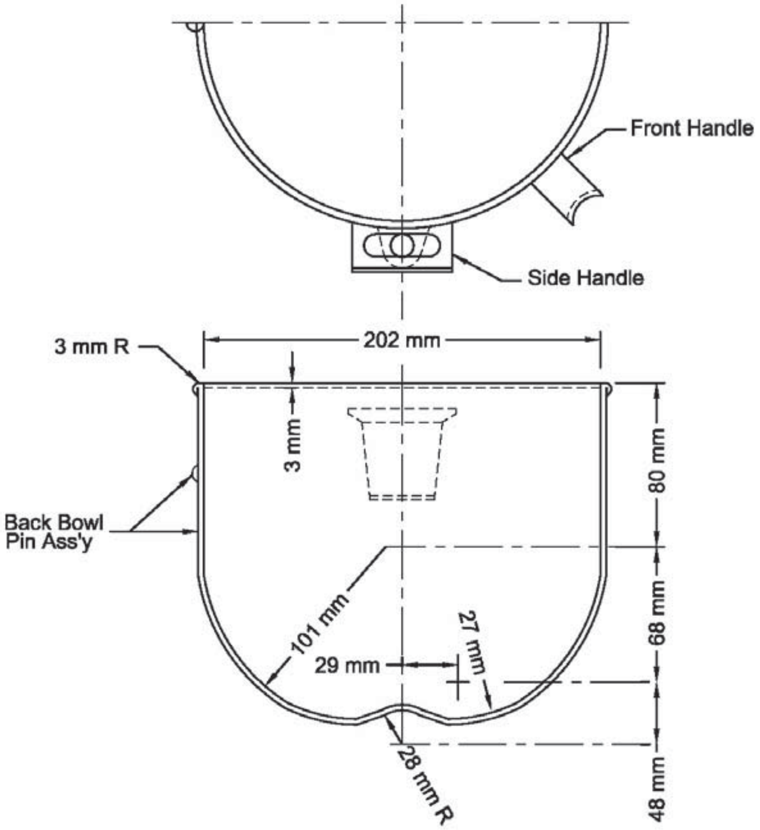


Figure 3—Mixing Bowl

4.4. *Scraper*—The scraper shall consist of a semirigid rubber blade attached to a handle about 150 mm long. The blade shall be about 75 mm long, 50 mm wide, and tapered to a thin edge about 2 mm thick.

Note 3—A kitchen tool known as a plate and bowl scraper conforms to these requirements.

4.5. *Supplementary Apparatus*—The balances, weights, glass graduates, and any other supplementary apparatus used in measuring and preparing the mortar materials prior to mixing shall conform to the respective requirements for such apparatus as specified in the method for the particular test for which the mortar is being prepared.

5. TEMPERATURE AND HUMIDITY

5.1. The temperature of the room shall be maintained between 20.0 and 27.5ºC (68.0 and 81.5ºF), and the temperature of the dry materials, paddle, and bowl shall be within the above range at the time of test. The temperature of the mixing water shall not vary from 23.0ºC (73.4ºF) by more than ±1.7ºC (3ºF).

5.2. The relative humidity of the laboratory shall not be less than 50 percent.

6. MATERIALS, PROPORTIONING, CONSISTENCY

6.1. The materials and their proportions and quantities shall conform to the requirements contained in the particular method for which the paste or mortar is being prepared.

7. PROCEDURE FOR MIXING PASTES

7.1. Place the dry paddle and the dry bowl in the mixing position in the mixer. Then introduce the materials for a batch into the bowl and mix in the following manner:

7.1.1. Place all the mixing water in the bowl.

7.1.2. Add the cement to the water and allow 30 seconds for the absorption of the water.

7.1.3. Start the mixer and mix at slow speed (140 ± 5 r/min) for 30 seconds.

7.1.4. Stop the mixer for 15 seconds and during this time scrape down into the batch any paste that may have collected on the side of the bowl.

7.1.5. Start the mixer at medium speed (285 ± 10 r/min) and mix for 60 seconds.

8. PROCEDURE FOR MIXING MORTARS

8.1. Place the dry paddle and the dry bowl in the mixing position in the mixer. Then introduce the materials for a batch into the bowl and mix in the following manner:

8.1.1. Place all the mixing water in the bowl.

8.1.2. Add the cement to the water; then start the mixer and mix at the slow speed (140 ± 5 r/min) for 30 seconds.

8.1.3. Add the entire quantity of sand slowly over a 30-second period, while mixing at slow speed.

8.1.4. Stop the mixer, change to medium speed (285 ± 10 r/min), and mix for 30 seconds.

8.1.5. Stop the mixer and let the mortar stand for 90 seconds. During the first 15 seconds of this interval, quickly scrape down into the batch any mortar that may have collected on the side of the bowl; then for the remainder of this interval, close the mixer enclosure or cover the bowl with the lid.

8.1.6. Finish by mixing for 60 seconds at medium speed (285 ± 10 r/min).

8.1.7. In any case requiring a remixing interval, any mortar adhering to the side of the bowl shall be quickly scraped down into the batch with the scraper prior to remixing.

Note 4—Warning—The clearances between paddle and bowl specified in this method are suitable when using the standard mortar made with standard sand as described in ASTM C 778. To permit the mixer to operate freely and to avoid serious damage to the paddle and bowl when coarser aggregates are used, it may be necessary to set the clearance adjustment bracket to provide greater clearances than those specified in Section 4.1.

Standard Method of Test for

Early Stiffening of Hydraulic Cement (Mortar Method)

AASHTO Designation: T 185-09[1]
ASTM Designation: C 359-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Early Stiffening of Hydraulic Cement (Mortar Method)

AASHTO Designation: T 185-09[1]
ASTM Designation: C 359-08

1. SCOPE

1.1. This method covers the determination of early stiffening in hydraulic cement mortar.

1.2. The values stated in SI units are the standard. The values in parentheses are for information only.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4. **Warning**—Fresh hydraulic-cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 minutes. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.

1.5. The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *early stiffening, n*—the early development of stiffness in the working characteristics of a hydraulic-cement paste, mortar, or concrete. Varieties include false set and flash set.

3.1.2. *false set, n*—the early development of stiffness in the working characteristics of a portland-cement paste, mortar, or concrete without the evolution of much heat, which stiffness can be dispelled and plasticity regained by further mixing without addition of water; also known as "grab set," "premature stiffening," "hesitation set," and "rubber set."

3.1.3. *flash set, n*—the early development of stiffness in the working characteristics of a hydraulic-cement paste, mortar, or concrete, usually with the evolution of considerable heat, which stiffness cannot be dispelled nor can the plasticity be regained by further mixing without addition of water; also known as "quick set."

4. SUMMARY OF TEST METHOD

4.1. A mortar is prepared with the cement to be tested, using specified quantities of cement, standard sand, and an amount of water that will produce a mortar with an initial penetration of 46 ± 3 mm, using the modified Vicat apparatus. Measurements of penetration are made at stipulated intervals after the beginning of the mixing procedure. Upon completion of the first series of penetration measurements, the mortar is returned to the mixer to be remixed. Following the remix procedure, an additional penetration, termed the remix penetration, is determined. The report is a tabulation of the penetration measurements and the amount of mixing water used.

5. SIGNIFICANCE AND USE

5.1. The purpose of this test method is to determine the degree to which a cement mortar develops early stiffening. It is intended for use by those interested in methods for determining the potential early stiffening of hydraulic cement.

5.2. When used for estimating the relative tendency of a cement to manifest early stiffening, a judgment may be made by comparing the behavior in the penetration series (Sections 10.4.1 and 10.4.2) and the remix procedure (Section 10.4.3) to differentiate a relatively less serious and less persistent tendency to early stiffening from one that is more persistent and, consequently, more serious (flash set).

5.3. Severe false setting in a cement may cause difficulty from a placing and handling standpoint, but it is not likely to cause difficulties where concrete is mixed for a longer time than usual, as usually occurs in transit mixing, or where it is remixed prior to placing or transporting, in concrete pumping operations. It is most likely noticed where concrete is mixed for a short period of time in stationary mixers and transported to the forms in nonagitating equipment, as on some paving jobs, and when concrete is made in an on-site batch plant.

5.4. Cements with severe false setting usually require slightly more mixing water to produce the same consistency, which may result in slightly lower strengths and increased drying shrinkage.

5.5. Early stiffening resulting from false set is not likely to cause a cement to fail the applicable time of setting requirement.

5.6. Early stiffening resulting from flash set, depending on severity, can cause a cement to fail the applicable time of setting requirement.

6. APPARATUS

6.1. *Vicat Apparatus,* conforming to the requirements of Figure 1 in T 129, with the following modifications:

6.1.1. The 1-mm needle shall be replaced by a mass, such that the total mass of the 10-mm plunger, indicator, and added mass shall be 400 ± 0.5 g.

6.2. *Spoon,* conforming to the requirement of T 137.

6.3. *Mixer, Bowl, Paddle, and Scraper,* conforming to the requirements of T 162.

6.4. *Glass Graduates,* 200- or 250-mL capacity, conforming to the requirements of ASTM C 1005.

6.5. *Masses and Mass Determining Devices,* conforming to the requirements of ASTM C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

6.6. *Thermometer,* ASTM No. S12C or S12F, conforming to the requirements of ASTM E 2251.

6.7. *Flat Trowel,* having a sharpened straightedged steel blade 100 to 150 mm (4 to 6 in.) in length. The edges, when placed on a plane surface, shall not depart from straightness by more than 1 mm.

6.8. *Clock Timer*, having readability to the nearest second.

6.9. *Containers,* approximately 50 by 50 by 150 mm (2 by 2 by 6 in.) inside dimensions (Figure 1). These containers, which may be made of any suitable materials such as sheet metal or plastic, shall be rigid, watertight, and at least 50 mm (2 in.) deep.

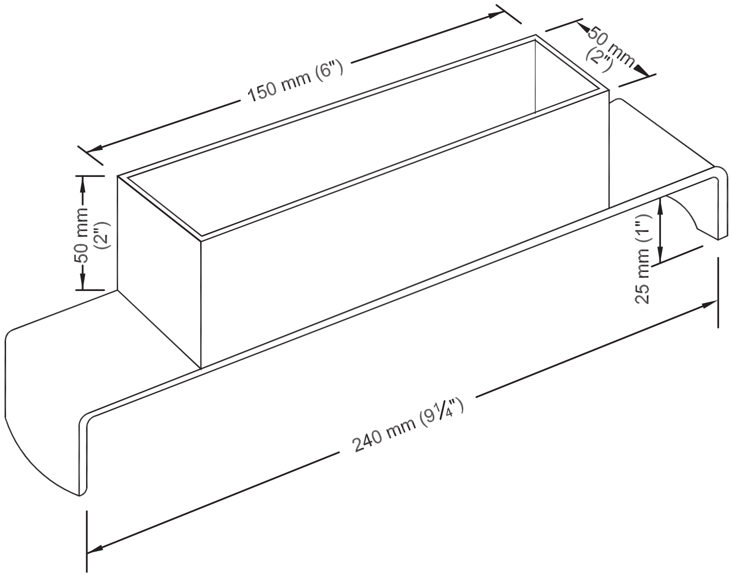

Figure 1—Container for Early Stiffening Test

7. REAGENTS AND MATERIALS

7.1. *Standard Sand*, *20-30 and Graded,* conforming to the requirements of ASTM C 778.

7.2. *Mixing Water*—Potable water is satisfactory for routine tests. For all referee and cooperative tests, reagent water conforming to the requirements of ASTM D 1193 for Type III or Type IV grades of reagent water shall be used.

8. SAMPLING

8.1. When the test is part of acceptance testing, sample the cement in accordance with T 129.

9. CONDITIONING

9.1. The temperature of the room, dry materials, paddle, bowl, and containers shall be maintained between 23.0 ± 3.0ºC (73.4 + 5.4ºF).

9.2. The relative humidity of the mixing room shall not be less than 50 percent.

10. PROCEDURE

10.1. *Batch*—Mix at one time 600 g of cement, 300 g of graded standard sand, 300 g of 20-30 standard sand, and an amount of water that produces a mortar with an initial penetration of 46 ± 3 mm.

10.2. *Mixing of Mortar*—Mix in the mechanical mixer as follows:

10.2.1. Place the sand and cement in the dry bowl, and mix the dry materials for a few seconds with the spoon.

10.2.2. Place the bowl in the mixer, set the paddle in place and mix the dry materials for 10 seconds at slow speed (140 ± 5 r/min).

10.2.3. With the mixer operating at slow speed (140 ± 5 r/min), add the entire quantity of mixing water within 5 seconds. Stop the mixer, quickly change to medium speed (285 ± 10 r/min), and continue the mixing for 1 minute, timing from the first addition of water.

10.2.4. Stop the mixer, scrape the sides of the mixing bowl with the rubber scraper, and quickly place the thermometer in the mortar. Allow it to stand undisturbed for the remainder of a 45-second interval from the time of stopping the mixer.

10.2.5. Read the temperature, remove the thermometer, start the mixer, and mix for 15 seconds at medium speed (285 ± 10 r/min). If the mortar temperature is not in the range from 23 ± 2.0ºC (73.4 ± 3.6ºF), discard the batch and adjust the temperature of the water or sand, or both, to give the required temperature.

10.3. *Filling Container*:

10.3.1. Immediately after completion of the mixing, remove the bowl from the mixer and with a spoon, uniformly distribute a portion of the mortar into the container until the container is heaping full. Quickly and gently place each spoonful of mortar in the container. When removing the mortar from the bowl, do not remove the material pushed up on the side of the bowl by the paddle. After the container has been filled, reassemble the mixer, cover the bowl with a lid, and retain the remaining mortar for a remix test to be performed later. To compact the mortar in the container, lift the container approximately 80 mm (3 in.) from the table with both hands and rap it twice against the surface of the table.

10.3.2. With the leading edge slightly raised, strike off the mortar with one stroke of the trowel along the length of the container. Then remove the excess mortar by means of a sawing motion with the straight edge of the trowel along the length of the container in a direction opposite to that used in striking off. Then, smooth the surface of the mortar with a single stroke of the trowel.

10.4. *Penetration Tests*:

10.4.1. After filling the container, immediately place the 10-mm plunger of the Vicat apparatus in contact with the surface of the mortar at the midpoint of the container on the longitudinal center line. Set the movable indicator at zero. Release the plunger 3 minutes after the beginning of the wet mixing and record, as the initial penetration, the depth in millimeters to which the plunger has settled below the surface 10 seconds after being released. If the plunger does not settle to a depth of 46 ± 3 mm, discard the batch and adjust the quantity of water to produce the required consistency.

10.4.2. Immediately withdraw and clean the plunger. In a similar manner, determine, after moving the Vicat apparatus to the desired location, the penetrations at intervals of 5, 8, and 11 minutes after the beginning of mixing. Do not move the filled container until these measurements are completed. Make all penetrations along the longitudinal center line of the container. Obtain 5- and 8-minute penetrations at a distance of approximately 40 mm ($1^1/_2$ in.) from each end of the container, respectively, and determine the 11-minute penetration at a point approximately midway between the points at which the initial and 5-minute penetrations were determined.

10.4.3. At the completion of the measurement of the 11-minute penetration, immediately return the mortar in the container to the bowl. Start the mixer, raise the bowl into mixing position, and remix the contents of the bowl at medium speed (285 ± 10 r/min) for one minute. Fill a clean container as outlined in Sections 10.3.1 and 10.3.2, and determine the penetration 45 seconds after completion of mixing.

11. CALCULATION

11.1. *Early Stiffening Amount*—The change in penetration from the initial penetration to the 11-min penetration.

11.1.1. Calculate as follows:

$$A - D$$

where:

A = Initial Penetration,
B = Penetration at 5 min,
C = Penetration at 8 min,
D = Penetration at 11 min, and
E = Penetration after Remix.

11.1.2. Report to the nearest mm.

11.2. *Average Early Stiffening Rate*—An average of the rate penetration change between each set of measurements.

11.2.1. Calculate as follows:

$$\frac{\frac{A-B}{2}+\frac{B-C}{3}+\frac{C-D}{3}}{3}$$

where:

A = Initial Penetration,
B = Penetration at 5 min,
C = Penetration at 8 min, and
D = Penetration at 11 min.

11.2.2. Report to the nearest 0.1 mm/mm.

11.3. *Early Stiffening Recovery*—The percent penetration recovery accomplished with the REMIX procedure.

11.3.1. Calculate as follows:

$$100 \times \frac{E}{A}$$

where:

E = Penetration after Remix, and
A = Initial Penetration.
(See Note 1.)

Note 1—Since it is possible for the remix penetration to exceed the initial penetration, this number may exceed 100 percent.

11.3.2. Report to the nearest percent.

12. REPORT

12.1. The report shall show the depths of the penetration as follows in Table 1:

Table 1—Penetration Report

Mixing Water	_________	mL
Initial penetration	_________	mm
5-minute penetration	_________	mm
8-minute penetration	_________	mm
11-minute penetration	_________	mm
Remix penetration	_________	mm
Early Stiffening Amount	_________	mm
Average Early Stiffening Rate	_________	mm/min
Early Stiffening Recovery	_________	percent

13. PRECISION AND BIAS

13.1. Interlaboratory test data for the determination of statements of precision and bias in accordance with ASTM C 670 are being evaluated by ASTM subcommittee C01.30. Statements of precision and bias will be included in a later revision of this test method.

14. KEYWORDS

14.1. Early stiffening; false set; flash set; hydraulic cement mortar.

---

[1] Except for the section on Precision and Bias, this method agrees with ASTM C 359-08.

Standard Method of Test for

Early Stiffening of Hydraulic Cement (Paste Method)

AASHTO Designation: T 186-09[1]
ASTM Designation: C 451-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Early Stiffening of Hydraulic Cement (Paste Method)

AASHTO Designation: T 186-09[1]
ASTM Designation: C 451-08

1. SCOPE

1.1. This test method covers the determination of early stiffening in hydraulic cement paste.

1.2. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3. *This standard does not purport to address all the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic-cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure. The use of gloves, protective clothing, and eye protection is recommended. Wash contact area with copious amounts of water after contact. Wash eyes for a minimum of 15 minutes. Avoid exposure of the body to clothing saturated with the liquid phase of the unhardened material. Remove contaminated clothing immediately after exposure.

1.4. The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. REFERENCED DOCUMENTS

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *early stiffening, n*—the early development of stiffness in the working characteristics of a hydraulic cement paste, mortar, or concrete; varieties include false set and flash set.

3.1.2. *false set, n*—the early development of stiffness in the working characteristics of a hydraulic cement paste, mortar, or concrete without the evolution of much heat, which stiffness can be dispelled and plasticity regained by further mixing without addition of water; also known as "grab set," "premature stiffening," "hesitation set," and "rubber set."

3.1.3. *flash set, n*—the early development of stiffness in the working characteristics of a hydraulic cement paste, mortar, or concrete, usually with the evolution of considerable heat, which stiffness cannot be dispelled nor can the plasticity be regained by further mixing without addition of water; also known as "quick set."

3.1.4. Refer to ASTM C 219 for definitions of other terms.

4. SUMMARY OF TEST METHOD

4.1. A paste is prepared with the cement to be tested, using sufficient water to give a required initial penetration as measured by the Vicat apparatus at a stipulated time after completion of mixing. A second penetration, termed the final penetration, is measured at a later stipulated time. The ratio of final penetration to initial penetration is calculated as a percentage.

5. SIGNIFICANCE AND USE

5.1. The purpose of this test method is to determine the degree to which a cement paste develops early stiffening or to establish whether or not a cement complies with a specification limit on early stiffening.

5.2. When used for establishing compliance with a specification limit, the specification requirement is customarily stated in terms of the minimum allowable final penetration, in percent, calculated in accordance with Section 11, Calculation. When used for estimating the relative tendency of a cement to manifest early stiffening, additional information of value may be obtained if the remix procedure described in the Section 10, Procedure, is employed. Under some conditions, a judgment may be made by comparing the behavior in the initial test and in the remix procedure to differentiate a relatively less serious and less persistent tendency to early stiffening (false set) from one that is more persistent and, consequently, more serious (flash set).

5.3. Severe false setting in a cement may cause difficulty from a placing and handling standpoint, but it is not likely to cause difficulties where concrete is mixed for a longer time than usual, as usually occurs in transit mixing, or where it is remixed prior to placing or transporting, as occurs in concrete-pumping operations. It is most likely to be noticeable where concrete is mixed for a short period of time in stationary mixers and transported to the forms in nonagitating equipment, such as on some paving jobs, and when concrete is made in an on-site batch plant.

5.4. Cements with severe false setting usually require slightly more water to produce the same consistency, which may be expected to result in slightly lower strengths and increased drying shrinkage.

5.5. Early stiffening resulting from false set is not likely to cause a cement to fail the applicable time of setting requirement.

5.6. Early stiffening resulting from flash set, depending on severity, can cause a cement to fail the applicable time of setting requirement.

6. APPARATUS

6.1. *Vicat Apparatus,* conforming to the requirements of T 129.

6.2. *Flat Trowel,* having a sharpened straightedge steel blade 100 to 150 mm (4 to 6 in.) in length. The edges when placed on plane surface shall not depart from straightness by more than 1 mm.

6.3. *Mixer, Bowl, Paddle, and Scraper,* conforming to the requirements of T 162.

6.4. *Glass Graduates,* 200- or 250-mL capacity, conforming to the requirements of ASTM C 1005.

6.5. *Masses and Mass Determining Devices,* conforming to the requirements of ASTM C 1005. The devices for determining mass shall be evaluated for precision and accuracy at a total load of 1000 g.

6.6. *Conical Ring*, made of rigid, non-corroding, nonabsorbent material, having a height of 40 ± 1 mm, an inside diameter at the bottom of 70 ± 3 mm, and an inside diameter at the top of 60 ± 3 mm (see T 129, Figure 1, item G).

6.7. *Plane Non-Absorptive Plate*, 100 ± 5 mm square, of similar planeness, corrosivity, and absorptivity to that of glass (see T 129, Figure 1, item H).

6.8. Inspect and document Section 6 apparatus for conformance to the requirements of this test method at least every 2 ½ years.

7. REAGENTS

7.1. *Mixing Water*—Potable water is satisfactory for routine tests. For all referee and cooperative tests, use reagent water conforming to the requirements of ASTM D 1193 for Type III or Type IV grades of reagent water.

8. SAMPLING

8.1. When the test is part of acceptance testing, sample the cement in accordance with T 127.

9. CONDITIONING

9.1. Maintain the temperature of the room, dry materials, paddle, bowl, conical ring, and base plate at 23.0 ± 3.0°C. Maintain the temperature of the mixing water at 23.0 ± 2.0°C.

9.2. Maintain the relative humidity of the mixing room at no less than 50 percent.

10. PROCEDURE

10.1. *Preparation of Cement Paste*—Mix 500 g of cement with sufficient water to produce a paste with an initial penetration of 32 ± 4 mm using the following procedure:

10.1.1. Place the dry paddle and the dry bowl in the mixing position in the mixer.

10.1.2. Introduce the materials for a batch into the bowl and mix in the following manner:

10.1.2.1. Place all the mixing water in the bowl.

10.1.2.2. Add the cement to the water and allow 30 seconds for the water to absorb.

10.1.2.3. Start the mixer and mix at a slow speed (140 ± 5 r/min) for 30 seconds.

10.1.2.4. Stop the mixer for 15 seconds and during this time scrape down into the batch any paste that may have collected on the sides of the bowl.

10.1.2.5. Start the mixer at a medium speed (285 ± 10 r/min) and mix for $2^1/_2$ minutes.

10.2. *Molding Test Specimens*—Quickly form the cement paste into a ball with gloved hands. Press the ball, resting in the palm of one hand, into the larger end of the conical ring held in the other hand, completely filling the ring with paste. Remove the excess at the larger end by a single movement of the palm of the hand. Place the ring on its larger end on the non-absorptive plate, *H*, and slice off the excess paste at the smaller end at the top of the ring by a single oblique stroke of a sharp-edged trowel held at a slight angle with the top of the ring. Smooth the top of the specimen, if necessary, with one or two light touches of the pointed end of the trowel. During the operation of cutting and smoothing, take care not to compress the paste.

10.3. *Determination of Initial Penetration*—Set the paste confined in the ring resting on the plate, *H*, under the rod, *B*, Figure 1 of T 129, about one-third of the diameter from the edge, and bring the plunger end, *C,* in contact with the surface of the paste and the tightened setscrew, *E*. Then set the movable indicator, *F*, to the upper zero mark of the scale, and release the rod exactly 20 seconds after completion of the mixing. Keep the apparatus free of all vibrations during the penetration test. Consider the paste to have proper consistency when the rod settles to a point 32 ± 4 mm below the original surface in 30 seconds after being released. Make trial pastes with varying percentages of water until this consistency is obtained. This consistency is the initial penetration. During the 30-second interval for the initial penetration, return the excess paste to the bowl and cover the bowl and mixing paddle with a lid.

10.4. *Determination of Final Penetration*—After completion of the initial reading, remove the plunger from the paste, clean it, and reset the ring and plate in a new position. Perform this operation with as little disturbance as possible to the paste confined in the Vicat ring. Then bring the plunger again in contact with the surface of the paste, tighten the set screw, and set the movable indicator to the upper zero mark of the scale. Release the plunger a second time 5 minutes (± 10s) after completion of the mixing period; determine the final penetration 30 seconds after the plunger is released.

10.5. *Determination of Remix Penetration*—If the penetrations determined by the foregoing procedure show the cement to be stiffening rapidly, at the option of the tester, obtain information as to the nature of the stiffening by testing as follows:

10.5.1. After completing the measurement of the 5-minute penetration, immediately return the paste in the ring to the bowl.

10.5.2. Start the mixer, raise the bowl into mixing position, and remix the contents of the bowl at a medium speed (285 ± 10 r/min) for 60 seconds.

10.5.3. Fill the ring and determine the penetration following the procedures specified in Sections 10.2 and 10.3.

11. CALCULATION

11.1. Calculate the percent final penetration, based on the ratio of final penetration to initial penetration, as follows:

$$P, \% = \frac{B}{A} \times 100 \qquad (1)$$

where:

P = percent final penetration;

B = final penetration, mm; and

A = initial penetration, mm.

12. REPORT

12.1. Report the results of the test as follows in Table 1:

Table 1—Early Stiffening Report

Initial penetration	_________ mm
Final penetration	_________ mm
Percent final penetration	_________ %
Remix penetration	_________ mm

13. PRECISION AND BIAS

13.1. *Precision*:

13.1.1. On samples testing between 8 percent and 89 percent Paste False Set, the single-operator (within laboratory) standard deviation has been found to be 10 percent (1s), therefore, results of two properly conducted tests by the same operator on samples of the same cement should not differ from each other by more than 28 percent (1s and d2s are defined in ASTM C 670).

13.1.2. On samples testing between 8 percent and 89 percent Paste False Set, the multilaboratory standard deviation has been found to be 12 percent (1s); therefore, results of two properly conducted tests from two different laboratories on samples of the same cement should not differ by more than 34 percent (1s and d2s are defined in ASTM C 670). (See Note 1.)

13.2. *Bias*:

13.2.1. Since an acceptable reference material suitable for determining any bias of this method does not exist, no statement on bias is being made.

Note 1—These data are based upon CCRL portland cement round robin test samples 47 to 138. The data indicate that precision decreases as the false set values fall below approximately 60 percent. These decreases are not clearly statistically significant; however, they do indicate the duplication difficulties on cements that exhibit false set tendencies severe enough to fail or possibly fail specification M 85 optional limits.

14. KEYWORDS

14.1. Early stiffening; false set; flash set; hydraulic cement paste; Vicat.

---

[1] Except for the use of SI units, this method agrees with ASTM C 451-08.

Standard Method of Test for

Evaluation by Freezing and Thawing of Air-Entraining Additions to Hydraulic Cement

AASHTO Designation: T 188-05 (2009)

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Evaluation by Freezing and Thawing of Air-Entraining Additions to Hydraulic Cement

AASHTO Designation: T 188-05 (2009)

1. SCOPE

1.1. This method is intended for use in determining the ability of cement containing an air-entraining agent to produce frost-resistant concrete when tested in accordance with the procedures described below.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 85, Portland Cement
- M 240, Blended Hydraulic Cement
- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 161, Resistance of Concrete to Rapid Freezing and Thawing

2.2. *ASTM Standard*:

- C 215, Standard Test Method for Fundamental Transverse, Longitudinal, and Torsional Resonant Frequencies of Concrete Specimens

3. APPARATUS

3.1. *Molds and Tamping Rod*—The molds and tamping rods shall be as specified in R 39.

3.2. *Freezing and Thawing Apparatus*—The freezing and thawing apparatus shall be as specified in T 161, Procedure A or B.

3.3. *Dynamic Testing Apparatus*—The dynamic testing apparatus shall be as specified in ASTM C 215.

4. AGGREGATES

4.1. The fine and coarse aggregates used in making the concrete specimens shall conform to the requirements of M 6 and M 80, respectively, and shall be the laboratory standards for the intended use (concrete) of the department or agency that will use the cement under test. These aggregates shall be of such a quality that they will not cause concrete (as described in this method) containing them to show a durability factor of less than 80 after 200 cycles of freezing and thawing, if the concrete is made with a paste that is protected against frost damage by an adequate system of air voids.

4.1.1. *Fine Aggregate*—The fine aggregates shall be graded as follows:

Sieve Designation		Mass Percent Passing
mm	No.	
4.75	4	100
2.36	8	85 plus or minus 3
1.18	16	65 plus or minus 5
0.600	30	45 plus or minus 5
0.300	50	21 plus or minus 2
0.150	100	7 plus or minus 5

4.1.2. *Coarse Aggregate*—The coarse aggregates shall be graded as follows:

Sieve Designation		Mass Percent Passing
mm	in.	
19.0	$^3/_4$	100
12.5	$^1/_2$	66 plus or minus 3
9.5	$^3/_8$	33 plus or minus 3
4.75	No. 4	0–3

5. CONCRETE MIXTURE

5.1. A concrete mixture, using cement containing the air-entraining agent in an amount such that the cement meets the requirements of M 85 or M 240 for air-entraining cements. shall be proportioned to have an actual cement content of 335 ± 2.8 kg/m^3 (564 ± 5 lb/yd^3). The water content of the mixtures shall be adjusted to provide a slump of 63.5 ± 12.7 mm ($2^1/_2 \pm {}^1/_2$ in.). The ratio of fine aggregate to total aggregate shall be adjusted to the optimum for concrete to be consolidated by hand rodding. Recommended values for the percentage of fine aggregate in the total aggregate by absolute volume are: for angular coarse aggregate, 41; for rounded coarse aggregate, 36. If other admixtures are to be used in the intended concrete application, they shall be included in the concrete mixture.

5.1.1. The concrete shall be machine mixed according to the applicable provisions of R 39.

6. SPECIMENS AND PROCEDURE

6.1. The specimens and testing procedure shall be as described in T 161, Procedure A or B. For this test the dimensions of the specimens shall be either 75 × 105 × 405 mm (3 × 4 × 16 in.) or 90 × 115 × 405 mm ($3^1/_2 \times 4^1/_2 \times 16$ in.). The testing shall be continued until the specimens have been subjected to 200 cycles or until the relative modulus of each specimen reaches 80 percent of the initial modulus, whichever occurs first.

Standard Method of Test for

Fineness of Hydraulic Cement by the 45-µm (No. 325) Sieve

AASHTO Designation: T 192-99 (2007)
ASTM Designation: C 430-96

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Fineness of Hydraulic Cement by the 45-µm (No. 325) Sieve

AASHTO Designation: T 192-99 (2007)
ASTM Designation: C 430-96

1. SCOPE

1.1. This test method covers the determination of the fineness of hydraulic cement by means of the 45-µm (No. 325) sieve.

1.2. The values stated in SI units are to be regarded as the standard. The inch-pound equivalents of SI units may be approximate.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:
- M 92, Wire-Cloth Sieves for Testing Purposes

2.2. *ASTM Standards*:
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 161, Standard Specification for Precision Electroformed Sieves
- E 177, Standard Practice for Use of the Terms Precision and Bias in ASTM Test Methods

3. APPARATUS

3.1. *Sieve*:

3.1.1. *Sieve Frame*—The sieve frame shall be of metal not subject to corrosion by water and shall be circular either 51 ± 6 mm (2.0 in. ± 0.25 in.) when woven-wire cloth is mounted in the frame or to 76 ± 6 mm (3.0 ± 0.25 in.) in diameter when an electroformed sheet is mounted in the frame. The depth of the sieve from the top of the frame to the cloth or sheet shall be 76 ± 6 mm (3.0 in. ± 0.25 in.). The frame shall have either side walls of 89 ± 6 mm (3.5 ± 0.25 in.) in total height, or legs at least to 12.0 mm (0.5 in.) in length, sufficient to allow air circulation beneath the sieve cloth or electroformed sheet.

3.1.2. *Sieve Cloth or Electroformed Sheet*—The sieve frame shall be fitted with either a 45-µm (No. 325) stainless steel AISI Type 304 woven-wire sieve cloth, conforming to the requirements of M 92 or a 45-µm electroformed reinforced nickel sieve sheet conforming to the requirements of ASTM E 161 with the exception that the number of openings shall be 71 ± 2 per linear centimeter (180 ± 5 per linear in.).

3.1.3. *Cloth or Sheet Mounting*:

3.1.3.1. *Woven-Wire Cloth Mounting*—Type 304 stainless steel woven-type cloth shall be mounted in the frame without distortion, looseness, or wrinkling. For a sieve fabricated by soldering the cloth to the frame, the joint shall be made smooth to prevent the cement from catching in the joints between the sieve cloth and the frame. Two-piece sieves shall clamp tightly on the cloth to prevent the cement from catching in the joints between the sieve cloth and the frame.

3.1.3.2. *Electroformed Sieve Sheet Mounting*—Electroformed reinforced nickel sieve sheet shall be mounted in the frame without distortion, looseness, or wrinkling. The joint between the sieve cloth and the frame shall be made smooth with a material impervious to water.

3.2. *Spray Nozzle*—The spray nozzle (Figure 1) shall be constructed of metal not subject to corrosion by water and shall be to 17.5 mm (0.69 in.) in inside diameter with a central hole drilled in line with the longitudinal axis, an intermediate row of eight holes drilled 6 mm (0.23 in.) center-to-center at an angle of 5 degrees from the longitudinal axis, and an outer row of eight holes drilled center-to-center at an angle of 10 degrees from the longitudinal axis. All holes shall be to 0.5 mm (0.02 in.) in diameter. The spray nozzle shall be checked at least every 6 months to ensure that the flow rate is between 1500 and 3000 g/min at 69 ± 3 kPa (10 ± 0.4 psi).

3.3. *Pressure Gauge*—The pressure gauge shall be 76 mm (3 in.) minimum diameter, and shall be graduated in 7 kPa (1 psi) increments, and shall have a maximum capacity of 207 kPa (30 psi). The accuracy at 69 kPa (10 psi) shall be ± 2 kPa (0.25 psi).

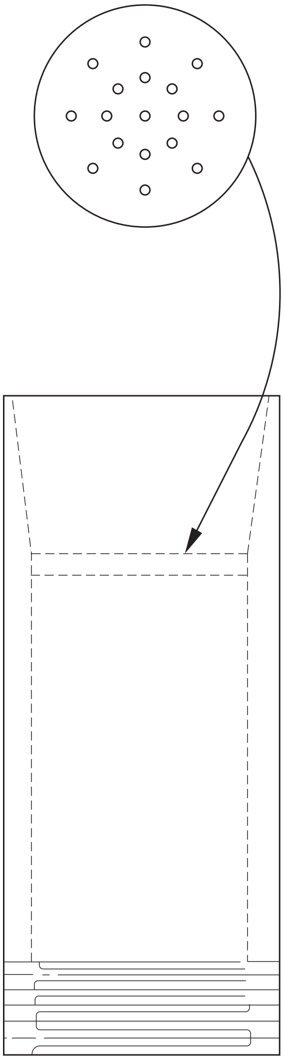

Figure 1—Spray Nozzle with Seventeen 0.5-mm (0.02-in.) Holes

4. CALIBRATION OF 45-μM (NO. 325) SIEVE

4.1. Place 1.000 g of the current lot of National Institute of Standards and Technology standard sample No. 114 on the clean, dry, 45-μm (No. 325) sieve and proceed as in Section 5. The sieve correction factor is the difference between the test residue obtained and the assigned residue value indicated by the electroformed sheet sieve fineness specified for the standard sample, expressed as a percentage of the test residue.

Note 1—It should be observed that the sieve correction as specified is a factor to be multiplied by the residue obtained and that the amount to be added to or subtracted from the residue in any given test is therefore proportional to the amount of residue.

Table 1—Example of Determination of Sieve Correction Factor

Residue on 45-µm (No. 325) Sieve, Sample No. 114	=	12.2%
Residue for a 1-g sample	=	0.122 g
Residue on sieve being calibrated	=	0.093 g
Difference	=	+ 0.029 g
Correction factor = 0.029/0.093 × 100 = +31.18	=	31.2%

5. PROCEDURE

5.1. Place a 1.000 g sample of the cement on the clean, dry 45-µm (No. 325) sieve. Wet the sample thoroughly with a gentle stream of water. Remove the sieve from under the nozzle and adjust the pressure on the spray nozzle to 69 ± 4 kPa (10 ± 0.5 psi). Return the sieve to its position under the nozzle and wash for 1 minute, moving the sieve with a circular motion in a horizontal plane at the rate of one motion per second in the spray. The bottom of the spray nozzle should extend below the top of the sieve frame about 12 mm (0.5 in.). Immediately upon removing the sieve from the spray, rinse once with about 50 cm^3 of distilled or deionized water, using caution not to lose any of the residue, and then blot the lower surface gently upon a damp cloth. Dry the sieve and residue in an oven or over a hot plate (Note 2), supporting the sieve in such a manner that air may pass freely beneath it. Cool the sieve; then brush the residue from the sieve and weigh on an analytical balance capable of reproducing results within 0.0005 g.

Note 2—Care should be taken not to heat the sieve hot enough to soften the solder.

6. CLEANING OF 45-µM (NO. 325) SIEVES

6.1. *Frequency of Cleaning and Calibration*—Sieves fitted with woven wire sieve cloth shall be cleaned after no more than five determinations. Sieves fitted with an electroformed reinforced sieve sheet having 71 openings per linear centimeter shall be cleaned after no more than three determinations. Both types of sieves shall be recalibrated after no more than 100 determinations.

6.2. *Acceptable Cleaning Procedures*—One option for cleaning is to place the sieve in a low-power (150 W maximum power input) ultrasonic bath containing an appropriate laboratory cleaning solution. The bath is to be operated for sufficient time (approximately 10 to 15 minutes at room temperature) to remove particles lodged in the openings. Be apprised that electroformed sieve sheets containing more than 71 openings per linear centimeter may well be damaged by ultrasonic cleaning. An option for cleaning that does not require an ultrasonic bath can also be employed. Immerse the sieve in a bath of appropriate laboratory cleaning solution heated to just below boiling point. Cover with a watch glass to reduce evaporation. Continue this soaking for a time sufficient to loosen lodged particles with a rinse following the bath. Overnight soaking in similar but unheated cleaning solutions is also acceptable, provided a rinse following the bath is able to wash away lodged particles. Cleaning or rinsing with dilute hydrochloric or acetic acid solutions is to be avoided. Appropriate cleaning solutions are restricted to soap or detergent-type solutions.

7. CALCULATION

7.1. Calculate the fineness of the cement to the nearest 0.1 percent as follows:

$$R_c = R_s \times (100 + C) \tag{1}$$

$$F = 100 - R_c \tag{2}$$

where:

F = fineness of the cement expressed as the corrected percentage passing the 45-µm (No. 325) sieve;

R_c = corrected residue, percent;

R_s = residue from the sample retained on the 45-µm (No. 325) sieve, g; and

C = sieve correction factor (determined as prescribed in Section 4) which may be either plus or minus.

Table 2—Example of Determination of Sieve Correction Factor

Sieve correction factor, C	= +31.2%
Residue from sample being tested, R_s	= 0.088 g
Corrected residue, R_c	= 0.088 × (100 + 31.2)
	= 11.5%
Corrected amount passing, F	= 100 – 11.5%
	= 88.5%

8. PRECISION AND BIAS

8.1. *Normal-Fineness Product*—The multilaboratory precision has been found to be ±0.75 percent (1s) as defined in ASTM E 177; therefore, results of properly conducted tests from two different laboratories on identical samples of cement should agree 95 percent of the time within ±2.1 percent.

8.2. *High-Fineness Product*—The multilaboratory precision has been found to be ±0.50 percent (1s) as defined in ASTM E 177; therefore, results of properly conducted tests from two different laboratories on identical samples of cement should agree 95 percent of the time within ±1.4 percent.

Note 3—The use of outside threads instead of inside threads as shown in Figure 1 is permissible.

8.3. Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

9. KEYWORDS

9.1. Fineness of hydraulic cement.

Standard Method of Test for

Determining the Shear Strength at the Interface of Bonded Layers of Portland Cement Concrete

AASHTO Designation: T 323-03 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Shear Strength at the Interface of Bonded Layers of Portland Cement Concrete

AASHTO Designation: T 323-03 (2007)

1. SCOPE

1.1. This test method covers the determination of the interface shear strength of a drilled concrete core sampled from a bonded concrete overlay pavement or bridge deck.

1.2. This test shall be performed on 100-mm (4-in.) diameter cores of portland cement concrete.

1.3. This test is applicable if, when retrieved by coring, the concrete overlay thickness is at least 25 mm (1 in.) and the thickness of the base concrete is at least 50 mm (2 in.).

1.4. This test procedure is based on the Iowa Department of Transportation Test Method No. Iowa 406-B (1984).

1.5. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 22, Compressive Strength of Cylindrical Concrete Specimens

2.2. *Other Documents*:

- Iowa Test Method No. 406-B, Method of Test for Determining the Shearing Strength of Bonded Concrete, Iowa Department of Transportation, 1984.

3. SUMMARY OF METHOD

3.1. This method consists of applying a continuous load to the vertical diametral plane of the test specimen along the bonded interface between the overlay concrete and base concrete (Figure 1).

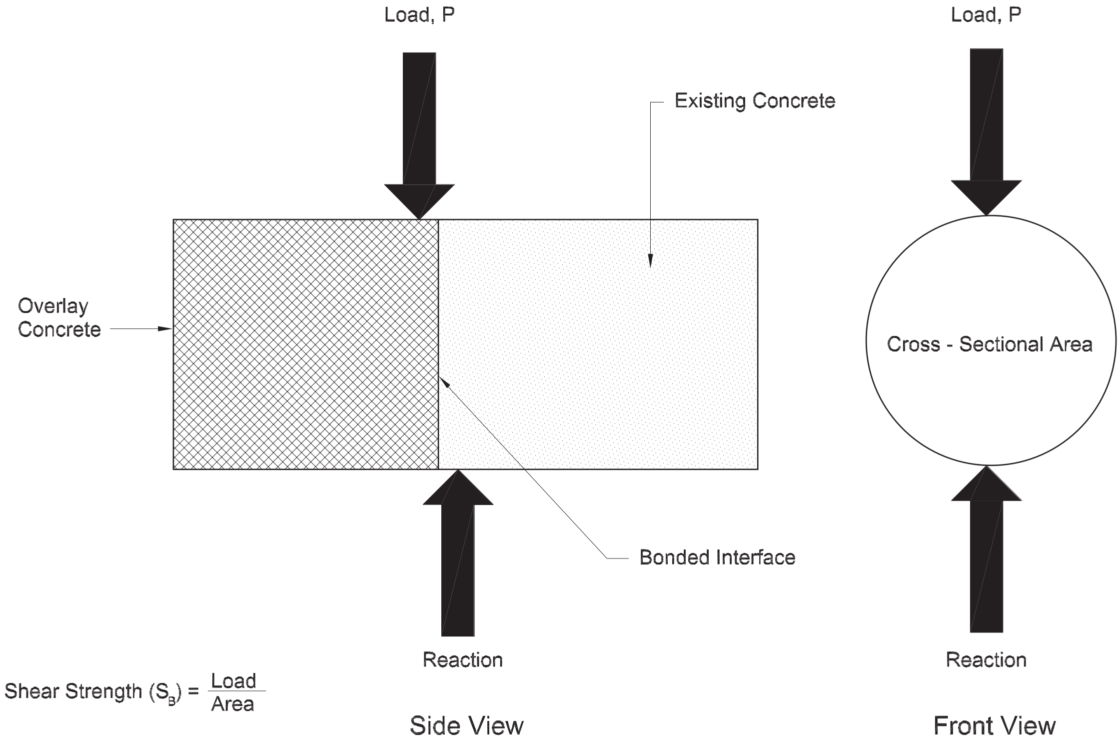

Figure 1—Loading Scheme Used for the Shear Strength Test

3.2. The load is applied until a shear failure occurs at the bonded interface.

3.3. The bond shear strength is calculated by dividing the maximum load attained during the test by the cross-sectional area of the test specimen.

4. SIGNIFICANCE AND USE

4.1. The bond shear strength may be used to assess the integrity of the bond between a bonded concrete overlay and the underlying concrete pavement or bridge deck.

5. APPARATUS

5.1. *Loading Block*—The loading block used for the bond shear test shall be designed to accommodate a 100-mm (4-in.) diameter test specimen. A typical loading block is illustrated in Figure 2.

5.2. *Loading Head*—A metal loading head with a concave surface having a 50-mm (2-in.) radius of curvature is required to apply load to the specimen. The loading head shall be 13 mm (0.5 in.) wide. Edges should be rounded by grinding to remove sharp edges. A typical loading head is illustrated in Figure 2.

5.3. *Testing Machine*—The testing machine shall conform to the requirements of T 22, possessing sufficient capacity and providing the rate of loading described in Section 6.3.

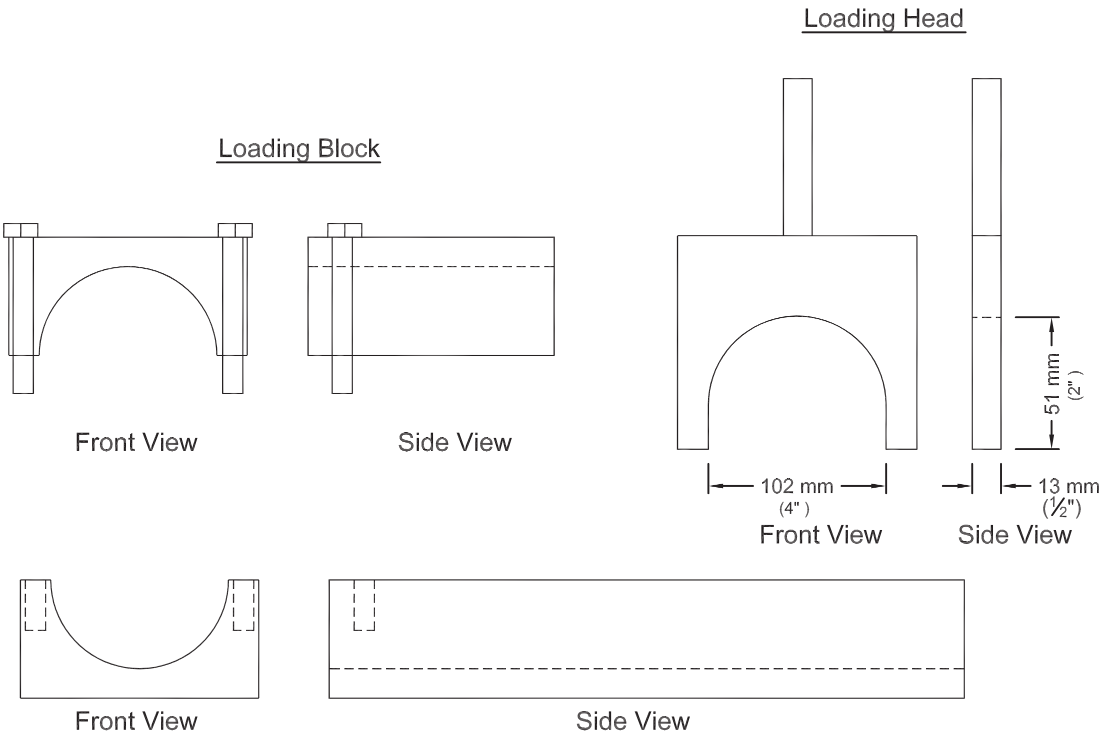

Figure 2—Typical Loading Block and Loading Head

6. PROCEDURE

6.1. *Specimen Preparation*—Measure the diameter of the core, the thickness of the overlay and the thickness of the original concrete to the nearest millimeter (mm) (0.004 in.).

6.2. *Specimen Positioning*—Secure the specimen in the loading block. The bonded interface shall be centered between the edge of the loading block and the edge of the loading head.

6.2.1. Align the loading head adjacent to the bonded interface. The loading head shall rest parallel to the bonded interface on the overlay concrete portion of the specimen. Sample positioning and loading is shown in Figure 3.

6.3. *Rate of Loading*—Apply the load continuously and without shock, at a constant rate within the range of 2760 to 3450 kPa (400 to 500 psi) per minute until failure occurs. Record the maximum applied load, P_{MAX}, carried by the specimen during the test.

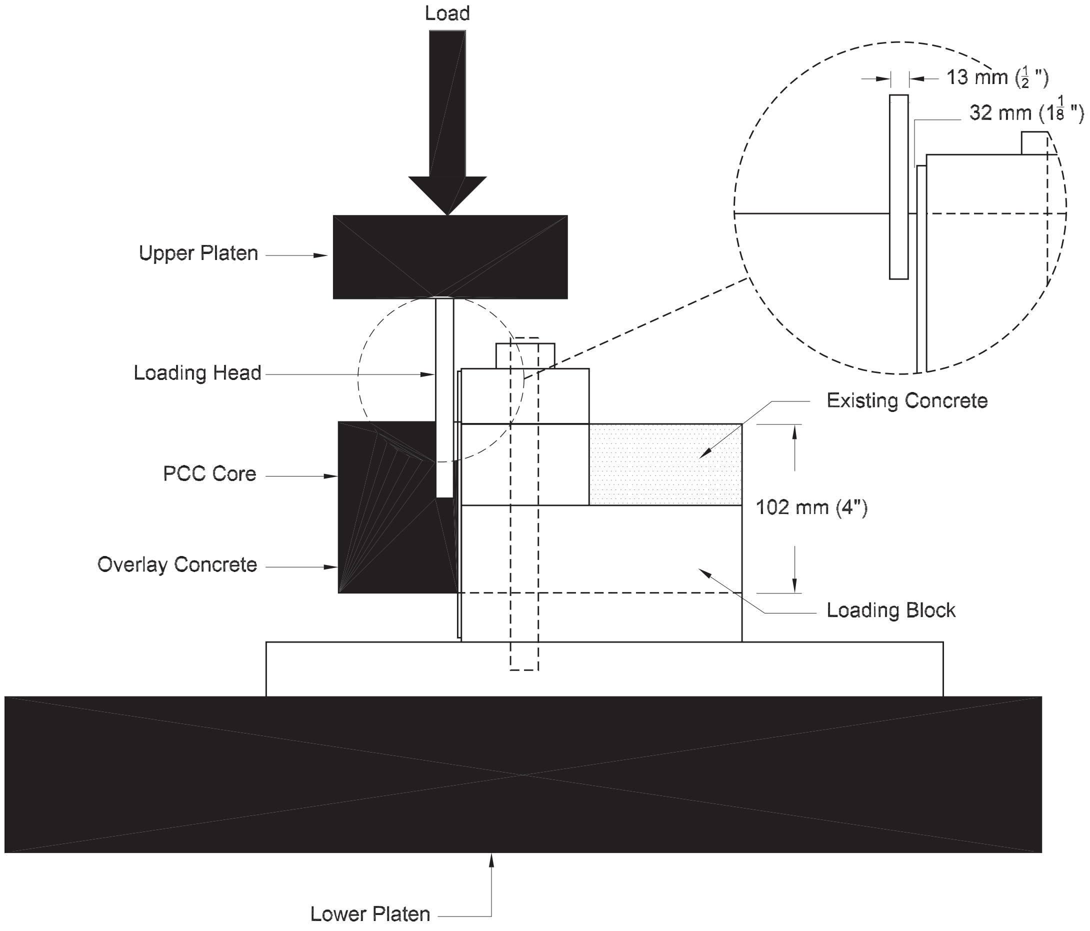

Figure 3—Illustration of Sample Positioning and Loading

7. CALCULATIONS

7.1. Calculate the bond shear strength, S_B, as follows in Equation 1:

SI units:

$$S_B = \frac{P_{MAX} \times 10^3}{A} \tag{1}$$

U.S. units:

$$S_B = \frac{P_{MAX}}{A}$$

where:

S_B = bond shear strength, kPa (psi);

P_{MAX} = maximum load applied to specimen, N (lb); and

A = cross-sectional area of test specimen, mm^2 (in.^{2}).

and in Equation 2:

$$A = \frac{\pi D^2}{4} \quad (2)$$

where:

A = cross-sectional area of test specimen, mm^2 (in.^{2}); and

D = diameter of test specimen, mm (in.).

8. REPORT

8.1. Sampling date and test date.

8.2. *Failure Plane*—Identify if failure occurred at the interface, in the base concrete layer, or in the overlay concrete layer.

8.3. *Test Results*:

8.3.1. *Specimen Dimensions*—including thickness of the overlay concrete, thickness of existing concrete, and the diameter, nearest 1.0 mm (0.05 in.) and the cross-sectional area, nearest 1.0 mm^2 (0.005 in.^{2}).

8.3.2. Maximum load applied, nearest 10 N (2.0 lb).

8.3.3. Bond shear strength, nearest 50 kPa (1.0 psi).

9. PRECISION AND BIAS

9.1. No precision and bias statements are available at this time.

10. KEYWORDS

10.1. Bonded layers; portland cement concrete; shear strength.

Standard Method of Test for

Preformed Expansion Joint Filler for Concrete Construction

AASHTO Designation: T 42-10
ASTM Designation: D 545-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Preformed Expansion Joint Filler for Concrete Construction

AASHTO Designation: T 42-10
ASTM Designation: D 545-08

AASHTO T 42-10 is identical to ASTM D 545-08 except for the following:

1. Change the first and second sentences of Section 1.2 of ASTM D 545-08 to the following:

   1.2 The values stated in SI units are to be regarded as the standard.

2. In Section 2 of ASTM D 545-08, add AASHTO reference documents as follows:

   2.2 *AASHTO Standards*:

   M 231, Weighing Devices Used in the Testing of Materials
   R 16, Regulatory Information for Chemicals Used in AASHTO Tests
   T 164, Quantitative Extraction of Asphalt Binder from Hot Mix Asphalt (HMA)

3. Change the first sentence of Section 4.7 of ASTM D 545-08 to the following:

   One steel template 102 by 102 mm, machined from 6.4-mm steel plate to fit the extrusion mold.

4. Change Section 4.8 of ASTM D 545-08 to the following:

   4.8 Metal Plate, 114 by 114 mm ±2.5 mm with parallel faces machined from 12.7-mm steel plate.

5. Change Section 5.1 of ASTM D 545-08 to the following:

   5.1 One representative sample approximately 0.2 m^2/90 m^2 of joint filler shall be obtained and properly packaged for safe transporting to the testing agency.

6. Change the fourth sentence of Section 7.1.1 of ASTM D 545-08 to the following:

   Measure the final thickness of each specimen to the nearest 0.03 mm.

7. In Section 7.1.1 of ASTM D 545-08, for SI units, change the definition of the numerator and denominator in the formula to the following:

   A = thickness in millimeters after boiling in water, and
   B = thickness in millimeters before boiling in water.

8. In Section 7.3.4 of ASTM D 545-08, change the third sentence to the following:

   Determine the amount of extrusion in millimeters by measuring the maximum movement of the free edge of the test specimen during the 50 percent compression of the specimen.

9. In Section 7.6.1 of ASTM D 545-08, for SI units, change the formula and definitions to the following:

   $$\text{Absorption by Volume, \%} = \frac{W_1 - W}{10.4t} \times 100 \qquad (1)$$

   where:

   W_1 = mass after immersion, g;
   W = mass before immersion, g; and
   t = thickness of specimen, mm.

10. Change Section 7.6.2 of ASTM D 545-08 to the following:

    7.6.2 In the event that the metal template or the test specimen, or both, does not measure to within the tolerances established in Section 4.7, the length and width of the specimen must be measured to within 0.3 mm and percent water absorption by volume calculated as follows:

11. In Section 7.6.2 of ASTM D 545-08, for SI units, change the formula and definitions to the following:

$$\text{Absorption by Volume, \%} = \frac{1000(W_1 - W)}{l \times w \times t} \times 100 \qquad (2)$$

where:

W_1 = mass after immersion, g;

W = mass before immersion, g;

l = length of specimen, mm;

w = width of specimen, mm; and

t = thickness of specimen, mm.

12. Change Section 7.7.3 of ASTM D 545-08, for SI units, to the following:

    7.7.3 Calculate the density in kg/m^3, as follows:

$$\text{Density} = \frac{96.117\ W}{t} \qquad (3)$$

where:

W = mass, g; and

t = thickness, mm.

13. In Section 7.7.4 of ASTM D 545-08, for SI units, change Section 7.7.4 to the following:

    7.7.4 In the event that the metal template or the test specimen, or both, does not measure to within the tolerances established in Section 4.7, the length and width of the specimen must be measured to within 0.3 mm and density calculated in kg/m^3 as follows:

$$\text{Density} = \frac{10^6 W}{l \times w \times t} \qquad (4)$$

where:

W = mass, g;

l = length, mm;

w = width, mm; and

t = thickness, mm.

Standard Method of Test for

Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

---

AASHTO Designation: T 65M/T 65-08[1]
ASTM Designation: A 90/A 90M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

AASHTO Designation: T 65M/T 65-08[1]
ASTM Designation: A 90/A 90M-07

1. SCOPE

1.1. This test method covers procedures for determining the mass [weight] of coating on iron or steel sheet, wire, and other articles in which the coating is zinc or a zinc alloy, such as zinc-5 percent aluminum (including zinc-5 percent aluminum-mischmetal and zinc-5 percent aluminum-0.1 percent magnesium) or 55 percent aluminum-zinc. In the body of this test method, reference to zinc coating shall be interpreted to also include zinc-alloy coating except where specifically stated otherwise.

1.2. The final results determined by this test method shall be expressed in SI units or inch-pound units, depending on the units used in the material specification to which the results are to be compared. Certain portions of the procedure involving determination of specimen mass [weight] traditionally have been performed in SI units, and corresponding inch-pound units are not included.

1.3. For sheet products, the final results are expressed as either coating mass [weight] total both sides, or coating mass [weight] separately on each side, depending on the specified requirements.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. For specific hazards statements, see Section 5.1.

1.5. Current regulation codes and hazard classifications for chemicals used in this test method are listed in R 16.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- R 16, Regulatory Information for Chemicals Used in AASHTO Tests

2.2. *ASTM Standards*:

- A 653/A 653M, Standard Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process
- A 792/A 792M, Standard Specification for Steel Sheet, 55 Percent Aluminum-Zinc Alloy-Coated by the Hot-Dip Process
- A 875/A 875M, Standard Specification for Steel Sheet, Zinc-5 Percent Aluminum Alloy-Coated by the Hot-Dip Process

- D 1193, Standard Specification for Reagent Water
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. SIGNIFICANCE AND USE

3.1. This test method provides a standard method for determining the mass [weight] of coating for comparison with specification requirements. A coating of zinc on iron or steel articles provides protection against corrosion. As the protection is provided by sacrificial loss of zinc, the degree of protection is proportional to the mass [weight] of zinc coating. Specifications for zinc-coated articles frequently provide for different classes of coating so that the purchaser can select the coating mass [weight] most suitable to his needs.

4. REAGENTS

4.1. *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.[2] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

4.2. *Purity of Water*—Water used to prepare chemical solutions shall be reagent water as defined by Type IV of ASTM D 1193.

4.3. *Antimony Trichloride Solution*—Dissolve 20 g of Sb_2O_3 or 32 g of $SbCl_3$ in 1000 mL of HCl (sp gr 1.18 to 1.19).

4.4. *Hydrochloric Acid (sp gr 1.18 to 1.19)*—Concentrated hydrochloric acid (HCl).

4.5. *Hydrochloric Acid—Antimony Trichloride Solution*—Add 5 mL of antimony trichloride solution to 100 mL of HCl (sp gr 1.18 to 1.19).

4.6. *Hydrochloric Acid (1 + 1)*—Mix 500 mL of HCl (sp gr 1.18 to 1.19) with 500 mL of reagent water and cool to room temperature.

5. HAZARDS

5.1. **Warning**—Small amounts of the poisonous gas stibine (SbH_3) may be evolved during the stripping process using the hydrochloric acid-antimony trichloride method. Hydrochloric acid fumes are present, and hydrogen gas is evolved in the stripping process. Therefore, the test should be performed under conditions of adequate ventilation. A fume hood is recommended for large numbers of samples or where the test is to be carried out frequently over extended periods of time.

6. SAMPLING

6.1. *Zinc-Coated Sheets*—Samples for mass [weight]-of-coating determination shall be secured in accordance with ASTM A 653/A 653M, A 792/A 792M, or A 875/A 875M, depending on the type of coating.

Note 1—For convenience in calculating test results in SI units, the specimen should have an area of 3330 mm^2 of sheet (57.7 ± 0.1 mm square or 65.1 ± 0.1 mm in diameter). For results to be reported in inch-pound units, the specimen should have an area of 5.08 $in.^2$ of sheet (2.25 ± 0.01 in. square or 2.54 ± 0.01 in. in diameter). The mass [weight] of coating in grams on a specimen of that area is numerically equal to the mass [weight] of coating in ounces per square foot of sheet.

6.2. *Zinc-Coated Wire*—Samples shall be secured as designated in the appropriate specification. The specimen of wire may be of any length greater than 305 mm [12 in.], but preferably about 610 mm [24 in.]. Where a continuous length is not available, shorter lengths totaling more than 305 mm [12 in.], but preferably about 610 mm [24 in.], shall be used. Since the density of the steel is known to be 7830 kg/m^3 or [0.283 $lb/in.^3$], it is not necessary to use a specific length of specimen.

6.3. *Zinc-Coated Articles Other Than Sheet or Wire*—Samples for mass [weight] of coating determination shall be secured as designated in the appropriate specification. Except as otherwise provided, the specimens should have a minimum area of 2000 mm^2 [3 $in.^2$] of zinc-coated surface. For very small items, several pieces may have to be stripped to obtain the minimum area.

6.3.1. In the case of threaded articles, such as bolts and screws, the determination shall be made on a portion of the articles that does not include any thread.

7. PROCEDURE

7.1. Stripping of zinc-alloy coatings containing less than 90 percent zinc shall be done using the dilute hydrochloric acid method. Stripping of coatings containing 90 percent or more zinc may be done using either hydrochloric acid-antimony trichloride solution or dilute hydrochloric acid (1 + 1) (alternative standard method).

7.2. Clean the specimens by washing with solvent naphtha or other suitable solvent, then rinse with alcohol, and dry thoroughly.

7.3. Determine the mass [weight] of the specimens individually to the nearest 0.01 g, except for articles other than sheet or wire with a specimen mass [weight] greater than 125 g, determine the mass [weight] to at least the nearest 0.1 g. After determining the mass [weight], immerse each specimen singly in the stripping solution and allow to remain until the violent evolution of hydrogen has ceased and only a few bubbles are being evolved. This requires about 15 to 30 seconds, except in the case of sherardized coatings, which require a somewhat longer time. The same solution may be used repeatedly until the time required for stripping becomes inconveniently long. The temperature of the stripping solution shall at no time exceed 38ºC [100ºF]. After stripping, wash the specimens by scrubbing them under running water, dip in hot water, and wipe or blow dry. Determine the mass [weight] of the specimens again, to the same precision as in the initial determination.

7.4. *Sheet Specimens*—When measuring the total coating mass [weight] on both sides, or the single side coating mass [weight] on each side, determine the area of sheet (one surface) to the nearest 5 mm^2 [0.01 $in.^2$]. If specimens were prepared to the dimensions as provided in Note 1, they shall be presumed to have an area of 3330 mm^2 [5.08 $in.^2$]. When it is not possible to determine the area accurately, as in specimens from corrugated sheets, the thickness of the stripped sheet shall be determined to the nearest 0.01 mm [0.001 in.].

7.4.1. When determining the coating mass [weight] on one side of sheet material, use the procedure described in Section 7.3, except use a "stop-off" to protect one side from the stripping medium. Acid-resistant paints or lacquers, acid-resistant tape, or mechanical devices fastened to the test specimen are examples of commonly used "stop-off" materials. Apply the "stop-off" to the specimen after the initial determination of mass [weight], and remove before the second determination of mass [weight]. Because of the possibility of moisture absorption during the stripping process, the "stop-off" must not be on the specimen during either mass [weight] determination. Determine the coating mass [weight] on the second side subsequently without a "stop-off" on the first side.

7.5. *Wire Specimens*—Determine the diameter of the stripped wire to the nearest 0.01 mm [0.001 in.] by taking the average of two measurements at right angles to each other.

7.6. *Specimens Other Than Sheet or Wire*—Determine the total coated area of the original specimen to the nearest 5 mm^2 [0.01 in.^{2}]. Alternatively, for specimens of uniform thickness of base metal, such as a piece of plate or pipe, determine the average thickness of the stripped specimen to the nearest 0.01 mm [0.001 in.].

---

8. CALCULATION

8.1. *Zinc-Coated Sheet*:

8.1.1. *Results in SI Units*:

8.1.1.1. When the area of sheet is determined, calculate the mass of coating as follows:

$$C = \left[(W_1 - W_2) / A \right] \times K \tag{1}$$

where:

C = mass of coating, g/m^2 of sheet;

W_1 = original mass of specimen, g;

W_2 = mass of stripped specimen, g;

A = area of one surface of the sheet in mm^2 (or in.^{2}); and

K = a constant = 1×10^6 when A is in mm^2, or = 1.55×10^3 when A is in in.^{2}

Note 2—If the specimen was prepared to the dimensions as provided in Note 1, having an area of 3330 mm^2 of sheet, the factor *K/A* is approximately 300, which may be used in the calculation.

8.1.1.2. When it is not possible to obtain a specimen of measurable area, calculate the mass of coating as follows:

$$C = \left[(W_1 - W_2) / W_2 \right] \times T \times K \tag{2}$$

where:

C = mass of coating, g/m^2 of sheet;

W_1 = original mass of the specimen, g;

W_2 = mass of stripped specimen, g;

T = thickness of stripped sheet, mm (or in.); and

K = a constant = 7.83×10^3 when T is in mm, or = 1.99×10^5 when T is in in.

8.1.2. *Results in Inch-Pound Units*:

8.1.2.1. When the area of one surface of the sheet is determined, calculate the weight of coating as follows:

$$C = \left[(W_1 - W_2) / A \right] \times K \tag{3}$$

where:

C = weight of coating, oz/ft^2 of sheet;

W_1 = original weight of specimen, g;

W_2 = weight of stripped specimen, g;

A = area of one surface of the sheet, mm^2 (or in.^{2}); and

K = a constant = 3.28×10^3 when A is in mm^2, or = 5.08 when A is in in.^{2}

Note 3—If the specimen was prepared to the dimensions as provided in Note 1, having an area of 5.08 in.^{2}, the loss of weight in grams is numerically equal to the weight of coating in ounces per square foot of sheet.

8.1.2.2. When it is not possible to secure a specimen of measurable area, calculate the weight of coating as follows:

$$C = \left[\left(W_1 - W_2\right)/W_2\right] \times T \times K \qquad (4)$$

where:

C = weight of coating, oz/ft^2 of sheet;

W_1 = original weight of specimen, g;

W_2 = weight of stripped specimen, g;

T = thickness of stripped sheet, mm (or in.); and

K = a constant = 25.7 when T is in mm, or = 652 when T is in in.

8.2. *Zinc-Coated Wire*:

8.2.1. *Results in SI Units*:

8.2.1.1. Calculate the mass of zinc coating as follows:

$$C = \left[\left(W_1 - W_2\right)/W_2\right] \times D \times M \qquad (5)$$

where:

C = mass of coating, g/m^2 of stripped wire surface;

W_1 = original mass of specimen, g;

W_2 = mass of stripped specimen, g;

D = diameter of stripped wire, mm (or in.); and

M = a constant = 1.96×10^3 when D is in mm, or = 4.97×10^4 when D is in in.

8.2.2. *Results in Inch-Pound Units*:

8.2.2.1. Calculate the weight of zinc coating as follows:

$$C = \left[\left(W_1 - W_2\right)/W_2\right] \times D \times M \qquad (6)$$

where:

C = weight of coating, oz/ft^2 of stripped wire surface;

W_1 = original weight of specimen, g;

W_2 = weight of stripped specimen, g;

D = diameter of stripped wire, mm (or in.); and

M = a constant = 6.42 when D is in mm, or = 163 when D is in in.

8.3. *Zinc-Coated Articles Other Than Sheet or Wire*:

8.3.1. *Results in SI Units*:

8.3.1.1. Calculate the mass of zinc coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / A \right] \times N \qquad (7)$$

where:

C = mass of coating, g/m^2 of surface;

W_1 = original mass of specimen, g;

W_2 = mass of stripped specimen, g;

A = coated area of original specimen, mm^2 (or in.^{2}); and

N = a constant = 1×10^6 when A is in mm^2, or = 1.55×10^3 when A is in in.^{2}

8.3.1.2. If the specimen has a uniform thickness of base metal, calculate the mass of coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / W_2 \right] \times G \times Z \qquad (8)$$

where:

C = mass of coating, g/m^2, of surface;

W_1 = original mass of specimen, g;

W_2 = mass of stripped specimen, g;

G = thickness of stripped specimen, mm (or in.); and

Z = a constant = 3.92×10^3 when G is in mm, or = 9.95×10^4 when G is in in.

8.3.2. *Results in Inch-Pound Units*:

8.3.2.1. Calculate the weight of coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / A \right] \times N \qquad (9)$$

where:

C = weight of coating, oz/ft^2 of surface;

W_1 = original weight of specimen, g;

W_2 = weight of stripped specimen, g;

A = coated area of original specimen, mm^2 (or in.^{2}); and

8.3.2.2. N = a constant = 3.28×10^3 when A is in mm^2, or = 5.08 when A is in in.^{2}

8.3.2.3. If the specimen has a uniform thickness of base metal, calculate the weight of coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / W_2 \right] \times G \times Z \qquad (10)$$

where:

C = weight of coating, oz/ft^2 of surface;

W_1 = original weight of specimen, g;

W_2 = weight of stripped specimen, g;

G = thickness of stripped specimen, mm (or in.); and

Z = a constant = 12.8 when G is in mm, or = 326 when G is in in.

9. REPORT

9.1. Mass [weight] of coating on zinc-coated sheet is expressed in mass [weight] per unit area of sheet, and is either the sum of the masses [weights] of coating on both sides of the sheet or single side mass [weight] on each of two sides. Masses [weights] of coating on each side of the sheet are not necessarily equal, even when both sides are exposed to the molten metal or plating solution simultaneously. Coating masses [weights] on all zinc-coated articles other than sheets are expressed in mass [weight] per unit area of surface. The minimum or range of mass [weight] per unit area for each side of the sheet shall be determined by the purchaser and shall be directly stated in the purchase order.

9.2. Report the mass of zinc coating to the nearest 1 g/m^2 when reporting in metric units.

9.3. Report the weight of zinc coating to the nearest 0.01 oz/ft^2 when reporting in inch-pound units.

9.4. When the mass [weight] of coating of a number of specimens is to be averaged to determine conformance with a specification limit, the average value shall be reported to the precision described in Sections 9.2 and 9.3 in accordance with ASTM E 29.

10. PRECISION AND BIAS

10.1. The precision of this test method is based on an interlaboratory study of ASTM A 90/A 90M conducted in 2006. Each of ten laboratories tested three replicates of two different materials.[3] Data were recorded in inch-pound units only and should not be considered metric equivalents. See Table 1 for a statistical summary of the test results.

Note 4—S_r means the standard deviation of r (repeatability). S_R means the standard deviation for R (reproducibility).

Table 1—Mass Weight Coating (in oz/ft^2)

Material	$\overline{x}$	S_x	S_r	S_R	r	R
Hot-Dipped Zinc-Coated Samples	1.100780	0.021895	0.015333	0.025222	0.042933	0.070621
Electrolytic Zinc-Coated Samples	0.403221	0.008790	0.008378	0.011138	0.023457	0.031187

10.1.1. *Repeatability*—Two test results obtained within one laboratory shall be judged not equivalent if they differ by more that the "*r*" value for that material; "*r*" is the interval representing the critical difference between two test results for the same material, obtained by the same operator using the same equipment on the same day in the same laboratory.

10.1.2. *Reproducibility*—Two test results shall be judged not equivalent if they differ by more than the "*R*" value for that material; "*R*" is the interval representing the difference between two test results for the same material, obtained by different operators using different equipment in different laboratories.

10.1.3. Any judgment in accordance with these two statements would have an approximate 95 percent probability of being correct.

10.2. *Bias*—At the time of the study, there was no accepted reference material suitable for determining the bias for this test method, therefore no statement on bias is being made.

10.3. The precision statement was determined through statistical examination of three results, from ten laboratories, on two materials.

11. KEYWORDS

11.1. Fifty-five (55) percent aluminum-zinc alloy coating; coating mass [weight]; steel sheet; steel wire; zinc-alloy coatings; zinc coating; zinc-5 percent aluminum-alloy coating; zinc-5 percent aluminum-0.1 percent magnesium alloy coating; zinc-5 percent aluminum-mischmetal alloy coating.

---

[1] Except for giving preference to SI units, the addition of R 16, and the additional requirement at the end of Section 9.1, this test method agrees with ASTM A 90/A 90M-07.

Washington, D.C. 20001

Standard Method of Test for

Tension Testing of Metallic Materials

AASHTO Designation: T 68M/T68-09
ASTM Designation: E 8/E 8M-08

The AASHTO equivalent of this method of test has been discontinued. Please refer to ASTM E 8/E 8M-08 for the information formerly contained in this standard.

Standard Method of Test for

Mass [Weight] of Coating on Aluminum-Coated Iron or Steel Articles

AASHTO Designation: T 213M/T 213-08[1]
ASTM Designation: A 428/A 428M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Mass [Weight] of Coating on Aluminum-Coated Iron or Steel Articles

AASHTO Designation: T 213M/T 213-08[1]
ASTM Designation: A 428/A 428M-06

1. SCOPE

1.1. This test method covers procedures for determining the mass [weight] of coating on aluminum-coated iron or steel sheets and wire, and on other aluminum-coated iron and steel articles.

1.2. The final results determined by this test method shall be expressed in SI or inch-pound units, depending on the units used in the material specification to which the results are to be compared. Certain portions of the procedure involving determination of specimen mass [weight] traditionally have been performed in SI units, and corresponding inch-pound units are not included.

1.3. For sheet products, the final results are expressed as either coating mass [weight] total both sides, or coating mass [weight] separately on each side, depending on the specified requirements.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. For a specific precautionary statement, see Note 1.

1.5. Current regulation codes and hazard classifications for chemicals used in this test method are listed in R 16.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- R 16, Regulatory Information for Chemicals Used in AASHTO Tests

2.2. *ASTM Standards*:

- D 1193, Standard Specification for Reagent Water
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 691, Standard Practice for Conducting an Interlaboratory Study to Determine the Precision of a Test Method

3. SIGNIFICANCE AND USE

3.1. This test method provides a standard method of determining the mass [weight] of coating for comparison with specification requirements. A coating of aluminum on iron or steel articles provides protection against corrosion by forming a relatively inert barrier. Specifications for aluminum-coated articles occasionally provide for different masses [weights] of coating so that the purchaser can select the coating mass [weight] most suited to his needs. The heavier coating will provide greater protection against mechanical damage, which may break the coating.

4. REAGENTS

4.1. *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.[2] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

4.2. *Purity of Water*—Water used in preparation of reagent solutions shall conform to ASTM D 1193, Type IV or better.

4.3. *Antimony Trichloride Solution*—Dissolve 200 g of antimony trichloride ($SbCl_3$) in 1000 mL of concentrated hydrochloric acid (HCl, sp gr 1.18 to 1.19) without heating.

4.4. *Hydrochloric Acid (*sp gr 1.18 to 1.19*)*—Concentrated hydrochloric acid (HCl).

4.5. *Sodium Hydroxide Solution*—(20 percent). Dissolve 20 parts by mass [weight] of sodium hydroxide (NaOH) in 80 parts of water.

4.6. *Stannous Chloride Solution*—Dissolve 100 g of stannous chloride ($SnCl_2 \cdot 2H_2O$) in 1000 mL of concentrated hydrochloric acid (HCl, sp gr 1.18 to 1.19) without heating. Add a few granules of reagent-grade tin.

4.7. *Hydrochloric Acid (1+1)*—Mix 500 mL of HCl (sp.gr. 1.18 to 1.19) with 500 mL of reagent water and cool to room temperature.

Note 1—**Warning**: Small amounts of the poisonous gas stibine (SbH_3) may be evolved during the stripping process using the hydrochloric acid-antimony trichloride-stannous chloride method. Hydrochloric acid fumes are present, and hydrogen gas is evolved in the stripping process. Therefore, the test should be performed under conditions of adequate ventilation. A fume hood is recommended for large numbers of samples or where the test is to be carried out frequently over extended periods of time.

5. SAMPLING

5.1. *Aluminum-Coated Sheets*—Samples for mass-of-coating [weight-of-coating] determination shall be secured as designated in the appropriate specification. Test specimens shall have a minimum area of 2000 mm^2 [3 in.^{2}] of sheet, but preferably approximately 3300 mm^2 [5 in.^{2}] of sheet.

Note 2—For results to be reported in SI units, the specimen should have an area of 3300 mm^2 of sheet (57.7 ± 0.1-mm square or 65.1 ± 0.1 mm in diameter). For convenience in calculating test results in inch-pound units, the specimen should have an area of 5.08 in.^{2} of sheet (2.25 ± 0.01 in. square or 2.54 ± 0.01 in. in diameter). The mass [weight] of coating in grams on a specimen of that area is numerically equal to the mass [weight] of coating in ounces per square foot of sheet.

5.2. *Aluminum-Coated Wire*—Samples shall be secured as designated in the appropriate specification. The specimen of aluminum-coated wire may be of any length greater than 300 mm [approximately 12 in.], but preferably about 600 mm [approximately 24 in.]. Where a continuous length is not available, shorter lengths totaling more than 300 mm, but preferably about 600 mm, shall be used. Since the density of the steel is known (7830 kg/m^3 or 0.283 lb/in.^{3}), it is not necessary to use a specific length of specimen.

5.3. *Aluminum-Coated Articles Other Than Sheet or Wire*—Samples for mass [weight] of coating determination shall be secured as designated in the appropriate specification. Except as otherwise provided, the specimens should have a minimum area of 1935 mm^2 [3 in.^{2}] of aluminum-coated surface. For very small items, several pieces may have to be stripped to obtain the minimum area.

5.3.1. In the case of threaded articles, such as bolts and screws, the determination shall be made on a portion of the article that does not include any thread.

6. PROCEDURE

6.1. Strip the aluminum coating from the specimens by using one of the following methods—the sodium hydroxide-hydrochloric acid method (Method A), the hydrochloric acid-antimony trichloride-stannous chloride method (Method B), or the dilute hydrochloric acid method (Method C).

Note 3—Methods A and B are the most common methods used for sheets.

6.2. Clean the specimens immediately before determining the mass [weight] by washing in petroleum ether or other suitable solvent, and dry thoroughly.

6.3. Determine the mass [weight] of the specimens individually to the nearest 0.01 g.

6.4. *Sodium Hydroxide-Hydrochloric Acid Method (Method A)*—Heat the NaOH solution to approximately 90ºC [195°F] (Note 4) and immerse each specimen in the hot solution until the strong reaction ceases. With silicon-free coatings, evolution of gas for considerable time is likely, but do not leave the specimens in the solution for more than a few minutes. Longer immersion inhibits the removal of coating during subsequent dips. Immersion of several specimens simultaneously is permitted provided all surfaces are freely exposed to the solution. Remove specimens from solution and scrub all surfaces under running tap water with a clean cellulose sponge to remove the loose deposit formed in the NaOH solution. Use vigorous scrubbing as necessary for some types of coating, but do not use abrasive materials to remove the deposit. Blot with a towel to remove most of the water (Note 5) and immerse each specimen singly for not more than three seconds in HCl (sp gr 1.18 to 1.19) at room temperature. Remove, scrub again under running tap water with a sponge, and re-immerse in the hot NaOH solution for not more than a few minutes or until action again ceases. Repeat this cycle until immersion in HCl shows no visible reaction (Note 6). Use one to three or more cycles as required, depending on the type and weight of coating. After the final immersion in the NaOH and HCl solutions, scrub as before, dry thoroughly, and determine the mass [weight] of each specimen to the nearest 0.01 g.

Note 4—The temperature is not critical, but the solution should be held several degrees below the boiling point (approximately 105ºC) to prevent excessive foaming during the first immersion. The beaker used for heating the solution and immersing the specimens should be less than half full of solution to avoid the danger of foaming over when the specimens are immersed.

Note 5—Most of the water should be removed to prevent dilution of the HCl, as dilute HCl will attack the base metal to a greater extent than concentrated HCl.

Note 6—It is sometimes difficult to determine the point at which all of the alloy layer has been removed, when stripping silicon-free coatings. If in doubt, determine the mass [weight] of the specimen (after scrubbing and drying) and then put it through one additional stripping cycle. Loss in mass [weight] due to the additional cycle will be on the order of 0.005 g on a 57.2-mm [2.25-in.] square sheet specimen, if all the coating had been removed before the extra cycle.

6.5. *Hydrochloric Acid-Antimony Trichloride-Stannous Chloride Method (Method B)*—After determining the mass [weight], immerse each specimen singly in a solution made by mixing 100 mL of antimony trichloride solution and 100 mL of stannous chloride solution (Note 7). Allow the specimen to remain immersed until the evolution of hydrogen has ceased. Action will stop after 1 to 4 minutes, or somewhat longer, depending on the thickness and silicon content of the coating. Use fresh solution for each test (Note 8). The temperature of the stripping solution shall not exceed 38ºC [100°F]. After stripping, wash the specimen and scrub it with a soft cloth, using a small amount of abrasive cleansing powder if necessary. Rinse the specimens and dry thoroughly with an absorbent cloth or paper and determine the mass [weight] of each specimen to the nearest 0.01 g.

Note 7—Mix the antimony trichloride and stannous chloride solutions together as needed.

Note 8—Very heavy coatings may show residual coating after all action has stopped. If, on examination after stripping, any coating still remains, repeat the immersion step using fresh solution.

6.6. *Dilute Hydrochloric Acid Method (1+1) (Method C)*—After determining the mass [weight], immerse each specimen singly in the stripping solution and allow to remain until the violent evolution of hydrogen has ceased and only a few bubbles are being evolved. Action will stop after 1 to 4 minutes or somewhat longer depending on the thickness and silicon content of the coating. Use of the same solution is permitted until the time for stripping becomes inconveniently long. The temperature of the stripping solution shall at no time exceed 38°C [100°F]. After stripping, wash the specimens by scrubbing them under running water, dip in hot water and wipe or blow dry. Determine the mass [weight] of each specimen to the nearest 0.01 g.

6.7. *Sheet Specimens*—When measuring the total coating mass [weight] on both sides, or the single side coating mass [weight] on each side, determine the area of sheet (one surface) to the nearest 5 mm^2 [0.01 in.^{2}]. If specimens were prepared to the dimensions as provided in Note 2, they shall be presumed to have an area of 3330 mm^2 [5.08 in.^{2}]. When it is not possible to determine the area accurately, as in specimens from corrugated sheets, determine the average thickness of the stripped sheets to the nearest 0.01 mm [0.001 in.].

6.7.1. When determining the single side coating mass [weight] of sheet material, use the procedures described in Sections 6.4, 6.5, or 6.6, except use a "stop-off" to protect the second side from the stripping medium. Acid-resistant paints or lacquers, acid-resistant tape, or mechanical devices fastened to the test specimen are examples of commonly used "stop-off" materials. Apply the "stop-off" to the specimen after the first determination of mass [weight] and remove before the second determination of mass [weight]. Because of the possibility of moisture absorption during the stripping process, the "stop-off" must not be on the specimen during either mass [weight] determination. Determine the coating mass [weight] on the second side subsequently without a "stop-off" on the first side.

6.8. *Wire Specimens*—Determine the diameter of the stripped wire to the nearest 0.01 mm [0.001 in.] by taking the average of two measurements at right angles to each other.

6.9. *Specimens Other Than Sheet or Wire*—Determine the total coated area of the original specimen to the nearest 5 mm^2 [0.01 in.^{2}]. Alternatively, for specimens of uniform thickness of base metal, such as a piece of plate or pipe, determine the average thickness of the stripped specimen to the nearest 0.01 mm [0.001 in.].

7. CALCULATION

7.1. *Aluminum-Coated Sheet*:

7.1.1. *Results in SI Units*:

7.1.1.1. When the area of one surface of the sheet is determined, calculate the mass [weight] of aluminum coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / A \right] \times K \tag{1}$$

where:

C = mass of coating, g/m^2 of sheet;
W_1 = original mass of specimen, g;
W_2 = mass of stripped specimen, g;
A = area of one surface of the sheet in mm^2 (or in.^{2}); and
K = a constant = 1×10^6 when A is in mm^2, or = 1.55×10^3 when A is in in.^{2}

Note 9—If the specimen was prepared to the dimensions as provided in Note 2, having an area of 3330 mm^2 of sheet, the factor K/A is approximately 300, which may be used in the calculation.

7.1.1.2. When it is not possible to obtain a specimen of measurable area, calculate the mass of the coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / W_2 \right] \times T \times K \tag{2}$$

where:

C = mass of coating, g/m^2 of sheet;
W_1 = original mass of the specimen, g;
W_2 = mass of the stripped specimen, g;
T = thickness of stripped sheet, mm (or in.); and
K = a constant = 7.83×10^3 when T is in mm, or = 1.99×10^5 when T is in in.

7.1.2. *Results in Inch-Pound Units*:

7.1.2.1. When the area of one surface of the sheet is determined, calculate the weight of aluminum coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / A \right] \times K \tag{3}$$

where:

C = weight of coating, oz/ft^2 of sheet;
W_1 = original weight of specimen, g;
W_2 = weight of stripped specimen, g;
A = area of one surface of the sheet, mm^2 (or in.^{2}); and
K = a constant = 3.28×103 when A is in mm^2, or = 5.08 when A is in in.^{2}

Note 10—If the specimen was prepared to the dimensions as provided in Note 2, having an area of 5.08 in.^{2}, the loss of weight in grams is numerically equal to the weight of coating in ounces per square foot of sheet.

7.1.2.2. When it is not possible to secure a specimen of measurable area, calculate the weight of coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / W_2 \right] \times T \times K \qquad (4)$$

where:

C = weight of coating, oz/ft^2 of sheet;
W_1 = original weight of specimen, g;
W_2 = weight of stripped specimen, g;
T = thickness of stripped sheet, mm (or in.); and
K = a constant = 25.7 when T is in mm, or = 652 when T is in in.

7.2. *Aluminum-Coated Wire*:

7.2.1. *Results in SI Units*:

7.2.1.1. Calculate the mass of aluminum coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / W_2 \right] \times D \times M \qquad (5)$$

where:

C = mass of coating, g/m^2 of stripped wire surface;
W_1 = original mass of specimen, g;
W_2 = mass of stripped specimen, g;
D = diameter of stripped wire, mm (or in.); and
M = a constant = 1.96×10^3 when D is in mm, or = 4.97×10^4 when D is in in.

7.2.2. *Results in Inch-Pound Units*:

7.2.2.1. Calculate the weight of aluminum coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / W_2 \right] \times D \times M \qquad (6)$$

where:

C = weight of coating, oz/ft^2 of stripped wire surface;
W_1 = original weight of specimen, g;
W_2 = weight of stripped specimen, g;
D = diameter of stripped wire, mm (or in.); and
M = a constant = 6.42 when D is in mm, or = 163 when D is in in.

7.3. *Aluminum-Coated Articles Other Than Sheet or Wire*:

7.3.1. *Results in SI Units*:

7.3.1.1. Calculate the mass of aluminum coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / A \right] \times N \qquad (7)$$

where:

C = mass of coating, g/m^2 of surface;
W_1 = original mass of specimen, g;
W_2 = mass of stripped specimen, g;

A = coated area of original specimen, mm^2 (or $in.^2$); and

N = a constant = 1×10^6 when A is in mm^2, or = 1.55×10^3 when A is in $in.^2$

7.3.1.2. If the specimen has a uniform thickness of base metal, as an option to the procedure in Section 7.3.1.1, calculate the mass of the aluminum coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / W_2 \right] \times G \times Z \qquad (8)$$

where:

C = mass of coating, g/m^2, of surface;

W_1 = original mass of specimen, g;

W_2 = mass of stripped specimen, g;

G = thickness of stripped specimen, mm (or in.); and

Z = a constant = 3.92×10^3 when G is in mm, or = 9.95×10^4 when G is in in.

7.3.2. *Results in Inch-Pound Units*:

7.3.3. Calculate the weight of aluminum coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / A \right] \times N \qquad (9)$$

where:

C = weight of coating, oz/ft^2 of surface;

W_1 = original weight of specimen, g;

W_2 = weight of stripped specimen, g;

A = coated area of original specimen, mm^2 (or $in.^2$); and

N = a constant = 3.28×10^3 when A is in mm^2, or = 5.08 when A is in $in.^2$

7.3.3.1. If the specimen has a uniform thickness of base metal, as an option to the procedure in Section 7.3.2.1, calculate the weight of the aluminum coating as follows:

$$C = \left[\left(W_1 - W_2 \right) / W_2 \right] \times G \times Z \qquad (10)$$

where:

C = weight of coating, oz/ft^2 of surface;

W_1 = original weight of specimen, g;

W_2 = weight of stripped specimen, g;

G = thickness of stripped specimen, mm (or in.); and

Z = a constant = 12.8 when G is in mm, or = 326 when G is in in.

8. REPORT

8.1. Mass [weight] of coating on aluminum-coated sheet is expressed in mass [weight] per unit area of sheet, and is either the sum of the masses [weights] of coating on both sides of the sheet, or single side mass [weight] on each of the two sides. Masses [weights] of coating on each side of the sheet are not necessarily equal, even when both sides are exposed to the molten metal simultaneously. Coating masses [weights] on all aluminum-coated articles other than sheets are expressed in mass [weight] per unit area of surface. The minimum or range of mass [weight] per unit area for each side of the sheet shall be determined by the purchaser and shall be directly stated in the purchase order.

8.2. Report the mass [weight] of aluminum coating to the nearest 1 g/m^2 when reporting in metric (SI) units.

8.3. Report the mass [weight] of aluminum coating to the nearest 0.01 oz/ft^2 when reporting in inch-pound units.

8.4. When the mass [weight] of coating of a number of specimens is to be averaged to determine conformance with a specification limit, the average value shall be reported to the precision of Sections 8.2 and 8.3 in accordance with the rounding method of E 29.

9. PRECISION AND BIAS[3]

9.1. *Precision*—The precision of this test method for sheet products has been determined in accordance with ASTM E 691.

9.1.1. The repeatability of the test method was found to be 9.5 g/m^2 [0.031 oz/ft^2] of sheet and the reproducibility was found to be 10.4 g/m^2 [0.034 oz/ft^2].

Note 11—These precision results are based on testing specimens having an area of 3280 mm^2 (5.08 $in.^2$) of sheet. Other test specimen sizes may yield different precision results.

9.1.2. The precision of this test method for products other than sheet steel has not been determined.

Note 12—Repeatability and reproducibility, based on test error alone, are defined as the difference, in absolute value, of two test results obtained in the same laboratory, or between laboratories on the same material (the difference will be expected to exceed the repeatability or reproducibility only about 5 percent of the time).

9.2. *Bias*—Since there is no accepted reference material suitable for determining bias for the procedures in this test method, no statement on bias is being made.

10. KEYWORDS

10.1. Aluminum coating; coating mass [weight]; steel sheets; steel wire.

---

[1] This test is identical to ASTM A 428/A 428 M-06 except for inch-pound units, rather than SI units, shown in brackets; the addition of Section 1.5; and the additional requirement at the end of Section 8.1.

Standard Method of Test for

Sampling Procedure for Impact Testing of Structural Steel

AASHTO Designation: T 243M/T 243-08[1]
ASTM Designation: A 673/A 673M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling Procedure for Impact Testing of Structural Steel

AASHTO Designation: T 243M/T 243-08[1]
ASTM Designation: A 673/A 673M-07

1. SCOPE

1.1. This specification establishes the procedure for longitudinal Charpy V-notch testing of structural steel and contains two frequencies of testing. The impact properties of steel can vary within the same heat and piece, be it as-rolled, control-rolled or heat-treated. The purchaser should, therefore, be aware that testing of one plate, bar, or shape does not provide assurance that all plates, bars, or shapes of the same heat as processed will be identical in toughness with the product tested. Normalizing or quenching and tempering the product will reduce the degree of variation.

1.2. This specification is intended to supplement specifications for structural steel when so specified.

1.3. This specification does not necessarily apply to all product specifications; therefore, the manufacturer or processor should be consulted for energy absorption levels and minimum testing temperatures that can be expected or supplied.

1.4. Two frequencies of testing (P and H) are prescribed.

1.5. The values stated in either SI units or inch-pound units are to be regarded as standard. Within the text, the English units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

3. ORDERING INFORMATION

3.1. The inquiry and order shall indicate the following:

3.1.1. The frequency of testing, (P) or (H);

3.1.2. The test temperature to be used (Sections 4.5 and 4.6);

3.1.3. Minimum average absorbed energy value (see Sections 4.1 and 4.6);

3.1.4. Transverse impact test orientation for plate widths greater than 24 in. [600 mm], if desired (see Section 4.2.2);

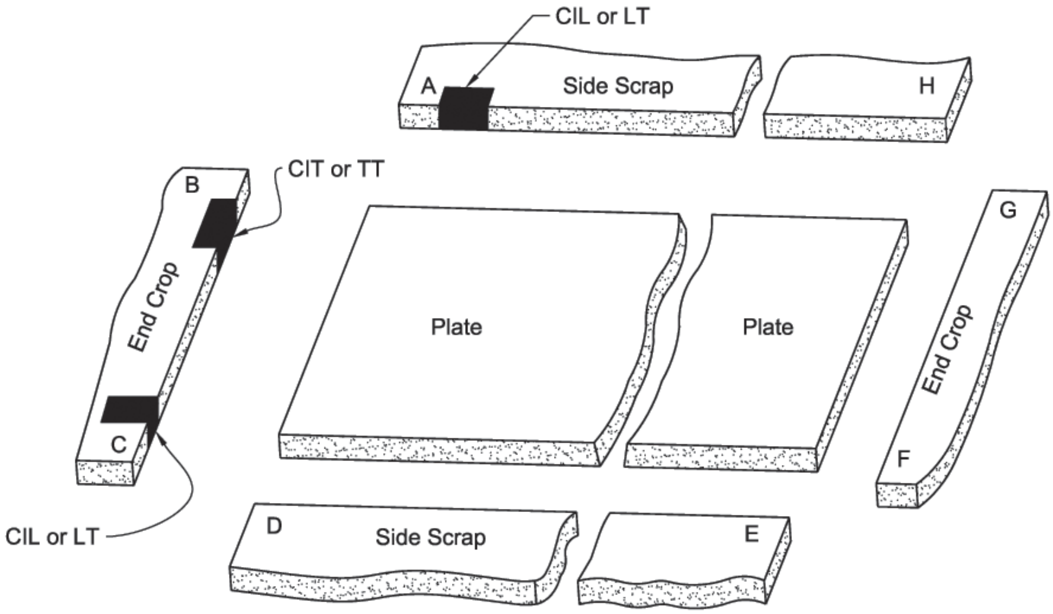
3.1.5. Alternate core location (see Section 4.3), if applicable; and

3.1.6. Condition (as-rolled, stress relieved normalized, normalized and stress relieved, or quenched and tempered).

4. TESTS

4.1. Impact testing shall be in accordance with Test Methods and Definitions in T 244. An impact test shall consist of testing three specimens taken from a single test coupon or test location, the average result of which is to be not less than the minimum average absorbed energy specified in the purchase order, which in no case shall be less than 10 J (7 ft-lbf) for full size specimens.

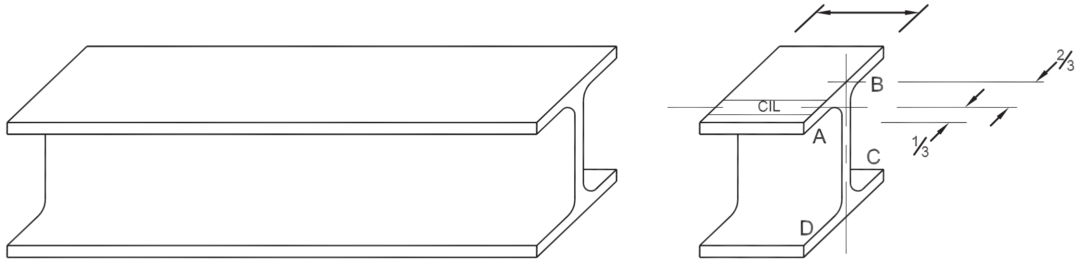
4.2. Except as allowed by Section 4.3, specimen for plates and bars shall be taken from a location adjacent to the location specified for the tension test specimen and the specimen for shapes shall be taken from a location at an end of a shape at a point one-third the distance from the outer edge of the flange or leg to the web or heel of the shape. (See Figures 1 and 2.) For plates produced from coils, three impact tests shall be taken from the product of each coil or qualifying coil (see Section 5). One test coupon shall be obtained from a location adjacent to the location specified for each of the two required tension tests (see M 160M/M 160), and a third test coupon shall be obtained immediately after the last plate produced to the qualifying specification.



Notes:

1. LT (Longitudinal tensile test). For widths through 600 mm [24 in.], may be taken at any location, A through H.
2. TT (Transverse tensile test). For widths more than 600 mm [24 in.], may be taken at locations B, C, F, or G.
3. CIL (Charpy impact longitudinal). May be taken at any location, A through H.
4. CIT (Charpy impact transverse). For widths more than 600 mm [24 in.], may be taken at location B, C, F, or G.

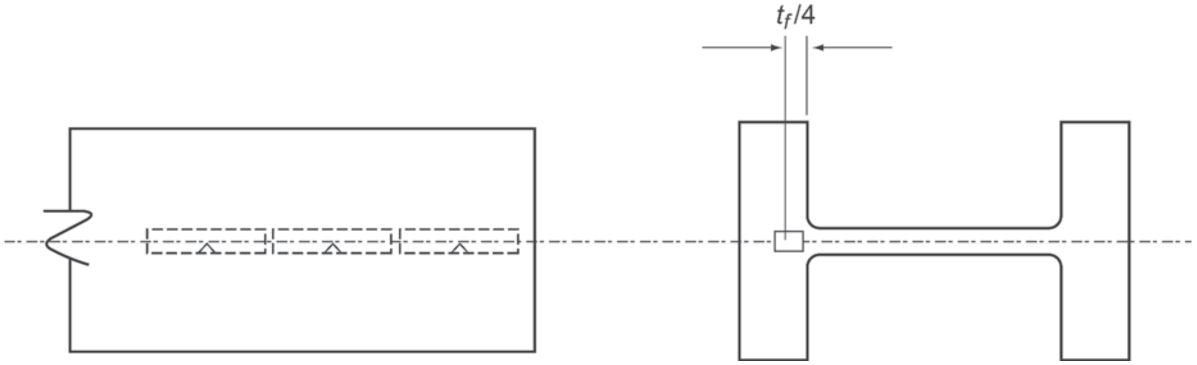
Figure 1—Plate Test Location



Notes:

1. CIL = Charpy impact longitudinal.
2. Test coupon for impact specimens may be taken from locations A, B, C, or D as shown laid out at location A.

Figure 2—Shape Test Location



Note—The notch for any of the specimens can be on either side of the beam centerline.

Figure 3—Alternate Core Location for Charpy V-Notch Specimens

4.2.1. Except as allowed by Section 4.2.2, the longitudinal axis of each specimen shall be parallel to the final direction of rolling of the plate or parallel to the major axis of the shape.

4.2.2. If specified in the purchase order, for plate widths greater than 600 mm [24 in.], the longitudinal axis of each specimen shall be transverse to the final direction of rolling of the plate.

4.2.3. The longitudinal axis of each specimen shall be located, as near as practicable, midway between the surface and the center of the product thickness and the length of the notch shall be perpendicular to the rolled surface of the material.

4.3. For shapes with a flange thickness equal to or greater than 38.1 mm ($1^1/_2$ in.), where alternate core location resting is specified in the purchase order, the longitudinal axis of each specimen shall be located midway between the inner flange surface and the center of the flange thickness at the intersection with the web mid-thickness. (See Figure 3.)

4.4. The absorbed energy values obtained for sub-size specimens shall not be less than the applicable values given in Table 1, which are proportional to the absorbed energy values required for full size specimens.

Table 1—Equivalent Absorbed Energy for Various Specimen Sizes

Full Size, 10 × 10 mm		$^3/_4$ Size, 10 × 7.5 mm		$^2/_3$ Size, 10 × 6.7 mm		$^1/_2$ Size, 10 × 5 mm		$^1/_3$ Size, 10 × 3.3 mm		$^1/_4$ Size, 10 × 2.5 mm	
J	[ft/lbf]	J	[ft/lbf]	J	[ft/lbf]	J	[ft/lbf]	J	[ft/lbf]	J	[ft/lbf]
54	[40]	41	[30]	37	[27]	27	[20]	18	[13]	14	[10]
48	[35]	35	[26]	31	[23]	24	[18]	16	[12]	12	[9]
41	[30]	30	[22]	27	[20]	20	[15]	14	[10]	11	[8]
34	[25]	26	[19]	23	[17]	16	[12]	11	[8]	8	[6]
27	[20]	20	[15]	18	[13]	14	[10]	10	[7]	7	[5]
22	[16]	16	[12]	15	[11]	11	[8]	7	[5]	5	[4]
20	[15]	15	[11]	14	[10]	11	[8]	7	[5]	5	[4]
18	[13]	14	[10]	12	[9]	8	[6]	5	[4]	4	[3]
16	[12]	12	[9]	11	[8]	8	[6]	5	[4]	4	[3]
14	[10]	11	[8]	10	[7]	7	[5]	4	[3]	3	[2]
10	[7]	7	[5]	7	[5]	5	[4]	3	[2]	3	[2]

4.5. Except as allowed by Section 4.6, the test temperature shall be as specified in the purchase order.

4.6. The manufacturer shall have the option of using a lower test temperature than is specified in the purchase order, provided that the absorbed energy values specified in the purchase order are met.

4.7. The actual test temperature used shall be reported with the test results.

5. FREQUENCY OF TESTING

5.1. *Frequency (H) Heat Testing for Plates, Shapes, and Bars*—One impact test (a set of three specimens) shall be made for each 45 Mg [50 tons] of the same type of product subject to the requirements of this specification produced on the same mill from the same heat of steel. The impact test(s) shall be taken from different as-rolled or heat-treated pieces. Impact specimens shall be selected from the thickest material rolled subject to the following modifications: When material rolled up to 50 mm [2 in.] inclusive in thickness differs 10 mm [$^3/_8$ in.] or more in thickness, one impact test shall be made from both the thickest and thinnest material rolled. When material rolled more than 50 mm [2 in.] in thickness differs by more than 25 mm [1 in.] in thickness, one impact test or more shall be made from both the thickest and thinnest material rolled that is more than 50 mm [2 in.] in thickness. If insufficient pieces of the thickest or thinnest material are produced to permit compliance with the above, then testing may proceed to the next nearest thickness available. When plates are produced from coils, three impact tests shall be taken from each qualifying coil. (See Section 4.2.) One such coil shall be tested for 45 Mg [50 tons] of the same product produced on the same mill from the same heat of steel. When material from one heat differs 2 mm [$^1/_{16}$ in.] or more in thickness, tests shall be made from both the thickest and thinnest material rolled regardless of the number of coils represented.

5.2. *Frequency (P) Piece Testing*:

5.2.1. *Plates*—One Charpy V-notch impact test (a set of three specimens) shall be made from each plate as-rolled except for material that has been heat treated by quenching and tempering, in which case specimens shall be selected from each heat-treated plate. When plates are produced from coils, three impact tests shall be taken from each coil.

5.2.2. *Shapes*—One Charpy V-notch impact test (a set of three specimens) shall be made from at least each 15 Mg [15 tons] or each single length of 15 Mg [15 tons] or more, of the same nominal shape size, excluding length, from each heat in the as-rolled condition. If the shapes are heat-treated, one test shall be taken from each heat of each furnace lot. For shapes heat-treated in a continuous furnace, a lot shall not exceed 15 Mg [15 tons].

5.2.3. *Bars*—One Charpy V-notch impact test (a set of three specimens) shall be made for each 5 Mg [5 tons] of the same heat and same diameter or thickness if the material is furnished as-rolled or is heat-treated in a continuous-type furnace. For material heat-treated in a noncontinuous furnace, one test shall be taken from each heat of the same bar diameter or thickness for each furnace charge.

6. HEAT TREATMENT

6.1. The material shall be heat-treated when specified on the purchase order.

6.2. When the plates are to be supplied in the as-rolled condition, the manufacturer or processor (M 160M/M 160) has the option to heat-treat the plates by normalizing, stress relieving, or normalizing and stress relieving to meet the desired toughness properties.

6.3. When the fabricator elects to perform the required heat-treatment or fabricates by hot forming instead of heat-treating, the plates shall be accepted on the basis of tests made on full thickness specimens heat-treated in accordance with the purchaser's order requirements. If the heat-treatment temperatures are not indicated on the purchase order, the manufacturer or processor shall heat-treat the specimens under conditions considered appropriate for grain refinement and to meet the toughness requirements. The plate manufacturer or processor shall inform the purchaser of the procedure followed in treating the specimens.

7. RETESTS

7.1. If more than one individual test value is below the specified minimum average value, or if one individual test value is below the greater of 7 J [5 ft·lbf] or two-thirds of the specified minimum average value, a retest of three additional specimens shall be made, each of which must have a test value equal to or exceeding the specified minimum average value.

7.2. If the required energy values are not obtained upon retest, the material may, at the option of the manufacturer or processor, be heat-treated in the case of as-rolled material or reheat treated in the case of heat-treated material.

7.3. After heat-treatment or reheat treatment, a set of three specimens shall be tested and qualified in the same manner as for the original material.

7.4. If the impact test fails for the thickest product tested when testing to frequency (H), that material shall be rejected and the next thickest material tested to qualify the heat in accordance with Section 4.1. At the option of the manufacturer or processor, retests may be made on the rejected material, in which case each piece shall be accepted or rejected on the basis of the results of its own test.

8. TEST REPORTS

8.1. Test reports for each heat supplied are required when specified by the purchase order.

8.1.1. Test reports shall show the results of each test required by the specification. However, for (H) frequency, only one test need be reported when the amount of materials from shipment is less than 45 Mg [50 tons], or two tests, when the amount of materials from a shipment is 45 Mg [50 tons] or more.

8.1.2. The thickness of the product tested may not necessarily be the same as an individual ordered thickness when (H) heat-testing is ordered. Tests from materials thicknesses in accordance with Section 5.1 and encompassing the thicknesses in a shipment shall be sufficient for qualifying the material in the shipment. These test thicknesses may or may not be within previously tested and shipped thicknesses from the same heat.

8.1.3. For plates produced from coils, all three test results shall be reported for each qualifying coil. If only half or less of a coil is utilized, then only one test from the outer lap and one from the innermost portion shipped need be reported.

8.1.4. For plates produced from coils, both the manufacturer and processor shall be identified on the test report.

8.1.5. A signature is not required on the test report. However, the document shall clearly identify the organization submitting the report. Notwithstanding the absence of a signature, the organization submitting the report is responsible for the content of the report.

8.1.6. When finished material is supplied to a purchase order specifying T 243M/T 243, the organization supplying that material shall provide the purchaser with a copy of the original manufacturer's test report.

9. KEYWORDS

9.1. Charpy V-notch; impact; sampling procedure; steel; structural steel; testing.

APPENDIX

(Nonmandatory Information)

X1. VARIATION IN CHARPY V-NOTCH TESTS

X1.1. A survey of the variation to be expected in Charpy V-notch test results obtained from three common fine grain plate steels was conducted by the American Iron and Steel Institute (AISI).[2] The results of the survey are contained in a Contributions to the Metallurgy of Steel entitled, “The Variations of Charpy V-notch Impact Test Properties in Steel Plates,” (SU/24), published January 1979. The survey data consist of test values obtained from six locations in addition to the locations shown in Figure 1 of this specification. The plate conditions tested involved as-rolled, normalized, and quench and tempered. Sufficient full sized specimens were taken from each sample so that three longitudinal and three transverse specimens could be broken at three test temperatures defined for each grade. The data are presented in tables of probability that impact properties at other than the official location, which may differ from those of the reported test location. Additional data of the same type, but utilizing samples from thicker plates, were published by AISI as SU/27.[3] Another survey sponsored by the AISI, entitled “Statistical Analysis of Structural Plate Mechanical Properties,” was published in January 2003.[4] That study analyzed the impact properties of more modern, higher strength as-rolled structural plate steels.

---

[1] This test method is identical to ASTM A 673/A 673M-07 except for inch-pound units, rather than SI units, shown in brackets.

Standard Method of Test for

Mechanical Testing of Steel Products

AASHTO Designation: T 244-10[1]
ASTM Designation: A 370-09a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Mechanical Testing of Steel Products

AASHTO Designation: T 244-10[1]
ASTM Designation: A 370-09a

1. SCOPE

1.1. These test methods cover procedures and definitions for the mechanical testing of steel, stainless steels, and related alloys. The various mechanical tests herein described are used to determine properties required in the product specifications. Variations in testing methods are to be avoided and standard methods of testing are to be followed to obtain reproducible and comparable results. In those cases in which the testing requirements for certain products are unique or at variance with these general procedures, the product specification testing requirements shall control.

1.2. The following mechanical tests are described:

	Sections
Tension	5 to 13
Bend	14
Hardness	15
Brinell	16
Rockwell	17
Portable	18
Impact	19 to 28
Keywords	29

1.3. Annexes covering details peculiar to certain products are appended to these test methods as follows:

Bar products	Annex A1
Tubular products	Annex A2
Fasteners	Annex A3
Round wire products	Annex A4
Significance of notched-bar impact testing	Annex A5
Converting percentage elongation of round specimens to equivalents for flat specimens	Annex A6
Testing multi-wire strand	Annex A7
Rounding of test data	Annex A8
Methods for testing steel reinforcing bars	Annex A9
Procedure for use and control of heat-cycle simulation	Annex A10

1.4. The values stated in SI (MPa) units are to be regarded as the standard.

1.5. When this document is referenced in a metric product specification, the yield and tensile values may be determined in inch-pound (ksi) units then converted into SI (MPa) units. The elongation determined in inch-pound gauge lengths of 2 or 8 in. may be reported in SI unit gauge lengths of 50 or 200 mm, respectively, as applicable. Conversely, when this document is referenced in an inch-pound product specification, the yield and tensile values may be determined in SI units, then converted into inch-pound units. The elongation determined in SI unit gauge lengths of 50 or 200 mm may be reported in inch-pound gauge lengths of 2 or 8 in., respectively, as applicable.

1.6. Attention is directed to R 18 when there may be a need for information on criteria for evaluation of testing laboratories.

1.7. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. GENERAL PRECAUTIONS

3.1. Certain methods of fabrication, such as bending, forming, and welding, or operations involving heating, may affect the properties of the material under test. Therefore, the product specifications cover the stage of manufacture at which mechanical testing is to be performed. The properties shown by testing prior to fabrication may not necessarily be representative of the product after it has been completely fabricated.

3.2. Improper machining or preparation of test specimens may give erroneous results. Care should be exercised to assure good workmanship in machining. Improperly machined specimens should be discarded and other specimens substituted.

3.3. Flaws in the specimen may also affect results. If any test specimen develops flaws, the retest provision of the applicable product specification shall govern.

3.4. If any test specimen fails because of mechanical reasons such as failure of testing equipment or improper specimen preparation, it may be discarded and another specimen taken.

4. ORIENTATION OF TEST SPECIMENS

4.1. The terms "longitudinal test" and "transverse test" are used only in material specifications for wrought products and are not applicable to castings. When such reference is made to a test coupon or test specimen, the following definitions apply:

4.1.1. *Longitudinal Test*, unless specifically defined otherwise, signifies that the lengthwise axis of the specimen is parallel to the direction of the greatest extension of the steel during rolling or forging. The stress applied to a longitudinal tension test specimen is in the direction of the greatest extension, and the axis of the fold of a longitudinal bend test specimen is at right angles to the direction of greatest extension (Figures 1, 2(a), and 2(b)).

4.1.2. *Transverse Test*, unless specifically defined otherwise, signifies that the lengthwise axis of the specimen is at right angles to the direction of the greatest extension of the steel during rolling or forging. The stress applied to a transverse tension test specimen is at right angles to the greatest extension, and the axis of the fold of a transverse bend test specimen is parallel to the greatest extension (Figure 1).

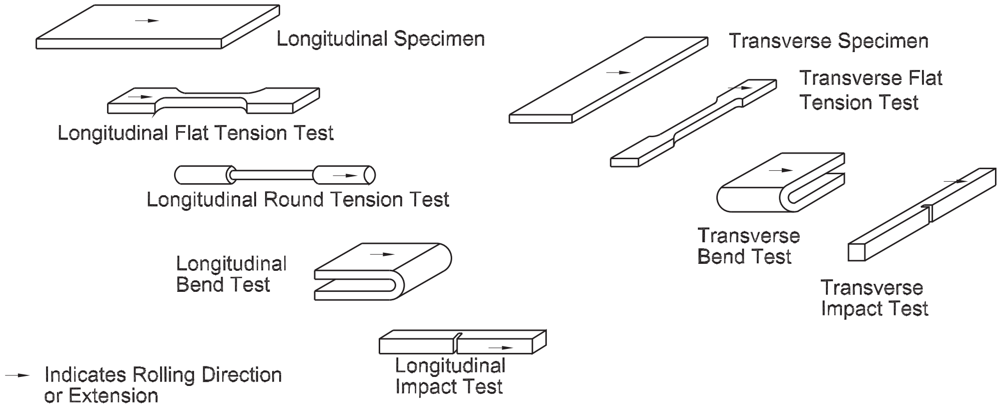

Figure 1—The Relation of Test Coupons and Test Specimens to Rolling Direction or Extension (Applicable to General Wrought Products)

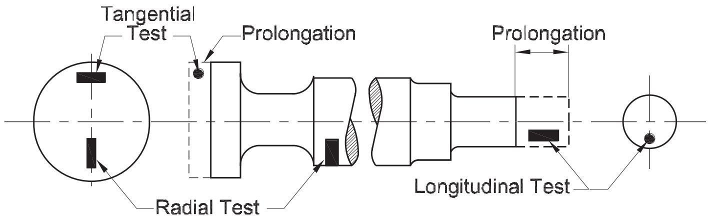
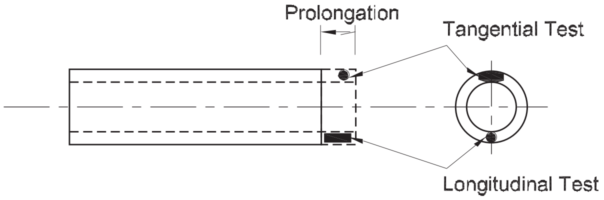
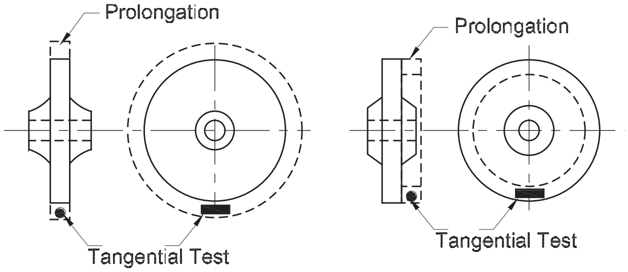


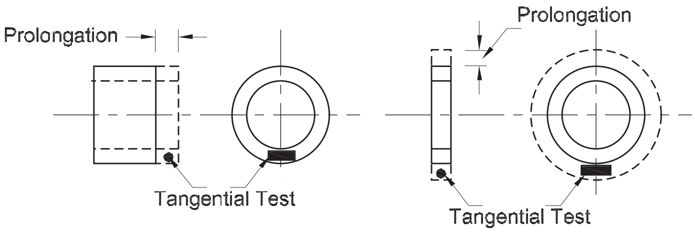
(a) Shafts and Rotors



(b) Hollows Forgings



(c) Disk Forgings



(d) Rings Forgings

Figure 2—Locations of Longitudinal Tension Test Specimens in Rings Cut from Tubular Products

4.2. The terms "radial test" and "tangential test" are used in material specifications for some wrought circular products and are not applicable to castings. When such reference is made to a test coupon or test specimen, the following definitions apply:

4.2.1. *Radial Test*, unless specifically defined otherwise, signifies that the lengthwise axis of the specimen is perpendicular to the axis of the product and coincident with one of the radii of a circle drawn with a point on the axis of the product as a center (Figure 2(a)).

4.2.2. *Tangential Test*, unless specifically defined otherwise, signifies that the lengthwise axis of the specimen is perpendicular to a plane containing the axis of the product and tangent to a circle drawn with a point on the axis of the product as a center (Figures 2(a), 2(b), 2(c), and 2(d)).

TENSION TEST

5. DESCRIPTION

5.1. The tension test related to the mechanical testing of steel products subjects a machined or full-section specimen of the material under examination to a measured load sufficient to cause rupture. The resulting properties sought are defined in ASTM E 6.

5.2. In general, the testing equipment and methods are given in T 68M. However, there are certain exceptions to T 68M practices in the testing of steel, and they are covered in these test methods.

6. TERMINOLOGY

6.1. For definitions of terms pertaining to tension testing, including tensile strength, yield point, yield strength, elongation, and reduction of area, reference should be made to ASTM E 6.

7. TESTING APPARATUS AND OPERATIONS

7.1. *Loading Systems*—There are two general types of loading systems, mechanical (screw power) and hydraulic. These differ chiefly in the variability of the rate of load application. The older screw power machines are limited to a small number of fixed free-running crosshead speeds. Some modern screw power machines and all hydraulic machines permit stepless variation throughout the range of speeds.

7.2. The tension testing machine shall be maintained in good operating condition, used only in the proper loading range, and calibrated periodically in accordance with the latest revision to T 67.

Note 1—Many machines are equipped with stress-strain recorders for autographic plotting of stress-strain curves. It should be noted that some recorders have a load measuring component entirely separate from the load indicator of the testing machine. Such recorders are calibrated separately.

7.3. *Loading*—It is the function of the gripping or holding device of the testing machine to transmit the load from the heads of the machine to the specimen under test. The essential requirement is that the load shall be transmitted axially. This implies that the centers of the action of the grips shall be in alignment, insofar as practicable, with the axis of the specimen at the beginning and during the test, and that bending or twisting be held to a minimum. For specimens with a reduced section, gripping of the specimen shall be restricted to the grip section. In the case of certain sections tested in full size, nonaxial loading is unavoidable and in such cases shall be permissible.

7.4. *Speed of Testing*—The speed of testing shall not be greater than that at which load and strain readings can be made accurately. In production testing, speed of testing is commonly expressed (1) in terms of free-running crosshead speed (rate of movement of the crosshead of the testing machine when not under load), or (2) in terms of rate of separation of the two heads of the testing machine under load, or (3) in terms of rate of stressing the specimen, or (4) in terms of rate of straining the specimen. The following limitations on the speed of testing are recommended as adequate for most steel products:

Note 2—Tension tests using closed-loop machines (with feedback control of rate) should not be performed using load control, as this mode of testing will result in acceleration of the crosshead upon yielding and elevation of the measured yield strength.

7.4.1. Any convenient speed of testing may be used up to one-half the specified yield point or yield strength. When this point is reached, the free-running rate of separation of the crossheads shall be adjusted so as not to exceed 0.063 millimeters per minute per millimeter ($^1/_{16}$ in. per minute per inch) of reduced section, or the distance between the grips for test specimens not having reduced sections. This speed shall be maintained through the yield point or yield strength. In determining the tensile strength, the free-running rate of separation of the heads shall not exceed 0.5 millimeters per minute per millimeter ($^1/_2$ in. per minute per inch) of reduced section, or the distance between the grips for test specimens not having reduced sections. In any event, the minimum speed of testing shall not be less than $^1/_{10}$ the specified maximum rates for determining yield point or yield strength and tensile strength.

7.4.2. It shall be permissible to set the speed of the testing machine by adjusting the free-running crosshead speed to the above specified values, inasmuch as the rate of separation of heads under load at these machine settings is less than the specified values of free-running crosshead speed.

7.4.3. As an alternative, if the machine is equipped with a device to indicate the rate of loading, the speed of the machine from half the specified yield point or yield strength through the yield point or yield strength may be adjusted so that the rate of stressing does not exceed 690 MPa (100000 psi)/min. However, the minimum rate of stressing shall not be less than 70 MPa (10000 psi)/min.

8. TEST SPECIMEN PARAMETERS

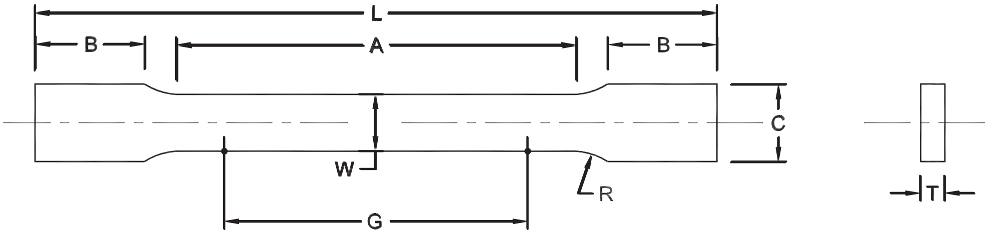
8.1. *Selection*—Test coupons shall be selected in accordance with the applicable product specifications.

8.1.1. *Wrought Steels*—Wrought steel products are usually tested in the longitudinal direction, but in some cases, where size permits and the service justifies it, testing is in the transverse, radial, or tangential direction. (See Figures 1 and 2.)

8.1.2. *Forged Steels*—For open die forgings, the metal for tension testing is usually provided by allowing extensions or prolongations on one or both ends of the forgings, either on all or a representative number as provided by the applicable product specifications. Test specimens are normally taken at mid-radius. Certain product specifications permit the use of a representative bar or the destruction of a production part for test purposes. For ring or disk-like forgings, test metal is provided by increasing the diameter, thickness, or length of the forging. Upset disk or ring forgings, which are worked or extended by forging in a direction perpendicular to the axis of the forging, usually have their principal extension along concentric circles and, for such forgings, tangential tension specimens are obtained from extra metal on the periphery or end of the forging. For some forgings, such as rotors, radial tension tests are required. In such cases, the specimens are cut or trepanned from specified locations.

8.2. *Size and Tolerances*—Test specimens shall be the full thickness or section of material as rolled, or may be machined to the form and dimensions shown in Figures 3 through 6, inclusive. The selection of size and type of specimen is prescribed by the applicable product specification. Full section specimens shall be tested in 200-mm (8-in.) gauge length unless otherwise specified in the product specification.

8.3. *Procurement of Test Specimens*—Specimens shall be sheared, blanked, sawed, trepanned, or oxygen-cut from portions of the material. They are usually machined so as to have a reduced cross section at mid-length in order to obtain uniform distribution of the stress over the cross section and to localize the zone of fracture. When test coupons are sheared, blanked, sawed, or oxygen-cut, care shall be taken to remove by machining all distorted, cold-worked, or heat-affected areas from the edges of the section used in evaluating the test.



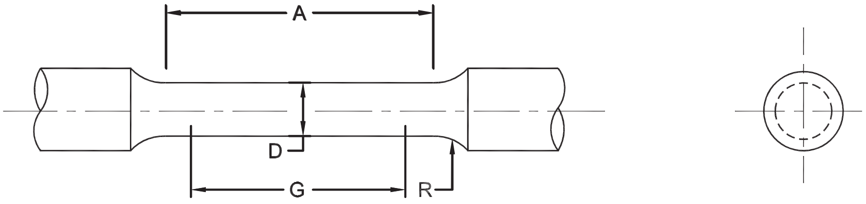
Dimensions

	Standard Specimens						Subsize Specimens	
	Plate-Type, 40-mm ($1^1/_2$ in.) Wide				Sheet Type, 12.5-mm ($^1/_2$ in.) Wide		6-mm ($^1/_4$-in.) Wide	
	200-mm (8-in.) Gauge Length		50-mm (2-in.) Gauge Length					
	mm	in.	mm	in.	mm	in.	mm	in.
G–Gauge length (Notes 1 and 2)	200 ± 0.25	8.00 ± 0.01	50.0 ± 0.10	2.000 ± 0.005	50.0 ± 0.10	2.000 ± 0.005	25.0 ± 0.08	1.000 ± 0.003
W–Width (Notes 3, 5, and 6)	40 + 3 – 6	$1^1/_2 + {}^1/_8 - {}^1/_4$	40 + 3 – 6	$1^1/_2 + {}^1/_8 - {}^1/_4$	12.5 ± 0.25	0.500 ± 0.010	6.25 ± 0.05	0.250 ±0.002
T–Thickness (Note 7)	Thickness of Material							
R–Radius of fillet, min (Note 4)	13	$^1/_2$	13	$^1/_2$	13	$^1/_2$	6	$^1/_4$
L–Overall length, min (Notes 2 and 8)	450	18	200	8	200	8	100	4
A–Length of reduced section, min	225	9	60	$2^1/_4$	60	$2^1/_4$	32	$1^1/_4$
B–Length of grip section, min (Note 9)	75	3	50	2	50	2	32	$1^1/_4$
C–Width of grip section, approximate (Notes 4, 10, and 11)	50	2	50	2	20	$^3/_4$	10	$^3/_8$

Notes:

1. For the 40-mm ($1^1/_2$-in.) wide specimen, punch marks for measuring elongation after fracture shall be made on the flat or on the edge of the specimen and within the reduced section. For the 200-mm (8-in.) gauge length specimen, a set of nine or more punch marks 25 mm (1 in.) apart, or one or more pairs of punch marks 200 mm (8 in.) apart may be used. For the 50-mm (2-in.) gauge length specimen, a set of three or more punch marks 25 mm (1 in.) apart, or one or more pairs of punch marks 50 mm (2 in.) apart may be used.
2. For the 12.5-mm ($^1/_2$-in.) wide specimen, punch marks for measuring the elongation after fracture shall be made on the flat face or edge of the specimen and within the reduced section. Either a set of three or more punch marks 25 mm (1 in.) apart or one or more pairs of punch marks 50 mm (2 in.) may be used.
3. For the four sizes of specimens, the ends of the reduced section shall not differ in width by more than 0.10, 0.10, 0.05, or 0.025 mm (0.004, 0.004, 0.002, or 0.001 in.), respectively. Also, there may be a gradual decrease in width from the ends to the center, but the width at either end shall not be more than 0.40, 0.40, 0.10, or 0.06 mm (0.015, 0.015, 0.005, 0.003 in.), respectively, larger than the width at the center.
4. For each specimen type, the radii of all fillets shall be equal to each other with a tolerance of 1.25 mm (0.05 in.), and the centers of curvature of the two fillets at a particular end shall be located across from each other (on a line perpendicular to the centerline) within a tolerance of 2.5 mm (0.10 in.).
5. For each of the four sizes of specimens, narrower widths (W or C) may be used when necessary. In such cases, the width of the reduced section should be as large as the width of the material being tested permits; however, unless stated specifically, the requirements for elongation in a product specification shall not apply when these narrower specimens are used. If the width of the material is less than W, the sides may be parallel throughout the length of the specimen.
6. The specimen may be modified by making the sides parallel throughout the length of the specimens, the width and tolerances being the same as those specified above. When necessary, a narrower specimen may be used, in which case the width should be as great as the width of the material being tested permits. If the width is 38 mm ($1^1/_2$ in.) or less, the sides may be parallel throughout the length of the specimen.
7. The dimension T is the thickness of the test specimen as provided for in the applicable product specifications. Minimum nominal thickness of 40-mm ($1^1/_2$-in.) wide specimens shall be 5 mm ($^3/_{16}$ in.), except as permitted by the product specification. Maximum nominal thickness of 12.5-mm ($^1/_2$-in.) and 6.25-mm ($^1/_4$-in.) wide specimens shall be 19 mm ($^3/_4$ in.) and 6 mm ($^1/_4$ in.), respectively.
8. To aid in obtaining axial loading during testing of 6.25-mm ($^1/_4$-in.) wide specimens, the overall length should be as the material will permit.
9. It is desirable, if possible, to make the length of the grip section large enough to allow the specimen to extend into the grips a distance equal to two-thirds or more of the length of the grips. If the thickness of 12.5-mm ($^1/_2$-in.) wide specimens is greater than 10 mm ($^3/_8$ in.), longer grips and correspondingly longer grip sections of the specimen may be necessary to prevent failure in the grip section.
10. For standard sheet type specimens and sub-size specimens, the ends of the specimen shall be symmetrical with the centerline of the reduced section within 0.25 and 0.13 mm (0.01 and 0.005 in.), respectively, except that, for steel, if the ends of the 12.5-mm ($^1/_2$-in.) wide specimen are symmetrical within 1.0 mm (0.05 in.), a specimen may be considered satisfactory for all but referee testing.
11. For standard plate-type specimens, the ends of the specimen shall be symmetrical with the centerline of the reduced section within 6.4 mm (0.25 in.) except for referee testing, in which case the ends of the specimen shall be symmetrical with the centerline of the reduced section within 2.5 mm (0.10 in.).

Figure 3—Rectangular Tension Test Specimens



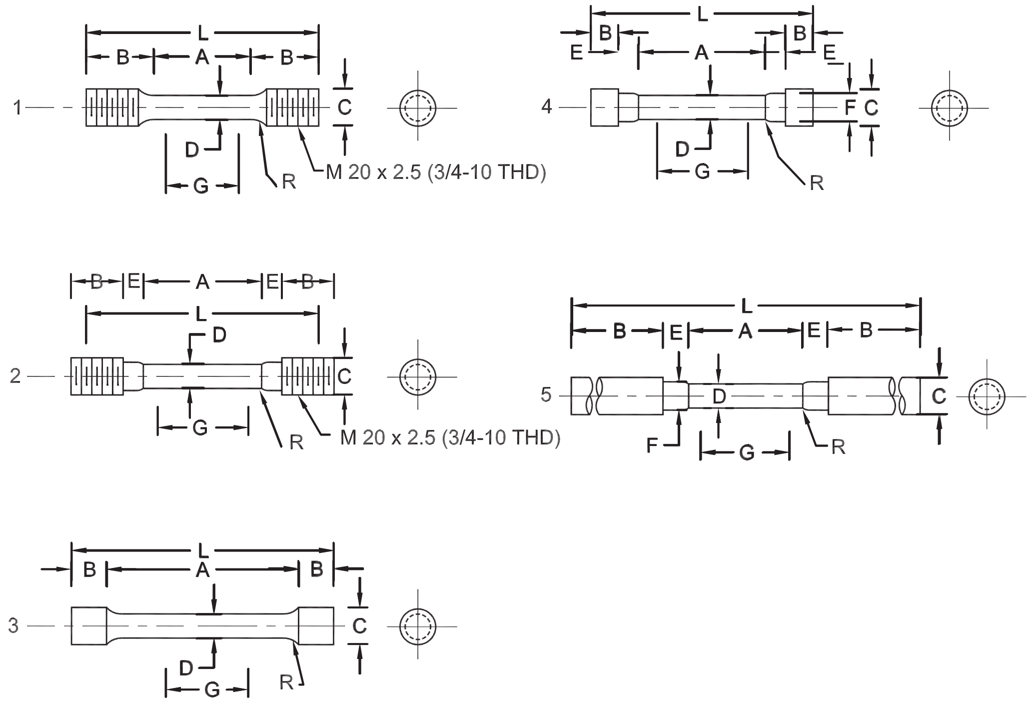
Dimensional Equivalents

	Standard Specimen		Small-Size Specimen Projectional to Standard							
	mm	in.	mm	in.	mm	in.	mm	in.	mm	in.
Nominal Diameter	12.50	0.500	8.75	0.350	6.25	0.250	4.00	0.160	2.50	0.113
G–Gauge length	50.00 ± 0.10	2.000 ± 0.005	35.00 ± 0.10	1.400 ± 0.005	25.00 ± 0.10	1.000 ± 0.005	16.00 ± 0.10	0.640 ± 0.005	10.00 ± 0.10	0.450 ± 0.005
D–Diameter (Note 1)	12.50 ± 0.25	0.500 ± 0.010	8.75 ± 0.18	0.350 ± 0.007	6.25 ± 0.12	0.250 ± 0.005	4.00 ± 0.08	0.160 ± 0.003	2.50 ± 0.05	0.113 ± 0.002
R–Radius of fillet, minimum	10	$^3/_8$	6	$^1/_4$	5	$^3/_{16}$	4	$^5/_{32}$	2	$^3/_{32}$
A–Length of reduced section, minimum (Note 2)	60	$2^1/_4$	45	$1^3/_4$	32	$1^1/_4$	20	$^3/_4$	16	$^5/_8$

Notes:

1. The reduced section may have a gradual taper from the ends toward the center, with the ends not more than 1 percent larger in diameter than the center (controlling dimension).
2. If desired, the length of the reduced section may be increased to accommodate an extensometer of any convenient gauge length. Reference marks for the measurement of elongation should, nevertheless, be spaced at the indicated gauge length.
3. The gauge length and fillets shall be as shown, but the ends may be of any form to fit the holders of the testing machine in such a way that the load shall be axial. (See Figure 9.) If the ends are to be held in wedge grips, it is desirable, if possible, to make the length of the grip section great enough to allow the specimen to extend into the grips a distance equal to two-thirds or more of the length of the grips.
4. On the round specimens in Figures 5 and 6, the gauge lengths are equal to four times the nominal diameter. In some product specifications, other specimens may be provided for, but unless the 4-to-1 ratio is maintained within dimensional tolerances, the elongation values may not be comparable with those obtained from the standard test specimen.
5. The use of specimens smaller than 6.25-mm (0.250-in.) diameter shall be restricted to cases in which the material to be tested is of sufficient size to obtain larger specimens or when all parties agree to their use for acceptance testing. Smaller specimens require suitable equipment and greater skill in both matching and testing.
6. Five sizes of specimens often used have diameters of approximately 0.505, 0.357, 0.252, 0.160, and 0.113 in., the reason being to permit easy calculations of stresses from loads, since the corresponding cross-sectional areas are equal to 0.200, 0.100, 0.0500, 0.0200, and 0.0100 in.^{2}, respectively. Thus, when the actual diameters agree with these values, the stresses (or strengths) may be computed using the simple multiplying factors 5, 10, 20, 50, and 100, respectively. (The metric equivalents of these fixed diameters do not result in correspondingly convenient cross-sectional area and multiplying factors.)

Figure 4—Standard 12.5-mm (0.500-in.) Round Tension Test Specimen with 50-mm (2-in.) Gauge Length and Examples of Small-Size Specimens Proportional to the Standard Specimen



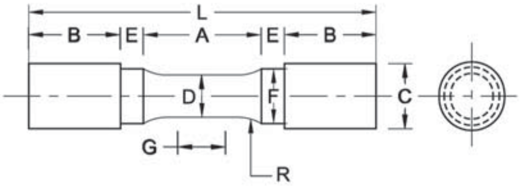
Dimensional Equivalents

	Specimen 1		Specimen 2		Specimen 3		Specimen 4		Specimen 5	
	mm	in.	mm	in.	mm	in.	mm	in.	mm	in.
G–Gauge length	50.00 ± 0.10	2.000 ± 0.005	50.00 ± 0.10	2.000 ± 0.005	50.00 ± 0.10	2.000 ± 0.005	50.00 ± 0.10	2.000 ± 0.005	50.00 ± 0.10	2.000 ± 0.005
D–Diameter (Note 1)	12.50 ± 0.25	0.500 ± 0.010	12.50 ± 0.25	0.500 ± 0.010	12.50 ± 0.25	0.500 ± 0.010	12.50 ± 0.25	0.500 ± 0.010	12.50 ± 0.25	0.500 ± 0.010
R–Radius of fillet, min	10	$^{3}/_{8}$	10	$^{3}/_{8}$	2	$^{1}/_{16}$	10	$^{3}/_{8}$	10	$^{3}/_{8}$
A–Length of reduced section	60, min	$2^{1}/_{4}$, min	60, min	$2^{1}/_{4}$, min	100, approximately	4, approximately	60, min	$2^{1}/_{4}$, min	60, min	$2^{1}/_{4}$, min
L–Overall length, approximate	125	5	140	$5^{1}/_{2}$	140	$5^{1}/_{2}$	120	$4^{3}/_{4}$	240	$9^{1}/_{2}$
B–Length grip section (Note 2)	35, approximately	$1^{3}/_{8}$, approximately	25, approximately	1, approximately	20, approximately	$^{3}/_{4}$, approximately	13, approximately	$^{1}/_{2}$, approximately	75, min	3, min
C–Diameter of end section	20	$^{3}/_{4}$	20	$^{3}/_{4}$	18	$^{23}/_{32}$	22	$^{7}/_{8}$	20	$^{3}/_{4}$
E–Length of shoulder and fillet section, approximate	—	—	16	$^{5}/_{8}$	—	—	20	$^{3}/_{4}$	16	$^{5}/_{8}$
F–Diameter of shoulder	—	—	16	$^{5}/_{8}$	—	—	16	$^{5}/_{8}$	15	$^{19}/_{32}$

Notes:

1. The reduced section may have a gradual taper from the ends towards the center, with the ends not more than 0.10 mm (0.005 in.) larger in diameter than the center.
2. On Specimen 5, it is desirable, if possible, to make the length of the grip section great enough to allow the specimen to extend into the grips a distance equal to two-thirds or more of the length of the grips.
3. The types of ends shown are applicable for the standard 0.500-in. round tension test specimen; similar types can be used for sub-size specimens. The use of UNF series of threads ($^{3}/_{4}$ by 16, $^{1}/_{2}$ by 20, $^{3}/_{8}$ by 24, and $^{1}/_{4}$ by 28) is suggested for high-strength brittle materials to avoid fracture in the thread portion.

Figure 5—Suggested Types of Ends for Standard Round Tension Test Specimen



Dimensional Equivalents

	Specimen 1		Specimen 2		Specimen 3	
	mm	in.	mm	in.	mm	in.

R–Radius of fillet, min	25	1	25	1	50	2
A–Length of reduced section, min	32	$1^{1}/_{4}$	38	$1^{1}/_{2}$	60	$2^{1}/_{4}$
L–Overall length, min	95	$3^{3}/_{4}$	100	4	160	$6^{3}/_{8}$
B–Length of grip section, approximate	25	1	25	1	45	$1^{3}/_{4}$
C–Diameter of end section, approximate	20	$^{3}/_{4}$	30	$1^{1}/_{8}$	48	$1^{7}/_{8}$
E–Length of shoulder, min	6	$^{1}/_{4}$	6	$^{1}/_{4}$	8	$^{5}/_{16}$
F–Diameter of shoulder	16.00 ± 0.40	$^{5}/_{8} \pm {}^{1}/_{64}$	24.00 ± 0.40	$^{15}/_{16} \pm {}^{1}/_{64}$	36.50 ± 0.40	$1^{7}/_{16} \pm {}^{1}/_{64}$

Note: The reduced section and shoulders (dimensions A, D, E, F, G, and R) shall be shown, but the ends may be of any form to fit the holders of the testing machine in such a way that the load shall be axial. Commonly, the ends are threaded and have the dimensions *B* and *C* given above.

Figure 6—Standard Tension Test Specimens for Cast Iron

8.4. *Aging of Test Specimens*—Unless otherwise specified, it shall be permissible to age tension test specimens. The time–temperature cycle employed must be such that the effects of previous processing will not be materially changed. It may be accomplished by aging at room temperature 24 to 48 hours, or in shorter time at moderately elevated temperatures by boiling in water, or heating in oil or in an oven.

8.5. *Measurement of Dimensions of Test Specimens*:

8.5.1. *Standard Rectangular Tension Test Specimens*—These forms of specimens are shown in Figure 3. To determine the cross-sectional area, the center width dimension shall be measured to the nearest 0.13 mm (0.005 in.) for the 200-mm (8-in.) gauge length specimen and 0.025 mm (0.001 in.) for the 50-mm (2-in.) gauge length specimen in Figure 3. The center thickness dimension shall be measured to the nearest 0.025 mm (0.001 in.) for both specimens.

8.5.2. *Standard Round Tension Test Specimens*—These forms of specimens are shown in Figures 4 and 5. To determine the cross-sectional area, the diameter shall be measured at the center of the gauge length to the nearest 0.025 mm (0.001 in.). (See Tables 1 and 2.)

8.6. *General*—Test specimens shall be either substantially full-sized or machined, as prescribed in the product specifications for the material being tested.

8.6.1. Improperly prepared test specimens often cause unsatisfactory test results. It is important, therefore, that care be exercised in the preparation of specimens, particularly in the machining, to assure good workmanship.

8.6.2. It is desirable to have the cross-sectional area of the specimen smallest at the center of the gauge length to ensure fracture within the gauge length. This is provided for by the taper in the gauge length permitted for each of the specimens described in the following sections.

8.6.3. For brittle materials, it is desirable to have fillets of a large radius at the ends of the gauge length.

Table 1—Multiplying Factors to Be Used for Various Diameters of Round Test Specimens

[a] The values in parentheses may be used for ease in calculation of stresses, in pounds per square inch, as permitted in Note 6 of Figure 4.

9. PLATE-TYPE SPECIMENS

9.1. The standard plate-type test specimens are shown in Figure 3. Such specimens are used for testing metallic materials in the form of plate, structural and bar-sized shapes, and flat material having a nominal thickness of 5 mm ($^3/_{16}$ in.) or more. When product specifications so permit, other types of specimens may be used.

Note 3—When called for in the product specification, the 200-mm (8-in.) gauge length specimen of Figure 3 may be used for sheet and strip material.

10. SHEET-TYPE SPECIMEN

10.1. The standard sheet-type test specimen is shown in Figure 3. This specimen is used for testing metallic materials in the form of sheet, plate, flat wire, strip, band, and hoop ranging in nominal thickness from 0.13 to 25 mm (0.005 to 1 in.). When product specifications so permit, other types of specimens may be used, as provided in Section 9. (See Note 3.)

11. ROUND SPECIMENS

11.1. The standard 12.5-mm (0.500-in.) diameter round test specimen shown in Figure 4 is used quite generally for testing metallic materials..

11.2. Figure 4 also shows small-sized specimens proportional to the standard specimen. These may be used when it is necessary to test material from which the standard specimen or specimens shown in Figure 3 cannot be prepared. Other sizes of small round specimens may be used. In any such small-sized specimen, it is important that the gauge length for measurement of elongation be four times the diameter of the specimen. (See Note 4 in Figure 4.)

11.3. The type of specimen ends outside of the gauge length shall accommodate the shape of the product tested, and shall properly fit the holders or grips of the testing machine so that axial loads are applied with a minimum of load eccentricity and slippage. Figure 5 shows specimens with various types of ends that have given satisfactory results.

12. GAUGE MARKS

12.1. The specimens shown in Figures 3 through 6 shall be gauge-marked with a center punch, scribe marks, multiple device, or drawn with ink. The purpose of these gauge marks is to determine the percent elongation. Punch marks shall be light, sharp, and accurately spaced. The localization of stress at the marks makes a hard specimen susceptible to starting fracture at the punch marks. The gauge marks for measuring elongation after fracture shall be made on the flat or on the edge of the flat tension test specimen and within the parallel section; for the 200-mm (8-in.) gauge length specimen, Figure 3; one or more sets of 200-mm (8-in.) gauge marks may be used, intermediate marks within the gauge length being optional. Rectangular 50-mm (2-in.) gauge length specimens, Figure 3, and round specimens, Figure 4, are gauge-marked with a double-pointed center punch or scribe marks. One or more sets of gauge marks may be used; however, one set must be approximately centered in the reduced section. These same precautions shall be so observed when the test specimen is full section.

13. DETERMINATION OF TENSILE PROPERTIES

13.1. *Yield Point*—Yield point is the first stress in a material, less than the maximum obtainable stress, at which an increase in strain occurs without an increase in stress. Yield point is intended for application only for materials that may exhibit the unique characteristic of showing an increase in strain without an increase in stress. The stress–strain diagram is characterized by a sharp knee or discontinuity. Determine yield point by one of the following methods:

13.1.1. *Drop of the Beam or Halt-of-the-Load Method*—In this method, apply an increasing load to the specimen at a uniform rate. When a lever and poise machine is used, keep the beam in balance by running out the poise at approximately a steady rate. When the yield point of the material is reached, the increase of the load will stop, but run the poise a trifle beyond the balance position, and the beam of the machine will drop for a brief but appreciable interval of time. When a machine equipped with a load-indicating dial is used, there is a halt or hesitation of the load-indicating pointer corresponding to the drop of the beam. Note the load at the "drop of the beam" or the "halt of the pointer" and record the corresponding stress as the yield point.

13.1.2. *Autographic Diagram Method*—When a sharp-kneed stress–strain diagram is obtained by an autographic recording device, take the stress corresponding to the top of the knee (Figure 7), or the stress at which the curve drops as the yield point.

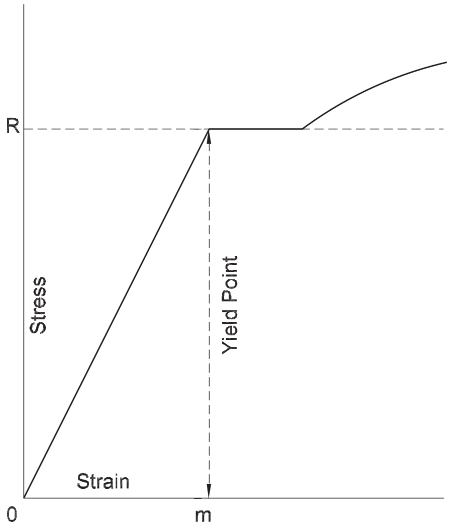

Figure 7—Stress–Strain Diagram Showing Yield Point Corresponding with Top of Knee

13.1.3. *Total Extension-Under-Load Method*—When testing material for yield point and the test specimens may not exhibit a well-defined disproportionate deformation that characterizes a yield point as measured by the drop of the beam, halt-of-the-load, or autographic diagram methods described in Sections 13.1.1 and 13.1.2, a value equivalent to the yield point in its practical significance may be determined by the following method and may be recorded as yield point: Attach a Class C or better extensometer (Notes 4 and 5) to the specimen. When the load producing a specified extension (Note 6) is reached, record the stress corresponding to the load as the yield point (Figure 8).

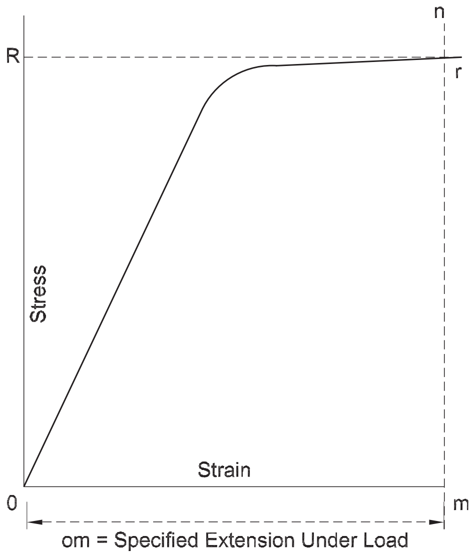

Figure 8—Stress–Strain Diagram Showing Yield Point or Yield Strength by Extension-Under-Load Method

Note 4—Automatic devices are available that determine the load at the specified total extension without plotting a stress–strain curve. Such devices may be used if their accuracy has been demonstrated. Multiplying calipers and other such devices are acceptable for use provided their accuracy has been demonstrated to be equivalent to a Class C extensometer.

Note 5—Reference should be made to ASTM E 83.

Note 6—For steel with a yield point specified not over 550 MPa (80000 psi), an appropriate value is 0.12 mm/mm (0.005 in./in.) of gauge length. For values above 550 MPa (80000 psi), this method is not valid unless the limiting total extension is increased.

Note 7—The shape of the initial portion of an autographically determined stress–strain (or a load-elongation) curve may be influenced by numerous factors, such as the seating of the specimen in the grips, the straightening of a specimen bent due to residual stresses, and the rapid loading permitted in Section 7.4.1. Generally, the aberrations in this portion of the curve should be ignored when fitting a modulus line, such as that used to determine the extension-under-load yield, to the curve.

13.2. *Yield Strength*—Yield strength is the stress at which a material exhibits a specified limiting deviation from the proportionality of stress to strain. The deviation is expressed in terms of strain, percent offset, total extension under load, etc. Determine yield strength by one of the following methods:

13.2.1. *Offset Method*—To determine the yield strength by the "offset method," it is necessary to secure data (autographic or numerical) from which a stress–strain diagram with a distinct modulus characteristic of the material being tested may be drawn. Then, on the stress–strain diagram (Figure 9), lay off *Om* equal to the specified value of the offset, draw *mn* parallel to *OA*, and thus locate *r*, the intersection of *mn* with the stress–strain curve corresponding to load *R,* which is the yield strength load. In recording values of yield strength obtained by this method, the value of offset specified or used, or both, shall be stated in parentheses after the term "yield strength"; for example:

Yield strength (0.2% offset) = 360 MPa (52000 psi) *(1)*

When the offset is 0.2 percent or larger, the extensometer used shall qualify as a Class B2 device over a strain range of 0.05 to 1.0 percent. If a smaller offset is specified, it may be necessary to specify a more accurate device (that is, a Class B1 device) or reduce the lower limit of the strain range (for example, to 0.01 percent) or both. See also Note 9 for automatic devices.

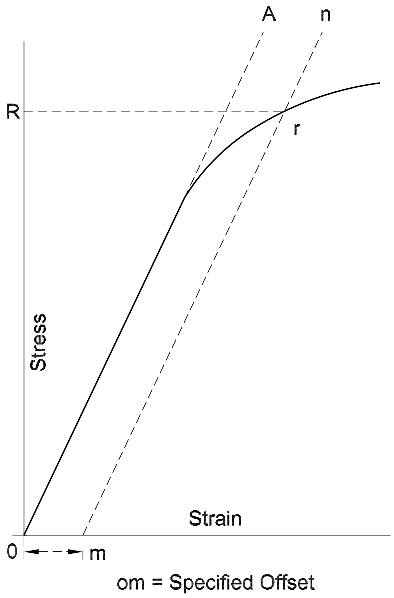

Figure 9—Stress–Strain Diagram for Determination of Yield Strength by the Offset Method

Note 8—For stress–strain diagrams not containing a distinct modulus, such as for some cold-worked materials, it is recommended that the extension-under-load method be utilized. If the offset method is used for materials without a distinct modulus, a modulus value appropriate for the material being tested should be used: 207000 MPa (30000000 psi) for carbon steel; 200000 MPa (29000000 psi) for ferritic stainless steel; 193 000 MPa (28000000 psi) for austenitic stainless steel. For special alloys, the producer should be contacted to discuss appropriate modulus values.

13.2.2. *Extension-Under-Load Method*—For tests to determine the acceptance or rejection of material for which stress–strain characteristics are well known from previous tests of similar material in which stress–strain diagrams were plotted, the total strain corresponding to the stress at which the specified offset (Notes 9 and 10) occurs will be known within satisfactory limits. The stress on the specimen, when this total strain is reached, is the value of the yield strength. In recording values of yield strength obtained by this method, the value of “extension” specified or used, or both, shall be stated in parentheses after the term "yield strength"; for example:

$$\text{Yield strength (0.5\% EUL)} = 360\text{ MPa (52000 psi)} \qquad (2)$$

The total strain can be obtained satisfactorily by use of a Class B1 extensometer (Notes 4, 5, and 7).

Note 9—Automatic devices are available that determine offset yield strength without plotting a stress–strain curve. Such devices may be used if their accuracy has been demonstrated.

Note 10—The appropriate magnitude of the extension under load obviously will vary with the strength range of the particular steel under test. In general, the value of extension under load applicable to steel at any strength level may be determined from the sum of the proportional strain and the plastic strain expected at the specified yield strength. The following equation is used:

$$\text{Extension under load mm/mm (in./in.) of gauge length} = (YS/E) + r \qquad (3)$$

where:

YS = specified yield strength, MPa (psi);

E = modulus of elasticity, MPa (psi); and

r = limiting plastic strain, mm/mm (in./in.).

13.3. *Tensile Strength*—Calculate the tensile strength by dividing the maximum load the specimen sustains during a tension test by the original cross-sectional area of the specimen.

13.4. *Elongation*:

13.4.1. Fit the ends of the fractured specimen together carefully and measure the distance between the gauge marks to the nearest 0.25 mm (0.01 in.) for gauge lengths of 50 mm (2 in.) and less, and to the nearest 0.5 percent of the gauge length for gauge lengths greater than 50 mm (2 in.). A percentage scale reading to 0.5 percent of the gauge length may be used. The elongation is the increase in length of the gauge length, expressed as a percentage of the original gauge length. In recording elongation values, give both the percentage increase and the original gauge length.

13.4.2. If any part of the fracture takes place outside of the middle half of the gauge length or in a punched or scribed mark within the reduced section, the elongation value obtained may not be representative of the material. If the elongation so measured meets the minimum requirements specified, no further testing is indicated, but if the elongation is less than the minimum requirements, discard the test and retest.

13.4.3. Automated tensile testing methods using extensometers allow for the measurement of elongation in a method described below. Elongation may be measured and reported either this way, or as in the method described above, fitting the broken ends together. Either result is valid.

13.4.4. Elongation at fracture is defined as the elongation measured just prior to the sudden decrease in force associated with fracture. For many ductile materials not exhibiting a sudden decrease in force, the elongation at fracture can be taken as the strain measured just prior to when the force falls below 10 percent of the maximum force encountered during the test.

13.4.4.1. Elongation at fracture shall include elastic and plastic elongation and may be determined with autographic or automated methods using extensometers verified over the strain range of interest. Use a Class B2 or better extensometer for materials having less than 5 percent elongation; a Class C or better extensometer for materials having an elongation greater than or equal to 5 percent but less than 50 percent; and a Class D or better extensometer for materials having 50 percent or greater elongation. In all cases, the extensometer gauge length shall be the nominal gauge length required for the specimen being tested. Due to the lack of precision in fitting fractured ends together, the elongation after fracture using the manual methods of the preceding paragraphs may differ from the elongation at fracture determined with extensometers.

13.4.4.2. Percent elongation at fracture may be calculated directly from elongation at fracture data and be reported instead of percent elongation as calculated in Section 13.4.1. However, these two parameters are not interchangeable. Use of the elongation at fracture method generally provides more repeatable results.

13.5. *Reduction of Area*—Fit the ends of the fractured specimen together and measure the mean diameter or the width and thickness at the smallest cross section to the same accuracy as the original dimensions. The difference between the area thus found and the area of the original cross section expressed as a percentage of the original area is the reduction of area.

BEND TEST

14. DESCRIPTION

14.1. The bend test is one method for evaluating ductility, but it cannot be considered as a quantitative means of predicting service performance in bending operations. The severity of the bend test is primarily a function of the angle of bend and the inside diameter to which the specimen is bent, and of the cross section of the specimen. These conditions are varied according to location and orientation of the test specimen and the chemical composition, tensile properties, hardness, type, and quality of the steel specified. ASTM E 190 and ASTM E 290 may be consulted for methods of performing the test.

14.2. Unless otherwise specified, it shall be permissible to age bend-test specimens. The time–temperature cycle employed must be such that the effects of previous processing will not be materially changed. It may be accomplished by aging at room temperature 24 to 48 hours, or in shorter time at moderately elevated temperatures by boiling in water, or heating in oil or an oven.

14.3. Bend the test specimen at room temperature to an inside diameter, as designated by the applicable product specification, to the extent specified without major cracking on the outside of the bent portion. The speed of bending ordinarily is not an important factor.

HARDNESS TEST

15. GENERAL

15.1. A hardness test is a means of determining resistance to penetration and is occasionally employed to obtain a quick approximation of tensile strength. Tables 2, 3, 4, and 5 are for the conversion of hardness measurements from one scale to another or to approximate tensile strength. These conversion values have been obtained from computer-generated curves and are presented to the nearest 0.1 point to permit accurate reproduction of those curves. Since all converted hardness values must be considered approximate, however, all converted Rockwell hardness numbers shall be rounded to the nearest whole number.

15.2. *Hardness Testing*:

15.2.1. If the product specification permits alternative hardness testing to determine conformance to a specified hardness requirement, the conversions listed in Tables 2, 3, 4, and 5 shall be used.

15.2.2. When recording converted hardness numbers, the measured hardness and test scale shall be indicated in parentheses; for example: 353 HBW (38 HRC). This means that a hardness value of 38 was obtained using the Rockwell C scale and converted to a Brinell hardness of 353.

[a] This table gives the approximate interrelationships of hardness values and approximate tensile strength of steels. It is possible that steels of various compositions and processing histories will deviate in hardness–tensile strength relationship from the data presented in this table. The data in this table should not be used for austenitic stainless steels, but have been shown to be applicable for ferritic and martensitic stainless steels. Where more precise conversions are required, they should be developed specially for each steel composition, heat-treatment, and part. Caution should be exercised if conversions from this table are used for the acceptance or rejection of product. The approximate interrelationships may affect acceptance or rejection.

Table 4—Approximate Hardness Conversion Numbers for Nonaustenitic Steels[a] (Rockwell B to Other Hardness Numbers)

[a] This table gives the approximate interrelationships of hardness values and approximate tensile strength of steels. It is possible that steels of various compositions and processing histories will deviate in hardness–tensile strength relationship from the data presented in this table. The data in this table should not be used for austenitic stainless steels, but have been shown to be applicable for ferritic and martensitic stainless steels. Where more precise conversions are required, they should be developed specially for each steel composition, heat-treatment, and part.

Table 5—Approximate Hardness Conversion Numbers for Austenitic Steels (Rockwell C to Other Hardness Numbers)

16. BRINELL TEST

16.1. *Description*:

16.1.1. A specified load is applied to a flat surface of the specimen to be tested, through a hard ball of specified diameter. The average diameter of the indentation is used as a basis for calculation of the Brinell hardness number. The quotient of the applied load divided by the area of the surface of the indentation, which is assumed to be spherical, is termed the Brinell hardness number (HBW) in accordance with the following equation:

For applied loads in newtons of force:

$$HBW = \frac{2P}{\pi D\left(D - \sqrt{D^2 - d^2}\right)} \tag{4}$$

where:

HBW = Brinnell hardness number;

P = applied load, N;

D = diameter of the ball, mm; and

d = average diameter of the indentation, mm.

For applied loads in kilogram-force units:

$$HBW = \frac{2P}{\pi D\left(D - \sqrt{D^2 - d^2}\right)} \qquad (5)$$

where:

HBW = Brinnell hardness number;

P = applied load, kgf;

D = diameter of the ball, mm; and

d = average diameter of the indentation, mm.

Note 11—The Brinell hardness is more conveniently secured from standard tables such as Table 6, which show numbers corresponding to the various indentation diameters, usually in increments of 0.05 mm.

Note 12—In Test Method ASTM E 10; the values are in SI units, whereas in this section kg/m units are used.

16.1.2. The standard Brinell test using a 10-mm tungsten carbide ball employs a 29.42-kN (3000 kgf) load for hard materials and a 14.71 or 4.903-kN (1500 or 500 kgf) load for thin sections or soft materials. (See Annex A2 on Steel Tubular Products.) Other loads and different size indentors may be used when specified. In recording hardness values, the diameter of the ball and the load must be stated when a 10-mm ball and 29.42-kN (3000 kgf) load are used.

16.1.3. A range of hardness can properly be specified only for quenched and tempered or normalized and tempered material. For annealed material, a maximum figure only should be specified. For normalized material, a minimum or a maximum hardness may be specified by agreement. In general, no hardness requirements should be applied to untreated material.

16.1.4. Brinell hardness may be required when tensile properties are not specified.

16.2. *Apparatus*—Equipment shall meet the following requirements.

16.2.1. *Testing Machine*—A Brinell hardness testing machine is acceptable for use over a loading range within which its load measuring device is accurate to ±1 percent.

16.2.2. *Measuring Microscope*—The divisions of the micrometer scale of the microscope or other measuring devices used for the measurement of the diameter of the indentations shall be such as to permit the direct measurement of the diameter to 0.1 mm and the estimation of the diameter to 0.05 mm.

Note 13—This requirement applies to the construction of the microscope only and is not a requirement for measurement of the indentation. See Section 16.4.3.

16.2.3. *Standard Ball*—The standard tungsten carbide ball for Brinell hardness testing is 10 mm (0.3937 in.) in diameter with a deviation from this value of not more than 0.005 mm (0.0002 in.) in any diameter. A tungsten carbide ball suitable for use must not show a permanent change in diameter greater than 0.01 mm (0.0004 in.) when pressed with a force of 29.42-kN (3000 kgf) against the test specimen. Steel ball indentors are no longer permitted for use in Brinell hardness testing in accordance with these test methods.

16.3. *Test Specimen*—Brinell hardness tests are made on prepared areas and sufficient metal must be removed from the surface to eliminate decarburized metal and other surface irregularities. The thickness of the piece tested must be such that no bulge or other marking showing the effect of the load appears on the side of the piece opposite the indentation.

16.4. *Procedure*:

16.4.1. It is essential that the applicable product specification state clearly the position at which Brinell hardness indentations are to be made and the number of such indentations required. The distance of the center of the indentation from the edge of the specimen or edge of another indentation must be at least $2^1/_2$ times the diameter of the indentation.

16.4.2. Apply the load for 10 to 15 seconds.

16.4.3. Measure two diameters of the indentation at right angles to the nearest 0.1 mm, estimate to nearest 0.05 mm and average to nearest 0.05 mm. If the two diameters differ by more than 0.1 mm, discard the readings and make a new indentation.

16.4.4. Do not use a steel ball on steels having a hardness greater than 450 HBW nor a carbide ball on steels having a hardness more than 650 HBW. The Brinell hardness test is not recommended for materials having a hardness greater than 650 HBW.

16.4.4.1. If a ball is used in a test of a specimen that shows a Brinell hardness number greater than the limit for the ball as detailed in Section 16.4.4, the ball shall be either discarded and replaced with a new ball or remeasured to ensure conformance with the requirements of ASTM E 10.

16.5. *Detailed Procedure*—For detailed requirements of this test, reference shall be made to the latest revision of ASTM E 10.

17. ROCKWELL TEST

17.1. *Description*:

17.1.1. In this test, a hardness value is obtained by determining the depth of penetration of a diamond point or a steel ball into the specimen under certain arbitrarily fixed conditions. A minor load of 98 N (10 kgf) is first applied, which causes an initial penetration, sets the penetrator on the material, and holds it in position. A major load that depends on the scale being used is applied, increasing the depth of indentation. The major load is removed and, with the minor load still acting, the Rockwell number, which is proportional to the difference in penetration between the major and minor loads, is determined; this is usually done by the machine and shows on a dial, digital display, printer, or other device. This is an arbitrary number that increases with increasing hardness. The scales most frequently used appear in Table 7.

Table 7—Scales I

Scales I			
Scale Symbol	Penetrator	Major Load, N (kgf)	Minor Load, N (kgf)
B	1.588-mm ($^1/_{16}$-in.) steel ball	981 (100)	98 (10)
C	Diamond brale	1471 (150)	98 (10)

17.1.2. Rockwell superficial hardness machines are used for testing very thin steel or thin surface layers. Loads of 147, 294, or 441 N (15, 30, or 45 kgf) are applied on a hardened steel ball or diamond penetrator to cover the same range of hardness values as for the heavier loads. The superficial hardness scales appear in Table 8.

Table 8—Scales II

Scales II			
Scale Symbol	Penetrator	Major Load, N (kgf)	Minor Load, N (kgf)
15T	1.588-mm ($^1/_{16}$-in.) steel ball	147 (15)	29 (3)
30T	1.588-mm ($^1/_{16}$-in.) steel ball	294 (30)	29 (3)
45T	1.588-mm ($^1/_{16}$-in.) steel ball	441 (45)	29 (3)
15N	Diamond brale	147 (15)	29 (3)
30N	Diamond brale	294 (30)	29 (3)
45N	Diamond brale	441 (45)	29 (3)

17.2. *Reporting Hardness*—In recording hardness values, the hardness number should always precede the scale symbol, for example 96 HRB, 40 HRC, 75 HR15N, or 77 HR 30T.

17.3. *Test Blocks*—Machines should be checked to make certain they are in good order by means of standardized Rockwell test blocks.

17.4. *Detailed Procedure*—For detailed requirements of this test, reference shall be made to the latest revision of T 80.

18. PORTABLE HARDNESS TEST

18.1. Although the use of the standard, stationary Brinell or Rockwell hardness tester is generally preferred, it is not always possible to perform the hardness test using such equipment due to the part size or location. In this event, hardness testing using portable equipment as described in ASTM A 833 or ASTM E 110 shall be used.

CHARPY IMPACT TESTING

19. SUMMARY

19.1. A Charpy V-notch impact test is a dynamic test in which a notched specimen is struck and broken by a single blow in a specially designed testing machine. The measured test values may be the energy absorbed, the percentage shear fracture, the lateral expansion opposite the notch, or a combination thereof.

19.2. Testing temperatures other than room (ambient) temperature often are specified in product or general requirement specifications (hereinafter referred to as the specification). Although the testing temperature is sometimes related to the expected service temperature, the two temperatures need not be identical.

20. SIGNIFICANCE AND USE

20.1. *Ductile vs. Brittle Behavior*—Body-centered-cubic or ferritic alloys exhibit a significant transition in behavior when impact tested over a range of temperatures. At temperatures above transition, impact specimens fracture by a ductile (usually microvoid coalescence) mechanism, absorbing relatively large amounts of energy. At lower temperatures, they fracture in a brittle (usually cleavage) manner, absorbing less energy. Within the transition range, the fracture generally will be a mixture of areas of ductile fracture and brittle fracture.

20.2. The temperature range of the transition from one type of behavior to the other varies according to the material being tested. This transition behavior may be defined in various ways for specification purposes.

20.2.1. The specification may require a minimum test result for absorbed energy, fracture appearance, lateral expansion, or a combination thereof, at a specified test temperature.

20.2.2. The specification may require the determination of the transition temperature at which either the absorbed energy or fracture appearance attains a specified level when testing is performed over a range of temperatures. Alternatively, the specification may require the determination of the fracture appearance transition temperature (FATTn) as the temperature at which the required minimum percentage of shear fracture (n) is obtained.

20.3. Further information on the significance of impact testing appears in Annex A5.

21. APPARATUS

21.1. *Testing Machines*:

21.1.1. A Charpy impact machine is one in which a notched specimen is broken by a single blow of a freely swinging pendulum. The pendulum is released from a fixed height. Since the height to which the pendulum is raised prior to its swing and the mass of the pendulum are known, the energy of the blow is predetermined. A means is provided to indicate the energy absorbed in breaking the specimen.

21.1.2. The other principal feature of the machine is a fixture (see Figure 10) designed to support a test specimen as a simple beam at a precise location. The fixture is arranged so that the notched face of the specimen is vertical. The pendulum strikes the other vertical face directly opposite the notch. The dimensions of the specimen supports and striking edge shall conform to Figure 10.

21.1.3. Charpy machines used for testing steel generally have capacities in the 300 to 400 J (220 to 300 ft-lbf) energy range. Sometimes machines of lesser capacity are used; however, the capacity of the machine should be substantially in excess of the absorbed energy of the specimens. (See T 266.) The linear velocity at the point of impact should be in the range of 4.9 to 5.8 m/s (16 to 19 ft/s)

Note 14—An investigation of striker radius effect is available as Research Report A01-1001 from ASTM International Headquarters.

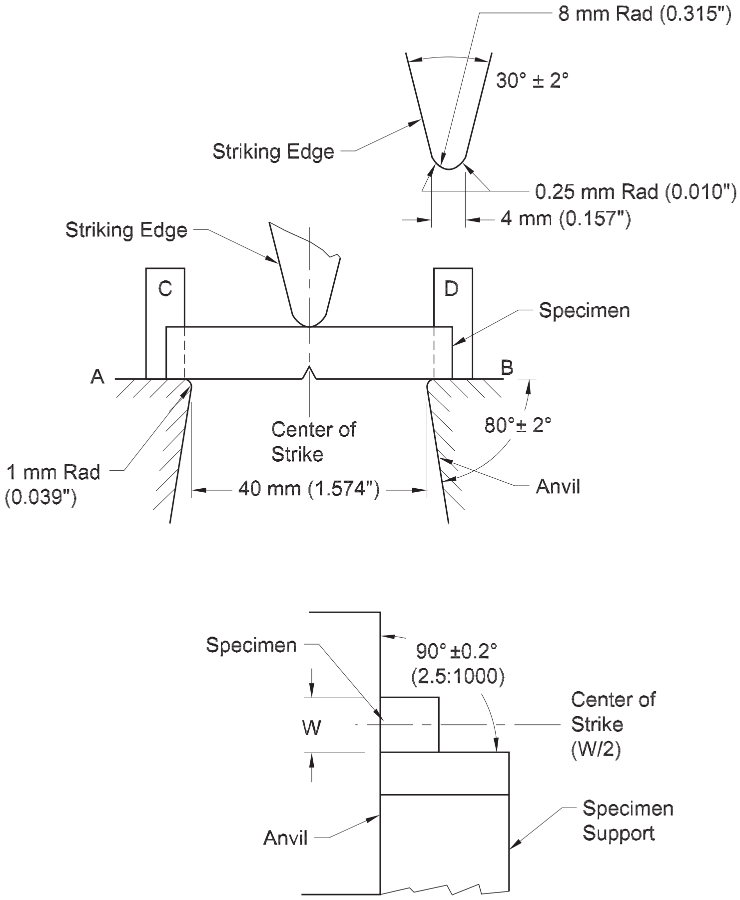
21.2. *Temperature Media*:

21.2.1. For testing at other than room temperature, it is necessary to condition the Charpy specimens in media at controlled temperatures.

21.2.2. Low temperature media usually are chilled fluids (such as water, ice plus water, dry ice plus organic solvents, or liquid nitrogen) or chilled gases.

21.2.3. Elevated temperature media are usually heated liquids, such as mineral or silicone oils. Circulating air ovens may be used.

21.3. *Handling Equipment*—Tongs, especially adapted to fit the notch in the impact specimen, normally are used for removing the specimens from the medium and placing them on the anvil (refer to T 266). In cases in which the machine fixture does not provide for automatic centering of the test specimen, the tongs may be precision machined to provide centering.



Notes:

1. All dimensional tolerances shall be ±0.05 mm (0.002 in.) unless otherwise specified.
2. *A* shall be parallel to *B* within 2:1000 and coplanar with *B* within 0.05 mm (0.002 in.).
3. *C* shall be parallel to *D* within 20:1000 and coplanar with *D* within 0.125 mm (0.005 in.).
4. Finish on unmarked parts shall be 4 µm (125 µ in.).

Note: Ball 10 mm in diameter, applied loads of 4.903, 14.71, and 29.42 kN (500, 1500, and 3000 kgf).

[a] Prepared by the Engineering Mechanics Section, National Institute of Standards and Technology.

22. SAMPLING AND NUMBER OF SPECIMENS

22.1. *Sampling*:

22.1.1. Test location and orientation should be addressed by the specifications. If not, for wrought products, the test location shall be the same as that for the tensile specimen and the orientation shall be longitudinal with the notch perpendicular to the major surface of the product being tested.

22.1.2. *Number of Specimens*:

22.1.2.1. A Charpy impact test consists of all specimens taken from a single test coupon or test location.

22.1.2.2. When the specification calls for a minimum average test result, three specimens shall be tested.

22.1.2.3. When the specification requires determination of a transition temperature, 8 to 12 specimens are usually needed.

22.2. *Type and Size*:

22.2.1. Use a standard full-sized Charpy V-notch specimen (Type A) as shown in Figure 11, except as allowed in Section 22.2.2.

22.2.2. *Sub-sized Specimens*:

22.2.2.1. For flat material less than 11 mm ($^7/_{16}$ in.) thick, or when the absorbed energy is expected to exceed 80 percent of full scale, use standard sub-sized test specimens.

22.2.2.2. For tubular materials tested in the transverse direction, where the relationship between diameter and wall thickness does not permit a standard full-sized specimen, use standard sub-sized test specimens or standard-sized specimens containing outer diameter (OD) curvature as follows:

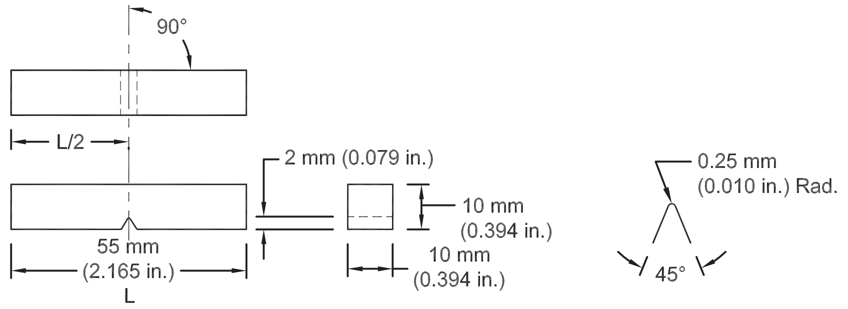
1. Standard-sized specimens and sub-sized specimens may contain the original OD surface of the tubular product as shown in Figure 12. All other dimensions shall comply with the requirements of Figure 11.

Note 15—For materials with toughness levels in excess of about 70 J (50 ft-lbf), specimens containing the original OD surface may yield values in excess of those resulting from the use of conventional Charpy specimens.

22.2.2.3. If a standard full-sized specimen cannot be prepared, the largest feasible standard sub-sized specimen shall be prepared. The specimens shall be machined so that the specimen does not include material nearer to the surface than 0.5 mm (0.020 in.).

22.2.2.4. Tolerances for standard sub-sized specimens are shown in Figure 11. Standard sub-sized test specimen sizes are: 10 by 7.5 mm, 10 by 6.7 mm, 10 by 5 mm, 10 by 3.3 mm, and 10 by 2.5 mm.

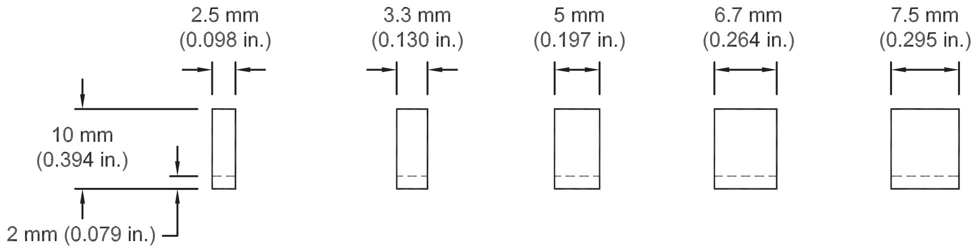
22.2.2.5. Notch the narrow face of the standard sub-sized specimens so that the notch is perpendicular to the 10-mm wide face.



Note: Permissible variations shall be as follows :

Notch Length to Edge	90.0 ± 0.2°
Adjacent Sides shall be at	90.0 ± 10 Min
Cross-Section Dimensions	± 0.075 mm (0.003 in.)
Length of Specimen (L)	+0, −0.25 mm (+0, −0.100 in.)
Centering of Notch (L/2)	± 1 mm (±0.039 in.)
Angle of Notch	±1°
Radius of Notch	±0.025 mm (±0.001 in.)
Notch Depth	±0.025 mm (±0.001 in.)
Finish Requirements	2 µm (63 µ in.) on Notched Surface and Opposite Face; 4 µm (125 µ in.) on Other Two Surfaces

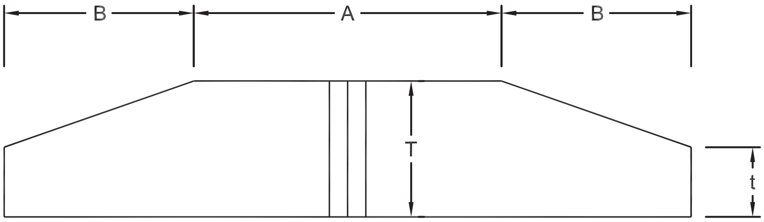
(a) Standard Full-Size Specimen



Note: On sub-size specimens, all dimensions and tolerances of the standard specimen remain constant with the exception of the width, which varies as shown above and for which the tolerance shall be ±1 percent.

(b) Standard Sub-Size Specimens

Figure 11—Charpy (Simple Beam) Impact Test Specimens



Dimension	Description	Requirement
A	Machined Surfaced	28 mm Minimum
B	Original OD Surface	13.5 mm Maximum
T	Specimen Thickness	Figure 11
t	End Thickness	½ T Minimum

Figure 12—Tubular Impact Specimen Containing Original OD Surface

23. CALIBRATION

23.1. *Accuracy and Sensitivity*—Calibrate and adjust Charpy impact machines in accordance with the requirements of T 266.

24. CONDITIONING—TEMPERATURE CONTROL

24.1. When a specific test temperature is required by the specification or purchaser, control the temperature of the heating or cooling medium with ±1ºC (2ºF).

Note 16—For some steels, there may not be a need for this restricted temperature; for example, austenitic steels.

Note 17—Because the temperature of a testing laboratory often varies from 15 to 32ºC (60 to 90ºF), a test conducted at "room temperature" might be conducted at any temperature in this range.

25. PROCEDURE

25.1. *Temperature*:

25.1.1. Condition the specimens to be broken by holding them in the medium at test temperature for at least 5 minutes in liquid media and 30 minutes in gaseous media.

25.1.2. Prior to each test, maintain the tongs for handling test specimens at the same temperature as the specimen, so as not to affect the temperature at the notch.

25.2. *Positioning and Breaking Specimens*:

25.2.1. Carefully center the test specimen in the anvil and release the pendulum to break the specimen.

25.2.2. If the pendulum is not released within 5 seconds after removing the specimen from the conditioning medium, do not break the specimen. Return the specimen to the conditioning medium for the period required in Section 25.1.1.

25.3. *Recovering Specimens*—In the event that fracture appearance or lateral expansion must be determined, recover the matched pieces of each broken specimen before breaking the next specimen.

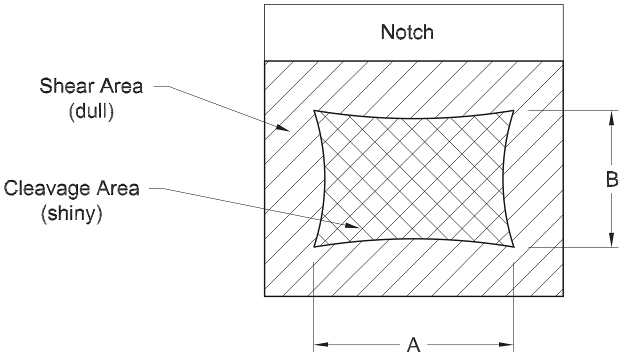
25.4. *Individual Test Values*:

25.4.1. *Impact Energy*—Record the impact energy absorbed to the nearest J (ft-lbf).

25.4.2. *Fracture Appearance*:

25.4.2.1. Determine the percentage of shear fracture area by any of the following methods:

1. Measure the length and width of the brittle portion of the fracture surface, as shown in Figure 13 and determine the percent shear area from either Table 10 or 11 depending on the units of measurement.
2. Compare the appearance of the fracture of the specimen with a fracture appearance chart as shown in Figure 14.
3. Magnify the fracture surface and compare it to a pre-calibrated overlay chart or measure the percent shear fracture area by means of a planimeter.
4. Photograph the fractured surface at a suitable magnification and measure the percent shear fracture area by means of a planimeter.



Notes:
1. Measure average dimensions *A* and *B* to the nearest 0.5 mm (0.02 in.).
2. Determine the percent shear fracture using Table 10 or Table 11.

Figure 13—Determination of Percent Shear Fracture

Figure 14—Fracture Appearance Charts and Percent Shear Fracture Comparator

25.4.2.2. Determine the individual fracture appearance values to the nearest 5 percent shear fracture and record the value.

25.4.3. *Lateral Expansion*:

25.4.3.1. Lateral expansion is the increase in specimen width, measured in 0.025-mm increments (thousandths of an inch), on the compression side, opposite the notch of the fractured Charpy V-notch specimen as shown in Figure 15.

25.4.3.2. Examine each specimen half to ascertain that the protrusions have not been damaged by contacting the anvil, machine mounting surface, and so forth. Discard such samples since they may cause erroneous readings.

25.4.3.3. Check the sides of the specimens perpendicular to the notch to ensure that no burrs were formed on the sides during impact testing. If burrs exist, remove them carefully by rubbing with an emery cloth or similar abrasive surface, making sure that the protrusions being measured are not rubbed during the removal of the burr.

25.4.3.4. Measure the amount of expansion on each side of each half relative to the plane defined by the undeformed portion of the side of the specimen using a gauge similar to that shown in Figures 16 and 17.

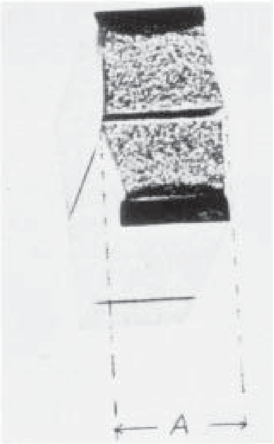


Figure 15—Halves of Broken Charpy V-Notch Impact Specimen Joined for the Measurement of Lateral Expansion, Dimension A

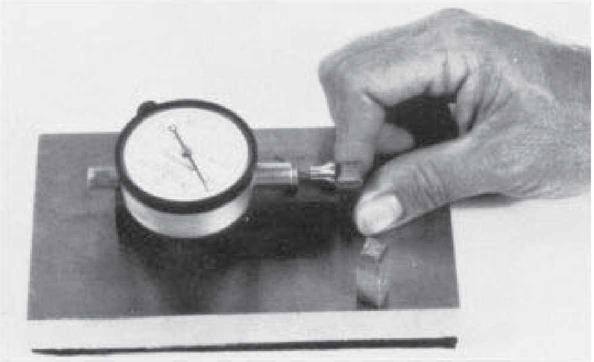

Figure 16—Lateral Expansion Gauge for Charpy Impact Specimens

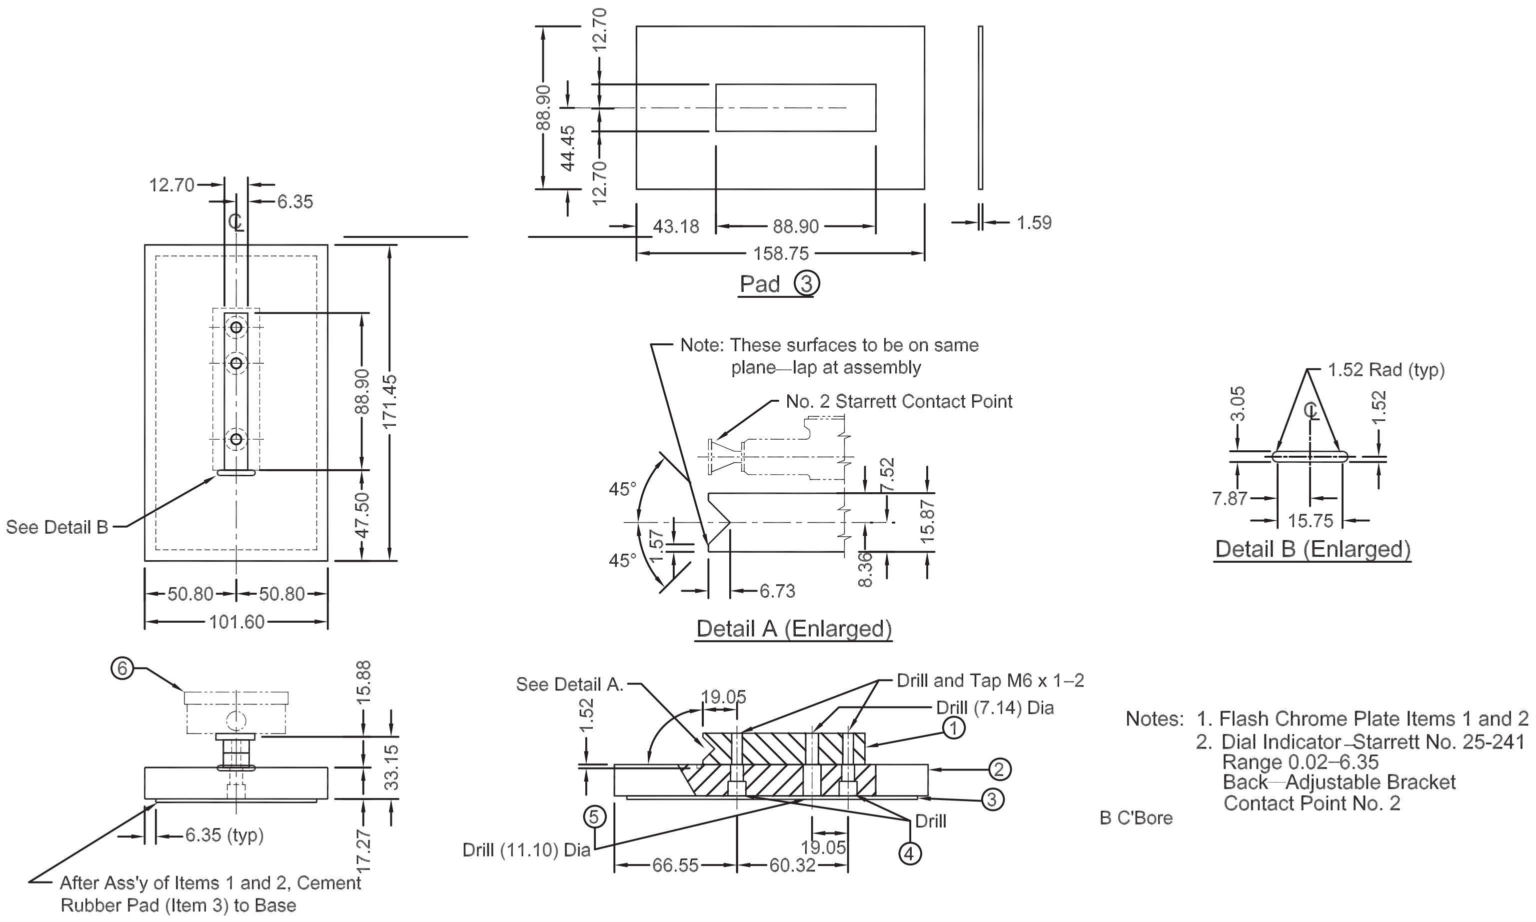

Note: All dimensions in millimeters unless otherwise indicated.

Figure 17—Assembly and Details for Lateral Expansion Gauge

Bill of Material

Item No.	Quantity	Description	Material and Size
1	1	Dual Mount and Stop 102 by 16 by 13	Steel SAE 1015-1020
2	1	Base Plate 178 by 102 by 19	Steel SAE 1015-1020
3	1	Pad 159 by 102 by 19	Rubber
4	2	Screw-Socket Head Cap	Steel M6 by 1 by 25
5	1	Screw-Socket Head Cap	Steel M6 by 1 by 19
6	1	Dial Indicator	(See Note 2)

Figure 17—Assembly and Details for Lateral Expansion Gauge (*continued*)

25.4.3.5. Since the fracture path seldom bisects the point of maximum expansion on both sides of a specimen, the sum of the larger values measured for each side is the value of the test. Arrange the halves of one specimen so that compression sides are facing each other. Using the gauge, measure the protrusion on each half specimen, ensuring that the same side of the specimen is measured. Measure the two broken halves individually. Repeat the procedure to measure the protrusions on the opposite side of the specimen halves. The larger of the two values for each side is the expansion of that side of the specimen.

25.4.3.6. Measure the individual lateral expansion values to the nearest 0.025 mm (0.001 in.) and record the values.

25.4.3.7. With the exception described as follows, any specimen that does not separate into two pieces when struck by a single blow shall be reported as unbroken. If the specimen can be separated by force applied by bare hands, the specimen may be considered as having been separated by the blow.

26. INTERPRETATION OF TEST RESULT

26.1. When the acceptance criterion of any impact test is specified to be a minimum average value at a given temperature, the test result shall be the average (arithmetic mean) of the individual test values of three specimens from one test location.

26.1.1. When a minimum average test result is specified:

26.1.1.1. The test result is acceptable when all of the below are met:

1. The test result equals or exceeds the specified minimum average (given in the specification),
2. The individual test value for not more than one specimen measures less than the specified minimum average, and
3. The individual test value for any specimen measures not less than two-thirds of the specified minimum average.

26.1.1.2. If the acceptance requirements of Section 26.1.1.1 are not met, perform one retest of three additional specimens from the same test location. Each individual test value of the retested specimens shall be equal to or greater than the specified minimum average value.

Table 10—Percent Shear for Measurements Made in Millimeters

Note: Since this table is set up for finite measurements or dimensions A and B, 100 percent shear is to be reported when either A or B is zero.

26.2. *Test Specifying a Minimum Transition Temperature*:

26.2.1. *Definition of Transition Temperature*—For specification purposes, the transition temperature is the temperature at which the designated material test value equals or exceeds a specified minimum test value.

26.2.2. *Determination of Transition Temperature*:

26.2.2.1. Break one specimen at each of a series of temperatures above and below the anticipated transition temperature using the procedures in Section 25. Record each test temperature to the nearest 0.5ºC (1ºF).

26.2.2.2. Plot the individual test results m/N (ft/lbf or percent shear) as the ordinate versus the corresponding test temperature as the abscissa and construct a best-fit curve through the plotted data points.

26.2.2.3. If transition temperature is specified as the temperature at which a test value is achieved, determine the temperature at which the plotted curve intersects the specified test value by graphical interpolation (extrapolation is not permitted). Record this transition temperature to the nearest 3ºC (5ºF). If the tabulated test results clearly indicate a transition temperature lower than specified, it is not necessary to plot the data. Report the lowest test temperature for which test value exceeds the specified value.

26.2.2.4. Accept the test result if the determined transition temperature is equal to or lower than the specified value.

26.2.2.5. If the determined transition temperature is higher than the specified value, but not more than 12ºC (20ºF) higher than the specified value, test sufficient samples in accordance with Section 25 to plot two additional curves. Accept the test results if the temperatures determined from both additional tests are equal to or lower than the specified value.

26.3. When sub-sized specimens are permitted or necessary, or both, modify the specified test requirement according to Table 12 or test temperature according to ASME Boiler and Pressure Vessel Code, Table UG-84.2, or both. Greater energies or lower test temperatures may be agreed upon by purchaser and supplier.

27. RECORDS

27.1. The test record should contain the following information as appropriate:

27.1.1. Full description of material tested (that is, specification number, grade, class or type, size, heat number).

27.1.2. Specimen orientation with respect to the material axis.

27.1.3. Specimen size.

27.1.4. Test temperature and individual test value for each specimen broken, including initial tests and retests.

27.1.5. Test results.

27.1.6. Transition temperature and criterion for its determination, including initial tests and retests.

28. REPORT

28.1. The specification should designate the information to be reported.

29. KEYWORDS

29.1. Bend test; Brinell hardness; Charpy impact test; elongation; FATT (Fracture Appearance Transition Temperature); hardness test; portable hardness; reduction of area; Rockwell hardness; tensile strength; tension test; yield strength.

(Mandatory Information)

A1. STEEL BAR PRODUCTS

A1.1 *Scope*:

A1.1.1 This annex contains testing requirements for steel bar products that are specific to the product. The requirements contained in this annex are supplementary to those found in the general section of this specification. In the case of conflict between requirements provided in this annex and those found in the general section of this specification, the requirements of this annex shall prevail. In the case of conflict between requirements provided in this annex and requirements found in product specifications, the requirements in the product specifications shall prevail.

A1.2 *Orientation of Test Specimens*:

A1.2.1 Carbon and alloy steel bars and bar-size shapes, due to their relatively small cross-sectional dimensions, are customarily tested in the longitudinal direction. In special cases in which size permits and the fabrication or service of a part justifies testing in a transverse direction, the selection and location of test or tests are a matter of agreement between the manufacturer and the purchaser.

A1.3 *Tension Test*:

A1.3.1 *Carbon Steel Bars*—Carbon steel bars are not commonly specified to tensile requirements in the as-rolled condition for sizes of rounds, squares, hexagons, and octagons under 13 mm ($^1/_2$ in.) in diameter or distance between parallel faces nor for other bar-sized sections, other than flats, less than 645 mm^2 (1 in.^{2}) in cross-sectional area.

A1.3.2 *Alloy Steel Bars*—Alloy steel bars are usually not tested in the as-rolled condition.

A1.3.3 When tension tests are specified, the practice for selecting test specimens for hot-rolled and cold-finished steel bars of various sizes shall be in accordance with Table A1.1, unless otherwise specified in the product specification.

A1.4 *Bend Test*:

A1.4.1 When bend tests are specified, the recommended practice for hot-rolled and cold-finished steel bars shall be in accordance with Table A1.2.

A1.5 *Hardness Test:*

A1.5.1 *Hardness Tests on Bar Products*—flats, rounds, squares, hexagons, and octagons—is conducted on the surface after a minimum removal of 0.4 mm (0.015 in.) to provide for accurate hardness penetration.

Table A1.1—Practices for Selecting Tension Test Specimens for Steel Bar Products

Flats

Thickness, mm (in.)	Width, mm (in.)	Hot-Rolled Bars	Cold-Finished Bars
Under 16 ($^{5}/_{8}$)	Up to 40 ($1^{1}/_{2}$), incl	Full section by 200-mm (8-in.) gauge length (Figure 3)	Mill reduced section to 50-mm (2-in.) gauge length and approximately 25 percent less than test specimen width
	Greater than 40 ($1^{1}/_{2}$)	Full section, or mill to 40-mm ($1^{1}/_{2}$-in.) wide by 200-mm (8-in.) gauge length (Figure 3)	Mill reduced section to 50-mm (2-in.) gauge length and 40-mm ($1^{1}/_{2}$-in.) wide
16 to 40 ($^{5}/_{8}$ to $1^{1}/_{2}$), excl	Up to 40 ($1^{1}/_{2}$), incl	Full section by 200-mm (8-in.) gauge length or machine standard 12.5- by 50-mm ($^{1}/_{2}$- by 2-in.) gauge length specimen from center of section (Figure 4)	Mill reduced section to 50-mm (2-in.) gauge length and approximately 25 percent less than test specimen width or machine standard 12.5- by 50-mm ($^{1}/_{2}$- by 2-in.) gauge length specimen from center of section (Figure 4)
	Greater than 40 ($1^{1}/_{2}$)	Full section, or mill to 40-mm ($1^{1}/_{2}$-in.) width by 200-mm (8-in.) gauge length (Figure 3) or machine standard (12.5- by 50-mm ($^{1}/_{2}$- by 2-in.) gauge length specimen from midway between edge and center of section (Figure 4)	Mill reduced section to 50-mm (2-in.) gauge length and 40-mm ($1^{1}/_{2}$-in.) wide or machine standard 12.5- by 50-mm ($^{1}/_{2}$- by 2-in.) gauge length specimen from midway between edge and center of section (Figure 4)
40 ($^{1}/_{2}$) and over		Full section by 200-mm (8-in.) gauge length, or machine standard 12.5 by 50 mm ($^{1}/_{2}$ by 2 in.) gauge length specimen from midway between surface and center (Figure 4)	Machine standard 12.5 by 50 mm ($^{1}/_{2}$ in. by 2 in.) gauge length specimen from midway between surface and center (Figure 4)

Rounds, Squares, Hexagons, and Octagons

Diameter or Distance between Parallel Faces, mm (in.)	Hot-Rolled Bars	Cold-Finished Bars
Under 16 ($^{5}/_{8}$)	Full section by 200-mm (8-in.) gauge length or machine to sub-size specimen (Figure 4)	Machine to sub-size specimen (Figure 4)
16 to 40 ($^{5}/_{8}$ to $1^{1}/_{2}$), excl	Full section by 200-mm (8-in.) gauge length or machine standard 12.5- by 50-mm ($^{1}/_{2}$- by 2-in.) gauge length specimen from center of section (Figure 4)	Machine standard 12.5- by 50-mm ($^{1}/_{2}$- by 2-in.) gauge length specimen from center of section (Figure 4)
40 ($1^{1}/_{2}$) and over	Full section by 200-mm (8-in.) gauge length or machine standard 12.5- by 50-mm ($^{1}/_{2}$- by 2-in.) gauge length specimen from midway between surface and center of section (Figure 4)	Machine standard 12.5- by 50-mm ($^{1}/_{2}$- by 2-in.) gauge length specimen from midway between surface and center of section (Figure 4)

Other Bar-Size Sections

	Hot-Rolled Bars	Cold-Finished Bars
All sizes	Full section by 200-mm (8-in.) gauge length or prepare test specimen 40-mm ($1^{1}/_{2}$-in.) wide (if possible) by 200-mm (8-in.) gauge length	Mill reduced section to 50-mm (2-in.) gauge length and approximately 25 percent less than test specimen width

Note: For bar sections for which it is difficult to determine the cross-sectional area by simple measurement, the area in square inches may be calculated by dividing the weight per linear inch of specimen in pounds by 0.2833 (weight of 1 in.^{3} of steel) or by dividing the weight per linear foot of specimen by 3.4 (weight of steel 1 in. square and 1 ft long).

Table A1.2—Recommended Practice for Selecting Bend Test Specimens for Steel Bar Products

Flats		
Thickness, mm (in.)	Width, mm (in.)	Recommended Size
Up to 13 ($^1/_2$), incl	Up to 19 mm ($^3/_4$), incl	Full section
	Over 19 mm ($^3/_4$)	Full section or machine to not less than 19 mm ($^3/_4$ in.) in width by thickness of specimen
Over 13 ($^1/_2$)	All	Full section or machine to 25 by 13 mm (1 by $^1/_2$ in.) specimen from midway between center and surface

Rounds, Squares, Hexagons, and Octagons	
Diameter or Distance Between Parallel Faces, mm (in.)	Recommended Size
Up to 38 (1$^1/_2$), incl	Full section
Over 38 (1$^1/_2$)	Machine to 25 mm by 13-mm (1 by $^1/_2$-in.) specimen from midway between center and surface

Notes: 1. The length of all specimens is to be not less than 150 mm (6 in.).
2. The edges of the specimens may be rounded to a radius not exceeding 1.6 mm ($^1/_{16}$ in.).

A2. STEEL TUBULAR PRODUCTS

A2.1 *Scope*:

A2.1.1 This annex contains testing requirements for steel bar products that are specific to the product. The requirements contained in this annex are supplementary to those found in the general section of this specification. In the case of conflict between requirements provided in this annex and those found in the general section of this specification, the requirements of this annex shall prevail. In the case of conflict between requirements provided in this annex and requirements found in product specifications, the requirements in the product specifications shall prevail.

A2.1.2 Tubular shapes covered by this specification include, round, square, rectangle, and special shapes.

A2.2 *Tension Test*:

A2.2.1 *Full-Sized Longitudinal Test Specimens*:

A2.2.1.1 As an alternative to the use of longitudinal strip test specimens or longitudinal round test specimens, tension test specimens of full-size tubular sections are used, provided that the testing equipment has sufficient capacity. Snug-fitting metal plugs should be inserted far enough in the end of such tubular specimens to permit the testing machine jaws to grip the specimens properly without crushing. A design that may be used for such plugs is shown in Figure A2.1. The plugs shall not extend into that part of the specimen on which the elongation is measured (Figure A2.1). Care should be exercised to see that insofar as practicable, the load in such cases is applied axially. The length of the full-section specimen depends on the gauge length prescribed for measuring the elongation.

A2.2.1.2 Unless otherwise required by the individual product specification, the gauge length is 50 mm (2 in.), except that for tubing having an outside diameter of 9.5 mm ($^3/_8$ in.) or less, it is customary for a gauge length equal to four times the outside diameter to be used when elongation comparable to that obtainable with larger test specimens is required.

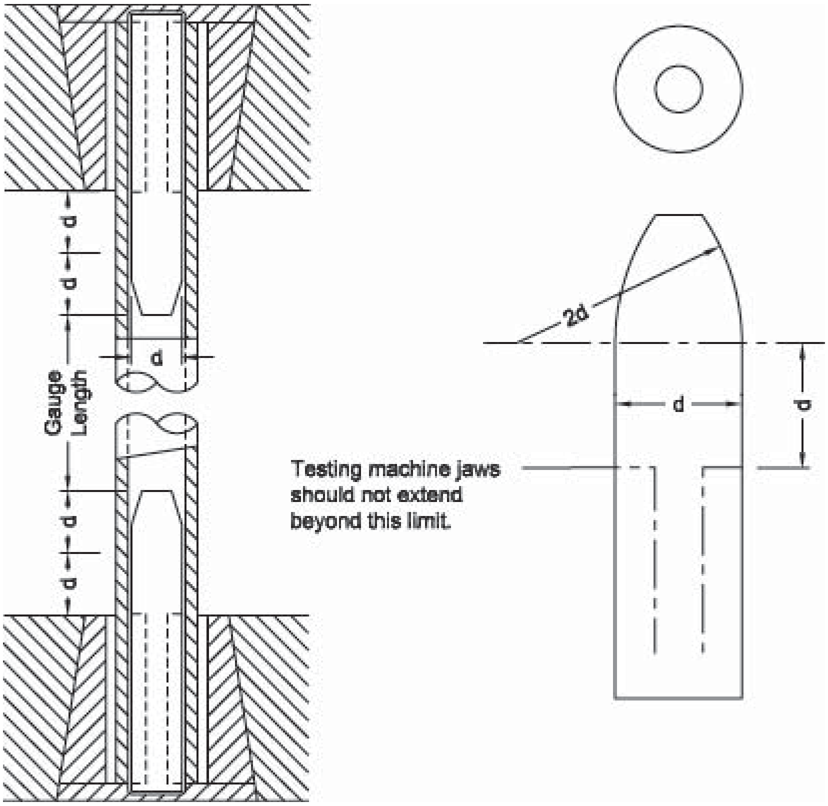

Figure A2.1—Metal Plugs for Testing Tubular Specimens, Proper Location of Plugs in Specimen and of Specimen in Heads of Testing Machine

A2.2.1.3 To determine the cross-sectional area of the full-section specimen, measurements shall be recorded as the average or mean between the greatest and least measurements of the outside diameter and the average or mean wall thickness, to the nearest 0.025 mm (0.001 in.) and the cross-sectional area is determined by the following equation:

$$A = 3.1416t\,(D - t) \qquad (A2.1)$$

where:

A = sectional area, mm^2 (in.^{2});

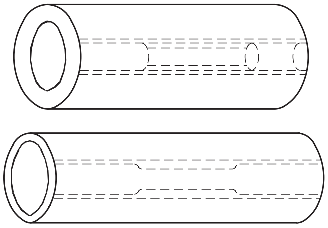
D = outside diameter, mm (in.); and

t = thickness of tube wall, mm (in.).

Note A1—There are other methods of cross-sectional area determination, such as by weighing of the specimens, that are equally accurate or appropriate for this purpose.

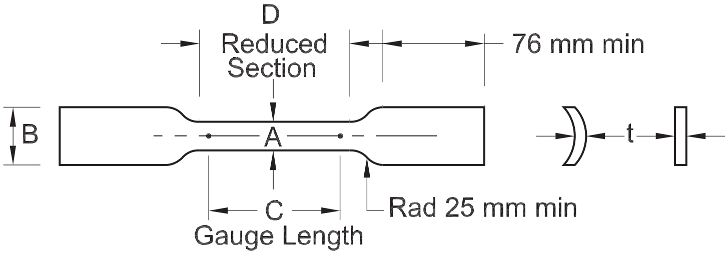
A2.2.2 *Longitudinal Strip Test Specimens*:

A2.2.2.1 As an alternate to the use of full-size longitudinal test specimens or longitudinal round test specimens, longitudinal strip test specimens, obtained from strips cut from the tubular product as shown in Figure A2.2 and machined to the dimensions shown in Figure A2.3, are used. For welded structural tubing, such test specimens shall be from a location at least 90 degrees from the weld; for other welded tubular products, such test specimens shall be from a location approximately 90 degrees from the weld. Unless otherwise required by the product specification, the gauge length is 50 mm (2 in.). The test specimen shall be tested using grips that are flat or have a surface contour corresponding to the curvature of the tubular product, or the ends of the test specimens shall be flattened without heating prior to the test specimens being tested using flat grips. The test specimen shown as Specimen No. 4 in Figure A2.3 shall be used, unless the capacity of the testing equipment or the dimensions and nature of the tubular product to be tested makes the use of specimen notes 1, 2, or 3 necessary.



Note: The edges of the blank for the specimen shall be cut parallel to each other.

Figure A2.2—Location of Strip Tension Test Specimens in Large Diameter Tubing



Dimensional Equivalents

Specimen No.	Dimensions, mm (in.)			
	A	B	C	D
1	12.50 ± 0.38 ($^{1}/_{2}$ ± 0.015)	17 ($^{11}/_{16}$) approximately	50.00 ± 0.13 (2 ± 0.005)	57 min (2$^{1}/_{4}$) minutes
2	19.00 ± 0.79 ($^{3}/_{4}$ ± 0.031)	25 (1) approximately	50.00 ± 0.13 (2 ± 0.005) 100.00 ± 0.13 (4 ± 0.005)	57 min (2$^{1}/_{4}$) minutes 114 minutes (4$^{1}/_{2}$) minutes
3	25.00 ± 1.57 (1 ± 0.062)	40 (1$^{1}/_{2}$) approximately	50.00 ± 0.13 (2 ± 0.005) 100.00 ± 0.13 (4 ± 0.005)	57 minutes (2$^{1}/_{4}$) minutes 114 minutes (4$^{1}/_{2}$) minutes
4	40.00 ± 3.18 (1$^{1}/_{2}$ ± $^{1}/_{8}$)	50 (2) approximately	50.00 ± 0.25 (2 ± 0.010) 100.00 ± 0.38 (4 ± 0.015) 200 ± 0.51 (8 ± 0.020)	57 minutes (2$^{1}/_{4}$) minutes 114 minutes (4$^{1}/_{2}$) minutes 229 minutes (9) minutes

Notes:

1. Cross-sectional area may be calculated by multiplying A and t.
2. The dimension t is the thickness of the test specimen as provided for in the applicable material specifications.
3. The reduced section shall be parallel within 0.25 mm (0.010 in.) and may have a gradual taper in width from the ends toward the center, with the ends not more than 0.25 mm (0.010 in.) wider than the center.
4. The ends of the specimen shall be symmetrical with the centerline of the reduced section within 2.5 mm (0.10 in.).
5. Dimensional equipment: 25.4 mm = 1 in.
6. Specimens with sides parallel throughout their length are permitted, except for referee testing, provided: (a) the above tolerances are used; (b) an adequate number of marks are provided for determination of elongation; and (c) when yield strength is determined, a suitable extensometer is used. If the fracture occurs at a distance of less than 2A from the edge of the gripping device, the tensile properties determined may not be representative of the material. If the properties meet the minimum requirements specified, no further testing is required, but if they are less than the minimum requirements, discard the test and retest.

Figure A2.3—Dimensions and Tolerances for Longitudinal Strip Tension Test Specimens Tubular Products

Note A2—An exact formula for calculating the cross-sectional area of specimens of the type shown in Figure A2.3 taken from a circular tube is given in T 68/T 68M.

A2.2.2.2 The width should be measured at each end of the gauge length to determine parallelism and also at the center. The thickness should be measured at the center and used with the center measurement of the width to determine the cross-sectional area. The center width dimension should be recorded to the nearest 0.13 mm (0.005 in.), and the thickness measurement to the nearest 0.025 mm (0.001 in.).

A2.2.3 *Transverse Strip Test Specimens*:

A2.2.3.1 In general, transverse tension tests are not recommended for tubular products in sizes smaller than 200 mm (8 in.) in nominal diameter. When required, transverse tension tests specimens may be taken from rings cut from ends of tubes or pipe as shown in Figure A2.4. Flattening of the specimen may be done either after separating it from the tube as in Figure A2.4 (A), or before separating it as in Figure A2.4 (B), and may be done hot or cold; but if the flattening is done cold, the specimen may subsequently be normalized. Specimens from tubes or pipe for which heat-treatment is specified, after being flattened either hot or cold, shall be given the same treatment as the tubes or pipe. For tubes or pipe having a wall thickness of less than 19 mm ($^{3}/_{4}$ in.), the transverse test specimen shall be of the form and dimensions shown in Figure A2.5 and either or both surfaces may be machined to secure uniform thickness. Specimens for transverse tension tests on welded steel tubes or pipe to determine strength of welds shall be located perpendicular to the welded seams with the weld at about the middle of their length.

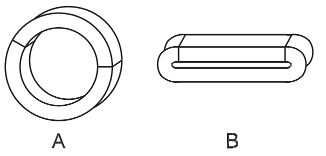


Figure A2.4—Location of Transverse Tension Test Specimens in Ring Cut from Tubular Products

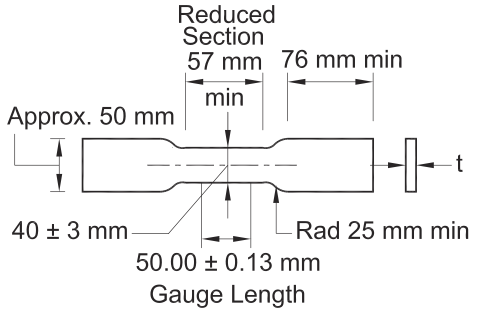

Dimensional Equivalents

mm	76	57	50.00 ± 0.13	50	40 ± 3	25
(in.)	(3)	($2^{1}/_{4}$)	(2.000 ± 0.005)	(2)	($1^{1}/_{2} \pm {}^{1}/_{8}$)	(1)

Notes:

1. The dimension t is the thickness of the test specimen as provided for in the applicable material specifications.
2. The reduced section shall be parallel within 0.25 mm (0.010 in.) and may have a gradual taper in width from the ends toward the center, with the ends not more than 0.25 mm (0.010 in.) wider than the center.
3. The ends of the specimen shall be symmetrical with the centerline of the reduced section within 2.5 mm (0.10 in.).

Figure A2.5—Transverse Tension Test Specimen Machined from Ring Cut from Tubular Products

A2.2.3.2 The width should be measured at each end of the gauge length to determine parallelism and also at the center. The thickness should be measured at the center and used with the center measurement of the width to determine the cross-sectional area. The center width dimension should be recorded to the nearest 0.13 mm (0.005 in.) and the thickness measurement to the nearest 0.025 mm (0.001 in.).

A2.2.4 *Round Test Specimens*:

A2.2.4.1 When provided for in the product specification, the round test specimen shown in Figure 4 may be used.

A2.2.4.2 The diameter of the round test specimen is measured at the center of the specimen to the nearest 0.025 mm (0.001 in.).

A2.2.4.3 Small-sized specimens proportional to standard, as shown in Figure 4, may be used when it is necessary to test material from which the standard specimen cannot be prepared. Other sizes of small-sized specimens may be used. In any such small-sized specimen, it is important that the gauge length for measurement of elongation be four times the diameter of the specimen. (See note 4 of Figure 4.) The elongation requirements for the round specimen 50-mm (2-in.) gauge length in the product specification shall apply to the small-sized specimens.

A2.2.4.4 For transverse specimens, the section from which the specimen is taken shall not be flattened or otherwise deformed.

A2.2.4.5 Longitudinal test specimens are obtained from strips cut from the tubular product as shown in Figure A2.2.

A2.3 *Determination of Transverse Yield Strength, Hydraulic Ring-Expansion Method*:

A2.3.1 Hardness tests are made on the outside surface, inside surface, or wall cross section depending upon product specification limitation. Surface preparation may be necessary to obtain accurate hardness values.

A2.3.2 A testing machine and method for determining the transverse yield strength from an annular ring specimen have been developed and described in Sections A2.3.3 through A2.3.5.

A2.3.3 A diagrammatic vertical cross-sectional sketch of the testing machine is shown in Figure A2.6.

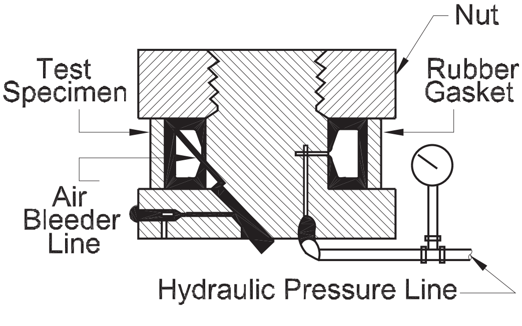

Figure A2.6—Testing Machine for Determination of Transverse Yield Strength from Annular Ring Specimens

A2.3.4 In determining the transverse yield strength on this machine, a short ring (commonly 76 mm (3 in.) in length) test specimen is used. After the large circular nut is removed from the machine, the wall thickness of the ring specimen is determined and the specimen is telescoped over the oil-resistant rubber gasket. The nut is then replaced, but is not turned down tight against the specimen. A slight clearance is left between the nut and specimen for the purpose of permitting free radial movement of the specimen as it is being tested. Oil under pressure is then admitted to the interior of the rubber gasket through the pressure line under the control of a suitable valve. An accurately calibrated pressure gauge serves to measure oil pressure. Any air in the system is removed through the bleeder line. As the oil pressure is increased, the rubber gasket expands, which, in turn, stresses the specimen circumferentially. As the pressure builds up, the lips of the rubber gasket act as a seal to prevent oil leakage. With continued increase in pressure, the ring specimen is subjected to a tension stress and elongates accordingly. The entire outside circumference of the ring specimen is considered as the gauge length and the strain is measured with a suitable extensometer, which will be described later. When the desired total strain or extension under load is reached on the extensometer, the oil pressure in pascals (pounds per square inch) is read and by employing Barlow's formula, the unit yield strength is calculated. The yield strength, thus determined, is a true result since the test specimen has not been cold worked by flattening and closely approximates the same condition as the tubular section from which it is cut. Further, the test closely simulates service conditions in pipe lines. One testing machine unit may be used for several different sizes of pipe by the use of suitable rubber gaskets and adapters.

Note A3—Barlow's formula may be stated two ways:

$$P = 2St/D \qquad (A2.2)$$

$$S = PD/2t \qquad (A2.3)$$

where:

P = internal hydrostatic pressure, Pa (psi);

S = unit circumferential stress in the wall of the tube produced by the internal hydrostatic pressure, Pa (psi);

t = thickness of the tube wall, mm (in.); and

D = outside diameter of the tube, mm (in.).

A2.3.5 A roller chain type extensometer that has been found satisfactory for measuring the elongation of the ring specimen is shown in Figures A2.6 and A2.7. Figure A2.6 shows the extensometer in position, but unclamped, on a ring specimen. A small pin, through which the strain is transmitted to and measured by the dial gauge, extends through the hollow threaded stud. When the extensometer is clamped, as shown in Figure A2.7, the desired tension which is necessary to hold the instrument in place and to remove any slack is exerted on the roller chain by the spring. Tension on the spring may be regulated as desired by the knurled thumbscrew. By removing or adding rollers, the roller chain may be adapted for different sizes of tubular sections.

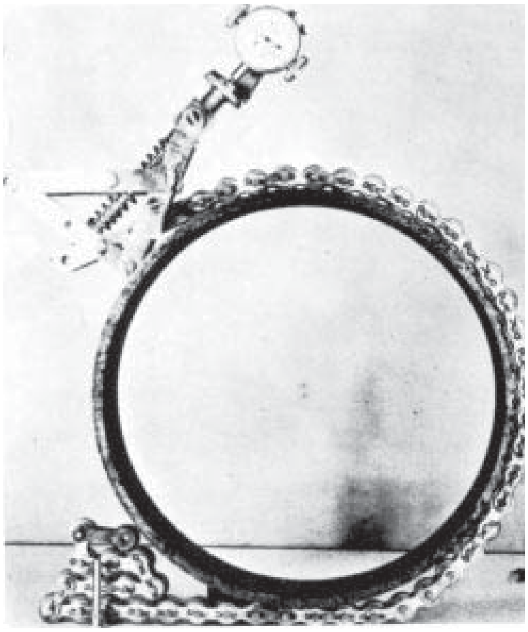

Figure A2.6—Roller Chain Type Extensometer, Unclamped

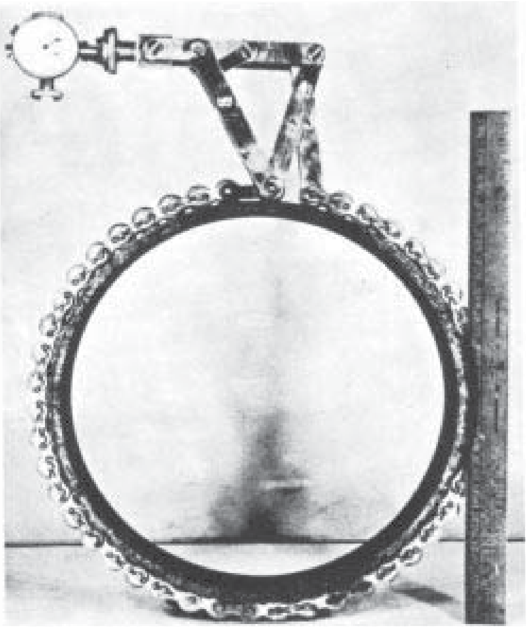

Figure A2.7—Roller Chain Type Extensometer, Clamped

A2.4 *Hardness Tests*:

A2.4.1 Hardness tests are made either on the outside or the inside surfaces on the end of the tube as appropriate.

A2.4.2 The standard 29.42 kN (3000 kgf) Brinell load may cause too much deformation in a thin-walled tubular specimen. In this case, the 4.903 kN (500 kgf) load shall be applied or inside stiffening by means of an internal anvil should be used. Brinell testing shall not be applicable to tubular products less than 50 mm (2 in.) in outside diameter, or less than 5.1 mm (0.200 in.) in wall thickness.

A2.4.3 The Rockwell hardness tests are normally made on the inside surface, a flat on the outside surface, or on the wall cross section, depending upon the product limitation. Rockwell hardness tests are not performed on tubes smaller than 8 mm ($^5/_{16}$ in.) in outside diameter, nor are they performed on the inside surface of tubes with less than 6.4 mm ($^1/_4$ in.) inside diameter. Rockwell hardness tests are not performed on annealed tubes with walls less than 1.65 mm (0.065 in.) thick or cold-worked or heat-treated tubes with walls less than 1.24 mm (0.049 in.) thick. For tubes with wall thicknesses less than those permitting the regular Rockwell hardness test, the Superficial Rockwell test is sometimes substituted. Transverse Rockwell hardness readings can be made on tubes with a wall thickness of 4.75 mm (0.187 in.) or greater. The curvature and the wall thickness of the specimen impose limitations on the Rockwell hardness test. When a comparison is made between Rockwell determinations made on the outside surface and determinations made on the inside surface, adjustment of the readings will be required to compensate for the effect of curvature. The Rockwell B scale is used on all materials having an expected hardness range of B 0 to B 100. The Rockwell C scale is used on material having an expected hardness range of C 20 to C 68.

A2.4.4 Superficial Rockwell hardness tests are normally performed on the outside surface whenever possible and whenever excessive spring back is not encountered. Otherwise, the tests may be performed on the inside. Superficial Rockwell hardness tests shall not be performed on tubes with an inside diameter of less than 6.4 mm ($^1/_4$ in.). The wall thickness limitations for the Superficial Rockwell hardness test are given in Tables A2.1 and A2.2.

Table A2.1—Wall Thickness Limitations of Superficial Hardness Test on Annealed or Ductile Materials for Steel Tubular Products[a]

"T" Scale [1.588-mm ($^1/_{16}$-in.) Ball]

Wall Thickness, mm (in.)	Load, N (kgf)
Over 1.27 (0.050)	441 (45)
Over 0.89 (0.035)	294 (30)
0.51 (0.020) and over	147 (15)

[a] The heaviest load recommended for a given wall thickness is generally used.

Table A2.2—Wall Thickness Limitations of Superficial Hardness Test on Cold-Worked or Heat-Treated Material for Steel Tubular Products[a]

"N" Scale [Diamond Penetrator]

Wall Thickness, mm (in.)	Load N, (kgf)
Greater than 0.89 (0.035)	441 (45)
0.51 (0.025) and larger	294 (30)
0.38 (0.015) and larger	147 (15)

[a] The heaviest load recommended for a given wall thickness is generally used.

A2.4.5 When the outside diameter, inside diameter, or wall thickness precludes obtaining accurate hardness values, tubular products shall be specified to tensile properties and so tested.

A2.5 *Manipulating Tests*:

A2.5.1 The following tests are made to prove ductility of certain tubular products:

A2.5.1.1 *Flattening Test*—The flattening test as commonly made on specimens cut from tubular products is conducted by subjecting rings from the tube or pipe to a prescribed degree of flattening between parallel plates (Figure A2.4). The severity of the flattening test is measured by the distance between the parallel plates and is varied according to the dimensions of the tube or pipe. The flattening test specimen should not be less than 63.5 mm ($2^1/_2$ in.) in length and should be flattened cold to the extent required by the applicable material specification.

A2.5.1.2 *Reverse Flattening Test*—The reverse flattening test is designed primarily for application to electric-welded tubing for the detection of lack of penetration or overlaps resulting from flash removal in the weld. The specimen consists of a length of tubing approximately 100 mm (4 in.) long, which is split longitudinally 90 degrees on each side of the weld. The sample is then opened and flattened with the weld at the point of maximum bend (Figure A2.8).

A2.5.1.3 *Crush Test*—The crush test, sometimes referred to as an upsetting test, is usually made on boiler and other pressure tubes, for evaluating ductility (Figure A2.9). The specimen is a ring cut from the tube, usually about 63.5 mm ($2^1/_2$ in.) long. It is placed on end and crushed endwise by hammer or press to the distance prescribed by the applicable material specification.

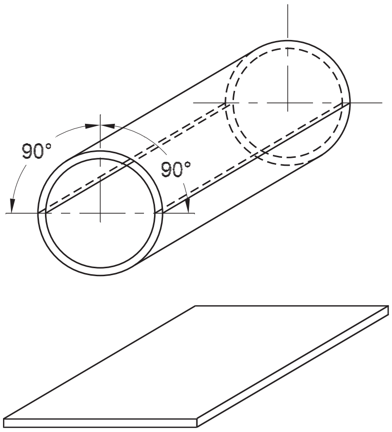

Figure A2.9—Reverse Flattening Test

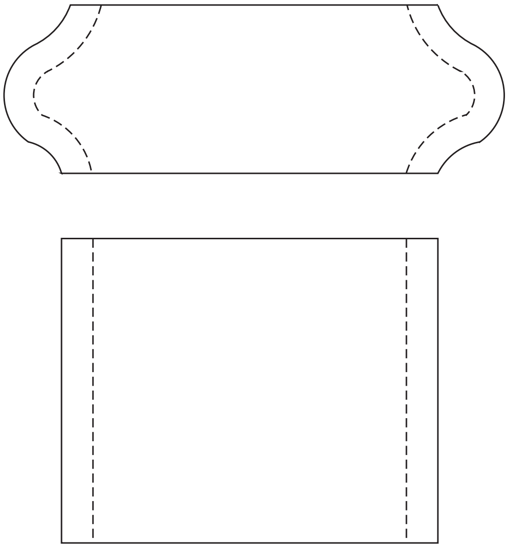

Figure A2.10—Crush-Test Specimen

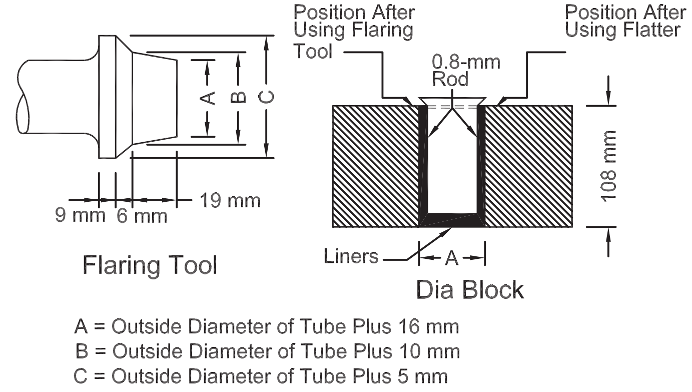
A2.5.1.4 *Flange Test*—The flange test is intended to determine the ductility of boiler tubes and their ability to withstand the operation of bending into a tube sheet. The test is made on a ring cut from a tube, usually not less than 100 mm (4 in.) long and consists of having a flange turned over at right angles to the body of the tube to the width required by the applicable material specifications. The flaring tool and die block shown in Figure A2.10 are recommended for use in making this test.

A2.5.1.5 *Flaring Test*—For certain types of pressure tubes, an alternate to the flange test is made. This test consists of driving a tapered mandrel having a slope of 1 in 10 as shown in Figure A2.11 or a 60-degree included angle as shown in Figure A2.11 into a section cut from the tube, approximately 100 mm (4 in.) in length, and thus expanding the specimen until the inside diameter has been increased to the extent required by the applicable material specifications.



Note: Dimensional equivalent: 25.4 mm = 1 in.

Figure A2.11—Flaring Tool and Die Block for Flange Test

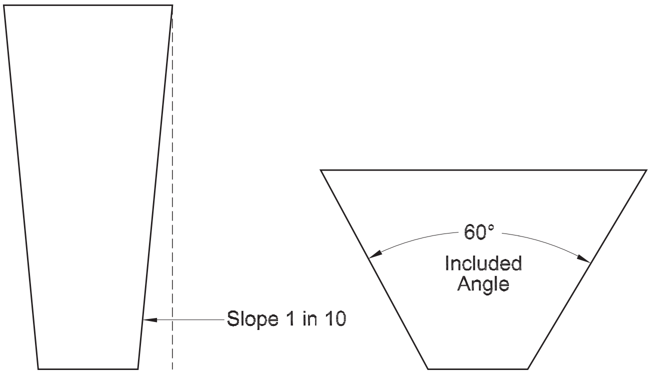


Figure A2.12—Tapered Mandrels for Flaring Test

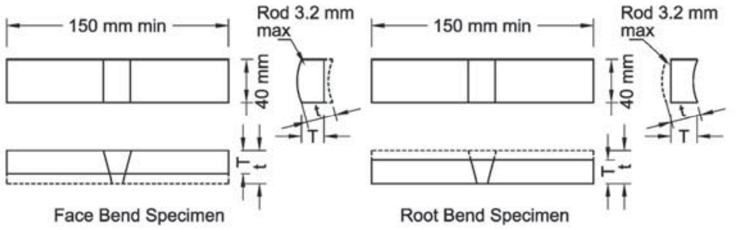
A2.5.1.6 *Bend Test*—For pipe used for coiling in sizes 50 mm (2 in.) and under, a bend test is made to determine its ductility and the soundness of weld. In this test, a sufficient length of full-sized pipe is bent cold through 90 degrees around a cylindrical mandrel having a diameter 12 times the nominal diameter of the pipe. For close coiling, the pipe is bent cold through 180 degrees around a mandrel having a diameter eight times the nominal diameter of the pipe.

A2.5.1.7 *Transverse Guided Bend Test of Welds*—This bend test is used to determine the ductility of fusion welds. The specimens used are approximately 40 mm ($1^1/_2$ in.) wide, at least 150 mm (6 in.) in length with the weld at the center, and are machined in accordance with Figure A2.13 for face and root bend tests and in accordance with Figure A2.14 for side bend tests. The dimensions of the plunger shall be as shown in Figure A2.15 and the other dimensions of the bending jig shall be substantially as given in this same figure. A test shall consist of a face bend specimen and a root bend specimen or two side bend specimens. A face bend test requires bending with the inside surface of the pipe against the plunger; a root bend test requires bending with the outside surface of the pipe against the plunger; and a side bend test requires bending so that one of the side surfaces becomes the convex surface of the bend specimen.

Failure of the bend test depends upon the appearance of cracks in the area of the bend, of the nature and extent described in the product specifications.

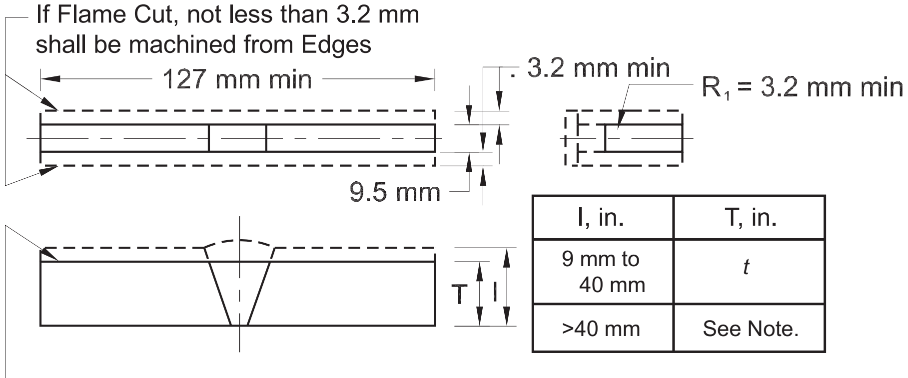


Pipe Wall and Test Specimen Thicknesses

Pipe Wall Thickness (*t*), mm (in.)	Test Specimen Thickness, mm (in.)
Up to 9.5 ($^3/_8$), incl	t
More than 9.5 ($^3/_8$)	9.5 ($^3/_8$)

Note: Dimensional equivalent: 25.4 mm = 1 in.

Figure A2.13—Transverse Face and Root Bend Test Specimens



I, in.	T, in.
9 mm to 40 mm	*t*
>40 mm	See Note.

When I exceeds 40 mm, use one of the following:

1. Cut along line indicated by arrow. Edge may be flame cut and may or may not be machined.
2. Specimens may be cut into approximately equal strips between 19 mm and 40 mm wide for testing or the specimens may be bent at full width. (See Requirements on Jig Width in Figure A2.15.)

Note: Dimensional equivalent: 25.4 mm = 1 in.

Figure A2.15—Guided-Bend Test Jig

A3. STEEL FASTENERS

A3.1 *Scope*:

A3.1.1 This annex contains testing requirements for steel fasteners that are specific to the product. The requirements contained in this annex are supplementary to those found in the general section of this specification. In the case of conflict between requirements provided in this annex and those found in the general section of this specification, the requirements of this annex shall prevail. In the case of conflict between requirements provided in this annex and requirements found in product specifications, the requirements in the product specifications shall prevail.

A3.1.2 These tests are set up to facilitate production control testing and acceptance testing with certain more precise tests to be used for arbitration in case of disagreement over test results.

A3.2 *Tension Tests*:

A3.2.1 It is preferred that bolts be tested full sized, and it is customary, when so testing bolts, to specify a minimum ultimate load in newtons (pounds), rather than a minimum ultimate strength in pascals (pounds per square inch). Three times the bolt nominal diameter has been established as the minimum bolt length subject to the tests described in the remainder of this section. Sections A3.2.1.1 through A3.2.1.3 apply when testing bolts full sized. Section A3.2.1.4 shall apply where the individual product specifications permit the use of machined specimens.

A3.2.1.1 *Proof Load*—Due to particular uses of certain classes of bolts, it is desirable to be able to stress them, while in use, to a specified value without obtaining any permanent set. To be certain of obtaining this quality, the proof load is specified. The proof load test consists of stressing the bolt with a specified load that the bolt must withstand without permanent set. An alternate test that determines yield strength of a full sized bolt is also allowed. Either of the following Methods, 1 or 2, may be used, but Method 1 shall be the arbitration method in case of any dispute as to acceptance of the bolts.

A3.2.1.2 *Proof Load Testing Long Bolts*—When full-sized tests are required, proof load Method 1 is to be limited in application to bolts the length of which does not exceed 200 mm (8 in.) or eight times the nominal diameter, whichever is greater. For bolts longer than 200 mm (8 in.) or eight times the nominal diameter, whichever is greater, proof load Method 2 shall be used.

- *Method 1, Length Measurement*—The overall length of a straight bolt shall be measured at its true centerline with an instrument capable of measuring changes in length of 0.0025 mm (0.0001 in.) with an accuracy of 0.0025 mm (0.0001 in.) in any 0.025-mm (0.001 in.) range. The preferred method of measuring the length shall be between conical centers machined on the centerline of the bolt, with mating centers on the measuring anvils. The head or body of the bolt shall be marked so that it can be placed in the same position for all measurements. The bolt shall be assembled in the testing equipment as outlined in Section A3.2.1.4, and the proof load specified in the product specification shall be applied. Upon release of this load, the length of the bolt shall be again measured and shall show no permanent elongation. A tolerance of ±0.0127 mm (0.0005 in.) shall be allowed between the measurement made before loading and that made after loading. Variables, such as straightness and thread alignment (plus measurement error), may result in apparent elongation of the fasteners when the proof load is initially applied. In such cases, the fastener may be retested using a 3 percent greater load, and may be considered satisfactory if the length after this loading is the same as before this loading (within the 0.0127 mm (0.0005 in.) tolerance for measurement error).
- *Method 2, Yield Strength*—The bolt shall be assembled in the testing equipment as outlined in Section A3.2.1.4. As the load is applied, the total elongation of the bolt or any part of the bolt that includes the exposed six threads shall be measured and recorded to produce a load–strain or a stress–strain diagram. The load or stress at an offset equal to 0.2 percent of the length of bolt occupied by six full threads shall be determined by the method described in Section 13.2.1 of T 244. This load or stress shall not be less than that prescribed in the product specification.

A3.2.1.3 *Proof Load Time of Loading*—The proof load is to be maintained for a period of 10 seconds before release of load when using Method 1.

A3.2.1.4 *Axial Tension Testing of Full-Sized Bolts*—Bolts are to be tested in a holder with the load axially applied between the head and a nut or suitable fixture (Figure A3.1), either of which shall have sufficient thread engagement to develop the full strength of the bolt. The nut or fixture shall be assembled on the bolt leaving six complete bolt threads unengaged between the grips, except for heavy hexagon structural bolts which shall have four complete threads unengaged between the grips. To meet the requirements of this test, there shall be a tensile failure in the body or threaded section with no failure at the junction of the body and head. If it is necessary to record or report the tensile strength of bolts as MPa (psi) values, the stress area shall be calculated from the mean of the mean root and pitch diameters of Class 3 external threads as follows:

$$A_s = 0.7854\,[D - (0.9743)/n]^2 \qquad (A3.1)$$

where:

A_s = stress area, mm^2 (in.^{2});

D = nominal diameter, mm (in.); and

n = number of threads per mm (in.).

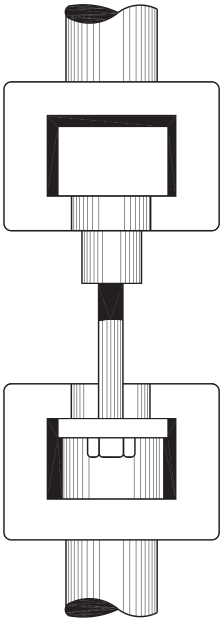

Figure A3.1—Tension Testing Full-Size Bolt

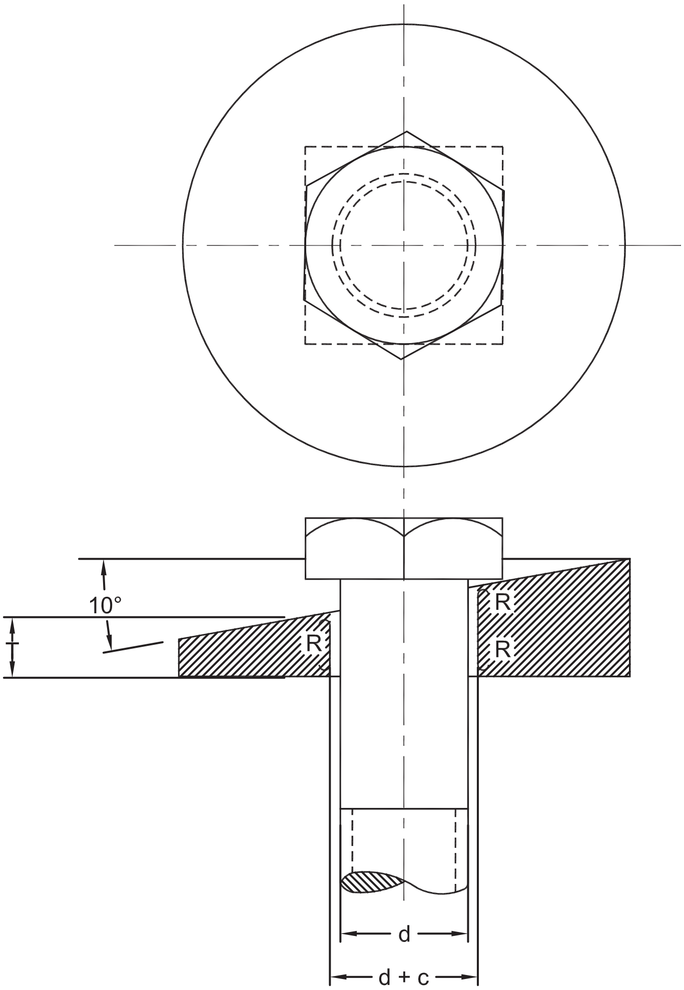
A3.2.1.5 *Tension Testing of Full-Sized Bolts with a Wedge*—The purpose of this test is to obtain the tensile strength and demonstrate the "head quality" and ductility of a bolt with a standard head by subjecting it to eccentric loading. The ultimate load on the bolt shall be determined as described in Section A3.2.1.4, except that a 10-degree wedge shall be placed under the same bolt previously tested for the proof load. (See Section A3.2.1.1.) The bolt head shall be so placed that no corner of the hexagon or square takes a bearing load; that is, a flat of the head shall be aligned with the direction of uniform thickness of the wedge (Figure A3.2). The wedge shall have an included angle of 10 degrees between its faces and shall have a thickness of one-half of the nominal bolt diameter at the short side of the hole. The hole in the wedge shall have the following clearance over the nominal size of the bolt, and its edges, top and bottom, shall be rounded to the radius in Table A3.1.

A3.2.1.6 *Wedge Testing of HT Bolts Threaded to Head*—For heat-treated bolts over 690 MPa (100000 psi) minimum tensile strength and threaded one diameter and closer to the underside of the head, the wedge angle shall be six degrees for sizes 6.4 to 19.0 mm ($^1/_4$ to $^3/_4$ in.) and four degrees for sizes greater than 19.0 mm ($^3/_4$ in.).

Table A3.1—Radius

Nominal Bolt Size, mm (in.)	Clearance in Hole, mm (in.)	Radius on Corners of Hole, mm (in.)
6.4 to 12.7 ($^1/_4$ to $^1/_2$)	0.76 (0.030)	0.76 (0.030)
14.3 to 19.0 ($^9/_{16}$ to $^3/_4$)	1.27 (0.050)	1.52 (0.060)
22.2 to 25.4 ($^7/_8$ to 1)	1.60 (0.063)	1.52 (0.060)
28.6 to 31.8 ($1^1/_8$ to $1^1/_4$)	1.60 (0.063)	3.18 (0.125)
34.9 to 38.4 ($1^3/_8$ to $1^1/_2$)	2.39 (0.094)	3.18 (0.125)



Note: *c* = clearance of pf wedge hole; *d* = diameter of bolt; *r* = radius; and *T* = thickness of wedge at short side of hole equal to one-half diameter of bolt.

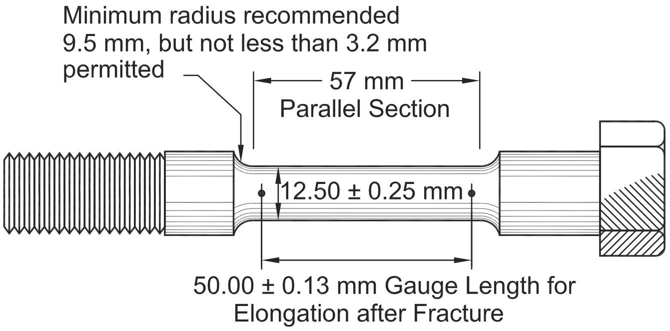
Figure A3.2—Wedge Test Details

A3.2.1.7 *Tension Testing of Bolts Machined to Round Test Specimens*:

1. Bolts less than 40 mm ($1^1/_2$ in.) in diameter that require machined tests shall use a standard 12.5-mm ($^1/_2$-in.) round 50-mm (2-in.) gauge length test specimen (Figure 4); however, bolts of small cross section that will not permit the taking of this standard test specimen shall use one of the small-sized specimens proportional to standard (Figure 4) and the specimen shall have a reduced section as large as possible. In all cases, the longitudinal axis of the specimen

shall be concentric with the axis of the bolt; the head and threaded section of the bolt may be left intact, as in Figures A3.3 and A3.4, or shaped to fit the holders or grips of the testing machine so that the load is applied axially. The gauge length for measuring the elongation shall be four times the diameter of the specimen.

2. For bolts 40 mm ($1^1/_2$ in.) and more in diameter, a standard 12.5-mm ($^1/_2$-in.) round 50-mm (2-in.) gauge length test specimen shall be turned from the bolt, having its axis midway between the center and outside surface of the body of the bolt as shown in Figure A3.5.
3. Machined specimens are to be tested in tension to determine the properties prescribed by the product specifications. The methods of testing and determination of properties shall be in accordance with Section 13 of these methods.



Note: Dimensional equivalent: 25.4 mm = 1 in.

Figure A3.4—Examples of Small-Sized Specimens Proportional to Standard 50-mm (2-in.) Gauge Length Specimen

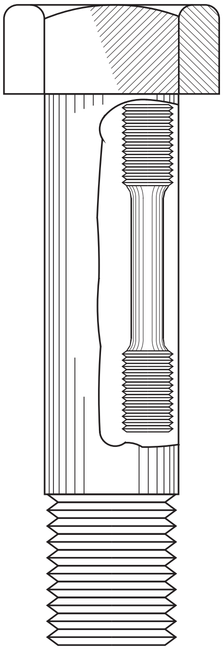

Figure A3.5—Location of Standard Round 50-mm (2-in.) Gauge Length Tension Test Specimen When Turned from Large Size Bolt

A3.3 *Hardness Tests for Externally Threaded Fasteners*:

A3.3.1 When specified, externally threaded fasteners shall be hardness tested. Fasteners with hexagonal or square heads shall be Brinell or Rockwell hardness tested on the side or top of the head. Externally threaded fasteners with other types of heads and those without heads shall be Brinell or Rockwell hardness tested on one end. Due to possible distortion from the Brinell load, care should be taken that this test meets the requirements of Section 16 of these test methods. Where the Brinell hardness test is impractical, the Rockwell hardness test shall be substituted. Rockwell hardness test procedures shall conform to Section 17 of these test methods.

A3.3.2 In cases in which a dispute exists between buyer and seller as to whether externally threaded fasteners meet or exceed the hardness limit of the product specification, for purposes of arbitration, hardness may be taken on two transverse sections through a representative sample fastener selected at random. Hardness readings shall be taken at the locations shown in Figure A3.6. All hardness values must conform to the hardness limit of the product specification for the fasteners represented by the sample to be considered in compliance. This provision for arbitration of a dispute shall not be used to accept clearly rejectable fasteners.

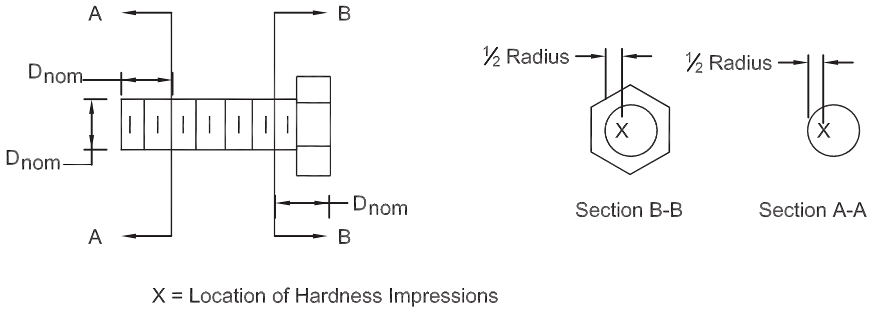

Figure A3.6—Hardness Test Locations for Bolts in a Dispute

A3.4 *Testing of Nuts*:

A3.4.1 *Hardness Test*—Rockwell hardness of nuts shall be determined on the top or bottom face of the nut. Brinell hardness shall be determined on the side of the nuts. Either method may be used at the option of the manufacturer, taking into account the size and grade of the nuts under test. When the standard Brinell hardness test results in deforming the nut, it will be necessary to use a minor load or substitute a Rockwell hardness test.

A4. ROUND WIRE PRODUCTS

A4.1 *Scope*:

A4.1.1 This annex contains testing requirements for round wire products that are specific to the product. The requirements contained in this annex are supplementary to those found in the general section of this specification. In the case of conflict between requirements provided in this annex and those found in the general section of this specification, the requirements of this annex shall prevail. In the case of conflict between requirements provided in this annex and requirements found in product specifications, the requirements in the product specifications shall prevail.

A4.2 *Apparatus*:

A4.2.1 *Gripping Devices*—Grips of either the wedge or snubbing types as shown in Figures A4.1 and A4.2 shall be used (Note A4). When using grips of either type, care shall be taken that the axis of the test specimen is located approximately at the centerline of the head of the testing machine (Note A5). When using wedge grips, the liners used behind the grips shall be of the proper thickness.

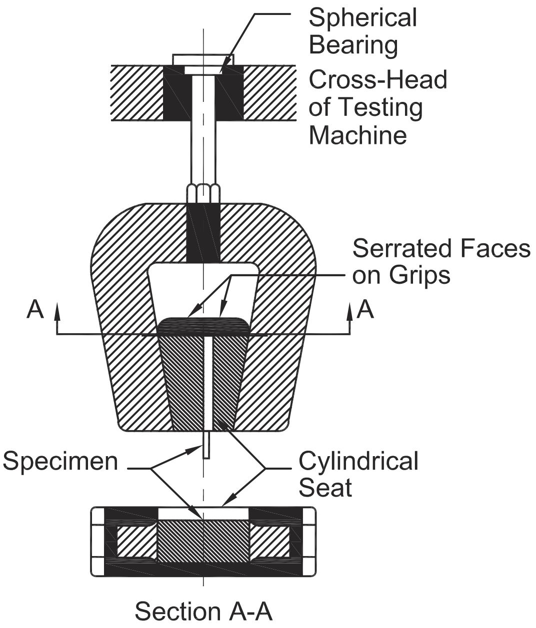

Figure A4.1—Wedge-Type Gripping Device

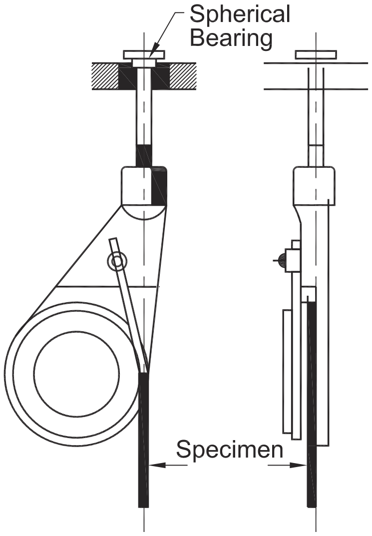

Figure A4.2—Snubbing-Type Gripping Device

Note A4—Testing machines usually are equipped with wedge grips. These wedge grips, irrespective of the type of testing machine, may be referred to as the "usual type" of wedge grips. The use of fine (180 to 240) grit abrasive cloth in the "usual" wedge type grips, with the abrasive contacting the wire specimen, can be helpful in reducing specimen slipping and breakage at the grip edges at tensile loads up to about 454 kg (1000 lb). For tests of specimens of wire that are liable to be cut at the edges by the "usual type" of wedge grips, the snubbing type gripping device has proved satisfactory.

For testing round wire, the use of cylindrical seat in the wedge gripping device is optional.

Note A5—Any defect in a testing machine that may cause non-axial application of load should be corrected.

A4.2.2 *Pointed Micrometer*—A micrometer with a pointed spindle and anvil suitable for reading the dimensions of the wire specimen at the fractured ends to the nearest 0.025 mm (0.001 in.) after breaking the specimen in the testing machine shall be used.

A4.3 *Test Specimens*:

A4.3.1 Test specimens having the full cross-sectional area of the wire they represent shall be used. The standard gauge length of the specimens shall be 254 mm (10 in.). However, if the determination of elongation values is not required, any convenient gauge length is permissible. The total length of the specimens shall be at least equal to the gauge length (254 mm (10 in.)) plus twice the length of wire required for the full use of the grip employed. For example, depending upon the type of testing machine and grips used, the minimum total length of specimen may vary from 360 to 610 mm (14 to 24 in.) for a 254-mm (10-in.) gauge length specimen.

A4.3.2 Any specimen breaking in the grips shall be discarded and a new specimen tested.

A4.4 *Elongation*:

A4.4.1 In determining permanent elongation, the ends of the fractured specimen shall be carefully fitted together and the distance between the gauge marks measured to the nearest 0.25 mm (0.01 in.) with dividers and scale or other suitable device. The elongation is the increase in length of the gauge length, expressed as a percentage of the original gauge length. In recording elongation values, both the percentage increase and the original gauge length shall be given.

A4.4.2 In determining total elongation (elastic plus plastic extension) autographic or extensometer methods may be employed.

A4.4.3 If fracture takes place outside of the middle third of the gauge length, the elongation value obtained may not be representative of the material.

A4.5 *Reduction of Area*:

A4.5.1 The ends of the fractured specimen shall be carefully fitted together and the dimensions of the smallest cross section measured to the nearest 0.025 mm (0.001 in.) with a pointed micrometer. The difference between the area thus found and the area of the original cross section, expressed as a percentage of the original area, is the reduction of area.

A4.5.2 The reduction of area test is not recommended in wire diameters less than 2.34 mm (0.092 in.) due to the difficulties of measuring the reduced cross section.

A4.6 *Rockwell Hardness Test*:

A4.6.1 On heat-treated wire of diameter 2.54 mm (0.100 in.) and larger, the specimen shall be flattened on two parallel sides by grinding before testing. The hardness test is not recommended for any diameter of hard drawn wire or heat-treated wire less than 2.54 mm (0.100 in.) in diameter. For round wire, the tensile strength test is greatly preferred over the hardness test.

A4.7 *Wrap Test*:

A4.7.1 This test is used as a means for testing the ductility of certain kinds of wire.

A4.7.2 The test consists of coiling the wire in a closely spaced helix tightly against a mandrel of a specified diameter for a required number of turns. (Unless otherwise specified, the required number of turns shall be five.) The wrapping may be done by hand or a power device. The wrapping rate may not exceed 15 turns per minute. The mandrel diameter shall be specified in the relevant wire product specification.

A4.7.3 The wire tested shall be considered to have failed if the wire fractures or if any longitudinal or transverse cracks develop that can be seen by the unaided eye after the first complete turn. Wire that fails in the first turn shall be retested, as such fractures may be caused by bending the wire to a radius less than specified when the test starts.

A4.8 *Coiling Test*:

A4.8.1 This test is used to determine whether imperfections are present to the extent that they may cause cracking or splitting during spring coiling and spring extension. A coil of specified length is closed wound on an arbor of a specified diameter. The closed coil is then stretched to a specified permanent increase in length and examined for uniformity of pitch with no splits or fractures. The required arbor diameter, closed coil length, and permanent coil extended length increase may vary with wire diameter, properties, and type.

A5. NOTES ON SIGNIFICANCE OF NOTCHED-BAR IMPACT TESTING

A5.1 *Notch Behavior*:

A5.1.1 The Charpy and Izod type tests bring out notch behavior (brittleness versus ductility) by applying a single overload of stress. The energy values determined are quantitative comparisons on a selected specimen but cannot be converted into energy values that would serve for engineering design calculations. The notch behavior indicated in an individual test applies only to the specimen size, notch geometry, and testing conditions involved and cannot be generalized to other sizes of specimens and conditions.

A5.1.2 The notch behavior of the face-centered cubic metals and alloys, a large group of nonferrous materials and the austenitic steels, can be judged from their common tensile properties. If they are brittle in tension, they will be brittle when notched, while if they are ductile in tension, they will be ductile when notched, except for unusually sharp or deep notches (much more severe than the standard Charpy or Izod specimens). Even low temperatures do not alter this characteristic of these materials. In contrast, the behavior of the ferritic steels under notch conditions cannot be predicted from their properties as revealed by the tension test. For the study of these materials, the Charpy and Izod type tests are accordingly very useful. Some metals that display normal ductility in the tension test may nevertheless break in brittle fashion when tested or when used in the notched condition. Notched conditions include restraints to deformation in directions perpendicular to the major stress, or multiaxial stresses, and stress concentrations. It is in this field that the Charpy and Izod tests prove useful for determining the susceptibility of a steel to notch-brittle behavior, though they cannot be directly used to appraise the serviceability of a structure.

A5.1.3 The testing machine itself must be sufficiently rigid or tests on high-strength, low-energy materials will result in excessive elastic energy losses either upward through the pendulum shaft or downward through the base of the machine. If the anvil supports the pendulum striking edge, or the machine foundation bolts are not securely fastened, tests on ductile materials in the range of 108 J (80 ft·lbf) may actually indicate values in excess of 122 to 136 J (90 to 100 ft·lbf).

A5.2 *Notch Effect*:

A5.2.1 The notch results in a combination of multiaxial stresses associated with restraints to deformation in directions perpendicular to the major stress, and a stress concentration at the base of the notch.

A severely notched condition is generally not desirable, and it becomes of real concern in those cases in which it initiates a sudden and complete failure of the brittle type. Some metals can be deformed in a ductile manner even down to the low temperatures of liquid air, while others may crack. This difference in behavior can be best understood by considering the cohesive strength of a material (or the property that holds it together) and its relation to the yield point. In cases of brittle fracture, the cohesive strength is exceeded before significant plastic deformation occurs and the fracture appears crystalline. In cases of the ductile or shear type of failure, considerable deformation precedes the final fracture and the broken surface appears fibrous instead of crystalline. In intermediate cases, the fracture comes after a moderate amount of deformation and is part crystalline and part fibrous in appearance.

A5.2.2 When a notched bar is loaded, there is a normal stress across the base of the notch that tends to initiate fracture. The property that keeps it from cleaving, or holds it together, is the "cohesive strength." The bar fractures when the normal stress exceeds the cohesive strength. When this occurs without the bar deforming it, this is the condition for brittle fracture.

A5.2.3 In testing, though not in service, because of side effects, it happens more commonly that plastic deformation precedes fracture. In addition to the normal stress, the applied load also sets up shear stresses, which are about 45 degrees to the normal stress. The elastic behavior terminates as soon as the shear stress exceeds the shear strength of the material and deformation or plastic yielding sets in. This is the condition for ductile failure.

A5.2.4 This behavior, whether brittle or ductile, depends on whether the normal stress exceeds the cohesive strength before the shear stress exceeds the shear strength. Several important facts of notch behavior follow from this. If the notch is made sharper or more drastic, the normal stress at the root of the notch will be increased in relation to the shear stress and the bar will be more prone to brittle fracture. (See Table A5.1.) Also, as the speed of deformation increases, the shear strength increases and the likelihood of brittle fracture increases. On the other hand, by raising the temperature, leaving the notch and the speed of deformation the same, the shear strength is lowered and ductile behavior is promoted, leading to shear failure.

Table A5.1—Effect of Varying Notch Dimensions on Standard Specimens

	High-Energy Specimens, J (ft·lbf)	High-Energy Specimens, J (ft·lbf)	Low-Energy Specimens, J (ft·lbf)
Specimen with standard dimensions	103.0 ± 5.2 (76.0 ± 3.8)	60.3 ± 3.0 (44.5 ± 2.2)	16.9 ± 1.4 (12.5 ± 1.0)
Depth of notch, 2.13 mm (0.084 in.)[a]	97.9 (72.2)	56.0 (41.3)	15.5 (11.4)
Depth of notch, 2.04 mm (0.0805 in.)[a]	101.8 (75.1)	57.2 (42.2)	16.8 (12.4)
Depth of notch, 1.97 mm (0.0775 in.)[a]	104.1 (76.8)	61.4 (45.3)	17.2 (12.7)
Depth of notch, 1.88 mm (0.074 in.)[a]	107.9 (79.6)	62.4 (46.0)	17.3 (12.8)
Radius at base of notch, 0.13 mm (0.005 in.)[b]	98.0 (72.3)	56.5 (41.7)	14.6 (10.8)
Radius at base of notch, 0.38 mm (0.015 in.)[b]	108.5 (80.0)	64.3 (47.4)	21.4 (15.8)

[a] Standard 2.00 ± 0.05 mm (0.079 ± 0.002 in.).

[b] Standard 0.25 ± 0.02 mm (0.010 ± 0.001 in.).

A5.2.5 Variations in notch dimensions will seriously affect the results of the tests. Tests on E4340 steel specimens have shown the effect of dimensional variations on Charpy results. (See Table A5.1.)[3]

A5.3 *Size Effect*:

A5.3.1 Increasing either the width or the depth of the specimen tends to increase the volume of metal subject to distortion, and by this factor, tends to increase the energy absorption when breaking the specimen. However, any increase in size, particularly in width, also tends to increase the degree of restraint and, by tending to induce brittle fracture, may decrease the amount of energy absorbed. Where a standard-sized specimen is on the verge of brittle fracture, this is particularly true, and a double-width specimen may actually require less energy for rupture than one of standard width.

A5.3.2 In studies of such effects where the size of the material precludes the use of the standard specimen, as for example when the material is 6-mm ($^1/_4$-in.) plate, sub-sized specimens are necessarily used. Such specimens (Figure A3.1 of T 266) are based on the Type A specimen of Figure 1 of T 266.

A5.3.3 General correlation between the energy values obtained with specimens of different size or shape is not feasible, but limited correlations may be established for specification purposes on the basis of special studies of particular materials and particular specimens. On the other hand, in a study of the relative effect of process variations, evaluation by use of some arbitrarily selected specimen with some chosen notch, in most instances, will place the methods in their proper order.

A5.4 *Effects of Testing Conditions*:

A5.4.1 The testing conditions also affect the notch behavior. So pronounced is the effect of temperature on the behavior of steel when notched, the comparisons are frequently made by examining specimen fractures and by plotting energy value and fracture appearance versus temperature from tests of notched bars at a series of temperatures. When the test temperature has been carried low enough to start cleavage fracture, there may be an extremely sharp drop in impact value or there may be a relatively gradual falling off toward the lower temperatures. This drop in energy value starts when a specimen begins to exhibit some crystalline appearance in the fracture. The transition temperature at which this embrittling effect takes place varies considerably with the size of the part or test specimen and with the notch geometry.

A5.4.2 Some of the many definitions of transition temperature currently being used are: (1) the lowest temperature at which the specimen exhibits 100 percent fibrous fracture, (2) the temperature where the fracture shows a 50 percent crystalline and a 50 percent fibrous appearance, (3) the temperature corresponding to the energy value 50 percent of the difference between values obtained at 100 percent and zero percent fibrous fracture, and (4) the temperature corresponding to a specific energy value.

A5.4.3 A problem peculiar to Charpy type tests occurs when high-strength, low-energy specimens are tested at low temperatures. These specimens may not leave the machine in the direction of the pendulum swing but rather in a sidewise direction. To ensure that the broken halves of the specimens do not rebound off some component of the machine and contact the pendulum before it completes its swing, modifications may be necessary in older model machines. These modifications differ with machine design. Nevertheless, the basic problem is the same in that provisions must be made to prevent rebounding of the fractured specimens into any part of the swinging pendulum. Where design permits, the broken specimens may be deflected out of the sides of the machine and yet in other designs it may be necessary to contain the broken specimens within a certain area until the pendulum passes through the anvils. Some low-energy high-strength steel specimens leave impact machines at speeds in excess of 15 m/s (50 ft/s) although they were struck by a pendulum traveling at speeds approximately 5 m/s (17 ft/s). If the force exerted on the pendulum by the broken specimens is sufficient, the pendulum will slow down and erroneously high-energy values will be recorded. This problem accounts for many of the inconsistencies in Charpy results reported by various investigators within the 14- to 34-J (10- to 25-ft·lbf) range. The Apparatus Section (the paragraph regarding Specimen Clearance) of T 266 discusses the two basic machine designs and a modification found to be satisfactory in minimizing jamming.

A5.5 *Velocity of Straining*:

A5.5.1 Velocity of straining is likewise a variable that affects the notch behavior of steel. The impact test shows somewhat higher energy absorption values than the static tests above the transition temperature and yet, in some instances, the reverse is true below the transition temperature.

A5.6 *Correlation with Service*:

A5.6.1 While Charpy or Izod tests may not directly predict the ductile or brittle behavior of steel as commonly used in large masses or as components of large structures, these tests can be used as acceptance tests of identity for different lots of the same steel or in choosing between different steels, when correlation with reliable service behavior has been established. It may be necessary to make the tests at properly chosen temperatures other than room temperature. In this, the service temperature or the transition temperature of full-scale specimens does not give the desired transition temperatures for Charpy or Izod tests since the size and notch geometry may be so different. Chemical analysis, tension, and hardness tests may not indicate the influence of some of the important processing factors that affect susceptibility to brittle fracture, nor do they comprehend the effect of low temperatures in inducing brittle behavior.

A6. PROCEDURE FOR CONVERTING PERCENTAGE ELONGATION OF A STANDARD ROUND TENSION TEST SPECIMEN TO EQUIVALENT PERCENTAGE ELONGATION OF A STANDARD FLAT SPECIMEN

A6.1 *Scope*:

A6.1.1 This method specifies a procedure for converting percentage elongation after fracture obtained in a standard 12.5-mm (0.500-in.) diameter by 50-mm (2-in.) gauge length test specimen to standard flat test specimens 12.5 mm by 50 mm ($^1/_2$ in. by 2 in.) and 40 mm by 200 mm ($1^1/_2$ in. by 8 in.).

A6.2 *Basic Equation*:

A6.2.1 The conversion data in this method are based on an equation by Bertella,[4] and used by Oliver[5] and others. The relationship between elongations in the standard 12.5-mm (0.500-in.) diameter by 50-mm (2.0-in.) test specimen and other standard specimens can be calculated as follows:

$$e = e_o\left[4.47\left(\sqrt{\mathrm{A}}\right)/\mathrm{L}\right]^a \qquad (A6.1)$$

where:

e_o = percentage elongation after fracture on a standard test specimen having a 50-mm (2-in.) gauge length and a 12.5-mm (0.5-in.) diameter,

e = percentage elongation after fracture on a standard test specimen having a gauge length L and a cross-sectional area A, and

a = constant characteristic of the test material.

A6.3 *Application*:

A6.3.1 In applying the above equation, the constant a is characteristic of the test material. The value $a = 0.4$ has been found to give satisfactory conversions for carbon, carbon-manganese, molybdenum, and chromium-molybdenum steels within the tensile strength range of 275 to 585 MPa (40000 to 85000 psi) and in the hot-rolled, in the hot-rolled and normalized, or in the annealed condition, with or without tempering. Note that the cold-reduced and quenched and the tempered states are excluded. For annealed austenitic stainless steels, the value $a = 0.127$ has been found to give satisfactory conversions.

A6.3.2 Table 19 has been calculated taking $a = 0.4$, with the standard 12.5-mm (0.500-in.) diameter by 50-mm (2-in.) gauge length test specimen as the reference specimen. In the case of the sub-sized specimens 8.89 mm (0.350 in.) in diameter by 35.6-mm (1.4-in.) gauge length, and 6.35-mm (0.250-in.) diameter by 25-mm (1.0-in.) gauge length, the factor in the equation is 4.51 instead of

4.47. The small error introduced by using Table 19 (20) for the sub-sized specimens may be neglected. Table 21 (22) for annealed austenitic steels has been calculated taking $a = 0.127$, with the standard 12.5-mm (0.5-in.) diameter by 50-mm (2-in.) gauge length test specimen as the reference specimen.

A6.3.3 Elongation given for a standard 12.5-mm (0.5-in.) diameter by 50-mm (2-in.) gauge length specimen may be converted to elongation for 12.5-mm by 50-mm ($^1/_2$-in. by 2-in.) or 40-mm by 200-mm ($1^1/_2$-in. by 8-in.) flat specimens by multiplying by the indicated factor in Tables A6.1, A6.2, A6.3, and A6.4.

Table A6.1—*Carbon and Alloy Steels*—Material Constant *a* = 0.4 Multiplication Factors for Converting Percent Elongation from 12.5-mm Diameter by 50-mm Gauge Length Standard Tension Test Specimen to Standard 12.5-mm by 50-mm Flat Specimens and 40-mm by 200-mm Flat Specimens

A6.3.4 These elongation conversions shall not be used where the width-to-thickness ratio of the test piece exceeds 20, as in sheet specimens under 0.635 mm (0.025 in.) in thickness.

A6.3.5 While the conversions are considered to be reliable within the stated limitations and may generally be used in specification writing where it is desirable to show equivalent elongation requirements for the several standard AASHTO tension specimens covered in Method T 244, consideration must be given to the metallurgical effects dependent on the thickness of the material as processed.

A7. METHOD OF TESTING MULTI-WIRE STRAND FOR PRESTRESSED CONCRETE

A7.1 *Scope*:

A7.1.1 This method provides procedures for the tension testing of multi-wire strand for prestressed concrete. This method is intended for use in evaluating the strand properties prescribed in specifications for "prestressing steel strands."

A7.2 *General Precaution*:

A7.2.1 Premature failure of the test specimens may result if there is any appreciable notching, cutting, or bending of the specimen by the gripping devices of the testing machine.

A7.2.2 Errors in testing may result if the seven wires constituting the strand are not loaded uniformly.

A7.2.3 The mechanical properties of the strand may be materially affected by excessive heating during specimen preparation.

A7.2.4 These difficulties may be minimized by following the suggested methods of gripping described in Section A7.3.

A7.3 *Gripping Devices*:

A7.3.1 The true mechanical properties of the strand are determined by a test in which fracture of the specimen occurs in the free span between the jaws of the testing machine. Therefore, it is desirable to establish a test procedure with suitable apparatus that will consistently produce such results. Due to inherent physical characteristics of individual machines, it is not practical to recommend a universal gripping procedure that is suitable for all testing machines. Therefore, it is necessary to determine which of the methods of gripping described in Section A7.3.2 to A7.3.8 is most suitable for the testing equipment available.

A7.3.2 *Standard V-Grips with Serrated Teeth (Note A6)*:

A7.3.3 *Standard V-Grips with Serrated Teeth (Note A6), Using Cushioning Material*—In this method, some material is placed between the grips and the specimen to minimize the notching effect of the teeth. Among the materials that have been used are lead foil, aluminum foil, carborundum cloth, brass shims, etc. The type and thickness of material required are dependent on the shape, condition, and coarseness of the teeth.

A7.3.4 *Standard V-Grips with Serrated Teeth (Note A6), Using Special Preparation of the Gripped Portions of the Specimen*—One of the methods used is tinning, in which the gripped portions are cleaned, fluxed, and coated by multiple dips in molten tin alloy held just above the melting point. Another method of preparation is encasing the gripped portions in metal tubing or flexible conduit, using epoxy resin as the bonding agent. The encased portion should be approximately twice the length of lay of the strand.

A7.3.5 *Special Grips with Smooth, Semi-Cylindrical Grooves (Note A7)*—The grooves and the gripped portions of the specimen are coated with an abrasive slurry, which holds the specimen in the smooth grooves, preventing slippage. The slurry consists of an abrasive, such as Grade 3-F aluminum oxide, and a carrier, such as water or glycerin.

A7.3.6 *Standard Sockets of the Type Used for Wire Rope*—The gripped portions of the specimen are anchored in the sockets with zinc. The special procedures for socketing usually employed in the wire rope industry must be followed.

A7.3.7 *Dead-End Eye Splices*—These devices are available in sizes designed to fit each size of strand to be tested.

A7.3.8 *Chucking Devices*—Use of chucking devices of the type generally employed for applying tension to strands in casting beds is not recommended for testing purposes.

Note A6—The number of teeth should be approximately 600 to 1200 per meter (15 to 30 per inch) and the minimum effective gripping length should be approximately 100 mm (4 in.).

Note A7—The radius of curvature of the grooves is approximately the same as the radius of the strand being tested, and is located 0.8 mm ($^1/_{32}$ in.) above the flat face of the grip. This prevents the two grips from closing tightly when the specimen is in place.

A7.4 *Specimen Preparation*:

A7.4.1 If the molten-metal temperatures employed during hot-dip tinning or socketing with metallic material are too high, more than approximately 370ºC (700ºF), the specimen may be heat affected, with a subsequent loss of strength and ductility. Careful temperature controls should be maintained if such methods of specimen preparation are used.

A7.5 *Procedure*:

A7.5.1 *Yield Strength*—For determining the yield strength use a Class B-1 extensometer (Note A8) as described in ASTM E 83. Apply an initial load of 10 percent of the expected minimum breaking strength to the specimen, then attach the extensometer and adjust it to a reading of 1 mm/m (0.001 in./in.) of gauge length. Then increase the load until the extensometer indicates an extension of 1 percent. Record the load for this extension as the yield strength. The extensometer may be removed from the specimen after the yield strength has been determined.

A7.5.2 *Elongation*—For determining the elongation, use a Class D extensometer (Note A8), as described in ASTM E 83, having a gauge length of not less than 600 mm (24 in.) (Note A9). Apply an initial load of 10 percent of the required minimum breaking strength to the specimen, then attach the extensometer (Note A8) and adjust it to a zero reading. The extensometer may be removed from the specimen prior to rupture after the specified minimum elongation has been exceeded. It is not necessary to determine the final elongation value.

A7.5.3 *Breaking Strength*—Determine the maximum load at which one or more wires of the strand are fractured. Record this load as the breaking strength of the strand.

Note A8—The yield strength extensometer and the elongation extensometer may be the same instrument or two separate instruments. Two separate instruments are advisable since the more sensitive yield strength extensometer, which could be damaged when the strand fractures, may be removed following the determination of yield strength. The elongation extensometer may be constructed with less sensitive parts or be constructed in such a way that little damage would result if fracture occurs while the extensometer is attached to the specimen.

Note A9—Specimens that break outside of the extensometer or in the jaws and yet meet the minimum specified values are considered as meeting the mechanical property requirements of the product specification, regardless of what procedure of gripping has been used. Specimens that break outside of the extensometer or in the jaws and do not meet the minimum specified values are subject to retest. Specimens that break between the jaws of the extensometer and do not meet the minimum specified values are subject to retest as provided in the applicable specification.

A8. ROUNDING OF TEST DATA

A8.1 *Rounding*:

A8.1.1 An observed value or a calculated value shall be rounded off in accordance with the applicable product specification. In the absence of a specified procedure, the rounding-off method of E 29 shall be used.

A8.1.1.1 Values shall be rounded up or rounded down as determined by the rules of E 29.

A8.1.1.2 In the special case of rounding the number "5" when no additional numbers other than "0" follow the "5", rounding shall be done in the direction of the specification limits if following E 29 would cause rejection of material.

A8.1.2 Recommended levels for rounding reported values of test data are given in Table A8.1. These values are designed to provide uniformity in reporting and data storage, and should be used in all cases except where they conflict with specific requirements of a product specification.

Table A8.1—Recommended Values for Rounding Test Data

Test Quantity	Test Data Range	Rounded Value[a]
Yield Point, Yield Strength, Tensile Strength	Up to 500 MPa	1 MPa
	500 to 1000 MPa	5 MPa
	1000 MPa and above	10 MPa
	Up to 50 000 psi	100 psi
	50 000 to 100 000 psi	500 psi
	100 000 psi and above	1000 psi
Elongation	0 to 10 percent	0.5 percent
	10 percent and above	1 percent
Reduction of Area	0 to 10 percent	0.5 percent
	10 percent and above	1 percent
Impact Energy	0 to 325 J (0 to 240 ft·lbf)	1 J (1 ft·lbf)[b]
Brinnell Hardness	All values	Tabular Value[c]
Rockwell Hardness	All scales	1 Rockwell Number

[a] Round test data to the nearest integral multiple of the values in this column. If the data value is exactly midway between two rounded values, round to the higher value.

[b] These units are not equivalent but the rounding occurs in the same numerical ranges for each (1.356 J = 1 ft·lbf).

[c] Round the mean diameter of the Brinell impression to the nearest 0.05 mm and report the corresponding Brinell hardness number read from the table without further rounding.

Note A10—To minimize cumulative errors, whenever possible, values should be carried to at least one figure beyond that of the final (rounded) value during intervening calculations (such as calculation of stress from load and area measurements) with rounding occurring as the final operation. The precision may be less than that implied by the number of significant figures.

A9. METHODS FOR TESTING STEEL REINFORCING BARS

A9.1 *Scope*:

A9.1.1 This annex contains testing requirements for steel reinforcing bars that are specific to the product. The requirements contained in this annex are supplementary to those found in the general section of this specification. In the case of conflict between requirements provided in this annex and those found in the general section of this specification, the requirements of this annex shall prevail. In the case of conflict between requirements provided in this annex and requirements found in product specifications, the requirements in the product specifications shall prevail.

A9.2 *Test Specimens*:

A9.2.1 All test specimens shall be the full section of the bar as rolled.

A9.3 *Tension Testing*:

A9.3.1 *Test Specimen*—Specimens for tension tests shall be long enough to provide for a 200-mm (8-in.) gauge length, a distance of at least two bar diameters between each gauge mark and the grips, plus sufficient additional length to fill the grips completely, leaving some excess length protruding beyond each grip.

A9.3.2 *Gripping Device*—The grips shall be shimmed so that no more than 13 mm ($^1/_2$ in.) of a grip protrudes from the head of the testing machine.

A9.3.3 *Gauge Marks*—The 200-mm (8-in.) gauge length shall be marked on the specimen using a preset 200-mm (8-in.) punch or, alternately, may be punch marked every 50 mm (2 in.) along the 200-mm (8-in.) gauge length, on one of the longitudinal ribs, if present, or in clear spaces of the deformation pattern. The punch marks shall not be put on a transverse deformation. Light punch marks are desirable because deep marks severely indent the bar and may affect the results. A bullet-nose punch is desirable.

A9.3.4 The yield strength or yield point shall be determined by one of the following methods:

A9.3.4.1 Extension under load using an autographic diagram method or an extensometer as described in Sections 13.1.2 and 13.1.3.

A9.3.4.2 By the drop of the beam or halt in the gauge of the testing machine as described in Section 13.1.1 where the steel tested has a sharp-kneed or well-defined type of yield point.

A9.3.5 The unit stress determinations for yield and tensile strength on full-sized specimens shall be based on the nominal bar area.

A9.4 *Bend Testing*:

A9.4.1 Bend tests shall be made on specimens of sufficient length to ensure free bending and with apparatus that provides:

A9.4.1.1 Continuous and uniform application of force throughout the duration of the bending operation,

A9.4.1.2 Unrestricted movement of the specimen at points of contact with the apparatus and bending around a pin free to rotate, and

A9.4.1.3 Close wrapping of the specimen around the pin during the bending operation.

A9.4.2 Other acceptable, more severe methods of bend testing, such as placing a specimen across two pins free to rotate and applying the bending force with a fix pin, may be used.

A9.4.3 When retesting is permitted by the product specification, the following shall apply:

A9.4.3.1 Sections of bar containing identifying roll marking shall not be used.

A9.4.3.2 Bars shall be so placed that longitudinal ribs lie in a plane at right angles to the plane of bending.

A10. PROCEDURE FOR USE AND CONTROL OF HEAT-CYCLE SIMULATION

A10.1 *Purpose*:

A10.1.1 To ensure consistent and reproducible heat treatments of production forgings and the test specimens that represent them when the practice of heat-cycle simulation is used.

A10.2 *Scope*:

A10.2.1 Generation and documentation of actual production time–temperature curves (master charts).

A10.2.2 Controls for duplicating the master cycle during heat-treatment of production forgings. (Heat-treating within the essential variables established during Section A10.1.).

A10.2.3 Preparation of program charts for the simulator unit.

A10.2.4 Monitoring and inspection of the simulated cycle within the limits established by the ASME Code.

A10.2.5 Documentation and storage of all controls, inspections, charts, and curves.

A10.3 *Referenced Documents*:

A10.3.1 *ASME Standards*:[2]

- ASME Boiler and Pressure Vessel Code Section III, latest edition.
- ASME Boiler and Pressure Vessel Code Section VIII, Division 2, latest edition.

A10.4 *Terminology*:

A10.4.1 *Definitions*:

A10.4.1.1 *master chart*—a record of the heat treatment received from a forging essentially identical to the production forgings that it will represent. It is a chart of time and temperature showing the output from thermocouples embedded in the forging at the designated test immersion and test location or locations.

A10.4.1.2 *program chart*—the metalized sheet used to program the simulator unit. Time–temperature data from the master chart are manually transferred to the program chart.

A10.4.1.3 *simulator chart*—a record of the heat-treatment that a test specimen had received in the simulator unit. It is a chart of time and temperature and can be compared directly to the master chart for accuracy of duplication.

A10.4.1.4 *simulator cycle*—one continuous heat-treatment of a set of specimens in the simulator unit. The cycle includes heating from ambient, holding at temperature, and cooling. For example, a simulated austenitize and quench of a set of specimens would be one cycle; a simulated temper of the same specimens would be another cycle.

A10.5 *Procedure*:

A10.5.1 *Production Master Charts*:

A10.5.1.1 Thermocouples shall be embedded in each forging from which a master chart is obtained. Temperature shall be monitored by a recorder with resolution sufficient to clearly define all aspects of the heating, holding, and cooling process. All charts are to be clearly identified with all pertinent information and identification required for maintaining permanent records.

A10.5.1.2 Thermocouples shall be embedded 180 degrees apart if the material specification requires test locations 180 degrees apart.

A10.5.1.3 One master chart (or two, if required in accordance with Section A10.5 3.1) shall be produced to represent essentially identical forgings (same size and shape). Any change in size or geometry (exceeding rough machining tolerances) of a forging will necessitate that a new master cooling curve be developed.

A10.5.1.4 If more than one curve is required per master forging (180 degrees apart) and a difference in cooling rate is achieved, then the most conservative curve shall be used as the master curve.

A10.5.2 *Reproducibility of Heat Treatment Parameters on Production Forgings*:

A10.5.2.1 All information pertaining to the quench and temper of the master forging shall be recorded on an appropriate permanent record, similar to the one shown in Table A10.1.

A10.5.2.2 All information pertaining to the quench and temper of the production forgings shall be appropriately recorded, preferably on a form similar to that used in Section A10.5.2.1. Quench records of production forgings shall be retained for future reference. The quench and temper record of the master forging shall be retained as a permanent record.

A10.5.2.3 A copy of the master forging record shall be stored with the heat-treatment record of the production forging.

A10.5.2.4 The essential variables, as set forth on the heat-treat record, shall be controlled within the given parameters on the production forging.

A10.5.2.5 The temperature of the quenching medium prior to quenching each production forging shall be equal to or lower than the temperature of the quenching medium prior to quenching the master forging.

Table A10.1—Heat-Treat Record—Essential Variables

	Master Forging	Production Forging 1	Production Forging 2	Production Forging 3	Production Forging 4	Production Forging 5
Program chart number						
Time at temperature and actual temperature of heat treatment						
Method of cooling						
Forging thickness						
Thermocouple immersion						
Beneath buffer (yes/no)						
Forging number						
Product						
Material						
Thermocouple location—zero degrees						
Thermocouple location—180 degrees						
Quench tank number						
Data of heat treatment						
Furnace number						
Cycle number						
Heat-treater						
Starting quench medium temperature						
Time from furnace to quench						
Heating rate above 538˚C (1000˚F)						
Temperature upon removal from quench after 5 minutes						
Orientation of forging in quench						

A10.5.2.6 The time elapsed from opening the furnace door to quench for the production forging shall not exceed that elapsed for the master forging.

A10.5.2.7 If the time parameter is exceeded in opening the furnace door to beginning of quench, the forging shall be placed back into the furnace and brought back up to equalization temperature.

A10.5.2.8 All forgings represented by the same master forging shall be quenched with like orientation to the surface of the quench bath.

A10.5.2.9 All production forgings shall be quenched in the same quench tank, with the same agitation as the master forging.

A10.5.2.10 *Uniformity of Heat-Treat Parameters*—(1) The difference in actual heat-treating temperature between production forgings and the master forging used to establish the simulator cycle for them shall not exceed ±14ºC (±25ºF) for the quench cycle. (2) The tempering temperature of the production forgings shall not fall below the actual tempering temperature of the master forging. (3) At least one contact surface thermocouple shall be placed on each forging in a production load. Temperature shall be recorded for all surface thermocouples on a Time–Temperature Recorder and such records shall be retained as permanent documentation.

A10.5.3 *Heat-Cycle Simulation*:

A10.5.3.1 Program charts shall be made from the data recorded on the master chart. All test specimens shall be given the same heating rate above the AC1, the same holding time, and the same cooling rate as the production forgings.

A10.5.3.2 The heating cycle above the AC1, a portion of the holding cycle, and the cooling portion of the master chart shall be duplicated and the allowable limits on temperature and time, as specified in (1)–(3), shall be established for verification of the adequacy of the simulated heat treatment.

1. *Heat-Cycle Simulation of Test Coupon Heat Treatment for Quenched and Tempered Forgings and Bars*—If cooling rate data for the forgings and bars and cooling rate control devices for the test specimens are available, the test specimens may be heat-treated in the device.
2. The test coupons shall be heated to substantially the same maximum temperature as the forgings or bars. The test coupons shall be cooled at a rate similar to and no faster than the cooling rate representative of the test locations and shall be within 14ºC (25ºF) and 20 seconds at all temperatures after cooling begins. The test coupons shall be subsequently heat-treated in accordance with the thermal treatments below the critical temperature, including tempering and simulated postweld heat-treatment.
3. *Simulated Postweld Heat-Treatment of Test Specimens (for ferritic steel forgings and bars)*—Except for carbon steel (P Number 1, Section 1X of the Code) forgings and bars with a nominal thickness or diameter of 50 mm (2 in.) or less, the test specimens shall be given a heat-treatment to simulate any thermal treatments below the critical temperature that the forgings and bars may receive during fabrication. The simulated heat-treatment shall utilize temperatures, times, and cooling rates as specified on the order. The total time at temperature(s) for the test material shall be at least 80 percent of the total time at temperature(s) to which the forgings and bars are subjected during postweld heat-treatment. The total time at temperature(s) for the test specimens may be performed in a single cycle.

A10.5.3.3 Prior to heat-treatment in the simulator unit, test specimens shall be machined to standard sizes that have been determined to allow adequately for subsequent removal of decarb and oxidation.

A10.5.3.4 At least one thermocouple per specimen shall be used for continuous recording of temperature on an independent external temperature-monitoring source. Due to the sensitivity and design peculiarities of the heating chamber of certain equipment, it is mandatory that the hot junctions of control and monitoring thermocouples always be placed in the same relative position with respect to the heating source (generally infrared lamps).

A10.5.3.5 Each individual specimen shall be identified, and such identification shall be clearly shown on the simulator chart and simulator cycle record.

A10.5.3.6 The simulator chart shall be compared to the master chart for accurate reproduction of simulated quench in accordance with Section A10.5.3.2(1). If any one specimen is not heat-treated within the acceptable limits of temperature and time, such specimen shall be discarded and replaced by a newly machined specimen. Documentation of such action and reasons for deviation from the master chart shall be shown on the simulator chart and on the corresponding nonconformance report.

A10.5.4 *Reheat Treatment and Retesting*:

A10.5.4.1 In the event of a test failure, retesting shall be handled in accordance with rules set forth by the material specification.

A10.5.4.2 If retesting is permissible, a new test specimen shall be heat-treated the same as previously. The production forging that it represents will have received the same heat-treatment. If the test passes, the forging shall be acceptable. If it fails, the forging shall be rejected or shall be subject to reheat treatment if permissible.

A10.5.4.3 If reheat treatment is permissible, proceed as follows: (1) Reheat treatment same as original heat treatment (time, temperature, cooling rate): Using new test specimens from an area as close as possible to the original specimens, repeat the austenitize and quench cycles twice, followed by the tempering cycle (double quench and temper). The production forging shall be given the identical double quench and temper as its test specimens above. (2) Reheat treatment using a new heat-treatment practice. Any change in time, temperature, or cooling rate shall constitute a new heat-treatment practice. A new master curve shall be produced and the simulation and testing shall proceed as originally set forth.

A10.5.4.4 In summation, each test specimen and its corresponding forging shall receive identical heat-treatment or repeated heat-treatment; otherwise the testing shall be invalid.

A10.5.5 *Storage, Recall, and Documentation of Heat-Cycle Simulation Data*—All records pertaining to heat-cycle simulation shall be maintained and held for a period of 10 years or as designated by the customer. Information shall be so organized that all practices can be verified by adequate documented records.

---

[1] This test method agrees technically with ASTM A 370-09a, except for minor differences.

Standard Method of Test for

Notched Bar Impact Testing of Metallic Materials (CVN)

AASHTO Designation: T 266-08
ASTM Designation: E 23-07a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Notched Bar Impact Testing of Metallic Materials (CVN)

AASHTO Designation: T 266-08
ASTM Designation: E 23-07a

AASHTO T 266-08 is identical to ASTM E 23-07a except that the Izod Method is not included.

Standard Method of Test for

Non-Instrumental Determination of Metallic Zinc in Zinc-Rich Primers

AASHTO Designation: T 337-09[1]

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Non-Instrumental Determination of Metallic Zinc in Zinc-Rich Primers

AASHTO Designation: T 337-09[1]

1. SCOPE

1.1. This test method determines the amount of metallic zinc in the dried paint film (nonvolatile matter) of inorganic zinc-rich and organic zinc-rich primers.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- D 521, Standard Test Methods for Chemical Analysis of Zinc Dust (Metallic Zinc Powder)
- D 2369, Standard Test Method for Volatile Content of Coatings
- D 2371, Standard Test Method for Pigment Content of Solvent-Reducible Paints

3. PROCEDURES

3.1. *Procedure A—Individual Components*:

Note 1—Procedure A does not purport to determine the percentage of metallic zinc in the total pigment. Procedure A does not take into account any additional pigmentation that may be present in the mixed primer.

3.1.1. Prepare a sample of the liquid primer by mixing weighed amounts of the zinc-dust pigment component with weighed amounts of the liquid component(s), using mix ratios (by mass) supplied by the manufacturer. The quantity of mixed primer shall be a minimum of 100 g, with the mass of each component determined to the nearest 0.1 g.

3.1.2. Determine the nonvolatile matter percentage by mass of the mixed primer in accordance with ASTM D 2369.

Note 2—It is extremely important to keep the mixed primer sample well agitated immediately prior to performing the ASTM D 2369 or D 2371 test method so as not to allow the zinc dust to appreciably settle out of the sample.

3.1.3. Determine the percentage of metallic zinc in the initial, dry zinc-dust pigment component in accordance with ASTM D 521.

3.2. *Procedure B—Premixed Components*:

3.2.1. Prepare a sample of the liquid primer by mixing weighed amounts of the liquid components (the zinc-dust pigment will be supplied incorporated in one of the liquid components) using the mix ratios by mass supplied by the manufacturer. The quantity of mixed primer shall be a minimum of 100 g, with the mass of each component determined to the nearest 0.1 g.

3.2.2. Determine the nonvolatile matter percentage by mass of the mixed primer in accordance with ASTM D 2369. See Note 2.

3.2.3. Determine the pigment content percentage by mass of the mixed primer in accordance with ASTM D 2371 (high-speed centrifugation). See Note 2.

3.2.4. Determine the metallic zinc percentage by mass of the pigment in accordance with ASTM D 521 using the extracted dried pigment obtained from the ASTM D 2371 test method.

---

4. CALCULATIONS

4.1. *Procedure A Calculations*:

4.1.1. Calculate the percentage of volatile matter, V, in the mixed primer as follows (ASTM D 2369):

$$V_A = 100 - [((W_2 - W_1)/S_A) \times 100] \qquad (1)$$

where:

V_A = percentage of volatiles (first determination);

W_1 = weight of dish;

W_2 = weight of dish plus specimen after heating;

S_A = specimen weight; and

V_B = percentage of volatiles (duplicate determination, calculated in the same manner as V_A).

$$V = (V_A + V_B)/2$$

4.1.2. Calculate the percentage of nonvolatile matter, N, in the mixed primer as follows (ASTM D 2369):

$$N = (N_A + N_B)/2 \qquad (2)$$

where:

N_A = $100 - V_A$; and

N_B = $100 - V_B$.

4.1.3. Calculate the percentage of zinc dust by mass of the mixed primer, Zn_{PT}, as follows:

$$Zn_{PT} = (Z/(Z + L)) \times 100 \qquad (3)$$

where:

Z = mass of zinc-dust component; and

L = mass of liquid component(s).

4.1.4. Calculate the percentage of metallic zinc, Zn_{PG}, by mass of the zinc-dust component as follows (ASTM D 521):

$Zn_{PG} = [(V_3 - B_3)(N \times 0.0327)/S_2] \times 100$ (4)

where:

V_3 = titrant solution required for titration of the specimen, mL;

B_3 = titrant solution required for titration of the blank, mL;

N = normality of the titrant solution;

S_2 = sample used, grams; and

0.0327 = milliequivalent weight of zinc.

4.1.5. Determine the amount of metallic zinc in the dried paint film (nonvolatile matter), by calculating the percentage of metallic zinc of the nonvolatile matter, Zn_{NV}, as follows:

$Zn_{NV} = (Zn_{PG} \times Zn_{PT})/N$ (5)

where:

Zn_{PG} = percentage of metallic zinc, percentage by mass of zinc dust component, from Section 4.1.4;

Zn_{PT} = percentage of zinc-dust component by mass of mixed primer, from Section 4.1.3; and

N = percentage of nonvolatile matter, from Section 4.1.2.

4.2. *Procedure B Calculations*:

4.2.1. Calculate volatile and nonvolatile content as in Sections 4.1.1 and 4.1.2.

4.2.2. Calculate the percentage of pigment, P, as follows (ASTM D 2371):

$P = [(W_1 - W_2)/S] \times 100$ (6)

where:

W_1 = weight of the tube (including stirring rod) plus pigment, grams;

W_2 = weight of tube (including stirring rod), grams; and

S = weight of paint sample used, grams.

4.2.3. Calculate the percentage of metallic zinc, Zn_P, in the pigment as follows (ASTM D 521):

$Zn_P = [(V_3 - B_3)(N \times 0.0327)/S_2] \times 100$ (7)

where:

V_3 = titrant solution required for titration of the specimen, mL;

B_3 = titrant solution required for titration of the blank, mL;

N = normality of the titrant solution;

S_2 = sample used, grams; and

0.0327 = milliequivalent weight of zinc.

4.2.4. Calculate the percentage of pigment in the nonvolatile matter, P_{NV}, as follows:

$P_{NV} = (P/N) \times 100$ (8)

where:

P = percentage of pigment calculated from Section 4.2.2; and

N = percentage of nonvolatile matter (total solids) from Section 4.2.1.

4.2.5. Determine the amount of metallic zinc in the dried paint film (nonvolatile matter), by calculating the percentage of metallic zinc of the nonvolatile matter, Zn_{NV}, as follows:

$$Zn_{NV} = (Zn_p/100) \times P_{NV} \qquad (9)$$

where:

Zn_p = percentage of metallic zinc, percent by mass of pigment, from Section 4.2.3; and

P_{NV} = percentage of pigment, by mass of the nonvolatile matter, from Section 4.2.4.

[1] Formerly AASHTO Provisional Standard TP 65.

Standard Method of Test for

Analysis of Structural Steel Coatings for Hindered Amine Light Stabilizer (HALS)

AASHTO Designation: T 338-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Analysis of Structural Steel Coatings for Hindered Amine Light Stabilizer (HALS)

AASHTO Designation: T 338-09[1]

1. SCOPE

1.1. This method is designed to determine the presence of hindered amine light stabilizer (HALS) in the polyol portion of a two-component acrylic urethane coating.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. APPARATUS AND MATERIALS

2.1. Gas Chromatograph with Mass Spectrometer Detector.

2.2. 5 percent Phenyl Methyl Siloxane Capillary Column.

2.3. Reference HALS sample.

2.4. Hexane, HPLC grade.

2.5. Centrifuge.

3. INSTRUMENT CONDITIONS

3.1. Install and condition the column in the chromatograph in accordance with manufacturer's recommendations. Establish operating conditions which yield acceptable separation of the components. See Table 1 as a guide for initial instrument conditions. Values may need to be altered to achieve necessary resolution of components. Allow sufficient time for the instrument to reach equilibrium and to produce a stable base line.

Table 1—Initial Instrument Conditions

Injection Port	
Mode	Splitless
Carrier gas	Helium
Initial temperature	250°C
Pressure	7.6 psi
Total flow	54 mL/min
Purge flow	50 mL/min
Purge time	2 min
Injection volume	1.0 µl
Column Parameters	
Nominal length	30 m
Nominal diameter	0.25 mm
Nominal film thickness	0.25 µm
Maximum temperature	325°C
Mode	Constant flow
Initial flow	1.0 mL/min
Oven Parameters	
Initial temperature	50°C
Maximum temperature	325°C
Equilibration time	0.5 min
Initial time	1.0 min
Temperature ramp 1	25.0°C/min to 250°C
Hold time 1	15.0 min
Temperature ramp 2	50.0°C/min to 300°C
Hold time 2	5.0 min
Mass Spectrometer	
Transfer line heater	280°C
Solvent delay	2.0 min

4. PROCEDURE

4.1. Prepare standards by adding reference HALS compounds to hexane to obtain the desired concentrations. Record the weights of hexane and reference HALS used to the nearest 0.1 mg. These standards will be used to obtain retention time data and atomic masses incidental to the specific HALS.

4.2. Prepare samples by thoroughly mixing two parts hexane to one part polyol in a centrifuge tube. (Note: 10.0 mL of hexane and 5.0 mL of polyol is a suitable working volume.) Record the weights of hexane and sample polyol used to the nearest 0.1 mg. Cap the centrifuge tube and centrifuge for five minutes at a minimum relative centrifugal force (RCF) of 43. See Section 5.1 for RCF equation. Fill a sample vial with the resulting supernate.

4.3. Inject a 1.0 µl aliquot of the appropriately prepared reference HALS standard. Determine the retention times for the associated peaks and the atomic masses of the reference HALS compounds.

4.4. Inject a 1.0 µl aliquot of the prepared sample. Determine qualitative presence of the specific HALS by comparing retention times and verifying atomic masses of the HALS compounds.

5. CALCULATIONS

5.1. Calculation for Relative Centrifugal Force (RCF):

$$\mathrm{RCF} = 0.00001118 \times r \times N^2 \quad (1)$$

where:

RCF = Relative Centrifugal Force,

r = rotating radius (cm), and

N = revolutions per minute.

6. REPORT

6.1. Report qualitative results for the presence of the HALS compound.

6.2. Report quantitative results to the nearest 0.01 percent.

---

[1] Formerly AASHTO Provisional Standard TP 66.

Standard Method of Test for

Analysis of Structural Steel Coatings for Isocyanate Content

AASHTO Designation: T 339-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Analysis of Structural Steel Coatings for Isocyanate Content

AASHTO Designation: T 339-10[1]

1. SCOPE

1.1. This method is designed for the determination of the isocyanate (NCO) content of the resin system found in polyurethane paints.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. APPARATUS AND MATERIALS

2.1. Analytical balance.

2.2. High-speed centrifuge.

2.3. Centrifuge tubes, minimum 50-mL heavy-wall glass with vinyl-lined screw caps or 50-mL high-speed [9400 relative centrifugal force (RCF)] polypropylene tubes with screw caps.

2.4. 10-mL syringes with Luer slip tip and caps.

2.5. Automatic titrator with stirrer (Mettler-Toledo DL 50 or equivalent).

2.6. pH electrodes.

2.7. Fleaker or other vessel with stopper or cap, 200 mL minimum volume.

2.8. o-xylene, reagent grade, dried over 3A molecular sieve (see Section 4.1).

2.9. Standard buffer solutions, pH 4.00 and pH 7.00.

2.10. Dibutylamine, 99 percent assay.

2.11. Methanol, ACS reagent grade, dried over 3A molecular sieve (see Section 4.1).

2.12. Hydrochloric acid solution, 1.0 N.

3. PROCEDURE

3.1. To analyze a one-component material, the resin system must first be separated from the whole paint.

3.2. Place a 45-mL sample of the whole paint into a high-speed centrifuge tube and cap immediately.

3.3. Centrifuge the sample to produce a minimum RCF of 4300 until the pigment and resin have separated. See Section 5.1 for RCF equation.

3.4. No separation is required for multi-component materials when the resin system is packaged separately. The resin system is generally labeled "curing agent" or "part B."

3.5. Calibrate the titrimeter and pH electrodes with standard buffer pH 7.00 and pH 4.00 solutions.

3.6. Place 25 mL of dried o-xylene into an appropriately sized vessel.

3.7. Weigh a 10.0 g sample of resin solution from materials having an expected isocyanate value of less than 15.0 percent or 4.0 g sample of resin solution from materials having an expected isocyanate value of 15.0 percent or greater into the vessel from Section 3.6.

3.8. Record the sample weight to the nearest 1.0 mg.

3.9. Add 20.00 mL of 1.7 N dibutylamine solution to the vessel from Section 3.6. The 1.7 N dibutylamine solution is prepared by diluting 290 mL of dibutylamine to 1.0 L with dried o-xylene.

3.10. Cap the vessel immediately.

3.11. Allow the sample to stir for a minimum of 15 minutes but no longer than 60 minutes at 25 ± 2ºC.

3.12. Prepare a blank in the same manner, omitting the resin solution.

3.13. Wash down the sides of each vessel with 100 mL of dried methanol.

3.14. Titrate the stirred blank with 1.0 N hydrochloric acid to the end point, which occurs at pH 5.0.

3.15. Record the volume of titrant used to the nearest 0.01 mL.

3.16. Titrate the stirred sample with 1.0 N hydrochloric acid to the end point, which occurs at pH 5.0.

3.17. Record the volume of titrant used to the nearest 0.01 mL.

3.18. Prepare and titrate a duplicate sample.

3.19. Calculate the weight percent isocyanate. Duplicate analyses should not differ by more than 0.1 weight percent. See Section 5.2 for weight percent isocyanate calculation.

4. NOTES

4.1. Methanol and o-xylene used for this titration should be passed through separate columns containing 3A molecular sieve to remove any moisture that may be present. A recommended flow rate for passing methanol or o-xylene through a drying column is approximately 100 mL per minute. Dried stock may be collected into amber bottles and preserved by placing a small amount of 3A molecular sieve in the bottles.

5. CALCULATIONS

5.1. Calculation for Relative Centrifugal Force (RCF):

$$\text{RCF} = 0.00001118 \times r \times N^2 \qquad (1)$$

where:

RCF = Relative Centrifugal Force,
r = rotating radius (cm), and
N = revolutions per minute.

5.2. Calculation of weight percent isocyanate of the sample:

$$\%\text{NCO} = (((B - S) \times N \times 42)/(1000 \times W)) \times 100 \qquad (2)$$

where:

B = the amount of titrant used to titrate the blank in milliliters,
S = the amount of titrant used to titrate the sample in milliliters,
N = the normality of the hydrochloric acid solution in equivalents per liter,
42 = the equivalent weight of an isocyanate group,
1000 = the factor converting liters to milliliters, and
W = the weight of the resin solution sample in grams.

6. REPORT

6.1. Report the resin solution sample weight to the nearest milligram, 0.001 g.

6.2. Report the percent isocyanate of the resin system in duplicate to the nearest 0.1 percent.

---

Standard Method of Test for

Pavement Deflection Measurements

AASHTO Designation: T 256-01 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Pavement Deflection Measurements

AASHTO Designation: T 256-01 (2006)

1. SCOPE

1.1 This test method provides standards for measuring pavement surface deflections, directly under, or at locations radially outward (offset) from a known static, steady-state, or impulse load. Deflections are measured with sensors that monitor the vertical movement of a pavement surface due to the load. This test method describes procedures for the deflection measurement using various deflection testing devices and provides the general information that should be obtained regardless of the type of testing device used.

1.2 This test method is applicable for deflection measurements performed on flexible asphalt concrete (AC), rigid portland cement concrete (PCC), or composite (AC/PCC) pavements. Rigid pavements may be plain, jointed, jointed reinforced, or continuously reinforced or fractured concrete.

1.3 The values stated in SI units are to be regarded as standard. Inch-pound units given in parentheses are for information purposes only.

1.4 *This standard does not purport to address the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1 *Definitions of Terms Specific to This Standard*:

3.1.1 *deflection sensor*—electronic device(s) capable of measuring the relative vertical movements of a pavement surface and mounted in such a manner as to minimize angular rotation with respect to its measuring plane at the expected movement. Such devices may include seismometers, velocity transducers, or accelerometers.

3.1.2 *load cell*—capable of accurately measuring the load that is applied perpendicular to the loading plate and is placed in a position to minimize the mass between the load cell and the pavement. The load cell shall be positioned in such a way that it does not restrict the ability to obtain deflection measurements under the center of the load plate. The load cell shall be water resistant, and shall be resistant to mechanical shocks from road impacts during testing or traveling.

3.1.3 *loading plate*—capable of an even distribution of the load over the pavement surface. Loading plates may be circular in shape (or rectangular in some cases), one piece or segmented, for measurements on conventional roads and airfields or similar stiff pavements. The plate shall be suitably constructed to allow pavement surface deflection measurements at the center of the plate.

3.1.4 *deflection basin*—the idealized bowl shape of the deformed pavement surface due to a specified load as depicted from the peak measurements of a series of deflection sensors placed at radial offsets from the center of the loading plate.

3.1.5 *deflection basin test*—a test with deflection sensors placed at various radial offsets from the center of the loading plate. The test is used to record the shape of the deflection basin resulting from an applied load. Information from this test can be used to estimate material properties for a given pavement structure.

3.1.6 *load transfer test*—a test, usually on PCC pavement, with deflection sensors on both sides of a transverse break in the pavement. The test is used to determine the ability of the pavement to transfer load from one side of the break to the other. Also, the load-deflection data can be used to predict the existence of voids under the pavement.

3.1.7 *test location*—the point at which the center of the applied load(s) is located.

4. SUMMARY OF TEST METHOD AND LIMITATIONS

4.1 This test method consists of standards for measuring pavement surface deflections directly under and/or at appropriate offset locations from the load center. Each nondestructive testing (NDT) device is operated according to the standard operating procedure applicable to the device.

4.2 This test method includes general descriptions of the various types of static and semi-continuous deflection testing devices, and procedures for deflection measurement corresponding to each testing device.

4.3 Standards for collection of general information, such as test setup, ambient temperature, pavement temperature, equipment calibration, number of tests, and test locations, pertain to all devices.

5. SIGNIFICANCE AND USE

5.1 NDT measurement of pavement surface deflections provides information that can be used for the structural evaluation of new or in-service pavements. These deflection measurements may be used to determine the following pavement characteristics:

5.1.1 Modulus of each layer;

5.1.2 Overall stiffness of the pavement system;

5.1.3 Load transfer efficiency of PCC pavement joints;

5.1.4 Modulus of subgrade reaction; and

5.1.5 Effective thickness, structural number, or soil support value.

5.2 These parameters may be used for the analysis and design of reconstructed and rehabilitated flexible and rigid pavements, pavement structural adequacy assessment including joint efficiency of PCC pavement, void detection in PCC pavements, research, and/or network structural inventory purposes.

6. APPARATUS

6.1 The apparatus used in this test method shall be one of the deflection measuring devices described in Section 6.2 and shall consist of some type of probe or surface contact sensor(s) to measure vertical pavement movements or deformations when subjected to a given load.

6.2 *Deflection Measuring Devices*:

6.2.1 *Noncontinuous Static Loading Device*[1] that operates on a single lever-arm principle. This device should have a minimum 2.5-m (8.2-ft) long probe, and the extension of the probe shall depress a dial gauge or electronic sensor that measures maximum pavement surface deflection with a resolution of 0.025 mm (0.001 in.) or better. The vehicle used to carry the static deflection device shall be a truck carrying an 80-kN (18 000-lbf) test load on a single rear axle. The loading configuration, including axle loads, tire sizes, and inflation pressures, can be obtained using the manufacturer's specification; however, this information must be clearly indicated in the engineering report.

6.2.2 *Semi-Continuous Static Loading Device*[2] that operates on a double lever-arm principle. The vehicle used to carry this device shall be a truck carrying a l30-kN (29 000-lbf) single-axle test load. The loading configuration, including axle loads, tire sizes, and inflation pressures, can be obtained using the manufacturer's specification; however, this information must be clearly indicated in the engineering report. The test vehicle should be equipped with a double lever arm with probes, the geometry and size of which makes it possible to measure the maximum pavement surface deflection in both wheelpaths with a resolution of 0.025 mm (0.001 in.) or better. The extension of each lever arm holding the probe should depress an electronic sensor, which may be of any type provided the sensor delivers an analog or digital signal. The digital signal shall be correlated with the movement of this extension and, therefore, with the deflection of the pavement surface under the effect of the moving test load. The truck should be able to lift and move the probes from one measurement point to the next, lower them onto the pavement surface, and make another set of measurements in a fully automated process at a constant vehicle speed.

6.2.3 *Steady-State Loading Device*[3] that uses a dynamic force generator to produce a dynamic load. The force generator may use, for example, a counter-rotating mass or a servo-controlled hydraulic actuator to produce the dynamic load. The device that uses a counter-rotating mass operates at a fixed frequency to produce a dynamic load under a static weight applied through a pair of rigid steel wheels. Both loading frequency and the magnitude of the dynamic loads may be varied by the operator of the devices that use a servo-controlled hydraulic actuator. Depending on the model, normal operating frequencies range from 8 to 60 Hz and maximum dynamic forces range from 2.2 to 35.5 kN (500 to 8000 lbf) applied through a single circular or dual rectangular plate. These loading devices may be mounted in a van, on the front of a vehicle, or on a trailer. Deflection measurement devices should have five or more sensors to satisfactorily measure the deflection basin with a resolution of 0.001 mm (0.00004 in.) or better.

6.2.4 *Impulse Loading Device*[4] that creates an impulse load on the pavement by dropping a mass from different heights onto a rubber or spring buffer system. Generally known as a Falling Weight Deflectometer (FWD), the force-generating device shall be capable of being raised to one or more predetermined heights and dropped. The resulting force pulse, transmitted to the pavement through a 300-mm (11.8-in.) diameter loading plate, shall not vary from each other by more than 3 percent. The force pulse shall approximate the shape of a haversine or half-sine wave and a peak force that can be varied within the range of 7 to 105 kN (1500 to 24 000 lbf) shall be achievable. The impulse loading device shall measure pavement surface deflections using six or more sensors with a resolution of 0.001 mm (0.00004 in.) or better.

7. CALIBRATION

7.1 The deflection sensor(s) and load cell (if applicable) of the deflection device should be calibrated to ensure that all readings are accurate within specified limits. For devices in which the load is assumed to be constant and is not measured, the accuracy of the magnitude of load imparted should be checked periodically.

7.2 *Load Cell:*

7.2.1 *General*—The procedure for calibrating the load cell (if the device uses a load cell) depends upon the type of device used. The calibration of the load cell may be checked informally by observing the load cell readings and comparing them against expected readings based on experience or shunt calibration values in the case of a FWD. Load cell reference (or absolute) calibration shall be performed at least once a year except for the noncontinuous and semi-continuous loading devices. (See Table 1.)

Table 1—Load Cell Frequency of Calibration

Device Type	Frequency of Calibration
Noncontinuous and Semi-Continuous Static Loading Types	Prior to testing
Steady-State Loading Types (see Section 7.2.3 for devices that do not have a load cell)	At least once a year using manufacturer's instructions or using the procedure in Appendix A of SHRP Report SHRP-P-661
Impulse Loading Types (Falling Weight Deflectometer)	At least once a year using the procedure in Appendix A of SHRP Report SHRP-P-661

7.2.2 *Noncontinuous and Semi-Continuous Static Loading Devices*—Immediately prior to testing, weigh the axle load of the truck if the ballast consists of a material that can absorb moisture (sand or gravel, etc.) or could have changed for any reason. Trucks with steel or concrete block loads only need to be weighed if the loads are changed or could have shifted.

7.2.3 *Steady-State Loading Devices*—Devices that are equipped with load cells may be calibrated by measuring the load cell output under known static loading conditions, such as the load of the device itself. Load cells should be calibrated at least once a year following the manufacturer's instructions or using the SHRP procedure in Appendix A of SHRP Report SHRP-P-661. Calibration of a dynamic load application device that does not have a load cell requires specialized equipment generally not available except at the manufacturer's location. Potential error from variations in applied loads for this device is nominal; retesting after leaving the factory may not be considered a requirement. Calibration for applied load should be conducted indirectly once a month by checking the frequency of the counter-rotating fly wheels with a strobe light.

7.2.4 *Impulse Loading Devices*—Reference load cell calibration should be carried out at least once per year. Appendix A of SHRP Report SHRP-P-661[5] contains an example outline for such a task.

7.3 *Deflection Sensors*:

7.3.1 *General*—The procedure for calibrating the deflection sensors depends upon the type of apparatus used. Calibration of the deflection sensors should be checked at least once a month during production testing except noncontinuous and semi-continuous loading devices. (See Table 2.)

7.3.2 *Noncontinuous and Semi-Continuous Static Loading Devices*—Static loading devices should be calibrated daily with feeler gauges. When performing deflection sensor calibration, induced deflections should be similar in magnitude to the deflections encountered during normal testing.

7.3.3 *Steady-State Loading Devices*—A routine calibration check of the deflection sensors shall be conducted once a month. If significant differences are noted for a sensor, it shall be returned to the manufacturer for check or calibration under standard calibration oscillatory vibrations. Deflection sensors shall be calibrated annually.

Table 2—Deflection Sensor Frequency of Calibration

Device Type	Frequency of Calibration	Min Frequency of Calibration Check
Noncontinuous and Semi-Continuous Static Loading Types	Daily during operation	Daily during operation
Steady-State Loading Types	At least once a year	Once a month during operation
Impulse Loading Types (Falling Weight Deflectometer)	Reference calibration at least once a year using the procedure in Appendix A of SHRP Report SHRP-P-661	Relative calibration once a month during operation using the procedure in Appendix A of SHRP Report SHRP-P-661

7.3.4 *Impulse Loading Devices*—Reference deflection sensor calibration should be carried out in accordance with the SHRP Protocol (see Appendix A of SHRP Report SHRP-P-661 for impulse loading devices). A relative calibration check should be conducted once a month using the SHRP Protocol (see Appendix A of SHRP Report SHRP-P-661).

7.4 *Temperature Sensors*:

Pavement temperature sensor calibration should be carried out using a calibrated reference thermometer and two reference surfaces such as a "cool" and "hot" surface. Air temperature sensor (if equipped) calibration should be carried out using two reference temperatures; e.g., stirred ice-water (0°C) and boiling water (100°C). Calibration of the temperature sensors should be carried out at least once a year.

8. FIELD DATA COLLECTION AND TESTING PROCEDURE

8.1 *General*—The procedure to be followed is, to some extent, dependent upon which type of device is used. The following general information is suggested as the minimum data that need to be collected, regardless of the type of device used.

8.1.1 *Load*—For impulse loading devices, record the peak load applied to the pavement surface by the deflection device. For steady-state loading devices, record the calculated peak-to-peak load. For static loading devices, record the axle load of the test vehicle.

8.1.2 *Load Frequency*—If applicable, record the frequency of calculated oscillatory load for vibratory loading devices.[6]

8.1.3 *Geometry of the Loaded Area and Deflection Sensor Locations*—For proper modeling of the pavement structure and/or backcalculation of layer parameters, etc., it is necessary that the locations of the load, deflection sensors, pavement surface cracks, and PCC joints are known and recorded. Record the location of cracks and joints between the load and each sensor within 2 m (6.5 ft) from the center of the load toward the sensors. Record the location and orientation of all sensors as measured radially outward from the center of the load; for example, "300 mm (11.8 in.) ahead of the applied load." In accordance with the selected method of evaluating joint efficiency or load transfer, the load(s) and deflection sensor(s) should be properly positioned; for example, with one or more sensors on each side of the joint and the load placed as close as possible to the leave (downstream) side of the joint in question. Failure to note the presence of joints and cracks within the zone of influence of the load could result in errors in the subsequent analysis of the recorded deflections. Similarly, failure to properly note the actual position of the deflection sensors could result in major analysis errors.

8.1.4 *Time of Test*—Record the date and time the deflection measurements are obtained.

8.1.5 *Stationing or Chainage*—Record the station number or location of the test point for each deflection test conducted.

8.1.6 *Air and Pavement Temperatures*—At a minimum, record the ambient air temperature and pavement surface temperature at specified intervals as recommended by the engineer. Additional temperatures may be required for specific postprocessing methods. For example, pavement layer temperatures may be determined by drilling holes to one or more depths within the pavement layer and filling the bottom of these holes with water, glycerin, or an oil-based product and recording the temperature of the fluid at the bottom of each hole. If testing is conducted over an extended period of time, take temperature measurements of the fluid every hour to establish a direct correlation between the air, pavement surface, and/or at-depth temperature measurements. If this is not possible, some procedures also exist for estimating the pavement temperature as a function of depth using the high and low air temperatures for the previous 24-hour day and the current pavement surface temperature.[7]

8.2 *Testing Locations*—Record the test location at the beginning of the testing sequence. The frequency of field testing is dependent upon the testing level selected, as discussed in Section 9 of this standard.

8.3 *Test Method*—Depending on the type of apparatus used, different test methods can be used. Steady-state loading devices capable of variable loads and frequencies can be used to conduct "frequency sweeps" (multiple tests at various frequencies, at the same test location and load). Impulse loading devices are typically capable of applying various loads; some devices can control the shape and duration of the load pulse. Joint efficiency measurements on jointed PCC pavements can be carried out with devices equipped with multiple deflection sensors by placing the load on one side of the joint and positioning one or more sensors on each side of the joint.

8.4 *Procedure for Deflection Measurements*:

8.4.1 *General*—Procedures for conducting the specific deflection testing should be those furnished by the manufacturer of the device, as supplemented to reflect the general guidelines provided in this standard. The following steps shall be performed irrespective of the device used.

8.4.1.1 Calibrate the deflection sensor and load cell (if applicable) of the device, following the procedure discussed in Section 7.

8.4.1.2 Transport the device to the test location over the desired test point.

8.4.1.3 Measure the ambient air temperature and pavement temperatures in accordance with the guidelines in Section 8.1.6.

8.4.1.4 Record the following information for each pavement tested: project location, operator name, date and time, calibration factors, the beginning and ending station or physical location such as the "Jct. IH 635 and Beltline road," location of cut and fill, culvert locations, bridges, and other vertical control features, and the limits and extent of surface distress, weather condition, and a description of the pavement type.

8.4.1.5 The test location shall be free from all rocks and debris to ensure that the loading plate (if applicable) will be properly seated. Gravel or soil surfaces shall be as smooth as possible and all loose material shall be avoided or removed.

8.4.2 *Noncontinuous Static Loading Device (e.g., Benkelman Beam)*:

8.4.2.1 Position the beam between the tires so that the probe is 1.37 m (4.5 ft) forward of and perpendicular to the rear axle.

8.4.2.2 Adjust the dial gauge to read 0.000 mm (0.000 in.).

8.4.2.3 Drive the test vehicle approximately 8 m (26.3 ft) forward at creep speed and record the maximum dial reading (D_m) with a resolution of 0.025 mm (0.001 in.) or better.

8.4.2.4 After the dial needle has stabilized, record the final dial reading (D_f) with a resolution of 0.025 mm (0.001 in.) or better.

8.4.2.5 Pavement surface deflection = 2 ($D_m - D_f$).

8.4.2.6 Repeat this process at the measurement intervals specified in Section 10. Normally, both wheel tracks are measured using two instruments. However, when testing with only one instrument, the testing can be alternated between wheel tracks, obtaining two measurements in the outer wheel track for every one measurement in the inner wheel track throughout the test section.

8.4.2.7 Report the average (mean) deflection for each wheel track.

8.4.3 *Semi-Continuous Static Loading Device*:

8.4.3.1 Obtain pavement surface deflection measurements for both wheel tracks as specified in Section 9 on a continuous chart.

8.4.3.2 Read the deflection measurements from the deflection traces with a resolution of 0.025 mm (0.001 in.) or better, and tabulate using deflection data sheets along with any accompanying notes.

8.4.3.3 Calculate and report the average (mean) deflections for both wheel tracks.

8.4.4 *Steady-State Loading Device*:

8.4.4.1 Record the information that identifies the exact configuration of the deflection device at the time of testing. The device configuration data usually include number and spacing of deflection sensors and orientation of the deflection sensors.

8.4.4.2 Locate the device such that the center of load is at the selected test location and the sensor bar is parallel to the direction of travel (or across the joint for longitudinal or skewed joints).[8]

8.4.4.3 Lower the sensor bar to position the sensors and the loading plate (or plates) or loading wheels. Initiate force generation until stability is reached at the selected loading frequency and load magnitude.[9]

8.4.4.4 Read and record the measured deflections for each of the sensors, either manually on data sheets or directly if data recording is automated.

8.4.5 *Impulse Loading Device*:

8.4.5.1 Set up the software for data collection.

8.4.5.2 Input the information that identifies the exact configuration of the deflection device at the time of testing. The device configuration data are stored in the data output file and are a direct input to data analysis. This information usually includes the size of load plate, number and spacing of deflection sensors, and the orientation of deflection sensors with respect to the load plate.

8.4.5.3 Select the appropriate data file format. Several file formats are available; e.g., U.S. Customary units, SI units, and other options.

8.4.5.4 Lower the loading plate and sensors to ensure that they are resting on a firm and stable surface.

8.4.5.5 Raise the force generator to the desired height and drop the “weight.” Perform at least one seating drop and one or more test drop(s) at any load level. Record the peak surface deflections and peak load (excluding seating drops) or record the full load response and deflection-time history as recommended by the engineer.

8.4.5.6 When the engineer desires to determine the nonlinearity of the pavement materials, perform testing at multiple-load levels. The analyst may use basin averaging if random error is of sufficient concern.

9. LOCATION AND SAMPLING FREQUENCY

9.1 The test location will vary with the intended application of the data. For the most part, the common approach is to test primarily in wheelpaths, since the pavement response at these locations reflects the effect of damage that has been accumulated. Deflection testing between wheelpaths on AC pavement may be performed to compare testing in the wheelpaths to indicate relative damage.

9.2 *Network Level Testing*—This testing level provides for a general overview of a pavement's bearing capacity with limited testing. Deflection testing is typically performed at 200 m to 500 m (656 ft to 1640 ft) intervals, depending on the specific pavement conditions. A minimum of seven tests per uniform pavement section is recommended to ensure a statistically significant sample. At a minimum, the load for AC and continuously reinforced concrete pavements (CRCP) should be positioned along the outer wheelpath or, alternatively, along the centerline of CRCP slabs. For jointed concrete pavements (JCP), the load should first be positioned at the geometric center of the slab. For network level testing, at least 10 percent of the slabs covered should be tested at the joints, as well, for deflection or load transfer efficiency.

9.3 *General Project Level Testing*—This testing level provides for a more detailed analysis of the pavement; for example, for the purpose of overlay or rehabilitation design. Testing should be performed at 50 to 200-m (164 to 656-ft) intervals, depending on the specific pavement conditions, with a minimum of 15 tests recommended per uniform pavement section. At a minimum, the load for AC or CRCP pavements is generally positioned along the outer wheelpath or, alternatively, along the centerline of CRCP slabs. For JCP pavements, the load should first be positioned at or near the geometric center of the slab, and then moved to the nearest joint and positioned along the same line, generally on the leave side of the joint. On roads, streets, and highways, joint tests are often conducted along the outer wheelpath. For general project level testing, generally, not every joint associated with each interior slab test is covered; however, a minimum joint coverage rate of 25 percent is recommended. On airfield JCP pavements, joint efficiency measurements should be carried out on both transverse and longitudinal joints.

9.4 *Detailed Project Level Testing*—This test level provides for a highly detailed and specific analysis of the pavement, for purposes such as identifying localized areas of high deflection or detecting subsurface voids on PCC pavements, etc. For AC or CRCP pavements, testing is typically performed at 10 to 50-m (32.8 to 164-ft) intervals as recommended by the engineer. On roads, streets, and highways, testing is often carried out in both wheelpaths. For JCP pavements, the load should first be positioned at or near the geometric center of every slab along the length of the test section, and then moved to the nearest joint or crack on each slab, either along the outer wheelpath or at the corner of the slab, or both. On airfield JCP pavements, joint efficiency measurements should be carried out on both transverse and longitudinal joints.

10. OTHER DATA NEEDED PRIOR TO DEFLECTION ANALYSIS

10.1 The following pavement system data may be needed to facilitate the load-deflection analysis:

10.1.1 Pavement layer material types and thicknesses.

10.1.2 Depth to bedrock or stiff layer.

10.1.3 Project ID or roadway name and subsection.

11. DEFLECTION TESTING REPORT

11.1 Field reports (both electronic and hard copy) for each deflection test that was performed should contain information on the following items as a minimum.

11.2 Purpose of deflection testing.

11.3 Date and time of testing.

11.4 Operator identification.

11.5 Vehicle information.

11.6 Weather conditions.

11.7 Air and pavement temperatures.

11.8 *Section Information*—These are usually agency-specified, but the section information generally includes the following:

11.8.1 Roadway and county or district in which it is located.

11.8.2 Type of pavement being tested.

11.8.3 Direction of travel.

11.8.4 Lane being tested (e.g., driving or passing lane).

11.9 *Load and Deflection Data*:

11.9.1 Type of deflection device.

11.9.2 Type of deflection test, such as deflection basin or load transfer.

11.9.3 Location of sensors.

11.9.4 Applied load and load frequency.

11.9.5 Measured deflections under load.

12. DATA ACQUISITION SOFTWARE

12.1 Some deflection testing devices use their own field program to acquire load and deflection data. Traditionally, pavement surface deflection data files have been structured using ASCII formats that are very device dependent. Although ASCII format allows users and agencies to easily access the data output files, a separate program is needed to access the output file for each type of testing device. To mitigate this problem, AASHTO has developed a universal pavement surface deflection data exchange (PDDX) format specification. A description of this specification can be found in the first reference in Section 2.2 of this standard (AASHTO, *Pavement Deflection Data Exchange: Technical Data Guide,* Version 1.0 April 1998).

13. DATA PROCESSING SOFTWARE (FOR REFERENCE)

13.1 Several backcalculation software programs have been developed for deflection data processing and analysis. An ASTM Standard (see Section 2 for reference) provides a discussion regarding some of the major differences among the most commonly used backcalculation programs. If backcalculation techniques are employed, use the latest program version for backcalculation of pavement layer moduli.

14. PRECISION AND BIAS

14.1 Since this test method covers the use of various NDT devices used on any type of bound pavement surface, the precision and bias of this test method will be a function of both the characteristics of the pavement tested and the device used. Information on reliability, accuracy, and repeatability of various vibratory and impulse loading devices can be found in the experiment performed at the Waterways Experiment Station (WES) in Vicksburg, Mississippi.[10]

15. KEYWORDS

15.1 Benkelman beam; deflection sensor; deflection surveys; falling-weight deflectometer (FWD); impulse deflection testing device; load cell; load/deflection testing; nondestructive testing (NDT); pavement surface deflection; pavement testing; sampling frequency; static deflection testing device; and steady-state dynamic deflection testing device.

Standard Method of Test for

Instrumental Photometric Measurements of Retroreflective Materials and Retroreflective Devices

AASHTO Designation: T 257-96 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Instrumental Photometric Measurements of Retroreflective Materials and Retroreflective Devices

AASHTO Designation: T 257-96 (2008)

1. SCOPE

1.1. This standard covers procedures for instrumental determinations of photometric characteristics of retroreflective materials and retroreflective devices.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- E 184, Standard Practice for Effects of High-Energy Neutron Radiation on the Mechanical Properties of Metallic Materials, E706 (IB) (Withdrawn 2002)
- E 308, Standard Practice for Computing the Colors of Objects by Using the CIE System
- E 809, Standard Practice for Measuring Photometric Characteristics of Retroreflectors
- E 810, Standard Test Method for Coefficient of Retroreflection of Retroreflective Sheeting Utilizing the Coplanar Geometry

3. SIGNIFICANCE AND USE

3.1. This method describes procedures used to measure photometric quantities that relate to the visual perception of retroreflected light. The most significant usage is in the relation of the night time vehicle headlamps, retroreflector, and driver's eye geometry. For this reason, the CIE Standard Source A is used to represent a tungsten vehicle headlamp and the receptor has the photopic, $V(\lambda)$, spectral responsivity corresponding to the light-adapted human eye. Although the geometry must be specified by the user, it will, in general, correspond to the relation between the vehicle headlamp, the retroreflectometer, and the driver's eye position.

4. TERMINOLOGY

4.1. *Retroreflective Terms*:

4.1.1. *retroreflector*—a surface or device which reflects and returns a relatively high proportion of light in a direction close to the direction from which it came. This characteristic is maintained over a wide variation of the angle made by the incident light ray and the normal to the retroreflective surface.

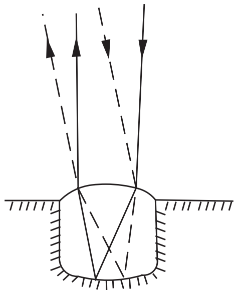
4.1.2. *retroreflective element*—One optical unit which by refraction and/or reflection produces the phenomenon of retroreflection.

4.1.3. *retroreflective device*—a complete device, ready for use, consisting of one or more retroreflective elements (for example, a device containing cats' eyes, a cube corner device, or a safety retroreflective device).

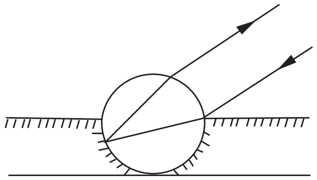
4.1.4. *retroreflective material*—a retroreflective material which consists of a thin continuous layer of small retroreflective elements on or very near the exposed surface (for example, retroreflective sheeting, beaded paint, highway sign surfaces, or pavement striping).

4.1.4.1. *retroreflective sheeting*—a retroreflective material preassembled as a thin film ready for use.

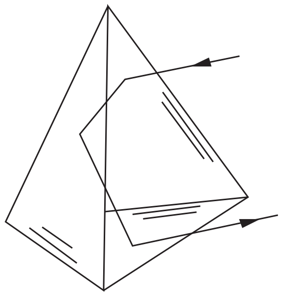
4.2. *geometric terms*—(Figures 1–3).



Cat's Eye Element



Spherical Element



Cube Corner Element

Figure 1—Geometry of Retroflective Elements

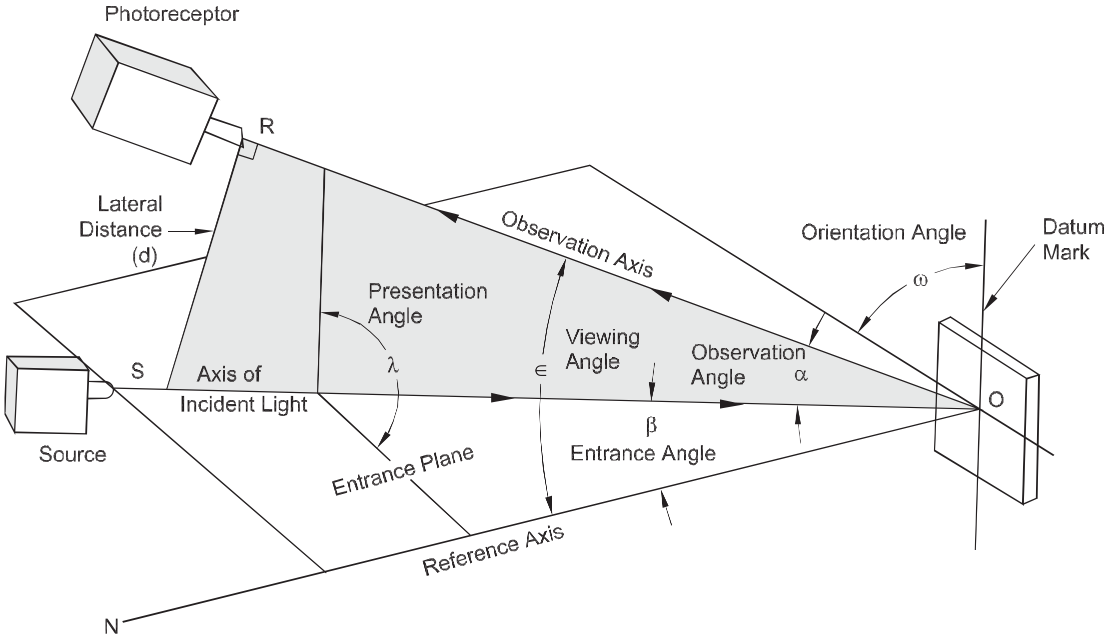


Figure 2—Pictorial View with the Presentation Angle (λ) Illustrated at 90 Degrees (A presentation angle of 0 degrees is normally used.)

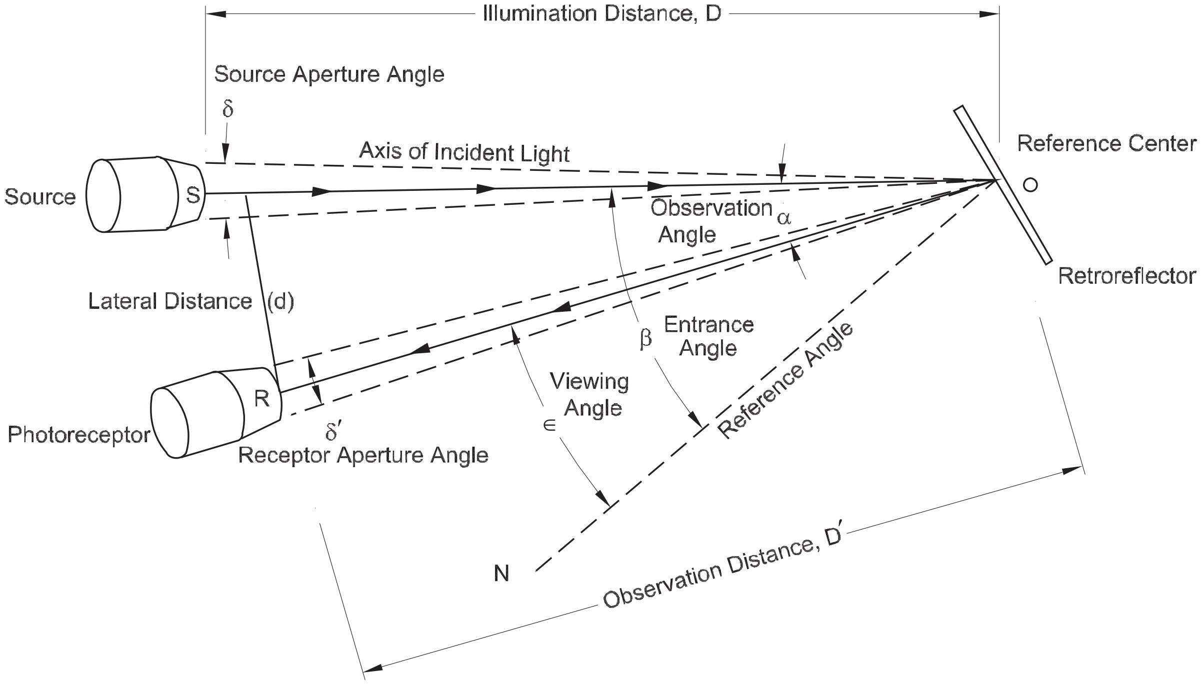

Figure 3—Plane View from Above with the Presentation Angle Illustrated at 0 Degrees

4.2.1. *reference center (O)*—the defined center of a retroreflector.

4.2.2. *reference axis (ON)*—the defined axis used to determine the entrance angle in photometric measurements and in practical use. This axis passes through the reference center (O) (Note 13).

4.2.3. *axis of incident light (OS)*—the line between the reference center and the center of the exit aperture of the light source.

4.2.4. *observation axis (OR)*—the line between the reference center and the center of the entrance aperture of the photoreceptor.

4.2.5. *entrance angle (β)*—the angle between the reference axis and the axis of incident light. Counter-clockwise rotation of the reference axis relative to the axis of incident light is considered positive as shown in Figure 3.

Note 1—Entrance angles are normally in the range of 0 to 90 degrees. However, negative entrance angles can be used to indicate a change of 180 degrees in the presentation angle, provided the 0 degree orientation of the datum mark is defined relative to the observation plane.

4.2.6. *viewing angle (∊)*—the angle between the observation axis and the reference axis.

Note 2—Since this angle is determined by other defined angles, the viewing angle is introduced simply for convenience in defining the specific luminance and the luminance factor.

4.2.7. *observation angle (a)*—the angle between the axis of incident light and the observation axis (“divergence angle” is an obsolete term for this angle).

4.2.8. *datum mark*—the mark placed on the sample by the manufacturer which defines the initial (0 degree) orientation position, and from which the orientation angle is measured.

4.2.9. *orientation angle (ω)*—the angle, when viewed from Point N, through which the sample may be rotated about the reference axis, from the initial 0 degree orientation of the datum mark. The initial 0 degree orientation angle may be defined relative to either the observation plane or the entrance plane.

4.2.9.1. When defined relative to the observation plane, the 0 degree orientation is when the datum mark is in the observation plane and on the same side of the axis of incident light as the photoreceptor.

4.2.9.2. When defined relative to the entrance plane, the 0 degree orientation is when the datum mark is in the entrance plane and on the same side of the axis of incident light as the reference axis.

4.2.10. *presentation angle (λ)*—the dihedral angle between the entrance plane formed by the axis of incident light and the reference axis, and the observation plane formed by the axis of incident light and the observation axis. Zero degree is formed when the photoreceptor is placed in the plane formed by the axis of incident light and the reference axis, with the receptor on the same side of the source as the reference axis. A presentation angle of 0 degree as shown in Figure 3 is used, unless otherwise specified. Figure 2 shows the presentation angle at plus 90 degrees.

4.2.11. *illumination distance (D Equal to OS)*—the distance between the center of the exit aperture of the light source and the reference center.

4.2.12. *observation distance (D′ Equal to OR)*—the distance between the reference center and the center of the entrance aperture of the photoreceptor.

4.2.13. *lateral distance (d)*—the distance from the center of the entrance aperture of the photoreceptor to the axis of incident light, measured perpendicularly to the observation axis. It may be computed by multiplying the observation distance *D′* by the tangent of the observation angle.

$$d = D' \tan\alpha \qquad (1)$$

4.2.14. *source aperture angle (δ)*—the angle at the sample subtended by a given dimension of the source aperture.

4.2.15. *receptor aperture angle (δ′)*—the angle at the sample subtended by a given dimension of the receptor aperture.

4.3. *Photometric Terms*:

4.3.1. *Commission Internationale de l'Eclairage (CIE) photopic standard observer*—a receptor of radiation with a spectral sensitivity curve (Table 1) which conforms to the V(λ) distributions specified in Table 1.

Table 1—Spectral Response of the CIE Standard Photopic Observer (Section 13.1)

Wavelength (mm)	Relative V(λ), %	Wavelength (mm)	Relative V(λ), %
380	0.00	570	95.20
390	0.01	580	87.00
400	0.04	590	75.70
410	0.12	600	63.10
420	0.40	610	50.30
430	1.16	620	38.10
440	2.30	630	26.50
450	3.80	640	17.50
460	6.00	650	10.70
470	9.10	660	6.10
480	13.90	670	3.20
490	20.80	680	1.70
500	32.30	690	0.82
510	50.30	700	0.41
520	71.00	710	0.21
530	86.20	720	0.10
540	95.40	730	0.05
550	99.50	740	0.02
555	100.00	750	0.01
560	99.50		

4.3.2. *illuminance (E)*—the ratio of the luminous flux to the area of the surface, when the latter is uniformly illuminated.

$$E = \frac{\varphi}{A} \qquad (2)$$

where:

φ = luminous flux (lumen), and

A = area of the surface.

4.3.2.1. *normal illuminance (E_n)*—normal illuminance is an expression used in the photometry of retroreflectors to designate the normal illuminance from the source on a retroreflective surface, and is measured in the plane which passes through the reference center and is perpendicular to the axis of incident light. In SI units, normal illuminance is measured in lux; in U.S. units, it is measured in foot-candles.

4.3.3. *inverse-square law*—the normal illuminance which a point-source produces at a point on a surface varies directly with the luminous intensity of the point source and inversely as the square of the distance between the source and that point, expressed as follows:

$$E_n = \frac{I}{D^2} \tag{3}$$

where:

I = luminous intensity.

4.3.4. *photoreceptor*—an instrument for measuring luminous flux.

4.3.4.1. *photometer*—a photoreceptor used for determining illuminance at a surface, and usually calibrated in units of foot-candles or lux.

4.3.4.2. *telephotometer*—a photoreceptor used for determining luminance at a distance or illuminance from a restricted field of view. The device is equipped with an objective lens that may be focused on a target.

4.3.5. *goniometer*—an instrument for measuring or setting angles.

5. QUANTITIES AND UNITS FOR RETROREFLECTIVE PHOTOMETRIC MEASUREMENTS

5.1. Photometric quantities used to specify the performance of retroreflective materials and devices are specific intensity (SI), specific luminance (SL), specific intensity per unit area (SIA), specific intensity per unit length (SIL), and luminance factor (LF).

5.1.1. *Specific Intensity (SI)*—The ratio of the luminous intensity of the retroreflector to the normal illuminance.

$$SI = \frac{E'\left(D'\right)^2}{E_n} \tag{4}$$

where:

E' = illuminance at the observation position, and

D' = distance between the center of the photoreceptor entrance aperture and the reference center.

Specific intensity is expressed in candelas per foot-candle (cd fc^{-1}).

Note 3—The CIE vocabulary defines the above relationship as the coefficient of luminous intensity (CIL), which is expressed in metric units of candelas per lux.

Note 4—The quantity SI is recommended for determining the performance of such retroreflectors as button reflectors, delineators, or automotive reflectors, since it depends on a unit device and the area need not be measured.

5.1.2. *Specific Luminance (SL)*—The ratio of the luminous intensity of the projected surface to the normal illuminance at the surface on a plane normal to the incident light. The ratio is expressed as follows:

$$SL = \frac{E'\left(D'\right)^2 \big/ \left(A \cos \in\right)}{E_n} = \frac{I' \big/ \left(A \cos \in\right)}{E_n} = \frac{SI}{A \cos \in} \tag{5}$$

where:

I' = $E'(D')^2$ = retroflective luminous intensity of the sample,

A = surface area of the sample, and

$\in$ = viewing angle.

Specific luminance is expressed in candelas per square meter per lux (candelas per square foot per foot-candle). Candela replaces the term candlepower. It is used in both SI and U.S. units.

Note 5—The CIE vocabulary defines this relationship as the coefficient of luminance, which is expressed in metric units of candelas per square meter per lux.

Note 6—The quantity SL treats the retroreflector as a surface source whose projected area is visible as an area at the observation position. The quantity SL relates to the way the effective retroreflective surface is focused on the retina of the human eye and to the visual effect thereby produced. It is recommended for describing the performance of highway signs and striping, or large vehicular markings, which are commonly viewed as discernible surface areas.

5.1.3. *Specific Intensity per Unit Area (SIA)*—The ratio of the luminous intensity of the surface to the normal illuminance and to the area of the retroreflective surface.

$$SIA = \frac{E'\left(D'\right)^2 / E_n}{A} \qquad (6)$$

Specific intensity per unit area is expressed in candelas per lux per square meter (candelas per foot-candle per square foot).

Note 7—The CIE vocabulary defines this relationship as the coefficient of luminous intensity (CIL) per unit area, which is expressed in SI units of candelas per lux per square meter.

Note 8—The quantity SIA treats the retroreflector as an apparent point source whose retroreflected luminous intensity is dependent on the area of the retroreflective surface involved. It is a useful engineering quantity for determining the photometric performance of such retroreflective surfaces as highway delineators or warning devices. SIA may also be used to determine the minimum area of retroreflective sheeting necessary for a desired level of photometric performance.

5.1.4. *Specific Intensity per Unit Length (SIL)*—The ratio of the luminous intensity of the sample to the normal illuminance and to the length of the retroreflective sample.

$$SIL = \frac{E'\left(D'\right)^2 / E_n}{L} \qquad (7)$$

where:

L = length of the sample.

Specific intensity per unit length is candelas per lux per meter (candelas per foot-candle per foot).

Note 9—The CIE vocabulary defines the above relationship as the coefficient of luminous intensity (CIL) per unit length, which is expressed in metric units of candelas per lux per meter.

5.1.5. *Luminance Factor (LF)*—The ratio of the luminance of the surface to that of a perfect diffusing surface such that:

$$LF = \frac{\pi E'\left(D'\right)^2}{A\ E_n \cos\beta \cos\in} = \frac{\pi\left(SIA\right)}{\cos\beta \cos\in} \qquad (8)$$

The luminance factor has no dimensions.

Note 10—In this formula, the dimensions associated with the reflectance of the perfect diffusing surface are the same as those of SIA, and are thus canceled.

6. REQUIREMENTS TO BE STATED IN SPECIFICATIONS

6.1. When stating photometric retroreflective requirements, the following shall be specified in the specification for the material.

6.1.1. The retroreflective photometric quantities to be measured, limited to the following: specific intensity (SI), specific luminance (SL), specific intensity per unit area (SIA), specific intensity per unit length (SIL), or luminance factor (LF).

6.1.2. The units (SI or English) in which each quantity is to be measured.

6.1.3. The minimum acceptable quantitative value.

6.1.4. The observation angle.

6.1.5. The entrance angle.

Note 11—When specifying an entrance angle near 0 degrees, care must be taken to prevent specular reflection from entering the photoreceptor. In this case, the entrance angle should be specified so that specular light will be reflected away from the photoreceptor.

6.1.6. The orientation angle and the 0 degree orientation of the datum mark shall be specific if random orientation of the sample is not suitable.

6.1.7. The presentation angle shall be specified if other than 0 degrees.

6.1.8. The minimum test distance between the sample and the photoreceptor.

6.1.9. Sample dimensions and shape.

6.1.10. The maximum photoreceptor angular aperture [the angle at the sample (δ' in Figure 3) subtended by the maximum dimension of this aperture]. The solid angle subtended by the photoreceptor aperture at the reference center shall be specified. This can be accomplished by specifying the photoreceptor dimensions and test distance, or the maximum receptor aperture angle (generally 6 minutes of arc).

Note 12—The maximum value of the angle at the sample subtended by the maximum aperture diameter of the photoreceptor should be specified in the material specification; it should be in the order of 6 minutes of arc. (See Figure 3.) However, the maximum diameter of both apertures varies with the test distance. Reading R_1 and R_2 must be made with the same apertures. (See Section 10.3.)

6.1.11. The maximum angular aperture of the light projector [the angle at the sample (δ' in Figure 3) subtended by the maximum dimension of this aperture]. The solid angle subtended by the light source aperture at the reference center shall be specified. This can be accomplished by specifying the source aperture dimensions and test distance or the maximum source aperture angle (generally 6 minutes of arc).

6.1.12. The reference center.

6.1.13. The reference axis.

Note 13—The reference axis usually is perpendicular to the surface of sheeting. In such complex devices as automobile or bicycle reflectors, the reference axis and reference center may be defined with respect to the viewing direction.

Note 14—When evaluation requirements are different from those stated in this standard, it is recommended that the variations be defined relative to the test conditions used in this standard.

7. APPARATUS

7.1. The apparatus shall consist of a photoreceptor, a light projector source, a goniometer sample holder, and a photometric range.

7.1.1. *Photoreceptor*—The photoreceptor shall be equipped with:

7.1.1.1. *CIE Standard Observer Filter*—A light filter to yield a response curve matching that of the CIE standard observer. (See Note 21.)

7.1.1.2. *Photoreceptor Stability and Linearity*—The stability and linearity of the photometric scale reading shall be within ±1 percent over the range to be measured.

7.1.1.3. *Light Filter Holder Attachment*—If the filter correction factor is to be used, the photoreceptor shall be equipped with an attachment to mount filters in a way which prevents inter-reflection between the filter and the photoreceptor.

7.1.1.4. *Angular Field Aperture*—If the photoreceptor is equipped with field apertures, a range of 2 minutes to 3 degrees is desirable. In any case, baffling shall be used to reduce the effect of stray light to a negligible factor. This is particularly important when a photometer-type instrument is used.

Note 15—Because retroreflective material specifications require various test distances that affect the actual field aperture, a selection of angular field apertures may be necessary. The field of view should be limited to the smallest aperture that includes the entire sample. (See Section 10.3.1.)

7.1.1.5. *Objective Lens*—If the photoreceptor is equipped with an objective lens, it shall focus at the test distance.

7.2. *Light Projector Source*—The light source shall be a lamp with appropriate reflector and lenses to provide normal illumination on the test sample with a spectral energy distribution conforming to the 1931 CIE Standard Source A (a tungsten filament lamp operated at a color temperature of 2583ºC (2856 K) (Table 2). The normal illuminance on the sample shall be uniform within 5 percent of the average normal illuminance over the area of the retroreflector at the test distance. The light projector shall be equipped with an adjustable iris diaphragm or a selection of fixed apertures. The intensity of light shall be regulated and shall not vary more than 1 percent for the duration of the test.

Table 2—Energy Distribution of CIE Source A (Section 13.2)

Wavelength (mm)	Relative Energy	Wavelength (mm)	Relative Energy
380	9.79	580	114.44
390	12.09	590	121.73
400	14.71	600	129.04
410	17.68	610	136.34
420	21.00	620	143.62
430	24.67	630	150.83
440	28.70	640	157.98
450	33.09	650	165.03
460	37.82	660	171.96
470	42.87	670	178.77
480	48.25	680	185.43
490	53.91	690	191.93
500	59.86	700	198.26
510	66.06	710	204.41
520	72.50	720	210.36
530	79.13	730	216.12
540	85.95	740	221.66
550	92.91	750	227.00
560	100.00	760	232.11
570	107.18		

Note 16—Many projection lamps are designed to operate at color temperatures higher than 2583ºC (2856 K). In such cases, the terminal voltage at the lamp shall be adjusted to provide the specified temperature.

Note 17—The maximum diameter of the projector exit aperture and the angle at the test sample, thus subtended, should not exceed that specified in Section 6.

7.3. *Goniometer Sample Holder*—The goniometer shall support the test sample so that the complement of the specified entrance angle does not change more than ±0.5 percent. (A simple goniometer can be constructed using a rotary milling table and an adjustable angle milling vise attached to the table platform.) The vertical angle of the goniometer shall be set perpendicular to the axis of incident light. The horizontal angle movement (the goniometer table) shall permit photometric measurements which require plus or minus angle settings.

7.4. *Photometric Range*—To minimize the effect of stray light, the background behind the sample shall be flat black. Light baffles shall be located, as necessary, between the projector and the sample. Goniometer parts, range wall, ceiling, and floor exposed to the light beam shall be painted flat black.

Note 18—The working distance should be sufficiently large so that the focusing or beam displacement properties of the retroreflective elements do not affect the readings. For most materials, 30 m (100 ft) is sufficient. This facilitates measurements which require an observation angle of 0.2 degrees. In Table 3, the lateral distance (*d*) (Section 4.2.13) is given for various distances and observation angles.

Table 3—Lateral Distance as a Function of Observation Angle and Observation Distance

Observation Angle (α), (degrees)	Observation Distance (D'), m (ft)	Lateral Distance (d), mm (in.)
0.2	15.2 (50)	53.1 (2.09)
0.33	15.2 (50)	87.9 (3.46)
0.5	15.2 (50)	133.1 (5.24)
1.33	15.2 (50)	353.8 (13.93)
2.0	15.2 (50)	532.1 (20.95)
8.0	15.2 (50)	2141.7 (84.32)
0.1	30.5 (100)	53.1 (2.09)
0.2	30.5 (100)	106.4 (4.19)
0.33	30.5 (100)	175.5 (6.91)
0.5	30.5 (100)	265.9 (10.47)
1.33	30.5 (100)	707.6 (27.86)
2.0	30.5 (100)	1064.3 (41.90)
8.0	30.5 (100)	4283.7 (168.65)

8. TEST SPECIMENS

8.1. When testing retroreflective devices, the test specimen shall consist of one entire retroreflector. A large retroreflector may be tested by summing the values obtained from segments of the device.

8.2. When testing retroreflective sheeting, it is recommended that the minimum test area be 0.09 ± 0.05 m^2 (1 ± 0.5 ft^2). This may be accomplished, for example, by measuring a single square test specimen 0.3 m (1 ft) on each side or by averaging the measurements over several representative pieces totaling 0.09 m^2 (1 ft^2) in area.

9. CALIBRATION

9.1. The following components required in this standard practice must be calibrated prior to use.

9.2. *Projector Source*—The source must be calibrated to a correlated color temperature of 2583ºC (2856 K) and loosely duplicate the spectral power distribution of CIE Standard Source A. A method of calibration is described in Appendix X1 based on tristimulus colorimetry. Spectroradiometric methods of calibration are also suitable. A tolerance of *fi*-248ºC (25 K) allows about 1.5 percent variation in test results of colored retroreflectors.

9.3. *Photoreceptor Spectral Response*—The photoreceptor spectral response must be verified in terms of the spectral power distributions measured in this method. A procedure for verification of spectral response is described in Appendix X3. Errors in the photopic fit of the receptor are direct systematic errors in the test result. A maximum variation of *fi* 2 percent relative to both illuminant *A* and the spectral power distribution of the retroreflector when illuminated by source *A* is recommended.

9.4. *Photoreceptor Linearity*—The procedures in this method require the measurement of both incident and reflected light levels which may be several orders of magnitude different in value. To insure accuracy, the photoreceptor and readout system must be linear or appropriate corrections for nonlinearity applied. Appendix X2 describes a method for verification of photoreceptor linearity.

9.5. *Goniometer Calibration*—The goniometer shall be calibrated at the 0 degree entrance angle position. All measurements shall be made relative to this point and shall be checked each time the goniometer or light projector is moved. If measurements are to be made at extreme angles of 75 degrees to near 90 degrees, it is recommended that the goniometer be calibrated at the 90 degrees entrance angle position for greatest accuracy. Calibration of the goniometer may be accomplished by several means. One example is by locating an approximately 300-mm (12-in.) square, high-quality, plane mirror in place of the sample. A 300-mm (12-in.) cross, centered on the surface of the mirror, can be made with photographic black tape. A 600-mm (24-in.) square piece of white construction paper, with a hole in the center, can be placed over the light projector exit aperture. By observing the white paper, the goniometer can be adjusted so that the shadow of the cross is reflected directly on the exit aperture of the projector. This horizontal position of the goniometer is the 0 degree entrance angle of the test sample.

10. TEST PROCEDURES

10.1. *General*—The geometry used to determine the performance of retroreflective materials shall be in accordance with Figures 1 and 2.

10.2. *Goniometer Calibration*—The goniometer shall be calibrated at the 0 degree entrance angle position in the vertical and horizontal planes of the test sample. All measurements shall be made relative to this point and shall be checked each time the goniometer or light projector is moved.

10.3. *Photometric Measurements*—In this method, the same instrument with the same apertures and field of view shall be used to measure $E\tau$ and E_n. Therefore, the photoreceptor need not be calibrated, and the uncalibrated readings of $E\tau$ and E_n are referred to as R_1 and R_2, respectively.

10.3.1. *Procedure I*—The smallest available field aperture large enough to include both the entire retroreflector as seen from the photoreceptor, and the source as viewed from the retroreflector shall be chosen for measurement of R_1 and R_2. The normal illuminance at the face of the sample shall be measured by substituting the photoreceptor for the sample. The photoreceptor entrance aperture shall be placed where the sample is mounted and R_2 shall be recorded. Then, the photoreceptor and the sample shall be returned to their original positions, and R_1 shall be recorded in the same units as R_2.

A measure of the amount of stray light shall be made by replacing the sample with a black surface of the same shape and area. The stray light readings, R_s, shall be subtracted from the reading R_1. The value R_1 in the following equations is the value of R_1 less the stray light reading R_s.

Note 19—To stabilize the instrument and improve the accuracy of the measurements, the photoreceptor must remain energized between measurement of R_2 and R_1.

Note 20—Color correction of the photoreceptor may be necessary because of deficiencies in the photoreceptor's CIE photopic standard observer filter. A correction factor K can be applied by means of a filter having a spectral transmittance proportional to the spectral retroreflectance of the sample. If close spectral matches in permanent filters are not available, it is recommended that the correction factor not be used. When the calibration factor is used, it is determined by the following relation:

$$K = R_2 T / R_f \qquad (9)$$

where:

K = correction factor;

R_2 = reading of the photoreceptor while measuring the normal illuminance at the face of the retroreflective sample (i.e., an uncalibrated E_n);

R_f = reading of the photoreceptor placed at the same position as for the R_2 reading, but with the addition of the color filter placed immediately in front of the acceptance aperture; and

T = known (total) luminance transmittance of the filter for a 2583ºC (2856 K) source (CIE Source A).

10.3.1.1. *Specific Intensity (SI)*:

$$SI = \frac{R_1 \left(D'\right)^2}{R_2} \qquad (10)$$

where:

R_1 = uncalibrated E' (Section 10.3).

The color corrected specific intensity is:

$$SI = \frac{K\ R_1 \left(D'\right)^2}{R_2} = \frac{R_1 \left(D'\right)^2 T}{R_f} \qquad (11)$$

10.3.1.2. *Specific Luminance (SL)*:

$$SL = \frac{R_1 \left(D'\right)^2}{R_2 A \cos \in} \qquad (12)$$

The color corrected specified luminance is:

$$SL = \frac{K\ R_1 \left(D'\right)^2}{R_2 A \cos \in} = \frac{R_1 \left(D'\right) T}{R_f A \cos \in} \qquad (13)$$

10.3.1.3. *Specific Intensity per Unit Area (SIA)*:

$$SIA = \frac{R_1 \left(D'\right)^2}{R_2 A} \qquad (14)$$

The color corrected intensity per unit area is:

$$SIA = \frac{K\ R_1 \left(D'\right)^2}{R_2 A} = \frac{R_1 \left(D'\right)^2 T}{R_f A} \qquad (15)$$

10.3.1.4. *Specific Intensity per Unit Length (SIL)*:

$$SIL = \frac{R_1 \left(D'\right)^2}{R_2\ L} \qquad (16)$$

The color corrected intensity per unit length is:

$$SIL = \frac{K\ R_1 \left(D'\right)^2}{R_2 L} = \frac{R_1 \left(D'\right)^2 T}{R_f L} \qquad (17)$$

10.3.1.5. *Luminance factor (LF)*:

$$LF = \frac{\pi R_1 \left(D'\right)^2}{R_2 A \cos\beta \cos\in} \qquad (18)$$

The color corrected luminance factor is:

$$\begin{aligned} LF &= \frac{\pi\ K\ R_1 \left(D'\right)^2}{R_2 A \cos\beta \cos\in} \\ &= \frac{\pi\ R_1 \left(D'\right)^2 T}{R_f A \cos\beta \cos\in} \end{aligned} \qquad (19)$$

10.3.2. *Procedure II*—This procedure shall be used to determine the performance of a material or a device, using a working standard similar to the material or device being tested. The performance value of the working standard shall be determined in accordance with Procedure I. For each test condition, the values to be used for each of the geometric terms in Section 4.2 shall be defined. The photometric performance values [specific intensity (SI), specific luminance (SL), specific intensity per unit area (SIA), specific intensity per unit length (SIL), or the luminance factor (LF)] shall be assigned to the working standard. Photometric performance of the sample shall be determined by comparison of the sample to the working standard. These comparative measurements shall be accomplished by following Procedure I, except that the working standard shall be placed on the goniometer and reading $R_{1\text{std}}$ shall be taken. The standard shall then be replaced with the sample, and reading $R_{1\text{test}}$ shall be taken.

Note 21—Procedure II offers many advantages where a large number of performance measurements on similar samples are to be determined. However, the working standard and the sample must be similar in size, color, and performance value. Also, periodic recalibration of the working standard is required to compensate for aging. The photoreceptor must be corrected to the photopic standard observer, but does not require the color correction factor *K*, since the standard and the sample are similar in color. (See Note 20.) Optical means to shorten the photometric range, such as high quality mirrors, are allowable under Procedure II.

10.3.2.1. *Specific Intensity (SI)*:

$$SI = \frac{R_{1\text{test}}}{R_{1\text{std}}}\left(SI_{\text{std}}\right) \qquad (20)$$

10.3.2.2. *Specific Luminance (SL)*:

$$SL = \frac{A_{\text{std}} R_{1\text{test}}}{A_{\text{test}} R_{1\text{std}}}\left(SL_{\text{std}}\right) \qquad (21)$$

10.3.2.3. *Specific Intensity per Unit Area (SIA)*:

$$SIA = \frac{A_{\text{std}} R_{1\text{test}}}{A_{\text{test}} R_{1\text{std}}}\left(SIA_{\text{std}}\right) \qquad (22)$$

10.3.2.4. *Specific Intensity per Unit Length (SIL)*:

$$SIL = \frac{L_{\text{std}} R_{1\text{test}}}{L_{\text{test}} R_{1\text{std}}}\left(SIL_{\text{std}}\right) \qquad (23)$$

10.3.2.5. *Luminance Factor (LF)*:

$$LF = \frac{A_{\text{std}} R_{1\text{test}}}{A_{\text{test}} R_{1\text{std}}}\left(LF_{\text{std}}\right) \qquad (24)$$

where:

$R_{1\text{std}}$ = uncalibrated illuminance of the working standard at the aperture, measured in accordance with Procedure I;

$R_{1\text{test}}$ = uncalibrated illuminance of the sample at the photoreceptor aperture, measured in accordance with Procedure I;

SI_{std} = specific intensity determined by Procedure I (relative to a fixed set of test conditions) and assigned to the working standard;

SIA_{std} = specific intensity per unit area determined by Procedure I (relative to a fixed set of test conditions) and assigned to the working standard;

SIL_{std} = specific intensity per unit length determined by Procedure I (relative to a fixed set of test conditions) and assigned to the working standard;

SL_{std} = specific luminance per projected area determined by Procedure I (relative to a fixed set of test conditions) and assigned to the working standard;

LF_{std} = luminance factor determined by Procedure I (relative to a fixed set of test conditions) and assigned to the working standard;

A_{std} = retroreflective area of the working standard;

A_{test} = retroreflective area of the sample;

L_{std} = length of the working standard; and

L_{test} = length of the sample.

11. REPORT

11.1. The report shall indicate the value of the photometric quantity determined, the procedure used (I or II), and all of the measurement requirements stated in Section 6 of this method.

12. PRECISION AND ACCURACY

12.1. The precision and accuracy of this method will vary with the materials tested and the test geometry and, therefore, a specific statement is not included. In general, however, under some test geometries (0.2° observation angle and –4° entrance angle) agreement between laboratories in the order of 5 to 10 percent (standard deviation) has been reported (Section 13.4).

APPENDIX

(Nonmandatory Information)

X1. DETERMINING CORRELATED COLOR TEMPERATURE

X1.1. *Scope*:

X1.1.1. Procedure for determination of correlated color temperature of a projector source of illumination using a tristimulus photoreceptor and standard reference lamp for use in the photometry of retroreflectors.

X1.2. *Apparatus*:

X1.2.1. Standard reference lamp and holder with voltage and current specified for 2856 K.

X1.2.2. Voltmeter (accurate to 0.5 percent) or ammeter (accurate to 0.25 percent), as appropriate to voltages or currents specified for standard reference lamp.

X1.2.3. Photoreceptor equipped with tristimulus filters (X_r, X_b, Y, and Z filters).

X1.2.4. MgO, $BaSO_4$, or other neutral white diffusing surface.

X1.2.5. Test enclosure or photometric range.

X1.3. *Procedure*:

X1.3.1. Set up standard reference lamp, projector to be calibrated, white diffusing surface and tristimulus receptor in a darkroom as shown in Figure X1.1.

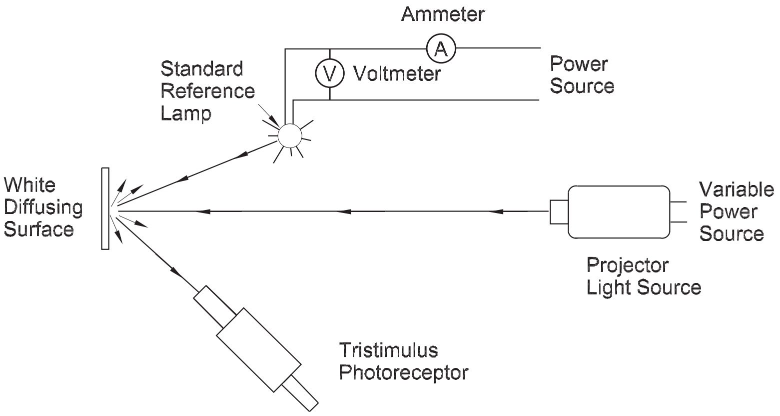

Figure X1.1—Arrangement of Apparatus for Correlated Temperature Measurement of Projector

X1.3.2. Adjust the position (distance between source and diffusing surface) of the standard lamp and projector so that the illumination of each individually on the white diffusing surface is about the same. Allow lamps to warm up until stable (usually about 30 minutes).

X1.3.3. Allow standard lamp only to illuminate white diffusing surface. Carefully adjust the voltage or current as specified on calibration report for the standard reference lamp to obtain 2583ºC (2856 K).

X1.3.4. Measure the relative X_r, X_b, Y, and Z tristimulus filter readings with the tristimulus photoreceptor.

X1.3.5. Turn off the standard lamp and turn on the projector. Measure and record the X_r, X_b, Y, and Z tristimulus values at several voltages bracketing the estimated correct setting for 2583ºC (2856 K).

X1.3.6. Calculate the CIE chromaticity coordinates for each voltage on the projector using the tristimulus readings of the standard lamp as a reference. That is, for 2583ºC (2856 K) the correct tristimulus values are:

- $X_r = 104.4$
- $X_b = 5.38$
- $Y = 100$
- $Z = 35.55$

Thus, each of the "as read" values on the projector must be corrected to the reference standard as follows:

$$X_r\ (\text{corrected}) = X_r\ (\text{as read}) \times \frac{104.4}{X_r\ (\text{as read std. lamp})} \tag{X1.1}$$

$$X_b\ (\text{corrected}) = X_b\ (\text{as read}) \times \frac{5.38}{X_b\ (\text{as read std. lamp})} \tag{X1.2}$$

$$Y\ (\text{corrected}) = Y\ (\text{as read}) \times \frac{100}{Y\ (\text{as read std. lamp})} \tag{X1.3}$$

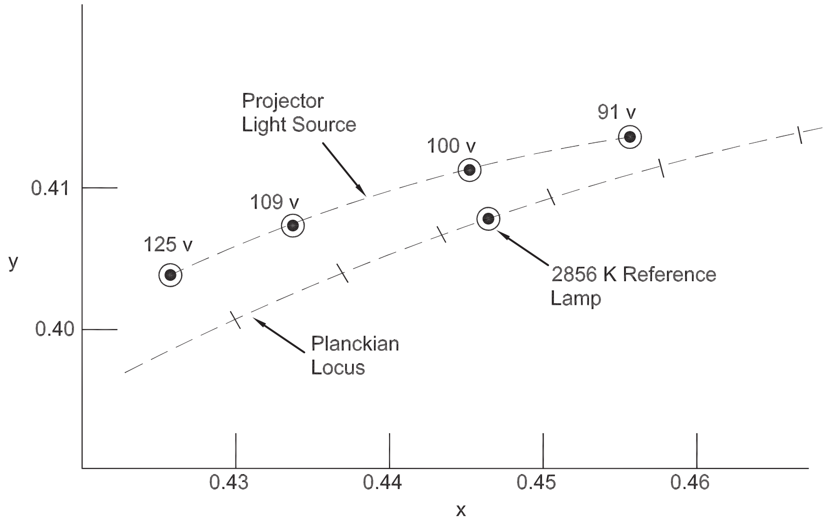
$$Z\ (\text{corrected}) = Z\ (\text{as read}) \times \frac{35.5}{Z\ (\text{as read std. lamp})} \tag{X1.4}$$

X1.3.7. Then the small x, small y chromaticity coordinates are calculated.

$$x = \frac{X_r + X_b}{X_r + X_b + Y + Z} \tag{X1.5}$$

$$y = \frac{Y}{X_r + X_b + Y + Z} \tag{X1.6}$$

X1.3.8. Finally, the chromaticity coordinates are plotted on graph paper and the nearest point of 2856 K is selected as the best voltage to operate the projector for CIE Source A. See Figure X1.2.



Note: 100 volts would be the proper voltage at which to operate the projector source.

X2. DETERMINING PHOTORECEPTOR LINEARITY

X2.1. *Scope*:

X2.1.1. Determination of Photoreceptor Linearity Corrections for use in the Photometry of Retroreflectors.

X2.2. *Equipment*:

X2.2.1. Two-projector sources of illumination.

X2.2.2. Two adjustable irises and holders.

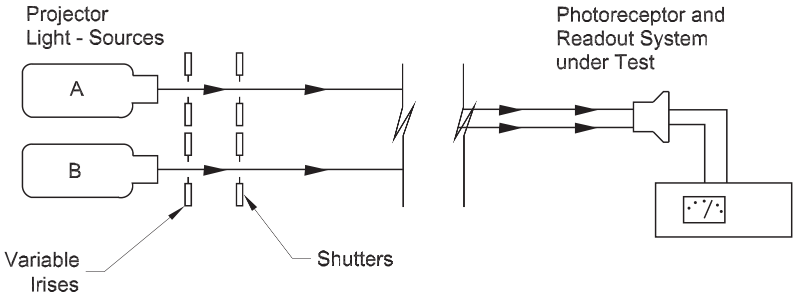
X2.2.3. Two shutters and holders.

X2.2.4. Enclosure or photometric range (large enough so that photoreceptor can be illuminated approximately perpendicularly from both light sources).

X2.3. *Procedure:*

X2.3.1. *Test Method*:

X2.3.1.1. Set up the two light sources, irises, shutters, and photoreceptor/readout system to be calibrated as shown in Figure X2.1. The light sources should be arranged such that the illumination from each source is perpendicular (±*fi*1º) to the entrance aperture of the photoreceptor. The light sources must be stabilized, and their voltages or currents monitored.



DATA SHEET FOR
PHOTO RECEIVER LINEARITY TEST

1 READING SOURCE A ONLY	**2 READING SOURCE B ONLY**	**3 READING SOURCE A & B ONLY**	**4 CALCULATED SUM A & B**	**5 RATIO 3 ÷ 4**	**6 CUMULATIVE RATIO**	**7 NORMALIZED CELL LINEARITY CORRECTION**

Figure X2.1—Arrangement of Apparatus for Two-Source Linearity Test

X2.3.1.2. Determine the lowest reading attainable on the photoreceptor/readout device (for example 0.000001 units). This will be the starting illumination level for the test.

X2.3.1.3. With both shutters closed, set the photoreceptor/readout device to read zero.

X2.3.1.4. Open the shutter on Source A and adjust the iris for the starting reading determined in Section X2.3.1.2 above. Close the shutter on Source A and open the shutter on Source B and adjust the iris for the same reading. Record these readings in Columns 1 and 2 of the data sheet. (Note: Switch back and forth between the two sources and the zero readings to be sure irises and zero are accurately set.)

X2.3.1.5. Now open both shutters simultaneously. Record the reading in Column 3 of the data sheet.

X2.3.1.6. Next, independently adjust each projector to combined reading obtained in Section X2.3.1.5. Record the individual readings in Columns 1 and 2 on the next line of the data sheet.

X2.3.1.7. Repeat Section X2.3.1.5 for the new illumination levels set in Section X2.3.1.6, and record the total in Column 3 of the data sheet.

X2.3.1.8. Repeat Sections X2.3.1.4, 5, and 6 until the maximum illumination levels available for the two light sources are reached.

X2.3.1.9. Starting with a new data sheet, repeat Sections X2.3.1.2 through 8 except use starting with illuminations 12, 14, 16, and 18 times the lowest illumination detectable with the photoreceptor/readout system.

X2.3.2. *Calculations*:

X2.3.2.1. Add each reading in Column 1 to the reading in Column 2 to determine the result expected if the system is linear. Enter this mathematical sum in Column 4.

X2.3.2.2. Determine the ratio of the theoretical result to the actual result by dividing the individual readings in Column 3 by the individual readings in Column 4 and enter in Column 5.

X2.3.2.3. Determine the cumulative nonlinearity by multiplying the proportion in Column 5 times the previous cumulative result in Column 4 and enter in Column 6.

X2.3.2.4. Repeat the above calculations for all data points taken.

X2.3.2.5. Now interpolate between reading the Column 3 and Column 6 to determine the correction factor for a readout response in the middle of the range (for example, 0.001 units) to use as a reference point. Divide all the values in Column 6 by this result and enter in Column 7.

X2.3.2.6. The result in Column 7 is the normalized correction factor computed about the midrange reference point (e.g., 0.001 units). Note: The correction factors are normalized in this way so that all will be on the same basis for averaging below.

X2.3.2.7. Repeat the calculations in Sections X2.3.2.1 through X2.3.2.6 for remaining data sheets.

X2.3.2.8. Finally, determine the correction factors at log equal spacing throughout the range of calibration by interpolation.

X2.3.2.9. Average these factors to determine the best linearity correction curve.

X2.3.2.10. These final values may be used to plot a linearity correction curve on semilog paper for manual correction or entered into a computer program for automatic correction of photometric test data for linearity.

X2.3.2.11. Linearity correction of data taken in the photometric test of a retroreflector is then obtained by dividing the "as read" value from the readout device by the correction factor obtained from the linearity correction curve just plotted.

X3. VERIFYING PHOTOPIC RESPONSIVITY

X3.1. *Scope*:

X3.1.1. This Appendix describes a procedure for verifying the adequacy of the spectral response of the photoreceptor used in the photometry of retroreflectors. Adequate color correction for one product does not necessarily imply adequate correction of other products. Color correction for whites and greens is much easier to obtain than for deep blues and highly saturated reds.

X3.2. *Introduction*:

X3.2.1. A method of determining the adequacy of the photopic match of the photoreceptor and the possible need for correction is to compare the photoreceptor responsivity to the retroreflected spectral curve. The spectroradiometric test in Section X3.3 provides an outline of this method. In many cases where facilities to actually make these spectroradiometric measurements are unavailable, the spectral responsivity and spectral reflectance factors can be obtained directly from the manufacturer of the photoreceptor and the manufacturer of the retroreflector.

X3.2.2. The use of the color correction factor *K* generated by using a colored filter with spectral transmittance matching the retroreflected spectrum is a suitable method of compensating for errors in the spectral responsivity of the photoreceptor. This method is described in Note 21 of the main document. The "Caution" paragraphs should be carefully followed if they apply.

X3.3. *Spectroradiometric Test Method*:

X3.3.1. *Determination of the Spectral Responsivity of a Photoreceptor*:

X3.3.1.1. Set up a regulated tungsten light source, a monochromator for the visible spectrum to negligible levels.

X3.3.1.2. Using either a thermopile reference receiver with a flat responsivity with respect to wavelength or a calibrated silicon detector, calibrate the monochromator and source through the visible spectrum at 10-nm intervals and as far into the UV and IR as necessary to cover the photoreceptor responsivity.

X3.3.1.3. Now replace the calibrated reference receivers with the photoreceptor to be used in the testing of the retroreflector. Measure and compute the responsivity of the photoreceptor at 10-nm intervals.

X3.3.1.4. Taking the response of the thermopile equal to 100 at each wavelength, tabulate the relative responsivity [$R(\lambda)$] of the photoreceptor at 10-nm intervals.

X3.3.1.5. Normalize the response of the photoreceptor at each wavelength so that the summation $\Sigma R(\lambda) = \Sigma V(\lambda)$, where $V(\lambda)$ is the CIE Standard Luminosity Curve (obtainable from standard reference texts on photometry and ASTM E 308).

X3.3.2. *Determination of the Retroflected Spectrum of the Retroflector*:

X3.3.2.1. Set up the apparatus used to test the retroreflector as described in the geometry section of the photometric test method, except substitute a spectroradiometer for the photoreceptor.

X3.3.2.2. Now tabulate the intensity of the retroreflected light [W(λ)] at 10-nm intervals using the spectroradiometer.

X3.3.3. *Calculation of Error in Integrated Response of Photoreceptor*:

X3.3.3.1. Calculate the percent difference between the integrated response of the photoreceptor and that of the standard luminosity curve times the retroreflected spectrum of retroreflector for Source A using the following equation:

Percent error:

$$100 \times \frac{\sum\left[V(\lambda)-R(\lambda)\right]\cdot W(\lambda)}{\sum V(\lambda)\cdot W(\lambda)} \qquad \textit{(X3.1)}$$

Perform this summation at 10-nm intervals over the visible spectrum and as far into the IR or UV as any appreciable response was detected.

X3.3.3.2. The "percent error" for the above equation is direct systematic error in the photometric test of the retroreflector for which the calculation is made.

X3.3.3.3. If the error is more than 2 percent, a suitable correction factor must be applied to the reading for that particular product color.

Standard Method of Test for

Sampling and Testing Calcium Chloride for Roads and Structural Applications

AASHTO Designation: T 143-04 (2009)
ASTM Designation: D 345-02

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling and Testing Calcium Chloride for Roads and Structural Applications

AASHTO Designation: T 143-04 (2009)
ASTM Designation: D 345-02

AASHTO T 143-04 is identical to ASTM D 345-02 except for the following provisions:

1. All references to ASTM Standards C 136 and D 98 shall be replaced with AASHTO Standards T 27 and M 144, respectively.
2. Replace Section 5 of ASTM D 345-02 with the following:

   5. Sampling

   5.1 *Solid*—Sample a shipment of the solid form calcium chloride for test purposes by selecting not less than three containers at random from the shipment. Sample each of the containers by scraping aside the top layer to a depth of approximately 25 mm (1 in.) and taking 0.5-kg (1-lb) samples by means of a sampling thief or other method that will ensure a sample that is representative of a cross section of the material in the container to a depth of at least 152 mm (6 in.). Take precautions during the sampling operation to avoid exposing the sample unduly to atmospheric moisture. Immediately and thoroughly mix the individual samples to form a representative composite sample of material and store in a sealed glass or suitable plastic container.

   5.2 *Liquid*—Sample a shipment of liquid form calcium chloride for testing purposes by selecting not less than three samples from each container of the shipment by means of an appropriate sampling device or other method that will ensure a sample that is representative of the contents of the container. Take precautions during the sampling operation to avoid exposing the sample unduly to atmospheric moisture. Immediately and thoroughly mix the individual samples to form a representative composite sample of material and store in a sealed glass or suitable plastic container.
3. Section X1.2.2 of ASTM D 345-02 is not included in AASHTO T 143-04.
4. Replace the first two sentences of Section X1.5.1 of ASTM 345-02 with the following sentence:

   In a weighing bottle, weigh a sample of approximately 20 g to the nearest 0.1 g and dissolve in distilled water.

Standard Method of Test for

Testing Epoxy Resin Adhesive

AASHTO Designation: T 237-05 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Testing Epoxy Resin Adhesive

AASHTO Designation: T 237-05 (2009)

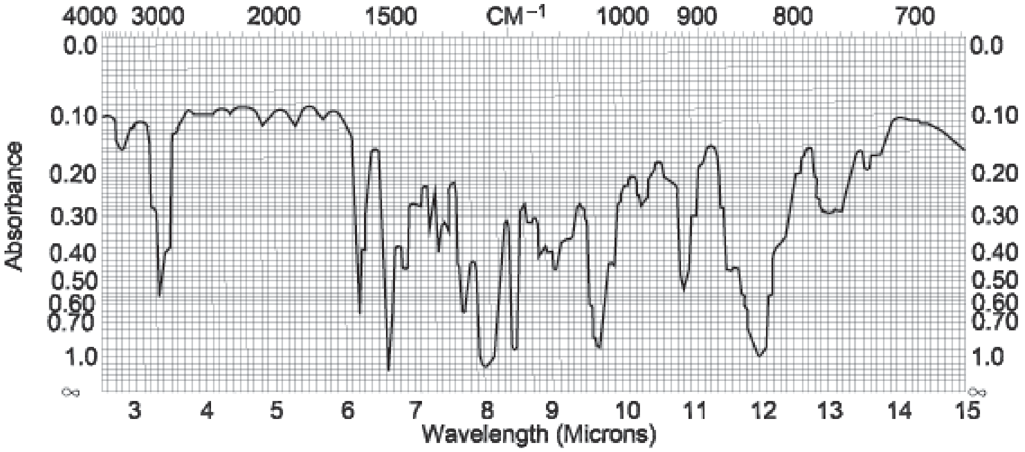
1. SCOPE

1.1. The methods given cover the examination of epoxy resin adhesives for use in bonding traffic markers to pavements, cured concrete to cured concrete, fresh concrete to cured concrete, and are divided into two parts:

1.2. Part I (Sections 3 through 25) covers AASHTO M 235M/M 235, Class I and II, and AASHTO M 237, Class I adhesives. (See Figure 1.)

1.3. Part II (Sections 26 through 35) covers AASHTO M 235M/M 235, Class III and AASHTO M 237, Class II adhesives. (See Figure 1.)

1.4. The values stated in SI units are to be regarded as the standard.



A Component

Epoxy adhesive for bonding traffic markers to cured concrete, AASHTO M 237 - Class I

Epoxy adhesive for bonding cured to cured concrete, AASHTO M 235 - Class II

Epoxy adhesive for bonding fresh to cured concrete, AASHTO M 235 - Class I

Figure 1—Epoxy Adhesive for Bonding Traffic Markers to Cured Concrete

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 85, Portland Cement
- M 235M/M 235, Epoxy Resin Adhesives
- T 106M/T 106, Compressive Strength of Hydraulic Cement Mortar (Using 50-mm or 2-in. Cube Specimens)
- T 132, Tensile Strength of Hydraulic Cement Mortars

2.2. *ASTM Standards*:

- C 778, Standard Specification for Standard Sand
- D 570, Standard Test Method for Water Absorption of Plastics
- D 1002, Standard Test Method for Apparent Shear Strength of Single-Lap-Joint Adhesively Bonded Metal Specimens by Tension Loading (Metal-to-Metal)

PART I

3. GEL TIME—APPARATUS AND MATERIALS

3.1. Gel Timer.

3.2. Disposable wire stirrers.

3.3. Unwaxed paper cups, 60 mL (2 oz), 38-mm (1-$^1/_2$ in.) diameter base.

3.4. Unwaxed paper cups, 240 mL (8 oz), 76-mm (3-in.) diameter base.

3.5. Stainless Steel Spatula with blade 150 × 25 mm (6 × 1 in.), and with end cut square.

3.6. Stop watch.

Note 1—Equipment available from: SHYODU Gel Timer Model 100, SHYODU Instrument Company, 6351 Old Tipton Road, Millington, TN 38053, Telephone (901) 872-6894, Facsimile (901) 872-6868.

4. GEL TIME—PROCEDURE

4.1. Condition both A and B components to 25 ± 1°C (77 ± 2°F).

4.2. Stir the separate components vigorously with a spatula to redisperse any settled material. Use separate spatula for each component.

4.3. Using the 60-mL cups, prepare 100 g of epoxy adhesive by measuring each component in the proper ratio into a 240-mL paper cup.

4.4. Start stopwatch immediately and mix the components for 60 seconds using a spatula and taking care to scrape the sides and bottom of the cup periodically.

4.5. Place the sample at 25 ± 1°C (77 ± 2°F) in a retaining ring on the gel timer.

4.6. Insert wire stirrer into the sample and attach to the gel timer. Check to insure the stirrer does not touch the side or bottom of the cup.

4.7. Zero the gel timer.

4.8. Start the gel timer.

4.9. Stop the stopwatch and record the initial mixing time.

4.10. Record the time from the gel timer when it stops.

4.11. The gel time is the initial time of mixing plus the elapsed time recorded by the gel timer.

5. POT LIFE (OPTIONAL PROCEDURE)—APPARATUS AND MATERIALS

5.1. Unwaxed paper cups, 240 mL (8 oz), 50 ± 6-mm (2 ± $^1/_4$-in.) diameter base.

5.2. Unwaxed paper cups, 60 mL (2 oz), 38-mm ($1^1/_2$-in.) diameter base.

5.3. Wooden tongue depressor with ends cut square.

5.4. Stainless steel spatula with blade 150 × 25 mm (6 × 1 in.), and with the end cut square.

6. POT LIFE (OPTIONAL PROCEDURE)—PROCEDURE

6.1. Condition both A and B components to 25 ± 1°C (77 ± 2°F).

6.2. Stir the separate components vigorously with a spatula to redisperse any settled materials. Use separate spatula for each component.

6.3. Using the 60-mL cups, measure each component, in the proper ratio, into the 240-mL cup.

6.4. Start stopwatch immediately and mix the components for 60 seconds using a wooden tongue depressor and taking care to scrape the sides and bottom of the cup periodically.

6.5. Place the sample at 25 ± 1°C (77 ± 2°F) on a wooden bench top that is free of excessive drafts.

6.6. Probe the mixture once with the tongue depressor every 30 seconds, starting 5 minutes prior to the minimum specified pot life.

6.7. The time at which a soft stringy mass forms in the center of the cup is the pot life.

INFRARED SPECTRUM

7. APPARATUS

7.1. Double-beam infrared recording spectrophotometer,[1] 2.5 microns to 15 microns.

7.2. Disk holder for a disk approximately 25 mm in diameter.

7.3. Two sodium chloride crystal disks approximately 25 mm in diameter.

7.4. Superspeed centrifuge able to separate the liquid and solid phases of the adhesive components without previous dilution with solvents.[2]

8. PROCEDURE

8.1. Place about 15 g of Component A into a stainless steel centrifugal tube.

8.2. Counterbalance with Component B in a second centrifuge tube.

8.3. Centrifuge the two components until there is a supernatant liquid layer present in each tube. This takes 20 to 30 minutes at 17 000 r/min.

8.4. Place a drop of Component A liquid layer on a sodium chloride disk.

8.4.1. Place another sodium chloride disk over the drop, rotate and press down until the liquid has flowed into a uniform layer of proper thickness between the two sodium chloride disks.

8.4.2. Place the disks in the holder and run an absorption curve with the infrared spectrophotometer.

8.4.2.1. More or less liquid may be used between the disks so as to produce a maximum absorption of 0.7 to 1.0 for the strongest absorption point on the curve.

8.4.3. Clean the disks with toluene and dry.

8.4.4. Repeat steps in Sections 8.4 through 8.4.3 with the liquid layer from Component B.

8.5. Compare each curve with the appended absorption curves for standard materials. Two materials are considered to be identical if all of the absorption points agree as to wave length and relative magnitude of the peaks in comparison with the other points of absorption. (See Figures 2a, 2b, and 2c.)

DENSITY

9. APPARATUS AND PROCEDURE

9.1. Follow Federal Standard No. 141, Method 4184.

BROOKFIELD VISCOSITY

10. APPARATUS AND MATERIALS

10.1. Brookfield Syncro-Electric Viscometer, Model RVT, Brookfield Engineering Laboratories, Stroughton, Massachusetts.

10.2. Brookfield Helipath Stand, Model C, with TD spindle and spindle weight.

10.3. Round 475-mL (1-pt) paint cans.

10.4. Stainless steel spatula having a blade 150 by 25 mm (6 by 1 in.) with the end cut square.

11. PROCEDURE

11.1. Fill a 475-mL (1-pt) can within 25 mm (1 in.) of the top with well-mixed Component A.

11.2. Condition the material to 25°C (77°F).

11.3. Stir the material vigorously for 30 seconds with a spatula.

11.4. Remove entrained air bubbles by vigorous tapping.

11.5. Insert the spindle and make a viscosity reading at 5 r/min within 10 minutes after stirring.

11.5.1. Make additional readings at 2.5 r/min and 0.5 r/min for use in the Shear Ratio Test (Sections 23 through 25).

11.6. Repeat to determine viscosity of Component B.

12. CALCULATION

12.1. Follow manufacturer's instructions for calculating Brookfield Viscosity.

SAG TEST

13. APPARATUS AND MATERIALS

13.1. Stiff glazed paper 254 by 139 mm (10 by $5^1/_2$ in.).[3]

13.2. Clipboard.

13.3. Metal shims 0.76 ± 0.03 mm (0.030 ± 0.001 in.) thick approximately 25 mm by 250 mm (1 by 10 in.).

13.4. Doctor blade.

14. PROCEDURE

14.1. Place the paper on the clipboard with glazed surface up.

14.2. Place two pieces of metal shim stock on top of the glazed paper to produce a space 230 mm (9 in.) long by 64 mm ($2^1/_2$ in.) wide. Use the clip to hold the shim stock and chart in place.

14.3. Condition both A and B components to 25°C (77°F).

14.4. Stir the components vigorously for 30 seconds with a spatula.

14.5. Mix for 30 seconds sufficient material in the specified ratio of Component A to Component B and immediately apply the mixed material to the glazed paper between the shim material.

14.6. Draw the doctor blade over the surface to produce a film 64 mm ($2^1/_2$ in.) wide by 152 mm (6 in.) long, 0.76 ± 0.10 mm (0.03 ± 0.004 in.) thick.

14.7. Release the clip and carefully remove the shims by lifting them upward while holding the glazed paper down.

14.8. Support the paper vertically with the 152-mm (6-in.) side of the strip in a horizontal position.

14.9. After 30 minutes, record the sag to the nearest 2.5 mm (0.1 in.).

BOND STRENGTH TO CONCRETE

15. APPARATUS AND MATERIALS

15.1. Stopwatch, 1 second or smaller divisions.

15.2. A sandblasted, 50-mm (2-in.) diameter steel or aluminum plug approximately 50 mm (2 in.) long, drilled, and threaded on one end to accept a threaded steel rod or hook for insertion into the testing press or apparatus.[4]

15.3. A sandblasted concrete block 305 mm (12 in.) square by 75 mm (3 in.) thick, prepared with 390 kg/m^3 (7 sack) concrete and having a tensile strength in excess of 1725 kPa (250 psi).

15.4. Testing press operating at a load rate of 22.2 kN/min (5000 lbf/min). Alternately, a maximum indicating dynamometer fitted with 25-mm (1-in.) eyes and mounted in a housing allowing application of an upward vertical pull may be used.

16. PROCEDURE

16.1. Condition the test equipment, materials and epoxy components for 24 hours at the testing temperature specified.

16.2. Stir the separate components vigorously for 30 seconds.

16.3. Measure the components in the proper ratio onto a tin plate and mix with a spatula for 60 ± 5 seconds.

16.4. Place the adhesive on the sandblasted surface of the plug and concrete surface.

16.5. Press the plug firmly in place and remove the excess adhesive.

16.6. Just before the required test time, insert the threaded rod or hook into the plug.

16.7. Apply loading at the specified rate until failure and record the maximum load attained before failure.

16.8. Calculate the bond strength to concrete attained before failure as follows:

$$\text{Bond Strength, kPa (psi)} = \frac{TL}{A} \qquad (1)$$

where:

TL = total load N (lbf), and

A = area of bond m^2 (in.^{2}).

TENSILE ADHESION AND COHESION

17. APPARATUS AND MATERIALS

17.1. Use the testing apparatus described in Section 15.

17.2. Cold box capable of maintaining –9.5 ± 1.0°C (15 ± 2°F).

17.3. Oven capable of maintaining 60 ± 1°C (140 ± 2°F).

17.4. As specimens, use pavement markers representative of those intended for installation.

18. PROCEDURE

18.1. Stir the separate components vigorously for 30 seconds.

18.2. Measure the components in the proper ratio onto a tin plate and mix with a trowel or spatula for 60 ± 5 seconds.

18.3. Place the adhesive on the plug and the marker surface.

18.4. Press the plug firmly in place and remove excess adhesive.

18.5. Cure all specimens for 24 hours at 25 ± 1°C (77 ± 2°F).

18.6. Proceed according to Sections 16.6 to 16.8.

18.7. Post cure at least one of the specimens further as follows:

18.7.1. Cure 48 hours at 60°C (140°F);

18.7.2. Return to 25°C, and then place in cold box for 24 hours at –9.5°C (15°F); and

18.7.3. Return to 25°C, and test as in Section 18.6.

SLANT SHEAR STRENGTH

19. MATERIALS

19.1. Graded standard (Ottawa) sand conforming to AASHTO T 106M/T 106, Section 6, “Materials,” and ASTM C 778.

19.2. Type II portland cement conforming to AASHTO M 85.

19.3. Water.

20. APPARATUS

20.1. Suitable mold to make diagonal concrete mortar blocks with a square base with 50.8-mm (2-in.) sides and having one diagonal face 50.8 by 101.6 mm (2 in. by 4 in.) standing about 19 mm ($^3/_4$ in.) above the base. After sandblasting, the diagonal faces of two such blocks are bonded together, producing a block 50.8 by 50.8 by 127 mm (2 in. by 2 in. by 5 in.).

20.2. Test blocks are made from the following composition in parts-by-mass.

- Standard, 20.1
- Portland cement, 12.1
- Water, 4.8

20.3. Suitable testing press.

21. PROCEDURE

21.1. Mix adhesive as described in Section 16.2 and apply a coat to each diagonal surface. Press diagonal surfaces of each block together by hand and remove excess adhesive.

21.2. Align the blocks so that the ends and sides are square and form a block 50.8 by 50.8 mm by 127 mm (2 in. by 2 in. by 5 in.). Use blocks of wood or metal against each end to keep diagonal faces from slipping.

21.3. After the required cure time as specified, apply a suitable capping compound to each end and test by applying a compression load at the rate of 22.2 kN/minute (5000 lbf/minute) until failure.

21.4. For wet shear strength, bond another set of blocks together as described above. Cure 24 hours at 25 ± 1°C (77 ± 2°F) and immerse in water 7 days at 25 ± 1°C (77 ± 2°F), remove and immediately test as described above in Section 21.3.

22. CALCULATIONS

22.1. Calculate the test value of kPa (psi) using the 50.8 by 50.8 mm (2 by 2 in.) dimensions to calculate specimen area:

$$\text{Stress, kPa (psi)} = \frac{TL}{A} \qquad (2)$$

where:

TL = total load N (lbf), and

A = end area of specimen.

SHEAR RATIO

23. APPARATUS AND MATERIALS

23.1. Same as Section 10.

24. PROCEDURE

24.1. Same as Section 11.

25. CALCULATIONS

25.1. Shear ratio = [viscosity in Pa·s (Centipoise) at 0.5 r/min)/(viscosity in Pa·s (Centipoise) at 2.5 r/min].

PART II

26. PREPARATION OF SAMPLE

26.1. For all tests on the mixed adhesive, the two components shall be proportioned by mass. The gallon mass of each component shall be determined by Federal Standard No. 141, Method 4184. The mass ratio of the components shall be calculated using the gallon masses and the proper volume ratio.

27. CONSISTENCY

27.1. A minimum sample of 475 mL (1 pt) of the mixed adhesive shall be used for viscosity determinations.

27.2. ASTM D 1084, Method B, using a speed of 20 r/min. Initial temperature of samples shall be 25 ± 0.5°C (77 ± 1°F). In the case of marker adhesives, the spindle shall be allowed to rotate for two minutes before taking a reading. For the concrete adhesives, a total of 400 g (0.88 lb) of the components shall be weighed into a pint can and stirred together for five minutes before determining viscosity. Allow spindle to rotate for 30 seconds before taking reading.

28. POT LIFE

28.1. The initial temperature of the adhesive components and the ambient temperature shall be 25 ± 1°C (77 ± 2°F) for this test. A total of 100 g (0.22 lb) of the adhesive shall be weighed into a 180-mL (6-oz) metal ointment can approximately 70 mm (2.75 in.) in diameter, the time recorded and the two components mixed for 3 minutes with a nonreactive spatula. The sides and bottom of the container should be scraped periodically during the mixing. The container shall then be set on a wooden block and probed with a glass stirring rod. For Type I and I-M through III and III-M marker adhesives, probe every minute starting 5 minutes from the initiation of mixing. For Type IV and IV-M marker adhesive and the concrete adhesives, probe every 2 minutes, starting 16 minutes from the initiation of mixing. In all cases, the time at which the material becomes unworkable or begins to solidify is recorded as the pot life.

29. SET TIME

29.1. The ambient temperature and the initial temperature of the individual components used in this test shall be either 4.4 ± 1.0°C or 25 ± 1°C (40 ± 2°F or 77 ± 2°F).

29.2. Cement mortar briquettes shall be prepared according to AASHTO T 132 using Type III cement complying with AASHTO M 85 and sand complying with AASHTO M 6. The briquettes shall be cured for a minimum of 7 days and then sawed at the centerline perpendicular to the long axis. A diamond tooth saw or other cutting tool capable of producing clean smooth faces on the briquette halves shall be used. The halves shall be allowed to dry before use. Approximately 50 g of the adhesive shall be mixed with a spatula in a 180-mL (6-oz) nonreactive container for 3 minutes. The cut faces of the briquettes shall then be coated with the adhesive and put together with light pressure. The excess adhesive shall be removed from the edges of the bonded area and the briquettes should remain undisturbed until time for testing. No more than 10 minutes after mixing shall elapse during preparation and bonding of the briquettes. A minimum of three briquettes shall be prepared. The briquettes shall be subjected to tensile loading with the Riehle briquette tester and the load at failure recorded.

29.3. This test shall be performed at the manufacturer's specified maximum set time and must yield an average strength of 1240 kPa (180 psi).

30. THIXOTROPY

30.1. This test shall be performed with the initial temperature of the adhesive and materials used in the test at 25 ± 1°C (77 ± 2°F) and also at 49 ± 1.5°C (120 ± 3°F).

30.2. The two components of the epoxy adhesive shall be stirred together for at least 1 minute, but not more than 2 minutes and then applied to a smooth, clean steel plate to form a panel of epoxy material 50 mm (2 in.) wide, 100 mm (4 in.) in length, and 2.5 mm (or 100 mL) in thickness. A removable form of the proper dimensions shall be used in placing the epoxy on the steel plate. The epoxy shall be poured into the form and the excess struck off level with the top edge and then the form removed. Immediately after forming the epoxy adhesive, the steel panel shall be placed so that the 100-mm (4-in.) dimension of the epoxy panel is vertical. For thixotropy at 25°C (77°F), the panel shall be placed in a room maintained at 25 ± 1°C (77 ± 2°F). For thixotropy at 49°C (120°F), the panel shall be placed in an oven maintained at 49 ± 1.5°C (120 ± 3°F). Not more than 4 minutes shall elapse between the initiation of mixing and placing the panel in the vertical position. After the adhesive has hardened, draw two lines parallel with the 100-mm (4-in.) dimension 13 mm (0.5 in.) from each edge of the epoxy and four lines parallel to the 50-mm (2-in.) dimension spaced 25 mm (1 in.) apart beginning 13 mm (0.5 in.) from the top edge of the panel. Measure the combined thickness of the panel and epoxy adhesive remaining within the original 50 by 100 mm (2 by 4 in.) area by averaging the eight readings and subtracting the thickness of the steel plate.

31. ADHESIVE SHEAR STRENGTH

31.1. The adhesive shear strength is to be determined in accordance with ASTM D 1002. Steel specimens shall be used. The surfaces of the test specimens used in the adhesive shear strength test shall be prepared by blasting to white metal using a 6.4-mm ($^1/_4$-in.) diameter nozzle and a gun pressure of 345 to 565 kPa (50 to 75 psi). The abrasive used shall be equivalent to Garnet Blasting Abrasive, 250 μm (60 mesh), manufactured by Idaho Garnet Abrasive Company, Kellogg, Idaho. The specimens shall be cured 7 days at 24 ± 3°C (75 ± 5°F).

32. WATER GAIN

32.1. The water gain (24 hours emerged at 23°C) shall be determined in accordance with ASTM D 570, with the following modifications. The specimens shall be prepared by casting disks of the epoxy adhesive 70 mm ($2^3/_4$ in.) in diameter and approximately 10 mm ($^3/_8$ in.) thick. Prior to testing, the plane surfaces of the disks shall be ground or machined flat and parallel. The machining or grinding must be done in such a way as to not heat the disks above 48.9°C (120°F). The thickness of the disks after preparing the surfaces shall be 7.6 ± 0.5 mm (0.30 ± 0.02 in.). The specimens shall be cured 7 days at 24 ± 3°C (75 ± 5°F).

33. IMPACT STRENGTH

33.1. The ambient temperature and temperature of equipment shall be 24 ± 3°C (75 ± 5°F). The specimens shall be prepared as outlined in Section 32, Water Gain. The specimens shall be cured 7 days at 24 ± 3°C (75 ± 5°F) before testing. The specimens shall be placed on a smooth concrete slab or a smooth steel plate at least 13 mm ($^1/_2$ in.) thick firmly attached to a concrete slab. A 454-g (1-lb) steel ball shall be dropped onto the center of the disks from an initial height of 1.5 m (5 ft). The height shall be increased by 0.150 m ($^1/_2$ ft) for each successive drop until the specimen fails by cracking or shattering. The height of drop at which failure occurs shall be recorded as the impact strength in joules (foot-pounds). A minimum of four specimens shall be tested and the average reported to the nearest 0.68 J ($^1/_2$ foot-pound).

34. BONDING OF FRESH PORTLAND CEMENT CONCRETE TO CURED PORTLAND CEMENT CONCRETE

34.1. Approximately 50 g of the adhesive shall be mixed with a spatula in a nonreactive container for 3 minutes. The adhesive shall then be applied to the cut faces of briquette halves prepared as described in Section 29.2, Set Time. After the adhesive has become tacky, new mortar prepared as described in the Set Time determination shall be molded against it to form a complete briquette. The resulting briquettes shall be cured according to the method set forth in T 132 and then subjected to tensile loading with a briquette tester after 7 days' cure.

34.2. A minimum of six briquettes shall be tested. If the average strength of the briquettes tested is less than 2755 kPa (400 psi) and any of these briquettes failed in the mortar at strengths below 2755 kPa (400 psi), an additional set of specimens shall be prepared and tested.

35. WET STRENGTH

35.1. A minimum of three specimens shall be prepared as described under Section 29.2, Set Time. The bonded briquettes shall be allowed to cure for 1 day at 24 ± 3°C (75 ± 5°F), followed by 2 days in an oven maintained at 49.0 ± 1.5°C (120 ± 3°F). The cured specimens shall be immersed in distilled water maintained at 38.0 ± 1.5°C (100 ± 3°F) for a total of 7 days. The specimens shall then be removed from the bath, placed in water maintained at 23.0 ± 1.5°C (75 ± 3°F) for 60 minutes, then subjected to tensile loading with a briquette tester and the load at failure recorded. If the average strength of the briquettes tested is less than 2070 kPa (300 psi) and any of these briquettes failed in the mortar at strengths below 2070 kPa (300 psi), an additional set of specimens shall be prepared and tested.

---

[1] The Perkin-Elmer Model 137-B Infracord Spectrophotometer has been found satisfactory.
[2] The Sorvall SS-3 Automatic Superspeed Centrifuge has been found satisfactory.
[3] Form 2A—Opacity obtained from The Leneta Co., P.O. Box 576, Ho Ho Kus, NJ 07428, has proven satisfactory.
[4] Other diameter plugs may be used. However, use of the specified diameter simplifies calculations.

Standard Method of Test for

Thermoplastic Traffic Line Material

AASHTO Designation: T 250-05 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Thermoplastic Traffic Line Material

AASHTO Designation: T 250-05 (2009)

1. SCOPE

1.1. The procedures used for testing thermoplastic traffic line material are described in this method. This includes the method for obtaining a representative test sample, preparation of the test specimens, and performing the specified tests. The material is a mixture of resins, fillers, pigments, and reflective spheres. These materials are combined by heating to obtain a product with the desired properties suitable for traffic line striping.

1.2. This test method is divided into the following parts:

1.2.1. Section 3, Sampling of Thermoplastic Material;

1.2.2. Section 4, Sample Meltdown and Preparation;

1.2.3. Section 5, Binder Content;

1.2.4. Section 6, Glass Bead Content;

1.2.5. Section 7, Glass Bead Grading Analysis;

1.2.6. Section 8, Reflectance, Color, and Yellowness Index;

1.2.7. Section 9, Titanium Dioxide Determination;

1.2.8. Section 10, Lead Chromate Determination;

1.2.9. Section 11, Flowability (Percent Residue);

1.2.10. Section 12, Low Temperature Stress Resistance;

1.2.11. Section 13, Bond Strength;

1.2.12. Section 14, Impact Resistance;

1.2.13. Section 15, Ring-and-Ball Softening Point;

1.2.14. Section 16, Specific Gravity;

1.2.15. Section 17, Flowability (Percent Residue) Extended Heating;

1.2.16. Section 18, Ultraviolet Light and Condensate Exposure;

1.2.17. Section 19, Hardness; and

1.2.18. Section 20, Flash Point.

1.3. The values stated in SI units are to be regarded as the standard.

Note 1—**Warning:** Due to the elevated temperatures used in these tests and the nature of the material, extreme care should be used when working with the thermoplastic materials. Use heat-resistant gloves and safety glasses or face shield when handling in the fluid state. Severe burns can result from spilled thermoplastics or mishandled equipment. Should melted thermoplastic come in contact with the skin, do not attempt to wipe off. Immediately hold or submerge the affected area under cold water. Inform someone in the immediate vicinity that an accident has occurred. Seek proper medical attention.

3. SAMPLING OF THERMOPLASTIC MATERIAL

3.1. It is important to obtain a truly representative sample of the thermoplastic material for testing. This can be difficult due to the wide ranges of sizes, shapes, and densities of the particular raw materials that are used in the material formulation. The following three methods provide a way to obtain representative samples from a production lot of thermoplastic pavement marking material for testing.

3.2. *Quartering Method*.

3.2.1. *Apparatus and Materials*:

3.2.1.1. 1.2 m by 1.2 m (4 ft by 4 ft) section of cardboard, smooth wood, or metal;

3.2.1.2. Metal scooping pan;

3.2.1.3. Metal splitting device;

3.2.1.4. Three 22-kg (50-lb) bags of thermoplastic (randomly selected); and

3.2.1.5. Unlined 3.8-L (1-gal) cans.

3.2.2. *Procedure*:

3.2.2.1. Randomly select three 22-kg (50-lb) bags from the lot to be sampled (up to 22 000 kg (50 000 lb)).

3.2.2.2. Place the selection of cardboard, wood, or metal on a level section of floor.

3.2.2.3. Empty the contents of one of the 22-kg (50-lb) bags onto the sample area. Using the metal scoop, mix the material, breaking up any large lumps. Shape the pile of thermoplastic into as high a pile as possible, forming a symmetrical inverted cone.

3.2.2.4. Take the metal splitting device and center it over the apex of the thermoplastic. Lower the device onto the material, thus splitting it into four quarter sections.

3.2.2.5. Take the material from any two opposing quarters and return it to the thermoplastic bag. The two remaining quarters are to be mixed and split in the same manner as explained above, rotating between the two quarters that are retained at the end of each step. Repeat the process for a total of four times. Retain the final two opposing quarters as a part of the composite sample and place in the unlined 3.8-L (1-gal) can.

3.2.2.6. Perform the same procedure as outlined using the two remaining bags. When the final quarters are taken from the two bags, the sum of the three bags should fill the 3.8-L (1-gal) sample container and should weigh between 4 and 4.5 kg (9 and 10 lb).

3.2.2.7. Label the outside of the 3.8-L (1-gal) sample can with adequate identification markings including: manufacturer, product number, batch number, date of manufacture, color, and specification.

3.2.2.8. The entire composite sample should be melted for the preparation of test samples as called for in Section 4, Sample Meltdown and Preparation.

3.3. *Splitter Method*.

3.3.1. *Apparatus and Material*:

3.3.1.1. 1:1 Splitter with pans;

3.3.1.2. Three 22-kg (50-lb) bags of thermoplastic (randomly selected); and

3.3.1.3. Unlined 3.8-L (1-gal) can.

3.3.2. *Procedure*:

3.3.2.1. Randomly select three 22-kg (50-lb) bags of thermoplastic from the lot to be tested (up to 22 000 kg (50 000 lb)).

3.3.2.2. Empty the contents of one of the bags into one of the pans and place on top of the 1:1 splitter.

3.3.2.3. Place a pan underneath each of the two discharge sections of the splitter.

3.3.2.4. Empty the contents in the top pan such that the material passes through the splitter.

3.3.2.5. Take each half and split individually to form quarters. Return two opposing pans, or quarters, to the bag. Split the two remaining pans individually to form quarters. Repeat the above procedure by splitting the two opposing pans while returning the others to the bag. This splitting procedure is performed four times before placing the final quarters into the sample container.

3.3.2.6. Perform the same procedure on the two remaining bags of thermoplastic. When the final quarters are taken from the two bags, the sum of the three bags should fill the 3.8-L (1-gal) sample container and should weigh between 4 and 4.5 kg (9 and 10 lb).

3.3.2.7. Label the outside of the 3.8-L (1-gal) sample can with adequate identification markings including: manufacturer, product number, batch number, date of manufacture, color, and specification.

3.3.2.8. The entire composite sample should be melted for the preparation of test samples as called for in Section 4, Sample Meltdown and Preparation.

3.4. *Thieving Method*.

3.4.1. *Apparatus and Materials*:

3.4.1.1. 5-cm (2-in.) ID metal pipe approximately 1 m (3 ft) long.

3.4.1.2. Three 22-kg (50-lb) bags of thermoplastic (randomly selected); and

3.4.1.3. Unlined 3.8-L (1-gal) cans.

3.4.2. *Procedure*:

3.4.2.1. Randomly select three 22-kg (50-lb) bags of thermoplastic from the lot to be sampled (up to 22 000 kg (50 000 lb)).

3.4.2.2. Place the bag on a flat surface.

3.4.2.3. Carefully cut the bag at the top or bottom to allow the pipe to be inserted into the bag.

3.4.2.4. Insert the sample pipe into the bag and push through the thermoplastic material through the entire length of the bag.

3.4.2.5. Carefully remove the pipe and empty the thermoplastic material that is retained in the pipe into the unlined 3.8-L (1-gal) can.

3.4.2.6. Repeat the process, pushing the pipe through a different area of the 22-kg (50-lb) bag. Continue with the process until an approximate 1.5-kg (3-lb) sample has been obtained from the 22-kg (50-lb) bag.

3.4.2.7. Repeat steps in Sections 3.4.2.2 through 3.4.2.6 with the other two 22-kg (50-lb) bags that were selected for testing. The final sample size should weigh between 4 and 5.5 kg (9 and 12 lb).

3.4.2.8. Label the outside of the 3.8-L (1-gal) sample can with adequate identification markings, including: manufacturer, product number, batch number, date of manufacture, color, and specification. The entire composite sample should be melted for the preparation of test samples as called for in Section 4, Sample Meltdown and Preparation.

4. SAMPLE MELTDOWN AND PREPARATION

4.1. This procedure covers the melting of thermoplastic road striping materials using a heating mantle and an air stirrer. This procedure stimulates the actual melting process and equipment found in the field.

4.2. *Apparatus and Materials*:

4.2.1. A stainless steel 4000-mL beaker, 15-cm (6-in.) diameter by 23 cm (9 in.) high, such as a Volrath No. 84000 or equivalent such as an unlined metal 3.8-L (1-gal) can.

4.2.2. Suitable heating mantle, such as a Glas-Col heating mantle, Model TM620 or equivalent.

4.2.3. Temperature indicator-controller, such as an Omega Engineering Model 400JF or equivalent.

4.2.4. Thermocouple, such as an Omega Engineering No. TJ36-ICSS-116G-12 with 1.6-mm ($^1/_{16}$-in.) 304SS sheath, or equivalent.

4.2.5. Air powered variable speed mixer, such as a Lightning Model 30 with two Lightning A310 stainless steel impellers or similar equipment.

4.2.6. Aluminum lid to cover the top of the stainless steel 4000-mL beaker with slot to clear the air motor agitator shaft and thermocouple.

4.2.7. Stainless steel ladle with pouring spout, 60-mL (2-oz) capacity.

4.2.8. Tachometer to measure shaft speed of mixer.

4.2.9. Copper or stainless steel tubing approximately 3 mm ($^1/_8$ in.) and 25 cm (10 in.) long.

4.2.10. Porcelain dish, 150 mL.

4.2.11. Crucibles, 30 mL.

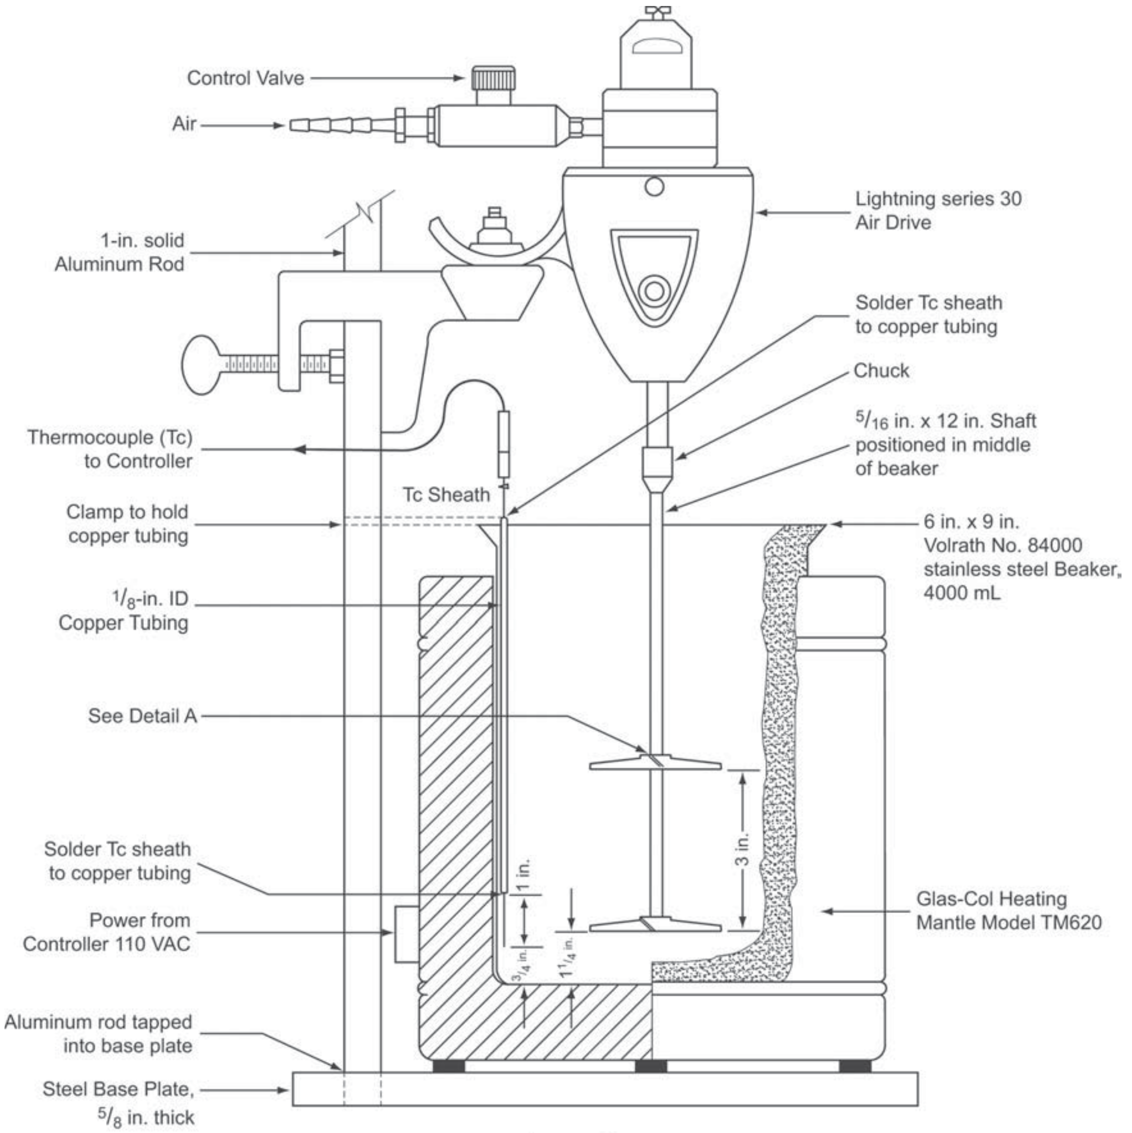
4.2.12. Glass beaker, 2 L.

4.3. *Procedure*:

4.3.1. Set up the apparatus as shown in Figure 1. Wire the heating mantle power cord to the temperature indicator controller according to manufacturer's instructions. Mount the controller-indicators in a panel that can be wall mounted to keep the unit away from heat, dirt, and vibrations. When the unit is ready for operation, make a test melt in order to set the proportional band and other adjustments to give a controlled temperature of 218 ± 1ºC (425 ± 2ºF).

4.3.2. Change about one-half the granular sample into the appropriate container and place in the heating mantle and attach the stirring shaft. Turn on the power to the mantle and controller. As the thermoplastic melts down, add the remainder of the sample. Start the variable speed air agitator when plastic has softened sufficiently to mix. Continue to mix and heat until the temperature reaches 218ºC (425ºF) and the sample is homogeneous, and maintain temperature at 218 ± 1°C (245 ± 2°F).

4.3.3. Remove the thermoplastic sample using a 60-mL (2-oz) ladle and prepare samples or run tests as required.



Assembly

Figure 1A

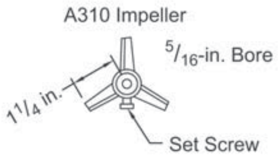


Figure 1—Thermoplastic Melter Apparatus

5. BINDER CONTENT

5.1. Using a 60-mL (2-oz) ladle, remove a portion of the molten thermoplastic from the sample during the first hour of the heating period (after the entire sample becomes molten). Run the binder content as specified in ASTM D 4797 with the exception of using a 50-g sample of thermoplastic marking material and a 150-mL (5-oz) porcelain dish in lieu of a 30-mL crucible.

6. GLASS BEAD CONTENT

6.1. Using the same sample obtained for the determination of binder content, determine the intermix bead content as specified in ASTM D 4797 utilizing a 2-L beaker in lieu of the 400-mL beaker and increasing the quantities of the HCl solution and water used in the rinses by a factor of five (5).

7. GLASS BEAD GRADING ANALYSIS

7.1. Grade the beads according to M 247 using the appropriate sieves. Determine the mass of fractions to the nearest 0.01g.

7.2. Perform a visual inspection of the material larger than 100 mesh to determine that the sample is composed of glass beads only. Any material other than glass beads that are insoluble in the acid wash will appear irregular and opaque. Presence of this type of material in sizes larger than 100 mesh constitutes a failure to comply with the specification or inadequate HCl digestion.

Note 2—All other bead analysis testing should be performed according to AASHTO M 247.

8. REFLECTANCE, COLOR, AND YELLOWNESS INDEX

8.1. Using a 60-mL (2-oz) ladle, remove a portion of the molten thermoplastic from the sample after the material has completed the 4-hour heating period. Cast an approximate 8-cm (3-in.) diameter disc on a tin plate, can lid, or on some other non-stick surface. After the material has reached room temperature, remove and test according to the requirements of ASTM D 4960. Make color measurement according to ASTM E 1349 using two-degree observer and Illuminant D 65. Calculate the Yellowness Index in accordance with ASTM E 313.

9. TITANIUM DIOXIDE DETERMINATION

9.1. *X-Ray Fluorescence Spectroscopy Method*:

9.1.1. Perform the test in accordance with the requirements of ASTM D 4764.

9.2. Jones Reduction Method (Referee Method): as noted in ASTM D 4797.

10. LEAD CHROMATE DETERMINATION

10.1. Calculate the lead chromate pigment content according to ASTM D 4797. X-ray fluorescence spectroscopy may also be used following the general requirements of ASTM D 4764.

11. FLOWABILITY (PERCENT RESIDUE)

11.1. *Apparatus and Materials*:

11.1.1. Round, unlined steel 475-mL (1-pt) can with rim removed from inside the cans.

11.1.2. *Balance*—The balance shall have sufficient capacity and conform to M 231, Class G 1.

11.1.3. *Holder for cans*, allowing suspension of cans at a 45-degree angle with point contact.

11.1.4. *Electric hotplate*, capable of heating material to 218ºC (425ºF).

11.1.5. *Glass stem thermometer*, having a maximum temperature range of at least 218ºC (450ºF).

11.2. *Procedure*:

11.2.1. From the 3.8-L (1-gal) sample of molten thermoplastic material, weigh 400.0 ± 0.1 g of the material into the tared 475-mL can. This sample should be taken after the 4-hour heating period has elapsed.

11.2.2. Using a glass stem thermometer as a stirring rod, place the sample onto a hotplate that has been set on the maximum temperature setting, and stir until the material reaches a temperature of 218 ± 1ºC (425 ± 2ºF). Avoid as much as possible splashing material on the inside of the can.

11.2.3. Remove the can from the hotplate and scrape the material from the thermometer on the rim of the can.

11.2.4. Immediately suspend the can at a 45-degree angle in a holder with point contact. Allow the material to flow over the rim where the thermometer was scraped until flow ceases.

11.2.5. Record the mass of each can plus residue.

11.2.6. Calculate the flowability (percent residue) as follows:

$$\text{Flowability, (percent residue)} = \frac{(A - B) \times 100}{400} \tag{1}$$

where:

A = mass of can plus residue, and

B = mass of can.

Note 3—Precision and Bias data are not available at this time for the flowability test.

12. LOW TEMPERATURE STRESS RESISTANCE

12.1. *Apparatus and Materials*:

12.1.1. *Concrete blocks*, 305 by 305 by 76 mm (12 by 12 by 3 in.), primed with primer recommended for use by the thermoplastic manufacturer.

12.1.2. 1.9-L (0.5-gal) cans with rims removed.

12.1.3. *Spatula*.

12.1.4. *Drawdown Blade*, 10 cm (4 in.) by 125 mL.

12.1.5. *Cold box or freezer*, capable of maintaining a temperature of –9.4 ± 2.0ºC (15 ± 3.6ºF) for 24 hours.

12.2. *Procedure*:

12.2.1. Prepare sample in accordance with Section 4, Sample Meltdown and Preparation. Heat the drawdown blade at 218ºC (425ºF) for one-half hour.

12.2.2. After heating for 4 hours at 218ºC (425ºF), quickly pour the thermoplastic into the heated drawdown blade and draw down a 10-cm (4-in.) wide line on the concrete block at room temperature.

12.2.3. When the test specimen has cooled to room temperature, place it in the cold box or freezer for 24 hours at –9.4 ± 2.0ºC (15 ± 3.6ºF).

12.2.4. At the end of 24 hours, remove and immediately inspect the specimen for cracking. Inspect the specimen from a distance of 305 mm (12 in.) under diffuse lighting.

12.2.5. Any cracking shall constitute failure of the test.

13. BOND STRENGTH

13.1. Using material from the molten sample of thermoplastic after the 4-hour heating period, prepare and test in accordance to ASTM D 4796.

14. IMPACT RESISTANCE

14.1. *Apparatus and Materials*:

14.1.1. *Molds*, 25 by 25 by 150 mm (1 by 1 by 6 in.), for casting impact specimens.

14.1.2. Izod-type impact test apparatus with 0 to 2.82 J (0 to 25 inch-pound) scale.

14.2. *Procedure*:

14.2.1. Preheat the specimen molds for approximately 1 hour at 218ºC (425ºF).

14.2.2. Using the 60-mL (2-oz) ladle, quickly fill the heated molds with the thermoplastic material. This material should be taken from the molten thermoplastic sample after the 4-hour heating period.

14.2.3. After cooling, carefully disassemble the molds and remove the solidified material. Cut each sample into approximately 76-mm (3-in.) long sections.

14.2.4. Determine the impact resistance using the Izod-type impact apparatus following the procedures for use of this apparatus as outlined generally in ASTM D 256, Method A. Do not use a notched specimen. Use the 0 to 2.82 J (0 to 25 inch-pound) scale with the appropriate load on the striker. Average the results of two or more breaks.

15. RING-AND-BALL SOFTENING POINT

15.1. *Apparatus and Materials*:

15.1.1. Ring-and-ball apparatus, refer to ASTM D 36.

15.2. *Procedure*:

15.2.1. Perform the test according to ASTM D 36. Using the 60-mL (2-oz) ladle, obtain a sample from the 4-hour heated molten thermoplastic material and carefully fill the rings and level the surface to the top of the rings. Allow to cool and proceed.

15.2.2. Average the results of two or more tests.

16. SPECIFIC GRAVITY

16.1. Determine the specific gravity of the white and yellow materials according to ASTM D 792, Method A. The sample shall be taken from the sample of molten thermoplastic material following the 4-hour heating period.

17. FLOWABILITY (PERCENT RESIDUE) EXTENDED HEATING

17.1. *Apparatus and Materials*:

17.1.1. Round, unlined steel 475-mL (1-pt) can with rim removed from inside the cans.

17.1.2. *Balance*—The balance shall have sufficient capacity and conform to M 231, Class G l.

17.1.3. *Holder for cans*, allowing suspension of cans at a 45-degree angle with point contact.

17.1.4. *Electric hotplate*, capable of heating material to 218°C (425ºF).

17.1.5. *Glass stem thermometer*, having a maximum temperature range of at least 232ºC (450ºF).

17.2. *Procedure*:

17.2.1. From the initial 3.8-L (1-gal) sample melt, weigh 400.0± 0.1 g of material into the tared 475-mL (1-pt) can. This sample should be taken after the sample has been heated under constant agitation for a period of eight hours. The time required for meltdown and reaching the application temperature of 218ºC (425ºF) is included as part of the eight-hour heating period.

17.2.2. Using the glass stem thermometer as a stirring rod, place the sample onto the hotplate that has been set on a temperature setting of high, and stir until the material reaches a temperature of 218 ± 1ºC (425 ± 2ºF). Avoid as much as possible splashing material on the inside of the can.

17.2.3. Remove the can from the hotplate and scrape the material from the thermometer rim of the can.

17.2.4. Immediately suspend the can at a 45-degree angle in a holder with point contact. Allow the material to flow over the rim where the thermometer was scraped until the flow ceases.

17.2.5. Record the mass of each can plus residue and calculate flowability (percent residue) as follows:

$$\text{Flowability, Extended Heating} = \frac{\left(A - B\right) \times 100}{400} \qquad (2)$$

where:

A = mass of can plus residue, and

B = mass of can.

Note 4—Precision and bias data are not available at this time for the extended heating flowability test.

18. ULTRAVIOLET LIGHT AND CONDENSATE EXPOSURE

18.1. *Apparatus*:

18.1.1. QUV Accelerated Weathering Tester, as described in ASTM G 154.

18.1.2. 7.5 cm by 15 cm (3 in. by 6 in.) aluminum Q panels, Type A or equivalent.

18.1.3. 5-cm (2-in.) wide duct tape.

18.1.4. Steel screed box with inside dimensions of 6 cm by 10 cm (2.5 in. by 4.0 in.) with a 6-mm (0.125-in.) opening across the entire length of one of the 6-cm (2.5-in.) sides.

18.1.5. Oven, capable of maintaining 218ºC (425ºF).

18.1.6. Masking tape, 1 cm ($^1/_2$ in.) wide.

18.2. *Procedure*:

18.2.1. One-half hour before test, place a screed box in the 218ºC (425ºF) oven.

18.2.2. Tape the 7.5 cm by 15 cm (3 in. by 6 in.) aluminum panel to the bench surface with masking tape to hold the panel firmly to the bench.

18.2.3. Remove the screed box from the oven and position at the right angles to the 15 cm (6 in.) length of the aluminum panel and in the middle of the panel.

18.2.4. With the 60-mL (2-oz) ladle, remove a sample from the molten thermoplastic sample and quickly draw down the sample across the aluminum panel.

18.2.5. While hot, trim off excess plastic from the edge of the aluminum panel.

18.2.6. When cool, wrap top and bottom edges of the plastic sample with duct tape to keep the sample in position on the aluminum panel. Lap the edges of the plastic with no more than 6 mm ($^1/_4$ in.) with duct tape.

18.2.7. For the white thermoplastic, measure the color of the samples as outlined in Section 8, Reflectance, Color, and Yellowness Index.

18.2.8. Expose the sample for 300 hours in the QUV apparatus utilizing UVA-340 lamps. Set the QUV for cycles of 4 hours UV exposure at 60ºC (140ºF) and 4 hours condensate exposure at 40ºC (104ºF).

18.2.9. Remove the samples from the QUV and allow them to dry at room temperature. Test the color as outlined in Section 8, Reflectance, Color, and Yellowness Index.

19. HARDNESS (D 2240 TEST METHOD FOR RUBBER PROPERTY–DUROMETER HARDNESS)

19.1. *Apparatus*:

19.1.1. Shore Durometer Hardness Tester Type A-2 with attached weights so that the total weight of the unit is 2002 g.

19.1.2. Incubator oven with the glass inner door, capable of maintaining 46 ± 1ºC (115 ± 2ºF).

19.1.3. Stopwatch.

19.1.4. Aluminum disposable weighing dish, approximately 63 mm (2.5 in.) in diameter and 17.5 mm (0.7 in.) deep.

19.1.5. Mold release.

19.2. *Procedure*:

19.2.1. With the 60-mL (2-oz) ladle, fill the aluminum dish with hot thermoplastic material taken from the 3.8-L (1-gal) molten sample.

19.2.2. Allow the dish to cool to room temperature and strip the aluminum from the sample.

19.2.3. Place the sample on a metal 0.9-L (1-qt) can lid previously coated with mold release to prevent sticking and place in the 46ºC (115ºF) oven for 3 hours. At the same time, place the durometer in the oven.

19.2.4. After 3 hours, place the durometer on top of sample, immediately start stopwatch and close inner glass door.

19.2.5. After 15 seconds contact, read durometer, open inner glass door, turn sample over, and repeat durometer reading.

19.2.6. Report the average of readings made on top and bottom of the sample.

20. FLASH POINT

20.1. Using a 60-mL (2-oz) ladle, remove a portion of the molten thermoplastic from the sample during the first hour of the heating period (after the entire sample becomes molten). Run the flash point as specified in ASTM D 92.

Standard Method of Test for

Linear Coefficient of Shrinkage on Cure of Adhesive Systems

AASHTO Designation: T 333-07

American Association of State Highway and Transportation Officials
444 North Capitol Street, N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Linear Coefficient of Shrinkage on Cure of Adhesive Systems

AASHTO Designation: T 333-07

1. SCOPE

1.1. This method describes the measurement of the linear coefficient of shrinkage on cure of adhesive systems.

1.2. The values stated in SI units shall be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 235M/M 235, Epoxy Resin Adhesives

3. TERMINOLOGY

3.1. *Adhesive system*—a multi-component material that results in a product used as a bonding material.

3.2. *Linear coefficient of shrinkage*—the measured shrinkage of a material on cure expressed as change in length divided by the original sample length.

4. SUMMARY OF TEST METHOD

4.1. This method describes the procedure used to measure the change in length following the cure of a fresh cast adhesive material. Test specimens are cast in a half-cylindrical shaped mold and allowed to cure completely before the linear coefficient of shrinkage is determined.

5. SIGNIFICANCE AND USE

5.1. The reactions that occur when an adhesive system cures generally results in a volume shrinkage of the adhesive specimen. The shrinkage associated with this standard generally occurs after the gelling phase of the material. The shrinkage is the result of a change in the specific volume, caused by the chemical cross-linking reaction, and a volume change as the cast material cools from its cure temperature or from its maximum reaction temperature. This method does not differentiate between these two effects.

5.2. The effects of the mold walls further complicate the measurement of shrinkage. As the reacting system gives off heat, it normally expands. Most of the expansion must take place toward the open side of the mold. When the maximum reaction temperature has passed, the solidifying adhesive should shrink uniformly in all directions. However, friction prevents the free movement of the adhesive over the mold surfaces allowing the greatest shrinkage to occur perpendicular to the open surface of the mold.

5.3. Usually the end user is concerned only with deviations from mold dimensions. It can be assumed that shrinkage perpendicular to surfaces other than the open side will be uniform and proportional to the distance over which the shrinkage occurs. Thus, the measurement of shrinkage in length, the linear shrinkage, when expressed in units such as centimeters shrinkage per centimeter of length (cm/cm) or inches per inch (in./in.), gives a value characteristic of the adhesive. This value is useful in predicting the behavior of the adhesive in molds of other shapes and sizes.

6. APPARATUS

6.1. *Mold*—The mold shall be composed of a material, such as cold-rolled steel, that will not significantly distort during testing and will regain its originally dimensions after cure. The mold shall be 25.400 ± 0.125 cm (10.00 ± 0.05 in.) in length and have an internal radius of 1.270 ± 0.125 cm (0.50 ± 0.05 in.). The wall of the mold shall be 0.630 ± 0.125 cm (0.25 ± 0.05 in.) thick. It will have a removable end plate on each end (Figure 1).

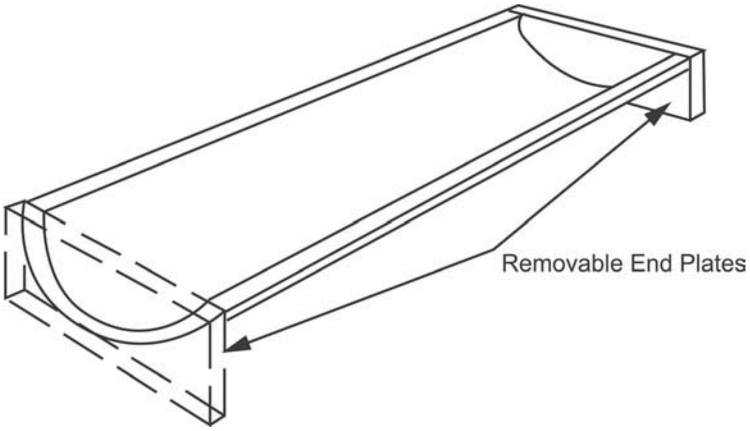

Figure 1—Mold

6.2. *Mineral Oil*.

6.3. *Film liner*—suitable for lining the mold, approximately 0.025 mm (0.001 in.) in thickness. Polytetrafluoroethylene or polyethylene films have been found acceptable.

6.4. *Micrometer*—capable of reading to the nearest 0.0025 mm (0.0001 in.).

6.5. *Temperature-Recording Device*—accurate to the nearest 1°C (2°F).

7. SAMPLING

7.1. The sampling shall be done in accordance with Section 10 of AASHTO M 235M/M 235.

8. PREPARATION OF TEST SPECIMENS

8.1. Measure and record the length of the mold.

8.2. Wipe all interior surfaces of the mold with a thin film of mineral oil, and apply the film to these surfaces, ensuring a smooth surface taking care to remove all wrinkles.

8.3. Condition the mold and the individual components of the system for at least four hours at 23 ± 1°C (73 ± 2°F).

8.4. Mix the components, taking care to minimize the entrapment of air since air inclusions affect the shrinkage characteristics.

8.5. Fill the mold with the mixed adhesive, taking care to avoid air entrapment. If the adhesive is a material that cures at room temperature, pour the mixture before the temperature exceeds 30°C (86°F).

8.6. Cure the casting in the mold at 23 ± 1°C (73 ± 2°F) for the cure time stated in the manufacturer's instructions.

8.7. Record the maximum reaction temperature of the material in cure using a suitable temperature-recording device in the geometric center of the reacting mass.

9. CONDITIONING

9.1. After casting and curing, condition the test specimen at 23 ± 1°C (73 ± 2°F) and 50 ± 5 percent relative humidity for not less than 40 hours prior to testing.

9.2. Conduct tests in the standard laboratory atmosphere of 23 ± 2°C (73.4 ± 3.6°F) and 50 ± 5 relative humidity, unless otherwise specified.

10. PROCEDURE

10.1. Following conditioning, remove the specimen from the mold by removing the end plates. The film liner may be removed at this time if necessary for accurate measurements.

10.2. Replace one end plate on the mold and return the specimen to the mold in the same position in which it was prior to removal.

10.3. Making sure that the specimen is in direct contact with the end plate, determine with a micrometer the change in length of the specimen with reference to the mold length. Record four readings spaced across the open end of the mold. Average the four readings and report as the change in length of the specimen.

11. CALCULATION OF RESULTS

11.1. Calculate the linear coefficient of shrinkage in centimeters per centimeter (or inches per inch) as follows:

$$\text{Linear Coefficient of Shrinkage} = (A - 2B)/C \qquad (1)$$

where:

A = change in length, cm (in.);

B = film thickness, if removed from the sample; and

C = inside mold length, cm (in.).

12. REPORT

12.1. Report the following information:

12.1.1. Size of the mold used;

12.1.2. Volume of the casting;

12.1.3. Ambient test temperature;

12.1.4. Maximum reaction temperature;

12.1.5. Conditions of cure of the specimen, if other than standard; and

12.1.6. Linear coefficient of shrinkage expressed in centimeters of shrinkage per centimeter of specimen length (or inches per inch).

13. PRECISION AND BIAS

13.1. *Precision*—The research required to develop precision values has not been conducted.

13.2. *Bias*—The research required to establish the bias of the method has not been conducted.

14. KEYWORDS

14.1. Adhesive system; cure; epoxy; epoxy cure; epoxy shrinkage; linear coefficient; linear coefficient of epoxy; linear coefficient of shrinkage; resin adhesive shrinkage; shrinkage.

Standard Method of Test for

Frictional Properties of Paved Surfaces Using a Full-Scale Tire

AASHTO Designation: T 242-96 (2009)[1]
ASTM Designation: E 274-97

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Frictional Properties of Paved Surfaces Using a Full-Scale Tire

AASHTO Designation: T 242-96 (2009)[1]
ASTM Designation: E 274-97

1. SCOPE

1.1. This method covers the measurement of the frictional properties of paved surfaces with a specified full-scale automotive tire.

1.2. This method utilizes a measurement representing the steady-state friction force on a locked test wheel as it is dragged over a wetted-pavement surface under constant load and at a constant speed while its major plane is parallel to its direction of motion and perpendicular to the pavement.

1.3. The values measured represent the frictional properties obtained with the equipment and procedures stated herein and do not necessarily agree or correlate directly with those obtained by other pavement friction measuring methods. The values are intended for use in comparing certain frictional properties of a pavement relative to those of other pavements or for evaluating changes in these frictional properties of a pavement with the passage of time. The values are insufficient to determine the distance required to stop a vehicle on either a wet or a dry pavement. They are also insufficient for determining the speed at which control of a vehicle would be lost, because peak and side-force friction are also required for these determinations.

1.4. The values stated in SI units are to be regarded as the standard.

1.5. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

---

3. SUMMARY OF METHOD

3.1. The test apparatus consists of an automotive vehicle with one or more test wheels incorporated into it or forming part of a suitable trailer towed by a vehicle. The apparatus contains a transducer, instrumentation, a water supply and proper dispensing system, and actuation controls for the brake of the test wheel. The test wheel is equipped with a standard pavement test tire, as specified in M 261 or M 286.

3.2. The test apparatus is brought to the desired test speed. Water is delivered ahead of the test tire and the braking system is actuated to lock the test tire. The resulting friction force acting between the test tire and the pavement surface (or some other quantity that is directly related to this force) and the speed of the test vehicle are recorded with the aid of suitable instrumentation.

3.3. Frictional properties of the paved surface are determined from the resulting force or torque record and reported as friction numbers (FN), which are determined from the force required to slide the locked test tire at a stated speed, divided by the effective wheel load and multiplied by 100.

---

4. APPARATUS

4.1. *Vehicle*—The vehicle with one test tire locked shall be capable of maintaining test speeds of 65 to 100 km/h (40 to 60 mph) within ±1.5 km/h (±1.0 mph) during a test on a level pavement having a FN of 50.

4.2. *Braking System*—The test wheel shall be equipped with a suitable brake. The brake system shall be capable of locking the wheel at the condition specified in Section 4.1 and maintaining the locked-wheel condition throughout the test.

4.3. *Wheel Load*—The apparatus shall be of such a design as to provide an equal static load of 4800 ± 65 N (1085 ± 15 lbf) to each test wheel and, on detachable trailers, a static download of 450 to 900 N (100 to 200 lbf) at the hitch point.

4.4. *Tire and Rim*—The test tire shall be one of the standard tires for the pavement test, as specified in M 261 or M 286, and it shall be mounted on a suitable 15- by 6-in. rim. Since all rims do not have the same offset from the hub, replacement rims must be of the same offset to ensure consistent alignment of the tire with the water path. The data from the two tires are not interchangeable. Alternative testing for special purposes may be performed with other tires, such as a standard rib tire for pavement skid resistance of M 261 or ASTM E 501.

4.5. *Instrumentation*:

4.5.1. *General Requirements for Measuring System*—The instrumentation system shall conform to the following overall requirements at ambient temperatures between 4 and 40ºC (40 and 100ºF):

4.5.1.1. *Overall System Accuracy*—$\pm 1^1/_2$ percent of applied load from 900 N (200 lbf) to full scale; for example, at 900 N (200 lbf), applied calibration force of the system output shall be determinable within ±14 N (±3 lbf).

4.5.1.2. *Time Stability of Calibration*—10-hour minimum.

4.5.1.3. The exposed portions of the system shall tolerate 100 percent relative humidity (rain or spray) and all other adverse conditions, such as dust, shock, and vibrations, which may be encountered in highway operations.

4.5.2. *Force-Measuring Transducer*—The tire force-measuring transducer shall be of such design as to measure the tire–road interface force with minimum inertial effects. Transducers are recommended to provide an output directly proportional to force with hysteresis less than 1 percent of the applied load, nonlinearity less than 1 percent of the applied load up to the maximum expected loading, and sensitivity to any expected cross-axis loading or torque loading less than 1 percent of the applied load. The force transducer shall be mounted in such a manner as to experience less than 1-degree angular rotation with respect to its measuring plane at the maximum expected loading.

4.5.3. *Torque-Measuring Transducer*—Torque transducers provide an output directly proportional to torque with hysteresis less than 1 percent of the applied load and nonlinearity up to the maximum expected loading less than 1 percent of the applied load. It should have sensitivity to any cross-axis loading less than 1 percent of the applied load.

4.5.4. *Additional Transducers*—Force transducers for measuring quantities such as vertical load, etc., shall meet the recommendations stated in Section 4.5.2.

4.5.5. *Vehicle Speed-Measuring Transducers*—Transducers such as “fifth-wheel” or free-rolling wheel coupled tachometers shall provide speed resolution and accuracy of ±1.5 percent of the indicated speed or ±1.0 km/h (±0.5 mph), whichever is greater. Output shall be directly viewable by the driver and shall be simultaneously recorded. Fifth-wheel systems shall conform to ASTM F 457.

4.6. *Signal Conditioning and Recorder System*:

4.6.1. Transducers that measure parameters sensitive to inertial loading shall be designed or located in such a manner as to minimize this effect. If the foregoing is not practical, data correction must be made for these effects if they exceed 2 percent of the actual data during expected operation. All signal conditioning and recording equipment shall provide linear output and shall allow data reading resolution to meet the requirements of Section 4.5.1. All systems, except the smoothing filter recommended in Section 4.6.2, shall provide a minimum bandwidth of at least 0 to 20 Hz (flat within ±1 percent).

4.6.2. It is recommended that an electronic filter, typically between 4.8 Hz/–3db/4 pole Bessel-type and a 10 Hz/–3db/8 pole Butterworth filter, selected from the types described in Reference (1) (see Section 13.1) be installed in the signal conditioning circuit preceding the electronic divider and integration calculation of FN as described in Section 9.4.

4.6.3. All strain-gauge transducers shall be equipped with resistance shunt calibration resistors or equivalent that can be connected before or after test sequences. The calibration signal shall be at least 50 percent of the normal vertical load and shall be recorded.

4.6.4. Tire friction force or torque and any additional desired inputs, such as vertical load, wheel speed, etc., shall be recorded in phase (±5 degrees over a bandwidth of 0 to 20 Hz). Vehicle speed shall also be recorded. All signals shall be referenced to a common time base.

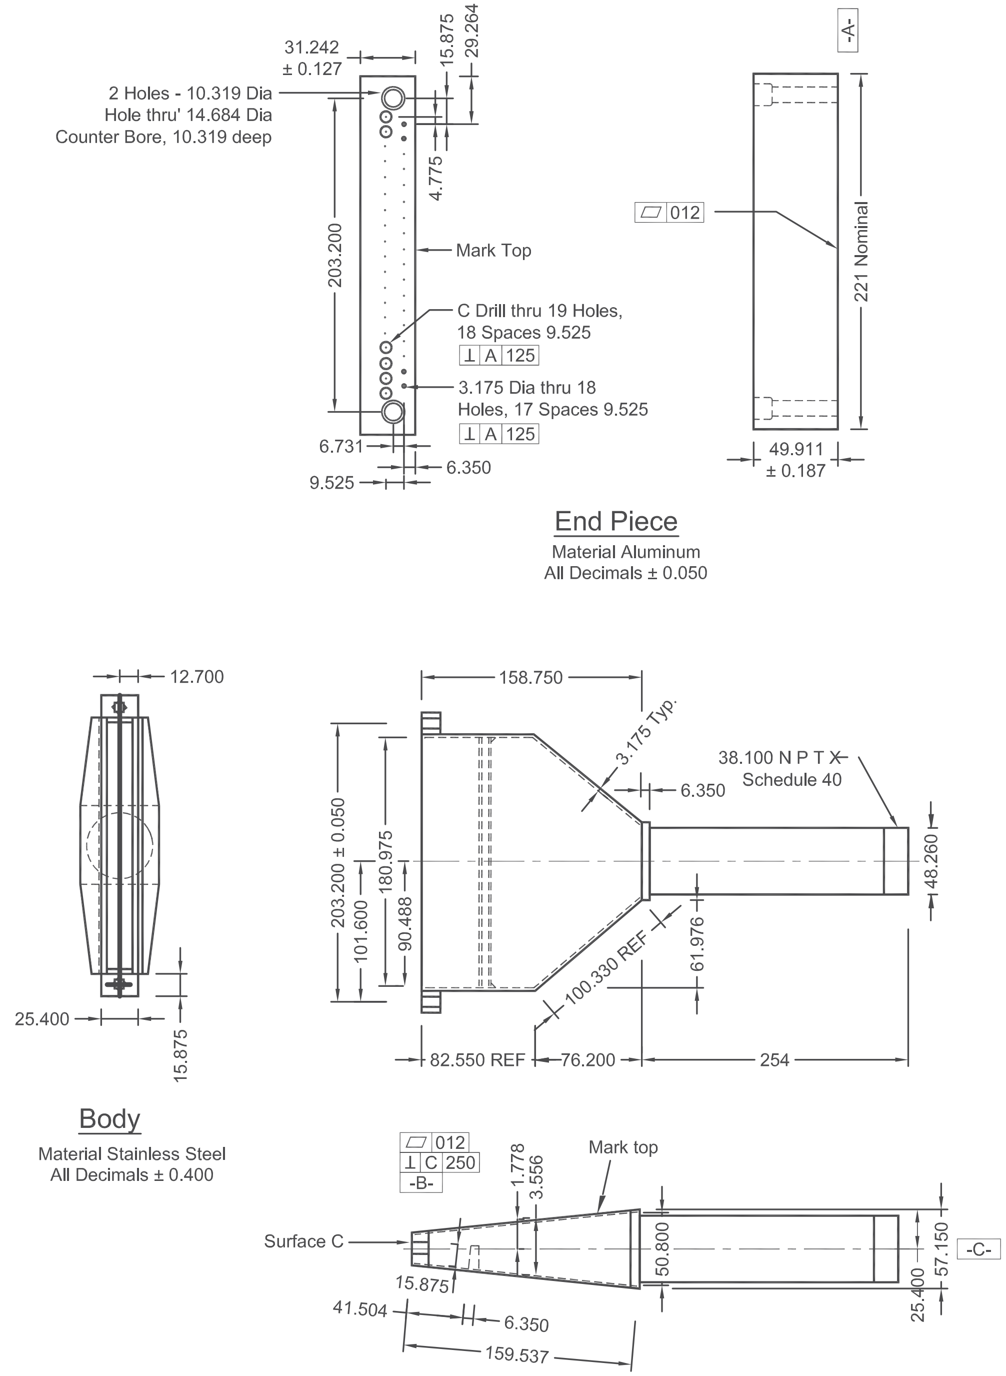
4.6.5. A signal-to-electrical noise ratio of at least 20 to 1 is desirable on all recorded channels.

4.7. *Pavement Wetting System*:

4.7.1. The water applied to the pavement ahead of the test tire shall be supplied by a nozzle conforming to the dimensions in Figure 1. The quantity of water applied at 65 km/h (40 mph) shall be 600 mL/min mm ± 10 percent (4.0 gal/min in. ± 10 percent) of wetted width. The water layer shall be at least 25 mm (1 in.) wider than the test tire tread and applied so the tire is centrally located between the edges. The volume of water per millimeter (inch) of wetted width shall be directly proportional to the test speed.

4.7.2. The nozzle configuration and position shall ensure that the water jets shall be directed toward the test tire and pointed toward the pavement at an angle of 20 to 30 degrees. The water shall strike the pavement 250 to 450 mm (10 to 18 in.) ahead of the vertical axis through the centerline of the test wheel. The nozzle shall be 25 mm (1 in.) above the pavement or the minimum height required to clear obstacles that the tester is expected to encounter, but in no case more than 100 mm (4 in.) above the pavement.

4.7.3. Water used for testing shall be reasonably clean and have no chemicals such as wetting agents or detergents added.



Notes: 1. Dimensions shown are for M 261 and M 286 Standard Tires.
2. All dimensions are in mm.
3. Surface A assembled to B.
4. Surface C must be milled flat and perpendicular to pipe centerline.

Figure 1—Nozzle

5. SAFETY PRECAUTIONS

5.1. The test vehicle, as well as all attachments to it, shall comply with all applicable state and federal laws. All necessary precautions shall be taken beyond those imposed by laws and regulations to ensure maximum safety of operating personnel and other traffic. No test shall be made when there is danger that the dispersed water may freeze on the pavement.

6. CALIBRATION

6.1. *Speed*—Calibrate the test vehicle speed indicator at the test speed by determining the time for traversing at constant speed a reasonably level and straight, accurately measured pavement of a length appropriate for the method of timing. Load the test vehicle to its normal operating mass for this calibration. Record speed variations during a traverse with the friction test system. Make a minimum of three runs at each test speed to complete the calibration. Other methods of equivalent accuracy may be used. Calibration of a fifth wheel shall be performed in accordance with ASTM F 457.

6.2. *Frictional Force*—Calibrate the frictional force in the manner described in T 282.

7. GENERAL

7.1. *Test Preparation*—Condition new tires by running them at or near their rated load and inflation pressure on the test vehicle (or on another suitable vehicle) at normal traffic speeds for at least 300 km (200 miles) or equivalent before they are used for test purposes. Prior to each series of tests, warm up the tire by traveling for at least 10 km (5 miles) at normal traffic speeds. Inspect the tire for flat spots, damage, or other irregularities that may affect test results, and replace if it has been damaged or is worn beyond the wear line. Check the test-wheel load (if adjustable) and adjust, if necessary, prior to each test series to within the value specified in Section 4.3. Set the test tire inflation pressure at 165 ± 3 kPa (24 ± 0.5 psi) at ambient temperature just before the 10-km (5-mi) warm-up.

7.2. *Test Sections*—Test sections shall be defined as sections of pavement of uniform age and uniform composition that have been subjected to essentially uniform wear. For instance, sharp curves and steep grades shall not be included in the same test section with level tangent sections, nor shall passing lanes be included with traffic lanes. Take frictional property measurements only on pavements that are free of obvious contamination.

7.3. *Frictional Properties of a Test Section*—Make at least five determinations of the frictional properties at intervals not greater than 1 km (0.5 mile), in each test section with the test vehicle at the same lateral position in any one lane and at each specified test speed. Consider the arithmetic average of all determinations to be the frictional properties of the test section. If statistical or other criteria applied to the FN for a long test section indicate that it cannot be considered as uniform, treat the section as two or more sections. For treatment of the results of faulty tests, see Section 10.

7.4. *Lateral Positioning of Test Vehicle on Highway*—Normally, testing shall be done in the center of the left wheel track of a traffic lane of a highway. Friction numbers for a highway surface may be quoted without qualification only if the test vehicle was so positioned during the test.

7.5. *Test Speeds*—The standard test speed shall be 65 km/h (40 mph), and tests shall normally be conducted at that speed. Where the legal maximum speed is less than 65 km/h, the tests may have to be conducted at a lower speed. Where the legal speed is considerably in excess of 65 km/h, tests may be made at the prevailing traffic speed, but it is recommended that at the same locations, additional tests be made at 65 km/h (40 mph). Maintain test speeds within 1.5 km/h (1 mph).

7.5.1. When the test speed is 65 km/h (40 mph), it is desirable, but not necessary, to cite the speed when quoting the obtained FN. In all other cases, the speed must be cited when quoting the obtained FN. This is done by adding the test speed in kilometers per hour (miles per hour) in parentheses after FN. For example, FN80 (FN50) indicates a test was run at a test speed of 80 km/h (50 mph). (When referencing a test speed in mph, add the test speed without parentheses in mph after FN. For example, FN50 indicates a test was run at 50 mph.) Unless otherwise indicated, it is understood that the standard ribbed test tire conforming to M 261 was used. When a blank test tire conforming to M 286 is used for the test, the letter "B" shall follow the speed. For example, FN50B indicates a test run at 50 mph with the ASTM E 524 blank test tire. When the SI system is used, the test speed shall be in parentheses. For example, FN(65) indicates that the test was run at a test speed of 65 km/h with a standard ribbed test tire conforming to M 261.

7.6. *Frictional Properties Speed Gradient Determination*—If speed gradients are obtained, report the change of the FN with speed as the slope of the FN versus speed curve, which is plotted from at least three speeds in increments of approximately 15 km/h (10 mph). The standard speed gradient shall be defined as the slope of the FN-speed curve at 65 km/h (40 mph) and shall be so indicated.

8. PROCEDURE

8.1. Bring the apparatus to the desired speed and deliver water to the pavement ahead of the test tire. Approximately 0.5 seconds after beginning of the water delivery, apply the test wheel brake so as to lock the wheel completely. The wheel shall remain locked for the duration of the data averaging interval (Section 8.4.1).

8.2. Water delivery may be terminated as soon as the brake is released.

8.3. Record electrical calibration signals prior to and after testing each section, or as needed to ensure valid data.

8.4. *Data Evaluation*—Evaluate the resulting frictional properties records as follows:

8.4.1. Mark the point of wheel lockup and measure the data from a point not less than 0.2 seconds after this mark for an interval not less than 1.0 seconds nor more than 3.0 seconds. Average the data between these points and use the mean value to read or to calculate the FN.

9. CALCULATION

9.1. Calculate the FN as follows:

$$\mathrm{FN} = \left(F/W\right) \times 100 \tag{1}$$

where:

F = tractive force (horizontal force applied to the test tire at the tire-pavement contact patch), N (lbf); and

W = dynamic vertical load on test wheel; N (lbf).

9.2. For trailers not of the parallelogram design or where the vertical wheel load is not measured directly, the wheel load, *W,* depends on the kinematic layout of the trailer and on the friction force.

Wheel load reduction due to unloading produced by the friction force must be taken into account and the following formula used:

$$\mathrm{FN} = \left(F/W\right) \times 100 \qquad (2)$$

where:

F = tractive force (horizontal force applied to the test tire at the tire-pavement contact patch), N (lbf); and

W = $W_o - (H/L)F$, where:

  W_o = static vertical load on the test tire, N (lbf).

  H = hitch height, mm (in.); and

  L = trailer wheelbase length (center of axle to center of hitch), mm (in.).

9.3. For a vehicle not of a trailer design, the dynamic vertical load must be either measured or computed by analysis of the statics and kinematics of the test vehicle.

9.4. For instrumentation systems that incorporate automatic dynamic FN computation equipment, the horizontal tractive force is automatically divided by the dynamic vertical load in real time (Section 9.1). The arithmetic mean FNs can be recorded on the strip chart as an amplitude trace to the same scale as the dynamic FN trace and scaled directly from the chart or may be digitized and recorded on magnetic tape, or other electronic storage medium, or punched tape, or by the printer on paper tape. When the smooth-tread tire of M 286 is used, the same calculations apply but the designation is FN^{B}. The following equations apply:

$$fn(t) = \frac{f_h(t)}{f_v(t)} \times 100 \qquad (3)$$

$$\mathrm{FN} = \left[1/\left(t_2 - t_1\right)\right] \int_{t_1}^{t_2} fn\left(t\right) dt \qquad (4)$$

where:

$fn(t)$ = dynamic friction number in real time;

$f_h(t)$ = dynamic tractive force in real time, N (lbf);

$f_v(t)$ = dynamic vertical load in real time, N (lbf);

t_1 = time of start of averaging period, s;

t_2 = time of end of averaging period, s; and

FN = mean friction number.

If a 1s averaging interval is used, then $t_1 = 0$, $t_2 = 1$, and the equation reduces to:

$$\mathrm{FN} = \int_0^1 fn\left(t\right) dt \qquad (5)$$

10. FAULTY TESTS

10.1. Test results that are manifestly faulty, or that differ by more than 5 FN from the average of all tests in the same test section, shall be treated in accordance with ASTM E 178.

11. REPORTS

11.1. *Field Report*—The field report for each section shall contain data on the following items:

11.1.1. Location and identification of test section;

11.1.2. Date and time of day;

11.1.3. Weather conditions, principally temperature, cloud cover, and wind;

11.1.4. Lane and wheel path tested;

11.1.5. Speed of test vehicle (for each test); and

11.1.6. Friction number (for each test).

11.2. *Summary Report*—The summary report shall include, for each test section, data on the following items insofar as they are pertinent to the variables or combinations of variables under investigation:

11.2.1. Location and identification of test section;

11.2.2. Number of lanes and presence of lane separators;

11.2.3. Grade and alignment;

11.2.4. Pavement type, mix design of surface course, condition, and aggregate type (specific source, if available);

11.2.5. Age of pavement;

11.2.6. Average of daily traffic;

11.2.7. Posted speed limit;

11.2.8. Date and time of day;

11.2.9. Weather conditions;

11.2.10. Lane and wheel path tested;

11.2.11. Average-, high-, and low-FN for the test section and speed at which the tests were made. (If values are reported that were not used in computing the average, this fact shall be recorded); and

11.2.12. Plot of speed gradient data (if obtained).

12. PRECISION AND BIAS

12.1. The relationship of observed FN units to some “true” value of locked-wheel sliding friction has not been established at this time. As a result, only repeatability is given for this test method.

12.2. The acceptable precision of FN units can be stated in the form of repeatability. As there is no significant correlation between standard deviation and arithmetic mean of sets of test values, it appears that standard deviations are applicable to this test method regardless of the average locked wheel sliding friction of the surface. An acceptable standard deviation of two FN units was obtained from numerous tests conducted on a variety of systems at the Field Test and Evaluation Centers.

12.3. This value is based on evaluations of many friction test trailers. The standard deviation of each was determined at each of three speeds on the basis of 36 individual friction tests, 12 each on each of three pads. It was also determined for each trailer on an overall speed basis of 108 individual friction tests, 12 at each of three speeds on each of three pads.

Standard Method of Test for

Surface Frictional Properties Using the British Pendulum Tester

AASHTO Designation: T 278-90 (2007)[1]
ASTM Designation: E 303-93 (2003)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Surface Frictional Properties Using the British Pendulum Tester

AASHTO Designation: T 278-90 (2007)[1]
ASTM Designation: E 303-93 (2003)

1. SCOPE

1.1. This method covers the procedure for measuring surface frictional properties using the British Pendulum Skid Resistance Tester. A method for calibration of the tester is included in the Annex.

1.2. The British Pendulum Tester is a dynamic pendulum impact-type tester used to measure the energy loss when a rubber slider edge is propelled over a test surface. The tester is used for laboratory as well as field tests on flat surfaces, and for polish value measurements on curved laboratory specimens from accelerated polishing wheel tests.

1.3. The value measured, British Pendulum (Tester) Number (BPN) for flat surfaces and polish values for accelerated polishing wheel specimens, represents the frictional properties obtained with the apparatus and procedures stated herein, and does not necessarily agree or correlate with other slipperiness measuring equipment results.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENT

2.1. *AASHTO Standard*:

- M 261, Rib-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests

2.2. *ASTM Standard*:

- E 501, Standard Specification for Standard Rib Tire for Pavement Skid-Resistance Tests

2.3. *Other Documents*:

- "Development and Performance of Portable Skid-Resistance Tester," Giles, C. G., Sabey, Barbara E., and Carden, K. W. F., *Road Research Technical Paper No. 66*, Road Research Laboratory, Department of Scientific and Industrial Research, Crowthorne, England, 1964

3. SUMMARY OF METHOD

3.1. This method consists of using a pendulum-type tester with a standard rubber slider to determine the frictional properties of a test surface.

3.2. The test surface is cleaned and thoroughly wetted prior to testing.

3.3. The pendulum slider is positioned to barely come in contact with the test surface prior to conducting the test. The pendulum is raised to a locked position, then released, thus allowing the slider to make contact with the test surface.

3.4. A drag pointer indicates the BPN. The greater the friction number between the slider and the test surface, the more the swing is retarded and the larger the BPN reading. Four pendulum swings are made on each test surface for natural rubber or five swings for M 261 rubber.

4. SIGNIFICANCE AND USE

4.1. This method provides a measure of a frictional property or microtexture of surfaces, either in the field or in the laboratory.

4.2. This method may be used to determine the relative effects of various polishing techniques on materials or material combinations.

4.3. The values measured in accordance with this method do not necessarily agree or directly correlate with those obtained utilizing other methods of determining friction properties or skid resistance.

Note 1—BPN and polish values from similar types of surfaces will not be numerically equal, primarily because of the differences in slide length and surface shape. Theoretical correction of the polish values to obtain numerical equality, either by mathematical manipulation or by use of special measuring scales, is not recommended.

5. APPARATUS

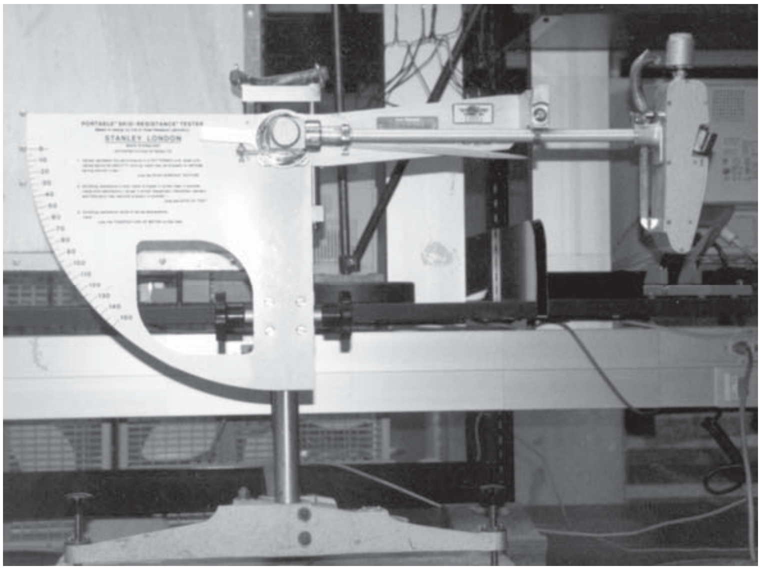

Figure 1—British Pendulum Tester

5.1. *British Pendulum Tester (Figure 1)*—The pendulum with slider and slider mount shall weigh 1500 ± 30 g. The distance of the center of gravity of the pendulum from the center of oscillation shall be 16.2 ± 0.2 in. (411 ± 5 mm). The tester shall be capable of vertical adjustment to provide a slider contact path of from $4^7/_8$ to 5.0 in. (124 to 127 mm) for tests on flat surfaces and $2^{15}/_{16}$ to $3^1/_{16}$ in. (75 to 78 mm) for tests on polishing wheel specimens. The spring and lever arrangement shown in Figure 2 shall give an average normal slider load between the 3 in. (76 mm) wide slider and test surface of 2500 ± 100 g as measured by the method prescribed in the Annex.

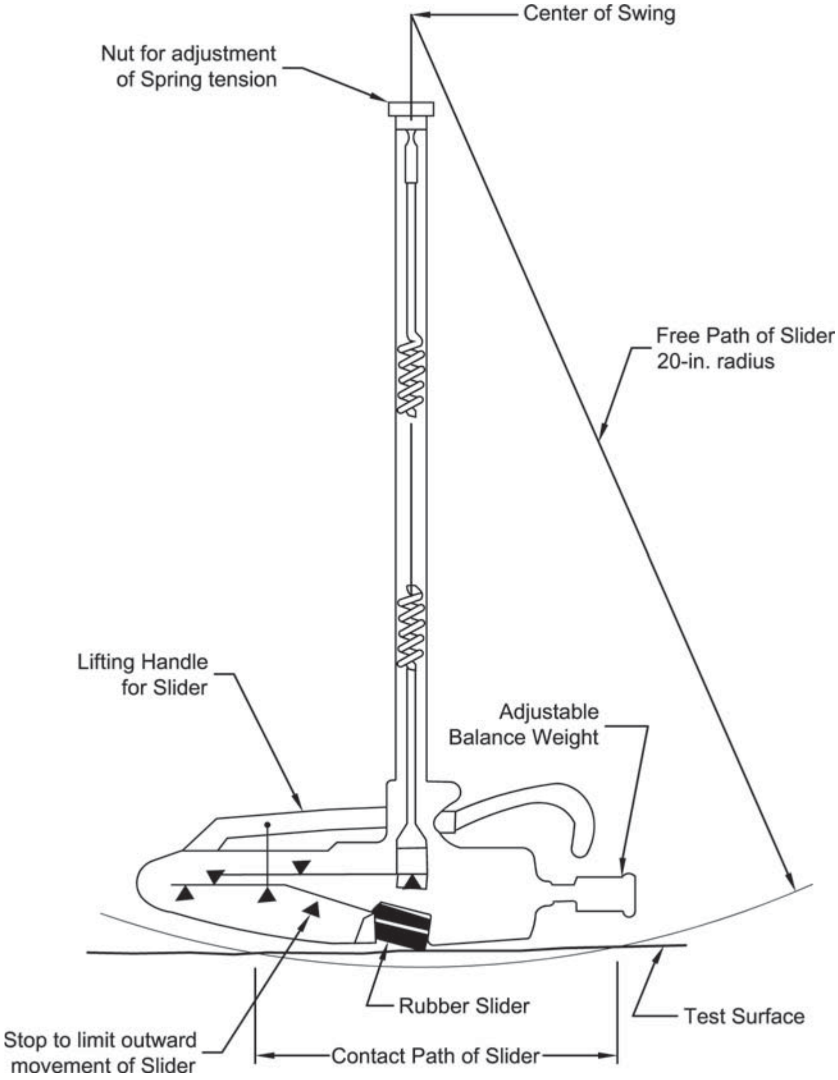

Figure 2—Schematic Drawing of Pendulum Showing Spring and Lever Arrangement

5.2. *Slider*—The slider assembly shall consist of an aluminum backing plate to which is bonded a $^1/_4$ by 1 by 3 in. (6 by 25 by 76 mm) rubber strip for testing flat surfaces or a $^1/_4$ by 1 by $1^1/_4$ in. (6 by 25 by 32 mm) rubber strip for testing curved polishing wheel specimens. The rubber compound shall be natural rubber meeting the requirements of the Road Research Laboratory (see reference under Section 2.3) or synthetic rubber as specified in M 261.

5.2.1. New sliders shall be conditioned prior to use by making 10 swings on No. 60 grade silicon carbide cloth or equivalent under dry conditions. The swings shall be made with a tester adjusted as in Section 7.

Note 2—Carbide cloth material known to be suitable for this purpose is available from 3M Company, St. Paul, MN, under the trade name Type B Safety-Walk.

5.2.2. Wear on the striking edge of the slider shall not exceed $^1/_8$ in. (3.2 mm) in the plane of the slider or $^1/_{16}$ in. (1.6 mm) vertical to it, as illustrated in Figure 3.

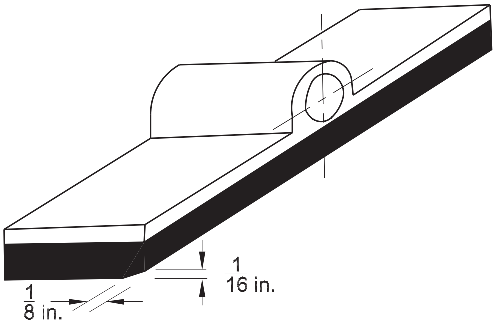

Figure 3—Slider Assembly Illustrating the Maximum Wear on Striking Edge

5.3. *Accessories*:

5.3.1. Contact path gauge shall consist of a thin ruler suitably marked for measuring contact path length between $4^7/_8$ and 5 in. (124 and 127 mm) or between $2^{15}/_{16}$ and $3^1/_{16}$ in. (75 and 78 mm) as required for the particular test.

5.3.2. Miscellaneous equipment, such as water container, surface thermometer, and brush is recommended.

6. TEST SPECIMEN

6.1. *Field*—Field test surfaces shall be free of loose particles and flushed with clean water. The test surface does not have to be horizontal provided the instrument can be leveled in the working position using only the leveling screws and the pendulum head will clear the surface.

6.2. *Laboratory*—Laboratory test panels shall be clean and free of loose particles and shall be held rigidly so as not to be moved by the force of the pendulum.

6.2.1. Flat laboratory samples shall have a test surface of at least $3^1/_2$ by 6 in. (89 by 152 mm).

6.2.2. Accelerated laboratory polishing wheel specimens shall have a test surface of at least $1^3/_4$ by $3^1/_2$ inches (45 by 90 mm) and shall be curved in the arc of a circle 16 in. (406 mm) in diameter.

7. PREPARATION OF APPARATUS

7.1. *Leveling*—Level the instrument accurately by turning leveling screws until the bubble is centered in the spirit level.

7.2. *Zero Adjustments*—Raise the pendulum mechanism by loosening the locking knob (directly behind pendulum pivot) and turn either of the pair of head movement knobs at the center of the tester to allow the slider to swing free of the test surface. Tighten the locking knob firmly. Place the pendulum in the release position and rotate the drag pointer counterclockwise until it comes to rest against the adjustment screw on the pendulum arm. Release the pendulum and note the pointer reading. If the reading is not zero, loosen the locking ring and rotate the friction ring on the bearing spindle slightly and lock again. Repeat the test and adjust the friction ring until the pendulum swing carries the pointer to zero.

7.3. *Slide Length Adjustment*:

7.3.1. With the pendulum hanging free, place the spacer under the adjusting screw of the lifting handle. Lower the pendulum so the edge of the slider just touches the test surface. Lock the pendulum head firmly, raise the lifting handle, and remove spacer.

7.3.2. Raise the slider by lifting the handle, move the pendulum to the right, lower the slider, and allow the pendulum to move slowly to the left until the slider edge touches the test surface. Place the contact path gauge beside the slider and parallel to the direction of swing to verify the length of the contact path. Raise the slider, using the lifting handle, and move the pendulum to the left, then slowly lower it until the slider edge again comes to rest on the surface. If the length of the contact path is not between $4^7/_8$ and 5 in. (124 and 127 mm) on flat test specimens or between $2^{15}/_{16}$ and $3^1/_{16}$ in. (75 and 78 mm) on curved polishing wheel specimens measured from trailing edge to trailing edge of the rubber slider, adjust by raising or lowering the instrument with the front leveling screws. The slide length may also be adjusted by means of the vertical height control knobs. Readjust the level of the instrument, if necessary. Place the pendulum in the release position and rotate the drag pointer counterclockwise until it comes to rest against the adjustment screw on the pendulum arm.

8. PROCEDURE

8.1. Apply sufficient water to cover the test area thoroughly. Execute several swings until consistent results are obtained, but do not record the readings.

Note 3—Always catch the pendulum during the early portion of its return swing. While returning the pendulum to its starting position, raise the slider with its lifting handle to prevent contact between slider and the test surface. Prior to each swing, the pointer should be returned until it rests against the adjustment screw.

8.2. Rewet the test area and without delay make four more swings, rewetting the test area prior to each swing and recording the results.

Note 4—Use four swings for natural rubber and five swings for AASHTO M 261 rubber. Care should be taken that the slider remains parallel to the test surface during the swings, and does not rotate so that one end rather than the entire striking edge makes the initial contact. Available data indicate that tilting of the slider may cause erroneous BPN readings. Installation of a small flat spring will relieve the problem. The spring can be inserted into a slot in the spring clip and the assembly secured by the cotter pin as shown in Figure 4. The free ends of the spring can rest on the slider backing-plate to restrain the slider from tilting.

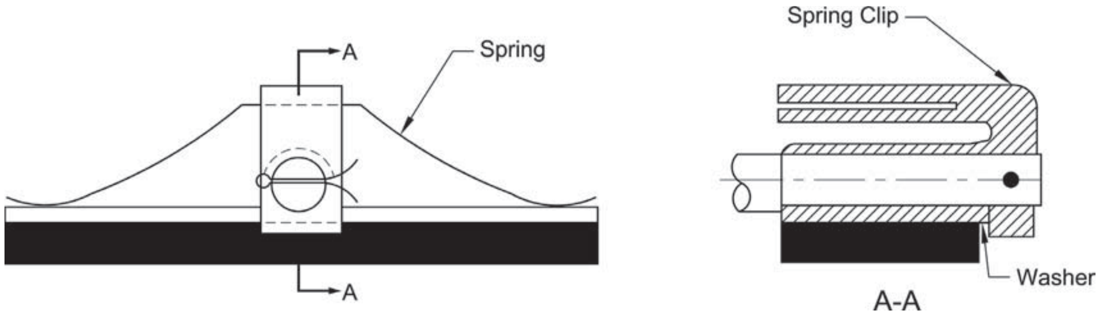

Figure 4—Spring Clip and Spring to Inhibit Slider Rotation

8.3. Recheck the slider contact length in accordance with Section 7.3.

8.4. Recheck the zero adjustment in accordance with Section 7.2.

9. REPORT

9.1. *The report shall include the following*:

9.1.1. Individual values in BPNs or polish values, and the average BPN or average polish value for each test surface.

9.1.2. Temperature of the test surface.

9.1.3. Type, age, condition, texture, and location of the test surface.

9.1.4. Type and source of aggregate for polish value tests.

9.1.5. Type and age of the rubber slider.

10. PRECISION AND BIAS

Note 5—The following material pertains only to the precision and bias of BPN units.

10.1. *Repeated tests show standard deviations as follows*:

- British rubber sliders, 1.0 BPN units
- Sliders conforming to M 261, 1.2 BPN units

In both cases, the upper quartile of variability is represented in prevailing test instruments. As there is no marked correlation between standard deviation and arithmetic mean of sets of test values, it appears that standard deviations are pertinent to this test regardless of the average frictional levels being tested.

10.2. The relationship, if any exists, of observed BPN units to some “true” value frictional level has not been and probably cannot be studied. As a result, precision and bias of this test in relation to a true frictional level measure cannot be evaluated, and only repeatability is given for the method.

10.3. *Determine the testing error as follows*:

$$E = \frac{t(\sigma)}{\sqrt{n}} \qquad (1)$$

where:

E = testing error,

t = normal curve of 1.96 or 2.0 rounded,

σ = standard deviation of individual test results (BPNs), and

n = number of tests.

10.4. In order to assure that the testing error stays within 1.0 BPN at a 95 percent confidence level (corresponding to a normal curve of 1.96 or 2.0 rounded), the following number of record swings are needed per sample:

- British natural rubber sliders, four
- Sliders conforming to M 261, five

ANNEX

(Mandatory Information)

A1. CALIBRATION

A1.1. *Weight of Pendulum*—The pendulum arm with mounted rubber slider shall be disconnected from the instrument and weighed to the nearest 1 g.

A1.2. *Center of Gravity*—The center of gravity of the pendulum with a mounted rubber slider shall be determined by placing the pendulum assembly over a knife edge and experimentally locating the point of balance as shown in Figure A1.1. The adapter nut shall be held at the far end of the arm by a lightweight paper wedge. After the point of balance has been obtained, the position of the balance weight shall be adjusted until the sides of the pendulum foot are horizontal.

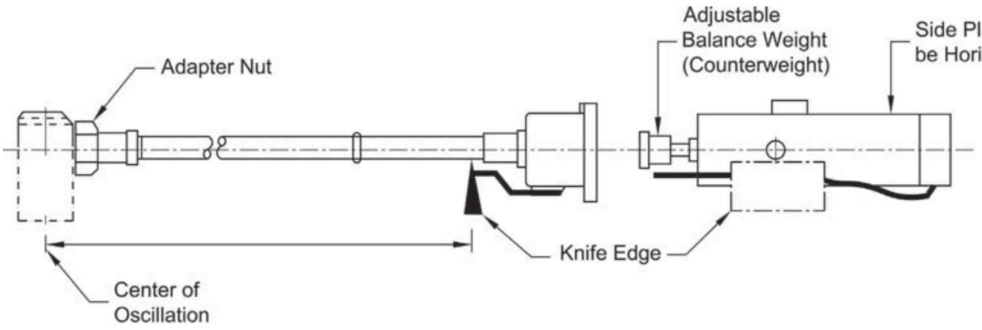

Figure A1.1—Pendulum Assembly Showing Location of the Point of Balance

A1.3. *Distance of Center of Gravity from Center of Oscillation*—With the pendulum reconnected to the tester and knurled bearing cap removed, the distance shall be measured from the center of oscillation (center of bearing nut) to the point of balance (center of gravity). This distance shall be measured directly to the nearest 0.04 in. (1 mm).

A1.4. *Slider Load*—The pendulum shall be clamped to a holder attached to the scale plate of the tester and the tester placed and leveled on a tripod stand as shown in Figure A1.2. Insert the spacer. Adjust the pan balance with a bearing assembly (Note 5) on one pan and tare weights on the other pan so that the balance pointer is at a center scale reading. The pendulum, with a slider, shall be lowered with the vertical height knobs of the tester until the slider is approximately 0.01 in. (0.25 mm) from the top surface of the bearing assembly. Lock the vertical height knob and remove the spacer. This will cause an unbalance, which shall be partially compensated by adding weights to the opposite pan to bring the indicator to within approximately 200 g of the center scale reading. To complete the balance procedure, the pointer is returned to the center scale reading by adding water slowly into a graduated cylinder. Empty the cylinder and repeat the pouring. Record the average weight required to raise the slider so that the balance pointer is at the center of the scale (Note A1). If the average, normal slider load between the 3-in. (76.2-mm) wide slider and the pan balance is not within the requirements stated in Section 5.1, adjust the spring tension nut illustrated in Figure 2 and redetermine the slider load.

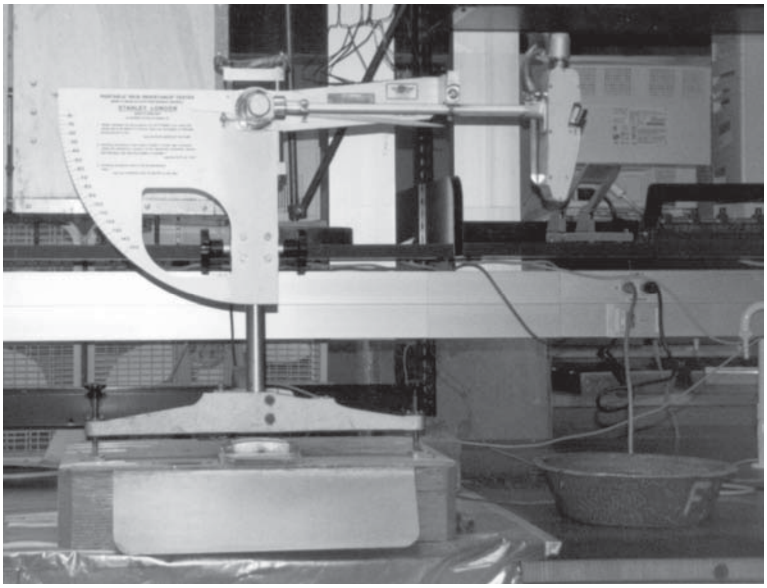

Figure A1.2—Arrangement of the British Pendulum Tester, Showing Pendulum Assembly and Pan Balance Used to Measure Slider Load

Note A1—The bearing assembly may be a "ladder" bearing with a rigid, free-moving top plate or a similar arrangement so that no horizontal loads are introduced while measuring the vertical slider load.

Note A2—It may be necessary to move the pans of the balance up and down to "work" the spring in order to get smooth and consistent readings. If the measurements of the slider load are still irregular after "working" the spring, remove the side and bottom panels of the pendulum foot and inspect for cleanliness of the bearing surfaces and knife edges illustrated in Figure 2 and redetermine the slider load.

---

[1] This method agrees with ASTM E 303-93 (2003), except for differences in the number of allowed unrecorded swings in the test procedure and the addition of an optional method of slide length adjustment.

Standard Method of Test for

Calibrating a Wheel Force or Torque Transducer Using a Calibration Platform (User Level)

AASHTO Designation: T 282-01 (2006)
ASTM Designation: E 556-95 (2000)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Calibrating a Wheel Force or Torque Transducer Using a Calibration Platform (User Level)

AASHTO Designation: T 282-01 (2006)
ASTM Designation: E 556-95 (2000)

1. SCOPE

1.1. This method covers the calibration of the force (or torque) transducer and associated instrumentation of a mounted test wheel by using a calibration platform. It is used for establishing correction factors for changes in transducer output due to changes in operating conditions.

1.2. This method is a static calibration, simulating the traction force between a tire and the pavement.

1.3. In the case of a force-measuring system, the instrumentation readout is directly proportional to the calibration force input.

1.4. In the case of a torque-measuring system, the instrumentation readout is a measure of the calibration force input and the effective tire radius.

1.5. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 261, Rib-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests
- M 286, Smooth-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests
- T 242, Frictional Properties of Paved Surfaces Using a Full-Scale Tire

2.2. *ASTM Standards*:

- E 274, Standard Test Method for Skid Resistance of Paved Surfaces Using a Full-Scale Tire
- F 377, Standard Practice for Calibration of Braking/Tractive Measuring Devices for Testing Tires

3. SUMMARY OF METHOD

3.1. The vertical static loads (forces) on the test wheel(s) and hitch are established. If the tester is of the trailer type, it must be connected to its tow vehicle. Traction forces are applied to the locked wheel(s) at the tire–platform interface. The wheel transducer is calibrated while trailer and tow vehicle displacements are measured from the initial position for the applied traction force. The calibration platform consists of a bearing that is frictionless in all directions of the horizontal plane supporting a rigid plate with a high-friction surface. The force applied to this platform is measured by a suitable transducer.

3.2. Wheel transducer linearity and hysteresis are determined by recording data using an electronic digital meter and/or an *x-y* plotter, and should also be correlated with data collected from the tow vehicle instrumentation. Techniques are given for establishing reference signals to be used as calibration points.

3.3. With calibration platforms having force-measurement capability also in the vertical direction, test-wheel load (force) is recorded as a function of the applied tractive calibration force.

3.4. With a wheel transducer also having normal load (force)-measuring capability, the transducer output is compared with the corresponding vertical output of the calibration platform.

4. SIGNIFICANCE AND USE

4.1. Wheel force or torque transducers are used under dynamic test conditions, and the measurements are subject to many error sources. The static calibration recommended by the present standard cannot eliminate all error sources. Its significance is in providing an accurate calibration of the transducer and the associated electronics, readout, and recording equipment.

4.2. The calibration result may be used to make either mechanical or electronic adjustments until the readout agrees with the calibration input. Alternatively, calibration curves or tables may be prepared to be used as corrections to measured results.

5. DESCRIPTION OF TERMS SPECIFIC TO THIS STANDARD

5.1. *wheel force transducer system*—a force-to-electrical signal converter system including transducer(s), associated signal condition, zeroing, amplifying, recording, and monitoring instrumentation.

5.2. *calibration reference signals*—repeatable signals in the range of expected wheel-force transducer system loading. These signals could be either constant voltages, preferably, or produced by a strain-gauge calibration shunt resistor.

5.3. *calibration platform*—a moving platform for applying a force in the contact plane of a tire, and associated means for measuring the applied force. The calibration platform consists of a rigid plate with a high-friction surface, in contact with the tire footprint, supported on a frictionless, preferably air, bearing. It may also be instrumented to measure vertical forces (loads).

5.4. *hysteresis*—the maximum difference between corresponding transducer outputs (of the wheel force transducer system) at increasing and decreasing applied calibration force, expressed as a percentage of full load. Proven outliers are excluded.

5.5. *linearity nonlinearity*—the maximum deviation of the transducer output(s) (of the wheel force transducer system) from the “best-fit” linear relation to the applied calibration force, expressed as a percentage of full scale. Proven outliers are excluded.

5.6. *test wheel*—a wheel and test tire assembly mounted to a test vehicle by means of a force or torque transducer.

5.7. *crosstalk*—the undesired effect of force readings appearing on an unloaded axis of a transducer while applying force to another.

5.8. *horizontal traction (traction)*—a force acting in a horizontal axis through the wheel transducer; i.e., locked wheel drag force.

5.9. *vertical load (load)*—force acting in a vertical axis through the wheel transducer; i.e., weight.

6. APPARATUS

6.1. The calibration apparatus shall consist of the basic components described below, and calibrated in accordance with Section 6.3 of ASTM F 377.

6.1.1. A calibration platform for applying tractive forces at the tire–platform interface of a test wheel, with a calibrated internal or external reference force transducer to measure these forces. Capability of measuring vertical forces (wheel loads) also is desirable.

6.1.2. A system for generating traction forces applied through the calibration platform.

6.1.3. Instrumentation for recording or indicating transducer outputs, including digital meters and, optionally, an *x-y* recorder.

6.1.4. An accurate level, tire pressure gauge, and thermometer for measuring ambient temperatures.

6.1.5. Scale(s) for measuring vertical wheel load, accurate within 0.5 percent of maximum expected axle load for the test trailer.

7. PREPARATION OF APPARATUS

7.1. *Site*—Select a sheltered, level, paved area. (A hard surface, preferably under cover, is desirable.)

7.2. *Calibration Platform and Associated Instrumentation*—Prepare the calibration platform and associated instrumentation following established set-up procedures and the manufacturers' manuals where applicable.

7.3. *Test Tires*—Set the inflation pressure under normal vertical load (force). Inflation pressure shall be 165.0 ± 3.5kPa (24.0. ± 0.5 psi) at ambient temperature (cold).

7.4. *Traction Tester Instrumentation*—Check the test vehicle instrumentation by following established set-up procedures for the system with reference to the recommended procedure in the manufacturer's manual, where applicable. Set all gains and offsets at values normally used during friction testing. Record the settings.

7.4.1. *Force-Type Transducer*—Load cross talk into traction; if, with full normal load back on the test wheel, the traction output is different from zero by more than 1 percent of the applied normal load, adjust by either rotating the transducer (if provisions for rotation have been made) or by changing the hitch height; that is, tilting the trailer to orient the transducer horizontal axis parallel to the calibration plane. Then apply 2.2 kN (500 lbf) of traction force and note the change in load reading. If more than 1 percent cross talk, check transducer leveling and repeat this test.

7.4.2. *Torque-Type Transducer*—Use steps in Sections 7.4 and 7.4.1, substituting the torque output for the traction. If the load into torque cross talk is greater than 1 percent of the applied normal load, refer to the manufacturer since there are normally no user adjustments.

7.5. *Test Trailer*—Position the trailer coupled to its tow vehicle on level ground and set the trailer variables such as tire pressure, high height, and inflation pressure of air shock absorbers, where present, to the normal operating values. Measure the hitch height from level ground to the center of the hitch. Decouple the trailer and weigh it at each point of support, maintaining its relative level. Correct the weights, if needed, to comply with T 242. Recouple the trailer to the towing vehicle.

Note 1—The tow vehicle should have one-half tank of water and a full fuel load before leveling the trailer.

7.6. *Wheel Transducer*—With the test wheel loaded, the wheel transducer traction output should be adjusted to zero. Then remove 2.2 kN (500 lbf) of the load and recheck traction zero.

7.7. Record all measures, weights, and dimensions, and the trailer leveling adjustments that give zero transducer outputs.

8. PROCEDURE

8.1. Determine that the calibration platform has been suitably calibrated within a reasonable period of time (see Section 6.1).

8.2. If the test vehicle is of the trailer type, it should be hitched and aligned with the tow vehicle. The calibration may be performed with auxiliary electrical power for the instrumentation. In this case, after completing the calibration, check the system when powered by the vehicle electrical system with the engine running, to assure that the output(s) have not changed. The preparations described in Section 7 shall have been performed.

8.3. Place the test wheel(s) on the calibration platform(s) using blocks, if needed, under the other wheels to maintain a level plane of support for all system tires.

8.4. With the test wheel raised clear of the platform, zero the output(s) of the calibration platform in accordance with established operating procedures. Zero the wheel transducer output(s).

Note 2—**Warning**: Make sure that the wheel brakes do not drag.

8.5. Align the calibration platform(s) and the associated force application system(s) with the test tire(s) and lower the test wheel onto the platform.

8.6. The platform shall be level within ±0.25 degree prior to calibration.

Note 3—Increased accuracy may be obtained by maintaining the aforementioned level throughout the calibration procedure.

8.7. Record the ambient temperature. To meet this standard, calibration can only be done when the ambient temperature is between 4 and 38°C (40 and 100°F).

8.8. Use digital meter(s) and, optionally, x-y recorder(s) to observe the wheel force transducer system signals at the input to the system recorder.

8.8.1. With the trailer level and with full vertical load and zero traction force applied to the test wheel(s), adjust the system vertical load indicator to correspond with the platform vertical load value.

8.8.2. Lock the test wheel and apply a mid-range tractive force (typically 2.2 kN (500 lbf)) via the platform to the test wheel. Adjust the system traction indicator to correspond with the platform traction value. Return the traction force to zero.

8.9. Record the wheel-transducer vertical load output and the force-plate transducer vertical output, on both the system recorder and the meter, while increasing and decreasing the vertical force applied by at least 20 percent of the static wheel load value in 445-N (100-lbf) increments. This can be done by adding 90-kg (200-lb) shot bags; e.g., to the trailer wheel load.

8.10. Establish the linearity and hysteresis characteristics for the vertical transducer output, if applicable, using data in Section 8.9.

8.11. Record the wheel transducer output(s). (Horizontal traction and vertical load readings on both the system recorder and the meter while increasing and decreasing the traction force by 445-N (100-lbf) increments through the full calibration range (typically 0 to 50 percent of vertical load).

Note 4—For a two-wheeled towed test trailer, the test wheel vertical load should decrease linearly from the zero traction value as the applied traction force increases at a slope proportional to the H/L ratio of the trailer, where H is the initial hitch height and L is the initial hitch-to-axle length (see T 242). The non-test wheel load (force) should remain constant at the zero traction value.

8.12. If the test wheel load and traction values obtained in Sections 8.9 and 8.11 agree with the platform values within ±1 percent, apply system load and traction calibration signals and record for future reference. If differences greater than 1 percent are found, the system may require maintenance or the cross talk should be rechecked as described in Section 7.6.

Note 5—Some calibration platforms use ball or roller bearings (instead of air bearings). Any side force on the wheel under calibration will generate additional friction forces in the calibration platform and cause erroneous readings and hysteresis.

8.13. Perform the calibration procedure of Section 8 for the second wheel transducer, if applicable.

9. REPORT

9.1. *The report shall contain the following information*:

9.1.1. Skid measuring system identification;

9.1.2. Wheel-transducer identification;

9.1.3. Date;

9.1.4. Test equipment identification in accordance with calibration report(s);

9.1.5. Test tires identification;

9.1.6. Static weight at wheels and hitch;

9.1.7. Setting of the skid tester variables;

9.1.8. Measured values *H* (hitch height), *L* (length from hitch to wheel center), and *T* (track width);

9.1.9. Tow-vehicle standardization details;

9.1.10. Instrumentation check-out details;

9.1.11. Orientation of the transducer-sensitive axis;

9.1.12. Statement of loading conditions under which the readouts are zeroed;

9.1.13. Loading conditions under which the reference calibration points are applicable;

9.1.14. Record of the on-board and external indicator outputs of each transducer output versus increasing and decreasing traction force and vertical load (force);

9.1.15. Statement of calibration values, linearity, and hysteresis characteristics for the transducer and its associated readout;

9.1.16. Correlation of external meter output with on-board meter or recorder output;

9.1.17. Report section for a second transducer, if applicable; and

9.1.18. Remainder of operating coefficient established in Section 8, ambient temperature range during the calibration; and notes on calibration procedures.

10. FREQUENCY OF CALIBRATION

10.1. It is recommended that the system be calibrated according to all sections of this specification at least once a year.

10.2. For a routine test to indicate normal system operations only, it may be sufficient to abbreviate the procedure in Section 8.

10.3. Calibration should be performed at least once a month according to Section 10.2.

10.4. Calibration should be performed whenever the measured friction is inconsistent with expected values for a given test site.

11. PRECISION AND BIAS

11.1. As a rule of thumb, instrumentation bias should be approximately ten times greater than the desired bias of the measurement. This would require the calibration to be made within 0.1 SN (skid number). To obtain this bias for skid testers in the mid-range of measurements (that is, SN = 40) and with a 4450-N (1000-lbf) vertical wheel load, the bias would have to be

±5 N (±1 lbf). Such an accuracy is difficult to obtain in practice, primarily because of the uncertain tire response. The recommended bias is 1 percent or better.

11.2. To obtain satisfactory test precision with a system so calibrated, it is recommended to conduct replicate tests. The preferred method for selecting the number of replicates is based on the desired precision and known performance of the test system. When replicate tests are conducted by experienced test crews and equipment that is in good condition, a precision of ±2 SN is readily achievable. Alternatively, a fixed number of replicates (such as recommended in T 242) may be used.

Standard Method of Test for

Prediction of Asphalt-Bound Pavement Layer Temperatures

AASHTO Designation: T 317-04 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Prediction of Asphalt-Bound Pavement Layer Temperatures

AASHTO Designation: T 317-04 (2009)

1. SCOPE

1.1. This test method provides a standard for measuring pavement surface temperature and predicting temperatures within the asphalt-bound layer(s) of a flexible pavement section. This test method provides a means of estimating the temperature at depth from the pavement surface temperature, the time of day, the previous day's high and low air temperatures, and the desired depth at which the temperature is to be estimated.

1.2. Deflection testing commonly involves the measurement of the pavement surface temperatures. This standard is based on temperature relationships developed as part of the Federal Highway Administration (FHWA) Long-Term Pavement Performance (LTPP) Seasonal Monitoring Program.

1.3. This test method is applicable for temperature predictions on flexible asphalt concrete (AC) and composite asphalt over portland cement concrete (AC/PCC) pavements.

1.4. *This standard does not purport to address the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *BELLS*—an acronym based on the initials of the four developers of the method: Baltzer, Ertman-Larsen, Lukanen, and Stubstad.

3.1.2. *depth*—the distance below the surface of the top layer of asphalt.

3.1.3. *one-day air temperature*—the average of the minimum and maximum air temperatures at the location of testing of the previous complete 24-hour day.

4. SUMMARY OF TEST METHOD

4.1. *Input Data Elements*:

4.1.1. *Infrared (IR) Temperature*—The exposed surface temperature of an asphalt pavement is measured, preferably with an infrared (IR) temperature-sensing device.

4.1.2. *Time of Day*—The time of day the temperature measurement takes place is recorded.

4.1.3. *One-Day Temperature*—The average 1-day air temperature of the previous complete 24-hour day is determined and recorded.

4.1.4. *Pavement Depth*—The depth at which an estimate of the asphalt layer temperature that is required is specified.

4.2. The input data elements are entered into a regression formula that predicts the temperature within the asphalt pavement at depth.

5. SIGNIFICANCE AND USE

5.1. Analysis of deflection data from asphalt pavements almost always requires that the deflections or analysis results be adjusted for the effects of temperature. Measuring the temperature at depth requires that a hole be drilled into the pavement, partially filled with fluid, and the temperature measured with hand-held devices. Alternatively, thermistors may be permanently installed at various locations. These processes are time consuming, resulting in a limited number of temperature measurements.

5.2. Current deflection testing equipment is often equipped with surface-temperature sensing devices, for example, an infrared thermometer that measures the surface temperature at every test location. To adequately adjust the deflection or deflection results for the effects of temperature, the temperature at some depth must be known.

5.3. Utilization of this method results in a significant savings in time over the conventional practice of manually drilling holes into the pavement, and it results in a significant increase in the volume of temperature data (one pavement temperature for each test point).

5.4. The BELLS temperature prediction model was based on temperature measurements made with surface temperature measurements between 0 and 40°C during the unfrozen times of the year. Application of BELLS outside of those conditions is not recommended. BELLS has been verified using the LTPP database at both mid-depth and third-depth temperature points. The use of BELLS to predict temperatures at depths shallower than the third point is not recommended.

6. APPARATUS

6.1. *Surface Temperature Measurement Device*:

6.1.1. The surface temperature measurement device can be an IR thermometer mounted on a deflection device, a hand-held IR thermometer, or a surface contact thermometer. The temperature measurement device should be calibrated according to the manufacturer's recommendations.

Note 1—The IR surface temperature is the most significant variable in the BELLS regression equation presented in Section 7.1.1. Thus, it is important that users verify the calibration of the surface temperature measurement device in the application of the equation.

7. CALCULATION

7.1. *BELLS Method*:

7.1.1. The BELLS method for production testing (called BELLS3 in other publications) has been derived based on temperature measurements taken on pavement surfaces that have been shaded for only a short time (less than 1 minute). The following equation is valid for approximately 30 seconds of shading:

$$T_d = 0.95 + 0.892*\mathrm{IR} + \{\log(d) - 1.25\}\{-0.448*\mathrm{IR} + 0.621*(1\text{-day}) + 1.83*\sin(\mathrm{hr}_{18} - 15.5)\} + 0.042*\mathrm{IR}*\sin(\mathrm{hr}_{18} - 13.5 \qquad (1)$$

where:

T_d = pavement temperature at depth d, °C;
IR = infrared surface temperature, °C;
log = base 10 logarithm;
d = depth at which asphalt temperature is to be predicted, mm;
1-day = average high and low air temperature, °C, for the day before the testing;
sin = sine function in 18-hour clock system, with 2π radians equal to one 18-hour cycle;
hr_{18} = time of day, in 24-hour system, but calculated using an 18-hour temperature rise and all cycle, as indicated in Sections 7.1.1 and 7.1.2.

7.1.2. When using the sin (hr18 – 15.5) decimal time function, only use times from 11:00 to 05:00 h. If the actual time is not within this time range, then calculate the sine as if the time is 11:00 h (where the sin = –1). If the time is between midnight and 05:00 h, add 24 to the actual decimal time. Then calculate as follows: If the time is 13:15, then in decimal form, 13.25 – 15.50 = –2.25; –2.25/18 = –0.125; –0.125 × 2π = –0.785 radians; sin (–0.785) = –0.707. [Note that an 18-hour sine function is assumed, with "flat" –1 sin segment between 05:00 and 11:00 h.]

Note 2—BELLS has been verified using the LTPP database at both mid-depth and third-depth temperature points. Since almost no difference exists in the regressions derived from the data at either depth, they were combined in deriving the BELLS equations.

7.2. *Alternate Calculation Method*:

7.2.1. Equation 1 can be calculated alternatively using degrees instead of radians and putting the sine function terms in a tabular form as shown below:

$$T_d = 0.95 + 0.892*\mathrm{IR} + \{\log(d) - 1.25\}*\{-0.44*\mathrm{IR} + 0.621*(1\text{-day}) + 1.83*A\} + 0.042*\mathrm{IR}*B \quad (2)$$

where:

A = dependent on time of day as in Table 1,

B = dependent on time of day as in Table 1,

sin = sine function – brackets contents { } are in degrees; (360 degrees equal to one 18-hour cycle).

Table 1—Values of *A* and *B* as Function of *h*

Time of Day*	*A*	*B*
$0.0 < h < 3.0$	Sin $\{(h + 24 - 15.5)*20\}$	Sin $\{(h + 24 - 13.5)*20\}$
$3.0 < h < 5.0$	Sin $\{(h + 24 - 15.5)*20\}$	–1
$5.0 < h < 9.0$	–1	–1
$9.0 < h < 11.0$	–1	Sin $\{(h - 13.5)*20\}$
$11.0 < h < 24.0$	Sin $\{(h - 15.5)*20\}$	Sin $\{(h - 13.5)*20\}$

* *h* = time of day in 24-hour format (military time) expressed as a decimal; i.e., 1:30 p.m. would be 1.5 + 12 or 13.5.

8. REPORT

8.1. The type of temperature measuring device, the measurement shading conditions, the time of measurement, the date of measurement, and the depth at which the temperature was calculated should be identified.

9. PRECISION AND BIAS

9.1. *Precision*:

9.1.1. The precision of the temperature estimation is described by the regression standard error of estimate. For the BELLS method for production testing (BELLS3), the regression standard estimate of error is ±1.9°C, based on an adjustment using the LTPP database for 30 seconds of shading.

9.2. *Bias*:

9.2.1. There was no means of measuring the bias during the development of the BELLS3 prediction equation.

10. KEYWORDS

10.1.1. Asphalt temperature; backcalculated moduli, Benkelman Beam; Dynaflect; Falling Weight Deflectometer; FWD; layer moduli; Road Rater; temperature correction.

APPENDIX

(Nonmandatory Information)

X1. EXAMPLE PROGRAM FOR CALCULATING THE PREDICTED ASPHALT TEMPERATURE BY THE BELLS METHOD

X1.1. *Explanation*:

X1.1.1. *Purpose*—The source code is presented to illustrate application of the temperature prediction equations, particularly the application of the 18-hour sine functions.

X1.1.2. *Language*—The source code is written in BASIC and can be run on a number of basic interpreters or compilers, or easily converted to other computer languages.

X1.2. *Source Code Listing*:

X1.2.1. Program to illustrate the implementation of the BELLS equation for routine testing with approximately 30 seconds of surface shade:

```

Standard Method of Test for

Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test

AASHTO Designation: T 87-86 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test

AASHTO Designation: T 87-86 (2008)

1. SCOPE

1.1 This method describes the dry preparation of soil and soil-aggregate samples, as received from the field, for mechanical analysis, physical tests, moisture-density relations test, and other tests as may be desired.

1.2 This method provides qualitative information only; therefore, a precision statement is not applicable.

1.3 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 88, Particle Size Analysis of Soils
- T 89, Determining the Liquid Limit of Soils
- T 90, Determining the Plastic Limit and Plasticity Index of Soils
- T 92, Determining the Shrinkage Factors of Soils
- T 99, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop
- T 100, Specific Gravity of Soils
- T 180, Moisture-Density Relations of Soils Using a 4.54-kg (10-lb) Rammer and a 457-mm (18-in.) Drop
- T 248, Reducing Samples of Aggregate to Testing Size

3. APPARATUS

3.1 The balance shall conform to the requirements of M 231, for the class of general purpose balance required for the principal sample mass of the sample being tested.

3.2 *Drying Apparatus*—Any suitable device capable of drying samples at a temperature not exceeding 60ºC (140ºF).

3.3 *Sieves*—A series of sieves of the following sizes: 19.0 mm ($^3/_4$ in.), 4.75 mm (No. 4), 2.00 mm (No. 10), 0.425 mm (No. 40) and others as required for preparing the sample for a specific test. The sieves shall conform to M 92.

Note 1—A 50-mm (2-in.) sieve is required if the sample includes particles retained on the 19.0-mm ($^3/_4$-in.) sieve, and it is desired that the sample for moisture-density relations (T 99 or T 180) contain material between 19.0-mm ($^3/_4$-in.) and 4.75-mm (No. 4) sieve size to represent the fraction between 50 and 19.0 mm (2 and $^3/_4$ in.).

3.4 *Pulverizing Apparatus*—Either a mortar and rubber-covered pestle or a mechanical device consisting of a power-driven, rubber-covered muller suitable for breaking up the aggregations of soil particles without reducing the size of the individual grains.

Note 2—Other types of apparatus, such as a revolving drum into which the soil sample and rubber-covered rollers are placed and tumbled until soil aggregations are pulverized, are satisfactory if the aggregations of soil particles are broken up without reducing the size of the individual grains.

3.5 *Sample Splitter*—A suitable riffle sampler or sample splitter for proportional splitting of the sample and capable of obtaining representative portions of the sample without appreciable loss of fines. The width of the container used to feed the riffle sample splitter should be equal to the total combined width of the riffle chutes. Proportional splitting of the sample on a canvas cloth is also permitted.

Note 3—The procedure for proportional splitting is described in T 248.

4. SAMPLE SIZE

4.1 The amounts of soil material required to perform the individual tests are as follows:

4.1.1 *Particle Size Analysis of Soils (T 88)*—For the particle size analysis, material passing a 2.00-mm (No. 10) sieve is required in amounts equal to approximately 110 g for sandy soils and approximately 60 g for silty or clayey soils. A sufficient amount of material retained on either the 4.75-mm (No. 4) sieve or 2.00-mm (No. 10) sieve is required (Note 4) to obtain a representative gradation, and, depending on the maximum particle size, shall not be less than the amount shown in the following table:

Diameter of Largest Particle, mm (in.)	Approximate Minimum Mass of Portion, kg
9.5 (3/8)	0.5
25 (1)	2.0
50 (2)	4.0
75 (3)	5.0

Note 4—The material for coarse sieve analysis may be separated by either of two alternate methods, Section 5.2.1 (2.00-mm sieve) or Section 5.2.2 (4.75-mm sieve). When only a small percentage of the material will be retained on the 4.75-mm or 2.00-mm sieve, a considerable total mass of sample will be required to provide the minimum quantity shown in the above table; consequently, adherence to the minimum mass requirements in the above table may not be necessary if the material represented by the sample is not to be used in a base or subbase course, select borrow, or other item having a requirement for coarse aggregate.

4.1.2 *Specific Gravity (T 100)*—For the specific gravity test performed in conjunction with T 88, material passing the 2.00-mm (No. 10) sieve is required in the amounts (oven-dry) of at least 25 g when the volumetric flask is used and at least 10 g when the stoppered bottle is used.

4.1.3 *Physical Tests*—For the physical tests, material passing the 0.425-mm (No. 40) sieve is required in the total amount of at least 300 g, allocated approximately as follows:

Test (and AASHTO Designation)	Approximate Mass, g
Liquid limit (T 89)	100
Plastic limit (T 90)	20
Shrinkage factors (T 92)	30
Field moisture equivalent (T 93)	50
Check and referee tests	100

4.1.4 *Other Tests*—For quantity of material required for testing, refer to the specific method of test.

5. INITIAL PREPARATION OF TEST SAMPLES

5.1 The soil sample as received from the field shall be dried thoroughly in air or the drying apparatus at a temperature not exceeding 60ºC (140ºF). A representative test sample of the amount required to perform the desired tests (Section 3) shall then be obtained with the sampler, or by splitting or quartering. The aggregations of soil particles shall then be broken up in the pulverizing apparatus in such a way as to avoid reducing the natural size of individual particles.

Note 5—Samples dried in an oven or other drying apparatus at a temperature not exceeding 60ºC (140ºF) are considered to be air-dried.

5.2 The portion of the dried sample selected for particle-sized analysis and physical tests (including specific gravity) shall be weighed, and that mass recorded as the mass of total sample uncorrected for hygroscopic moisture. This portion shall then be separated into fractions by one of the following methods:

5.2.1 *Alternate Methods Using 2.00-mm (No. 10) Sieve*—The dried sample shall be separated into two fractions using a 2.00-mm sieve. The fraction retained on the sieve shall be ground with the pulverizing apparatus until the aggregations of soil particles are broken into separate grains. The ground soil shall then be separated into two fractions using the 2.00-mm sieve.

5.2.2 *Alternate Method Using 4.75-mm and 2.00-mm (Nos. 4 and 10) Sieves*—The dried sample shall first be separated into two fractions using a 4.75-mm sieve. The fraction retained on this sieve shall be ground with the pulverizing apparatus until the aggregation of soil particles are broken into separate grains, and again separated on the 4.75-mm sieve. The fraction passing the 4.75-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for the desired tests shall be obtained and weighed. This split-off portion shall then be separated on the 2.00-mm sieve, and processed as in Section 5.2.1. The material from the split-off fraction that is retained on the 2.00-mm sieve shall be weighed for later use in coarse sieve analysis computations.

6. TEST SAMPLE FOR PARTICLE SIZE ANALYSIS AND SPECIFIC GRAVITY

6.1 The fraction retained on the 2.00-mm (No. 10) sieve in Section 5.2.1 or that retained on the 4.75-mm (No. 4) sieve in Section 5.2.2, after the second sieving, shall be set aside for use in sieve analysis of the coarse material.

6.2 The fraction passing the 2.00-mm (No. 10) sieve in both sieving operations in Sections 5.2.1 or 5.2.2 shall be thoroughly mixed together and, by the use of the sampler or by splitting or quartering, representative portions having approximate masses as follows shall be obtained: (1) for the hydrometer analysis and sieve analysis of the fraction passing the 2.00-mm sieve, 110 g for sandy soil and 60 g for silty or clayey soils; and (2) for specific gravity, 25 g when the volumetric flask is to be used and 10 g when the stoppered bottle is to be used.

7. TEST SAMPLE FOR PHYSICAL TESTS

7.1 The remaining portion of the material passing the 2.00-mm (No. 10) sieve shall then be separated into two parts by means of a 0.425-mm (No. 40) sieve. The fraction retained on the 0.425-mm (No. 40) sieve shall be ground with the pulverizing apparatus in such a manner as to break up the aggregations without fracturing the individual grains. If the sample contains brittle particles, such as flakes of mica, fragments of sea shells, etc., the pulverizing operation shall be done carefully and with just enough pressure to free the finer material that adheres to the coarser particles. The ground soil shall then be separated into two fractions by means of the 0.425-mm (No. 40) sieve, and the material shall be reground as before. When repeated grinding produces only a small quantity of soil passing the 0.425-mm sieve, the material retained on the 0.425-mm sieve shall be discarded. The several fractions passing the 0.425-mm sieve obtained from the grinding and sieving operations just described shall be thoroughly mixed together and set aside for use in performing the physical tests.

8. TEST SAMPLE FOR THE MOISTURE-DENSITY RELATIONS

8.1 The portion of dried soil selected for the moisture-density relations test shall be separated by means of the required sieve as specified in Section 4.1.4. If necessary, the pulverizing apparatus shall be used to break up the soil aggregations retained on this sieve into separate grains. The ground soil shall then be separated into two fractions using the required sieve.

8.2 The fraction retained on the sieve after the second sieving shall be saved, if required. The fractions passing the required sieve in both sieve operations shall be thoroughly mixed and used for the moisture-density test.

9. PRECISION

9.1 Since this preparation for testing produces no numerical values, determination of the precision and accuracy is not applicable.

Standard Method of Test for

Particle Size Analysis of Soils

AASHTO Designation: T 88-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Particle Size Analysis of Soils

AASHTO Designation: T 88-10

1. SCOPE

1.1. This method describes a procedure for the quantitative determination of the distribution of particle sizes in soils.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. Refer to R 16 for regulatory information for chemicals.

2. REFERENCED DOCUMENTS

- T 265, Laboratory Determination of Moisture Content of Soils

2.2. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 100, Standard Specification for ASTM Hydrometers

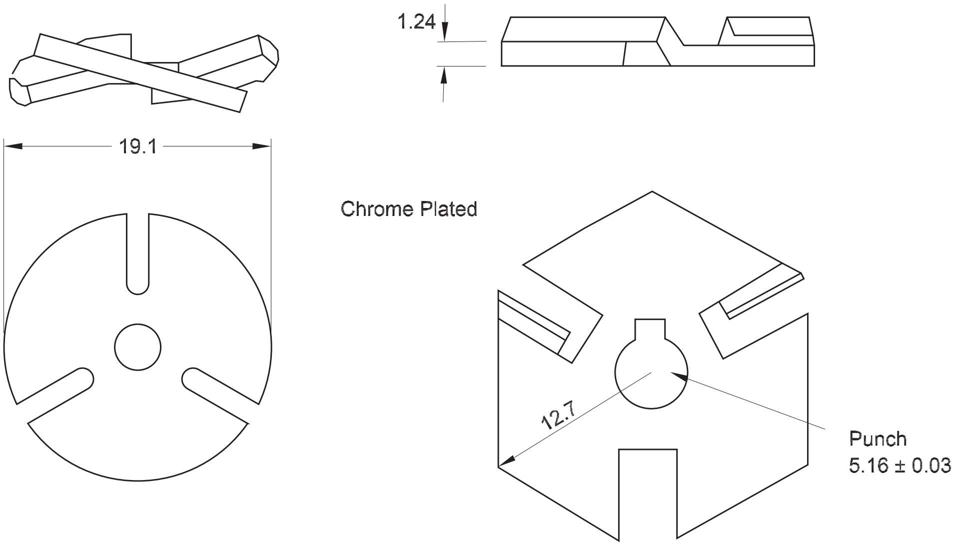
3. APPARATUS

3.1. *The apparatus shall consist of the following*:

3.1.1. *Oven*—A thermostatically controlled drying oven capable of maintaining temperatures of 110 ± 5ºC (230 ± 9ºF) for drying the sieve analysis samples.

3.1.2. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

3.1.3. *Stirring Apparatus*—A mechanically operated stirring apparatus consisting of an electric motor suitably mounted to turn a vertical shaft at a speed not less than 10,000 revolutions per minute without load, a replaceable stirring paddle made of metal, plastic, or hard rubber similar to one of the designs shown in Figure 1. The shaft shall be of such length that the stirring paddle will operate not less than 19.0 mm ($^3/_4$ in.) nor more than 38 mm (1.5 in.) above the bottom of the dispersion cup. A dispersion cup conforming to either of the designs shown in Figure 2.



Dimensional Equivalents

mm	in.
19.1	$^3/_4$
12.7	$^1/_2$
5.16 ± 0.025	0.203 ± 0.001
1.24	0.049 (No. 18 BW Ga.)

Note: All dimensions shown in millimeters unless otherwise noted.

Dimensional Equivalents

mm	in.
33.0	1.3
66.0	2.6
95.2	3.75
178	7.0

Note: All dimensions shown in millimeters unless otherwise noted.

Figure 2—Dispersion Cups

3.1.3.1. *(Alternate B)*—An air-jet type dispersing device similar to either of the designs shown in Figure 3.

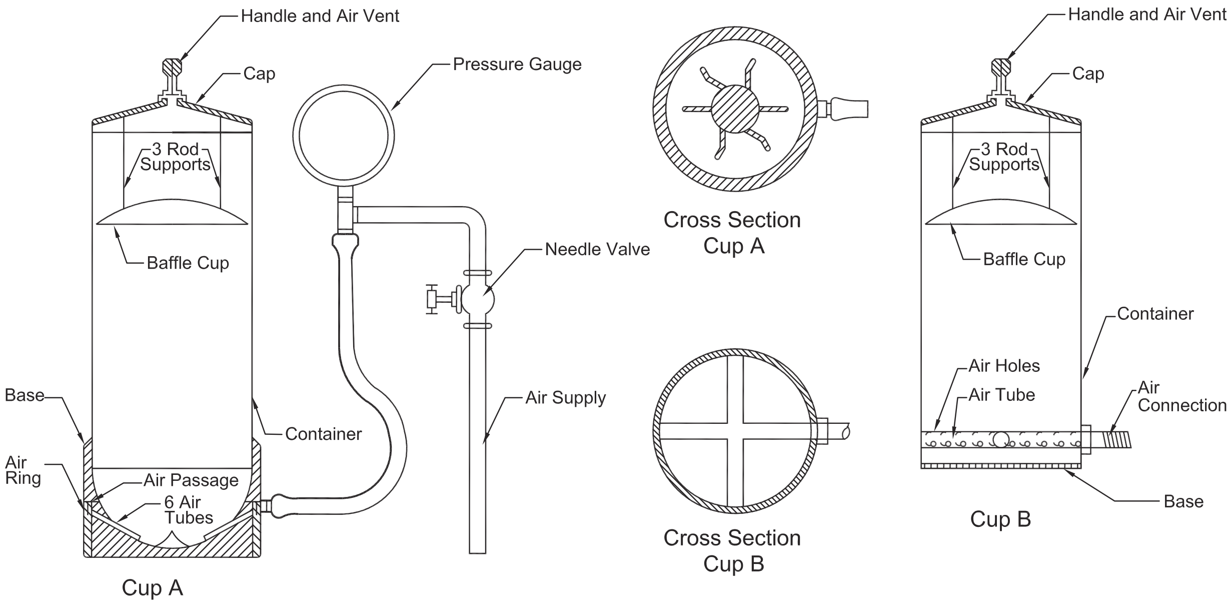

Figure 3—The Wintermyer Soil Dispersion Cups

Note 1—The amount of air required by an air-jet dispersion cup is of the order of 0.06 m^3/min (2 cfm); some small air compressors are not capable of supplying sufficient air to operate a cup.

Note 2—Another air-type dispersion device, known as a dispersion tube, developed by Chu and Davidson at Iowa State College, has been shown to give results equivalent to those secured by the air-jet dispersion cups. When it is used, soaking of the sample can be done in the sedimentation cylinder, thus eliminating the need for transferring the slurry. When the air-dispersion tube is used, it shall be so indicated in the report.

Note 3—Water may condense in air lines when not in use. This water must be removed, either by using a water trap on the air line, or by blowing the water out of the line before using any of the air for dispersion purposes.

3.1.4. *Hydrometer*—An ASTM hydrometer, graduated to read in either specific gravity of the suspension or grams per liter of suspension, and conforming to the requirements for hydrometers 151 H or 152 H in ASTM E 100. Dimensions of both hydrometers are the same, the scale being the only item of difference.

3.1.5. *Sedimentation Cylinders*—A glass cylinder approximately 460 mm (18 in.) in height and 60 mm ($2^1/_2$ in.) in diameter and marked for a volume of 1000 mL. The inside diameter shall be such that the 1000 mL mark is 360 ± 20 mm (14 ± 1.0 in.) from the bottom on the inside.

3.1.6. *Thermometer*—A calibrated thermometer readable to 0.5ºC (1ºF).

3.1.7. *Sieves*—A series of sieves of square mesh woven cloth, conforming to the requirements of M 92. The sieves normally required are as follows:

Standard Designation, mm	Alternate Designation
75	3 in.
50	2 in.
25	1 in.
9.25	$^3/_8$ in.
4.75	No. 4
2.00	No. 10
0.425	No. 40
0.075	No. 200

Note 4—The above sieves fulfill the requirements of M 145 and M 147. If desired, intermediate sieve sizes may be used in such sizes as:

Standard Designation, mm	Alternate Designation
75	3 in.
37.5	$1^1/_2$ in.
19	$^3/_4$ in.
9.5	$^3/_8$ in.
4.75	No. 4
2.36	No. 8
1.18	No. 16
0.60	No. 30
0.30	No. 50
0.15	No. 100
0.075	No. 200

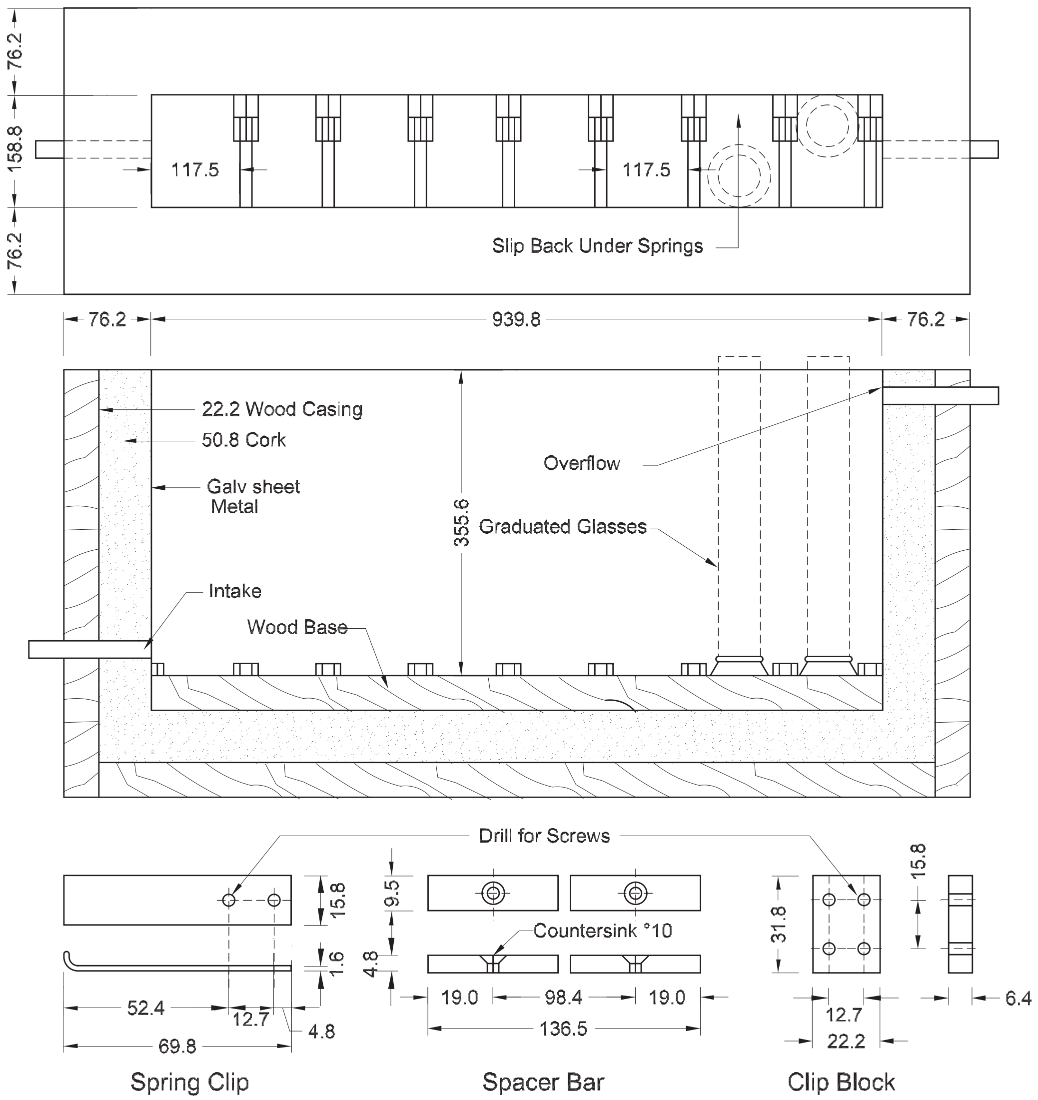
3.1.8. *Water Bath or Constant Temperature Room*—A water bath or constant temperature room for maintaining the soil suspension at a constant temperature during the hydrometer analysis. A satisfactory water bath is an insulated tank that maintains the suspension at a convenient constant temperature as near 20ºC (68ºF) as the room and faucet-water temperature will permit. Such a device is illustrated in Figure 4. In cases where the work is performed in a room at an automatically controlled constant temperature, the water bath is not necessary and subsequent reference to a constant temperature bath shall be interpreted as meaning either a water bath or a constant temperature room.

3.1.9. *Beaker*—A glass beaker having a capacity of at least 250 mL and not greater than 500 mL.

3.1.10. *Timing Device*—A watch or clock with a sweep second hand.

3.1.11. *Containers*—Suitable containers made of material resistant to corrosion and not subject to change in mass or disintegration on repeated heating and cooling. Containers shall have close-fitting lids to prevent loss of moisture from samples before initial mass determination and to prevent absorption of moisture from the atmosphere following drying and before final mass determination. One container is needed for each moisture content determination.

3.1.12. *Glass Rod*—Suitable for stirring the sample mixture.



Dimensional Equivalents

69.8	$2^{3}/_{4}$	4.8	$^{3}/_{16}$
52.4	$2^{1}/_{16}$	1.6	$^{1}/_{16}$
50.8	2		

Note: All dimensions are in millimeters unless otherwise noted.

Figure 4—Tank for Maintaining Soil Suspension at Constant Temperature During Hydrometer Analysis

4. DISPERSING AGENT

4.1. A solution of sodium hexametaphosphate shall be used in distilled or demineralized water, at the rate of 40 g of sodium hexametaphosphate per liter of solution.

4.1.1. Solutions of this salt, if acidic, slowly revert or hydrolyze back to the orthophosphate form with a resultant decrease in dispersing action. Solutions shall be prepared frequently (at least once a month) or adjusted to pH of 8 or 9 by means of sodium carbonate. Bottles containing solutions shall have the date of preparation marked on them.

5. GENERAL REQUIREMENTS FOR WEIGHING

5.1. The masses of subsamples and size fractions in the hydrometer analysis and hygroscopic moisture determination shall be determined to the nearest 0.01 g. The mass of the subsample for mechanical analysis of the fraction retained on the 4.75-mm sieve, the 2.00-mm sieve, or the 0.425-mm sieve for coarse sieve analysis, and each size fraction in the coarse sieve analysis, shall be determined to within 0.1 percent of the mass of the subsample. For example, a subsample with a mass of 1000 g, its size fractions in the coarse sieve analysis, must be weighed to the nearest gram.

6. SAMPLES

6.1. The test sample for particle size analysis shall be prepared in accordance with either T 87 for Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test, or T 146 for Wet Preparation of Disturbed Soil Samples for Test. The representative portion of the original air-dry sample selected for test shall be weighed. The mass of this sample shall be sufficient to yield quantities for particle size analysis as follows:

6.1.1. The minimum amount required of material retained on the 4.75-mm sieve, the 2.00-mm sieve, or the 0.425-mm sieve depends on the maximum particle size, but shall not be less than the amount shown in the following table:

Normal Size of Largest Particles Standard (Alternate)		Approximate Minimum Weight of Portion
mm	in.	kg
9.5	$^3/_8$	0.5
25	1	2
50	2	4
75	3	5

6.1.2. The size of the portion passing the 2.00-mm (No. 10) or 0.425-mm (No. 40) sieve shall be: (a) for the hydrometer test, approximately 100 g for sandy soil and approximately 50 g for silty or clayey soils, and (b) for hygroscopic moisture determination, at least 10 g.

6.2. The test sample selected in Section 5.1 shall be processed by one of the following methods:

6.2.1. *Alternate Method Using 4.75-mm and 2.00-mm (No. 4 and No. 10) Sieves*—After separating the test sample on the 4.75-mm sieve as described in Section 5.2.2 of T 87, the two fractions shall be weighed. A representative portion of the passing 4.75-mm sieve fraction adequate for mechanical analysis shall be selected and separated into two fractions using a 2.00-mm sieve. Each of these fractions shall be weighed and the subsamples for hydrometer analysis and hygroscopic moisture determination shall be obtained from the passing 2.00-mm sieve fraction by use of a riffle sampler or sample splitter, and either weighed immediately or placed in air-tight containers until tested.

6.2.2. *Alternate Method Using 2.00-mm (No. 10) Sieve*—The sample shall be separated on the 2.00-mm sieve as described in Section 5.2.1 of T 87. The portion retained on the 2.00-mm sieve after the second sieving shall be processed in accordance with Section 7, Sieve Analysis of Fraction Retained on 2.00-mm (No. 10) Sieve. The portion passing the 2.00-mm sieve in both sieving operations shall be weighed and prepared as described in Section 6.2 of T 87. Subsamples for hygroscopic moisture, hydrometer analysis, and sieve analysis shall be weighed immediately or placed in air-tight containers until tested.

6.2.3. *Alternate Method Using 0.425-mm (No. 40) Sieve*—The sample shall be processed as described in T 146, the portions retained on and passing the 0.425-mm sieve shall be weighed, and the subsamples for hydrometer analysis and hygroscopic moisture determination shall be obtained by use of a riffle sampler or sample splitter, and either weighed immediately or placed in air-tight containers until tested.

Note 4—Most laboratories prepare the sample in accordance with Section 5.2.1 of T 87, which provides for splitting the original sample on the 2.00-mm sieve. Hereafter in this method the triple designation, 4.75-mm, or 2.00-mm, or 0.425-mm sieve, is not used. When reference to the fraction retained or passing the 2.00-mm sieve is used, the 4.75-mm sieve is implied if the sample was processed in accordance with Section 6.2.1, and the 0.425-mm sieve is implied if the sample was processed in accordance with Section 6.2.3.

7. SIEVE ANALYSIS OF FRACTION RETAINED ON 2.00-MM (NO. 10) SIEVE

7.1. The portion of the sample retained on the 2.00-mm (No. 10) sieve shall be separated into a series of sizes by the use of the 75, 50, 25.0, 9.5, and 4.75-mm (3 in., 2 in., 1 in., $^3/_8$ in., and the No. 4) sieves, and using other sieves as may be needed depending on the sample or upon the specification for the material being tested. The 2.00-mm sieve shall be used if the sample was prepared in accordance with T 146.

7.2. The sieving operation shall be conducted by means of a lateral and vertical motion of the sieve, accomplished by jarring action so as to keep the sample moving continuously over the surface of the sieve. In no case shall fragments in the sample be turned or manipulated through the sieve by hand. Sieving shall be continued until not more than 1 percent by mass of the residue passes any sieve during 60 seconds. When sieving machines are used, their thoroughness of sieving shall be tested by comparison with hand methods of sieving as described in this paragraph.

7.3. The portion of the sample retained on each sieve shall be weighed and the mass recorded, although it shall be permissible to record the accumulated masses as the contents of each successive sieve are added to the fractions previously deposited on the scales pan.

8. DETERMINATION OF COMPOSITE CORRECTION FOR HYDROMETER READING

8.1. Equations for percentages of soil remaining in suspension, as given in Section 16.3, are based on the use of distilled or demineralized water. A dispersing agent is used in the water, however, and the specific gravity of the resulting liquid is appreciably greater than that of distilled or demineralized water.

8.1.1. Both soil hydrometers are calibrated at 20ºC (68ºF); variations in temperature from this standard temperature produce inaccuracies in the actual hydrometer readings. The amount of the inaccuracy increases as the variation from the standard temperature increases.

8.1.2. Hydrometers are graduated by the manufacturer to be read at the bottom of the meniscus formed by the liquid on the stem. Since it is not possible to secure readings of soil suspensions at the bottom of the meniscus, readings must be taken at the top and a correction applied.

8.1.3. The net amount of the corrections for the three items enumerated is designated as the composite correction, and may be determined experimentally.

8.2. For convenience, a graph or table of composite corrections for a series of 1-degree temperature differences for the range of expected test temperatures may be prepared and used as needed. Measurement of the composite corrections may be made at two temperatures spanning the range of expected test temperatures, and corrections for the intermediate temperatures calculated assuming a straight line relationship between the two observed values.

8.3. Prepare 1000 mL of liquid composed of distilled or demineralized water and dispersing agent in the selected dispersing agent specified in Section 4. Place the liquid in a sedimentation cylinder and the cylinder in the constant-temperature water bath, set for one of the two temperatures to be used. When the temperature of the liquid becomes constant, insert the hydrometer, and, after a short interval to permit the hydrometer to come to the temperature of the liquid, read the hydrometer at the top of the meniscus formed on the stem. For hydrometer 151 H the composite correction is the difference between this reading and one; for hydrometer 152 H it is the difference between the reading and zero. Bring the liquid and the hydrometer to the other temperature to be used, and secure the composite correction as before. (See Figure 5.)

9. HYGROSCOPIC MOISTURE

9.1. Determine the mass of the sample for the hygroscopic moisture determination. Dry the sample according to T 265, to determine the moisture content, and record the results.

10. DISPERSION OF SOIL SAMPLE

10.1. The approximately 100 or 50-g sample for hydrometer analysis shall be weighed, placed in a 250-mL beaker, covered with 125 mL of stock solution of the selected dispersing agent specified in Section 4, stirred thoroughly with a glass rod, and allowed to soak for a minimum of 12 hours. The contents of the beaker shall then be washed into one of the dispersion cups shown in Figure 2, distilled or demineralized water added until the cup is more than half full, and the contents dispersed for a period of 60 seconds in the mechanical stirring apparatus.

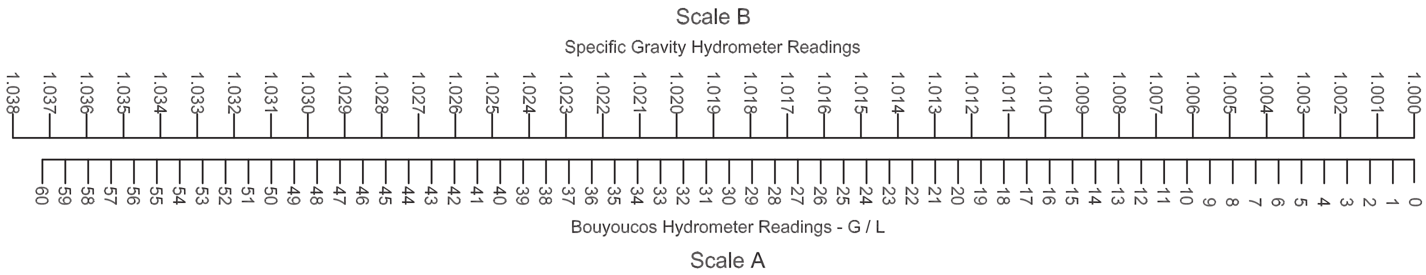
11. ALTERNATE METHOD FOR DISPERSION

11.1. The approximately 100 or 50-g sample for hydrometer analysis shall be weighed, placed in a 250-mL beaker, covered with 125 mL of the stock solution of the selected dispersing agent specified in Section 4, stirred thoroughly with a glass rod, and allowed to soak for a minimum of 12 hours.

11.2. The air-jet dispersion apparatus shall be assembled as shown in Figure 3 without the cover cap in place. The needle valve controlling the line pressure shall be opened until the pressure gauge indicates 6.9-kPa (1-psi) air pressure. This initial air pressure is required to prevent the soil-water mixture from entering the air-jet chamber when the mixture is transferred to the dispersion cup. After the apparatus is adjusted, the soil-water mixture shall be transferred from the beaker to the dispersion cup, using a wash bottle to assist in the transfer operation.

11.3. The volume of the soil-water mixture in the dispersion cup shall not exceed 250 mL. The cover containing the baffle plate shall be placed upon the dispersion cup and the needle valve opened until the pressure gauge reads 138 kPa (20 psi). The soil-water mixture shall be dispersed for 5, 10, or 15 minutes depending upon the plasticity index of the soil. Soils with a PI of five or less shall be dispersed for 5 minutes; soil with a PI between 6 and 20 for 10 minutes; and soils with a PI greater than 20 for 15 minutes. Soils containing large percentages of mica need be dispersed for 60 seconds only.

11.4. After the dispersion period is completed, the needle valve shall be closed until the pressure gauge indicates 6.9 kPa (1 psi). The cover shall be removed and all adhering soil particles washed back into the dispersion cup. The soil water suspension shall then be washed into the 1000-mL glass graduate and the needle valve closed.



The specific gravity scale (SP. G.) shall be calibrated to read 1.000 at 68° F and it shall extend beyond the limits shown, so as to read from 0.995 to 1.038. The grams per liter scale (G/L) shall be extended 5 G/L above zero (1.000 SP. G.) and down to 60 G/L. The bulb shall be symmetrical above and below the middle diameter, and shall be blown into a mold to assure uniformity of product.

* The diameter of the stem may be varied to adjust the length of the scale specified but the stem shall be uniform in diameter from top to bottom.
The accuracy of the scale shall be ± 1 scale division. Distributed uniformly over the scale length.

Hydrometer equipped with Scale B shall be identified as No. 151 H.

Hydrometer equipped with Scale A shall be identified as No. 152 H.

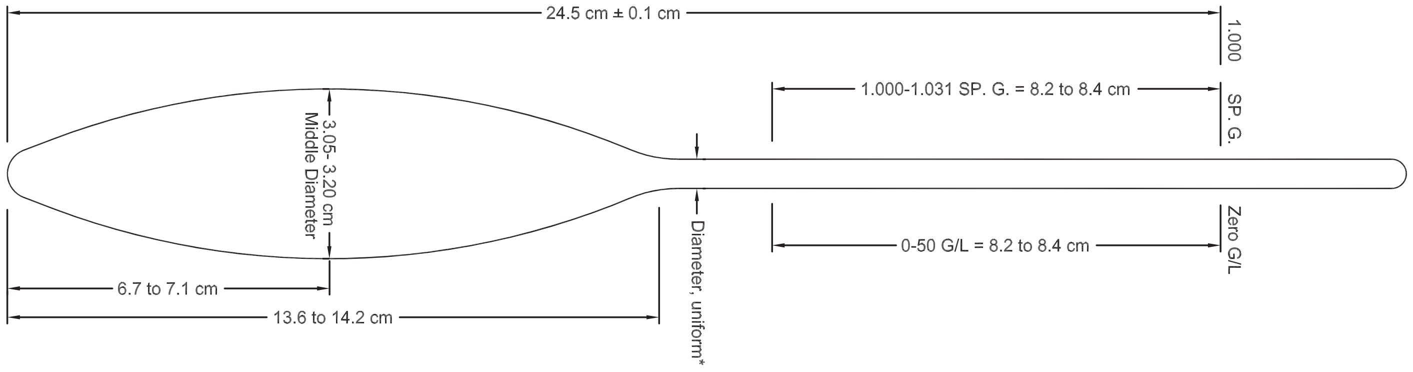


Figure 5—Hydrometer

12. HYDROMETER TEST

12.1. After dispersion, the mixture shall be transferred to the glass graduate and distilled or demineralized water having the same temperature as the constant temperature bath added until the mixture attains a volume of 1000 mL. The graduate containing the soil suspension shall then be placed in the constant temperature bath. Remove the graduate after the soil suspension attains the temperature of the bath. Using the palm of the hand over the open end of the cylinder (or a rubber stopper in the open end), turn the cylinder upside down and back for a period of 60 seconds to complete the agitation of the slurry.

Note 5—The number of turns during this minute should be approximately 60, counting the turn upside down and back as two turns. Any soil remaining in the bottom of the cylinder during the first few turns should be loosened by vigorous shaking of the cylinder while it is in the inverted position.

Note 6—Upon completion of the agitation period, if necessary, any material clinging to the inside walls of the top of the cylinder may be rinsed into the suspension with a small amount of water.

12.2. At the conclusion of this shaking, the time shall be recorded, the graduate placed in the bath, and readings taken with the hydrometer at the end of 120 seconds. The hydrometer shall be read at the top of the meniscus formed by the suspension around its stem. The hydrometer shall float freely and not touch the wall of the graduate or cylinder. If hydrometer with scale A is used, it shall be read to the nearest 0.5 g/L. Scale B shall be read to the nearest 0.0005 specific gravity. Subsequent readings shall be taken at intervals of 5, 15, 30, 60, 250, and 1440 minutes after the beginning of sedimentation. Readings of the thermometer placed in the soil suspension shall be made immediately following each hydrometer reading and recorded.

12.3. After each reading the hydrometer shall be very carefully removed from the soil suspension and placed with a spinning motion in a graduate of clean water. About 25 or 30 seconds before the time for a reading, it shall be taken from the clear water and slowly immersed in the soil suspension to assure that it comes to rest before the appointed reading time.

13. SIEVE ANALYSIS

13.1. At the conclusion of the final reading of the hydrometer, the suspension shall be washed on a 0.075-mm (No. 200) sieve. That fraction retained on the 0.075-mm sieve shall be dried in an oven at 110 ± 5ºC (230 ± 9ºF) and a sieve analysis made using the 0.425-mm and 0.075-mm sieves and such other sieves as may be required by the material under test.

Note 7—Following washing of the sample and flushing of any materials retained on the 75-µm (No. 200) sieve back into the container, no water should be decanted from the container except through the 75-µm (No. 200) sieve, to avoid loss of material. Excess water from flushing should be evaporated from the sample in the drying process.

CALCULATIONS

14. PERCENTAGE OF HYGROSCOPIC MOISTURE

14.1. The hygroscopic moisture shall be expressed as a percentage of the mass of the oven-dried soil and shall be determined as follows:

$$\text{Percentage of hygroscopic moisture} = \frac{W - W_1}{W_1} \times 100 \quad (1)$$

where:

W = mass of air-dried soil, and

W_1 = mass of oven-dried soil.

To correct the mass of the air-dried sample for hygroscopic moisture, the given value shall be multiplied by the expression:

$$\frac{100}{100 + \text{percentage of hygroscopic moisture}} \quad (2)$$

14.2. Calculate the percentage of moisture to the nearest 0.001 as described in Section 14.1.

15. COARSE MATERIAL

15.1. The percentage of coarse material shall be calculated from the masses of the fractions recorded during the sieving of the material retained on the 2.00-mm sieve, in accordance with Section 7.3, and the total mass recorded in Section 6.1. The calculations shall be made as follows:

15.1.1. From the mass of the air-dried sample, obtained in Section 6.1, subtract the mass of the fraction retained on the 2.00-mm sieve. The difference is assumed to equal the mass of the air-dried fraction passing the 2.00-mm sieve (Note 5).

15.1.2. Correct the mass of the fraction passing the 2.00-mm sieve for hygroscopic moisture, determined in Section 14.1.

15.1.3. To the corrected mass obtained in Section 15.1.2, add the mass of the fraction retained on the 2.00-mm sieve to obtain the mass of the total test sample corrected for hygroscopic moisture.

15.1.4. The fractions retained on the 2.00-mm and coarser sieves shall be expressed as percentages of the corrected mass obtained in Section 15.1.3.

Note 8—According to this assumption, no hygroscopic moisture is contained in the air-dried particles retained on the 2.00-mm sieve when as a matter of fact a small percentage of moisture may be present in this fraction. This amount of moisture, compared with that held in the pores of the fraction passing the 2.00-mm sieve, is relatively small. Therefore, any error produced by the assumption as stated may be considered negligible in amount.

Note 9—Somewhat different computations are required when the test sample is processed in accordance with Section 6.2.1 (Alternate Method Using 4.75-mm and 2.00-mm sieves). In Section 15.1, substitute the 4.75-mm sieve for the 2.00-mm sieve. The percentage passing the 2.00-mm sieve shall be calculated as follows: (1) correct the mass of the test fractions passing the 4.75-mm and 2.00-mm sieves for hygroscopic moisture; (2) divide the dry mass of the fraction passing the 2.00-mm sieve by the dry mass of the subsample passing the 4.75-mm sieve, and multiply this value by 100, giving the percent passing the 2.00-mm sieve in the selected subsample (Section 6.2.1); and (3) multiply this percentage by the percentage of the total sample passing the 4.75-mm sieve, to give the percentage passing the 2.00-mm sieve in the total sample.

16. PERCENTAGE OF SOIL IN SUSPENSION

16.1. Hydrometer readings shall be corrected by applying the approximate composite correction as determined by Section 8 to account for the dispersing agent used, temperature of the suspension, and height of the meniscus on the stem of the hydrometer.

16.2. The percentage of the dispersed soil in suspension represented by different corrected hydrometer readings depends upon both the amount and the specific gravity of the soil dispersed. The percentage of dispersed soil remaining in suspension shall be calculated as follows:

For hydrometer 152 H

$$P = \frac{Ra}{w} \times 100 \qquad (3)$$

For hydrometer 151 H

$$P = \frac{1606\left(R - 1\right) a}{w} \times 100 \qquad (4)$$

where:

P = percentage of originally dispersed soil remaining in suspension,

R = corrected hydrometer reading,

w = mass in grams of soil originally dispersed minus the hygroscopic moisture, and

a = constant depending on the density of the suspension.

For an assumed value of G for the specific gravity of the soil, and a water density of 1.000 at 20.0ºC (68ºF), the value of "a" may be obtained by the formula:

$$a = \frac{2.6500 - 1.000}{2.6500} \times \frac{G}{G - 1.000}$$

The values of "a," given to two decimal places, are shown in Table 1.

Table 1—Values of *a*, for Different Specific Gravities

Specific Gravity, *G*	Constant, *a*
2.95	0.94
2.85	0.96
2.75	0.98
2.65	1.00
2.55	1.02
2.45	1.05
2.35	1.08

16.2.1. It is sufficiently accurate for ordinary tests to select the constant for the specific gravity nearest to that of the particular soil tested.

16.3. To convert the percentages of soil in suspension to percentages of the total test sample including the fraction retained on the 2.00-mm (No. 10) sieve, the percentage of originally dispersed soil remaining in suspension shall be multiplied by the expression:

$$\frac{100 - \text{the percentage retained on 2.00-mm sieve}}{100} \qquad (5)$$

17. DIAMETER OF SOIL PARTICLES IN SUSPENSION

17.1. The maximum diameter, *d*, of the particles in suspension, corresponding to the percentage indicated by a given hydrometer reading, shall be calculated by the use of Stokes' law.

According to Stokes' law:

$$d = \sqrt{\frac{30\, nL}{980\left(G - G_1\right) T}} \qquad (6)$$

where:

d = maximum grain diameter in millimeters;

n = coefficient of viscosity of the suspending medium (in this case water) in Pa·s. Varies with changes in temperature of the suspending medium;

L = distance from the surface of the suspension to the level at which the density of the suspension is being measured, mm. (For a given hydrometer and sedimentation cylinder, values vary according to the hydrometer readings. This distance is known as effective depth (see Table 2).);

T = interval of time from beginning of sedimentation to the taking of the reading, min;

G = specific gravity of soil particles; and

G_1 = specific gravity of the suspending medium (approximately 1.0 for water).

Note 10—As Stokes' law considers the terminal velocity of a single sphere falling in an infinity of liquid, the sizes calculated represent the diameter of spheres that would fall at the same rate as the soil particles.

Table 2—Values of Effective Depth Based on Hydrometer and Sedimentation Cylinder of Specified Sizes[a]

Hydrometer 151 H		Hydrometer 152 H			
Actual Hydrometer Reading	Effective Depth, *L*, mm	Actual Hydrometer Reading	Effective Depth, *L*, mm	Actual Hydrometer Reading	Effective Depth, *L*, mm

1.032	78				
1.033	76				
1.034	73				
1.035	70				
1.036	68				
1.037	65				
1.038	62				

[a] Values of effective depth are calculated from the equation:

$$L = L_1 + {}^{1}\!/_{2}[L_2 - (V_B/A)] \quad (7)$$

where:

L = effective depth, mm;

L_1 = distance along the stem of the hydrometer from the top of the bulb to the mark for a hydrometer reading, mm;

L_2 = overall length of hydrometer bulb, mm;

V_B = volume of hydrometer bulb, mm^3; and

A = cross-sectional area of sedimentation cylinder, mm^2.

For both hydrometers, 151 H and 152 H:

L_2 = 140 mm

V_B = 67000 mm^3

A = 2780 mm^2

For hydrometer 151 H:

L_1 = 105 mm for a reading of 1.000

L_2 = 23 mm for a reading of 1.031

For hydrometer 152 H:

L_1 = 105 mm for a reading of 0 g/L

L_2 = 23 mm for a reading of 50 g/L

17.2. For convenience in calculations the above equation may be written as follows:

$$D = K\sqrt{\frac{L}{T}} \tag{8}$$

where:

K = constant depending on the temperature of the suspension and the specific gravity of the soil particles. Values of K for a range of temperatures and specific gravities are given in Table 3. The value of K may not change for a series of readings constituting a test, while values of L and T do vary.

Table 3—Values of *K* for Use in Equation for Computing Diameter of Particle in Hydrometer Analysis

18. FINE SIEVE ANALYSIS

18.1. The percentage of the dispersed soil sample retained on each of the sieves in the sieve analysis of the material washed on the 0.075-mm (No. 200) sieve shall be obtained by dividing the mass of fraction retained on each sieve by the oven-dry mass of the dispersed soil and multiplying by 100.

18.2. The percentages of the total test sample, including the fraction retained on the 2.00-mm (No. 10) sieve, shall be obtained by multiplying these values by the expression:

$$\frac{100 - \text{the percentage retained on 2.00-mm sieve}}{100}$$

19. PLOTTING

19.1. The accumulated percentages of grains of different diameters shall be plotted on semilogarithmic paper to obtain a "grain size accumulation curve," such as that shown in Figure 6.

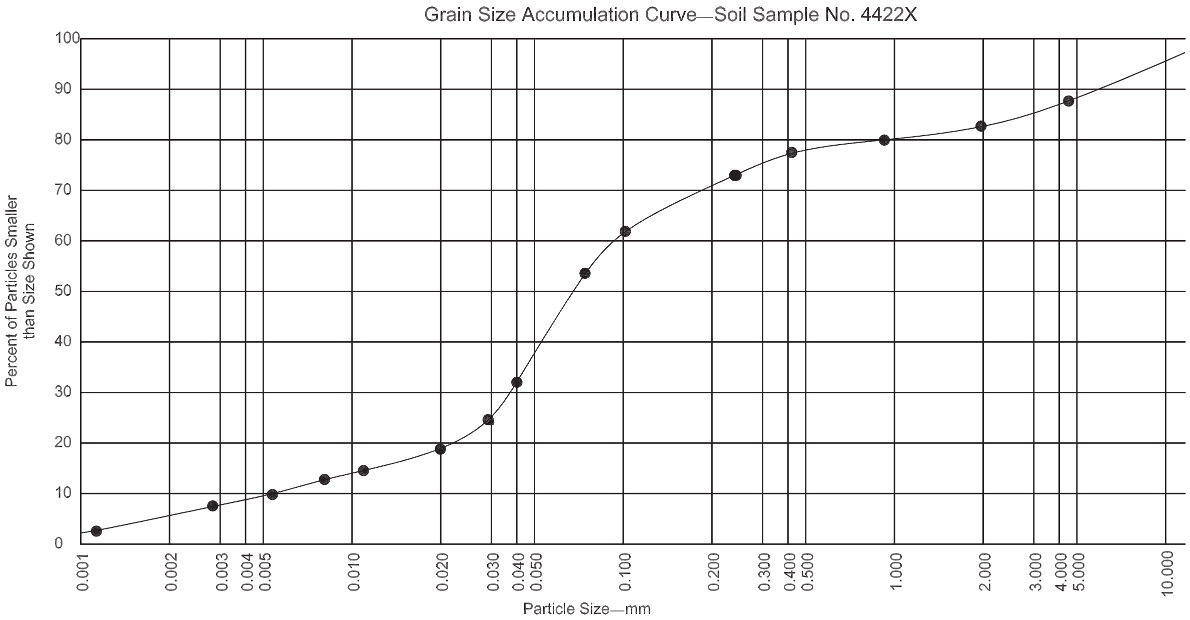

Figure 6—Grain Diameter Accumulation Curve for Soil Sample No. 4422X

20. REPORT

20.1. The results, read from the accumulation curve, shall be reported as follows:

20.1.1. Particles larger than 2-mm percent;

20.1.2. Coarse sand, 2.0 to 0.42-mm percent;

20.1.3. Fine sand, 0.42 to 0.074-mm percent;

20.1.4. Silt, 0.074 to 0.002-mm percent;

20.1.5. Clay, smaller than 0.002-mm percent; and

20.1.6. Colloids, smaller than 0.001-mm percent.

20.2. The results of complete mechanical analyses furnished by the combined sieve and hydrometer analysis shall be reported as follows:

Sieve Analysis		
Sieve Size		
Standard, mm	Alternate	Percent Passing
75	3 in.	
50	2 in.	
25	1 in.	
4.75	No. 4	
2.00	No. 10	
0.425	No. 40	
0.075	No. 200	

Hydrometer Analysis	
Smaller Than:	Percent
.02 mm	
.002 mm	
.001 mm	

For materials examined for any particular type of work or purpose, only such fractions shall be reported as are included in the specifications or other requirements for the work or purpose.

20.3. Report the Sieve Analysis to the nearest 0.1 percent passing.

20.4. Report the Hydrometer Analysis to the nearest 0.1 percent smaller than.

21. PRECISION

21.1. Criteria for judging the acceptability of the particle size analysis of soils is as follows:

Note 11—Colloids (smaller than 0.001 mm) are not normally required. However, if it is desired to obtain this size, it will then be necessary to extend the reading time to a minimum of 2880 minutes.

Note 12—The figures in Column 2 are the standard deviations that have been found to be appropriate for the tests described in Column 1. The figures in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests.

Table 4—Single-Operator Precision

Single-Operator Precision:

Test Performed	Standard Deviation[a]	Acceptable Range of Two Results[a]
Hygroscopic Moisture in Percent Moisture:		
4.75 mm (No. 4)	0.15	0.4
2.00 mm (No. 10)	0.21	0.6
Sieve Analysis in Percent Passing:		
2.00 mm (No. 10)	0.66	1.9
0.425 mm (No. 40)	1.07	3.0
0.075 mm (No. 200)	1.19	3.4
Hydrometer Analysis in Percent Smaller Than:		
0.02 mm	1.98	5.6
0.002 mm	1.34	3.8
0.001 mm	1.45	4.1

Multilaboratory Precision:

Test Performed	Standard Deviation[a]	Acceptable Range of Two Results[a]
Hygroscopic Moisture in Percent Moisture:		
4.75 mm (No. 4)	0.89	2.5
2.00 mm (No. 10)	0.88	2.4
Sieve Analysis in Percent Passing:		
2.00 mm (No. 10)	1.39	3.9
0.425 mm (No. 40)	1.98	5.6
0.075 mm (No. 200)	2.31	.5
Hydrometer Analysis in Percent Smaller Than:		
0.02 mm	4.32	12.2
0.002 mm	3.19	9.0
0.001 mm	3.16	8.9

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670 for Preparing Precision Statements for Test Methods for Construction Materials.

Standard Method of Test for

Determining the Liquid Limit of Soils

AASHTO Designation: T 89-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Liquid Limit of Soils

AASHTO Designation: T 89-10

1. SCOPE

1.1. The liquid limit of a soil is that water content, as determined in accordance with the following procedure, at which the soil passes from a plastic to a liquid state.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 87, Dry Preparation of Disturbed Soil and Soil–Aggregate Samples for Test
- T 146, Wet Preparation of Disturbed Soil Samples for Test
- T 265, Laboratory Determination of Moisture Content of Soils

2.2. *ASTM Standard*:

- D 4318, Standard Test Methods for Liquid Limit, Plastic Limit, and Plasticity Index of Soils
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. APPARATUS

3.1. *Dish*—A porcelain dish, preferably unglazed, or similar mixing dish, about 115 mm in diameter.

3.2. *Spatula*—A spatula or pill knife having a blade about 75 mm to 100 mm in length and about 20 mm in width.

3.3. *Liquid Limit Device*:

3.3.1. *Manually Operated*—A device consisting of a brass dish and carriage, constructed according to the plan and dimensions shown in Figure 1 (See Note 1.).

	Liquid Limit Device							Grooving Tool				
	Cup Assembly				Base			Curved End			Gauge	
Dimension	A	B	C	N	K	L	M	a	b	c	d	*e
Description	Radius of Cup	Thickness of Cup	Depth of Cup	Cup at Cam Follower to Base	Thickness	Length	Width	Thickness	Cutting Edge	Width	Depth	Length
Metric, mm	54	2.0	27	47	50	150	125	10.0	2.0	13.5	10.0	15.9
Tolerance, mm	2	0.1	1	1.5	5	5	5	0.1	0.1	0.1	0.2	—

Note: Plate "H" may be designed for using one (1) securing screw (I).
An additional wear tolerance of 0.1 mm shall be allowed for dimension "b" for used grooving tools.
Feet for base shall be of resilient material.
(*) Nominal dimensions.
All tolerances specified are plus or minus (±) except as noted above.

Figure 1—Manual Liquid Limit Device

3.3.2. *Mechanically Operated*—A motorized device equipped to produce the rise and rate of shocks to a brass cup as described in Sections 5.2 and 6.3 of this procedure, respectively. The cup and the critical dimensions of the device shall conform to those shown in Figure 1 of this procedure. The device shall give the same liquid limit values as obtained with the manually operated device (Note 1).

Note 1—The base of the liquid limit device should have a resilience of at least 80 percent and not more than 90 percent when determined in accordance with the procedure given in the Appendix.

3.4. *Grooving Tool*:

3.4.1. *Curved Grooving Tool*—A grooving tool conforming to the critical dimensions shown in Figure 1. The gauge need not be part of the tool.

3.4.2. *Flat Grooving Tool (Alternate)*—A grooving tool made of plastic or noncorroding metal conforming to the critical dimensions shown in ASTM D 4318, Figure 2. The gauge need not be part of the tool (Note 2).

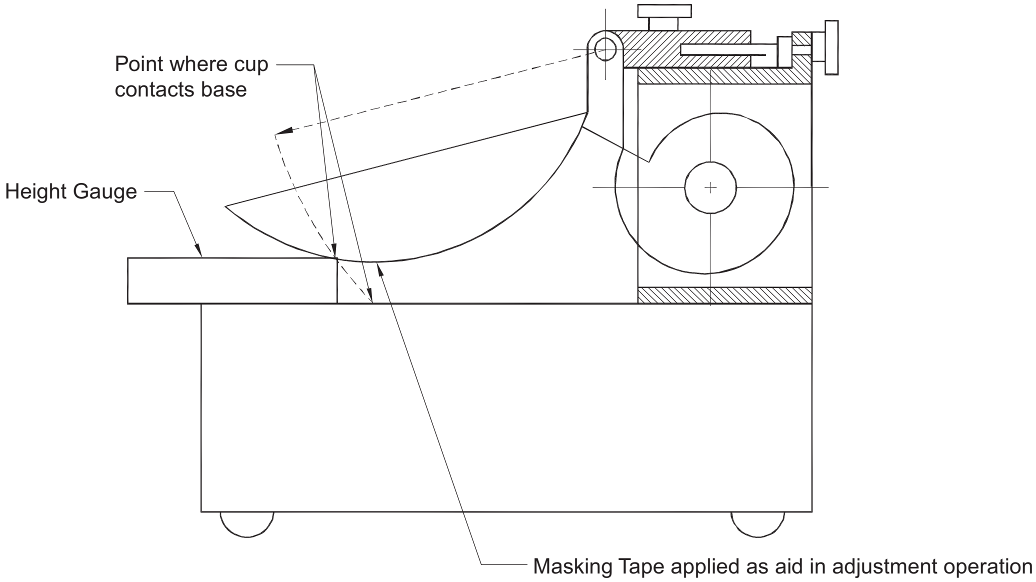

Figure 2—Calibration for Height of Drop

Note 2—The flat grooving tool should not be used interchangeably with the curved grooving tool. There are some data that indicate that the liquid limit is slightly increased when the flat tool is used instead of the curved tool.

3.5. *Gauge*—A gauge, whether attached to the grooving tool or separate, conforming to the critical dimension "d" shown in Figure 1 of this method or "K" in Figure 2 of ASTM D 4318, and may be, if separate, a metal bar 10.0 ± 0.2 mm thick and approximately 50 mm long.

3.6. *Containers*—Suitable containers made of material resistant to corrosion and not subject to change in mass or disintegration on repeated heating and cooling. Containers shall have close-fitting lids to prevent loss of moisture from samples before initial mass determination and to prevent absorption of moisture from the atmosphere following drying and before final mass determination. One container is needed for each moisture content determination.

3.7. *Balance*—The balance shall have sufficient capacity and conform to M 231, Class G 1.

3.8. *Oven*—A thermostatically controlled drying oven capable of maintaining temperatures of 110 ± 5ºC for drying moisture samples.

METHOD A

4. SAMPLE

4.1. A sample with a mass of about 100 g shall be taken from the thoroughly mixed portion of the material passing the 0.425-mm sieve that has been obtained in accordance with T 87 or T 146; for structural analysis use T 146, Method B.

5. ADJUSTMENT OF LIQUID LIMIT DEVICE

5.1. The Liquid Limit Device shall be inspected to determine that the device is in good working order; that the pin connecting the cup is not worn sufficiently to permit side play; that the screws connecting the cup to the hanger arm are tight; that the points of contact on the cup and base are not excessively worn; that the lip of the cup is not excessively worn; and that a groove has not been worn in the cup through long usage. The grooving tool shall be inspected to determine that the critical dimensions are as shown in Figure 1 of this method or ASTM D 4318, Figure 2.

Note 3—Wear is considered excessive when the point of contact on the cup or base exceeds approximately 13 mm in diameter, or when any point on the rim of the cup is worn to approximately $^1/_2$ the original thickness. Although a slight groove in the center of the cup is noticeable, it is not objectionable. If the groove becomes pronounced before other signs of wear appear, the cup should be considered excessively worn. Excessively worn cups shall be replaced. A base that is excessively worn may be refinished as long as the thickness does not exceed the tolerance shown in Figure 1 by more than –2.5 mm and the distance between the cup at the cam follower and the base is maintained within the tolerances specified in Figure 1.

5.2. Adjust the height of drop of the cup so that the point on the cup that comes in contact with the base rises to a height of 10.0 ± 0.2 mm. See Figure 2 for proper location of the gauge relative to the cup during adjustment.

Note 4—A convenient procedure for adjusting the height of drop is as follows: place a piece of masking tape across the outside bottom of the cup parallel with the axis of the cup hanger pivot. The edge of the tape away from the cup hanger should bisect the spot on the cup that contacts the base. For new cups, placing a piece of carbon paper on the base and allowing the cup to drop several times will mark the contact spot. Attach the cup to the device and turn the crank until the cup is raised to its maximum height. Slide the height gauge under the cup from the front, and observe whether the gauge contacts the cup or the tape. See Figure 2. If the tape and cup are both contacted, the height of drop is approximately correct. If not, adjust the cup until simultaneous contact is made. Check adjustment by turning the crank at two revolutions per second while holding the gauge in position against the tape and cup. If a ringing or clicking sound is heard without the cup rising from the gauge, the adjustment is correct. If no ringing is heard or if the cup rises from the gauge, readjust the height of drop. If the cup rocks on the gauge during this checking operation, the cam follower pivot is excessively worn and the worn parts should be replaced. Always remove tape after completion of adjustment operation.

6. PROCEDURE USING THE CURVED GROOVING TOOL

6.1. The soil sample shall be placed in the mixing dish and thoroughly mixed with 15 to 20 mL of distilled or demineralized water by alternately and repeatedly stirring, kneading, and chopping with a spatula. Further additions of water shall be made in increments of 1 to 3 mL. Each increment of water shall be thoroughly mixed with the soil as previously described before another increment of water is added. Once testing has begun, no additional dry soil should be added to the moistened soil. The cup of the Liquid Limit Device shall not be used for mixing soil and water. If too much moisture has been added to the sample, the sample shall either be discarded, or mixed and kneaded until natural evaporation lowers the closure point into an acceptable range.

Note 5—Some soils are slow to absorb water; therefore, it is possible to add the increments of water so fast that a false liquid limit value is obtained. This can be avoided if more mixing and/or time is allowed. Tap water may be used for routine testing if comparative tests indicate no differences in results between using tap water and distilled or demineralized water. However, referee or disputed tests shall be performed using distilled or demineralized water.

6.2. When sufficient water has been thoroughly mixed with the soil to form a uniform mass of stiff consistency, a sufficient quantity of this mixture shall be placed in the cup above the spot where the cup rests on the base and shall be squeezed and spread with the spatula to level and at the same time trimmed to a depth of 10 mm at the point of maximum thickness. As few strokes of the spatula as possible shall be used, care being taken to prevent the entrapment of air bubbles within the mass. The excess soil shall be returned to the mixing dish and covered to retain the moisture in the sample. The soil in the cup of the device shall be divided by a firm stroke of the grooving tool along the diameter through the centerline of the cam follower so that a clean sharp groove of the proper dimensions will be formed as shown in Figure 3. To avoid tearing of the sides of the groove or slipping of the soil cake on the cup, up to six strokes from front to back or from back to front counting as one stroke, shall be permitted. The depth of the groove should be increased with each stroke and only the last stroke should scrape the bottom of the cup.

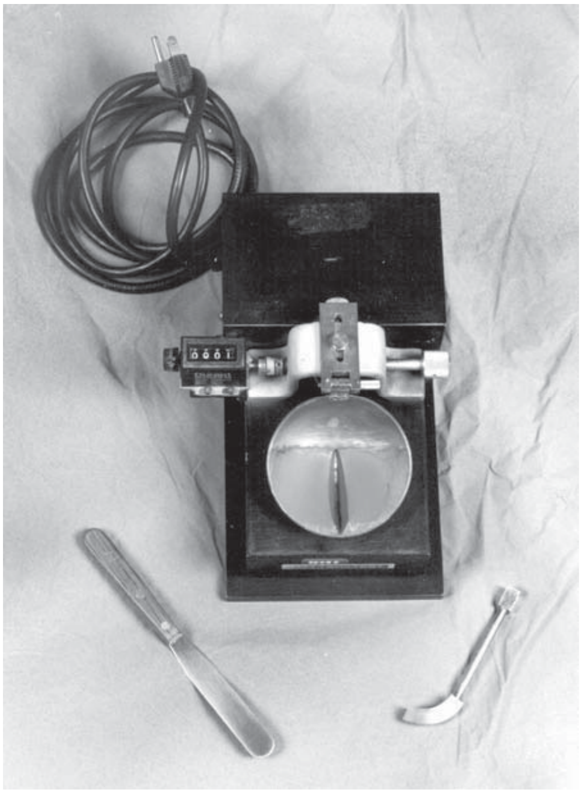

Figure 3—Liquid Limit Device with Soil Sample in Place

6.3. The cup containing the sample prepared as described in Section 6.2 shall be lifted and dropped by turning the crank F at the rate of approximately two revolutions per second until the two sides of the sample come in contact at the bottom of the groove along a distance of about 13 mm. The number of shocks required to close the groove this distance shall be recorded. The base of the machine shall not be held with the free hand while the crank F is turned.

Note 6—Some soils tend to slide on the surface of the cup instead of flowing. If this occurs, more water should be added to the sample and remixed, then the soil–water mixture placed in the cup, a groove cut with the grooving tool and Section 6.2 repeated. If the soil continues to slide on the cup at a lesser number of blows than 25, the test is not applicable and a note should be made that the liquid limit could not be determined.

6.4. A slice of soil approximately the width of the spatula, extending from edge to edge of the soil cake at right angles to the groove and including that portion of the groove in which the soil flowed together, shall be removed and placed in a suitable container. The soil in the container shall be dried in accordance with T 265 to determine the moisture content, and the results recorded.

6.5. The soil remaining in the cup shall be transferred to the mixing dish. The cup and grooving tool shall then be washed and dried in preparation for the next trial.

6.6. Repeat the foregoing operations, adding sufficient water to bring the soil to a more fluid condition. Obtain the first sample in the range of 25 to 35 shocks, the second sample in the range of 20 to 30 shocks, and the third sample in the range of 15 to 25 shocks. The range of the three determinations shall be at least 10 shocks.

7. ALTERNATE PROCEDURE USING THE FLAT GROOVING TOOL

7.1. The procedure shall be the same as prescribed in Sections 6.1 through 6.6, except for the procedure in Section 6.2 for forming the groove. Form a groove in the soil pat in accordance with Section 11.2 of ASTM D 4318.

8. CALCULATION

8.1. The water content of the soil shall be expressed as the moisture content in percentage of the mass of the oven-dried soil and shall be calculated as follows:

$$\text{Percentage moisture} = \frac{\text{mass of water}}{\text{mass of oven-dried soil}} \times 100 \qquad (1)$$

8.1.1. Calculate the percentage of moisture to the nearest whole percent.

9. PREPARATION OF FLOW CURVE

9.1. A “flow curve” representing the relation between moisture content and corresponding number of shocks shall be plotted on a semi-logarithmic graph with the moisture contents as abscissae on the arithmetical scale, and the number of shocks as ordinates on the logarithmic scale. The flow curve shall be a straight line drawn as nearly as possible through the three or more plotted points.

10. LIQUID LIMIT

10.1. The moisture content corresponding to the intersection of the flow curve with the 25 shock ordinate shall be taken as the liquid limit of the soil. Report this value to the nearest whole number.

METHOD B

11. SAMPLE

11.1. A sample with a mass of about 50 g shall be taken as described in Section 4.1.

12. PROCEDURE

12.1. Using the curved grooving tool (Section 6) or the flat grooving tool (Section 7) the procedure shall be the same as prescribed in Sections 6.1 through 6.5 except that the initial amount of water to be added in accordance with Section 6.1 shall be approximately 8 to 10 mL and the moisture sample taken in accordance with Section 6.4 shall be taken only for the accepted trial.

12.2. For accuracy equal to that obtained by the standard three-point method, the accepted number of blows for groove closure shall be restricted to between 22 and 28 blows. After obtaining a preliminary closure in the acceptable blow range, immediately return the soil remaining in the cup to the mixing dish and, without adding any additional water, repeat as directed in Sections 6.2 and 6.3. If the second closure occurs in the acceptable range (22 to 28, inclusive) and the second closure is within two (2) blows of the first closure, secure a water content specimen as directed in Section 6.4.

12.3. Groove closures between 15 and 40 blows may be accepted if variations of ±5 percent of the true liquid limit are tolerable.

13. CALCULATION

13.1. The water content of the soil at the time of the accepted closure shall be calculated in accordance with Section 8.1.

14. LIQUID LIMIT

14.1. The liquid limit shall be determined by one of the following methods: the nomograph, Figure 4; the correction factor method, Table 1; or by any other method of calculation that produces equally accurate liquid limit values. The standard three-point method shall be used as a referee test to settle all controversies.

14.2. The key in Figure 4 illustrates the use of the nomograph (mean slope).

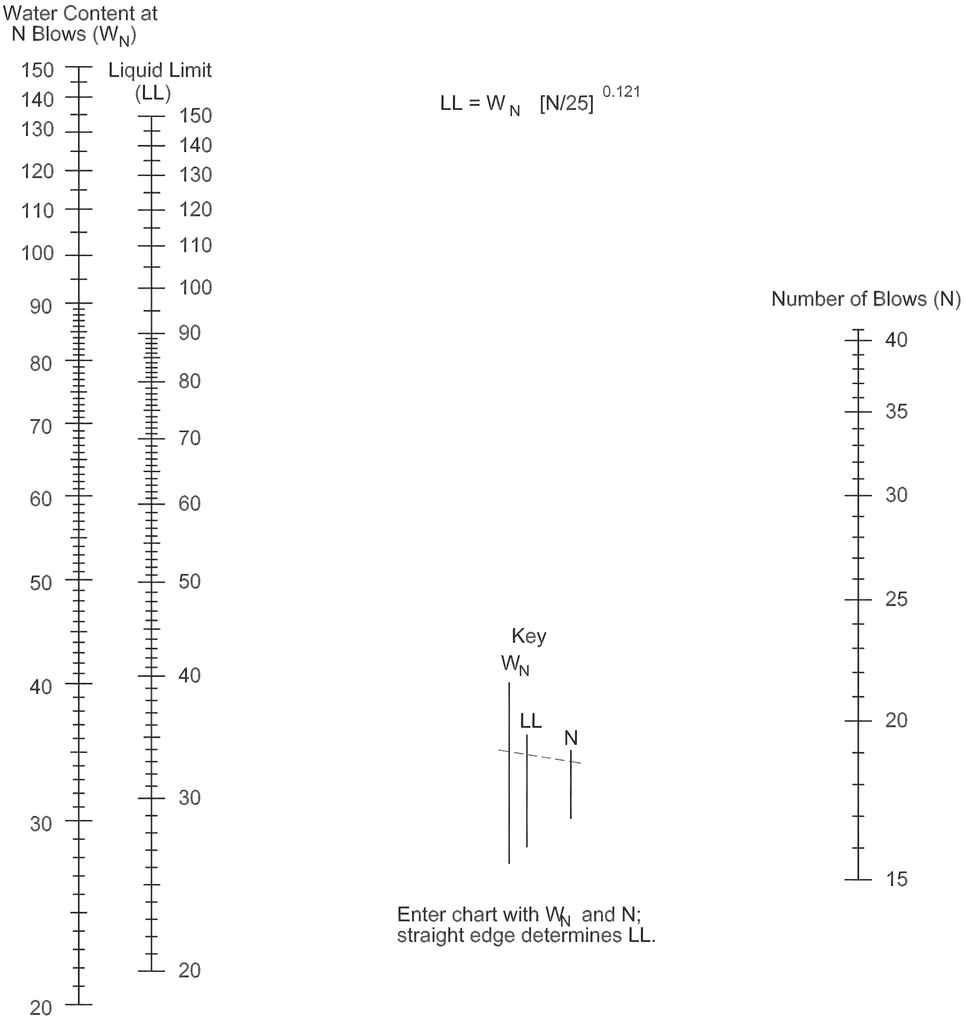

Figure 4—Nomographic Chart Developed by the Waterways Experiment Station, Corps of Engineers, U.S. Army, to Determine Liquid Limit Using Mean Slope Method

14.3. The correction factor method, Table 1, uses the moisture content of the liquid limit sample multiplied by a factor (k) of the second closure blow count. Figure 5 was developed for the Calculation of the Liquid Limit.

$$LL = W_N(N/25)^{0.121} \tag{2}$$

or

$$LL = kW_N \tag{3}$$

where:

N = number of blows causing closure of the groove at water content,

LL = Liquid limit corrected for closure at 25 blows,

W_N = water content, and

k = factor given in Table 1.

Table 1—Factors for Obtaining Liquid Limit from Water Content and Number of Blows Causing Closure of the Groove

Number of Blows, *N*	Factor for Liquid Limit, *k*
22	0.985
23	0.990
24	0.995
25	1.000
26	1.005
27	1.009
28	1.014

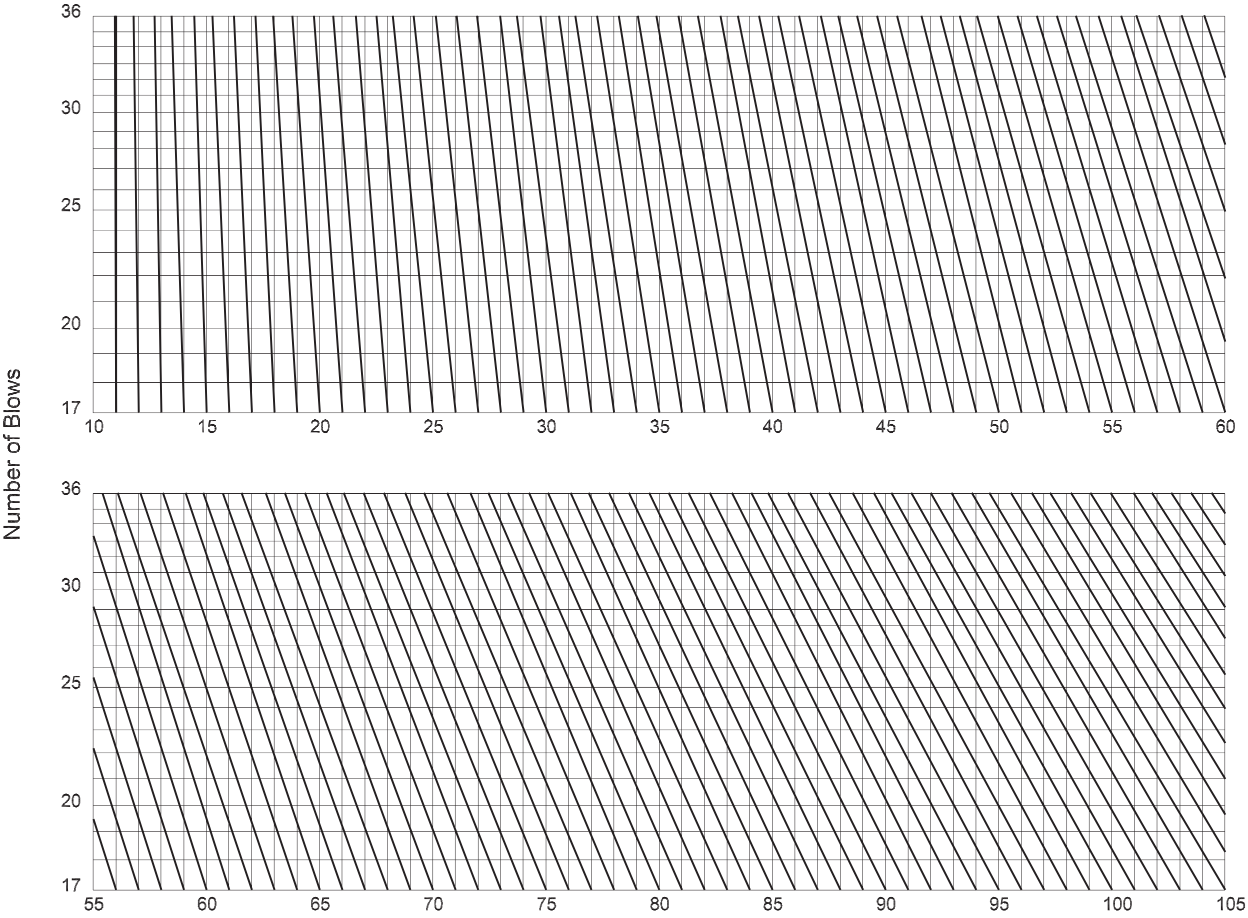

Figure 5—Chart Developed by Washington State Highway Department for the Calculation of the Liquid Limit

CHECK OR REFEREE TESTS

15. METHOD TO BE USED

15.1. Method A, using the curved grooving tool procedure (Section 6), shall be used in making check or referee tests. The results of liquid limit tests are influenced by:

15.1.1. The time required to make the test;

15.1.2. The moisture content at which the test is begun; and

15.1.3. The addition of dry soil to the seasoned sample.

16. PROCEDURE

16.1. Therefore, in making the liquid limit test for check or referee purposes, the following time schedule shall be used:

16.1.1. *Mixing of soil with water*—5 to 10 minutes, the longer period being used for the more plastic soils;

16.1.2. *Seasoning in the humidifier*—30 minutes;

16.1.3. *Remixing before placing in the brass cup*—add 1 mL of water and mix for 1 minute;

16.1.4. *Placing in the brass cup and testing*—3 minutes; and

16.1.5. *Adding water and remixing*—3 minutes.

16.2. No trial requiring more than 35 blows or fewer than 15 blows shall be recorded. In no case shall dried soil be added to the seasoned soil being tested.

17. PRECISION STATEMENT

17.1. This precision statement applies to soils having a liquid limit range from 21 to 67.

17.2. *Repeatability (Single Operator)*—Two results obtained by the same operator on the same sample in the same laboratory using the same apparatus, and on different days, should be considered suspect if they differ by more than 7 percent of their mean.

17.3. *Reproducibility (Multilaboratory)*—Two results obtained by different operators in different laboratories should be considered suspect if they differ from each other by more than 13 percent of their mean.

APPENDIX—RESILIENCE TEST

(Nonmandatory Information)

X1. MEASURING THE RESILIENCE OF LIQUID LIMIT DEVICE BASES

X1.1. A device for measuring the resilience of liquid limit device bases is shown in Figure X1.1 and Table X1.1. The device consists of a clear acrylic plastic tube and cap, an 8-mm diameter polished steel ball, and a small bar magnet. The cylinder may be cemented to the cap or threaded as shown. The small bar magnet is held in the recess of the cap, and the steel ball is fixed into the recess in the underside of the cap with the bar magnet. The cylinder is then turned upright and placed on the top surface of the base to be tested. Hold the tube lightly against the liquid limit device base with one hand, and release the ball by pulling the magnet out of the cap. Use the scale markings on the outside of the cylinder to determine the highest point reached by the bottom of the ball. Repeat the drop at least three times, placing the tester in a different location for each drop. The average rebound of the steel ball, expressed as a percent of the total drop, equals the resilience of the liquid limit device base. Tests should be conducted at room temperature.

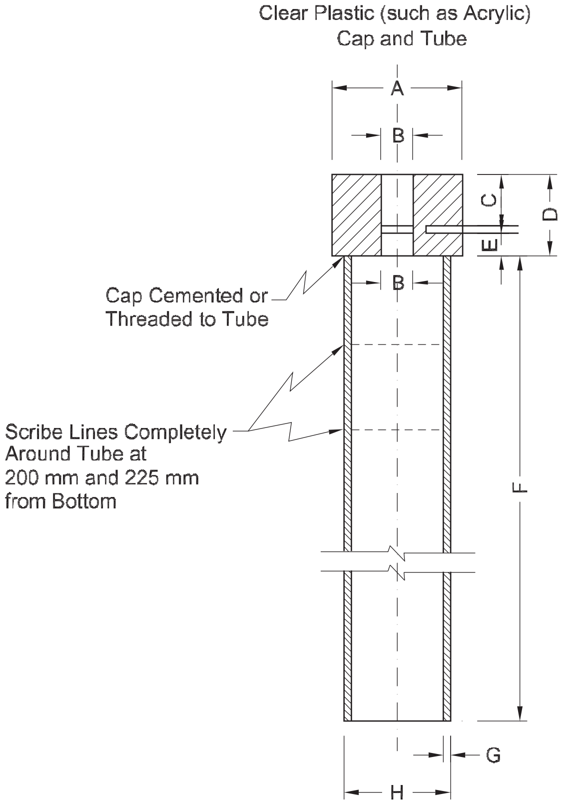

Figure X1.1—Resilience Tester

Table X1.1—Table of Measurements for Resilience Tester[a]

Dimension	Description	Metric, mm
A	Diam. of Cap	38.0[b]
B	Diam. of Hole	9.0[b]
C	Depth of Hole	18.0[b]
D	Height of Cap	25.5[b]
E	Depth of Hole	8.0
F	Length of Tube	250.0
G	Wall Thickness	3.2[b]
H	O.D. of Tube	31.8[b]
Scribed lines from bottom	Upper 90%	225.0
	Lower 80%	200.0

[a] Tube stands plumb.

[b] These dimensions are not critical in the performance of the test.

Standard Method of Test for

Determining the Plastic Limit and Plasticity Index of Soils

AASHTO Designation: T 90-00 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Plastic Limit and Plasticity Index of Soils

AASHTO Designation: T 90-00 (2008)

1. SCOPE

1.1. The plastic limit of a soil is the lowest water content determined in accordance with the following procedure at which the soil remains plastic. The plasticity index of a soil is the range in water content, expressed as a percentage of the mass of the oven-dried soil, within which the material is in a plastic state. It is the numerical difference between the liquid limit and plastic limit of the soil.

1.2. The following applies to all specified limits in this standard: For the purpose of determining conformance with these specifications, an observed value or a calculated value shall be rounded off “to the nearest unit” in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

1.3. The Hand Rolling Method shall be the referee procedure.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 87, Dry Preparation of Disturbed Soil and Soil–Aggregate Samples for Test
- T 89, Determining the Liquid Limit of Soils
- T 146, Wet Preparation of Disturbed Soil Samples for Test
- T 265, Laboratory Determination of Moisture Content of Soils

2.2. *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. APPARATUS

3.1. *Dish*—A porcelain evaporating dish or similar mixing dish about 115 mm in diameter.

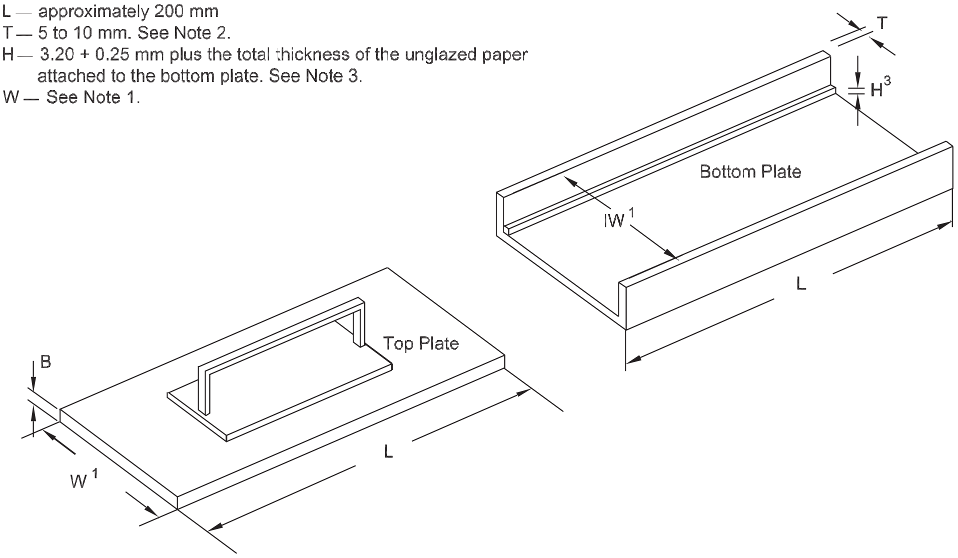
3.2. *Spatula*—A spatula or pill knife having a blade about 75 mm in length and about 20 mm in width.

3.3. *Surface for Rolling*—A ground glass plate or piece of smooth, unglazed paper on which to roll the sample.

3.4. *Plastic Limit Rolling Device*[1,2] (optional)—A device made of acrylic conforming to the dimensions shown in Figure 1.

Dimensions:

IW — approximately 100 mm
L — approximately 200 mm
T — 5 to 10 mm. See Note 2.
H — 3.20 + 0.25 mm plus the total thickness of the unglazed paper attached to the bottom plate. See Note 3.
W — See Note 1.



Notes:

1. The tolerance between the width of the top plate (W) and the inside width of the bottom plate (IW) shall be such that the top plate slides freely on the rails without wobbling.
2. The top plate shall be rigid enough so that the thickness of the soil threads is not influenced by flexure of the top plate.
3. The width of the side rails shall be between 3 and 6 mm.

Figure 1—Plastic Limit Rolling Device

3.5. *Paper for Rolling Device*—Unglazed paper that does not add foreign matter (fibers, paper fragments, etc.) to the soil during the rolling process. Such paper shall be attached to the top and bottom plates of the device either by a spray-on adhesive or by a self-adhesive backing.

Note 1—Take special care to remove the adhesive that remains on the plastic limit rolling device after testing. Repeated tests without such removal will result in a buildup of the residual adhesive and a decreased soil thread diameter.

3.6. *Containers*—Suitable containers made of material resistant to corrosion and not subject to change in mass or disintegration on repeated heating and cooling. Containers shall have close-fitting lids to prevent loss of moisture from samples before initial mass determination and to prevent absorption of moisture from the atmosphere following drying and before final mass determination. One container is needed for each moisture content determination.

3.7. *Balance*—The balance shall have sufficient capacity and conform to M 231, Class G 1.

3.8. *Oven*—A thermostatically controlled drying oven capable of maintaining temperatures of 110 ± 5ºC for drying samples.

4. SAMPLE

4.1. If the plastic limit only is required, take a quantity of soil with a mass of about 20 g from the thoroughly mixed portion of the material passing the 0.425-mm sieve, obtained in accordance with T 87 or T 146. Place the air-dried soil in a mixing dish and thoroughly mix with distilled or demineralized water until the mass becomes plastic enough to be easily shaped into a ball. Take a portion of this ball with a mass of about 8 g for the test sample.

Note 2—Tap water may be used for routine testing if comparative tests indicate no differences in results between using tap water and distilled or demineralized water. However, referee or disputed tests shall be performed using distilled or demineralized water.

4.2. If both the liquid and plastic limits are required, take a test sample with a mass of about 8 g from the thoroughly wet and mixed portion of the soil prepared in accordance with T 89. Take the sample at any stage of the mixing process at which the mass becomes plastic enough to be easily shaped into a ball without sticking to the fingers excessively when squeezed. If the sample is taken before completion of the liquid limit test, set it aside and allow to season in air until the liquid limit test has been completed. If the sample taken during the liquid limit test is too dry to permit rolling to a 3-mm thread, add more water and remix.

5. PROCEDURE

5.1. Select a 1.5- to 2.0-g portion from the mass of soil taken in accordance with Section 4. Form the selected portion into an ellipsoidal mass.

5.2. Use one of the following methods to roll the soil mass into a 3-mm diameter thread at a rate of 80 to 90 strokes per minute, counting a stroke as one complete motion of the hand forward and back to the starting position again.

5.2.1. *Hand Rolling Method*—Roll the mass between the palm or fingers and the ground-glass plate (or a piece of paper laying on a smooth horizontal surface) with just sufficient pressure to roll the mass into a thread of uniform diameter throughout its length. The thread shall be further deformed on each stroke so that its diameter reaches 3 mm, taking no more than 2 minutes. The amount of hand or finger pressure required will vary greatly, according to the soil. Fragile soils of low plasticity are best rolled under the outer edge of the palm or at the base of the thumb.

5.2.2. *Alternate Procedure, Plastic Limit Device Method*—Place the soil mass on the bottom plate. Place the top plate in contact with the soil mass. Simultaneously apply a slight downward force and back and forth motion to the top plate so the plate comes in contact with the side rails within 2 minutes. During this rolling process, do not allow the soil thread to contact the side rails.

Note 3—In most cases, more than one soil mass (thread) can be rolled simultaneously in the plastic limit rolling device.

5.3. When the diameter of the thread becomes 3 mm, break the thread into six or eight pieces. Squeeze the pieces together between the thumbs and fingers of both hands into a uniform mass roughly ellipsoidal in shape and then reroll. Continue this alternate rolling to a thread 3 mm in diameter, gathering together, kneading, and rerolling, until the thread crumbles under the pressure required for rolling and the soil can no longer be rolled into a thread. The crumbling may occur when the thread has a diameter greater than 3 mm. This shall be considered a satisfactory end point, provided the solid has been previously rolled into a thread 3 mm in diameter. The crumbling will manifest itself differently with various types of soil. Some soils fall apart in numerous small aggregations of particles; others may form an outside tubular layer that starts splitting at both ends. The splitting progresses toward the middle, and finally the thread falls apart in many small platy particles. Heavy clay soils require much pressure to deform the thread, particularly as they approach the plastic limit, and finally, the thread breaks into a series of barrel-shaped segments each about 6 to 9 mm in length. At no time shall the operator attempt to produce failure at exactly 3-mm diameter by allowing the thread to reach 3 mm, then reducing the rate of rolling or the hand pressure, or both, and continuing the rolling without further deformation until the thread falls apart. It is permissible, however, to reduce the total amount of deformation for feebly plastic soils by making the initial diameter of the ellipsoidal-shaped mass nearer to the required 3-mm final diameter.

5.4. Gather the portions of the crumbled soil together and place in a weighed container. Immediately cover the container.

5.5. Repeat the operations described in Sections 5.1 through 5.4 until the 8-g specimen is completely tested. Determine the moisture content of the soil in the containers in accordance with T 265, and record the results.

6. CALCULATIONS

6.1. Calculate the plastic limit, expressed as the water content in percentage of the mass of the oven-dry soil, as follows:

$$\text{Plastic Limit} = \frac{\text{mass of water}}{\text{mass of oven-dry soil}} \times 100 \qquad (1)$$

Report the plastic limit to the nearest whole number.

6.2. Calculate the plasticity index of a soil as the difference between its liquid limit and its plastic limit, as follows:

$$\text{Plasticity Index} = \text{liquid limit} - \text{plastic limit} \qquad (2)$$

6.3. Report the difference calculated as indicated in Section 6.2 as the plasticity index, except under the following conditions:

6.3.1. When the liquid limit or plastic limit cannot be determined, report the plasticity index as NP (non-plastic).

6.3.2. When the plastic limit is equal to, or greater than, the liquid limit, report the plasticity index as NP.

7. PRECISION STATEMENT

7.1. This precision statement applies to soils with a plastic limit range between 15 and 32, tested using the hand rolling method.

7.2. *Repeatability (Single Operator)*—Two results obtained by the same operator on the same sample in the same laboratory using the same apparatus should be considered suspect if they differ by more than 10 percent of their mean.

7.3. *Reproducibility (Multilaboratory)*—Two results obtained by different operators in different laboratories should be considered suspect if they differ from each other by more than 18 percent of their mean.

---

[1] The plastic limit-rolling device is covered by a patent (U.S. Patent No. 5,027,660). Interested parties are invited to submit information regarding the identification of an alternative(s) to this patent to AASHTO Headquarters. Your comments will receive careful consideration at a meeting of AASHTO Technical Section 1a on Soil Materials Tests.

Standard Method of Test for

Determining the Shrinkage Factors of Soils

AASHTO Designation: T 92-97 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Shrinkage Factors of Soils

AASHTO Designation: T 92-97 (2009)

1. SCOPE

1.1. This procedure furnishes data from which the following soil characteristics may be calculated: (a) shrinkage limit, (b) shrinkage ratio, (c) volumetric change, and (d) lineal shrinkage.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit'' in the last right-hand place of figures used in expressing the limited value, in accordance with E 29, Using Significant Digits in Test Data to Determine Conformance with Specifications.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. Refer to R 16 for regulatory information for chemicals.

1.5. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

DETERMINATION OF THE VOLUMETRIC SHRINKAGE

2. APPARATUS

2.1. The apparatus shall consist of the following:

2.1.1. *Dishes*:

2.1.1.1. A porcelain evaporating dish, or similar mixing dish, about 115-mm ($4^1/_2$-in.) in diameter.

2.1.1.2. A porcelain evaporating dish about 150 mm (6 in.) in diameter.

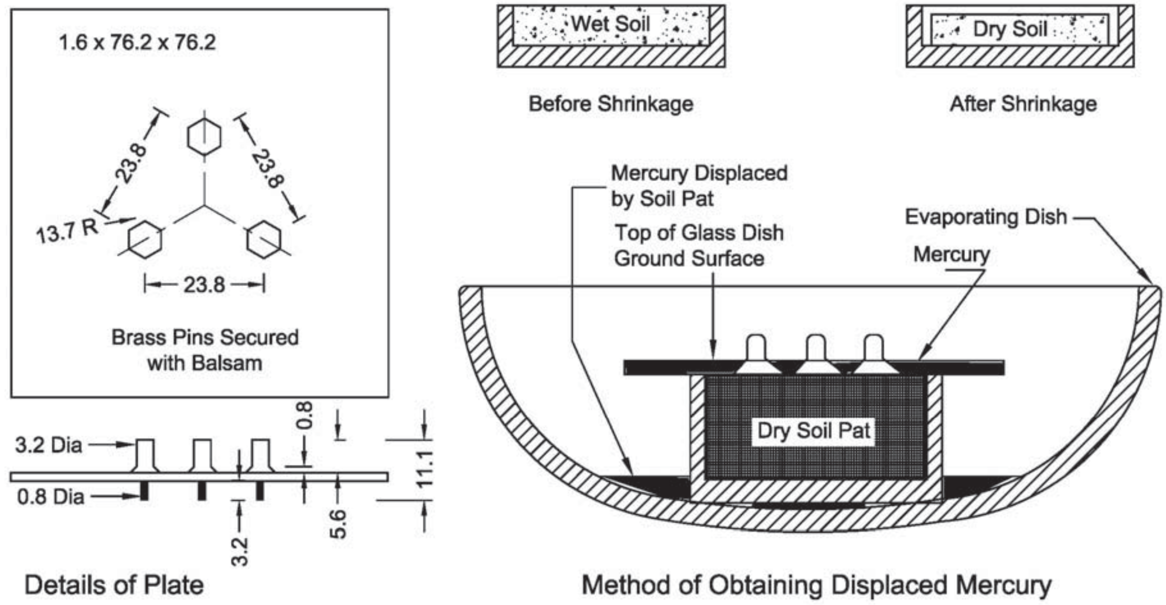
2.1.2. *Spatula*—A spatula or pill knife having a blade about 75 mm (3 in.) long and about 20 mm ($^3/_4$ in.) wide.

2.1.3. *Milk Dish*—A porcelain or Monel metal milk dish having a flat bottom and being about 45 mm ($1^3/_4$ in.) in diameter by about 12.7 mm ($^1/_2$ in.) high.

2.1.4. *Straightedge*—A steel straightedge 100 mm (4 in.) or more in length.

2.1.5. *Glass Cup*—A glass cup about 50 mm (2 in.) in diameter by 25 mm (1 in.) high, the top rim of which is ground smooth and parallel with its base.

2.1.6. *Transparent Plate*—A transparent plate with three metal prongs for immersing the soil pat in mercury as shown in Figure 1.



Dimensional Equivalents	
mm	in.
0.8	1/32
1.6	1/16
3.2	1/8
5.6	7/32
11.1	7/16
13.7	0.54
23.8	15/16
76.2	3

Note: All dimensions shown in millimeters unless otherwise noted.

Figure 1—Apparatus for Determining the Shrinkage Factors of Subgrade Soils

2.1.7. *Glass Graduate*—A glass graduate having a capacity of 25 mL and graduated to 0.2 mL.

2.1.8. *Balance*—The balance shall have sufficient capacity and conform to M 231, Class G 1.

2.1.9. *Mercury*—Sufficient mercury to fill the glass cup to overflowing.

2.1.10. *Oven*—A thermostatically controlled drying oven capable of maintaining temperatures of 110 ± 5ºC (230 ± 9ºF) for drying soil samples.

3. SAMPLE

3.1. A sample with a mass of about 30 g shall be taken from the thoroughly mixed portion of the material passing the 0.425-mm (No. 40) sieve prepared in accordance with the Standard Method of Dry Preparation of Disturbed Soil and Soil Aggregate Samples for Test (T 87), or the Standard Method of Wet Preparation of Disturbed Soil Samples for Test (T 146).

4. PROCEDURE

4.1. The sample shall be placed in the 115-mm ($4^1/_2$-in.) mixing dish and thoroughly mixed with water in amount sufficient to fill the soil voids completely and to make the soil pasty enough to be readily worked into the milk dish without inclusion of air bubbles. The amount of water required to produce the desired consistency in friable soils is equal to or slightly greater than the liquid limit, and the amount necessary to produce the desired consistency in plastic soils may exceed the liquid limit by as much as 10 percent.

4.2. The inside of the milk dish shall be coated with a thin layer of vaseline or some other heavy grease to prevent the adhesion of the soil to the dish. An amount of the wetted soil equal to about one-third of the volume of the milk dish shall be placed in the center of the dish, and the soil shall be caused to flow to the edges by tapping the dish on the firm surface cushioned by several layers of blotting paper or similar material. An amount of soil, approximately equal to the first portion, shall be added and the dish tapped until the soil is thoroughly compacted and all included air has been brought to the surface. More soil shall be added and the tapping continued until the dish is completely filled and excess soil stands out about its edge. The excess soil shall then be struck off with a straightedge and all soil adhering to the outside of the dish shall be wiped off.

4.3. The dish when filled, struck off, and wiped clean shall be weighed immediately and the mass recorded as the mass of dish and wet soil. The soil pat shall be allowed to dry at room temperature until the color of the pat turns from dark to light. It shall then be oven-dried to constant mass at 110 ± 5ºC (230 ± 9ºF) and the mass recorded as the mass of dish and dry soil. The mass of the empty dish shall be determined and recorded. The capacity of the dish in mL, which is also the volume of the wet soil pat, shall be determined by filling the dish to overflowing with mercury, removing the excess by pressing a glass plate firmly over the top of the dish, and measuring the volume of the mercury held in the dish in the glass graduate. The volume of the mercury shall be determined by the value at the top of the meniscus. Alternatively, determine the volume of the dish by weighing the mercury held in the dish to the nearest 0.1 g and calculate the volume in mL using the formula $V = M/D$, where M = mass of displaced mercury in grams and D = 13.5 g/mL (the density of mercury). This volume shall be recorded as the volume of the wet soil pat, V.

4.4. The volume of the dry soil pat shall be determined by removing the pat from the milk dish and immersing it in the glass cup full of mercury in the following manner:

4.4.1. The glass cup shall be filled to overflowing with mercury and the excess mercury shall be removed by pressing the glass plate with the three prongs (Figure 1) firmly over the top of the cup. Any mercury that may be adhering to the outside of the cup shall be carefully wiped off. The cup filled with mercury shall be placed in the 150-mm (6-in.) evaporating dish and the soil pat shall be placed on the surface of the mercury. The pat shall then be carefully forced under the mercury by means of the glass plate with the three prongs (Figure 1) and the plate shall be pressed firmly over the top of the cup. It is essential that no air be trapped under the soil pat. Determine the volume in mL of the dry soil pat, V_o, by measuring the mercury so displaced in the glass graduate or by determining the mass of the mercury to the nearest 0.1 g and calculating the volume in mL using the formula $V_o = M/D$, where, M = mass of mercury in grams and D = 13.5 g/mL (density of mercury).

5. CALCULATION OF WATER CONTENT

5.1. The water content of the soil at the time it was placed in the dish expressed as a percentage of the dry mass of the soil shall be calculated as follows:

$$w = \frac{W - W_o}{W_o} \times 100 \qquad (1)$$

where:

w = water content of the soil when placed in the dish,

W = mass of wet soil obtained by subtracting the mass of the shrinkage dish from the mass of the dish and wet pat, and

W_o = mass of dry soil pat obtained by subtracting the mass of the shrinkage dish from the mass of the dish and dry pat.

5.1.1. Calculate the water content to the nearest 0.1 percent.

6. CALCULATION OF THE SHRINKAGE LIMIT

6.1. *Definition*:

6.1.1. The shrinkage limit of a soil is defined as the maximum calculated water content, at which a reduction in water content will not cause a decrease in the volume of the soil mass.

6.2. *Calculation*:

6.2.1. The shrinkage limit, S, shall be calculated from the data obtained in the volumetric shrinkage determination by the following formula:

$$S = w - \frac{V - V_o}{W} \times 100 \qquad (2)$$

where:

S = shrinkage limit;

w = water content of wet soil, in percentage of the mass of oven-dried soil;

V = volume of wet soil pat;

V_o = volume of oven-dried soil pat; and

W = mass of oven-dried soil pat.

6.2.1.1. Calculate the shrinkage limit to the nearest 0.1 percent.

6.3. *Optional Method*:

6.3.1. When both the true specific gravity, G, and the shrinkage ratio, R, are known, the shrinkage limit may be calculated from the following formula:

$$S = \left(1/R - 1/G\right) \times 100 \qquad (3)$$

7. CALCULATION OF THE SHRINKAGE RATIO

7.1. *Definition*:

7.1.1. The shrinkage ratio of a soil is the ratio between a given volume change and the corresponding change in water content above the shrinkage limit.

7.2. *Calculation*:

7.2.1. The shrinkage ratio, *R,* shall be calculated from the data obtained in the volumetric shrinkage determination by the following formula:

$$R = \frac{W_o}{V_o} \qquad (4)$$

7.2.1.1. Calculate the shrinkage ratio to the nearest 0.1.

8. CALCULATION OF THE VOLUMETRIC CHANGE

8.1. *Definition*:

8.1.1. The volumetric change of a soil is the decrease in volume of the soil mass when the water content is reduced from a given percentage to the shrinkage limit.

8.2. *Calculation*:

8.2.1. The volumetric change, *VC,* shall be calculated from the data obtained from the volumetric shrinkage determination by the following formula:

$$VC = \left(w_1 - S\right)R \qquad (5)$$

where:

VC = the volumetric change, and

w_1 = a given water content.

8.2.1.1. Calculate the volumetric change to the nearest 0.1 percent.

9. CALCULATION OF THE LINEAL SHRINKAGE

9.1. *Definition*:

9.1.1. The lineal shrinkage of a soil is defined as the decrease in one dimension of the soil mass when the water content is reduced from a given percentage to the shrinkage limit.

9.1.2. The lineal shrinkage, *LS,* shall be obtained either by means of the formula:

$$LS = 100\left(1 - \sqrt[3]{\frac{100}{VC + 100}}\right) \qquad (6)$$

or by means of the curve in Figure 2, which represents this relation.

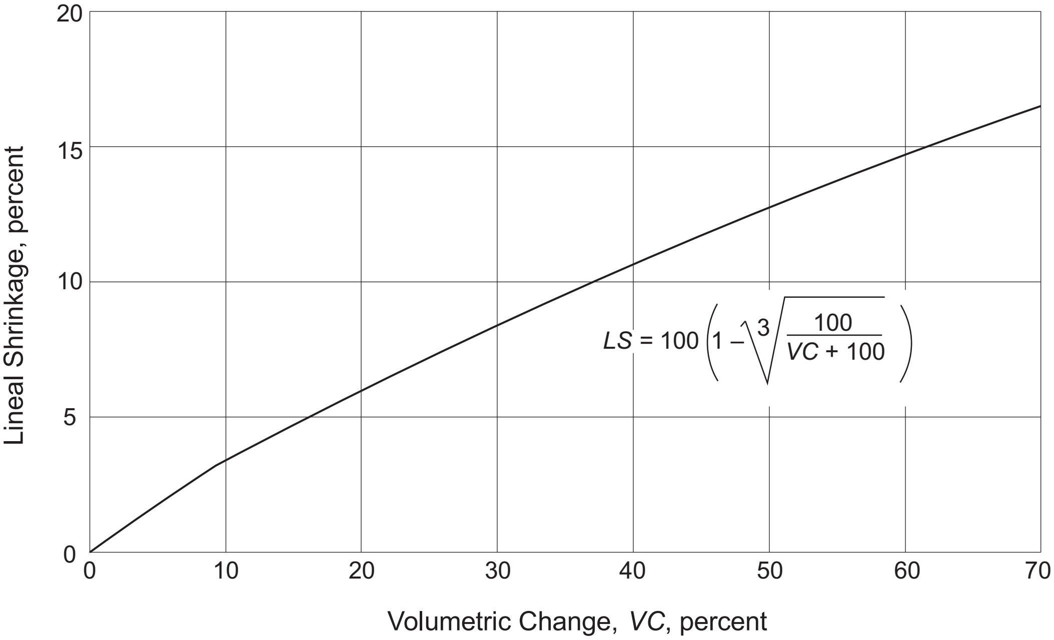


Figure 2—Relation between Volumetric Change and Lineal Shrinkage

9.1.2.1. Determine the lineal shrinkage to the nearest whole percent.

10. PRECISION

10.1. Criteria for judging the shrinkage factors of soils are as follows:

Note 1—The figures in Column 2 are the standard deviations that have been found to be appropriate for the tests described in Column 1. The figures in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests.

10.1.1. *Single-Operator Precision*:

Table 1—Single-Operator Precision

	Type of Test	Standard Deviation[a]	Acceptable Range of Two Results[a]
10.1.1.1	Water Content	no data	no data
10.1.1.2	Shrinkage Limit	0.91	2.6
10.1.1.3	Shrinkage Ratio	0.020	0.06
10.1.1.4	Volumetric Change	no data	no data
10.1.1.5	Lineal Shrinkage	no data	no data

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670 for Preparing Precision Statements for Test Methods for Construction Materials.

10.1.2. *Multilaboratory Precision*:

Table 2—Multilaboratory Precision

	Type of Test	Standard Deviation[a]	Acceptable Range of Two Results[a]
10.1.2.1	Water Content	no data	no data
10.1.2.2	Shrinkage Limit	2.42	6.8
10.1.2.3	Shrinkage Ratio	0.055	0.16
10.1.2.4	Volumetric Change	no data	no data
10.1.2.5	Lineal Shrinkage	no data	no data

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670 for Preparing Precision Statements for Test Methods for Construction Materials.

Standard Method of Test for

Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop

AASHTO Designation: T 99-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop

AASHTO Designation: T 99-10

1. SCOPE

1.1. These methods of test are intended for determining the relation between the moisture content and density of soils compacted in a mold of a given size with a 2.5-kg (5.5-lb) rammer dropped from a height of 305 mm (12 in.). Four alternate procedures are provided as follows:

- *Method A*—A 101.60-mm (4-in.) mold: Soil material passing a 4.75-mm (No. 4) sieve Sections 4 and 5.
- *Method B*—A 152.40-mm (6-in.) mold: Soil material passing a 4.75-mm (No. 4) sieve Sections 6 and 7.
- *Method C*—A 101.60-mm (4-in.) mold: Soil material passing a 19.0-mm ($^3/_4$-in.) sieve Sections 8 and 9.
- *Method D*—A 152.40-mm (6-in.) mold: Soil material passing a 19.0-mm ($^3/_4$-in.) sieve Sections 10 and 11.

1.2. The method to be used should be indicated in the specifications for the material being tested. If no method is specified, the provisions of Method A shall govern.

1.3. This test method applies to soil mixtures that have 40 percent or less retained on the 4.75 mm-(No. 4) sieve, when Method A or B is used and 30 percent or less retained on the 19.0-mm ($^3/_4$-in.) sieve, when Method C or D is used. The material retained on these sieves shall be defined as oversized particles (coarse particles).

1.4. If the test specimen contains oversize particles, and the test specimen is used for field density compaction control, corrections must be made according to T 224 to compare the total field density with the compacted specimen density. The person or agency specifying this method shall specify a minimum percentage of oversize particles below which correction for oversize need not be applied. If no minimum percentage is specified, correction shall be applied to samples with more than 5 percent by mass of oversize particles.

1.5. If the specified oversized maximum tolerances are exceeded, other methods of compaction control must be used.

Note 1—One method for the design and control of the compaction of such soils is to use a test fill to determine the required degree of compaction and a method to obtain that compaction. Then use a method specification to control the compaction by specifying the type and size of compaction equipment, the lift thickness, and the number of passes.

1.6. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off “to the nearest unit” in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

1.7. The values stated in SI units are to be regarded as the standard.

3. APPARATUS

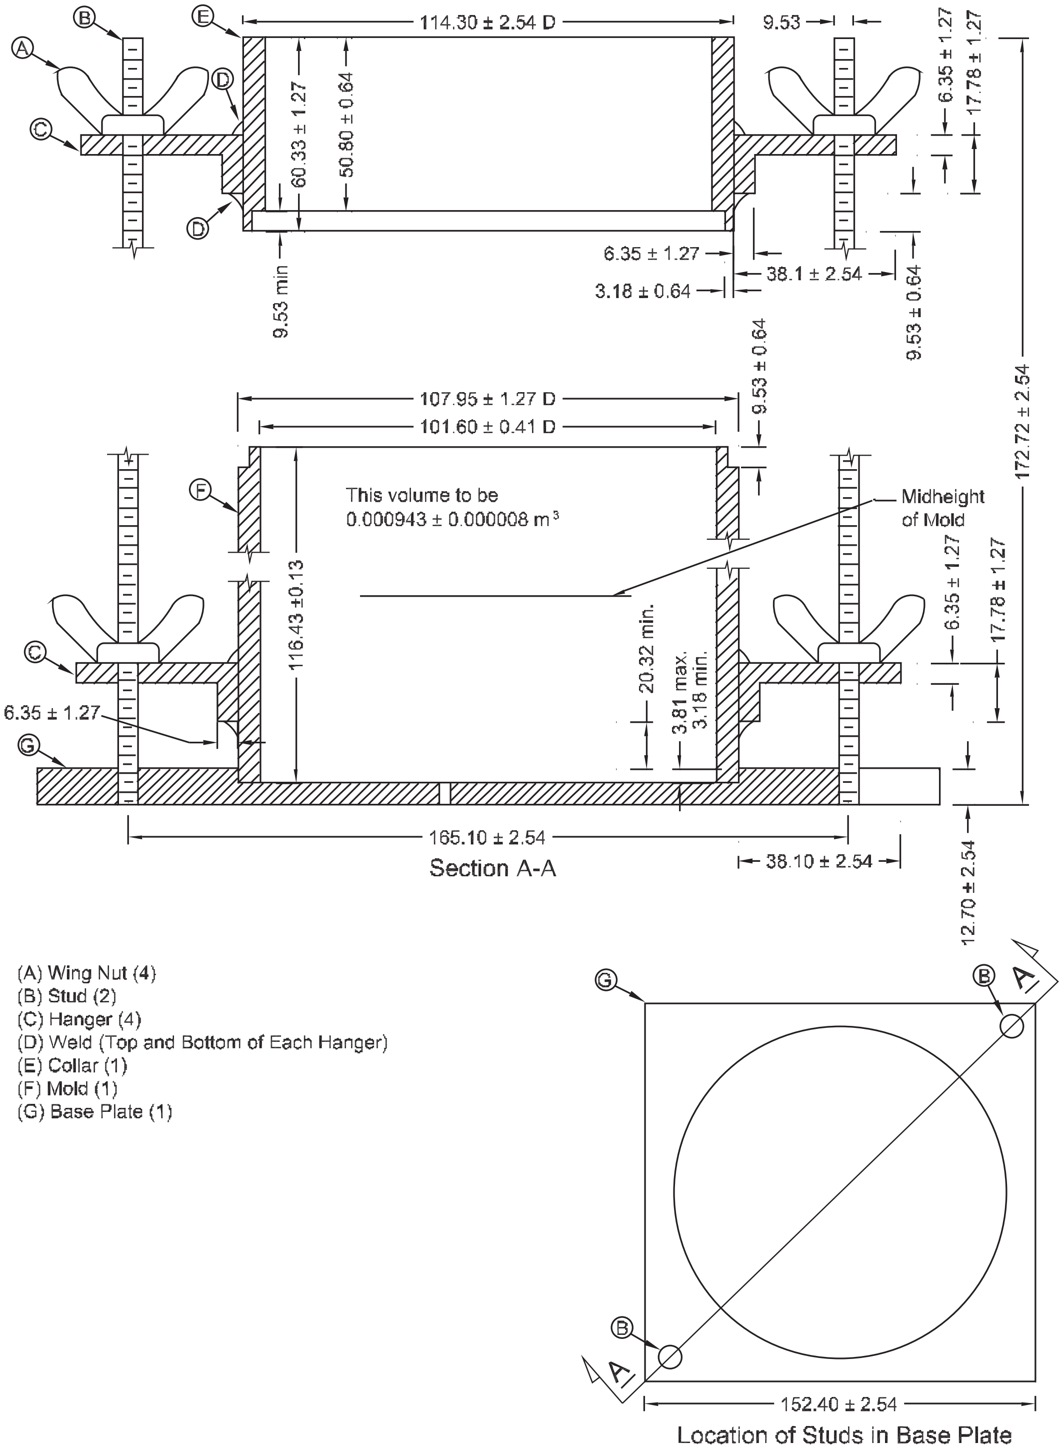
3.1. *Molds*—The molds shall be solid-wall, metal cylinders manufactured with dimensions and capacities shown in Sections 3.1.1, 3.1.2, and Figures 1 and 2. They shall have a detachable collar assembly approximately 60 mm (2.375 in.) in height, to permit preparation of compacted specimens of soil-water mixtures of the desired height and volume. The mold and collar assembly shall be so constructed that it can be fastened firmly to a detachable base plate made of the same material (Note 2). The base plate shall be plane to 0.005 in. as shown in Figures 1 and 2.

Note 2—Alternate types of molds with capacities as stipulated herein may be used, provided the test results are correlated with those of the solid-wall mold on several soil types and the same moisture-density results are obtained. Records of such correlation shall be maintained and readily available for inspection, when alternate types of molds are used.

3.1.1. A 101.6-mm (4-in.) mold having a capacity of 0.000943 ± 0.000008 m^3 ($^1/_{30}$ (0.0333) ± 0.0003 ft^3) with an internal diameter of 101.60 ± 0.41 mm (4.000 ± 0.016 in.) and a height of 116.43 ± 0.13 mm (4.584 ± 0.005 in.) (Figure 1).

3.1.2. A 152.4-mm (6-in.) mold having a capacity of 0.002124 ± 0.000021 m^3 ($^1/_{13.33}$ (0.07500) ± 0.00075 ft^3) with an internal diameter of 152.40 ± 0.66 mm (6.000 ± 0.026 in.) and a height of 116.43 ± 0.13 mm (4.584 ± 0.005 in.) (Figure 2).

3.1.3. *Molds Out of Tolerance Due to Use*—A mold that fails to meet manufacturing tolerances after continued service may remain in use provided those tolerances are not exceeded by more than 50 percent; and the volume of the mold, calibrated in accordance with T 19M/T 19 for Unit Mass of Aggregate, is used in the calculations.



Notes: 1. All dimensions shown in millimeters unless otherwise noted.

2. Hanger on the mold portion only cannot extend above the midheight line.

3. Figure 1 is to be used for all compaction molds purchased after the publication of the 21st edition (HM-21).

0.002124 ± 0.000021 m^3	1/13.33 ± 0.00075 ft^3		

3.2. *Rammer*:

3.2.1. *Manually Operated*—Metal rammer with a mass of 2.495 ± 0.009 kg (5.5 ± 0.02 lb), and having a flat circular face of 50.80-mm (2.000-in.) diameter with a manufacturing tolerance of ± 0.25 mm (0.01 in.). The in-service diameter of the flat circular face shall be not less than 50.42 mm (1.985 in.). The rammer shall be equipped with a suitable guide-sleeve to control the height of drop to a free fall of 305 ± 2 mm (12.00 ± 0.06 in.) above the elevation of the soil. The guide-sleeve shall have at least four vent holes, no smaller than 9.5-mm ($^3/_8$-in.) diameter spaced approximately 90 degrees (1.57 rad) apart and approximately 19 mm ($^3/_4$ in.) from each end; and shall provide sufficient clearance so the free fall of the rammer shaft and head is unrestricted.

3.2.2. *Mechanically Operated*—A metal rammer that is equipped with a device to control the height of drop to a free fall of 305 ± 2 mm (12.00 ± 0.06 in.) above the elevation of the soil and uniformly distributes such drops to the soil surface (Note 3). The rammer shall have a mass of 2.495 ± 0.009 kg (5.5 ± 0.02 lb), and have a flat circular face of 50.80-mm (2.000-in.) diameter with a manufactured tolerance of ± 0.25 mm (0.01 in.). The in-service diameter of the flat circular face shall be not less than 50.42 mm (1.985 in.). The mechanical rammer shall be calibrated by ASTM D 2168.

Note 3—It may be impractical to adjust the mechanical apparatus so the free fall is 305 mm (12 in.) each time the rammer is dropped, as with the manually operated rammer. To make the adjustment of free fall, the portion of loose soil to receive the initial blow should be slightly compressed with the rammer to establish the point of impact from which the 305-mm drop is determined. Subsequent blows on the layer of soil being compacted may all be applied by dropping the rammer from a height of 305 mm above the initial-setting elevation; or, when the mechanical apparatus is designed with a height adjustment for each blow, all subsequent blows should have a rammer free fall of 305 mm measured from the elevation of the soil as compacted by the previous blow. A more detailed calibration procedure for laboratory mechanical-rammer soil compactors can be found in ASTM D 2168.

3.2.3. *Rammer Face*—The circular face rammer shall be used, but a sector face may be used as an alternative, provided the report shall indicate type of face used other than the 50.8-mm (2-in.) circular face, and it shall have an area equal to that of the circular face rammer.

3.3. *Sample Extruder (for Solid-Walled Molds Only)*—A jack, lever, frame, or other device adopted for the purpose of extruding compacted specimens from the mold.

3.4. *Balances and Scales*—A balance or scale conforming to the requirements of M 231, Class G 20. Also, a balance conforming to the requirements of M 231, Class G 2.

Note 4—The capacity of the metric balance or scale should be approximately 11.5 kg when used to weigh the 152.40-mm (6-in.) mold and compacted, moist soil; however, when the 101.60-mm (4-in.) mold is used, a balance or scale of lesser capacity than the 11.5 kg may be used, if the sensitivity and readability is 5 g.

3.5. *Drying Oven*—A thermostatically controlled drying oven capable of maintaining a temperature of 110 ± 5ºC (230 ± 9ºF) for drying moisture samples.

3.6. *Straightedge*—A hardened-steel straightedge at least 250 mm (10 in.) in length. It shall have one beveled edge, and at least one longitudinal surface (used for final trimming) shall be plane within 0.250 mm per 250 mm (0.01 in. per 10 in.) (0.1 percent) of length within the portion used for trimming the soil (Note 5).

Note 5—The beveled edge may be used for final trimming if the edge is true within a tolerance of 0.250 mm per 250 mm (0.1 percent) of length; however, with continued use, the cutting edge may become excessively worn and not suitable for trimming the soil to the level of the mold. The straightedge should not be so flexible that trimming the soil with the cutting edge will cause a concave soil surface.

3.7. *Sieves*—50-mm (2-in.), 19.0-mm ($^3/_4$-in.), and 4.75-mm (No. 4) sieves conforming to the requirements of M 92.

3.8. *Mixing Tools*—Miscellaneous tools such as mixing pan, spoon, trowel, spatula, etc., or a suitable mechanical device for thoroughly mixing the sample of soil with increments of water.

3.9. *Containers*—Suitable containers made of material resistant to corrosion and not subject to change in mass or disintegration on repeated heating and cooling. Containers shall have close-fitting lids to prevent loss of moisture from samples before initial mass determination and to prevent absorption of moisture from the atmosphere following drying and before final mass determination. One container is needed for each moisture content determination.

METHOD A

4. SAMPLE

4.1. If the soil sample is damp when received from the field, dry it until it becomes friable under a trowel. Drying may be in air or by use of a drying apparatus that is maintained at a temperature not exceeding 60ºC (140ºF). Then thoroughly break up the aggregations in such a manner as to avoid reducing the natural size of individual particles.

4.2. Sieve an adequate quantity of the representative pulverized soil over the 4.75-mm (No. 4) sieve. Discard the coarse material, if any, retained on the 4.75-mm (No. 4) sieve.

4.3. Select a representative sample, with a mass of approximately 3 kg (7 lb) or more, of the soil prepared as described in Sections 4.1 and 4.2.

Note 6—When developing a compaction curve for free-draining soils, such as uniform sands and gravels, where seepage occurs at the bottom of the mold and base plate, taking a representative moisture content sample from the mixing bowl may be preferred to determine the amount of moisture available for compaction.

5. PROCEDURE

5.1. Thoroughly mix the selected representative sample with sufficient water to dampen it to approximately four percentage points below optimum moisture content.

5.2. Form a specimen by compacting the prepared soil in the 101.60-mm (4-in.) mold (with collar attached) in three approximately equal layers to give a total compacted depth of about 125 mm (5 in.). Prior to compaction, place the loose soil into the mold and spread into a layer of uniform thickness. Lightly tamp the soil prior to compaction until it is not in a loose or fluffy state, using either the manual compaction rammer or a similar device having a face diameter of approximately 50 mm (2 in.). Following compaction of each of the first two layers, any soil adjacent to the mold walls that has not been compacted or extends above the compacted surface shall be trimmed using a knife or other suitable device and evenly distributed on top of the layer. Compact each layer by 25 uniformly distributed blows from the rammer dropping free from a height of 305 mm (12 in.) above the elevation of the soil when a sleeve-type rammer is used, or from 305 mm above the approximate elevation of compacted soil when a stationary mounted type of rammer is used. During compaction, the mold shall rest firmly on a dense, uniform, rigid, and stable foundation or base. This base shall remain stationary during the compaction process (Note 7).

Note 7—Each of the following has been found to be a satisfactory base on which to rest the mold during compaction of the soil: a block of concrete, with a mass not less than 90 kg (200 lb), supported by a relatively stable foundation; a sound concrete floor; and for field application, such surfaces as are found in concrete box culverts, bridges, and pavements.

5.2.1. Following compaction, remove the extension collar, carefully trim the compacted soil even with the top of the mold by means of the straightedge, and determine the mass of the mold and moist soil in kilograms to the nearest five grams, or determine the mass in pounds to the nearest 0.01 pounds. Calculate the wet density, W_1, as described in Section 12.2 or 12.3.

5.3. Remove the material from the mold and slice vertically through the center. Take a representative sample of the material from one of the cut faces (Figure 3) and weigh immediately. Determine the moisture content in accordance with T 265 and record the results.

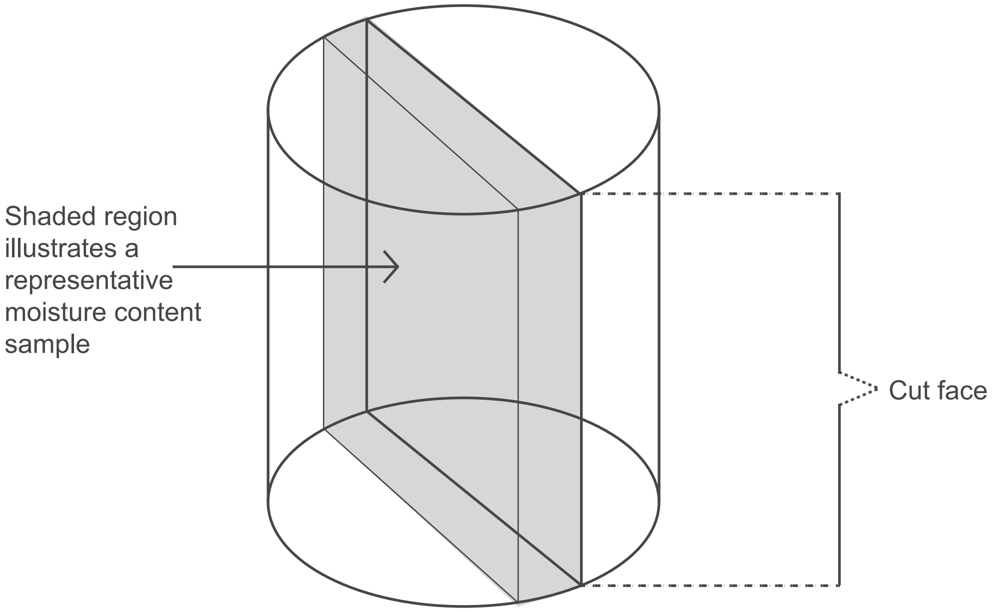

Figure 3—Representative Moisture Content Sample Selection

5.4. Thoroughly break up the remaining portion of the molded specimen until it will pass through a 4.75-mm (No. 4) sieve as judged by eye, and add to the remaining portion of the sample being tested. Add water in sufficient amount to increase the moisture content of the soil 1 to 2 percentage points (water content increments should not exceed 2.5 percent except when heavy clay soils or organic soils exhibiting flat elongated curves are encountered; the water content increments may be increased to a maximum of 4 percent) and repeat the above procedure for each increment of water added. Continue this series of determinations until there is either a decrease or no change in the wet unit mass, W_1, per cubic meter (cubic foot) of the compacted soil (Note 8).

Note 8—In instances where the soil material is fragile in character and will reduce significantly in grain size due to repeated compaction, and in cases where the soil is a heavy-textured clayey material into which it is difficult to incorporate water, a separate and new sample shall be used in each compaction test. In these cases, separate samples shall be thoroughly mixed with amounts of water sufficient to cause the moisture contents of the samples to vary by approximately two percentage points. The moisture points selected shall bracket the optimum moisture content, thus providing samples that, when compacted, will increase in mass to the maximum density and then decrease in mass. The samples of soil-water mixtures shall be placed in covered containers and allowed to stand for not less than 12 hours before making the moisture-density test.

5.4.1. In instances where the soil material is fragile in character and will be reduced significantly in grain size by repeated compaction, a separate and new sample shall be used in each compaction test.

METHOD B

6. SAMPLE

6.1. Select the representative sample in accordance with Section 4.3, except that it shall have a mass of approximately 7 kg (16 lb).

7. PROCEDURE

7.1. Follow the same procedure as described for Method A in Section 5, except for the following: Form a specimen by compacting the prepared soil in the 152.4-mm (6-in.) mold (with collar attached) in three approximately equal layers to give a total compacted depth of about 125 mm (5 in.), each layer being compacted by 56 uniformly distributed blows from the rammer. Calculate the wet density, W_1, as described in Section 12.2 or 12.3.

METHOD C

8. SAMPLE

8.1. If the soil sample is damp when received from the field, dry it until it becomes friable under a trowel. Drying may be in air or by use of a drying apparatus that is maintained at a temperature not exceeding 60ºC (140ºF). Then thoroughly break up the aggregations in such a manner as to avoid reducing the natural size of individual particles.

8.2. Sieve an adequate quantity of the representative pulverized soil over the 19.0-mm sieve. Discard the coarse material, if any, retained on the 19.0-mm sieve (Note 9).

Note 9—The discarded coarse material may be utilized in T 224.

8.3. Select a representative sample, having a mass of approximately 5 kg (11 lb) or more, of the soil prepared as described in Sections 8.1 and 8.2.

9. PROCEDURE

9.1. Thoroughly mix the selected representative sample with sufficient water to dampen it to approximately four percentage points below optimum moisture content.

9.2. Form a specimen by compacting the prepared soil in the 101.60-mm (4-in.) mold (with collar attached) in three approximately equal layers to give a total compacted depth of about 125 mm (5 in.). Prior to compaction, place the loose soil into the mold and spread into a layer of uniform thickness. Lightly tamp the soil prior to compaction until it is not in a loose or fluffy state, using either the manual compaction rammer or a similar device having a face diameter of approximately 50 mm (2 in.). Following compaction of each of the first two layers, any soil adjacent to the mold walls that has not been compacted or extends above the compacted surface shall be trimmed using a knife or other suitable device and evenly distributed on top of the layer. Compact each layer by 25 uniformly distributed blows from the rammer dropping free from a height of 305 mm (12 in.) above the elevation of the soil when a sleeve-type rammer is used, or from 305 mm (12 in.) above the approximate elevation of each finely compacted layer when a stationary mounted-type rammer is used. During compaction, the mold shall rest firmly on a dense, uniform, rigid, and stable foundation (Note 7).

9.2.1. Following compaction, remove the extension collar, carefully trim the compacted soil even with the top of the mold by means of the straightedge. Holes developed in the surface by removal of coarse material shall be patched with smaller-sized material. Determine the mass of the mold and moist soil in kilograms to the nearest five grams, or determine the mass in pounds to the nearest 0.01 pounds. Calculate the wet density, W_1, as described in Section 12.2 or 12.3.

9.3. Remove the material from the mold and slice vertically through the center. Take a representative sample of the material from one of the cut faces and weigh immediately. Determine the moisture content in accordance with T 265 and record the results.

9.4. Thoroughly break up the remainder of the material until it will pass through a 19.0-mm sieve and 90 percent of the soil aggregations will pass a 4.75-mm sieve as judged by eye, and add to the remaining portion of the sample being tested. Add water in sufficient amounts to increase the moisture content of the soil sample by one or two percentage points, and repeat the above procedure for each increment of water added. Continue this series of determinations until there is either a decrease or no change in the wet mass, W_1, per cubic meter (cubic foot) of compacted soil (Note 8).

METHOD D

10. SAMPLE

10.1. Select the representative sample in accordance with Section 8.3 except that it shall have a mass of approximately 11 kg (25 lb).

11. PROCEDURE

11.1. Follow the same procedure as described for Method C in Section 9, except for the following: Form a specimen by compacting the prepared soil in the 152.4-mm (6-in.) mold (with collar attached) in three approximately equal layers to give a total compacted depth of about 125 mm (5 in.), each layer being compacted by 56 uniformly distributed blows from the rammer. Calculate the wet density, W_1, as described in Section 12.2 or 12.3.

CALCULATIONS AND REPORT

12. CALCULATIONS

12.1. The mold factor can be related to the volume of the mold as follows:

$$F = 1 / V \tag{1}$$

where:

F = mold factor; and
V = volume of mold.

12.2. The wet density can be determined using the mold factor. For masses recorded in kilograms, the unit of wet density is kilograms per cubic meter of compacted soil. For masses recorded in pounds, the unit of wet density is pounds per cubic foot of compacted soil.

$$W_1 = (A - B) \times F \tag{2}$$

where:

A = mass of compacted specimen and mold;
B = mass of mold;
F = mold factor as given in Table 3; and
W_1 = wet density.

Table 3—Mold Factors for Molds in Compliance with Sections 3.1.1 or 3.1.2

	Mold Factor	
Method	For masses recorded in kilograms	For masses recorded in pounds
A	1060	30
B	471	13.3
C	1060	30
D	471	13.3

For used molds in compliance with Section 3.1.3, determine the mold factor in accordance with Section 3.1.3 and Equation 1.

12.3. Alternatively, the wet density can be determined using the mold volume. For masses recorded in kilograms, the unit of wet density is kilograms per cubic meter of compacted soil. For masses recorded in pounds, the unit of wet density is pounds per cubic foot of compacted soil.

$$W_1 = (A - B)/V \tag{3}$$

where:

V = mold volume as given in Section 3.1.1 for Methods A and C, or Section 3.1.2 for Methods B and D. For used molds in compliance with Section 3.1.3, determine the mold volume in accordance with Section 3.1.3.

12.4. The dry density is related to the wet density as follows:

$$W = \frac{W_1}{w + 100} \times 100 \tag{4}$$

where:

w = moisture content (percent) of the specimen, as determined by T 265; and

W = dry density, in kilograms per cubic meter of compacted soil, or pounds per cubic foot of compacted soil.

13. MOISTURE-DENSITY RELATIONSHIP

13.1. The calculations in Section 12 shall be made to determine the wet density (unit mass) and oven-dry density (unit mass) in kilograms per cubic meter or pounds per cubic foot of the compacted samples. The oven-dry densities of the soil shall be plotted as ordinates, and the corresponding moisture content as abscissas.

13.2. *Optimum Moisture Content*—When the densities and corresponding moisture contents for the soil have been determined and plotted as indicated in Section 13.1, it will be found that by connecting the plotted points with a smooth line, a curve is produced. The moisture content corresponding to the peak of the curve shall be termed the "optimum moisture content" of the soil under the above compaction.

13.3. *Maximum Density*—The oven-dry density in kilograms per cubic meter or pounds per cubic foot of the soil at optimum moisture content shall be termed "maximum density" under the above compaction.

14. REPORT

14.1. The report shall include the following:

14.1.1. The method used (Method A, B, C, or D).

14.1.2. The optimum moisture content, as a percentage, to the nearest whole number.

14.1.3. The maximum density in kilograms per cubic meter to the nearest 10 kg/m^3 or in pounds per cubic foot, to the nearest whole number.

14.1.4. Type of face if other than 50.8 mm (2 in.) circular.

15. PRECISION STATEMENT

15.1. *Repeatability (Single Operator)*—Two results obtained by the same operation on the same sample in the same laboratory using the same apparatus and on different days should be considered suspect if they differ by more than 10 percent of their mean for optimum moisture content and 35 kg/m^3 (2.2 lb/ft^3) for maximum density.

15.2. *Reproducibility (Multilaboratory)*—Two results obtained by different operators in different laboratories should be considered suspect if they differ by more than 15 percent of their mean for optimum moisture and 72 kg/m^3 (4.5 lb/ft^3) for maximum density.

Standard Method of Test for

Specific Gravity of Soils

AASHTO Designation: T 100-06[1]
ASTM Designation: D 854-00

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Specific Gravity of Soils

AASHTO Designation: T 100-06[1]
ASTM Designation: D 854-00

1. SCOPE

1.1. This method covers determination of the specific gravity of soils by means of a pycnometer. When the soil is composed of particles larger than the 4.75-mm (No. 4) sieve, the method outlined in T 85 shall be followed. When the soil is composed of particles both larger and smaller than the 4.75-mm sieve, the sample shall be separated on the 4.75-mm sieve and the appropriate test method used on each portion. The specific gravity value for the soil shall be the weighted average of the two values (Note 1). When the specific gravity value is to be used in calculations in connection with the hydrometer portion of AASHTO T 88, Particle Size Analysis of Soils, it is intended that the specific gravity test be made on that portion of the soil that passes the 2.00-mm (No. 10) sieve.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

Note 1—The weighted average specific gravity should be calculated using the following equation:

$$G_{\text{avg}} = \frac{1}{\dfrac{R_1}{100G_1} + \dfrac{P_1}{100G_2}} \qquad (1)$$

where:

G_{avg} = weighted average specific gravity of soils composed of particles larger and smaller than the 4.75-mm (No. 4) sieve,

R_1 = percent of soil particles retained on the 4.75-mm sieve,

P_1 = percent of soil particles passing the 4.75-mm sieve,

G_1 = apparent specific gravity of soil particles retained on the 4.75-mm sieve as determined by AASHTO T 85, and

G_2 = specific gravity of soil particles passing the 4.75-mm sieve as determined by this test method.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. DEFINITION

3.1. *specific gravity*—The ratio of the mass of a unit volume of a material at a stated temperature to the mass of the same volume of gas-free distilled water at a stated temperature (per Definition, E 1547).

4. SIGNIFICANCE AND USE

4.1. The specific gravity of a soil is used in almost every equation expressing the phase relationship of air, water, and solids in a given volume of material.

4.2. The term *solid particles*, as used in geotechnical engineering, is typically assumed to mean naturally occurring mineral particles that are not very soluble in water. Therefore, the specific gravity of materials containing extraneous matter (such as cement, lime, etc.), water-soluble matter (such as sodium chloride), and soils containing matter with a specific gravity of less than one, typically require special treatment or a qualified definition of specific gravity.

5. APPARATUS

5.1. *The apparatus shall consist of the following*:

5.1.1. *Pycnometer*—Either a volumetric flask having a capacity of at least 100 mL or a stoppered bottle having a capacity of at least 50 mL (Note 2). The stopper shall be of the same material as the bottle, and of such size and shape that it can be easily inserted to a fixed depth in the neck of the bottle, and shall have a small hole through its center to permit the emission of air and surplus water.

Note 2—The use of either the volumetric flask or the stoppered bottle is a matter of individual preference, but in general, the flask should be used when a larger sample than can be used in the stoppered bottle is needed due to maximum grain size of the sample. A 500 mL flask is required for samples of clayey soils containing their natural moisture content. (See Section 8.2.)

5.1.2. *Balance*—Either an M 231, Class G 1 balance for use with the volumetric flask, or an M 231, Class B balance for use with the stoppered bottle.

5.1.3. *Oven*—A thermostatically controlled drying oven capable of maintaining a temperature of 110º ± 5ºC (230 ± 9ºF).

5.1.4. *Thermometer*—Capable of measuring the temperature range within which the test is being performed, graduated in a 0.5ºC (1.0ºF) division scale and meeting the requirements of ASTM E 1 or any other thermometric device of equal accuracy, precision, and sensitivity.

6. GENERAL REQUIREMENTS FOR WEIGHING

6.1. When the volumetric flask is used in the specific gravity determination, all masses shall be determined to the nearest 0.01 g. When the stoppered bottle is used in the specific gravity determination, all masses shall be determined to the nearest 0.001 g.

7. CALIBRATION OF PYCNOMETER

7.1. The pycnometer shall be cleaned, dried, weighed, and the mass recorded. The pycnometer shall be filled with distilled water (Note 3) essentially at room temperature. The mass of the pycnometer and water, W_a, shall be determined and recorded. A thermometer shall be inserted in the water and its temperature, T_i, determined to the nearest whole degree.

Note 3—Kerosene is a better wetting agent than water for most soils and may be used in place of distilled water for oven-dried samples.

7.2. A table of values of mass W_a shall be prepared for a series of temperatures that are likely to prevail when the mass W_b of the pycnometer, sample, and water is determined at the end of testing (Note 4). These values of W_a shall be calculated as follows:

$$W_a\left(\text{at } T_x\right) = \left(\text{density of water at } T_x / \text{density of water at } T_i\right) \times \left(W_a\left(\text{at } T_i\right) - W_f\right) + W_f \tag{2}$$

where:

W_a = mass of pycnometer and water, in grams;

W_f = mass of pycnometer, in grams;

T_i = observed temperature of water, in degrees Celsius; and

T_x = any other desired temperature, in degrees Celsius.

Note 4—This method provides a procedure that is most convenient for laboratories making many determinations with the same pycnometer. It is equally applicable to a single determination. Bringing the pycnometer and contents to some designated temperature when masses W_a and W_b are taken requires considerable time. It is much more convenient to prepare a table of masses W_a for various temperatures likely to prevail when masses W_b (see Section 9.3) are taken. It is important that masses W_a and W_b be based on water at the same temperature. Values for the relative density of water at temperatures from 18 to 30ºC are given in Table 1.

Table 1—Relative Density of Water and Correction Factor *K* for Various Temperatures

Temperatures, ºC	Relative Density of Water	Correction Factor *K*
18	0.9986244	1.0004
19	0.9984347	1.0002
20	0.9982343	1.0000
21	0.9980233	0.9998
22	0.9978019	0.9996
23	0.9975702	0.9993
24	0.9973286	0.9991
25	0.9970770	0.9989
26	0.9968156	0.9986
27	0.9965451	0.9983
28	0.9962652	0.9980
29	0.9959761	0.9977
30	0.9956780	0.9974

8. SAMPLE

8.1. The soil to be used in the specific gravity test may contain its natural moisture or be oven-dried. The mass of the test sample on an oven-dry basis shall be at least 25 g when the volumetric flask is to be used, and at least 10 g when the stoppered bottle is to be used.

8.2. *Samples Containing Natural Moisture*—When the sample contains its natural moisture, the mass of the soil, W_o, on an oven-dry basis shall be determined at the end of the test by evaporating the water in an oven maintained at 110º ± 5ºC (230 ± 9ºF) (Note 5). Samples of clay soils containing their natural moisture content shall be dispersed in distilled water before placing in a 500 mL flask, using the dispersing equipment specified in T 88 (Note 6).

8.3. *Oven-Dried Samples*—When an oven-dried sample is to be used, the sample shall be dried for at least 12 hours, or to constant mass, in an oven maintained at 110º ± 5ºC (230 ± 9ºF) (Note 5), cooled to room temperature, then weighed and transferred to the pycnometer or transferred to the pycnometer and then weighed. Distilled water shall be added into the pycnometer in an amount that will provide complete sample coverage. The sample shall then soak for at least 12 hours.

Note 5—Drying of certain soils at 110ºC may bring about loss of moisture of composition or hydration, and in such cases drying shall be done, if desired, in reduced air pressure and at a lower temperature.

Note 6—The minimum volume of slurry that can be prepared by the dispersing equipment specified in T 88 is such that a 500-mL flask is needed as the pycnometer.

9. PROCEDURE

9.1. The sample as prepared in Section 8 shall have distilled water added to a level that will cover the soil to a maximum of about three-fourths full in the volumetric flask, or about one-half full in the stoppered bottle (Note 7).

9.2. Remove entrapped air by either of the following methods: (1) subject the contents to a partial vacuum of 13.33 kPa (100 mm Hg) or less absolute pressure or (2) boil gently for at least 10 min., while occasionally rolling the pycnometer to assist in the removal of the air. Subjection of the contents to reduced air pressure may be done either by connecting the pycnometer directly to an aspirator or vacuum pump, or by use of a bell jar. Some soils boil violently when subjected to reduced air pressure. It will be necessary in those cases to reduce the air pressure at a slower rate or to use a larger flask (Note 8). Samples that are heated shall be cooled to room temperature.

Note 7—If the vacuum method of air removal is used, the required amount of distilled water may be added in layers, with each layer being subjected to the vacuum until the sample ceases to release air.

Note 8—When using a partial vacuum, agitate the flask gently at intervals during the evacuation process. (A) Samples containing natural moisture with high plasticity may require 6 to 8 hours to remove air; samples with low plasticity may require 4 to 6 hours to remove air. (B) Oven-dried samples may require 2 to 4 hours to remove air.

9.3. Fill the pycnometer with distilled water to its calibrated capacity and then clean the outside and dry with a clean, dry cloth. Determine the mass of the pycnometer and contents, W_b, and the temperature in degrees Celsius, T_x, of the contents as described in Section 7.

10. CALCULATION AND REPORT

10.1. Calculate the specific gravity of the soil, based on water at a temperature T_x, as follows:

$$\text{Specific Gravity, } T_x / T_x = W_o / \left[W_o + \left(W_a - W_b \right) \right] \tag{3}$$

where:

T_x = temperature of the contents of the pycnometer when mass W_b was determined, in degrees Celsius;

W_o = mass of sample of oven-dried soil in grams;

W_a = mass of pycnometer filled with water at temperature T_x (Note 9), in grams; and

W_b = mass of pycnometer filled with water and soil at temperature T_x, in grams.

Note 9—This value shall be taken from the table of values of W_a, prepared in accordance with Section 7.2, for the temperature prevailing when mass W_b was taken.

10.2. Unless otherwise required, specific gravity values reported shall be based on water at 20ºC. The value based on water at 20ºC shall be calculated from the value based on water at the observed temperature T_x, as follows:

$$\text{Specific Gravity, } T_x / 20°\text{C} = K \times \text{ Specific Gravity, } T_x / T_x \tag{4}$$

where:

K = a number found by dividing the relative density of water at temperature T_x by the relative density of water at 20ºC. Values for a range of temperatures are given in Table 1.

10.3. When it is desired to report the specific gravity value based on water at 4ºC, such a specific gravity value may be calculated by multiplying the specific gravity value at temperature T_x by the relative density of water at temperature T_x.

10.4. When any portion of the original sample of soil is eliminated in the preparation of the test sample, the portion on which the test has been made shall be reported.

10.5. When using the volumetric flask to determine specific gravities, report results to at least the nearest 0.01.

10.6. When using the stoppered bottle to determine specific gravities, report results to at least the nearest 0.001.

11. PRECISION AND BIAS

11.1. Criteria for judging the acceptability of specific gravity test results obtained by this test method on material passing the 4.75-mm (No. 4) or 2.00-mm (No. 10) sieve are given in Table 2 (see Note 10):

Table 2—Specific Gravity Test Results

Material and Type Index	Standard Deviation[a]		Acceptable Range of Two Results (Percent of Mean)[a]	
	ASTM[b] Passing 4.75 mm (No. 4)	AASHTO[c] Passing 2.00 mm (No. 10)	ASTM[b] Passing 4.75 mm (No. 4)	AASHTO[c] Passing 2.00 mm (No. 10)
Single-Operator precision:				
Cohesive soils	0.021	0.02	0.06	0.05
Noncohesive soils	[d]	[d]	[d]	[d]
Multilaboratory precision:				
Cohesive soils	0.056	0.04	0.16	0.11
Noncohesive soils	[d]	[d]	[d]	[d]

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670 for Preparing Precision Statements for Test Methods for Construction Materials.

[b] These numbers represent standard deviation values assigned by ASTM Committee on Materials.

[c] These numbers represent standard deviation values assigned by AASHTO Subcommittee on Materials.

[d] Criteria for assigning standard deviation values for noncohesive soils are not available at the present time.

Note 10—The figures given in Column 2 are the standard deviations that have been found to be appropriate for the materials described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests.

---

[1] Except for the requirements given for the thermometer, reporting accuracy, minimum sampling size and weighing, and our deletion of the desiccator, this method is the same as ASTM D 854-00.

Standard Method of Test for

Moisture-Density Relations of Soil-Cement Mixtures

AASHTO Designation: T 134-05 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Moisture-Density Relations of Soil-Cement Mixtures

AASHTO Designation: T 134-05 (2009)

1. SCOPE

1.1. These methods of test are intended for determining the relation between moisture content and density of soil-cement mixtures when compacted before cement hydration as prescribed.

1.2. A 944-cm^3 (1/30-ft^3) mold and a 2.5-kg (5.5-lb) rammer dropped from a height of 305 mm (12 in.) are used and two methods, depending on soil gradation, are covered, as follows:

- *Method A*—Soil material passing a 4.75-mm (No. 4) sieve. This method shall be used when 100 percent of the soil sample passes the 4.75-mm (No. 4) sieve.
- *Method B*—Soil material passing a 19.0-mm ($^3/_4$-in.) sieve. This method shall be used when part of the soil sample is retained on the 4.75-mm (No. 4) sieve.

1.3. This test method applies to soil-cement mixtures that have 30 percent or less retained on the 19.0-mm ($^3/_4$-in.) sieve, when Method B is used. The material retained on these sieves shall be defined as oversized particles (coarse particles).

1.4. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

3. APPARATUS

3.1. *Molds*—The molds shall be solid-wall, metal cylinders manufactured with dimensions and capacities shown in Table 1. They shall have a detachable collar assembly approximately 60 mm (2.375 in.) in height to permit preparation of compacted specimens of soil-cement mixtures of the desired weight and volume. The mold and collar assembly shall be so constructed that it can be fastened firmly to a detachable base plate made of the same material (Figure 1).

Note 1—Alternate types of molds with capacities as stipulated herein may be used, provided the test results are correlated with those of the solid-wall mold on several soil types and the same moisture-density results are obtained. Records of such correlation shall be maintained and readily available for inspection, when alternate types of molds are used.

3.2. A 101.6-mm (4-in.) mold having a capacity of 0.000943 ± 0.000008 m^3 ($^1/_{30}$ (0.0333) ± 0.0003 ft^3) with an internal diameter of 101.60 ± 0.41 mm (4.000 ± 0.016 in.) and a height of 116.43 ± 0.13 mm (4.584 ± 0.005 in.) (Figure 1).

3.3. *Molds Out of Tolerance Due to Use*—A mold that fails to meet manufacturing tolerances after continued service may remain in use provided those tolerances are not exceeded by more than 50 percent; and the volume of the mold, calibrated in accordance with T 19M/T 19, for Unit Mass of Aggregate, is used in the calculations.

Table 1—Dimensional Equivalents for Figure 1

mm	in.	mm	in.
3.18 ± 0.64	0.125 ± 0.025	50.80 ± 0.64	2.000 ± 0.025

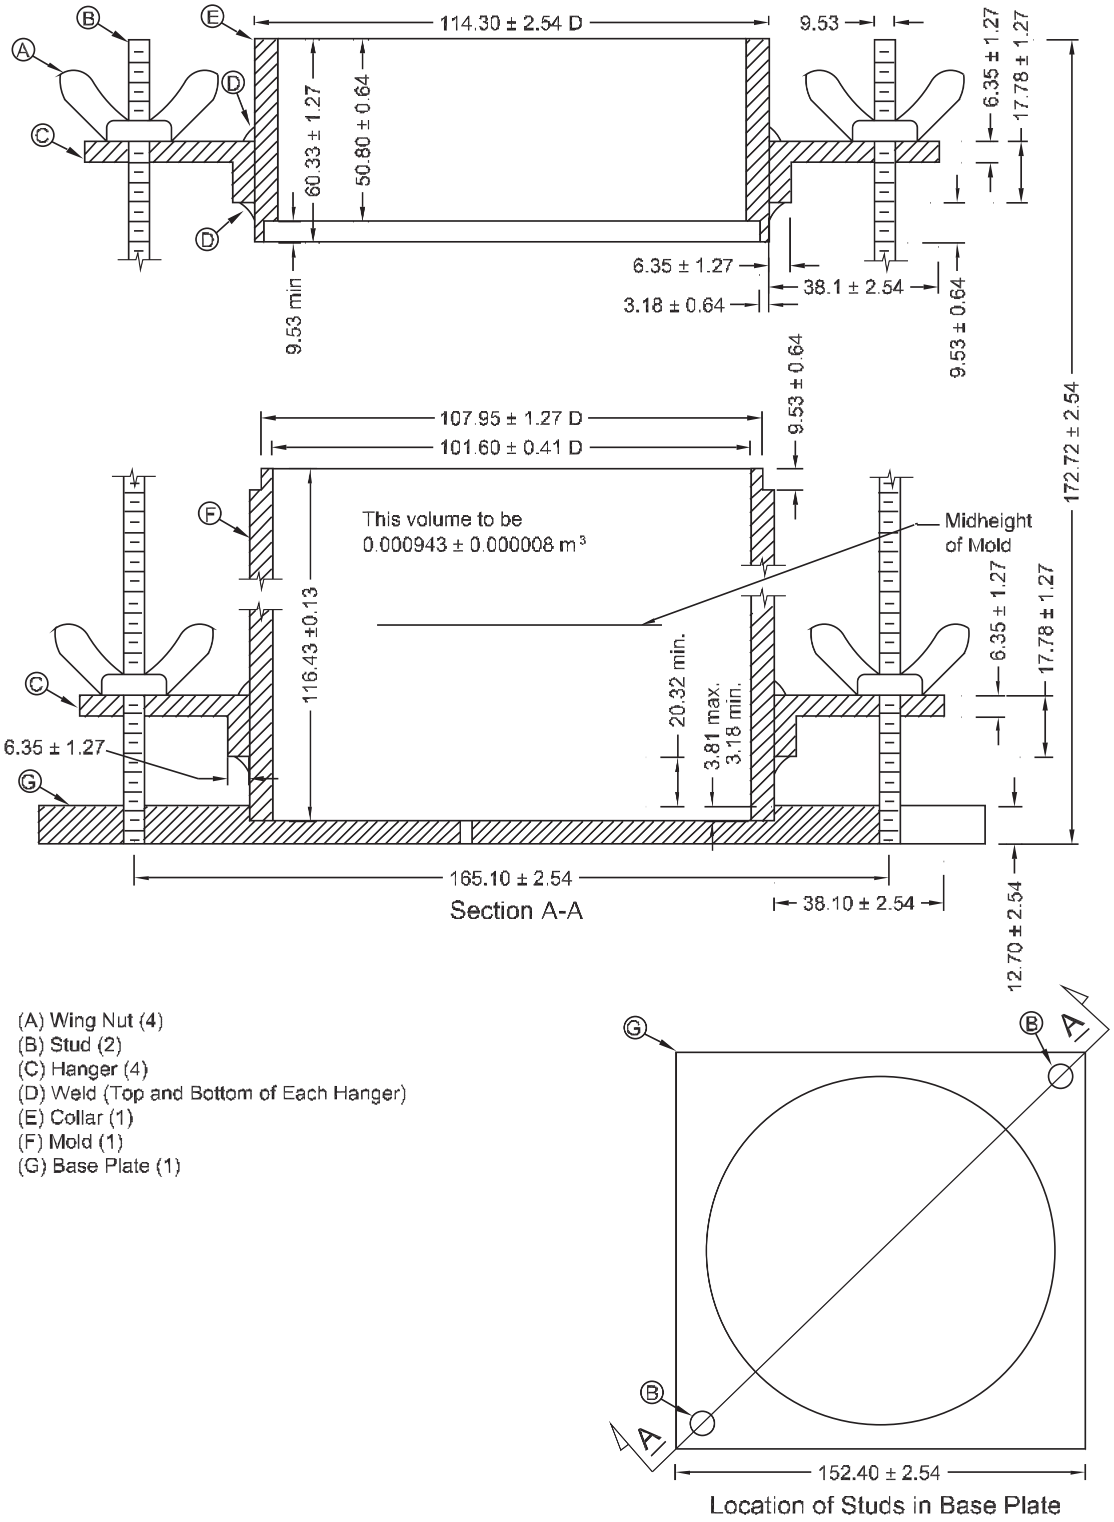
0.000943 ± 0.000008 m^3	$^1/_{30}$ ± 0.0003 ft^3		



Notes:
1. All dimensions shown in millimeters unless otherwise noted.
2. Hanger on the mold portion only cannot extend above the midheight line.
3. Figure 1 is to be used for all compaction molds purchased after the publication of the 21st edition (HM-21).
4. Not to scale.

Figure 1—Cylindrical Mold and Base Plate (101.6-mm Mold)

3.4. *Rammer*:

3.4.1. *Manually Operated*—Metal rammer with a mass of 2.495 ± 0.009 kg (5.5 ± 0.02 lb), and having a flat circular face of 50.80-mm (2.000-in.) diameter with a manufacturing tolerance of ± 0.25 mm (0.01 in.). The in-service diameter of the flat circular face shall be not less than 50.42 mm (1.985 in.). The rammer shall be equipped with a suitable guide-sleeve to control the height of drop to a free fall of 305 ± 2 mm (12.00 ± 0.06 in.) above the elevation of the soil. The guide-sleeve shall have at least four vent holes, no smaller than 9.5-mm ($^3/_8$-in.) diameter spaced approximately 90 degrees (1.57 radius) apart and approximately 19 mm ($^3/_4$ in.) from each end; and shall provide sufficient clearance so the free fall of the rammer shaft and head is unrestricted.

3.4.2. *Mechanically Operated*—A metal rammer that is equipped with a device to control the height of drop to a free fall of 305 ± 2 mm (12.00 ± 0.06 in.) above the elevation of the soil and uniformly distributes such drops to the soil surface (Note 2). The rammer shall have a mass of 2.495 ± 0.009 kg (5.5 ± 0.02 lb), and have a flat circular face of 50.80-mm (2.000-in.) diameter with a manufactured tolerance of ± 0.25 mm (0.01 in.). The in-service diameter of the flat circular face shall be not less than 50.42 mm (1.985 in.).

Note 2—The rammer apparatus shall be calibrated with several soil-cement mixtures and the mass of the rammer adjusted, if necessary, to give the same moisture-density results as with the manually operated rammer. It may be impractical to adjust the mechanical apparatus so the free fall is 305 mm (12 in.) each time the rammer is dropped, as with the manually operated rammer. To make the adjustment of free fall, the portion of loose soil to receive the initial blow should be slightly compressed with the rammer to establish the point of impact from which the 305-mm (12-in.) drop is determined. Subsequent blows on the layer of soil-cement may all be applied by dropping the rammer from a height of 305 mm (12 in.) above the initial-setting elevation, or when the mechanical apparatus is designed with a height adjustment for each blow, all subsequent blows should have rammer free fall of 305 mm (12 in.) measured from the elevation of the soil-cement as compacted by the previous blow.

3.4.3. *Rammer Face*—The circular face rammer shall be used, but a sector face may be used as an alternative, provided the report shall indicate type of face used other than the 50.8-mm (2-in.) circular face and it shall have an area equal to that of the circular face rammer.

3.5. *Sample Extruder*—A jack, lever, frame, or other device adopted for the purpose of extruding compacted specimens from the mold. Not required when a split-type mold is used.

3.6. *Balances and Scales*—A balance or scale conforming to the requirements of M 231, Class G 20. Also, a balance conforming to the requirements of M 231, Class G 2.

3.7. *Drying Oven*—A thermostatically controlled drying oven capable of maintaining a temperature of 110 ± 5ºC (230 ± 9ºF) for drying moisture samples.

3.8. *Straightedge*—A hardened-steel straightedge at least 254 mm (10 in.) in length. It shall have one beveled edge, and at least one longitudinal surface (used for final trimming) shall be plane within 0.250 mm per 250 mm (0.01 in. per 10 in.) (0.1 percent) of length within the portion used for trimming the soil (Note 3).

Note 3—The beveled edge may be used for final trimming if the edge is true within a tolerance of 0.250 mm per 250 mm (0.1 percent) of length; however, with continued use, the cutting edge may become excessively worn and not suitable for trimming the soil to the level of the mold. The straightedge should not be so flexible that trimming the soil with the cutting edge will cause a concave soil surface.

3.9. *Sieves*—75-mm (3-in.), 19.0-mm ($^3/_4$-in.), and 4.75-mm (No. 4) sieves conforming to the requirements of M 92.

3.10. *Mixing Tools*—Miscellaneous tools such as mixing pan, spoon, trowel, spatula, etc., or a suitable mechanical device for thoroughly mixing the sample of soil with cement and with increments of water.

3.11. *Container*—A flat, round pan for moisture absorption by soil-cement mixtures, about 305 mm (12 in.) in diameter and 50 mm (2 in.) deep.

3.12. *Moisture Containers*—Suitable containers made of material resistant to corrosion and not subject to change in weight or disintegration on repeated heating and cooling. Containers shall have close-fitting lids to prevent loss of moisture from samples before initial weighing and to prevent absorption of moisture from the atmosphere following drying and before final weighing. One container is needed for each moisture content determination.

3.13. *Butcher Knife*—A butcher knife approximately 250 mm (10 in.) in length for trimming the top of the specimens.

METHOD A

4. SAMPLE

4.1. If the soil sample is damp when received from the field, dry it until it becomes friable under a trowel. Drying may be in air or by use of a drying apparatus that is maintained at a temperature not exceeding 60ºC (140ºF). Then thoroughly break up the aggregations to pass the 4.75-mm (No. 4) sieve, in such a manner as to avoid reducing the natural size of individual particles.

4.2. Select a representative sample, with a mass of approximately 2.7 kg (6 lb) or more, of the soil prepared as described in Section 4.1.

5. PROCEDURE

5.1. Add to the soil the required amount of cement conforming to M 85 or M 240. Mix the cement and soil thoroughly to a uniform color.

5.2. When needed, add sufficient potable water to dampen the mixture to approximately four to six percentage points below optimum moisture content and mix thoroughly. At this moisture content, plastic soils, tightly squeezed in the palm of the hand, will form a cast that will fracture with only slight pressure applied by the thumb and fingertips; nonplastic soils will bulk noticeably.

5.3. When the soil is a heavy textured clayey material, compact the mixture of soil, cement, and water in the container to a depth of 50 mm (2 in.) using the rammer described in Section 3.2 or a similar hand tamper. Cover and allow to stand for not less than 5 minutes but not more than 10 minutes to aid dispersion of the moisture and to permit more complete absorption by the soil-cement.

5.4. After the absorption period, thoroughly break up the mixture, without reducing the natural size of individual particles, until it will pass a 4.75-mm (No. 4) sieve, and then remix.

5.5. Form a specimen by compacting the prepared soil-cement mixture in the mold (with collar attached) in three approximately equal layers to give a total compacted depth of about 130 mm (5 in.). Compact each layer by 25 uniformly distributed blows from the rammer dropping free from a height of 305 mm (12 in.) above the elevation of the soil-cement when a sleeve-type rammer is used, or from 305 mm (12 in.) above the approximate elevation of compacted soil when a stationary mounted type of rammer is used. During compaction, the mold shall rest firmly on a dense, uniform, rigid, and stable foundation or base. This base shall remain stationary during the compaction process (Note 4).

Note 4—Each of the following has been found to be a satisfactory base on which to rest the mold during compaction of the soil: a block of concrete, with a mass not less than 90 kg (200 lb), supported by a relatively stable foundation; a sound concrete floor; and for field application, such surfaces as found in concrete box culverts, bridges, and pavements.

5.6. Following compaction, remove the extension collar, carefully trim the compacted soil-cement mixture even with the top of the mold by means of the knife and straightedge, and determine the mass of the mold and moist soil in kilograms to the nearest five grams, or determine the mass in pounds to the nearest 0.01 pounds. For molds conforming to tolerances given in Table 1 and masses recorded in kilograms, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 1060, and record the result as the wet density, W_1, in kilograms per cubic meter, of compacted soil. For molds conforming to tolerances given in Table 1 and masses recorded in pounds, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 30, and record the result as the wet density, W_1, in pounds per cubic foot, of compacted soil. For used molds out of tolerance by not more than 50 percent (Table 1), use the factor for the mold as determined in accordance with Calibration of Measure in T 19M/T 19.

5.7. Remove the material from the mold and slice vertically through the center. Take a representative sample of the material from one of the cut faces, weighing not less than 100 g, from the full height of one of the cut faces, weigh immediately, and dry in accordance with T 265, to determine the moisture content, and record the results.

5.8. Thoroughly break up the remaining portion of the molded specimen until it will pass a 4.75-mm (No. 4) sieve as judged by eye, and add to the remaining portion of the sample being tested. Add water in sufficient amount to increase the moisture content of the soil one to two percentage points and repeat the above procedure for each increment of water added. Continue this series of determinations until there is either a decrease or no change in the wet unit mass, W_1, per cubic meter (cubic foot), of the compacted soil-cement mixture (Note 5).

Note 5—In instances where the soil material is fragile in character and will reduce significantly in grain size due to repeated compaction a separate and new sample shall be used in each compaction test.

Note 6—To minimize the effect of cement hydration, perform the test expeditiously and continuously to completion.

METHOD B

6. SAMPLE

6.1. If the soil sample is damp when received from the field, dry it until it becomes friable under a trowel. Drying may be in air or by use of a drying apparatus that is maintained at a temperature not exceeding 60ºC (140ºF). Then thoroughly break up the aggregations in such a manner as to avoid reducing the natural size of individual particles. Prepare the sample for testing by segregating the material retained on a 4.75-mm (No. 4) sieve and breaking up the remaining soil aggregations to pass the 4.75-mm (No. 4) sieve in such a manner as to avoid reducing the natural size of the individual particles.

6.2. Sieve the prepared soil over the 75-mm (3-in.), 19.0-mm ($^3/_4$-in.), and 4.75-mm (No. 4) sieves. Discard the material retained on the 75-mm (3-in.) sieve. Determine the percentage of material, by oven-dry mass, retained on the 19.0-mm ($^3/_4$-in.) and 4.75-mm (No. 4) sieves.

6.3. Saturate the aggregate passing the 19.0-mm ($^3/_4$-in.) sieve and retained on the 4.75-mm (No. 4) sieve by soaking in potable water; surface dry the material as required for later testing.

Note 7—Most soil-cement construction specifications covering soil gradation limit maximum size material to 75-mm (3-in.) or less.

6.4. Select and maintain separate representative samples of soil passing the 4.75-mm (No. 4) sieve and of saturated, surface dry aggregate passing the 19.0-mm ($^3/_4$-in.) sieve and retained on the 4.75-mm (No. 4) sieve so that the total sample will weigh approximately 4.99 kg (11 lb) or more. The percentage, by oven-dry mass, of aggregate passing the 19.0-mm ($^3/_4$-in.) sieve and retained on the 4.75-mm (No. 4) sieve shall be the same as the percentage passing the 75-mm (3-in.) sieve and retained on the 4.75-mm (No. 4) sieve in the original sample.

7. PROCEDURE

7.1. Add to the portion of the soil sample passing the 4.75-mm (No. 4) sieve the amount of cement conforming to Specification M 85 or Specification M 240, required for the total sample specified in Section 6.4. Mix the cement and soil thoroughly to a uniform color.

7.2. When needed, add water to this soil-cement mixture and facilitate moisture dispersion as described for Method A in Sections 5.2 to 5.4. After this preparation, add the saturated, surface-dry aggregate to the soil-cement mixture passing the 4.75-mm (No. 4) sieve and mix thoroughly.

7.3. Form a specimen by compacting the prepared soil-cement mixture in the mold (with collar attached) and trim and weigh the compacted specimen as described for Method A in Sections 5.5 and 5.6. Holes developed in the surface by removal of coarse material shall be patched with smaller sized material.

7.4. Remove the material from the mold and take a sample for determining the moisture content as described for Method A in Section 5.7, except the sample shall weigh not less than 500 g.

7.5. Thoroughly break up the remainder of the material as before until it will pass a 19.0-mm ($^3/_4$-in.) sieve and 90 percent of the soil aggregations will pass a 4.75-mm (No. 4) sieve as judged by eye, and add to the remaining portion of the sample being tested.

7.6. Add water in sufficient amounts to increase the moisture content of the soil-cement mixture by one or two percentage points, and repeat the above procedure for each increment of water added. Continue this series of determinations until there is either a decrease or no change in the wet mass, W_1, per cubic meter (cubic foot) of compacted soil (Notes 5 and 6).

CALCULATIONS AND REPORT

8. CALCULATIONS

8.1. Calculate the moisture content and the dry unit mass of the soil-cement mixture as compacted for each trial, as follows:

$$w = \frac{A - B}{B - C} \times 100 \tag{1}$$

and

$$W = \frac{W_1}{w + 100} \times 100 \tag{2}$$

where:

w = percentage of moisture in the specimen, based on oven-dry mass of soil-cement;

A = mass of container and wet soil-cement;

B = mass of container and oven-dry soil-cement;

C = mass of moisture container;

W = dry unit mass of compacted soil-cement, in kilograms per cubic meter, or pounds per cubic foot; and

W_1 = wet unit mass of compacted soil-cement, in kilograms per cubic meter, or pounds per cubic foot.

9. MOISTURE-DENSITY RELATIONSHIP

9.1. The calculations in Section 8 shall be made to determine the moisture content and corresponding oven-dry unit mass (density) in kilograms per cubic meter or pounds per cubic foot of the compacted soil-cement samples. The oven-dry densities (unit mass) of the soil-cement mixture shall be plotted as ordinates and the corresponding moisture content as abscissas.

9.2. *Optimum Moisture Content*—When the densities and corresponding moisture contents for the soil-cement mixture have been determined and plotted as indicated in Section 9.1, it will be found that by connecting the plotted points with a smooth line, a curve is produced. The moisture content corresponding to the peak of the curve shall be termed the "optimum moisture content" of the soil-cement mixture under the compaction prescribed in these methods.

9.3. *Maximum Density*—The oven-dry density in kilograms per cubic meter or pounds per cubic foot of the soil-cement mixture at optimum moisture content shall be termed "maximum density" under the compaction prescribed in these methods.

10. REPORT

10.1. The report shall include the following:

10.1.1. The method used (Method A or B).

10.1.2. The optimum moisture content, as a percentage, to the nearest whole number.

10.1.3. The maximum density in kilograms per cubic meter to the nearest 10 kg/m^3 or in pounds per cubic foot to the nearest whole number.

10.1.4. Type of rammer face if other than 50.8-mm (2-in.) circular.

11. PRECISION STATEMENT

11.1. Precision of this test method has not yet been established.

Standard Method of Test for

Wetting-and-Drying Test of Compacted Soil-Cement Mixtures

AASHTO Designation: T 135-97 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Wetting-and-Drying Test of Compacted Soil-Cement Mixtures

AASHTO Designation: T 135-97 (2009)

1. SCOPE

1.1. These methods of test cover procedures for determining the soil-cement losses, moisture changes, and volume changes (swell and shrinkage) produced by the repeated wetting and drying of hardened soil-cement specimens. The specimens are compacted in a mold, before cement hydration, to maximum density at optimum moisture content using the compaction procedure described in T 134.

1.2. Two methods, depending on soil gradation, are covered for preparation of material for molding specimens and for molding specimens as follows:

1.2.1. *Method A*—Using soil material passing the 4.75-mm (No. 4) sieve. This method shall be used when 100 percent of the soil samples passes the 4.75-mm (No. 4) sieve. See Sections 4 to 6.

1.2.2. *Method B*—Using soil material passing the 19.0-mm ($^{3}/_{4}$-in.) sieve. This method shall be used when part of the soil sample is retained on the 4.75-mm (No. 4) sieve. See Sections 7 to 9.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 85, Portland Cement
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- M 240, Blended Hydraulic Cement
- T 99, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop
- T 134, Moisture-Density Relations of Soil-Cement Mixtures
- T 265, Laboratory Determination of Moisture Content of Soils

3. APPARATUS

3.1. *Molds 101.6 mm (4 in.), Rammer, Sample Extruder, and Straightedge*—As specified in T 99.

3.2. Both scales and balances shall meet the requirements of M 231. A balance or scale having a capacity of at least 11.5 kg (25.4 lb) and conforming to the requirements for a G 20 class scale and a balance of at least 1 kg (2 lb) capacity and conforming to the requirements of a G 2 class scale.

3.3. *Drying Oven*—A thermostatically controlled drying oven capable of maintaining temperatures of 110 ± 5ºC (230 ± 9ºF).

3.4. *Moist Room*—A moist room or suitable covered container capable of maintaining a temperature of 21 ± 1.7ºC (70 ± 3ºF) and a relative humidity of 100 percent for seven-day storage of compacted specimens.

3.5. *Water Bath*—Suitable tank for submerging compacted specimens in water at room temperature.

3.6. *Wire Scratch Brush*—A wire scratch brush made of 50 by 1.6 mm (2 by $^1/_{16}$ in.) flat No. 26 gauge wire bristles assembled in 50 groups of 10 bristles each and mounted to form five longitudinal rows and 10 transverse rows of bristles on a 191 by 64 mm ($7^1/_2$ by $2^1/_2$ in.) hardwood block.

3.7. *Sieves*—75-mm (3-in.), 19.0-mm ($^3/_4$-in.), and 4.75-mm (No. 4) sieves conforming to the requirements of M 92.

3.8. *Mixing Tools*—Miscellaneous tools such as a mixing pan and trowel, or a suitable mechanical device, for thoroughly mixing the soil with cement and water.

3.9. *Butcher Knife*—A butcher knife approximately 254 mm (10 in.) in length for trimming the top of the specimens.

3.10. *Scarifier*—A six-pronged ice pick or similar apparatus to remove the smooth compaction plane at the top of the first and second layers of the specimen.

3.11. *Container*—A flat, round pan for moisture absorption by soil-cement mixtures, about 305 mm (12 in.) in diameter and 50 mm (2 in.) deep.

3.12. *Measuring Device*—A measuring device suitable for accurately measuring the heights and diameters of test specimens to the nearest 0.25 mm (0.01 in.).

3.13. *Pans and Carriers*—Suitable pans for handling materials and carriers or trays for handling test specimens.

3.14. *Graduate*—A graduated cylinder of 250-mL capacity for measuring water.

3.15. *Moisture Content Container*—As specified in T 265.

METHOD A—USING SOIL MATERIAL PASSING A 4.75-MM (NO. 4) SIEVE

4. PREPARATION OF MATERIAL FOR MOLDING SPECIMENS

4.1. Prepare the soil sample in accordance with the procedure described in Method A of T 134.

4.2. Select a sufficient quantity of the soil prepared as described in T 134 to provide two compacted specimens at the required moisture contents. (See Note 1.)

Note 1—*Optional*: Usually only one specimen (identified as No. 2) is required for routine testing. The other specimen (identified as No. 1) is made for research work and for testing unusual soils.

4.3. Add to the soil the required amount of cement conforming to M 85 or M 240. Mix the soil and cement thoroughly until the color of the mixture is uniform.

4.4. Add sufficient potable water to raise the soil-cement mixture to optimum moisture content at the time of compaction and mix thoroughly. When the soil used is a heavy textured clayey material, compact the mixture of soil, cement, and water in the container to a depth of about 51 mm (2 in.) using the rammer described in T 99 or a similar hand tamper; cover; and allow to stand for not less than 5 minutes but not more than 10 minutes to aid dispersion of the moisture and to permit more complete absorption by the soil-cement. After the absorption period, thoroughly break up the mixture, without reducing the material size of individual particles, until it will pass a 4.75-mm (No. 4) sieve as judged by eye, and then remix.

5. MOLDING SPECIMENS

5.1. Form a specimen by immediately compacting the soil-cement mixture in the mold, with the collar attached and later trimming the specimen in the same manner as directed in T 134, and in addition scarify the tops of the first and second layers to remove smooth compaction planes before placing and compacting the succeeding layers. This scarification shall form grooves at right angles to each other, approximately 3 mm ($^1/_8$ in.) in width and 6.4 mm ($^1/_4$ in.) in depth and approximately 6.4 mm ($^1/_4$ in.) apart. During compaction, take from the batch a representative sample of the soil-cement mixture having a mass of not less than 100 g. Determine the mass immediately and dry in accordance with T 265. Calculate the percentage of moisture content as prescribed in Section 7 of T 134 to check against design moisture content.

5.2. Determine the mass of the compacted specimen and mold, remove the specimen from the mold, weigh the oven-dry mass in kilograms, and calculate the dry density in kilograms per cubic meter (pounds per cubic foot) to check against the design density.

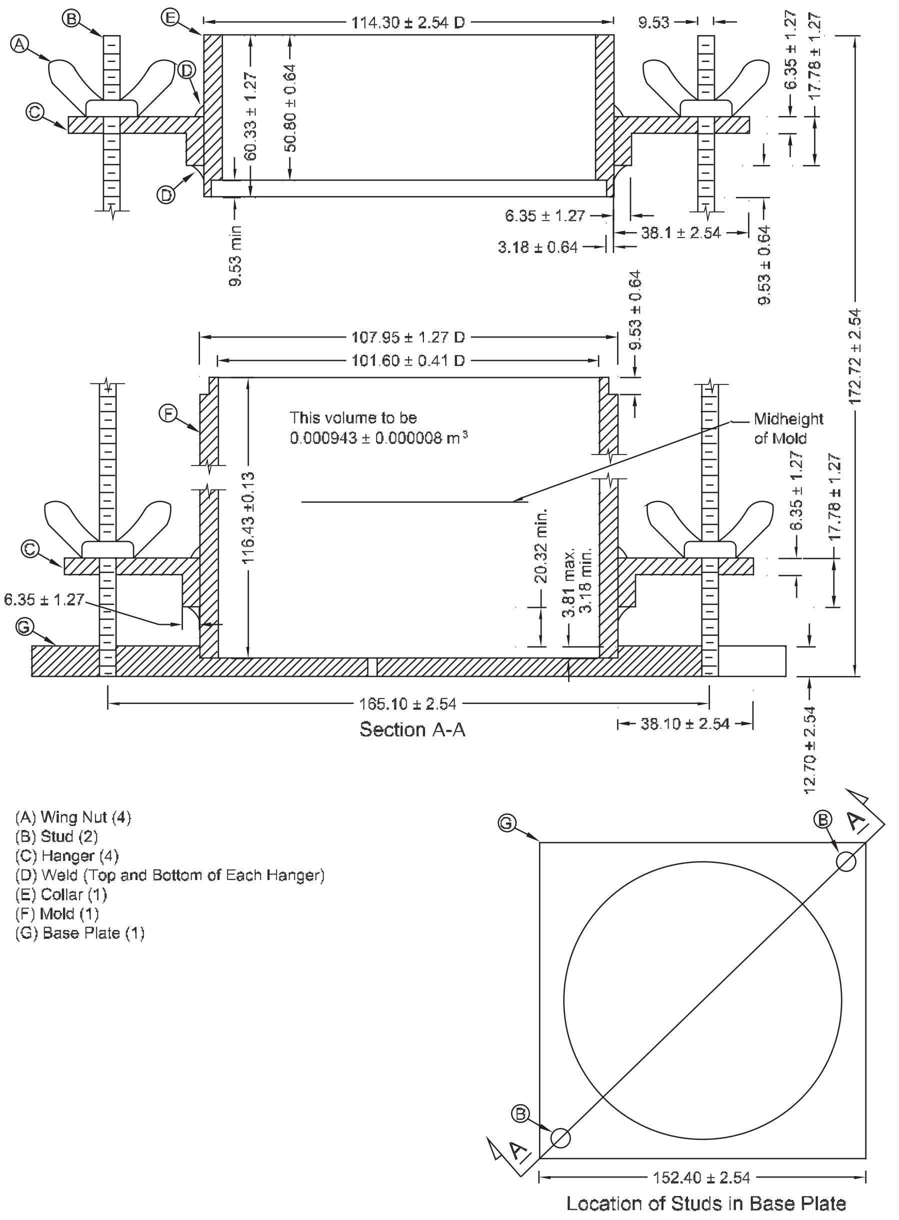
5.3. Identify the specimen on a metal tag (or other suitable device) as No. 1 (Note 3) together with other needed identification marks and use to obtain data on moisture and volume changes during the test.

5.4. Form a second specimen as rapidly as possible and determine the percentage of moisture content and oven-dry mass as described in Sections 5.1 and 5.2. Identify this specimen as No. 2, together with other needed identification marks, and use to obtain data on soil-cement losses during the test.

5.5. Determine the average diameter and height of the No. 1 specimen and calculate its volume.

5.6. Place the specimens on suitable carriers in the moist room and protect them from free water for a period of seven days. Determine the mass and measure the No. 1 specimen at the end of the seven-day storage period to provide data for calculating its moisture content and volume. (See Note 2.)

Note 2—It is important that all height and diameter measurements be accurate to within 0.25 mm (0.01 in.) and be taken at the same points on the specimen at all times.



Dimensional Equivalents

mm	in.	mm	in.	mm	in.
3.18 ± 0.64	(0.125 ± 0.025)	17.78 ± 1.27	(0.700 ± 0.050)	107.95 ± 1.27	(4.250 ± 0.050)
3.81	(0.150)	20.32	(0.800)	114.30 ± 2.54	(4.500 ± 0.100)
6.35 ± 1.27	(0.250 ± 0.050)	38.10 ± 2.54	(1.500 ± 0.100)	116.43 ± 0.13	(4.584 ± 0.005)
7.62	(0.300)	50.80 ± 0.64	(2.000 ± 0.025)	152.40 ± 2.54	(6.000 ± 0.100)
9.53 ± 0.64	(0.375 ± 0.025)	60.33 ± 1.27	(2.375 ± 0.050)	165.10 ± 2.54	(6.500 ± 0.100)
12.70 ± 2.54	(0.500 ± 0.100)	101.60 ± 0.41	(4.000 ± 0.016)	172.72 ± 2.54	(6.800 ± 0.100)

0.000943 ± 0.000008 m^3 (1/30 ± 0.0003 ft^3)

Notes:
1. All dimensions shown in millimeters unless otherwise noted.
2. Hanger on the mold portion only cannot extend above the midheight line.
3. Figure 1 is to be used for all compaction molds purchased after the publication of the 21st edition (HM-21).
4. Not to scale.

Figure 1—Cylindrical Mold and Base Plate (101.6 mm Mold)

6. PROCEDURE

6.1. At the end of the storage in the moist room, submerge the specimens in potable water at room temperature for a period of 5 hours. Blot, weigh, and measure the No. 1 specimen (volume and moisture change specimen).

6.2. Place both specimens in an oven at 71 ± 3ºC (160 ± 5ºF) for 42 hours and remove. Determine the mass and measure the No. 1 specimen. Give specimen No. 2 (soil-cement loss specimen) two firm strokes on all areas with the wire scratch brush. The brush shall be held with the long axis of the brush parallel to the longitudinal axis of the specimen or parallel to the ends as required to cover all areas of the specimen. Apply these strokes to the full height and width of the specimen with a firm stroke corresponding to approximately 13.3 N (3 lb). (See Note 3.) Eighteen to 20 vertical brush strokes are required to cover the sides of the specimen twice and four strokes are required on each end.

Note 3—This pressure is measured as follows: Clamp a specimen in a vertical position on the edge of a platform scale and zero the scale. Apply vertical brushing strokes to the specimen and note the force necessary to register approximately 13.3 N (3 lbf).

6.3. The procedures described in Sections 6.1 and 6.2 constitute one cycle (48 hours) of wetting and drying. Again submerge the specimens in water and continue the procedure for 12 cycles. (See Note 4.) The No. 1 specimen may be discontinued prior to 12 cycles should the measurements become inaccurate due to soil-cement loss of the specimen. (See Note 5.)

Note 4—Mass determinations of specimen No. 2 before and after brushing are usually made at the end of each cycle when conducting research and making special investigations.

Note 5—If it is not possible to run the cycles continuously because of Sundays, holidays, or for any other reason, hold the specimens in the oven during the layover period if possible.

6.4. After 12 cycles of test, dry the specimens in accordance with T 265, Section 5, and weigh to determine the oven-dry mass of the specimens.

6.5. The data collected will permit calculations of volume and moisture changes of specimen No. 1 and the soil-cement losses of specimen No. 2 after the prescribed 12 cycles of test.

METHOD B—USING MATERIAL PASSING A 19.0-MM ($^3/_4$-IN.) SIEVE

7. PREPARATION OF MATERIAL FOR MOLDING SPECIMENS

7.1. Prepare the soil sample in accordance with Method B (Section 5) of T 134.

7.2. Select and maintain separate representative samples of soil passing the 4.75-mm sieve (No. 4) and of saturated, surface-dry aggregate passing the 19.0-mm ($^3/_4$-in.) sieve and retained on the 4.75-mm (No. 4) sieve so that the total sample will be enough to provide (Note 1) compacted specimens and required moisture samples. The percentage, by oven-dry mass, of aggregate passing the 19.0-mm ($^3/_4$-in.) sieve and retained on the 4.75-mm (No. 4) sieve shall be the same as the percentage passing the 75-mm (3-in.) sieve and retained on the 4.75-mm (No. 4) sieve in the original sample.

7.3. Add to the sample passing the 4.75-mm (No. 4) sieve the required amount of cement conforming to M 85 or M 240 required for the total sample specified in Section 7.2. Mix the soil and cement thoroughly until the color of the mixture is uniform.

7.4. Add to the sample passing the 4.75-mm (No. 4) sieve sufficient water to raise the total soil-cement mixture prescribed in Section 7.2 to optimum moisture content at time of compaction and facilitate moisture dispersion as described for Method A in Section 4.4.

7.5. After preparation of the mixture as described in Sections 7.1 to 7.4, add the saturated, surface-dry aggregate to the mixture and mix thoroughly.

8. MOLDING SPECIMENS

8.1. Form a specimen by immediately compacting the soil-cement mixture in the mold (with the collar attached) and later trimming the specimen in accordance with Section 6.2 of T 134; and in addition, as the mixture for each layer is placed in the mold, spade along the inside of the mold with a butcher knife before compaction to obtain uniform distribution of the material retained on the 4.75-mm sieve and scarify the tops of the first and second layers as described in Section 5.1 of this method. During compaction, take from the batch a representative sample of the soil-cement mixture having a mass of not less than 500 g, determine the mass immediately, and dry in accordance with T 265, Section 5, to determine the moisture content to check against design moisture content. Form a second specimen as rapidly as possible in the same manner.

8.2. Determine the mass of each compacted specimen with mold, remove the specimen from the mold, weigh the oven-dry mass, and calculate the dry density to check against the design density, identify and measure the No. 1 specimen (Note 1), place in the moist room, and measure the No. 1 specimen again at the end of the seven-day storage period as described in Sections 5.2 to 5.6. (See Note 2.)

9. PROCEDURE

9.1. Proceed as directed in Section 6.

CALCULATIONS AND REPORT

10. CALCULATIONS

10.1. Calculate the volume and moisture changes and the soil-cement losses of the specimens as follows:

10.1.1. Calculate the difference between the volume of specimen No. 1 at the time of molding and subsequent volumes as a percentage of the original volume.

10.1.2. Calculate the moisture content of specimen No. 1 at the time of molding and subsequent moisture contents as a percentage of the original oven-dry mass of the specimen.

10.1.3. Correct the oven-dry mass of specimen No. 2 as obtained in Section 6.4 for water that has reacted with the cement and soil during the test and is retained in the specimen at 110ºC (230º F), as follows:

$$\text{Corrected Oven-Dry Mass} = \frac{A}{B} \times 100 \qquad (1)$$

where:

A = oven-dry mass after drying at 110ºC (230ºF), and

B = percentage of water retained in specimen, plus 100.

The percentage of water retained in specimen No. 2 after drying at 110ºC (230ºF) for use in the above formula can be assumed to be equal to the water retained in specimen No. 1. When No. 1 specimens are not molded, the foregoing data are not available and the average values prescribed in Table 2 are used.

Table 1—Average Values

Soil Classification (AASHTO Designation M 145)	Average Water Retained After Drying at 110°C, Mass Percent
A-1, A-3	1.5
A-2	2.5
A-4, A-5	3.0
A-6, A-7	3.5

10.1.4. Calculate the soil-cement loss of specimen No. 2 as a percentage of the original oven-dry mass of the specimen as follows:

$$\text{Soil-Cement Loss, Percent} = \frac{A}{B} \times 100 \tag{2}$$

where:

A = original calculated oven-dry mass minus final corrected oven-dry mass, and

B = original calculated oven-dry mass.

11. REPORT

11.1. The report shall include the following:

11.1.1. The designed optimum moisture content and maximum density of the molded specimens;

11.1.2. The moisture content and density obtained in molded specimens (See Note 6);

Note 6—Good laboratory practice permits the following tolerances between design factors and those obtained in the molded specimens:

- Moisture content, ±1 percentage point
- Density, ±48 kg/m^3 (3 lb/ft^3)

11.1.3. The designed cement content, in percent, of the molded specimens;

11.1.4. The cement content, in percent, obtained in molded specimens;

11.1.5. The maximum volume change, in percent, and maximum moisture content during test of specimen No. 1; and

11.1.6. The soil-cement loss, in percent, of specimen No. 2.

Standard Method of Test for

Freezing-and-Thawing Tests of Compacted Soil-Cement Mixtures

AASHTO Designation: T 136-97 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Freezing-and-Thawing Tests of Compacted Soil-Cement Mixtures

AASHTO Designation: T 136-97 (2009)

1. SCOPE

1.1. These methods cover procedures for determining the soil-cement losses, moisture changes, and volume changes (swell and shrinkage) produced by the repeated freezing and thawing of hardened soil-cement specimens. The specimens are compacted in a mold, before cement hydration, to maximum density at optimum moisture content using the compaction procedure described in T 134.

1.2. Two methods depending on soil gradation are covered for preparation of material for molding specimens and molding specimens as follows:

1.2.1. *Method A*—Using soil material passing the 4.75-mm (No. 4) sieve. This method shall be used when 100 percent of the soil sample passes the 4.75-mm (No. 4) sieve. (See Sections 4 to 6.)

1.2.2. *Method B*—Using soil material passing the 19.0-mm ($^3/_4$-in.) sieve. This method shall be used when part of the soil sample is retained on 4.75-mm sieve. (See Sections 7 to 9.)

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 85, Portland Cement
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- M 240, Blended Hydraulic Cement
- T 99, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop
- T 134, Moisture-Density Relations of Soil-Cement Mixtures
- T 265, Laboratory Determination of Moisture Content of Soils

3. APPARATUS

3.1. *Molds 101.6 mm (4 in.), Rammer, Sample Extruder, and Straightedge*—As specified in T 99.

3.2. Both scales and balances shall meet the requirements of M 231. A balance or scale having a capacity of at least 11.5 kg (25.4 lb) and conforming to the requirements for a G 20 class scale and a balance of at least 1-kg (2-lb) capacity and conforming to the requirements of a G 2 class scale.

3.3. *Drying Oven*—A thermostatically controlled drying oven capable of maintaining a temperature of 110 ± 5ºC (230 ± 9ºF) for drying moisture samples.

3.4. *Freezing Cabinet*—A freezing cabinet capable of maintaining temperatures of –23ºC (–10ºF) or lower.

3.5. *Moist Room*—A moist room or suitable covered container capable of maintaining a temperature of 21.0 ± 1.7ºC (70 ± 3ºF) and a relative humidity of 100 percent for seven-day storage of compacted specimens and for thawing frozen specimens.

3.6. *Wire Scratch Brush*—A wire scratch brush made of 50 by 1.6 mm (2 by $^1/_{16}$ in.) flat No. 26 gauge wire bristles assembled in 50 groups of 10 bristles each and mounted to form five longitudinal rows and 10 transverse rows of bristles on a 190 by 65 mm ($7^1/_2$ by $2^1/_2$ in.) hardwood block.

3.7. *Sieves*—75-mm (3-in.), 19.0-mm ($^3/_4$-in.), 4.75-mm (No. 4) sieves conforming to the requirements of M 92.

3.8. *Mixing Tools*—Miscellaneous tools such as mixing pan, and trowel, or a suitable mechanical device for thoroughly mixing the soil with cement and water.

3.9. *Butcher Knife*—A butcher knife approximately 254 mm (10 in.) in length for trimming the top of the specimens.

3.10. *Scarifier*—A six-pronged ice pick or similar apparatus to remove the smooth compaction plane at the top of the first and second layers of the specimen.

3.11. *Container*—A flat, round pan, for moisture absorption by soil-cement mixtures about 305 mm (12 in.) in diameter and 50 mm (2 in.) deep.

3.12. *Measuring Device*—A measuring device suitable for accurately measuring the heights and diameters of test specimens to the nearest 0.25 mm (0.01 in.).

3.13. *Pans and Carriers*—Suitable pans for handling materials and carriers or trays for handling test specimens.

3.14. *Absorptive Pads*—6.4-mm ($^1/_4$-in.) thick felt pads, blotters, or similar absorptive material for placing between specimens and specimen carriers.

3.15. *Graduate*—A graduated cylinder of 250-mL capacity for measuring water.

3.16. *Moisture Content Containers*—As specified in T 265.

METHOD A—USING SOIL MATERIAL PASSING A 4.75-MM (NO. 4) SIEVE

4. PREPARATION OF MATERIAL FOR MOLDING SPECIMENS

4.1. Prepare the soil sample in accordance with Method A of T 134.

4.2. Select a sufficient quantity of the soil prepared as described in T 134 to provide two compacted specimens and required moisture samples. (See Note 1.)

Note 1—*Optional*: Usually only one specimen (identified as No. 2) is required for routine testing. The other specimen (identified as No. 1) is made for research work and for testing unusual soils.

4.3. Add to the soil the required amount of cement conforming to M 85 or M 240. Mix the soil and cement thoroughly until the color of the mixture is uniform.

4.4. Add sufficient potable water to raise the soil-cement mixture to optimum moisture content at time of compaction and mix thoroughly. When the soil used is a heavy-textured, clayey material, compact the mixture of soil, cement, and water in a container to a depth of about 50 mm (2 in.) using the rammer described in T 99 or similar hand tamper; cover; and allow to stand for not less than 5 minutes but not more than 10 minutes to aid dispersion of the moisture and to permit more complete absorption by the soil-cement. After the absorption period, thoroughly break up the mixture, without reducing the natural size of individual particles, until it will pass a 4.75-mm (No. 4) sieve, as judged by eye, and then remix.

5. MOLDING SPECIMENS

5.1. Form a specimen by immediately compacting the soil-cement mixture in the mold, with the collar attached, and later trimming the specimen in the same manner as directed in T 134, and in addition scarify the tops of the first and second layers to remove smooth compaction planes before placing and compacting the succeeding layers. This scarification shall form grooves at right angles to each other, approximately 3 mm ($^1/_8$ in.) in width and 3 mm ($^1/_8$ in.) in depth and approximately 6 mm ($^1/_4$ in.) apart. During compaction, take from the batch a representative sample of the soil-cement mixture, having a mass of not less than 100 g. Determine the mass immediately and dry in accordance with T 265. Calculate the percentage of moisture as directed in T 134 to check against design moisture content.

5.2. Determine the mass of the compacted specimen and mold, remove the specimen from the mold, and calculate the oven-dry mass of each specimen in kilograms per cubic meter (lb/ft^3) to check against design density.

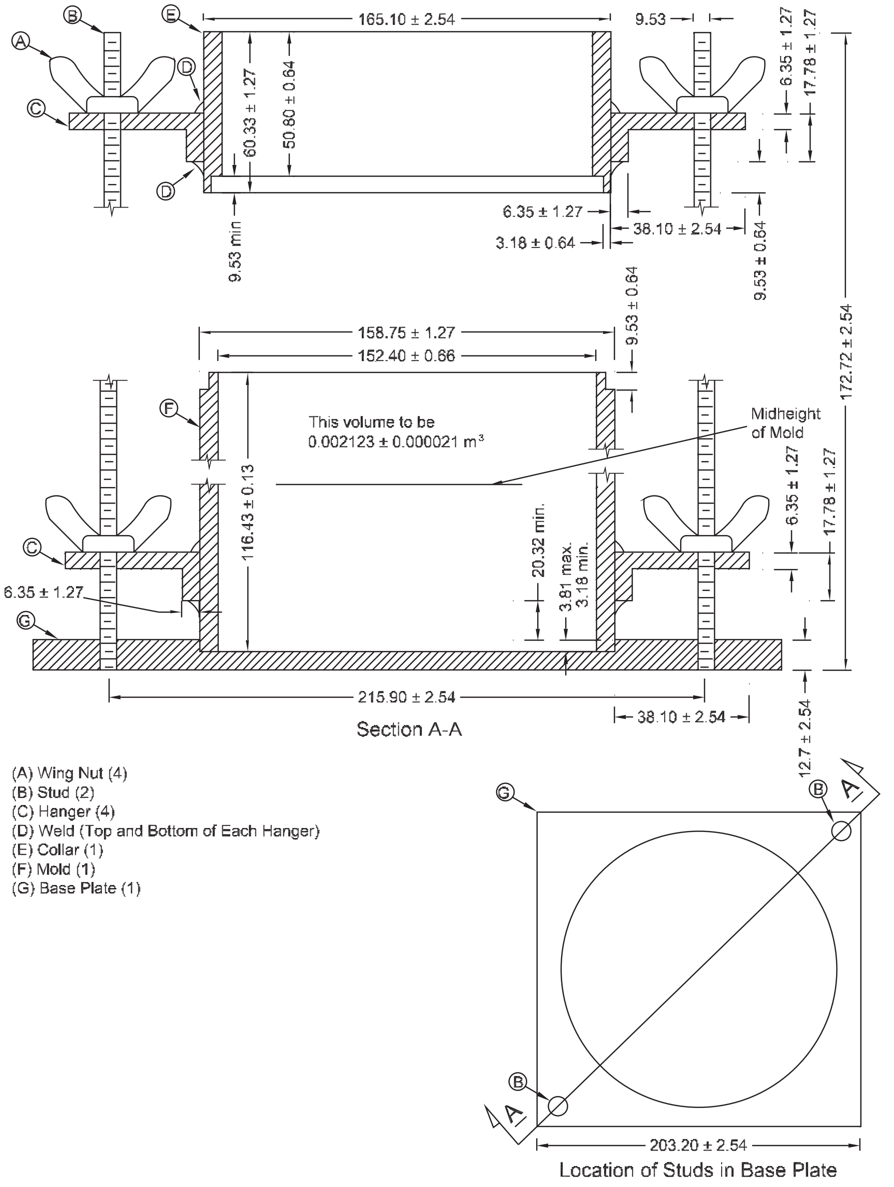
5.3. Identify the specimen on a metal tag (or other suitable device) as No. 1 (Note 3) together with other needed identification marks and use to obtain data on moisture and volume changes during the test.

5.4. Form a second specimen as rapidly as possible and determine the percentage of moisture and oven-dry mass as described in Sections 5.1 and 5.2. Identify this specimen as No. 2, together with other needed identification marks, and use to obtain data on soil-cement losses during the test.

5.5. Determine the average diameter and height of the No. 1 specimen and calculate its volume.

5.6. Place the specimens on suitable carriers in the moist room and protect them from free water for a period of seven days. Determine the mass and measure the No. 1 specimen at the end of the seven-day storage period to provide data for calculating its moisture content and volume. (See Note 2.)

Note 2—It is important that all height and diameter measurements be accurate to within 0.25 mm, (0.01 in.) and be taken at the same points on the specimen at all times.



Dimensional Equivalents

mm	in.	mm	in.	mm	in.
3.18 ± 0.64	(0.125 ± 0.025)	17.78 ± 1.27	(0.700 ± 0.050)	107.95 ± 1.27	(4.250 ± 0.050)
3.81	(0.150)	20.32	(0.800)	114.30 ± 2.54	(4.500 ± 0.100)
6.35 ± 1.27	(0.250 ± 0.050)	38.10 ± 2.54	(1.500 ± 0.100)	116.43 ± 0.13	(4.584 ± 0.005)
7.62	(0.300)	50.80 ± 0.64	(2.000 ± 0.025)	152.40 ± 2.54	(6.000 ± 0.100)
9.53 ± 0.64	(0.375 ± 0.025)	60.33 ± 1.27	(2.375 ± 0.050)	165.10 ± 2.54	(6.500 ± 0.100)
12.70 ± 2.54	(0.500 ± 0.100)	101.60 ± 0.41	(4.000 ± 0.016)	172.72 ± 2.54	(6.800 ± 0.100)

0.000943 ± 0.00008 m^3 (1/30 ± 0.0003 ft^3)

Notes:
1. All dimensions shown in millimeters unless otherwise noted.
2. Hanger on the mold portion only cannot extend above the midheight line.
3. Figure 1 is to be used for all compaction molds purchased after the publication of the 21st edition (HM-21).
4. Not to scale.

Figure 1—Cylindrical Mold and Base Plate (101.6-mm Mold)

6. PROCEDURE

6.1. At the end of the storage in the moist room, place water-saturated felt pads about 6.4 mm ($^1/_4$ in.) thick, blotters, or similar absorptive material between the specimens and the carriers, and place the assembly in a freezing cabinet having a constant temperature not warmer than –23ºC (–10ºF) for 24 hours and remove. Determine the mass and measure the No. 1 specimen (volume and moisture change specimen).

6.2. Place the assembly in the moist room or suitable covered container having a temperature of 21.0 ± 1.7ºC (70 ± 3ºF) and a relative humidity of 100 percent for 23 hours and remove. Free potable water shall be made available to the absorbent pads under the specimens to permit the specimens to absorb water by capillary action during the thawing period. Determine the mass and measure the No. 1 specimen. Give specimen No. 2 (soil-cement loss specimen) two firm strokes on all areas with the wire scratch brush. The brush shall be held with the long axis of the brush parallel to the longitudinal axis of the specimen or parallel to the ends as required to cover all areas of the specimen. Apply these strokes to the full height and width of the specimen with a firm stroke corresponding to approximately 13.3 N (3 lbf). (See Note 3.) Eighteen to 20 vertical brush strokes are required to cover the sides of the specimen twice and four strokes are required on each end. After being brushed, the specimens shall be turned over end for end before they are replaced on the water-saturated pads.

Note 3—This pressure is measured as follows: clamp a specimen in a vertical position on the edge of a platform scale and zero the scale. Apply vertical brushing strokes to the specimen and note the force necessary to register approximately 13.3 N (3 lbf).

6.3. The procedures described in Sections 6.1 and 6.2 constitute one cycle (48 h) of freezing and thawing. Again place the specimens in the freezing cabinet and continue the procedure for 12 cycles. (See Note 4.) The No. 1 specimen may be discontinued prior to 12 cycles should the measurements become inaccurate due to soil-cement loss of the specimen. (See Note 5.)

Note 4—Mass determinations of specimen No. 2 before and after brushing are usually made at the end of each cycle when conducting research and making special investigations. Some specimens made of silty and clayey soils tend to scale on sides and ends particularly after about the sixth cycle of test. This scale shall be removed with a sharp-pointed instrument such as an ice pick, since the regular brushing may not be effective.

Note 5—If it is not possible to run the cycles continuously because of Sundays, holidays, or for any other reason, the specimens shall be held in the freezing cabinet during the layover period if possible.

6.4. After 12 cycles of test, dry the specimens in accordance with T 265, Section 5, and weigh to determine the oven-dry mass of the specimens.

6.5. The data collected will permit calculations of volume and moisture changes of specimen No. 1 and the soil-cement losses of specimen No. 2 after the prescribed 12 cycles of test.

METHOD B—USING MATERIAL PASSING A 19.0-MM ($^3/_4$-IN.) SIEVE

7. PREPARATION OF MATERIAL FOR MOLDING SPECIMENS

7.1. Prepare the soil sample in accordance with Method B of T 134.

7.2. Select and maintain separate representative samples of soil passing the 4.75-mm (No. 4) sieve and of saturated, surface-dry aggregate passing the 19.0-mm ($^3/_4$-in.) sieve and retained on the 4.75-mm (No. 4) sieve so that the total sample will be enough to provide two (Note 1) compacted specimens and required moisture samples. The percentage, by oven-dry mass, of aggregate passing the 19.0-mm ($^3/_4$-in.) sieve and retained on the 4.75-mm (No. 4) sieve shall be the same as the percentage passing the 75-mm (3-in.) sieve and retained on the 4.75-mm (No. 4) sieve in the original sample.

7.3. Add to the sample passing the 4.75-mm (No. 4) sieve the required amount of cement conforming to M 85 or M 240. Mix the soil and cement thoroughly until the color of the mixture is uniform.

7.4. Add to the sample passing the 4.75-mm (No. 4) sieve sufficient water to raise the total soil-cement mixture specified in Section 7.2 to optimum moisture content at time of compaction and facilitate moisture dispersion as described for Method A in Section 4.4.

7.5. After preparation of the mixture as described in Sections 7.1 to 7.4, add the saturated, surface-dry aggregate to the mixture and mix thoroughly.

8. MOLDING SPECIMENS

8.1. Form a specimen by immediately compacting the soil-cement mixture in the mold (with the collar attached) and later trimming the specimen in accordance with T 134. In addition, as the mixture for each layer is placed in the mold, spade along the inside of the mold with a butcher knife before compaction to obtain uniform distribution of the material retained on the 4.75-mm (No. 4) sieve and scarify the tops of the first and second layers as described in Section 5.1 of this method. During compaction, take from the batch a representative sample of the soil-cement mixture having a mass of not less than 500 g, determine the mass immediately, and dry in accordance with T 265 to determine the moisture content to check against design moisture content. Form a second specimen as rapidly as possible in the same manner.

8.2. Determine the mass of each compacted specimen to check against design density, identify, measure the No. 1 specimen (Note 1), place in the moist room, and measure the No. 1 specimen again at the end of the seven-day storage period as described in Sections 5.2 to 5.6. (See Note 2.)

9. PROCEDURE

9.1. Proceed as directed in Section 6.

CALCULATIONS AND REPORT

10. CALCULATIONS

10.1. Calculate the volume and moisture changes and the soil-cement losses of the specimens as follows:

10.1.1. Calculate the difference between the volume of specimen No. 1 at the time of molding and subsequent volumes as a percentage of the original volume.

10.1.2. Calculate the moisture content of specimen No. 1 at the time of molding and subsequent moisture contents as a percentage of the original oven-dry mass of the specimen.

10.1.3. Correct the oven-dry mass of specimen No. 2 as obtained in Section 6.4 for water that has reacted with the cement and soil during the test and is retained in the specimen at 110ºC (230ºF) as follows:

$$\text{Corrected Oven-Dry Mass} = \frac{A}{B} \times 100 \quad (1)$$

where:

A = oven-dry mass after drying at 110ºC (230ºF), and

B = percentage of water retained in specimen, plus 100.

The percentage of water retained in specimen No. 2 after drying at 110ºC (230ºF) for use in the above formula can be assumed to be equal to the water retained in specimen No. 1. When No. 1 specimens are not molded, the foregoing data are not available and the average values prescribed in Table 2 are used.

Table 1—Average Values

Soil Classification (AASHTO Designation M 145)	Average Water Retained After Drying at 110°C, Mass Percent
A-1, A-3	1.5
A-2	2.5
A-4, A-5	3.0
A-6, A-7	3.5

10.1.4. Calculate the soil-cement loss of specimen No. 2 as a percentage of the original oven-dry mass of the specimen as follows:

$$\text{Soil-Cement Loss, Percent} = \frac{A}{B} \times 100 \quad (2)$$

where:

A = original calculated oven-dry mass minus final corrected oven-dry mass, and

B = original calculated oven-dry mass.

11. REPORT

11.1. The report shall include the following:

11.1.1. The designed optimum moisture and maximum density of the molded specimens;

11.1.2. The moisture content and density obtained in molded specimens (Note 6);

Note 6—Good laboratory practice permits the following tolerances between design factors and those obtained in the molded specimens:

- Moisture content, ±1 percentage point
- Density, ±48 kg/m^3 (3 lb/ft^3)

11.1.3. The designed cement content, in percent, of the molded specimens;

11.1.4. The cement content, in percent, obtained in molded specimens;

11.1.5. The maximum volume change, in percent, and maximum moisture content during test of specimen No. 1; and

11.1.6. The soil-cement loss, in percent, of specimen No. 2.

Standard Method of Test for

Wet Preparation of Disturbed Soil Samples for Test

AASHTO Designation: T 146-96 (2008)

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Wet Preparation of Disturbed Soil Samples for Test

AASHTO Designation: T 146-96 (2008)

1. SCOPE

1.1. These methods of test cover the wet preparation of soil samples, as received from the field, for mechanical analysis and the determination of soil constants.

1.2. Method A provides for drying the field samples at a temperature not exceeding 60ºC (140ºF), making a wet separation on the 0.425-mm (No. 40) sieve and drying to a temperature not exceeding 60ºC (140ºF). Method B provides that the field sample shall be kept at a moisture content equal to or greater than the natural moisture content. Samples of such soil should be shipped to the laboratory in sealed containers and not allowed to dry out before testing. If no procedure is specified, Method A shall govern.

1.3. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with E 29, Using Significant Digits in Test Data to Determine Conformance with Specifications.

1.4. The values stated in SI units are to be regarded as the standard.

2. SIZE OF SAMPLE

2.1. Moist samples having the dry masses designated for physical tests described in T 87, Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test, shall be obtained.

3. APPARATUS

3.1. The apparatus shall consist of that listed in Section 2 of T 87, and the following:

3.1.1. *Drying Apparatus*—A thermostatically controlled drying oven for use at 110 ± 5ºC (230 ± 9ºF) and a suitable device capable of drying samples at a temperature not exceeding 60ºC (140ºF).

3.1.2. *Filter Funnels or Candles (Optional)*—Buchner funnels 254 mm (10 in.) in diameter and filter paper or filter candles.

3.1.3. *Miscellaneous Equipment*—Pans 300 mm (12 in.) in diameter by 75 mm (3 in.) in depth or other suitable containers that can accommodate a 203-mm (8 in.) diameter sieve for collecting the wash water; a suitable container that will prevent loss of moisture during storage of the moist test sample.

METHOD A

4. PROCEDURE

4.1. The soil sample as received from the field shall be dried thoroughly in air, in a warming oven whose temperature is not above 60ºC (140ºF), or by means of a device that will not raise the temperature of the samples above 60ºC (140ºF). The aggregations shall then be thoroughly broken up in the mortar with a rubber-covered pestle or suitable mechanical device in such a way as to avoid reducing the natural size of individual particles. A representative test sample of the amount required to perform the desired tests shall then be selected by the method of quartering or by the use of a sampler.

4.2. The portion of the air-dried sample selected for the purpose of mechanical analysis and physical tests shall be weighed and the mass recorded as the mass of the total sample uncorrected for hygroscopic moisture. The test sample shall then be separated into two portions by means of a 0.425-mm sieve. The material passing the 0.425-mm sieve shall be set aside for later recombination with additional material as described in Sections 4.3 to 4.7.

4.3. The material retained on the 0.425-mm sieve shall be placed in a pan, covered with water, and allowed to soak for a period of 2 to 24 hours until the particle aggregations have become soft and broken down.

4.4. After soaking, the material shall be washed on a 0.425-mm sieve in the following manner: The empty 0.425-mm sieve shall be set in the bottom of a pan and the liquid from the sample poured into it. Enough additional water shall be added to bring the level of the water in the pan approximately 13 mm ($^1/_2$ in.) above the mesh of the sieve. A portion of the soaked material not to exceed 0.45 kg (one lb) in mass shall be placed in the water on the 0.425-mm sieve and stirred by hand at the same time the sieve is agitated up and down. If the material retained on the 0.425-mm sieve contains lumps that have not slaked or disintegrated, but which can be crumbled or mashed between the thumb and finger so as to pass the 0.425-mm sieve, such lumps shall be broken and washed through the sieve into the pan. After all lumps have been broken up, the sieve shall be held above the soil and water in the pan and the material remaining on the sieve shall be washed with a small amount of clean water. The washed material retained on the 0.425-mm sieve shall be transferred to a clean pan.

4.5. Another increment of the soaked material, not exceeding 0.5 kg (one lb) in mass shall be placed on the 0.425-mm sieve and washed as described in Section 4.4. This procedure shall be repeated until all of the soaked sample has been washed.

4.6. The material retained on the 0.425-mm sieve shall be dried and dry-sieved on the 0.425-mm sieve. The material passing the 0.425-mm sieve in this operation shall be added to the material passing the 0.425-mm sieve obtained by the procedure described in Section 4.2. The material retained on the 0.425-mm sieve shall be set aside for use in the mechanical analysis of the coarse material.

4.7. After all the soaked material has been washed, the pan containing the wash water shall be set aside and not disturbed for a period of several hours until all of the soil particles have settled to the bottom of the pan and the water above the soil is clear (Note 1). As much of the clear water as possible shall then be decanted or siphoned off. The soil remaining in the pan shall be dried at a temperature not exceeding 60ºC (140ºF). The dried soil shall be ground in the mortar with a rubber-covered pestle or suitable mechanical device and combined with the material passing the 0.425-mm sieve obtained by the procedures described in Sections 4.2 and 4.6.

Note 1—In some instances, the wash water will not become clear in a reasonable length of time, in which case the entire volume must be evaporated.

4.7.1. *(Alternate Section 4.7)*—After all of the soaked material has been washed, the wash water and material passing the 0.425-mm sieve shall be filtered on one or more Buchner funnels that have previously been fitted with filter paper. Vacuum shall be applied to the lower end of the Buchner funnels to speed up the filtering process. After filtering, the soil shall be removed from the filter, the filter paper stripped from the damp soil, and the soil dried at a temperature not exceeding 60ºC (140ºF). The dried soil shall be ground in the mortar with a rubber-covered pestle or suitable mechanical device and combined with the material passing the 0.425-mm sieve obtained by the procedures described in Sections 4.2 and 4.6.

5. TEST SAMPLE FOR MECHANICAL ANALYSIS AND SOIL CONSTANTS

5.1. The fractions passing the 0.425-mm sieve obtained as described in Sections 4.2, 4.6, and 4.7 shall be thoroughly mixed. A portion with a mass of approximately 60 g for silt and clay soils shall be selected for mechanical analysis. The remaining portion of the material passing the 0.425-mm sieve shall be used for the determination of the soil characteristics.

METHOD B

6. PROCEDURE

6.1. For rapid mechanical analysis results based on dry mass of the original material, select and weigh a representative portion of the material for oven-dried moisture determination. Determine the moisture content at 110 ± 5ºC (230 ± 9ºF).

6.1.1. Select a representative portion of the moist sample estimated to contain sufficient particles passing the 0.425-mm (No. 40) sieve to make the required tests for determination of soil constants. Soak this selected portion of the moist sample in water until the particle aggregations become soft (Note 2). Samples obviously containing only particles passing the 0.425-mm (No. 40) sieve may be used in the tests to determine soil constants without first washing on the 0.425-mm (No. 40) sieve.

Note 2—In some areas it is possible that the cations of salts present in the tap water may exchange with the natural cations in the soil and alter significantly the values of the soil constants should tap water be used in the soaking and washing operations. Unless it is known that such cations are not present in the tap water, distilled or demineralized water should be used. The soaking and washing operation will remove soluble salts contained in the soil. When soluble salts are present in the soil, the wash water should be saved and evaporated, and the salts returned to the soil sample.

6.2. After soaking, wash the material on a 0.425-mm (No. 40) sieve in the following manner: Place an empty 0.425-mm (No. 40) sieve on the bottom of a clean pan and pour the water from the soaked sample (Note 3) onto the sieve. Add sufficient water to bring the level approximately 13 mm ($^1/_2$ in.) above the mesh of the sieve. Transfer the soaked material to the sieve in workable increments, stirring each increment with the fingers while agitating the sieve up and down. Crumble or mash any lumps that have not slaked, using the thumb and fingers. Raise the sieve above the water in the pan and complete the washing operation using a small amount of clean water. Discard the washed material on the sieve before placing another increment of soaked material on the sieve.

Note 3—In cases where heavy clays are incurred it may be advantageous to use a mechanical stirrer to form a slurry that will more readily pass the 0.425-mm (No. 40) sieve.

6.3. Set aside the pan containing the washings for a period of several hours or until the water above the particles is clear. Decant, pipet, or siphon off as much of the clear water as possible (Note 1).

6.4. Alternatively, after all the soaked material has been washed, remove most of the water by filtering the wash water on one or more Buchner funnels fitted with a filter paper or by using filter candles. Remove the moist soil from the filter paper or filter candles, and combine with the sediment remaining in the pan.

6.5. Reduce the moisture content of the material passing the 0.425-mm (No. 40) sieve until the mass reaches a putty-like consistency (such as 30 to 35 drops of the cup in the liquid limit test) but never below the natural moisture content. Reduction of moisture content may be accomplished by exposure to air at ordinary room temperature, by heating in an oven at a temperature not exceeding 110ºC (230ºF), by boiling, by filtering on a Buchner funnel, or by use of filter candles. During evaporation and cooling, stir the sample often enough to prevent overdrying of the fringes and soil pinnacles on the surface. Cool the heated samples to normal room temperature before testing. For soil samples containing soluble salts, use a method of water reduction that will not eliminate the soluble salts from the test sample. Protect the prepared sample, in a moisture-tight container, from further drying until all required tests have been performed.

7. PRECISION

7.1. Since this preparation for tests produces no numerical values, determination of the precision and accuracy is not applicable.

Standard Method of Test for

Plastic Fines in Graded Aggregates and Soils by Use of the Sand Equivalent Test

AASHTO Designation: T 176-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Plastic Fines in Graded Aggregates and Soils by Use of the Sand Equivalent Test

AASHTO Designation: T 176-08

1. SCOPE

1.1 This test is intended to serve as a rapid test to show the relative proportions of fine dust or claylike material in soils or graded aggregates.

1.2 The following applies to all specified limits in this standard: For the purpose of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with E 29, Using Significant Digits in Test Data to Determine Conformance with Specifications.

1.3 The values stated in SI units are to be regarded as the standard.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 248, Reducing Samples of Aggregate to Testing Size

2.2 *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. SIGNIFICANCE AND USE

3.1 This test method is used to determine the proportion of detrimental fines in the portion passing the 4.75-mm (No. 4) sieve of soils or graded aggregates.

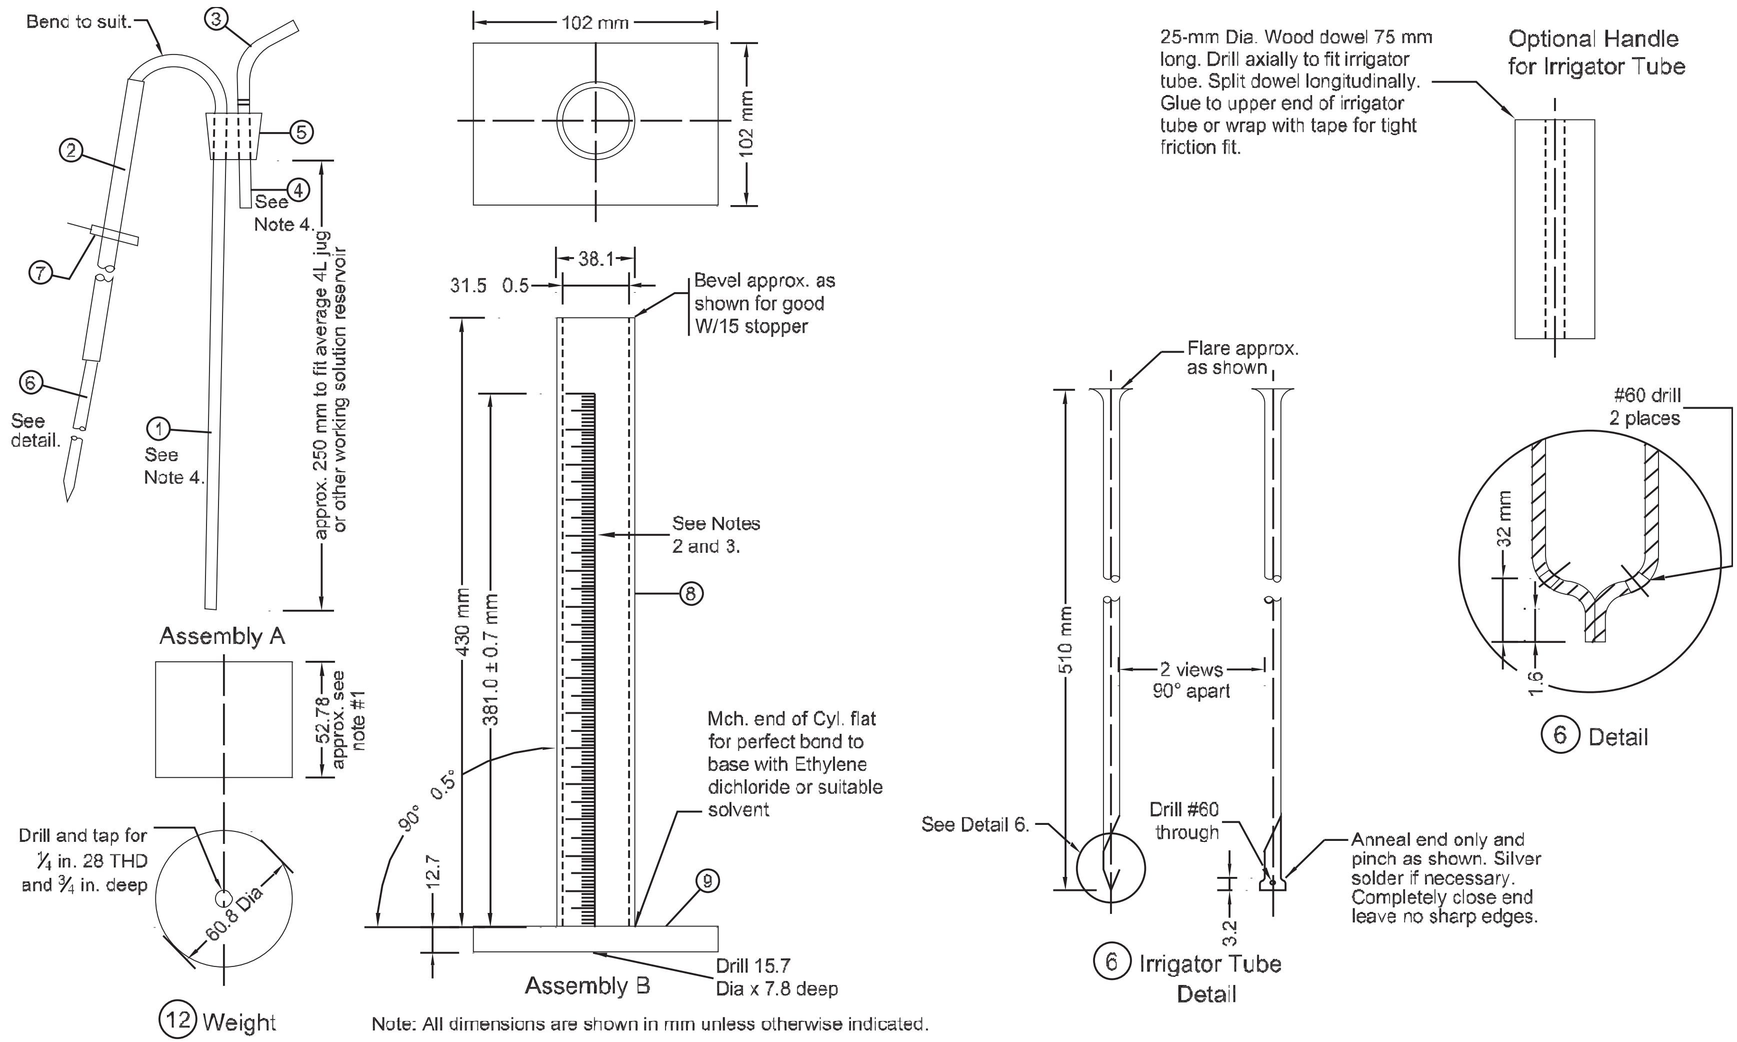
4. APPARATUS

4.1 *Sand Equivalent Apparatus*—A graduated plastic cylinder, rubber stopper, irrigator tube, weighted foot assembly, and siphon assembly, all conforming to their respective specifications and dimensions shown in Figure 1. Fit the siphon assembly to a 4-L (1 gal) bottle of working calcium chloride solution (see Section 2.8) placed on a shelf 915 ± 25 mm (36 ± 1 in.) above the work surface. In lieu of the specified 4-L (1 gal) bottle, a glass or plastic vat having a larger capacity may be used provided the liquid level of the working solution is maintained between 915 and 1170 mm (36 and 46 in.) above the work surface. (See Figure 2.)

Assembly	No. Reg.	Description	Stock Size	Material	Heat Treatment
A		Siphon Assembly			
	1	Siphon Tube	6.4 dia × 400	Copper Tube	
	2	Siphon Hose	4.8 ID × 1220	Rubber Tube	
	3	Blow Hose	4.8 ID × 50.8	Rubber Tube	
	4	Blow Tube	6.4 dia × 50.8	Copper Tube	
	5	Two-Hole Stopper	No. 6	Rubber	
	6	Irrigator Tube	6.4 OD 0.89 Wall × 500 Stainless Tube, Type 316		
	7	Clamp	Pinchcock, Day, BKH No. 21730 or Equiv		
B		Graduate Assembly			
	8	Tube	38.1 OD × 430	Trans Acrylic Plastic	
	9	Base	12.7 × 102 × 102	Trans Acrylic Plastic	
C		Weighted Foot Assembly			
	10	Sand Reading Indicator	6.4 dia × 14.9	Nylon 101 Type 66 Annealed	
	11	Rod	6.4 dia × 438.2	Brass	
	12	Weight	50.8 dia × 52.78	C.R.SH	
	13	Roll Pin	0.16 dia × 12.7	Steel	
	14	Foot	0.16 Hex × 13.7	Brass	
	15	Solid Stopper	No. 7	Rubber	

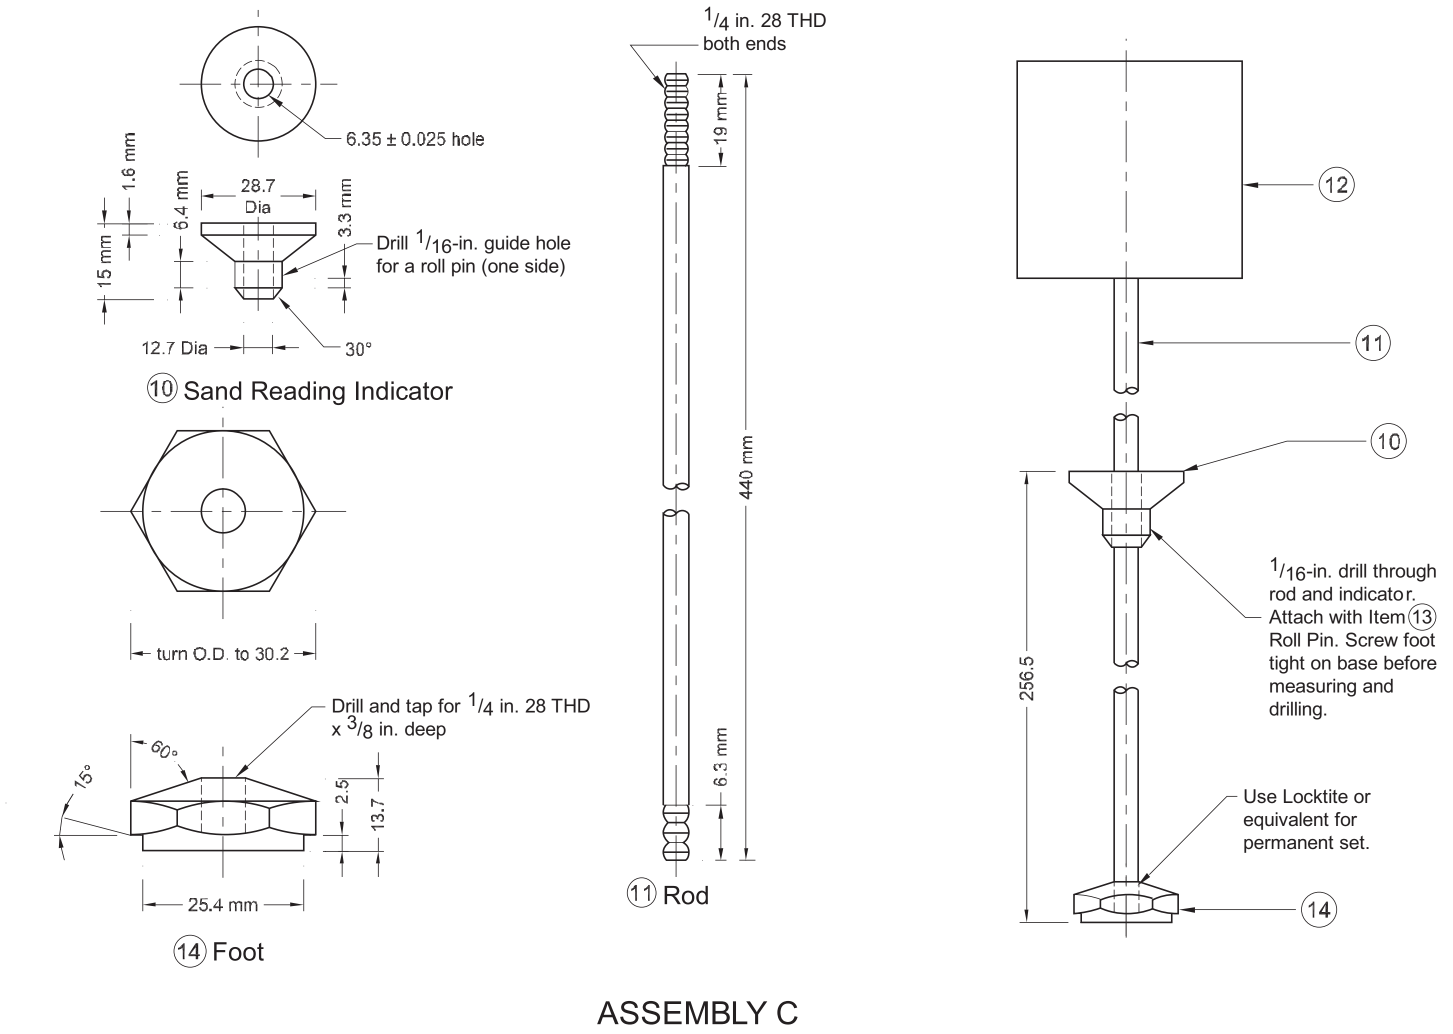
Notes:
1. "C" Weighted Foot Assembly to Weigh 1000 ± 5g.
2. Graduations on graduate to be 2.54 mm apart and every tenth mark to be numerically designated as shown. Every fifth line should be approximately 9.5 mm long. All other lines should be approximately 5.5 mm long. Depth is to be 0.4 mm. Width is to be 0.8 mm across the top.
3. Accuracy of scale to be ±0.25 mm per 2.5 mm. Error at any point on scale to be ±0.75 mm of true distance to zero.
4. Glass or stainless steel may be substituted as a material type for the copper siphon and blow tubing.

Figure 1—Sand Equivalent Apparatus (continued on the following two pages)



Note: All dimensions are shown in mm unless otherwise indicated.

Figure 1—Sand Equivalent Apparatus (*continued*)



Note: All dimensions are shown in mm unless otherwise indicated.

Figure 1—Sand Equivalent Apparatus (*continued*)

Figure 2—Graduated Cylinder, Irrigator Tube, Weighted Foot Assembly, and Siphon

Note 1—An older model of a weighted foot assembly has a guide cap that fits over the upper end of the graduated cylinder and centers the rod in the cylinder; the foot of the assembly has a conical upper surface and three centering screws to center it loosely in the cylinder. The older model does not have the sand reading indicator affixed to the rod (Figure 1), but a slot in the centering screws of the weighted foot is used to indicate the sand reading. Apparatus with the sand reading indicator (Figure 1) is preferred for testing clayey materials.

4.2 *Measure*—A tinned measure, having a capacity of 85 ± 5 mL (3 oz), approximately 57 mm (2.25 in.) in diameter.

4.3 *Balance*—The balance shall have sufficient capacity, be readable to not more than 0.1 percent of the sample mass, and conform to the requirements of M 231.

4.4 *Funnel*—A wide-mouth funnel approximately 100 mm (4 in.) in diameter at the mouth.

4.5 *Timer*—A clock or watch reading in minutes and seconds.

4.6 *Mechanical Shaker*—A mechanical shaker having a throw of 203.2 ± 1.0 mm (8.00 ± 0.04 in.) and operating at 175 ± 2 cycles per minute (2.92 ± 0.03 Hz) (Note 2). Prior to use, fasten the mechanical sand equivalent shaker securely to a firm and level mount.

4.7 *Manual Shaker*—A manually operated shaker, capable of producing an oscillating motion at the rate of 100 complete cycles in 45 ± 5 seconds, with a hand-assisted half stroke length of

127 ± 5 mm (5.0 ± 0.2 in.). The shaker shall be fastened securely to a firm and level mount by bolts or clamps if a large number of determinations are to be made.

Note 2—The mechanical shaker shall be used when performing referee sand equivalent determinations. Either the mechanical or manually operated shaker should be used in lieu of the hand method whenever possible.

4.8 *Stock Solution*—The materials listed in Sections 4.8.1, 4.8.2, or 4.8.3 may be used to prepare the stock solution. A fourth alternative is not to use any biocide, provided the time of storage of stock solution is not sufficient to promote the growth of fungi.

4.8.1 Stock solution with formaldehyde.

4.8.1.1 Anhydrous Calcium Chloride, 454 g (1.0 lb) of technical grade.

4.8.1.2 USP Glycerin, 2050 g (4.515 lb).

4.8.1.3 Formaldehyde, (40 volume percent solution) 47 g (0.10 lb).

4.8.1.4 Dissolve the 454 g (1.0 lb) of calcium chloride in 1.89 L ($^1/_2$ gal) of distilled water. Cool and filter it through ready pleated rapid filtering paper. Add the 2050 g (4.515 lb) of glycerin and the 47 g (0.10 lb) of formaldehyde to the filtered solution, mix well and dilute to 3.78 L (1 gal).

4.8.2 Stock solution with glutaraldehyde.

4.8.2.1 Calcium Chloride Dihydrate, 577 g (1.27 lb) of A.C.S. grade.

Note 3—A.C.S. grade calcium chloride dihydrate is specified for the stock solution prepared with glutaraldehyde because tests indicate that impurities in the technical grade anhydrous calcium chloride may react with the glutaraldehyde resulting in an unknown precipitate.

4.8.2.2 USP Glycerin, 2050 g (4.515 lb).

4.8.2.3 1.5-Pentanedial (Glutaraldehyde), 50 percent solution in water 59 g (0.13 lb).

4.8.2.4 Dissolve the 577 g (1.27 lb) of calcium chloride dihydrate in 1.89 L ($^1/_2$ gal) of distilled water. Cool and add the 2050 g (4.515 lb) of glycerin and the 59 g (0.13 lb) of glutaraldehyde to the solution, mix well, and dilute to 3.78 L (1 gal).

Note 4—1.5 pentanedial, also known as glutaraldehyde, glutaric dialdehyde, and trade name UCARCIDE 250, may be obtained as Glutaraldehyde Solution 50 percent.[1]

4.8.3 Stock solution with Kathon CG/ICP.

4.8.3.1 Calcium Chloride Dihydrate, 577 g (1.27 lb) of A.C.S. Grade.

4.8.3.2 USP Glycerin, 2050 g (4.515 lb).

4.8.3.3 Kathon CG/ICP, 63 g (0.14 lb).

4.8.3.4 Dissolve the 577 g (1.27 lb) of calcium chloride dihydrate in 1.89 L ($^1/_2$ gal) of distilled water. Cool and add the 2050 g (4.515 lb) of glycerin and the 63 g (0.14 lb) of Kathon CG/ICP to the solution, mix well, and dilute to 3.78 L (1 gal).[2]

4.9 *Working Solution*—Working calcium chloride solution: Prepare the working calcium chloride by diluting one measuring tin full (85 ± 5 mL) of the stock calcium chloride solution to 3.8 L (1 gal) with water. Use distilled or demineralized water for the normal preparation of the working solution. However, if it is determined that the local tap water is of such purity that it does not affect the test results, it is permissible to use in lieu of distilled or demineralized water except in the event of dispute. Working solutions more than 30 days old shall be discarded.

4.10 *Straightedge*—A straightedge or spatula, suitable for striking off the excess soil from the tin measure.

4.11 *Oven*—A thermostatically controlled drying oven capable of maintaining a temperature of 110 ± 5ºC (230 ± 9ºF).

4.12 *Quartering Cloth*—Quartering or splitting cloth, approximately 600 mm (2 ft) square, nonabsorbent material such as plastic or oil cloth.

4.13 *Sieve*—A 4.75-mm (No. 4) sieve conforming to the requirements of M 92.

4.14 *Optional Handle for Irrigation Tube*—A 25-mm diameter wooden dowel to aid in pushing the irrigation tube into firm materials. See Figure 1, Assembly B.

5. TEMPERATURE CONTROL

5.1 The temperature of the working solution should be maintained at 22 ± 3ºC (72 ± 5ºF) during the performance of this test. If field conditions preclude the maintenance of the temperature range, frequent reference samples should be submitted to a laboratory where proper temperature control is possible. It is also possible to establish temperature correction curves for each material being tested where proper temperature control is not possible. However, no general correction curve should be utilized for several materials even within a narrow range of sand equivalent values. Samples that meet the minimums and equivalent requirement at a working solution temperature below the recommended range need not be subject to reference testing.

6. SAMPLING

6.1 Obtain a sample of the material to be tested in accordance with T 2.

6.2 Reduce the sample according to T 248. The sample shall be of sufficient size to yield 1,000 to 1,500 g of material passing the 4.75-mm (No. 4) sieve.

6.3 Sieve the sample over a 4.75-mm (No. 4) sieve. All aggregations of fine-grained soil material shall be pulverized to pass the 4.75-mm (No. 4) sieve, and all fines shall be cleaned from the particles retained on the 4.75-mm (No. 4) sieve and included with the material passing the 4.75-mm (No. 4) sieve.

6.4 Split or quarter the material passing the 4.75-mm (No. 4) sieve to yield 500 to 750 g (1.1 to 1.6 lb) of material. Use extreme care to obtain a truly representative portion of the original sample (Note 5).

Note 5—Experiments show that as the amount of material being reduced by splitting or quartering is decreased, the accuracy of providing representative portions is reduced. It is imperative that the sample be split or quartered carefully. When it appears necessary, dampen the material before splitting or quartering, to avoid segregation or loss of fines.

7. SAMPLE PREPARATION

7.1 Prepare the desired number of test samples by one of the following methods:

7.1.1 *Alternate Method No. 1*—Air Dry.

7.1.1.1 Split or quarter enough material from the portion passing the 4.75-mm (No. 4) sieve to fill the 85-mL (3-oz) tin measure so it is slightly rounded above the brim. While filling the measure, tap the bottom edge of the tin on the work table or other hard surface to cause consolidation of the material and allow the maximum amount to be placed in the tin. Strike off the tin with the spatula or straightedge so the material is level with the top of the measuring tin.

7.1.2 *Alternate Method No. 2*—Pre-Wet.

7.1.2.1 The sample must be in the proper moisture condition to achieve reliable results. This condition is determined by tightly squeezing a small portion of the thoroughly mixed sample in the palm of the hand. If the cast that is formed permits careful handling without breaking, the correct moisture range has been obtained. If the material is too dry, the cast will crumble and it will be necessary to add water, remix, and retest until the material forms a cast. If the material shows any free water it is too wet to test and must be drained and air dried, mixing it frequently to insure uniformity. This overly wet material will form a good cast when checked initially, so the drying process should continue until a squeeze check on the drying material gives a cast which is more fragile and delicate to handle than the original. If the moisture content of the original sample prepared in Section 6.2 is within the limits described above, the test sample may be obtained immediately. If the moisture content is altered to meet these limits, the altered sample should be placed in a pan, covered with a lid or with a damp cloth which does not touch the material, and allowed to stand for a minimum of 15 minutes.

7.1.2.2 After the minimum 15-minute tempering period, place the sample on the splitting cloth and mix by alternately lifting each corner of the cloth and pulling it over the sample toward the diagonally opposite corner, causing the material to be rolled. When the material appears homogeneous, finish the mixing with the sample in a pile near the center of the cloth.

7.1.2.3 Fill the 85-mL (3-oz) tin measure by pushing it through the base of the pile while exerting pressure with the hand against the pile on the side opposite the measure. As the tin is moved through the pile, hold enough pressure with the hand to cause the material to fill the tin to overflowing. Press firmly with the palm of the hand, compacting the material and allowing the maximum amount to be placed in the tin. Strike off the tin with the spatula or straightedge so the material is level with the top of the measuring tin.

Note 6—Moist test specimens produce lower sand equivalent values than the corresponding over-dry specimens with almost no exceptions; therefore, if a dual specification encompassing both the wet and dry methods of sample preparation is utilized, it will be necessary to determine the appropriate correction for each material because a standard correction does not appear possible. Either method can be employed with equal confidence, however.

7.1.3 *Reference Method (Mechanical Shaker)*—Obtain the 85-mL (3-oz) tin measure of material by one of the alternate methods, Section 7.1.1 or 7.1.2, above; then dry the test sample to constant mass at 110 ± 5ºC (230 ± 9ºF) and cool to room temperature before testing.

8. PROCEDURE

8.1 Start the siphon by forcing air into the top of the solution bottle through the bent copper, glass, or stainless steel blow tube while the pinch clamp is open. The apparatus is now ready for use.

8.2 Siphon 101.6 ± 2.5 mm (4.0 ± 0.1 in.) of working calcium chloride solution into the plastic cylinder. Pour the prepared test sample from the measuring tin into the plastic cylinder using the funnel to avoid spillage. (See Figure 3.) Tap the bottom of the cylinder sharply on the heel of the hand several times to release air bubbles and to promote thorough wetting of the sample.

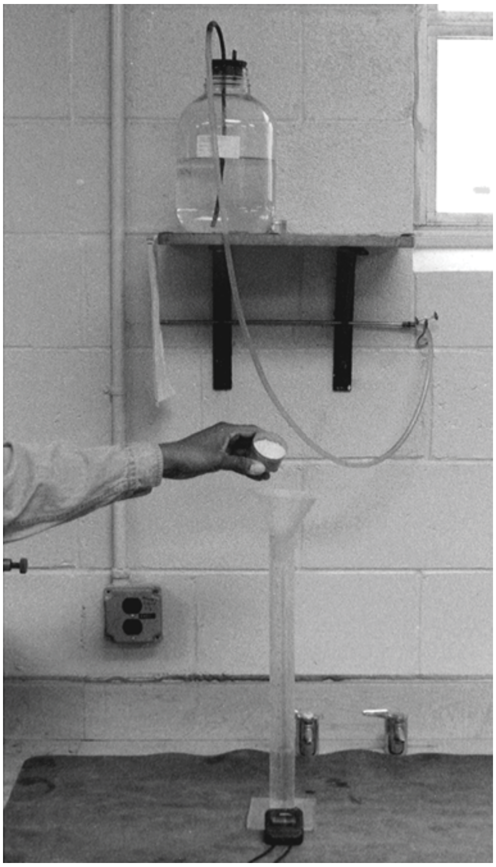


Figure 3—Transfer of Sample from Measuring Tin to Cylinder

8.3 Allow the wetted sample to stand undisturbed for 10 ± 1 minute. At the end of the 10-minute soaking period, stopper the cylinder, then loosen the material from the bottom by partially inverting the cylinder and shaking it simultaneously.

8.4 After loosening the material from the bottom of the cylinder, shake the cylinder and contents by any one of the following methods:

8.4.1 *Mechanical Shaker Method (Reference Method)*—Place the stoppered cylinder in the mechanical sand equivalent shaker, set the timer, and allow the machine to shake the cylinder and contents for 45 ± 1 second.

8.4.2 *Manual Shaker Method*—Secure the stoppered cylinder in the three spring clamps on the carriage of the hand-operated sand equivalent shaker and reset the stroke counter to zero. Stand directly in front of the shaker and force the pointer to the stroke limit marker painted on the backboard by applying an abrupt horizontal thrust to the upper portion of the right-hand spring steel strap. Then remove the hand from the strap and allow the spring action of the straps to move the carriage and cylinder in the opposite direction without assistance or hindrance. Apply enough force to the right-hand spring steel strap during the thrust portion of each stroke to move the pointer to the stroke limit marker by pushing against the strap with the ends of the fingers to maintain a smooth oscillating motion. The center of the stroke limit marker is positioned to provide the proper stroke length and its width provides the maximum allowable limits of variation. The proper shaking action is accomplished only when the tip of the pointer reverses direction within the marker limits. Proper shaking action can best be maintained by using only the forearm and wrist action to propel the shaker. Continue the shaking action for 100 strokes.

8.4.3 *Hand Method*—Hold the cylinder in a horizontal position as illustrated in Figure 4 and shake it vigorously in a horizontal linear motion from end to end. Shake the cylinder 90 cycles in approximately 30 seconds using a throw of 229 ± 25 mm (9 ± 1 in.). A cycle is defined as a complete back and forth motion. To properly shake the cylinder at this speed, it will be necessary for the operator to shake with the forearms only, relaxing the body and shoulders.

Figure 4—Using Hand Method of Shaking

8.5 Following the shaking operation, set the cylinder upright on the work table and remove the stopper.

8.6 *Irrigation Procedure*—Insert the irrigator tube in the cylinder and rinse material from the cylinder walls as the irrigator is lowered. Force the irrigator through the material to the bottom of the cylinder by applying a gentle stabbing and twisting action while the working solution flows from the irrigator tip. This flushes the fine material into suspension above the coarser sand particles. Continue to apply the stabbing and twisting action while flushing the fines upward until the cylinder is filled to the 381-mm (15-in.) mark. Then raise the irrigator slowly without shutting off the flow so the liquid level is maintained at about 381 mm (15 in.) while the irrigator is being withdrawn. Regulate the flow just before the irrigator is entirely withdrawn and adjust the final level to 381 mm (15 in.). The final level of the liquid shall be between the top two graduations on the tube but shall not be above the 381-mm (15-in.) mark when the liquid is read at the bottom of the meniscus.

Note 7—For certain soils, particularly on crushed materials, the stabbing action may not be possible. For these materials, the irrigation technique is as follows: Continue to apply a twisting action as the irrigation tube is slowly withdrawn. As the tube is withdrawn, it is essential that as many fines be flushed upward until the cylinder is filled to the 381-mm mark.

8.7 Allow the cylinder and contents to stand undisturbed for 20 minutes ± 15 seconds. Start the timing immediately after withdrawing the irrigator tube.

8.8 At the end of the 20-minute sedimentation period, read and record the level of the top of the clay suspension. This is referred to as the "clay reading." If no clear line of demarcation has formed at the end of the specified 20-minute sedimentation period, allow the sample to stand undisturbed until a clay reading can be obtained, then immediately read and record the level of the top of the clay suspension and the total sedimentation time. If the total sedimentation time exceeds 30 minutes, rerun the test using three individual samples of the same material. Read and record the clay column height of that sample requiring the shortest sedimentation period only.

8.9 After the clay reading has been taken, the "sand reading" shall be obtained by one of the following methods:

8.9.1 When using the weighted foot assembly having the sand indicator on the rod of the assembly, place the assembly over the cylinder and gently lower the assembly toward the sand. Do not allow the indicator to hit the mouth of the cylinder as the assembly is being lowered. As the weighted foot comes to rest on the sand, tip the assembly toward the graduations on the cylinder until the indicator touches the inside of the cylinder. Subtract 254 mm (10 in.) from the level indicated by the extreme top edge of the indicator and record this value as the "sand reading." (See Figure 5.)

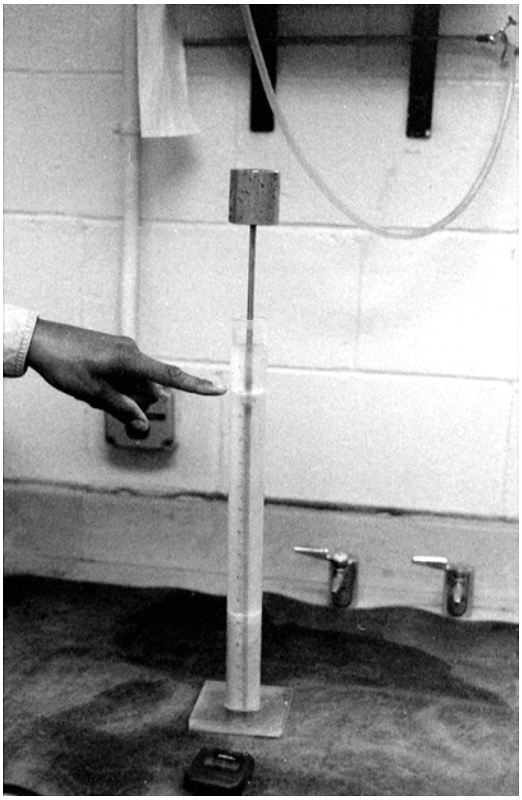

Figure 5—Sand Reading

8.9.2 If an older model weighted foot assembly having centering screws is used, keep one of the centering screws in contact with the cylinder wall near the graduations so it can be seen at all times while the assembly is being lowered. When the weighted foot has come to rest on the sand, read the level of the centering screw and record this value as the "sand reading."

8.10 If clay or sand readings fall between 2.5-mm (0.1-in.) graduations, record the level of the higher graduation as the reading. For example, a clay reading of 7.95 would be recorded as 8.0, and a sand reading of 3.22 would be recorded as 3.3.

Note 8—Samples obtained from aggregate proposed for use in hot-asphalt paving mixtures shall be prepared by oven-drying if acceptance of the material is based on tests on material that has passed through a hot-plant drier.

9. CALCULATIONS

9.1 Calculate the sand equivalent (SE) to the nearest 0.1 using the following formula:

$$SE = \frac{\text{Sand Reading}}{\text{Clay Reading}} \times 100 \qquad (1)$$

9.2 If the calculated sand equivalent is not a whole number, report it as the next higher whole number, as in the following example:

$$SE = \frac{3.3}{8} \times 100 = 41.25, \qquad (2)$$

which is reported as 42.

9.3 If it is desired to average a series of sand equivalent values, average the whole number values determined as described above. If the average of these values is not a whole number, raise it to the next higher whole number, as in the following example:
Calculated SE values: 41.2, 43.8, 40.9.

After raising each to the next higher whole number, they become: 42, 44, and 41.

The average of these values is then determined:

$$\frac{42 + 44 + 41}{3} = 42.3 \qquad (3)$$

9.3.1 Since the average value is not a whole number, it is raised to the next higher whole number and the reported averages and equivalent value is reported as 43.

10. PRECAUTIONS

10.1 Perform the test in a location free of vibrations; vibrations may cause the suspended material to settle at a rate greater than normal.

10.2 Do not expose the plastic cylinders to direct sunlight any more than is necessary.

10.3 *Removal of Organic Growth*—Occasionally it may be necessary to remove an organic growth from the working calcium chloride solution container and from the inside of the flexible tubing and irrigator tube. This organic material can easily be seen as a slimy substance in the solution. To remove this growth, prepare a cleaning solvent by diluting sodium hypochlorite[3] with an equal quantity of water. Fill the solution container with the prepared cleaning solvent, allow about a liter of the cleaning solvent to flow through the siphon assembly and irrigator tube, then place the pinch clamp on the end of the tubing to cut off the flow of solvent and to hold the solvent in the tube. Refill the container and allow to stand overnight. After soaking, allow the cleaning solvent to flow out through the siphon assembly and irrigator tube. Remove the siphon assembly from the solution container and rinse both with clear water. The irrigator tube and siphon assembly can be rinsed easily by attaching a hose between the tip of the irrigator tube and water faucet and backwashing fresh water through the tube.

10.4 Occasionally the holes in the tip of the irrigator tube may become clogged by a particle of sand. If the obstruction cannot be freed by any other method, use a pin or other sharp object to force it out, using extreme care not to enlarge the size of the opening.

[2] Kathon CG/ICP may be obtained from Rohm and Hass Chemical Company, Independence Mall West, Philadelphia, PA 19105. Kathon CG/ICP contains the following components: 5-chloro-2-methyl-4-isothiazolin-3-one; 2-methyl-4 isothiazolin-3-one; magnesium chloride; and magnesium nitrate.

[3] Clorox® or its equivalent has been found satisfactory for this purpose.

Standard Method of Test for

Moisture-Density Relations of Soils Using a 4.54-kg (10-lb) Rammer and a 457-mm (18-in.) Drop

AASHTO Designation: T 180-10

American Association of State Highway and Transportation Officials

Washington, D.C. 20001

Standard Method of Test for

Moisture-Density Relations of Soils Using a 4.54-kg (10-lb) Rammer and a 457-mm (18-in.) Drop

AASHTO Designation: T 180-10

1. SCOPE

1.1. This method of test is intended for determining the relationship between the moisture content and density of soils when compacted in a given mold of a given size with a 4.54-kg (10-lb) rammer dropped from a height of 457 mm (18 in.). Four alternate procedures are provided as follows:

- *Method A*—A 101.60-mm (4-in.) mold: Soil material passing a 4.75-mm (No. 4) sieve Sections 4 and 5.
- *Method B*—A 152.40-mm (6-in.) mold: Soil material passing a 4.75-mm (No. 4) sieve Sections 6 and 7.
- *Method C*—A 101.60-mm (4-in.) mold: Soil material passing a 19.0-mm ($^3/_4$-in.) sieve Sections 8 and 9.
- *Method D*—A 152.40-mm (6-in.) mold: Soil material passing a 19.0-mm ($^3/_4$-in.) sieve Sections 10 and 11.

1.2. The method to be used should be indicated in the specifications for the material being tested. If no method is specified, the provisions of Method A shall govern.

1.3. This test method applies to soil mixtures that have 40 percent or less retained on the 4.75-mm (No. 4) sieve, when Method A or B is used and 30 percent or less retained on the 19.0-mm ($^3/_4$-in.) sieve, when Method C or D is used. The material retained on these sieves shall be defined as oversize particles (coarse particles).

1.4. If the test specimen contains oversize particles and the test specimen used for field density compaction control, corrections must be made according to T 224 to compare the total field density with the compacted specimen. The person or agency specifying this method shall specify a minimum percentage of oversize particles below which correction for oversize need not be applied. If no minimum percentage is specified, correction shall be applied to samples with more than 5 percent by mass of oversize particles.

1.5. If the specified oversized maximum tolerances are exceeded, other methods of compaction control must be used.

Note 1—One method for the design and control of the compaction of such soils is to use a test fill to determine the required degree of compaction and a method to obtain that compaction. Then use a method specification to control the compaction by specifying the type and size of compaction equipment, the lift thickness, and the number of passes.

1.6. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off “to the nearest unit’’ in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

1.7. The values stated in SI units are to be regarded as the standard.

3. APPARATUS

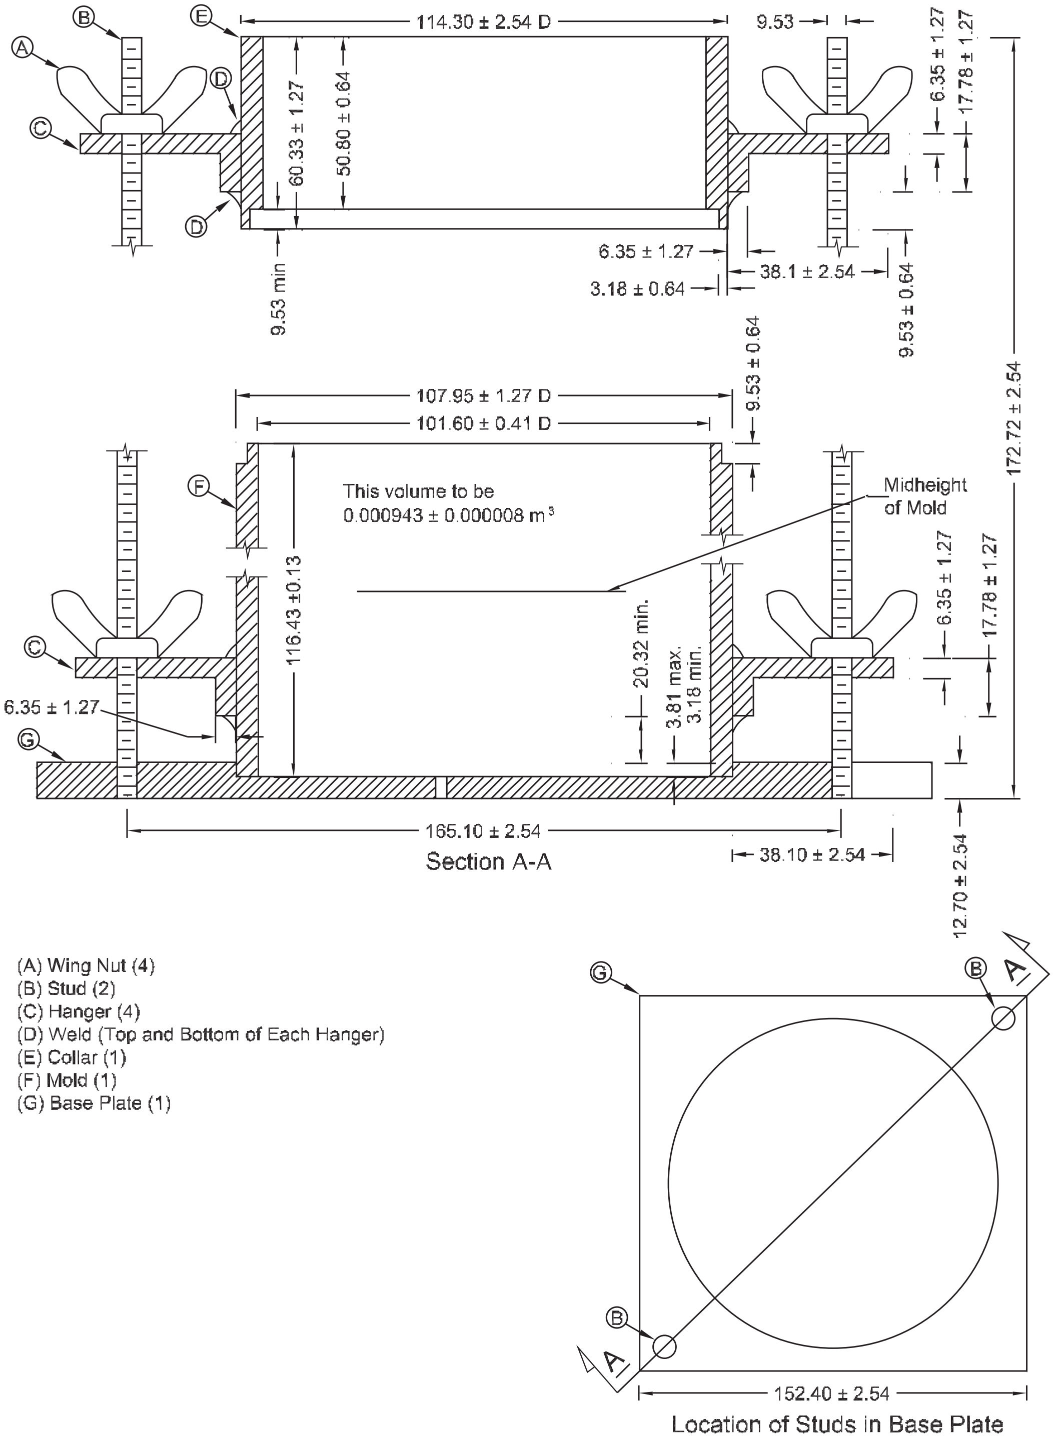
3.1. *Molds*—The molds shall be solid-wall, metal cylinders manufactured with dimensions and capacities shown in Sections 3.1.1, 3.1.2, and Figures 1 and 2 below. They shall have a detachable collar assembly approximately 60 mm ($2^{3}/_{8}$ in.) in height, to permit preparation of compacted specimens of soil-water mixtures of the desired height and volume. The mold and collar assembly shall be so constructed that it can be fastened firmly to a detachable base plate made of the same material (Note 2). The base plate shall be plane to 0.13 mm (0.005 in.) as shown in Figures 1 and 2.

Note 2—Alternate types of molds with capacities as stipulated herein may be used, provided the test results are correlated with those of the solid-wall mold on several soil types and the same moisture-density results are obtained. Records of such correlation shall be maintained and readily available for inspection when alternate types of molds are used.

3.1.1. A 101.6-mm (4-in.) mold having a capacity of 0.000943 ± 0.000008 m^3 ($^{1}/_{30}$ (0.0333) ± 0.0003 ft^3) with an internal diameter of 101.60 ± 0.41 mm (4.000 ± 0.016 in.) and a height of 116.43 ± 0.13 mm (4.584 ± 0.005 in.) (Figure 1).

3.1.2. A 152.4-mm (6-in.) mold having a capacity of 0.002124 ± 0.000021 m^3 ($^{1}/_{13.33}$ (0.07500) ± 0.00075 ft^3) with an internal diameter of 152.40 ± 0.66 mm (6.000 ± 0.026 in.) and a height of 116.43 ± 0.13 mm (4.584 ± 0.005 in.) (Figure 2).

3.1.3. *Molds Out of Tolerance Due to Use*—A mold that fails to meet manufacturing tolerances after continued service may remain in use provided those tolerances are not exceeded by more than 50 percent; and the volume of the mold, calibrated in accordance with T 19M/T 19, is used in the calculations.



Notes:
1. All dimensions shown in millimeters unless otherwise noted.
2. Hanger on the mold portion only cannot extend above the midheight line.
3. Figure 1 is to be used for all compaction molds purchased after the publication of the 21st edition (HM-21).
4. Not to scale.

3.2. *Rammer*:

3.2.1. *Manually Operated*—Metal rammer with a mass of 4.536 ± 0.009 kg (10.00 ± 0.02 lb) (Note 3), and having a flat circular face of 50.80 mm (2.000 in.) diameter with a manufacturing tolerance of ±0.25 mm (±0.01 in.). The in-service diameter of the flat circular face shall be not less than 50.42 mm (1.985 in.). The rammer shall be equipped with a suitable guide sleeve to control the height of drop to a free fall 457 ± 2 mm (18.00 ± 0.06 in.) above the elevation of the soil. The guide sleeve shall have at least four vent holes, no smaller than 9.5-mm ($^3/_8$-in.) diameter, spaced approximately 90 degrees (1.57 rad) apart and approximately 19 mm ($^3/_4$ in.) from each end; and shall provide sufficient clearance so the free fall of the rammer shaft and head is unrestricted.

3.2.2. *Mechanically Operated*—A metal rammer that is equipped with a device to control the height of drop to a free fall of 457 ± 2 mm (18.00 ± 0.06 in.) above the elevation of the soil, and uniformly distributes such drops to the soil surface (Note 3). The rammer shall have a mass of 4.536 ± 0.009 kg (10.00 ± 0.02 lb) (Note 2), and have a flat circular face of 50.80 mm (2.000 in.) diameter with a manufacturing tolerance of ±0.25 mm (±0.01 in.). The in-service diameter of the flat circular face shall be not less than 50.42 mm (1.985 in.). The mechanical rammer shall be calibrated by ASTM D 2168 to give the same moisture-density results as with a manually operated rammer.

Note 3—The mechanical rammer apparatus shall be calibrated with several soil types and the mass of the rammer adjusted, if necessary, to give the same moisture-density results as with the manually operated rammer.

It may be impractical to adjust the mechanical apparatus so the free fall is 457-mm (18 in.) each time the rammer is dropped, as with the manually operated rammer. To make the adjustment of free fall, the portion of loose soil to receive the initial blow should be slightly compressed with the rammer to establish the point of impact from which the 457-mm (18-in.) drop is determined; subsequent blows on the layer of soil being compacted may all be applied by dropping the rammer from a height of 457 mm (18 in.) above the initial-setting elevation, or when the mechanical apparatus is designed with a height adjustment for each blow, all subsequent blows should have a rammer free fall of 457 mm (18 in.) measured from the elevation of the soil as compacted by the previous blow. A more detailed calibration procedure for laboratory mechanical rammer soil compactors can be found in ASTM D 2168.

3.2.3. *Rammer Face*—The circular face rammer shall be used but a sector face rammer may be used as an alternative provided the report shall indicate type of face used other than the 50.8-mm (2-in.) circular face and it shall have an area equal to that of the circular face rammer.

3.3. *Sample Extruder (for Solid-Walled Molds Only)*—A jack, lever, frame, or other device adapted for the purpose of extruding compacted specimen from the mold.

3.4. *Balances and Scales*—A balance or scale conforming to the requirements of M 231, Class G 20. Also, a balance conforming to the requirements of M 231, Class G 2.

Note 4—The capacity of the metric balance or scale should be approximately 11.5 kg when used to determine the mass of the 152-mm (6-in.) mold and compacted, moist soil; however, when the 102-mm (4-in.) mold is used, a balance or scale of lesser capacity than 11.5 kg may be used, if the sensitivity and readability is 5 g.

3.5. *Drying Oven*—A thermostatically controlled drying oven capable of maintaining a temperature of 110 ± 5ºC (230 ± 9ºF) for drying moisture samples.

3.6. *Straightedge*—A hardened steel straightedge at least 250 mm (10 in.) in length. It shall have one beveled edge, and at least one longitudinal surface (used for final trimming) shall be plane within 0.1 percent of the length within the portion used for trimming the soil (Note 5).

Note 5—The beveled edge may be used for final trimming if the edge is true within a tolerance of 0.25 mm per 250 mm (0.1 percent) of length; however, with continued use, the cutting edge may become excessively worn and not suitable for trimming the soil to the level of the mold. The straightedge should not be so flexible that trimming the soil surface with the cutting edge will cause a concave soil surface.

3.7. *Sieves*—50-mm (2-in.), 19.0-mm ($^3/_4$-in.), and 4.75-mm (No. 4) sieves conforming to the requirements of M 92.

3.8. *Mixing Tools*—Miscellaneous tools such as mixing pan, spoon, trowel, spatula, etc., or a suitable mechanical device for thoroughly mixing the sample of soil with increments of water.

3.9. *Containers*—Suitable containers made of material resistant to corrosion and not subject to change in mass or disintegration on repeated heating and cooling. Containers shall have close-fitting lids to prevent loss of moisture from samples before initial mass determination and to prevent absorption of moisture from the atmosphere following drying and before final mass determination. One container is needed for each moisture content determination.

METHOD A

4. SAMPLE

4.1. If the soil sample is damp when received from the field, dry it until it becomes friable under a trowel. Drying may be in air or by use of a drying apparatus that is maintained at a temperature not exceeding 60ºC (140ºF). Then thoroughly break up the aggregation in such a manner as to avoid reducing the natural size of individual particles.

4.2. Sieve an adequate quantity of the representative pulverized soil over the 4.75-mm (No. 4) sieve. Discard the coarse material, if any, retained on the 4.75-mm (No. 4) sieve.

4.3. Select a representative sample, with a mass of approximately 3 kg (7 lb) or more, of the soil prepared as described in Sections 4.1 and 4.2.

Note 6—When developing a compaction curve for free draining soils, such as uniform sands and gravels, where seepage occurs at the bottom of the mold and base plate, taking a representative moisture content sample from the mixing bowl may be preferred in order to determine the amount of moisture available for compaction.

5. PROCEDURE

5.1. Thoroughly mix the selected representative sample with sufficient water to dampen it to approximately four percentage points below optimum moisture content.

5.2. Form a specimen by compacting the prepared soil in the 101.60-mm (4-in.) mold (with collar attached) in five approximately equal layers to give a total compacted depth of about 125 mm (5 in.). Prior to compaction, place the loose soil into the mold and spread into a layer of uniform thickness. Lightly tamp the soil prior to compaction until it is not in a loose or fluffy state, using either the manual compaction rammer or similar device having a face diameter of approximately 50 mm (2 in.). Following compaction of each of the first four layers, any soil adjacent to the mold walls that has not been compacted or extends above the compacted surface shall be trimmed using a knife or other suitable device, and be evenly distributed on top of the layer. Compact each layer by 25 uniformly distributed blows from the rammer dropping free from a height of 457 mm (18 in.) above the elevation of the soil when a sleeve-type rammer is used, or from 457 mm (18 in.) above the approximate elevation of the soil as compacted by the previous blow when a stationary mounted type of rammer is used (Note 7).

Note 7—Each of the following has been found to be a satisfactory base on which to rest the mold during compaction of the soil: a block of concrete, with a mass of not less than 90 kg (200 lb), supported by a relatively stable foundation; a sound concrete floor; and for field application, such surfaces as found in concrete box culverts, bridges, and pavements.

5.2.1. Following compaction, remove the extension collar, carefully trim the compacted soil even with the top of the mold by means of the straightedge, and determine the mass of the mold and moist soil in kilograms to the nearest 5 grams, or determine the mass in pounds to the nearest 0.01 pounds. During compaction, the mold shall rest firmly on a dense, uniform, rigid, and stable foundation or base. This base shall remain stationary during the compaction process (Note 7). Calculate the wet density, W_1, as described in Section 12.2 or 12.3.

5.3. Remove the material from the mold and slice vertically through the center. Take a representative sample of the material from one of the cut faces (Figure 3), and weigh immediately. Determine the moisture content in accordance with T 265, and record the results.

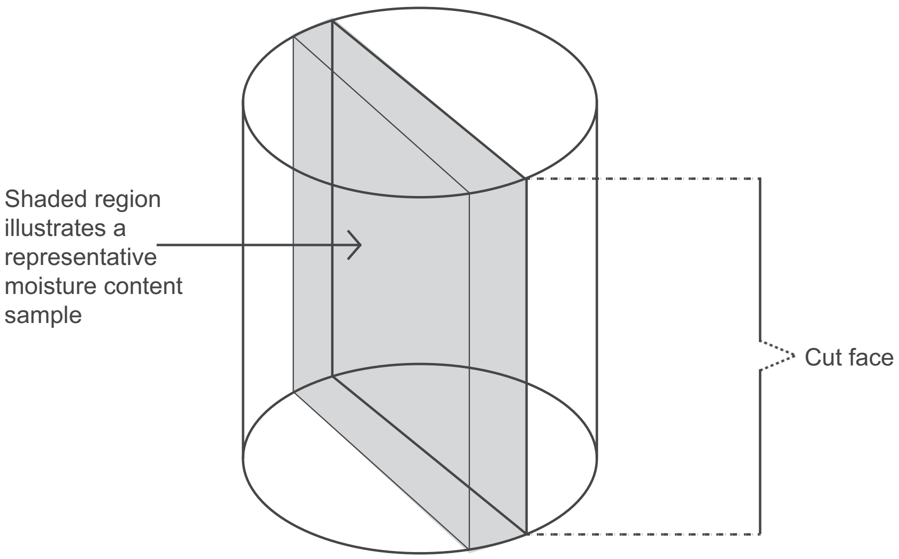

Figure 3—Representative Moisture Content Sample Selection

5.4. Thoroughly break up the remaining portion of the molded specimen until it will pass a 4.75-mm (No. 4) sieve as judged by eye, and add to the remaining portion of the sample being tested. Add water in sufficient amount to increase the moisture content of the soil by approximately one to two percentage points (water content increments should not exceed 2.5 percent, except when heavy clay soils or organic soils exhibiting flat elongated curves are encountered, the water content increments may be increased to a maximum of four percent), and repeat the above procedure for each increment of water added. Continue this series of determinations until there is either a decrease or no change in the wet unit mass per cubic meter (cubic foot) of the compacted soil (Note 8).

Note 8—In instances where the soil material is fragile in character and will reduce significantly in grain size due to repeated compaction, and in cases where the soil is heavy-textured, clayey material into which it is difficult to incorporate water, a separate and new sample shall be used in each compaction test. In these cases, separate samples shall be thoroughly mixed with amounts of water sufficient to cause the moisture contents of the samples to vary by approximately two percentage points. The moisture contents selected shall bracket the optimum moisture content, thus providing samples which, when compacted, will increase in mass to the maximum density and then decrease in mass. The samples of soil-water mixtures shall be placed in covered containers and allowed to stand for not less than 12 hours before making the moisture-density test.

5.4.1. In instances where the soil material is fragile in character and will be reduced significantly in grain size by repeated compaction, a separate and new sample shall be used in each compaction test.

METHOD B

6. SAMPLE

6.1. Select the representative sample in accordance with Section 4.3 except that it shall have a mass of approximately 7 kg (16 lb).

7. PROCEDURE

7.1. Follow the same procedure as described for Method A in Section 5, except for the following: Form a specimen by compacting the prepared soil in the 152.40-mm (6-in.) mold (with collar attached) in five approximately equal layers to give a total compacted depth of about 125 mm (5 in.), each layer being compacted by 56 uniformly distributed blows from the rammer. Calculate the wet density, W_1, as described in Section 12.2 or 12.3.

METHOD C

8. SAMPLE

8.1. If the soil sample is damp when received from the field, dry it until it becomes friable under a trowel. Drying may be in air or by use of a drying apparatus that is maintained at a temperature not exceeding 60ºC (140ºF). Then, thoroughly break up the aggregations in such a manner as to avoid reducing the natural size of individual particles.

8.2. Sieve an adequate quantity of the representative pulverized soil over the 19.0-mm ($^3/_4$-in.) sieve. Discard the coarse material, if any, retained on the 19.0-mm ($^3/_4$-in.) sieve.

8.3. Select a representative sample, with a mass of approximately 5 kg (12 lb) or more, of the soil prepared as described in Sections 8.1 and 8.2.

9. PROCEDURE

9.1. Thoroughly mix the selected representative sample with sufficient water to dampen it to approximately four percentage points below optimum moisture content.

9.2. Form a specimen by compacting the prepared soil in the 101.60-mm (4-in.) mold (with collar attached) in five approximately equal layers to give a total compacted depth of about 125 mm (5 in.). Prior to compaction, place the loose soil into the mold and spread into a layer of uniform thickness. Lightly tamp the soil prior to compaction until it is not in a loose or fluffy state, using either the manual compaction rammer or similar device having a face diameter of approximately 50 mm (2 in.). Following compaction of each of the first four layers, any soil adjacent to the mold walls that has not been compacted or extends above the compacted surface shall be trimmed using a knife or other suitable device, and be evenly distributed on top of the layer. Compact each layer by 25 uniformly distributed blows from a rammer dropping free from a height of 457 mm (18 in.) above the elevation of the soil when a sleeve-type rammer is used, or from 457 mm (18 in.) above the approximate elevation of each finely compacted layer when a stationary mounted type of rammer is used. During compaction, the mold shall rest firmly on a dense, uniform, rigid, and stable foundation or base. This base shall remain stationary during the compaction process (Note 7).

9.2.1. Following compaction, remove the extension collar, carefully trim the compacted soil even with the top of the mold by means of the straightedge, and determine the mass of the mold and moist soil in kilograms to the nearest 5 grams, or determine the mass in pounds to the nearest 0.01 pounds. Calculate the wet density, W_1, as described in Section 12.2 or 12.3.

9.3. Remove the material from the mold and slice vertically through the center. Take a representative sample of the material from one of the cut faces and weigh immediately. Determine the moisture content in accordance with T 265 and record the results.

9.4. Thoroughly break up the remainder of the material until it will pass a 19.0-mm ($^3/_4$-in.) sieve and 90 percent of the soil aggregations will pass a 4.75-mm (No. 4) sieve as judged by eye, and add to the remaining portion of the sample being tested. Add water in sufficient amounts to increase the moisture content of the soil sample by one or two percentage points, and repeat the above procedure for each increment of water added. Continue this series of determinations until there is either a decrease or no change in the wet unit mass, W_1, per cubic meter (cubic foot) of the compacted soil (Note 8).

METHOD D

10. SAMPLE

10.1. Select the representative sample in accordance with Section 8.3, except that it shall have a mass of approximately 11 kg (25 lb).

11. PROCEDURE

11.1. Follow the same procedure as described for Method C in Section 9, except for the following: Form a specimen by compacting the prepared soil in the 152.40-mm (6-in.) mold (with collar attached) in five approximately equal layers to give a total compacted depth of about 127 mm (5 in.), each layer being compacted by 56 uniformly distributed blows from the rammer. Calculate the wet density, W_1, as described in Section 12.2 or 12.3.

CALCULATIONS AND REPORT

12. CALCULATIONS

12.1. The mold factor can be related to the volume of the mold as follows:

$$F = 1/V$$

where:

F = mold factor; and

V = volume of mold.

12.2. The wet density can be determined using the mold factor. For masses recorded in kilograms, the unit of wet density is kilograms per cubic meter of compacted soil. For masses recorded in pounds, the unit of wet density is pounds per cubic foot of compacted soil.

$$W_1 = (A - B) \times F$$

where:

W_1 = wet density,

A = mass of compacted specimen and mold,

B = mass of mold, and

F = mold factor as given in Table 3.

Table 3—Mold Factors for Molds in Compliance with Sections 3.1.1 or 3.1.2

Method	Mold Factor	
	For masses recorded in kilograms	For masses recorded in pounds
A	1060	30
B	471	13.3
C	1060	30
D	471	13.3

Note: For used molds in compliance with Section 3.1.3, determine the mold factor in accordance with Section 3.1.3 and Equation 1.

12.3. Alternatively, the wet density can be determined using the mold volume. For masses recorded in kilograms, the unit of wet density is kilograms per cubic meter of compacted soil. For masses recorded in pounds, the unit of wet density is pounds per cubic foot of compacted soil.

$$W_1 = (A - B)/V$$

where:

V = mold volume as given in Section 3.1.1 for Methods A and C, or Section 3.1.2 for Methods B and D. For used molds in compliance with Section 3.1.3, determine the mold volume in accordance with Section 3.1.3.

12.4. The dry density is related to the wet density as follows:

$$W = \frac{W_1}{w + 100} \times 100$$

where:

W = dry density, in kilograms per cubic meter of compacted soil, or pounds per cubic foot of compacted soil; and

w = moisture content (percent) of the specimen, as determined by T 265.

13. MOISTURE–DENSITY RELATIONSHIP

13.1. The calculations in Section 12 shall be made to determine wet density (unit mass) and oven-dry density (unit mass) in kilograms per cubic meter or pounds per cubic foot for each of the compacted samples. The oven-dry densities of the soil shall be plotted as ordinates and corresponding moisture contents as abscissae.

13.2. *Optimum Moisture Content*—When the densities and corresponding moisture contents for the soil have been determined and plotted as indicated in Section 13.1, it will be found that by connecting the plotted points with a smooth line, a curve is produced. The moisture content corresponding to the peak of the curve shall be termed the "optimum moisture content" of the soil under the above compaction.

13.3. *Maximum Density*—The oven-dry density in kilograms per cubic meter or pounds per cubic foot of the soil at optimum moisture content shall be termed "maximum density" under the above compaction.

14. REPORT

14.1. The report shall include the following:

14.1.1. The method used (Method A, B, C, or D);

14.1.2. The optimum moisture content, as a percentage, to the nearest whole number;

14.1.3. The maximum density in kilograms per cubic meter to the nearest 10 kg/m^3 or in pounds per cubic foot, to the nearest whole number; and

14.1.4. Type of face if other than 50.8-mm (2-in.) circular.

Standard Method of Test for

Resistance R-Value and Expansion Pressure of Compacted Soils

AASHTO Designation: T 190-09
ASTM Designation: D 2844-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Resistance R-Value and Expansion Pressure of Compacted Soils

AASHTO Designation: T 190-09
ASTM Designation: D 2844-07

1. SCOPE

1.1. This method covers the procedure for testing both treated and untreated laboratory compacted soils or aggregates with the stabilometer and expansion pressure devices to obtain results indicative of performance when placed in the base, subbase, or subgrade of a road subjected to traffic.

1.2. The values stated in SI units are to be regarded as the standard.

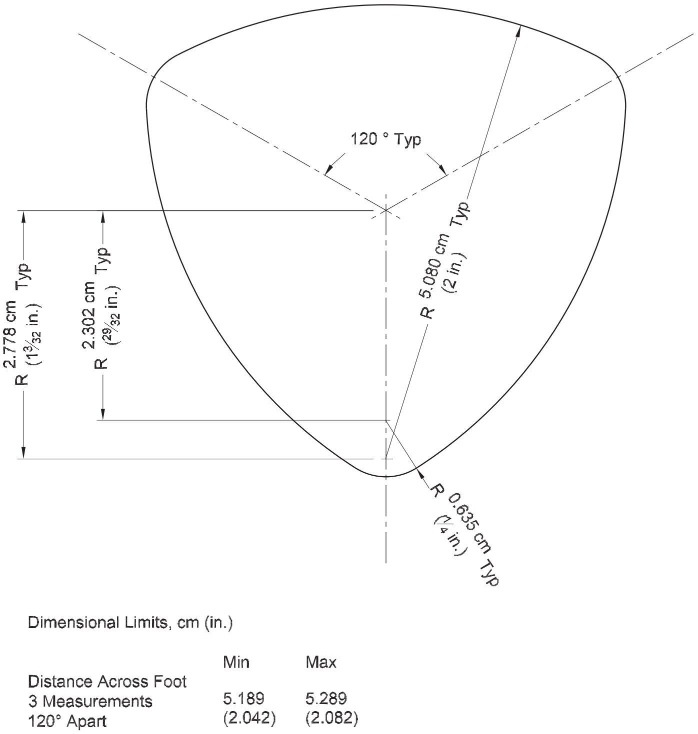
2. APPARATUS

2.1. Kneading Compactor capable of applying an average contact pressure of 2413 ± 110 kPa (350 ± 16 psi) to the tamper foot shown in Figure 1 and with provisions for maintaining this pressure during changes in sample height. The load-time trace shall be free of "chatter" or evidence of impact-associated changes in slope. The rise time for application of foot pressure, in the range from 241 to 2068 kPa (35 to 300 psi), shall not be less than 0.07 nor more than 0.20 seconds. The dwell time, measured at 2068 kPa (300 psi) foot pressure, shall not be less than 0.15 nor more than 0.45 seconds. The pressure-release or removal time shall not be greater than 0.60 seconds.

2.1.1. The compactor shall include a counter or timer for measuring the number of tamps applied to a specimen and a mold holder, for use in compacting specimens, that rotates equally between tamps to give five to seven tamps per revolution of the mold. The holder shall firmly restrain the mold during compaction. The base of the mold holder shall have a metal plate 100.8 mm ($33^1/_{32}$ in.) in diameter and 12.7 mm (1/2 in.) high to which is cemented a rubber disk having a diameter of 100.0 mm ($31^5/_{16}$ in.) and a height of 3.2 mm ($^1/_8$ in.). The plate shall be an integral part of the base of the mold holder. The compactor shall also include a trough for feeding the sample into the mold in 20 increments (Figure 2). Troughs with a semicircular cross section of 3871 mm^2 (6 in.^2) in area and 508 mm (20 in.) long have proven satisfactory.

2.2. Compression Testing Machine, with a minimum capacity of 45 kN (10000 lbf) and satisfying the requirements of ASTM E 4.

2.3. Mold, 101.6 ± 0.05 mm (4 ± 0.002 in.) inside diameter by 127.00 ± 0.20 mm (5 ± 0.008 in.) high. (See Figure 3 for surface roughness.)



mm	in.
50.80 ± 0.05	2.00 ± 0.002
6.35 ± 0.51	$^1/_4$ ± 0.020
6.35	$^1/_4$
50.80	2
22.22	$^7/_8$

Figure 1—Tamper Foot for Kneading Compactor

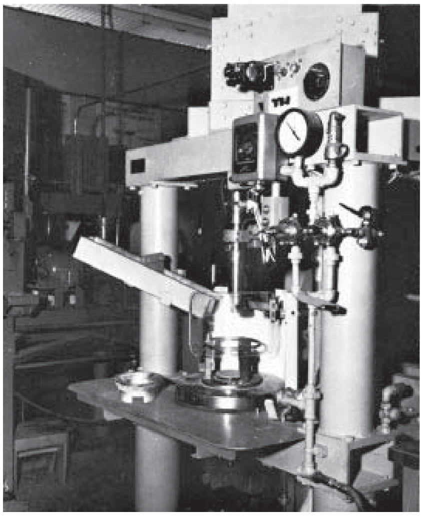


Figure 2—Compactor with Sample Feed Trough

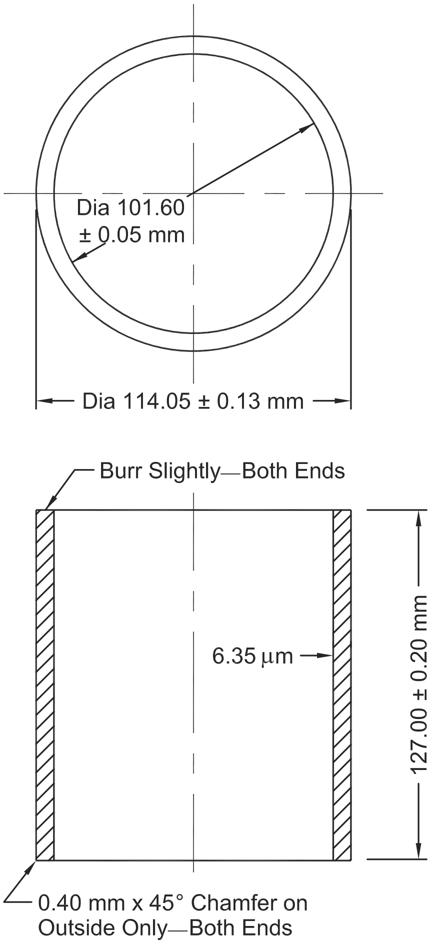

Note: Inside roughness is obtained by smooth machining inside to required diameter of 101.60 ± 0.05 mm (4.000 ± 0.002 in.) diameter followed on final operation with a boring tool ground to a 90-degree point with sharp point ground flat measuring 0.02 to 0.08 mm (0.001 to 0.003 in.) across. Depth of cut is 0.05 mm (0.002 in.) with 0.25 mm (0.010 in.) feed using sulfur-based oil coolant.

Figure 3—Mold

2.4. Rubber Disks, 100 mm ($31^{5}/_{16}$ in.) in diameter by 3.2 mm ($^{1}/_{8}$ in.) thick and having a durometer hardness of 60 ± 15.

2.5. Metal Follower, solid-walled, metal specimen follower 100.33 ± 0.13 mm (3.95 ± 0.005 in.) in outside diameter by 127 mm (5 in.) long.

2.6. Exudation-Indicator Device, as shown in Figures 4 and 5.

2.7. Phosphor Bronze Disk, as shown in Figure 6.

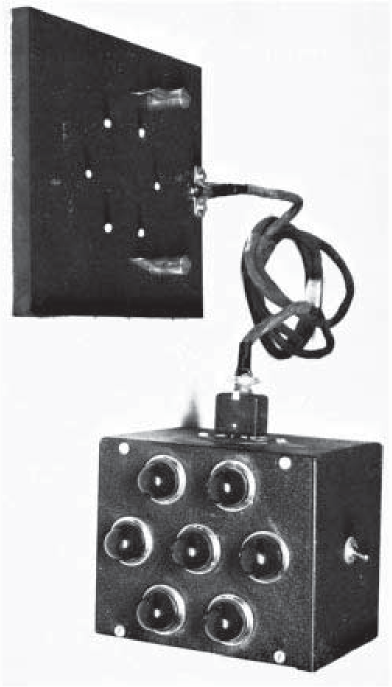

Figure 4—Exudation-Indicator Device

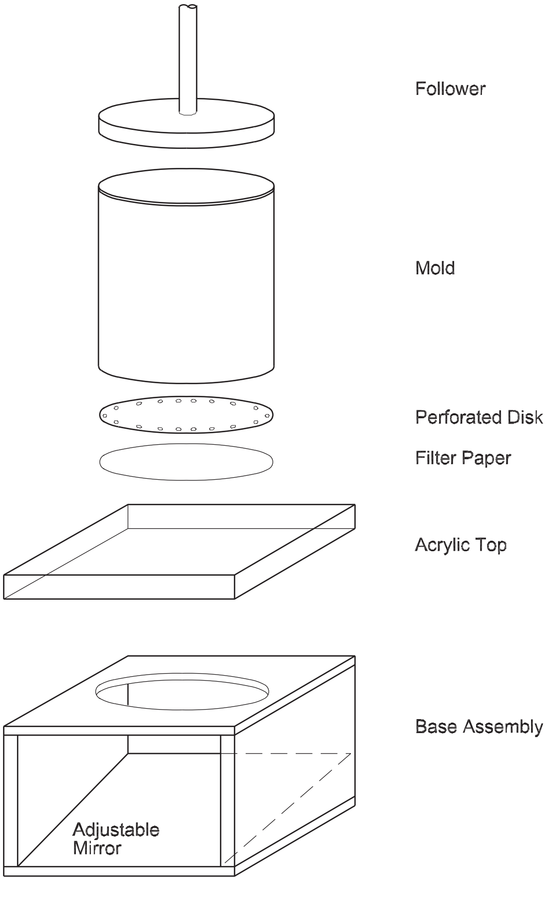

Figure 5—Exudation-Indicator Device (Alternate Method)

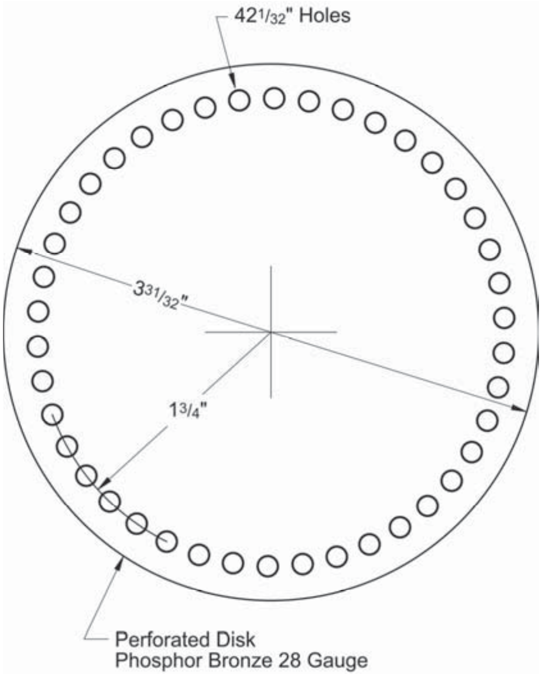

Figure 6—Phosphor-Bronze Disk

2.8. Filter Paper, 100 mm in diameter and 0.15 mm (0.006 in.) thick, smooth surface, medium filtering speed, medium retention.

2.9. Filter Paper, 110 mm in diameter and 0.15 mm (0.006 in.) thick, creped surface, medium-fast filtering speed, medium retention.

2.10. Expansion-Pressure Device, with accessories as shown in Figure 7. There should be at least three of these devices for each sample to be tested within a day's time.

2.11. Deflection Gauge, with divisions of 0.002 mm (0.0001 in.) and an Allen wrench as shown in Figure 7.

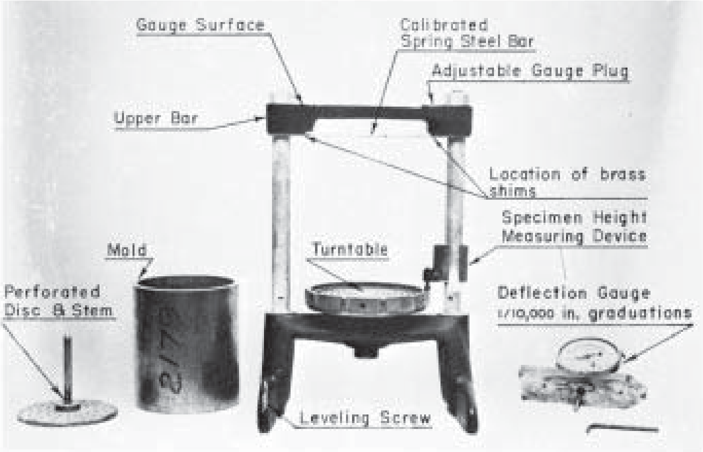

Figure 7—Expansion-Pressure Device and Accessories

2.12. Stabilometer, with accessories, as shown in Figures 8 and 9.

2.13. Standard Metal Specimen, 101.60 mm (4 in.) in outside diameter by 152.4 mm (6 in.) high as shown in Figure 9.

2.14. Balance, of sufficient capacity, conforming to the requirements of M 231, Class G 5.

2.15. Sieves, 25.0-mm (1-in.), 19.0-mm ($^3/_4$-in.) and 4.75-mm (No. 4) conforming to the requirements of M 92 for Wire-Cloth Sieves for Testing Purposes.

2.16. Miscellaneous equipment, including mixing pans, spoons, spatulas, and gallon cans with close-fitting lids.

2.17. Tamping Rod, a metal rod, 38 to 51 mm (1.5 in. to 2.0 in.) in diameter.

2.18. Expansion pressure calibration equipment, a suitable hanger and weights, and a calibrated proving ring.

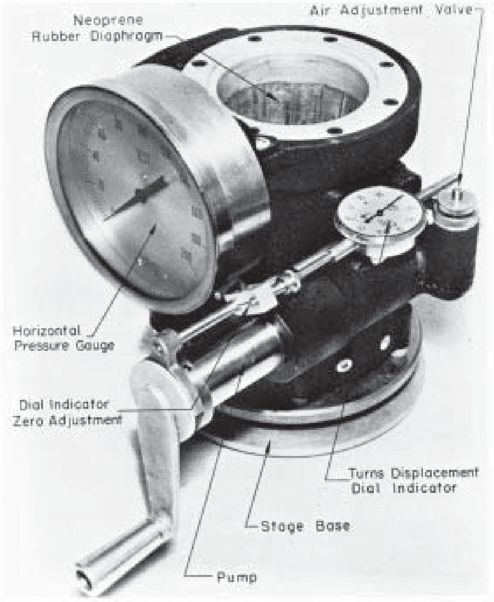

Figure 8—Hveem Stabilometer

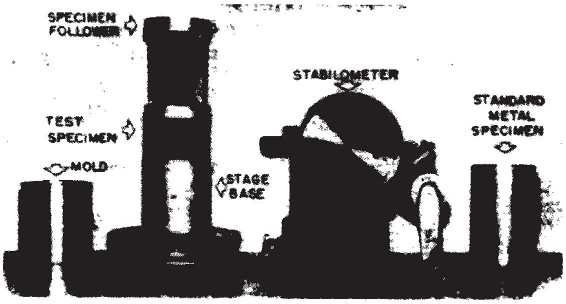

Figure 9—Stabilometer and Accessories

3. SOIL PREPARATION

3.1. Remove any coatings from coarse aggregate and break clay lumps to pass the 4.75-mm (No. 4) sieve.

3.2. Adjust the soil graduation when some of the material is retained on the 19.0-mm ($^{3}/_{4}$-in.) sieve. When 75 percent or more passes the 19.0-mm sieve, use that part of the sample passing the 19.0-mm sieve. If less than 75 percent of the sample passes the 19.0-mm sieve, use that part of the sample passing the 25.0-mm (1-in.) sieve.

4. PREPARATION OF SOIL SPECIMENS

4.1. Thoroughly mix four 1200-g samples of soil with the amount of water estimated to equal one-half to two-thirds of the water required to produce saturation as defined in Sections 4.3 and 4.4. Place the samples in covered containers and allow them to stand overnight. Just prior to compaction, mix the samples with the final amount of water required to produce saturation. The first sample is used as a pilot specimen to assist in determining the final amount of water required.

4.2. Weigh out enough material to fabricate a compacted sample 101.6 mm (4 in.) in diameter by 63.5 mm (2.5 in.) high. Compacted specimens having heights from 58.4 to 68.6 mm (2.3 to 2.7 in.) are acceptable. Compact the soil into the mold by means of the kneading compactor as follows: Place the mold in the mold holder that has a rubber disk, 100 mm ($31^{5}/_{16}$ in.) in diameter and 3 mm ($^{1}/_{8}$ in.) thick cemented to the plate. Adjust the mold for approximately 3-mm ($^{1}/_{8}$-in.) clearance between the lower edge of the mold and base of the mold holder by placing a shim under the edge of the mold or by tightening the set screw (if available) on the mold holder. With the compactor foot pressure set at 1724 ± 172 kPa (250 ± 25 psi), feed 76.2 mm (3 in.) of the soil in the trough into the mold. Feed the balance of the soil into the mold in 20 equal increments with one application of the ram after each increment. Allow 10 additional tamps to level the soil, then place a rubber disk on top of the specimen, loosen the set screw (if available), and remove the shim from under the mold. Apply 100 additional tamps with a foot pressure of 2413 kPa (350 psi). Stop compacting the soil at any time before 100 tamps if water appears around the bottom of the mold.

Note 1—Use lower compaction pressures when necessary to limit penetration of the ram into the soil to not greater than 6.35 mm ($^{1}/_{4}$ in.).

4.3. Remove the mold containing the compacted specimen from the compactor. Level the surface by hand tamping with the tamping rod. Place a phosphor-bronze disk on the tamped surface of the soil and place a filter paper on top of the bronze disk. Invert the mold and place it on the exudation-indicator device so the filter paper is on the bottom. Using the compression testing machine, apply a uniformly increasing pressure to the soil at the rate of 8896 N/minute (2000 lbf/minute). Water should be exuded from the soil at 2068 kPa (300 psi) as evidence that enough moisture is present to produce saturation. Stop the loading and record the exudation pressure when either five of the six outer lights on the exudation pressure device are lighted or three outer lights are lighted and free water is visible around the bottom of the mold. Do not exceed a loading of 5516 kPa (800 psi).

4.4. Mold at least two more specimens with different amounts of moisture so that a range of exudation pressures from 689 to 5516 kPa (100 to 800 psi) (Note 2) is obtained that brackets the 2068 kPa (300 psi) value. For some high volume-change soils, additional specimens having exudation pressures lower than 689 kPa (100 psi) may be necessary to obtain expansion pressures that are low enough to provide a suitable range of data for a complete expansion pressure analysis of the soil.

Note 2—Occasionally, material from very plastic, clay-test specimens will extrude from under the mold and around the follower ram during the loading operation. If this occurs when the 5516-kPa (800-psi) point is reached and fewer than five lights are lighted, or, for the alternate method, $^5/_6$ of the circumference of the filter paper is wet, the soil should be reported as less than five R-value. Coarse granular materials and clean sands may require the use of paper baskets to permit testing.

5. CALIBRATION OF EXPANSION-PRESSURE APPARATUS

5.1. Calibrate the spring steel bar of the expansion-pressure device (Figure 7) by applying upward measured loads at the center of the bar and measuring the respective deflections of the bar with the deflection gauge.

5.2. The spring steel bar is considered in calibration when the deflections are within the following tolerances:

Applied Load, N (lbf)	Dial Reading	
	(mm)	(in.)
36 (8)	0.053 ± 0.005	(0.0021 ± 0.0002)
71 (16)	0.107 ± 0.005	(0.0042 ± 0.0002)
107 (24)	0.160 ± 0.005	(0.0063 ± 0.0002)
142 (32)	0.213 ± 0.005	(0.0084 ± 0.0002)

5.3. If the deflection gauge does not check the above readings, loosen the top frame bar and adjust the position of the shims, between the frame and the spring steel bar, until the required readings are obtained.

Note 3—Some models of the expansion-pressure apparatus have set screw adjustments in lieu of shims.

6. EXPANSION-PRESSURE TESTING

6.1. Allow the test specimen to rebound in a covered mold for at least 30 minutes after determination of the exudation pressure and the compacted specimen height to the nearest 2.5 mm (0.1 in.).

6.2. Place the deflection gauge in position on the expansion-pressure device with the single-bearing end of the gauge base resting on the adjustment ring.

6.3. Using an Allen wrench, raise or lower the adjustment plug until the deflection gauge is on 0.025 mm (1.0010 in.). The deflection gauge will read 0.229 mm (0.0090 in.).

6.4. Place the perforated disk with stem firmly on the face of the compacted specimen in the mold and place the mold in the expansion-pressure device after placing creped surface filter paper on the turntable.

6.5. Seat the perforated disk firmly on the specimen with pressure applied by the fingers. Raise the turntable on the expansion device until the deflection gauge reads zero. If the device was properly adjusted, according to Section 6.3, this will apply the preset surcharge deflection of 0.025 mm (0.0010 in.).

6.6. Put approximately 200 mL of water into the mold and allow pressure from expansion of the specimen to develop for 16 to 24 hours.

Note 4—Do not leave a test specimen unconfined by the expansion-pressure device while there is free water on top of the specimen in the mold.

6.7. Read the deflection of the calibrated spring steel bar to 0.002 mm (0.0001 in.). When the deflection is greater than 0.254 mm (0.0100 in.), the expansion-pressure device should be recalibrated before using again.

6.8. Determine the expansion pressure, P, as follows:

$$P = kd \tag{1}$$

where:

k = spring constant of steel bar calculated from calibration of the expansion-pressure apparatus and expressed in kPa/0.025 mm (psi/0.0010 in.), and,

d = deflection shown by deflection gauge, mm (in.).

7. ADJUSTMENT OF STABILOMETER

7.1. Adjust the bronze nut on the stabilometer stage base so that the top of the stage is 89 mm ($3^1/_2$ in.) below the bottom of the upper tapered ring of the stabilometer. Perform all tests at this setting.

7.2. Adjust the amount of air in the stabilometer cell so that 2 ± 0.05 turns of the pump handle increase the liquid pressure from 34.4 to 689 kPa (5 to 100 psi) with the standard metal specimen in the stabilometer chamber.

8. RESISTANCE-VALUE TESTING OF SPECIMENS

8.1. After testing for expansion pressure, pour water off the top of the specimen (Note 5) and place the mold with the specimen on top of the stabilometer. Place the follower on top of the specimen and force the specimen from the mold into the stabilometer. Lower the testing machine head until it just engages the follower.

Note 5—If all the water has drained through the specimen, add water to the top and allow to stand for 15 minutes. Pour off any excess water and continue to test.

8.2. Apply a horizontal pressure of 34.5 kPa (5 psi) to the specimen by means of the displacement pump, then apply a vertical load using a uniform rate of movement of 1.3 mm/minute (0.05 in./minute).

8.3. Record the horizontal pressure when the vertical load is 8896 N (2000 lbf) and stop loading. Reduce the vertical load to 4448 N (1000 lbf). With the displacement pump, adjust the horizontal pressure to 34.5 kPa (5 psi).

Note 6—This will result in a further reduction in the applied load and should be ignored.

8.4. Turn the stabilometer pump handle at approximately two turns per second and measure the number of turns of the pump handle (using the turns-displacement dial indicator on the stabilometer) to raise the horizontal pressure from 34.5 to 689 kPa (5 to 100 psi). This is the turns displacement, *D*, of the specimen.

8.5. Determine the resistance, *R*, as follows:

$$R = 100 - \left[\frac{100}{\frac{2.5}{D}\left(\frac{1100}{P_h} - 1\right) + 1} \right] \quad \text{for SI units} \qquad (2)$$

$$R = 100 - \left[\frac{100}{\frac{2.5}{D}\left(\frac{160}{P_h} - 1\right) + 1} \right] \quad \text{for U.S. Customary units} \qquad (3)$$

where:

P_h = horizontal pressure, kPa (psi), and

D = turns displacement reading.

8.6. This is the R-value for specimens with compacted heights from 62 to 65 mm (2.45 to 2.55 in.). If the height of the specimen is between 58 and 62 mm or 65 and 68 mm (2.3 and 2.45 in. or 2.55 and 2.7 in., respectively) use the chart (Figure 10) for correcting R-values to a specimen height of 63 mm (2.5 in.).

Note 7—If the R-value is desired at a specific exudation pressure, for example, 2068 kPa (300 psi), within the range of pressures measured in tests of three specimens, it is convenient to construct a graph of R-value versus exudation pressure and interpolate.

Chart for correcting "R" values to
specimen height of 63 mm

Height correction should be
made using the chart below.

Note: No correction for specimen
heights between 62 and 65 mm.
Interpret R-value corrections
for other heights.

Example: Overall height of 67 mm
R-value (uncorrected) = 50
R-value (corrected) = 54

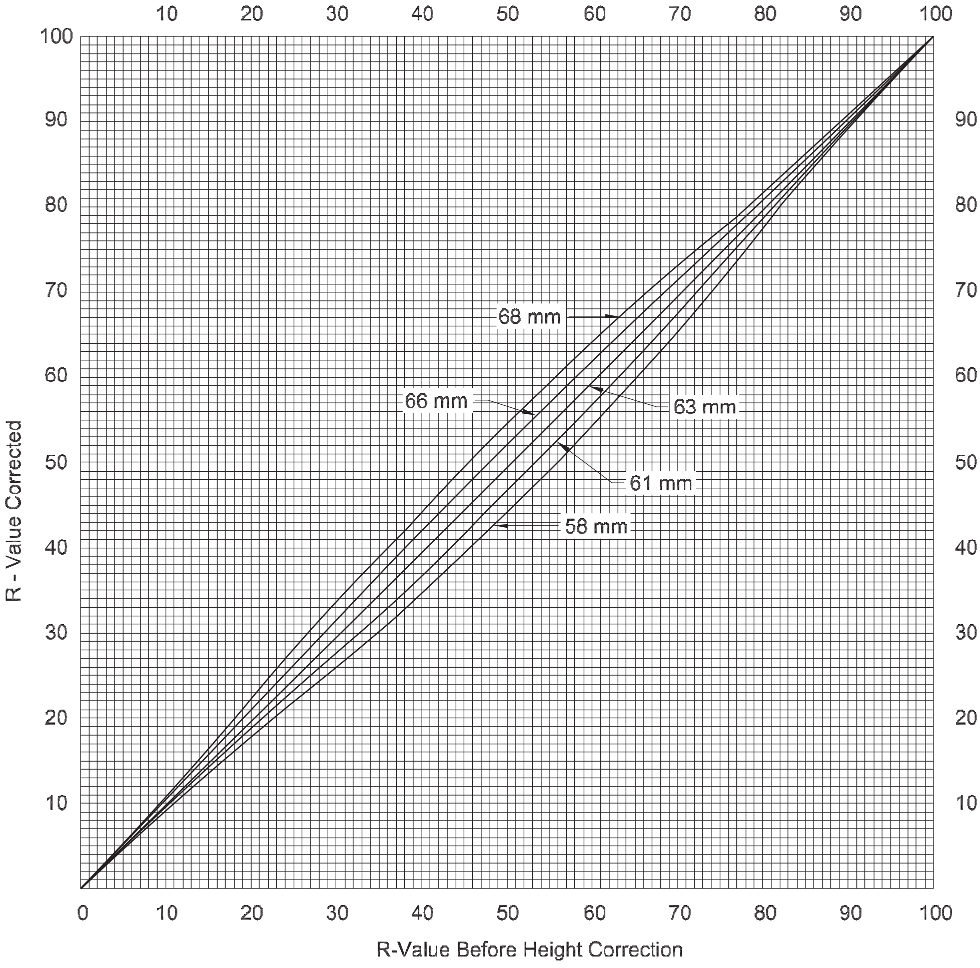

Figure 10—Height-Correction Chart

Standard Method of Test for

Density of Soil In-Place by the Sand-Cone Method

AASHTO Designation: T 191-02 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Density of Soil In-Place by the Sand-Cone Method

AASHTO Designation: T 191-02 (2006)

1. SCOPE

1.1. This method is intended for determining the in-place density of soils. The apparatus described herein is restricted to tests in soils containing particles not larger than 50 mm (2 in.) in diameter.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value shall be rounded off to "the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with the rounding-off method of ASTM E 29.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

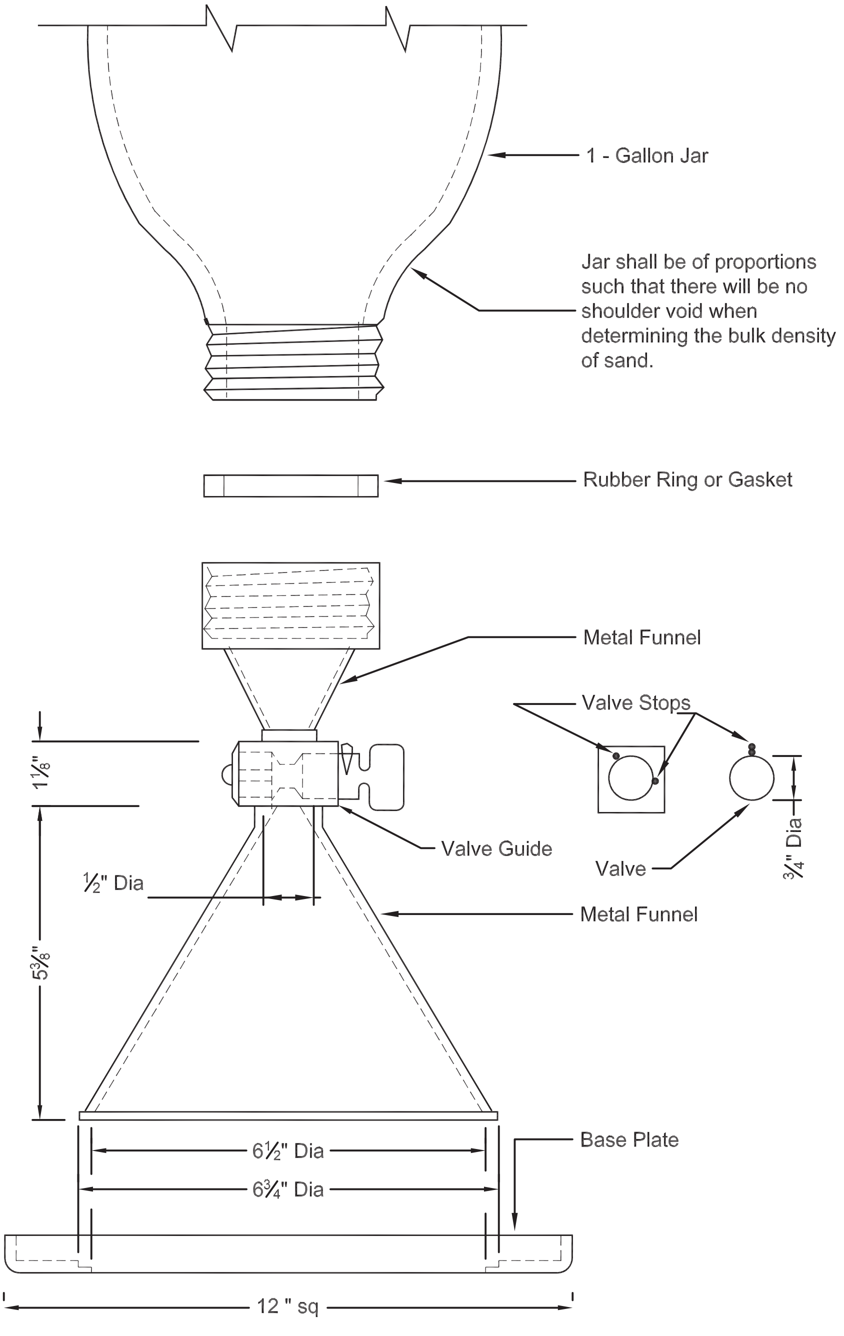
- M 231, Weighing Devices Used in the Testing of Materials
- T 19M/T 19, Bulk Density ("Unit Weight") and Voids in Aggregate
- T 99, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop
- T 217, Determination of Moisture in Soils by Means of a Calcium Carbide Gas Pressure Moisture Tester
- T 265, Laboratory Determination of Moisture Content of Soils

2.2. *ASTM Standards*:

- D 4959, Standard Test Method for Determination of Water (Moisture) Content of Soil by Direct Heating
- D 4643, Standard Test Method for Determination of Water (Moisture) Content of Soil by Microwave Oven Heating
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. APPARATUS

3.1. *Density Apparatus with Base Plate*—The density apparatus shall consist of a 4 L (1 gal) jar and a detachable appliance consisting of a cylindrical valve with an orifice 12.7 mm ($^1/_2$ in.) in diameter and having a small funnel continuing to a standard G mason jar top on one end and a large funnel on the other end. The valve shall have stops to prevent rotating the valve past the completely open or completely closed positions. The apparatus shall conform to the requirements shown in Figure 1. The apparatus described here represents a design that has proven satisfactory. Other apparatus of similar proportions will perform equally well so long as the basic principles of the sand-volume determination are observed. The base plate is required for calibrations and testing.



Metric Equivalents

in.	mm	in.	mm
$^{1}/_{2}$	12.7	$6^{1}/_{2}$	165.1
$^{3}/_{4}$	19.1	$6^{3}/_{4}$	171.5
$1^{1}/_{8}$	28.6	12	304.8
$5^{3}/_{8}$	136.5		

Figure 1—Density Apparatus

3.2. *Calibration Container*—A sturdy cylindrical container of known volume (V_c). The container shall be dimensionally approximate to the largest test hole that will be dug. The container shall be calibrated according to T 19M/T 19.

Note 1—The internal diameter of the container shall be equal to or slightly less than the diameter of the opening of the base plate used with the sand-cone.

3.3. *Sand*—Any clean, dry, free-flowing, uncemented sand having few, if any, particles passing the 0.075-mm or retained on the 2.00-mm sieves. In selecting a sand for use, several bulk density determinations should be made using the same representative sample for each determination. To be acceptable the sand shall not have a variation in bulk density greater than 1 percent.

3.4. *Balances*—A balance conforming to the requirements of M 231, Class G 20. Also, a balance conforming to the requirements of M 231, Class G 2.

3.5. *Drying Equipment*—Stove or oven or other suitable equipment for drying moisture content samples.

3.6. *Miscellaneous Equipment*—Small pick, chisels, or spoons for digging test hole; 254 mm (10 in.) frying pan or any suitable container for drying moisture samples; buckets with lids, canvas sacks, or other suitable containers for retaining the density sample, moisture sample, or density sand, respectively; small paintbrush, slide rule, and notebook.

4. CONE CORRECTION AND BULK DENSITY FACTORS

4.1. *Filling the apparatus*:

4.1.1. Place the empty apparatus upright on a firm, level surface, close the valve, and fill the funnel with sand.

4.1.2. Open the valve and keep the funnel at least half full with sand during filling. When the sand stops flowing into the apparatus, close the valve sharply and empty the excess sand (Note 2).

Note 2—Vibration of the sand during any mass-volume determination may increase the bulk density of the sand and decrease the accuracy of the determination. Appreciable time intervals between the bulk density determination of the sand and its use in the field may result in change in the bulk density caused by a change in the moisture content or effective gradation.

4.1.3. Determine and record the mass of the apparatus filled with sand (m_1).

4.2. Determine the mass of sand required to fill the funnel and base plate (cone correction).

4.2.1. Place the base plate on a clean, level, plane surface. Invert the sand-cone filled with sand and seat the funnel in the recess of the base plate.

4.2.2. Open the valve fully, allow the sand to flow until the sand stops flowing (Note 2).

4.2.3. Close the valve sharply, remove the apparatus, and determine the mass of the apparatus and the remaining sand (m_2).

4.2.4. The mass of sand required to fill the cone and base plate is calculated by the difference between the initial mass (Step 4.1.3) and final mass (Step 4.2.3). Record this mass as the cone correction ($C_c = m_1 - m_2$) (Note 3).

Note 3—For each container/bag of sand there will be a unique cone correction and sand calibration factor. Each sand-cone and matched base plate will also have a set of unique cone corrections and bulk sand densities. If more than one sand-cone apparatus is available, the sand-cone and base plate should be marked and the associated correction/density factors recorded.

4.3. Determine the bulk density of sand (D_B) to be used in the field test.

4.3.1. Replace the sand removed in the funnel determination according to Section 4.1, close the valve, and determine the mass of the apparatus and sand (m_3).

4.3.2. Position the calibration container on a clean, level, plane surface. Place the base plate on the calibration container (Note 1). Invert the apparatus and seat the funnel in the recess of the base plate.

4.3.3. Open the valve fully and keep open until the sand stops flowing (Note 2).

4.3.4. Close the valve sharply, remove the apparatus, and determine the remaining mass of the apparatus and sand (m_4).

4.3.5. Calculate the mass of the sand needed to fill the container, funnel, and base plate. Subtract the final mass (Step 4.3.4) from the initial mass (Step 4.3.1).

4.3.6. The mass of the sand needed to fill the container only is determined by subtracting the mass of the cone correction (Step 4.2.4) from the total mass required to fill the container with the funnel and base plate (Step 4.3.5).

4.3.7. Determine the bulk density of the calibration sand (sand calibration factor). Divide the mass of the sand needed to fill the container (Step 4.3.6) by the volume of the calibration container as determined according to T 19M/T 19.

$$D_B = (m_3 - m_4 - C_c)/V_c$$

4.3.8. Record this factor for future reference (Note 3).

5. PROCEDURE

5.1. Determine the density of the soil in place as follows:

5.1.1. Fill the apparatus with sand according to Section 4.1. Record the total mass (m_5).

5.1.2. Prepare the surface of the location to be tested so that it is a level plane.

5.1.3. Seat the base plate on the prepared surface. Dig the test hole inside the opening of the base plate, being very careful to avoid disturbing the soil that will bound the hole. Soils that are essentially granular require extreme care. Place all loosened soil in a container, being careful to avoid losing any material. Care must be taken to avoid moisture loss during excavation.

5.1.4. Place the apparatus on the base plate, open the valve. After the sand has stopped flowing, close the valve (Note 2).

5.1.5. Weigh the apparatus with the remaining sand (m_6) and record.

5.1.6. Weigh the moist material that was removed from the test hole.

5.1.7. Mix the material thoroughly and secure and weigh a representative sample for moisture determination.

5.1.8. Dry and weigh the soil sample for moisture content determination in accordance with T 265 or in accordance with rapid methods such as T 217, ASTM D 4959, or ASTM D 4643. The results obtained using these or other rapid test methods must be corrected to the values obtained in accordance with T 265. Calculate the moisture content to the nearest 0.1 percent.

5.1.9. The minimum test hole volumes suggested in determining the in-place density of soil mixtures are given in Table 1. This table shows the suggested minimum mass of the moisture content sample in relation to the maximum particle size in soil mixtures.

Table 1—Minimum Test Hole Volumes and Minimum Moisture Content Samples Based on Maximum Size of Particle

Maximum Particle Size		Minimum Test Hole, Volume		Minimum Moisture Content Sample, g
mm	Alternate	cm^3	ft^3	
4.75	No. 4 Sieve	710	0.025	100
12.5	$^1/_2$ in.	1415	0.050	250
25.0	1 in.	2125	0.075	500
50.0	2 in.	2830	0.100	1000

6. CALCULATIONS

6.1. Calculate the volume of the test hole (V_H):

$$V_H = (m_5 - m_6 - C_c)/D_B \qquad (1)$$

where:

V_H = volume of the test hole,
m_5 = initial mass of the apparatus and sand,
m_6 = final mass of the apparatus and sand,
C_c = cone correction, and
D_B = bulk density of the sand.

6.1.1. Calculate the volume of the test hole to the nearest 1 cm^3 (0.0001 ft^3).

6.2. Calculate the dry mass of the material removed from the test hole as follows:

$$M_{DS} = (M_{WS} / (1 + (w/100)) \qquad (2)$$

where:

M_{DS} = dry mass of the material removed from the test hole,

M_{WS} = moist mass of the material removed from the test hole, and

w = percentage of moisture, in material removed from the test hole.

6.2.1. Calculate the dry mass of the material to the nearest 1 g (0.01 lb).

6.3. Calculate the dry in-place dry density of the material removed from the test hole as follows:

$$D_D = M_{DS}/V_H \tag{3}$$

where:

D_D = in-place dry density of the material removed from the test hole,

M_{DS} = dry mass of the material removed from the test hole (Section 5.2), and

V_H = volume of the test hole (Section 5.1).

6.3.1. Calculate the in-place dry density to the nearest 1 kg/m^3 (0.1 lb/ft^3).

Note 4—0.001 g/cm^3 = 1 kg/m^3

Note 5—It may be desired to express the in-place density as a percentage of some other density, for example, the laboratory maximum density determined in accordance with T 99. This relationship can be determined by dividing the in-place density by the maximum density and multiplying by 100.

Standard Method of Test for

The California Bearing Ratio

AASHTO Designation: T 193-10

Washington, D.C. 20001

Standard Method of Test for

The California Bearing Ratio

AASHTO Designation: T 193-10

1. SCOPE

1.1 This test method covers the determination of the California Bearing Ratio (CBR) of pavement subgrade, subbase, and base/course materials from laboratory compacted specimens. The test method is primarily intended for, but not limited to, evaluating the strength of cohesive materials having maximum particle sizes less than 19 mm ($^3/_4$ in.).

1.2 When materials having maximum particle sizes greater than 19 mm ($^3/_4$ in.) are to be tested, this test method provides for modifying the gradation of the material so that the material used for tests all passes the 19.0-mm ($^3/_4$-in.) sieve while the total gravel 4.75-mm (No. 4) to 75-mm (3-in.) fraction remains the same. While traditionally this method of specimen preparation has been used to avoid the error inherent in testing materials containing large particles in the CBR test apparatus, the modified material may have significantly different strength properties than the original material. However, a large experience base has developed using this test method for materials for which the gradation has been modified and satisfactory design methods are in use based on the results of tests using this procedure.

1.3 Past practice has shown that CBR results for those materials having substantial percentages of particles retained on the 4.75-mm (No. 4) sieve are more variable than for finer materials. Consequently, more trials may be required for these materials to establish a reliable CBR.

1.4 This test method provides for the determination of the CBR of a material at optimum water content or a range of water content from a specified compaction test and a specified dry unit mass. The dry unit mass is usually given as a percentage of maximum dry unit mass from the compaction tests of T 99 or T 180.

1.5 The agency requesting the test shall specify the water content or range of water content and the dry unit mass for which the CBR is desired.

1.6 Unless specified otherwise by the requesting agency, or unless it has been shown to have no effect on test results for the material being tested, all specimens shall be soaked prior to penetration.

1.7 The values stated in SI units are to be regarded as the standard.

3. SIGNIFICANCE AND USE

3.1 This test method is used to evaluate the potential strength of subgrade, subbase, and base course material, including recycled materials, for use in road and airfield pavements. The CBR value obtained in this test forms an integral part of several flexible pavement design methods.

3.2 For applications where the effect of compaction water content on CBR is small, such as cohesionless, coarse-grained materials, or where an allowance is made for the effect of differing compaction water contents in the design procedure, the CBR may be determined at the optimum water content of a specified compaction effort. The dry unit mass specified is normally the minimum percent compaction allowed by using the agency's field compaction specification.

3.3 For applications where the effect of compaction water content on CBR is unknown or where it is desired to account for its effect, the CBR is determined for a range of water content, usually the range of water content permitted for field compaction by using the agency's field compaction specification.

3.4 The criteria for test specimen preparation of self-cementing (and other) materials that gain strength with time must be based on a geotechnical engineering evaluation. As directed by the engineer, self-cementing materials shall be properly cured until bearing ratios representing long-term service conditions can be measured.

4. APPARATUS

4.1 *Molds*—The molds shall be cylindrical in shape, made of metal, with an internal diameter of 152.40 ± 0.66 mm (6.0 ± 0.026 in.) and a height of 177.80 ± 0.46 mm (7.0 ± 0.018 in.), and provided with an extension collar approximately 50 mm (2.0 in.) in height and a perforated base plate that can be fitted to either end of the mold. (See Figure 1.) It is desirable to have at least three molds for each soil to be tested.

Figure 1—*Continued*

4.2 *Spacer Disk*—A circular spacer disk made of metal 150.8 ± 0.8 mm ($5^{15}/_{16} \pm {}^{1}/_{32}$ in.) in diameter and 61.37 ± 0.25 mm (2.416 ± 0.01 in.) in height. (See Figure 1.)

Note 1—When using molds having a height of 177.80 mm (7.0 in.) (Figure 1), a spacer disk height of 61.37 mm (2.416 in.) is needed to obtain a thickness of compacted specimen that conforms to the thickness: 116.43 mm (4.584 in.) of specimens in T 99 and T 180.

4.3 *Rammer*—A rammer as specified in either T 99 or T 180.

4.4 *Apparatus for Measuring Expansion*—This consists of a swell plate with adjustable stem (Figure 1) and a tripod support for a dial indicator (Figure 1). The swell plate is made of metal, 149.2 ± 1.6 mm ($5^{7}/_{8} \pm {}^{1}/_{16}$ in.) in diameter and is perforated with 1.6-mm (${}^{1}/_{16}$-in.) diameter holes. The tripod used to support the dial indicator is arranged to fit the mold extension collar.

4.5 *Indicators*—Two dial indicators: each indicator shall have a 25-mm (1-in.) throw and read to 0.02 mm (0.001 in.).

4.6 *Surcharge Weights*—One annular metal weight with a center hole approximately 54.0 mm ($2^{1}/_{8}$ in.) in diameter and several slotted or split metal weights, all 149.2 ± 1.6 mm ($5^{7}/_{8} \pm {}^{1}/_{16}$ in.) in diameter and each having a mass of 2.27 ± 0.04 kg (5 ± 0.10 lb) (Figure 1) (Note 2).

Note 2—When using split weights, the mass of the pair shall be 2.27 ± 0.04 kg (5 ± 0.10 lb).

4.7 *Penetration Piston*—A metal piston of circular cross-section having a diameter of 49.63 ± 0.13 mm (1.954 ± 0.005 in.) area = 1935 mm^2 (3 in.^2) and not less than 102 mm (4 in.) long. (See Figure 1.)

4.8 *Loading Device*—A compression-type apparatus capable of applying a uniformly increasing load up to a capacity sufficient for the material being tested at a rate of 1.3 mm/min. (0.05 in./min.), used to force the penetration piston into the specimen.

4.9 *Soaking Tank*—A soaking tank suitable for maintaining the water level 25 mm (1 in.) above the top of the specimens.

4.10 *Drying Oven*—A thermostatically controlled drying oven capable of maintaining a temperature of 110 ± 5ºC (230 ± 9ºF) for drying moisture samples.

4.11 *Moisture Content Containers*—As specified in T 265.

4.12 *Miscellaneous*—Miscellaneous tools such as mixing pans, spoons, straightedge, filter paper, balances, etc.

5. SAMPLE

5.1 The sample shall be handled and specimen(s) for compaction shall be prepared in accordance with the procedures given in T 99 or T 180 for compaction in a 152.4-mm (6-in.) mold except as follows:

5.1.1 If all material passes a 19.0-mm (${}^{3}/_{4}$-in.) sieve, the entire gradation shall be used for preparing specimens for compaction without modification. If there is material retained on the 19.0-mm sieve, the material retained on the 19.0-mm sieve shall be removed and replaced by an equal amount of material passing the 19.0-mm sieve and retained on the 4.75-mm (No. 4) sieve obtained by separation from portions of the sample not otherwise used for testing.

5.1.2 *Bearing Ratio at Optimum Water Content*—From a sample having a mass of 35 kg (75 lb) or more, select a representative portion having a mass of approximately 11 kg (25 lb) for a moisture-density test and divide the remainder of the sample to obtain three representative portions having a mass of approximately 6.8 kg (15 lb) each.

5.1.3 *Bearing Ratio for a Range of Water Content*—From a sample having a mass of 113 kg (250 lb) or more, select at least five representative portions having a mass of approximately 6.8 kg (15 lb) each for use in developing each compaction curve.

6. MOISTURE-DENSITY RELATION

6.1 *Bearing Ratio at Optimum Water Content*—Using the 11-kg (25-lb) portion prepared as described in Section 5.1, determine the optimum moisture content and maximum dry density in accordance with the compaction method specified, either T 99 or T 180. A previously performed compaction test on the same material may be substituted for the compaction test just described, provided that if the sample contains material retained on the 19.0-mm ($^3/_4$-in.) sieve, soil prepared as described in Section 5.1 is used (Note 3).

Note 3—Maximum dry unit mass obtained from a compaction test performed in a 101.6-mm (4-in.) diameter mold may be slightly greater than the maximum dry unit weight obtained from compaction in the 152.4-mm (6-in.) compaction mold or CBR mold.

6.2 *Bearing Ratio for a Range of Water Content*—Using the 6.8-kg (15-lb) specimens prepared as described in Section 5.1, determine the optimum moisture content and maximum dry density in accordance with the compaction method specified, either T 99 (Method D) or T 180 (Method D), except that the CBR molds shall be used and each specimen shall be penetrated for CBR determination. In addition, the complete moisture-density relationship for 25-blow and 10-blow per layer compactions shall be developed and each test specimen compacted shall be penetrated. Perform all compaction in CBR molds. In cases where the specified unit mass is at or near 100-percent maximum dry unit mass, it will be necessary to include a compactive effort greater than 56 blows per layer (Note 4).

Note 4—A semilog plot of dry unit mass versus compactive effort usually gives a straight-line relation when compactive effort in J/m^3 (ft-lb/ft^3) is plotted on the log scale. This type of plot is useful in establishing the compactive effort and number of blows per layer needed to bracket the specified dry unit mass and water content range.

6.2.1 If the soaked CBR is to be determined, take a representative sample of the material, for the determination of moisture, at the beginning of compaction of each specimen and another sample of the remaining material after compaction of each specimen. Use T 265 to determine the moisture content. If the unsoaked CBR is to be determined, take a moisture content sample in accordance with T 99 or T 180 if the average moisture content is desired.

7. PROCEDURE

7.1 *Bearing Ratio at Optimum Water Content*:

7.1.1 Normally, three specimens must be compacted so that their compacted densities range from 95 percent (or lower) to 100 percent (or higher) of the maximum dry density determined in Section 6.1

Note 5—Generally about 10, 30, and 65 blows per layer are suitable for compacting specimens 1, 2, and 3, respectively. More than 56 blows per layer are generally required to mold a CBR specimen to 100 percent of the maximum dry density determined by T 99 (Method D); this is due to the sample for the moisture-density test being reused, while the sample for the CBR specimen is mixed and compacted only once.

Note 6—Some laboratories may prefer to test only one specimen that would be compacted to maximum dry density at optimum moisture content as determined by either T 99 or T 180.

7.1.2 Clamp the mold to the base plate, attach the extension collar and weigh to the nearest 5 g (0.01 lb). Insert the spacer disk into the mold and place a coarse filter paper on top of the disk.

7.1.3 Mix each of the three 6.8-kg (15-lb) portions prepared in Section 5.1.2 with sufficient water to obtain the optimum moisture content determined in Section 6.1.

7.1.4 Compact the first of the three portions of soil-water mixture into the mold, using three equal layers and appropriate rammer, if maximum density was determined by T 99, or five equal layers if maximum density was determined by T 180, to give a total compacted depth of about 125 mm, compacting each layer with the lowest selected number of blows in order to give a compacted density of 95 percent or less of the maximum density.

7.1.5 Determine the moisture content of the material being compacted at the beginning and end of the compaction procedure (two samples). Each moisture sample shall have a mass of at least 100 g for fine-grained soils and 500 g for coarse-grained soils. Determination of moisture content shall be done in accordance with T 265, Laboratory Determination of Moisture Content of Soils.

7.1.6 Remove the extension collar, and using a straightedge, trim the compacted soil even with the top of the mold. Surface irregularities should be patched with small-sized material. Remove the spacer disk, place a coarse filter paper on the perforated base plate, invert the mold and compacted soil, and place on the filter paper so the compacted soil is in contact with the filter paper. Clamp the perforated base plate to the mold and attach the collar. Determine the mass of the mold and specimen to the nearest 5 g (0.01 lb).

7.1.7 Compact the other two 6.8-kg (15-lb) portions in accordance with the procedure in Sections 7.1.4 through 7.1.6, except that an intermediate number of blows per layer should be used to compact the second specimen and the highest number of blows per layer shall be used to compact the third specimen.

7.2 *Bearing Ratio for a Range of Water Content*:

7.2.1 Prepare specimens in accordance with Section 6.2. Perform all compaction in the CBR molds. Each specimen used to develop the compaction curves for the 10-blow, 25-blow, and 56-blow per layer compactive efforts shall be penetrated. In cases where the specified unit mass is at or near 100 percent maximum dry unit mass, it will be necessary to include a compactive effort greater than 56 blows per layer.

8. SOAKING

8.1 Place the swell plate with adjustable stem on the soil sample in the mold and apply sufficient annular weights to produce an intensity of loading equal to the mass of the subbase and base courses and surfacing above the tested material. The total mass shall be a minimum of 4.54 kg. Additional mass shall be added in increments of 2.26 kg.

8.2 Place the tripod with dial indicator on top of the mold and make an initial dial reading.

8.3 Immerse the mold in water to allow free access of water to top and bottom of the specimen. During soaking, maintain the water level in the mold and the soaking tank approximately 25 mm (1 in.) above the top of the specimen. Soak the specimen 96 hours (4 days).

Note 7—A shorter immersion period (not less than 24 hours) may be used for soil-aggregate materials that drain readily if tests show that the shorter period does not affect the test results. For some clay soils, a soaking period greater than 4 days may be required.

8.4 At the end of 96 hours, make a final dial reading on the soaked specimens and calculate the swell as a percentage of the initial sample length:

$$\text{Percent swell} = \frac{\text{Change in length in mm during soaking}}{116.43 \text{ mm}} \times 100 \qquad (1)$$

8.5 Remove the specimens from the soaking tank, pour the water off the top and allow to drain downward for 15 minutes. Care shall be taken not to disturb the surface of the specimens during removal of the water. After draining, remove the surcharge weights, perforated plates, and top filter paper.

Note 8—The mass of the specimens may be determined after draining when it is desired to determine the average wet density of the soaked and drained material.

9. PENETRATION TEST

9.1 *Application of Surcharge*—Place a surcharge of annular and slotted weights on the specimens equal to that used during soaking. To prevent displacement of soft materials into the hole of the surcharge weights, seat the penetration piston with a 44 N (10-lb) load after one surcharge weight has been placed on the specimen. After seating the penetration piston the remainder of the surcharge weights shall then be placed around the piston.

9.2 *Seating Piston*—Seat the penetration piston with a 44 N (10-lb) load, then set both the penetration dial indicator and the load indicator to zero.

9.3 *Application of Load*—Apply the loads to the penetration piston so the rate of penetration is uniform at 1.3 mm (0.05 in.)/min. Record the load when the penetration is 0.64, 1.27, 1.91, 2.54, 3.81, 5.08, and 7.62 mm (0.025, 0.050, 0.075, 0.100, 0.150, 0.200, and 0.300 in.). Load readings at penetrations of 10.16 and 12.70 mm (0.400 and 0.500 in.) may be obtained if desired.

Note 9—The moisture content of the upper 25 mm (1 in.) may be determined after testing if desired. Moisture samples shall weigh at least 100 g for fine-grained soils and 500 g for granular soils.

10. CALCULATIONS

10.1 *Stress-Strain Curve*—Plot the stress-strain (resistance to penetration-depth of penetration) curve for each specimen as shown in Figure 2. In some instances, the initial penetration takes place without a proportional increase in the resistance to penetration and the curve may be concave upward. To obtain the true stress-strain relationships, correct the curve having concave upward shape near the origin by adjusting the location of the origin by extending the straight line portion of the stress-strain curve downward until it intersects the abscissa. (See dashed lines.)

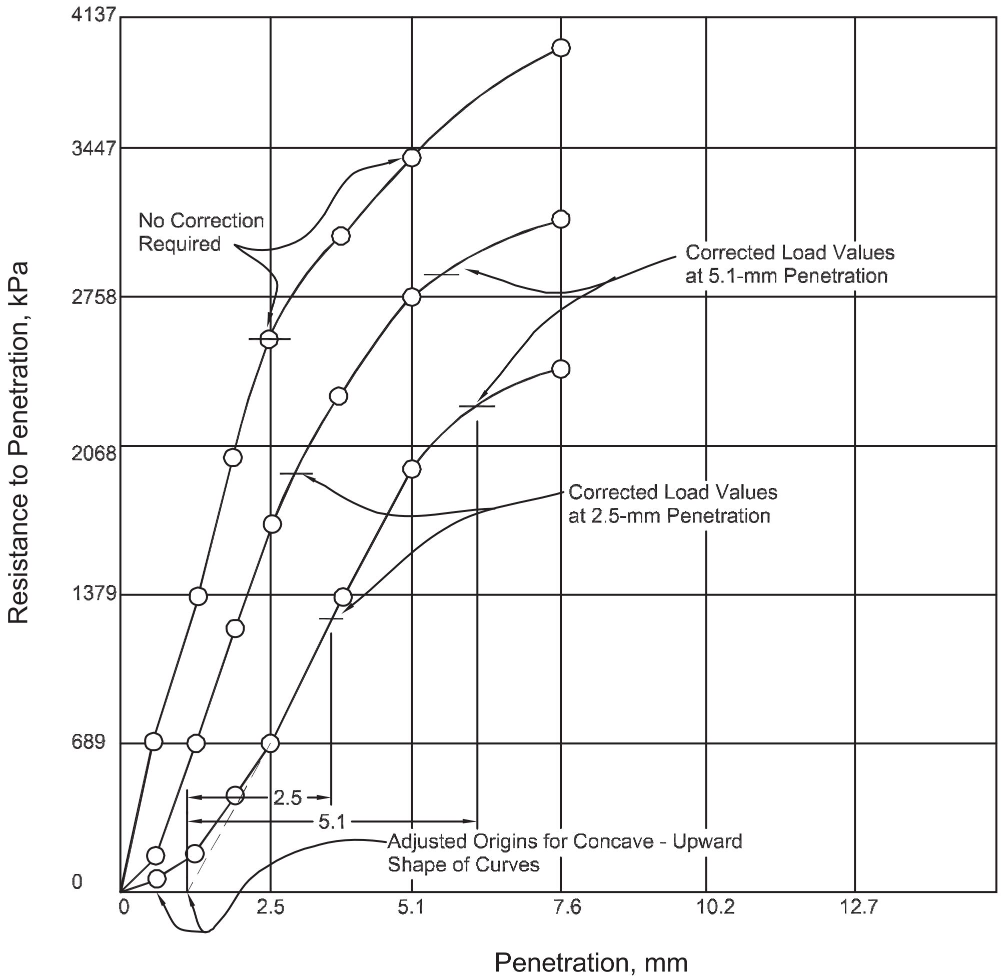

Figure 2—Correction of Stress-Strain Curves

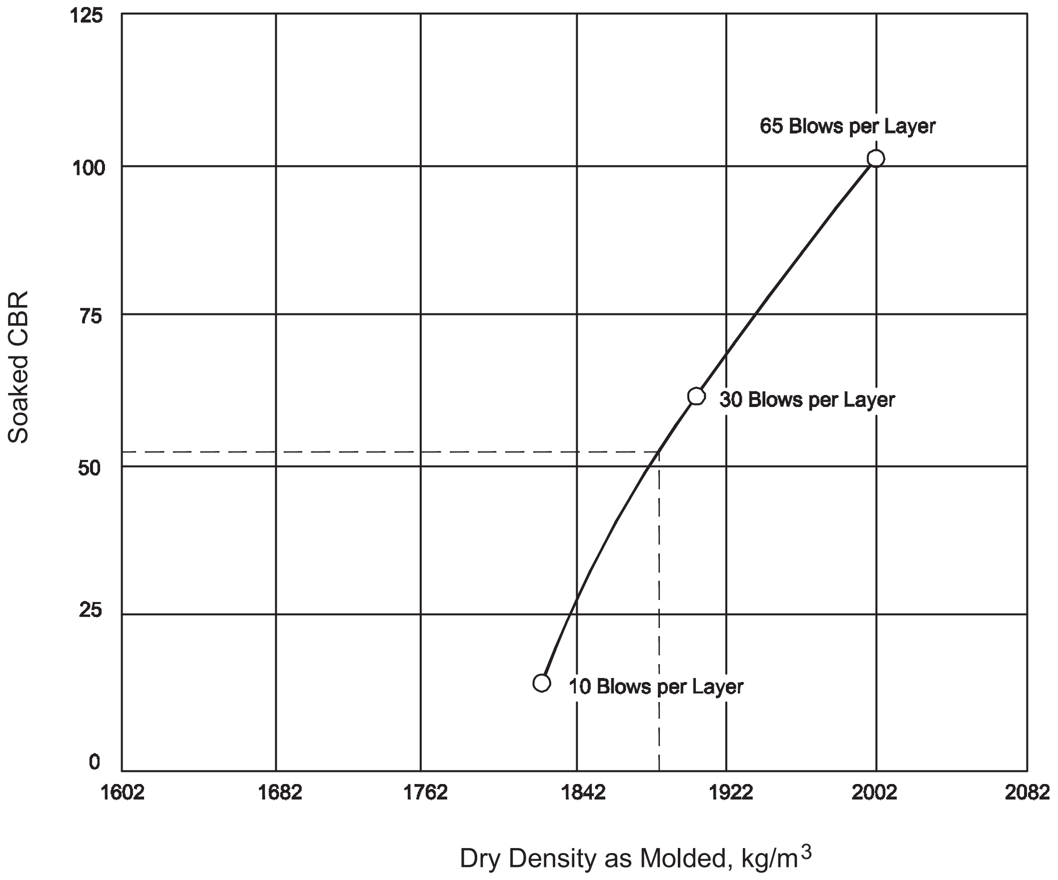
10.2 *California Bearing Ratio*—The corrected load values shall be determined for each specimen at 2.54 and 5.08 mm (0.10 and 0.20 in.) penetration. California Bearing Ratio values are obtained in percent by dividing the corrected load values at 2.54 and 5.08 mm (0.10 and 0.20 in.) by the standard loads of 6.9 and 10.3 MPa (1000 and 1500 psi), respectively, and multiplying these ratios by 100.

$$\text{CBR} = \frac{\text{Corrected load value}}{\text{Standard load}} \times 100 \qquad (2)$$

10.2.1 The CBR is generally selected at 2.54 mm (0.10 in.) penetration. If the ratio at 5.08 mm (0.20 in.) penetration is greater, the test shall be rerun. If the check test gives a similar result, the ratio at 5.08 mm (0.20 in.) penetration shall be used.

10.3 *Design CBR for One Water Content Only*—Using the data obtained from the three specimens, plot the CBR-Dry Density as Molded relation as shown in Figure 3. The design CBR may then be determined at the desired percentage of the maximum dry density, normally the minimum percentage compaction permitted by the agency's compaction specifications.



Example:

Given: Maximum dry density by T 99 = 1986 kg/m^3

Find: The CBR at 95 percent of the above maximum dry density.

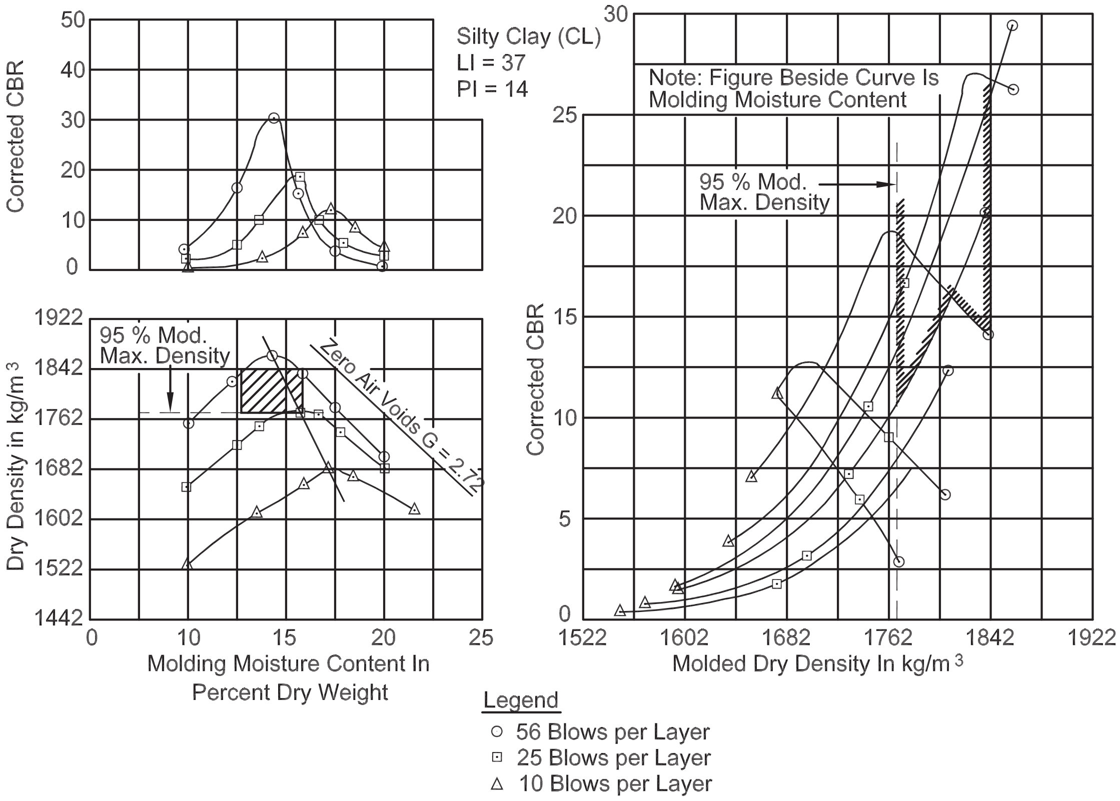
Solution: 95 percent of 1986 kg/m^3 = 1887 kg/m^3

At 1887 kg/m^3 > the CBR is 52.

Note: 1 pcf = 16.02 kg/m^3.

Figure 3—Dry Density Versus CBR

10.4 *Design CBR for Water Content Range*—Plot the data from the tests at the three compactive efforts as shown in Figure 4. The data plotted as shown represent the response of the soil over the range of water content specified. Select the CBR for reporting as the lowest CBR within the specified water content range having a dry unit mass between the specified minimum and the dry unit mass produced by compaction within the water content range.



Note: Surcharge = 50-lb soaking and penetration. All samples soaked top and bottom four days. All samples compacted in five layers, 10-lb rammer, 18-in. drop in CBR mold.

Figure 4—Determining CBR for Water Content Range and Minimum Dry Unit Weight

11. REPORT

11.1 The report shall include the following information for each specimen:

11.1.1 Compaction effort (number of blows per layer).

11.1.2 Dry density as molded, percent.

11.1.3 Moisture content as molded, percent.

11.1.4 Swell (percent of original length), percent.

11.1.5 California Bearing Ratio, percent.

Standard Method of Test for

Determination of Organic Matter in Soils by Wet Combustion

AASHTO Designation: T 194-97 (2008)

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Determination of Organic Matter in Soils by Wet Combustion

AASHTO Designation: T 194-97 (2008)

1. SCOPE

1.1. The "Wet Combustion" method for the determination of soil organic matter is most applicable when it is desired to determine the humus-like, easily-oxidized organic material to provide information relating to the suitability of the soil for plant growth. The method provides a good estimate of this type of organic matter, and, when the soil contains only this type, it can also provide a good estimate of the total organic content. However, the reagents used react only very slightly with fresh plant materials such as wood, roots, grass, and weed tops, etc., or with hydrocarbons, charcoal, lignite, coal, and the organic remains in ancient sediments. If such materials are present and the total organic matter is to be determined, the Loss on Ignition method found in T 267 must be used.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with E 29, Using Significant Digits in Test Data to Determine Conformance with Specifications.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. Refer to R 16 for regulatory information for chemicals.

2. REAGENTS

2.1. *1 Normal Potassium Dichromate*—Dissolve 49.04 g of dry reagent $K_2Cr_2O_7$ in distilled or deionized water and dilute to 1 L.

2.2. *0.5 Normal Ferrous Sulfate*—Dissolve 140 g of reagent grade $FeSO_4 \cdot 7H_2O$ in distilled water, add 40 mL of concentrated sulfuric acid, cool, and dilute to 1 L. Standardize this reagent each day by a "blank" titration against exactly 10.5 mL of 1 Normal potassium dichromate, as described in the method given below, but without a soil sample.

2.3. *Barium Diphenylamine-Sulfonate*—Dissolve 0.16 g of reagent grade barium diphenylamine-sulfonate in 100 mL of distilled water.

2.4. *Sulfuric Acid*—Concentrated (not less than 96 percent), reagent grade.

2.5. *Phosphoric Acid*—85 percent, reagent grade.

3. APPARATUS

3.1. *Balance*—The balance shall conform to AASHTO M 231, Class B.

3.2. *Erlenmeyer flasks*, 400 mL.

3.3. *Volumetric flasks*, 1000 mL.

3.4. *Transfer pipettes*, 10 mL and 20 mL (or burettes).

3.5. *Heat resistant pad.*

3.6. *Graduated cylinders*, 250 mL and 25 mL.

3.7. *Dropping bottles for indicator solutions*. For barium diphenylamine-sulfonate solution, add 0.80 mL, which equals 15 drops from a dropping bottle.

3.8. *Burettes*, 50 mL (two required).

3.9. *Burette holder and laboratory stand.*

3.10. *Washing bottle*, for distilled water.

3.11. *Glass or polyethylene bottle*, minimum capacity, 1 L, for storage of potassium dichromate and ferrous sulfate solutions (two required).

3.12. *Oven*, capable of maintaining 110º ± 5ºC (230º ± 9ºF).

4. PROCEDURE

4.1. Weigh 0.750 to 1.0 g (Note 1) of oven-dried soil passing the 0.425-mm sieve (No. 40), to the nearest 0.001 g, transfer quantitatively to a 400-mL Erlenmeyer flask, and add from a burette or pipette exactly 10 mL of the potassium dichromate solution. Immediately add from a graduate cylinder or a pipette 20 mL of concentrated sulfuric acid, directing the stream into the solution. Immediately swirl the flask vigorously to mix thoroughly and then allow it to stand on a sheet of asbestos for about 30 minutes. (See Note 2.) Add 200 mL of distilled or deionized water from a graduated cylinder, 10 mL of phosphoric acid from a graduated cylinder (Note 3), and 0.80 mL (15 drops) of barium diphenylamine-sulfonate indicator and swirl the flask to ensure thorough mixing. While still swirling the flask, add ferrous sulfate solution quantitatively from a burette. The solution will first turn purple, then from dark blue to light blue, after which the ferrous sulfate should be added slowly until the color changes—with little warning—to brilliant green. Add 0.5 mL (10 drops) more of the dichromate solution to restore an excess of dichromate, wash down the inside walls of the flask with a few mL of water from a wash bottle, and complete the titration to a one-drop, light green end-point by adding the ferrous sulfate drop by drop to the swirling flask. If less than 5 mL of the ferrous sulfate solution has been used in the titration, repeat the determination with less soil. Make a standardizing "blank" run without a soil sample, but using exactly 10.5 mL of dichromate and otherwise following the procedure given above.

Note 1—For peat, use the Loss on Ignition method (T 267). It may be necessary to decrease the amount of soil below the minimum specified under Section 4.1 for soils greater than approximately 10-percent organic. The Loss on Ignition method (T 267) must be used if the soil sample is less than 0.200 g.

Note 2—Because the action of chromic acid on organic matter is considerably affected by temperature, the flask should be kept in a relatively draft-free place at room temperature, 20º to 30ºC (68º to 86ºF) for the 30-minute period.

5. CALCULATIONS

5.1. Determine the amount of dichromate solution that was reduced by the soil organic matter. This requires (1) standardization of the ferrous sulfate solution so the amount of dichromate equivalent to the ferrous sulfate actually used in the test may be determined and subtracted from the total dichromate used in the test; and (2) correction for the small amount of dichromate reduced by impurities in the reagents used. Both of these requirements are satisfied by the "blank" determination described in the procedure. For example, in a blank determination, 10.50 mL of the dichromate solution might require 20.75 mL of ferrous sulfate. In the test procedure for a hypothetical 1.000 g soil sample, 10.50 mL of dichromate would have been used; and the subsequent titration might require 6.80 mL of ferrous sulfate. The amount of dichromate actually reduced by the organic matter of this soil sample would therefore be 10.50 $(1 - {}^{6.80}/_{20.75})$, or 7.06 mL; and since the dichromate is a 1 Normal solution, this corresponds to 7.06 milliequivalents of dichromate reduced.

5.2. A milliequivalent of carbon in the oxidation reaction involved in this test method is 0.003 g. The amount of carbon occurring in easily oxidized carbon would therefore be 7.06 × 0.003, or 0.021 g, and the percentage of easily oxidized carbon would be $0.021 \times {}^{100}/_{1.000} = 2.1$ percent.

5.3. It is widely accepted that humus-like soil organic matter contains about 58 percent carbon. Therefore, to convert the percentage of easily oxidized carbon to the percentage of easily oxidized organic matter, multiply by ${}^{100}/_{58}$ or 1.72. The percentage of easily oxidized organic matter in the example soil would accordingly be 2.1 × 1.72, or 3.6 percent.

5.4. It has been found for many agricultural soils that the amount of organic carbon indicated by the Wet Combustion method is about 77 percent of the total organic content, as determined by the Loss on Ignition method (T 267). Therefore, to approximate the total carbon or total organic matter percentage, the percentage of easily oxidized carbon or organic matter is multiplied by ${}^{100}/_{77}$ or 1.3. In the example soil, the percentage of total carbon would be 2.1 × 1.3, or 2.7 percent, and the percentage of total organic matter would be 3.6 × 1.3, or 4.7 percent.

5.5. The information given above in this section may be summarized in the following equations:

$$\text{Easily oxidized carbon, percent} = 10.5 \times \left(1 - \frac{\text{sample titre, mL}}{\text{blank titre, mL}}\right) \times 0.3 \div \text{mass of soil} \qquad (1)$$

Total carbon, percent = Equation (1) × 1.3. *(2)*

Easily oxidized matter, percent = Equation (1) × 1.72. *(3)*

Total organic matter, percent = Equation (1) × 1.3 × 1.72,
or Equation (1) × 2.236 *(4)*

Note 3—It is possible that a color change during titration with ferrous sulfate solution may be impossible to observe with certain types and/or colors of soil. If this occurs, filter the sample through No. 54 filter paper prior to the addition of the barium diphenylamine-sulfonate and then continue with the standard method.

Standard Method of Test for

Penetration Test and Split-Barrel Sampling of Soils

AASHTO Designation: T 206-09[1]
ASTM Designation: D 1586-99

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Penetration Test and Split-Barrel Sampling of Soils

AASHTO Designation: T 206-09[1]
ASTM Designation: D 1586-99

1. SCOPE

1.1. This test method describes the procedure, generally known as the Standard Penetration Test (SPT), for driving a split-barrel sampler to obtain a representative soil sample and a measure of the resistance of the soil to penetration of the sampler.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* For a specific precautionary statement, see Section 5.4.1.

1.3. The values stated in SI units are to be regarded as the standard.

Note 1—ASTM D 4633 can be used for measuring the energy that enters the drill rod string during testing due to the hammer impact.

Note 2—ASTM D 6066 can be used when testing loose sands below the water table for liquefaction studies or when a higher level of care is required when drilling these soils. This practice provides information on drilling methods, equipment variables, energy corrections, and blow-count normalization.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards:*

- R 13, Conducting Geotechnical Subsurface Investigations

2.2. *ASTM Standards*:

- D 4633, Standard Test Method for Energy Measurement for Dynamic Penetrometers
- D 6066, Standard Practice for Determining the Normalized Penetration Resistance of Sands for Evaluation of Liquefaction Potential

3. DESCRIPTIONS OF TERMS SPECIFIC TO THIS STANDARD

3.1. *anvil*—that portion of the drive-weight assembly that the hammer strikes and through which the hammer energy passes into the drill rods.

3.2. *cathead*—the rotating drum or windlass in the rope-cathead lift system around which the operator wraps a rope to lift and drop the hammer by successively tightening and loosening the rope turns around the drum.

3.3. *drill rods*—rods used to transmit downward force and torque to the drill bit while drilling a borehole.

3.4. *drive-weight assembly*—a device consisting of the hammer, hammer fall guide, the anvil, and any hammer drop system.

3.5. *hammer*—that portion of the drive-weight assembly consisting of the 63.5 ± 1 kg (140 ± 2 lb) impact weight that is successfully lifted and dropped to provide the energy that accomplishes the sampling and penetration.

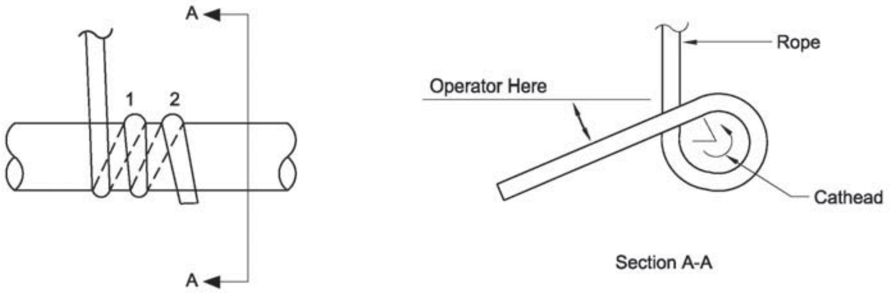
3.6. *hammer drop system*—that portion of the drive-weight assembly by which the operator accomplishes the lifting and dropping of the hammer to produce the blow.

3.7. *hammer fall guide*—that part of the drive-weight assembly used to guide the fall of the hammer.

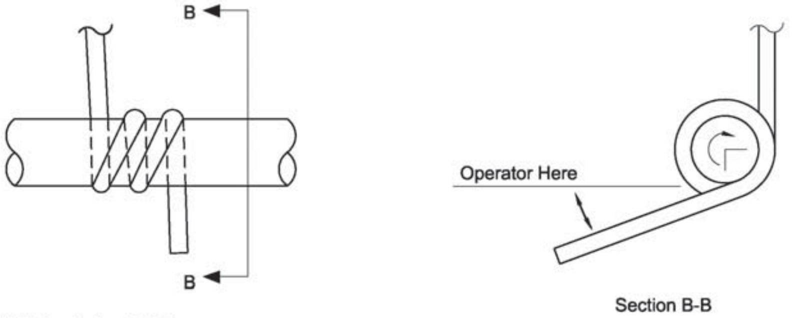
3.8. *N-value*—the blowcount representation of the penetration resistance of the soil. The *N*-value, reported in blows per foot, equals the sum of the number of blows required to drive the sampler over the depth interval of 150 to 450 mm (6 to 18 in.). (See Section 7.3.)

3.9. *ΔN*—the number of blows obtained from each of the 150-mm (6-in.) intervals of sampler penetration. (See Section 7.3.)

3.10. *number of rope turns*—the total contact angle between the rope and the cathead at the beginning of the operator's rope slackening to drop the hammer, divided by 360º. (See Figure 1.)



(a) Counterclockwise Rotation
Approximately 1¾ Turns



(b) Clockwise Rotation
Approximately 2¼ Turns

Figure 1—Definitions of the Number of Rope Turns and the Angle for *(a)* Counterclockwise Rotation and *(b)* Clockwise Rotation of the Cathead

3.11. *sampling rods*—rods that connect the drive-weight assembly to the sampler. Drill rods are often used for this purpose.

3.12. *SPT*—abbreviation for Standard Penetration Test, a term by which engineers commonly refer to this method.

4. SIGNIFICANCE AND USE

4.1. This test method provides a soil sample for identification purposes and for laboratory tests appropriate for soil obtained from a sampler that may produce large shear strain disturbance in the sample.

4.2. This test method is used extensively in a great variety of geotechnical exploration projects. Many local correlations and widely published correlations, which relate SPT blowcount, or *N*-value, and the engineering behavior of earthworks and foundations, are available.

5. APPARATUS

5.1. *Drilling Equipment*—Any drilling equipment that provides at the time of sampling a suitably clean open hole before insertion of the sampler and ensures that the penetration test is performed on undisturbed soil shall be acceptable. The following pieces of equipment have proven to be suitable for advancing a borehole in some subsurface conditions:

5.1.1. *Drag, Chopping, and Fishtail Bits*, less than 162 mm (6.5 in.) and greater than 56 mm (2.2 in.) in diameter may be used in conjunction with open-hole rotary drilling or casing-advancement drilling methods. To avoid disturbing the underlying soil, bottom discharge bits are not permitted; only side discharge bits are permitted.

5.1.2. *Roller-Cone Bits*, less than 162 mm (6.5 in.) and greater than 56 mm (2.2 in.) in diameter may be used in conjunction with open-hole rotary drilling or casing-advancement drilling methods if the drilling fluid discharge is deflected.

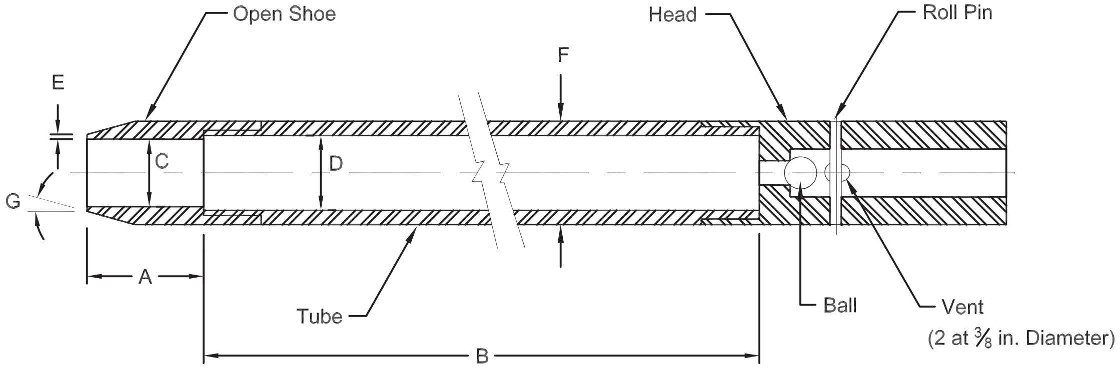
5.1.3. *Hollow-Stem Continuous Flight Augers*, with or without a center bit assembly, may be used to drill the boring. The inside diameter of the hollow-stem augers shall be less than 162 mm (6.5 in.) and greater than 56 mm (2.2 in.).

5.1.4. *Solid, Continuous Flight, Bucket, and Hand Augers*, less than 162 mm (6.5 in.) and greater than 56 mm (2.2 in.) in diameter may be used if the soil on the side of the boring does not cave onto the sampler or sampling rods during sampling.

5.2. *Sampling Rods*—Flush-joint steel drill rods shall be used to connect the split-barrel sampler to the drive-weight assembly. The sampling rod shall have a stiffness (moment of inertia) equal to or greater than that of parallel wall "A" rod (a steel rod that has an outside diameter of 41.2 mm ($1^5/_8$ in.) and an inside diameter of 28.5 mm ($1^1/_8$ in.).

Note 3—Recent research and comparative testing indicates the type of rod used, with stiffness ranging from "A" size rod to "N" size rod, will usually have a negligible effect on the *N*-values to depths of at least 30 m (100 ft).

5.3. *Split-Barrel Sampler*—The sampler shall consist of a heat-treated, case-hardened, steel head, split spoon and shoe assembly, constructed to the dimensions indicated in Figure 2. The driving shoe shall be of hardened steel and shall be replaced or repaired when it becomes dented or distorted. The use of liners to produce a constant inside diameter of 35 mm ($1^3/_8$ in.) is permitted, but shall be noted on the penetration record if used. The use of a sample retainer basket is permitted, and should also be noted on the penetration record if used.



A = 25 to 50 mm (1.0 to 2.0 in.)
B = 0.457 to 0.762 m (18.0 to 30.0 in.)
C = 34.93 ± 0.13 mm (1.375 ± 0.005 in.)
D = 38.1 ± 1.3-0.0 mm (1.50 ± 0.05-0.00 in.)
E = 2.54 ± 0.25 mm (0.10 ± 0.02 in.)
F = 50.8 ± 1.3-0.0 mm (2.00 ± 0.05-0.00 in.)
G = 16.0° to 23.0°

Note: The $1^{1}/_{2}$-in. (38-mm) inside diameter split barrel may be used with a 16-gauge wall thickness split liner. The penetrating end of the drive shoe may be slightly rounded. Metal or plastic retainers may be used to retain soil samples.

Figure 2—Split-Barrel Sampler

Note 4—Both theory and available test data suggest that *N*-values may increase between 10 to 30 percent when liners are used.

5.4. *Drive-Weight Assembly*:

5.4.1. *Hammer and Anvil*—The hammer shall weigh 63.5 ± 1 kg (140 ± 2 lb) and shall be a solid rigid metallic mass. The hammer shall strike the anvil and make steel on steel contact when it is dropped. A hammer fall guide permitting a free fall shall be used. Hammers used with the cathead and rope method shall have an unimpeded overlift capacity of at least 100 mm (4 in.). For safety reasons, the use of a hammer assembly with an internal anvil is encouraged.

Note 5—It is suggested that the hammer fall guide be permanently marked to enable the operator or inspector to judge the hammer drop height.

5.4.2. *Hammer Drop System*—Rope-cathead, trip, semiautomatic, or automatic hammer drop systems may be used, providing the lifting apparatus will not cause penetration of the sampler while re-engaging and lifting the hammer.

5.5. *Accessory Equipment*—Accessories such as labels, sample containers, data sheets, and groundwater level measuring devices shall be provided in accordance with the requirements of the project and other ASTM standards.

6. DRILLING PROCEDURE

6.1. The boring shall be advanced incrementally, using methods outlined in AASHTO R 13, to permit intermittent or continuous sampling. Test intervals and locations are normally stipulated by the project engineer or geologist. Typically, the intervals selected are 1.5 m (5 ft) or less in homogeneous strata with test and sampling locations at every change of strata.

6.2. Any drilling procedure that provides a suitably clean and stable hole before insertion of the sampler and assures that the penetration test is performed on essentially undisturbed soil shall be acceptable. Each of the following procedures has proven to be acceptable for some subsurface conditions. The subsurface conditions anticipated should be considered when selecting the drilling method to be used.

6.2.1. Open-hole rotary drilling method.

6.2.2. Continuous flight hollow-stem auger method.

6.2.3. Wash boring method.

6.2.4. Continuous flight solid auger method.

6.3. Several drilling methods produce unacceptable borings. The process of jetting through an open tube sampler and then sampling when the desired depth is reached shall not be permitted. The continuous flight solid auger method shall not be used for advancing the boring below a water table or below the upper confining bed of a confined noncohesive stratum that is under artesian pressure. Casing may not be advanced below the sampling elevation prior to sampling. Advancing a boring with bottom discharge bits is not permissible. It is not permissible to advance the boring for subsequent insertion of the sampler solely by means of previous sampling with the SPT sampler.

6.3.1. The sampler head is vented to prevent pressure buildup during sampling, and must be kept clean. A steel ball water check is located in the head to prevent downward water pressure from acting on the sample. Clogging of the air vents or removal of the water check frequently causes sample loss.

6.4. The drilling fluid level within the boring or hollow-stem augers shall be maintained at or above the *in situ* groundwater level at all times during drilling, removal of drill rods, and sampling.

7. SAMPLING AND TESTING PROCEDURE

7.1. After the boring has been advanced to the desired sampling elevation and excessive cuttings have been removed, prepare for the test with the following sequence of operations:

7.1.1. Attach the split-barrel sampler to the sampling rods and lower into the borehole. Do not allow the sampler to drop onto the soil to be sampled.

7.1.2. Position the hammer above and attach the anvil to the top of the sampling rods. This may be done before the sampling rods and sampler are lowered into the borehole.

7.1.3. Rest the dead weight of the sampler, rods, anvil, and drive weight on the bottom of the boring and apply a seating blow. If excessive cuttings are encountered at the bottom of the boring, remove the sampler and sampling rods from the boring and remove the cuttings.

7.1.4. Mark the drill rods in three successive 0.15-m (6-in.) increments so that the advance of the sampler under the impact of the hammer can be easily observed for each 0.15-m (6-in.) increment.

7.2. Drive the sampler with blows from the 63.5-kg (140-lb) hammer and count the number of blows applied in each 0.15-m (6-in.) increment until one of the following occurs:

7.2.1. A total of 50 blows have been applied during any one of the three 0.15-m (6-in.) increments described in Section 7.1.4.

7.2.2. A total of 100 blows have been applied.

7.2.3. There is no observed advance of the sampler during the application of 10 successive blows of the hammer.

7.2.4. The sampler is advanced the complete 0.45 m (18 in.) without the limiting blow counts occurring as described in Sections 7.2.1, 7.2.2, or 7.2.3.

7.3. Record the number of blows required to affect each 0.15 m (6 in.) of penetration or fraction thereof. The first 6 in. is considered to be a seating drive. The sum of the number of blows required for the second and third 6 in. of penetration is termed the “standard penetration resistance,” or the “*N*-value.” If the sampler is driven less than 0.45 m (18 in.), as permitted in Sections 7.2.1, 7.2.2, or 7.2.3, the number of blows per each complete 0.15-m (6-in.) increment and per each partial increment shall be recorded on the boring log. For partial increments, the depth of penetration shall be reported to the nearest 25 mm (1 in.), in addition to the number of blows. If the sampler advances below the bottom of the boring under the static weight of the drill rods or the weight of the drill rods plus the static weight of the hammer, this information should be noted on the boring log.

7.4. The raising and dropping of the 63.5-kg (140-lb) hammer shall be accomplished using either of the following two methods:

7.4.1. By using a trip, automatic, or semiautomatic hammer drop system that lifts the 63.5-kg (140-lb) hammer and allows it to drop 0.76 m ± 25 mm (30 ± 1.0 in.) unimpeded.

7.4.2. By using a cathead to pull a rope attached to the hammer. When the cathead and rope method is used, the system and operation shall conform to the following:

7.4.2.1. The cathead shall be essentially free of rust, oil, or grease and have a diameter in the range of 150 to 250 mm (6 to 10 in.).

7.4.2.2. The cathead should be operated at a minimum speed of rotation of 100 RPM, or the approximate speed of rotation shall be reported on the boring log.

7.4.2.3. No more than $2^1/_4$ rope turns on the cathead may be used during the performance of the penetration test, as shown in Figure 1.

Note 6—The operator should generally use either $1^3/_4$ or $2^1/_4$ rope turns, depending upon whether or not the rope comes off the top ($1^3/_4$ turns) or the bottom ($2^1/_4$ turns) of the cathead. It is generally known and accepted that $2^3/_4$ or more rope turns considerably impedes the fall of the hammer and should not be used to perform the test. The cathead rope should be maintained in a relatively dry, clean, and unfrayed condition.

7.4.2.4. For each hammer blow, a 0.76-m (30-in.) lift and drop shall be employed by the operator. The operation of pulling and throwing the rope shall be performed rhythmically without holding the rope at the top of the stroke.

7.5. Bring the sampler to the surface and open. Record the percent recovery or the length of sample recovered. Describe the soil samples recovered as to composition, color, stratification, and condition, then place one or more representative portions of the sample into sealable moisture-proof containers (jars) without ramming or distorting any apparent stratification. Seal each container to prevent evaporation of soil moisture. Affix labels to the containers bearing job designation, boring number, sample depth, and the blow count per 0.15-m (6-in.) increment. Protect the samples against extreme temperature changes. If there is a soil change within the sampler, make a jar for each stratum and note its location in the sampler barrel.

---

8. REPORT

8.1. Drilling information shall be recorded in the field and shall include the following:

8.1.1. Name and location of job;

8.1.2. Names of crew;

8.1.3. Type and make of drilling machine;

8.1.4. Weather conditions;

8.1.5. Date and time of start and finish of boring;

8.1.6. Boring number and location (station and coordinates, if available and applicable);

8.1.7. Surface elevation, if available;

8.1.8. Method of advancing and cleaning the boring;

8.1.9. Method of keeping boring open;

8.1.10. Depth of water surface and drilling depth at the time of a noted loss of drilling fluid, and time and date when reading or notation was made;

8.1.11. Location of strata changes;

8.1.12. Size of casing, depth of cased portion of boring;

8.1.13. Equipment and method of driving sampler;

8.1.14. Type of sampler and length and inside diameter of barrel (note use of liners);

8.1.15. Size, type, and section length of the sampling rods; and

8.1.16. Remarks.

8.2. Data obtained for each sample shall be recorded in the field and shall include the following:

8.2.1. Sample depth and, if utilized, the sample number, 8.2.2. Description of soil,

8.2.3. Strata changes within sample,

8.2.4. Sampler penetration and recovery lengths, and

8.2.5. Number of blows per 0.15-m (6-in.) or partial increment.

9. PRECISION AND BIAS

9.1. *Precision*—A valid estimate of test procedures has not been determined.

9.2. *Bias*—Because there is no reference material for this test method, there can be no bias statement.

9.3. Variations in *N*-values of 100 percent or more have been observed when using different standard penetration test apparatus and drillers for adjacent borings in the same soil formation. Current opinion, based on field experience, indicates that when using the same apparatus and driller, *N*-values in the same soil can be reproduced with a coefficient of variation of about 10 percent.

9.4. The use of faulty equipment, such as an extremely massive or damaged anvil, a rusty cathead, a low-speed cathead, an old oily rope, or massive or poorly lubricated rope sheaves can significantly contribute to differences in *N*-values obtained between operator-drill rig systems.

9.5. The variability in *N*-values produced by different drill rigs and operators may be reduced by measuring that part of the hammer energy delivered into the drill rods from the sampler and adjusting *N* on the basis of comparative energies. A method for energy measurement and *N*-value adjustment is currently under development.

---

[1] Except for the use of SI units, this method is technically equivalent to ASTM D 1586-99.

Standard Method of Test for

Thin-Walled Tube Sampling of Soils

AASHTO Designation: T 207-03 (2007)[1]
ASTM Designation: D 1587-00

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Thin-Walled Tube Sampling of Soils

AASHTO Designation: T 207-03 (2007)[1]
ASTM Designation: D 1587-00

1. SCOPE

1.1. This method covers a procedure for using a thin-walled metal tube to recover relatively undisturbed soil samples suitable for laboratory tests of engineering properties, such as strength, compressibility, permeability, and density. Thin-walled tubes used in piston, plug, or rotary-type samplers, such as the Denison or Pitcher, must comply with the portions of this practice, which describe the thin-walled tubes (Section 5.3).

Note 1—This method does not apply to liners used within the above samplers.

1.2. Not all tubes specified in this method may be of sufficient diameter to perform all strength or consolidation testing. Refer to the appropriate test method for the minimum sample size to determine if the tube will be appropriate for that test.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of whoever uses this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 13, Conducting Geotechnical Subsurface Investigations

3. SUMMARY OF METHOD

3.1. A relatively undisturbed sample is obtained by pressing a thin-walled metal tube into the *in situ* soil at the bottom of a boring, removing the soil-filled tube, and sealing the ends to prevent the soil from being disturbed or losing moisture.

4. SIGNIFICANCE AND USE

4.1. This method is used when it is necessary to obtain a relatively undisturbed specimen suitable for laboratory tests of engineering properties or other tests that might be influenced by soil disturbance.

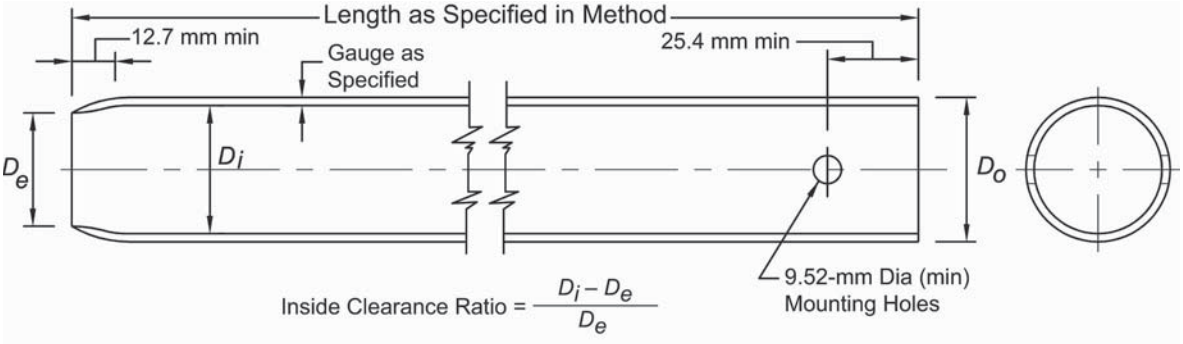
5. APPARATUS

5.1. *Drilling Equipment*—Any drilling equipment may be used that provides a reasonably clean hole; that minimizes disturbance of the soil to be sampled; and that does not hinder the penetration of the thin-walled sampler. Open borehole diameter and the inside diameter of driven casing or hollow stem auger shall not exceed 3.5 times the outside diameter of the thin-walled tube.

5.2. *Sampler Insertion Equipment*, shall be adequate to provide a relatively rapid continuous penetration force. For hard formations it may be necessary, although not recommended, to drive the thin-walled tube sampler.

5.3. *Sampler Head*, serves to couple the thin-walled tube to the insertion equipment and, together with the thin-walled tube, comprises the thin-walled tube sampler. The sampler head shall contain a suitable check valve and a venting area to the outside equal to or greater than the area through the check valve. In some special cases, a check valve may not be required, but venting is required to avoid sample compression. Attachment of the head to the tube shall be concentric and coaxial to assure uniform application of force to the tube by the sampler insertion equipment.

5.4. *Thin-Walled Tubes*, should be manufactured as shown in Figure 1. They should have an outside diameter of 50.8 to 127.0 mm (2 to 5 in.) and be made of metal having adequate strength for use in the soil and formation intended. Tubes shall be clean and free of all surface irregularities including projecting weld seams. Other diameters may be used, but the tube dimensions should be proportional to the tube designs presented here.



Notes:
1. Minimum of two mounting holes on opposite sides for 50.8- to 88.9-mm sampler.
2. Minimum of four mounting holes spaced at 90° for samplers 101.6 mm and larger.
3. Tube held with hardened screws.
4. Tubes with outside diameters of 50.8 mm are specified with an 18-gauge wall thickness to comply with area ratio criteria accepted for "undisturbed samples." Users are advised that such tubing is difficult to locate and can be extremely expensive in small quantities. Sixteen-gauge tubes are generally readily available.

English Equivalents

mm	in.
9.52	$^3/_8$
12.7	$^1/_2$
25.4	1
50.8	2
88.9	$3^1/_2$
101.6	4

Figure 1—Thin-Walled Tube for Sampling

5.4.1. *Length of Tubes*—See Table 1 and Section 6.4.

5.4.2. *Tolerances*, shall be within the limits shown in Table 2.

5.4.3. *Inside Clearance Ratio*, should not be greater than 1 percent or as specified by the engineer or geologist for the soil and formation to be sampled. Generally, the inside clearance ratio used should increase with the increase in plasticity of the soil being sampled, except for sensitive soils or where local experience indicates otherwise. See Figure 1 for definition of inside clearance ratio.

Table 1—Suitable Thin-Walled Steel Sample Tubes[a]

Outside diameter:			
mm	50.8	76.2	127.0
in.	2	3	5
Wall thickness:			
BWG	18	16	11
mm	1.24	1.65	3.05

in.	36	36	54
Clearance:			
ratio, percent	1	1	1

[a] The three diameters recommended in Table 1 are indicated for purposes of standardization, and are not intended to indicate that sampling tubes of intermediate or larger diameters are not acceptable. Lengths of tubes shown are illustrative. Proper lengths to be determined as suited to field conditions.

Table 2—Dimensional Tolerances for Thin-Walled Tubes

	Nominal Tube Diameters from Table 1[a] Tolerances		
Size Outside Diameter, mm in.	50.8 (2)	76.2 (3)	127 (5)
Outside diameter			
mm	+ 0.18	+ 0.25	+ 0.38
in.	(+ 0.007)	(+ 0.010)	(+ 0.015)
mm	– 0.00	– 0.00	– 0.00
in.	(– 0.000)	(– 0.000)	(– 0.000)
Inside diameter			
mm	+ 0.00	+ 0.00	+ 0.00
in.	(+ 0.000)	(+ 0.000)	(+ 0.000)
mm	– 0.18	– 0.25	– 0.38
in.	(– 0.007)	(– 0.010)	(– 0.015)
Wall thickness			
mm	± 0.18	± 0.25	± 0.38
in.	(± 0.007)	(± 0.010)	(± 0.015)
Ovality[b]			
mm	0.38	0.51	0.76
in.	(0.015)	(0.020)	(0.030)
Straightness			
mm/m	2.5	2.5	2.5
in./ft	(0.030)	(0.030)	(0.030)

[a] Intermediate or larger diameters should be proportional. Tolerances shown are essentially standard commercial manufacturing tolerances for seamless steel mechanical tubing. Specific only two of the first three tolerances: that is, OD and ID, or OD and Wall, or ID and Wall.

[b] *Ovality*—the cross-section of the tube that deviates from a perfect circle.

5.4.4. *Corrosion Protection*—Corrosion, whether from galvanic or chemical reaction, can damage or destroy both the thin-walled tube and the sample. Severity of damage is a function of time as well as interaction between the sample and the tube. Thin-walled tubes should have some form of protective coating. Tubes that will contain samples for more than 72 hours shall be coated. The type of coating to be used may vary depending upon the material to be sampled. Coatings may include a light coat of lubricating oil, lacquer, epoxy, Teflon, and others. Type of coating must be specified by the engineer or geologist if storage will exceed 72 hours. Plating of the tubes or alternate base metals may be specified by the engineer or geologist.

6. PROCEDURE

6.1. Advance the borehole using methods outlined in AASHTO R 13. Clean out the borehole to sampling elevation using whatever method is preferred that will ensure the material to be sampled is not disturbed. If groundwater is encountered, maintain the liquid level in the borehole at or above groundwater level during the sampling operation.

6.2. Bottom discharge bits are not permitted. Side discharge bits may be used, with caution. Jetting through an open-tube sampler to clean out the borehole to sampling elevation is not permitted. Remove loose material from the center of a casing or hollow stem auger as carefully as possible to avoid disturbance of the material to be sampled.

Note 2—Roller bits are available in downward-jetting and diffused-jet configurations. Downward-jetting configuration rock bits are not acceptable. Diffuse-jet configurations are generally acceptable.

6.3. Place the sample tube so that its bottom rests on the bottom of the hole. Record the depth to the bottom of the sample tube to the nearest 0.3 m (0.1 ft). Advance the sampler without rotation by a continuous relatively rapid motion.

6.4. Determine the length of advance by the resistance and condition of the formation, but the length shall never exceed 5 to 10 diameters of the tube in sands and 10 to 15 diameters of the tube in clays.

Note 3—The mass of the sample, laboratory-handling capabilities, transportation problems, and commercial availability of tubes will generally limit maximum practical lengths to those shown in Table 1.

6.5. When the formation is too hard for push-type insertion, the tube may be driven. Other methods, as directed by the engineer or geologist, may be used. If driving methods are used, the data regarding mass and fall of the hammer and penetration achieved must be shown in the report. Additionally, that tube must be prominently labeled a “driven sample.”

6.6. In no case shall a length of advance be greater than the sample-tube length minus an allowance for the sampler head and a minimum of 76.2 mm (3 in.) for sludge-end cuttings.

Note 4—The tube may be rotated to shear bottom of the sample after pressing is complete.

6.7. Withdraw the sampler from the formation as carefully as possible in order to minimize disturbance of the sample. Where the soil formation is soft, a delay before withdraw of the sampler (typically 5 to 30 minutes) may improve sample recovery.

7. PREPARATION FOR SHIPMENT

7.1. Upon removal of the tube, measure the length of sample in the tube. Remove the drill cuttings in the upper end of the tube and measure the length again. Seal the upper end of the tube. Remove at least 25 mm (1 in.) of material from the lower end of the tube. Use this material for soil description. Measure the overall sample length. Seal the lower end of the tube. Alternatively, after measurement, the tube may be sealed without removal of soil from the ends of the tube if so directed by the engineer or geologist.

Note 5—Field extrusion and packaging of extruded samples under the specific direction of a geotechnical engineer or geologist is permitted. Samples are extruded in special hydraulic jacks equipped with properly sized platens to extrude the core in a continuous smooth speed. Bent or damaged tubes should be cut off before extruding.

Note 6—Tubes sealed over the ends as opposed to those sealed with expanding packers should contain end padding in end voids in order to prevent drainage or movement of the sample within the tube.

7.2. Prepare and immediately affix labels or apply markings as necessary to identify the sample. Assure that the markings or labels are adequate to survive transportation and storage.

Note 7—Top end of tube should be labeled “TOP.”

8. REPORT

8.1. The appropriate information on the field log is required as follows:

8.1.1. Name and location of the project;

8.1.2. Boring number and precise location on project;

8.1.3. Surface elevation or reference to a datum;

8.1.4. Date and time of boring—start and finish;

8.1.5. Depth to top of sample and number of sample;

8.1.6. Description of sampler: size, type of metal, type of coating;

8.1.7. Method of sampler insertion—push or drive;

8.1.8. Method of drilling, size of hole, casing, and drilling fluid used;

8.1.9. Depth to groundwater level—date and time measured;

8.1.10. Any possible current or tidal effect on water level;

8.1.11. Soil description;

8.1.12. Length of sampler advance; and

8.1.13. Recovery: length of sample obtained.

9. PRECISION AND BIAS

9.1. This method does not produce numerical data; therefore, a precision and bias statement is not applicable.

---

[1] Except for the use of SI units, this method is technically equivalent to ASTM D 1587-00.

Standard Method of Test for

Unconfined Compressive Strength of Cohesive Soil

AASHTO Designation: T 208-10
ASTM Designation: D 2166-00

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Unconfined Compressive Strength of Cohesive Soil

AASHTO Designation: T 208-10
ASTM Designation: D 2166-00

1. SCOPE

1.1. This test method covers the determination of the unconfined compressive strength of cohesive soil in the undisturbed, remolded, or compacted condition, using strain-controlled application of the axial load.

1.2. This test method provides an approximate value of the strength of cohesive soils in terms of total stresses.

1.3. This test method is applicable only to cohesive materials that will not expel bleed water (water expelled from the soil due to deformation or compaction) during the loading portion of the test and that will retain intrinsic strength after removal of confining pressures, such as clays or cemented soils. Dry and crumbly soils, fissured or varved materials, silts, peats, and sands cannot be tested with this method to obtain valid unconfined compressive strength values.

Note 1—The determination of the unconsolidated, undrained strength of cohesive soils with lateral confinement is covered by T 296.

1.4. This test method is not a substitute for T 296.

1.5. The values stated in SI units are to be regarded as the standard.

1.6. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- D 4220, Standard Practices for Preserving and Transporting Soil Samples

3. TERMINOLOGY

3.1. Refer to ASTM D 653 for standard definitions of terms.

3.2. *Description of Terms Specific to This Standard*:

3.2.1. *Unconfined Compressive Strength (q_u)*—The compressive stress at which an unconfined cylindrical specimen of soil will fail in a simple compression test. In this test method, unconfined compressive strength is taken as the maximum load attained per unit area or the load per unit area at 15 percent axial strain, whichever is secured first during the performance of a test.

3.2.2. *Shear Strength (s_u)*—For unconfined compressive strength test specimens, the shear strength is calculated to be one-half of the compressive stress at failure, as defined in Section 3.2.1.

4. SIGNIFICANCE AND USE

4.1. The primary purpose of the unconfined compression test is to quickly obtain the approximate compressive strength of soils that possess sufficient cohesion to permit testing in the unconfined state.

4.2. Samples of soils having slickensided or fissured structure, samples of some type of loess, very soft clays, dry and crumbly soils and varved materials, or samples containing significant portions of silt or sand, or both (all of which usually exhibit cohesive properties), frequently display higher shear strengths when tested in accordance with T 296. Also, unsaturated soils will usually exhibit different shear strengths when tested in accordance with T 296.

4.3. If both an undisturbed and a remolded test are performed on the same sample, the sensitivity of the material can be determined. This method of determining sensitivity is suitable only for soils that can retain a stable specimen shape in the remolded state.

Note 2—For soils that will not retain a stable shape, a vane shear test or T 223 can be used to determine sensitivity.

5. APPARATUS

5.1. *Compression Device*—The compression device may be a platform weighing scale equipped with a screw-jack-activated load yoke, a hydraulic loading device, or any other compression device with sufficient capacity and control to provide the rate of loading prescribed in Section 7.1. For soil with an unconfined compressive strength of less than 100 kPa (1.0 ton/ft^2), the compression device shall be capable of measuring the compressive stress to within 1 kPa (0.01 ton/ft^2). For soil with an unconfined compressive strength of 100 kPa (1.0 ton/ft^2) or greater, the compression device shall be capable of measuring the compressive stress to the nearest 5 kPa (0.05 ton/ft^2).

5.2. *Sample Extruder*—Hand-operated, mechanical, and hydraulic extruders are acceptable provided the device (1) is capable of extruding the soil core from the sampling tube in the same direction of travel in which the sample entered the tube, (2) has a length of travel at least equal to the required untrimmed test length of the sample and permits the extrusion to occur in one operation without resetting the piston or extrusion mechanism, (3) can be operated at a relatively uniform rate, and (4) causes negligible disturbance of the sample.

5.3. *Deformation Indicator*—The deformation indicator shall be a dial indicator graduated to 0.02 mm (0.001 in.) or better and having a travel range of at least 20 percent of the length of the test specimen, or some other measuring device, such as an electronic deformation measuring device, meeting these requirements.

5.4. *Dial Comparator*, or other suitable device, for measuring the physical dimensions of the specimen to within 0.1 percent of the measured dimension.

Note 3—Vernier calipers are not recommended for soft specimens, which will deform as the calipers are set on the specimen.

5.5. *Timer*—A timing device indicating the elapsed testing time to the nearest second shall be used for establishing the rate of strain application prescribed in Section 7.1.

5.6. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

5.7. *Equipment*, as specified in T 265, for drying moisture content samples.

5.8. *Miscellaneous Apparatus*, including specimen trimming and carving tools, remolding apparatus, data sheets, and water content cans, as required.

6. PREPARATION OF TEST SPECIMENS

6.1. *Specimen Size*—Specimens shall have a minimum diameter of 30 mm (1.3 in.) and the largest particle contained within the test specimen shall be smaller than one-tenth of the specimen diameter. For specimens having a diameter of 72 mm (2.8 in.) or larger, the largest particle size shall be smaller than one-sixth of the specimen diameter. If, after completion of a test on an undisturbed specimen, it is found, based on visual observation, that larger particles than permitted are present, indicate this information in the remarks section of the report of test data (Note 4). The height-to-diameter ratio shall be between 2 and 2.5. Determine the average height and diameter of the test specimen using the apparatus specified in Section 5.4. Take a minimum of three height measurements (120 degrees apart) and at least three diameter measurements at the quarter points of the height.

Note 4—If large soil particles are found in the sample after testing, a particle-sized analysis performed in accordance with T 88 may be performed to confirm the visual observation and the results provided with the test report.

6.2. *Undisturbed Specimens*—Prepare undisturbed specimens from large undisturbed samples or from samples secured in accordance with T 207 and preserved and transported in accordance with the practices for Group C samples in ASTM D 4220. Tube specimens may be tested without trimming except for the squaring of ends, if conditions of the sample justify this procedure. Handle specimens carefully to prevent disturbance, changes in cross section, or loss of water content. If compression or any type of noticeable disturbance would be caused by the extrusion device, split the sample tube lengthwise or cut it off in small sections to facilitate removal of the specimen without disturbance. Prepare carved specimens without disturbance, and whenever possible, in a humidity-controlled room. Make every effort to prevent any change in water content of the soil. Specimens shall be of uniform circular cross section with ends perpendicular to the longitudinal axis of the specimen. When carving or trimming, remove any small pebbles or shells encountered. Carefully fill voids on the surface of the specimen with remolded soil obtained from the trimmings. When pebbles or crumbling result in excessive irregularity at the ends, cap the specimen with a minimum thickness of plaster of paris, hydrostone, or similar material. When sample condition permits, a vertical lathe that will accommodate the total sample may be used as an aid in carving the specimen to the required diameter. Where prevention of the development of appreciable capillary forces is deemed important, seal the specimen with a rubber membrane, thin plastic coatings, or with a coating of grease or sprayed plastic immediately after preparation and during the entire testing cycle. Determine the mass and dimensions of the test specimen. If the specimen is to be capped, its mass and dimensions should be determined before capping. If the entire test specimen is not to be used for determination of water content, secure a representative sample of cuttings for this purpose, placing them immediately in a covered container. The water content determination shall be performed in accordance with T 265.

6.3. *Remolded Specimens*—Specimens may be prepared either from a failed undisturbed specimen or from a disturbed sample, providing it is representative of the failed undisturbed specimen. In the case of failed undisturbed specimens, wrap the material in a thin rubber membrane and work the material thoroughly with the fingers to assure complete remolding. Avoid entrapping air in the specimen. Exercise care to obtain a uniform density, to remold to the same void ratio as the undisturbed specimen, and to preserve the natural water content of the soil. Form the disturbed material into a mold of circular cross section having dimensions meeting the requirements of Section 6.1. After removal from the mold, determine the mass and dimensions of the test specimens.

6.4. *Compacted Specimens*—Specimens shall be prepared to the predetermined water content and density prescribed by the individual assigning the test (Note 5). After a specimen is formed, trim the ends perpendicular to the longitudinal axis, remove from the mold, and determine the mass and dimensions of the test specimen.

Note 5—Experience indicates that it is difficult to compact, handle, and obtain valid results with specimens that have a degree of saturation that is greater than 90 percent.

7. PROCEDURE

7.1. Place the specimen in the loading device so it is centered on the bottom platen. Adjust the loading device carefully so the upper platen just makes contact with the specimen. Zero the deformation indicator. Apply the load so as to produce an axial strain at a rate of 0.5 to 2 percent per minute. Record load, deformation, and time values at sufficient intervals to define the shape of the stress-strain curve (usually 10 to 15 points are sufficient). The rate of strain should be chosen so the time to failure does not exceed about 15 minutes (Note 6). Continue loading until the load values decrease with increasing strain, or until 15 percent strain is reached. The rate of strain used for testing sealed specimens may be decreased if deemed desirable for better test results. Indicate the rate of strain in the report of the test data, as required in Section 9.1.7. Determine the moisture content of the test specimen in accordance with T 265, Laboratory Determination of Moisture Content of Soils, using the entire specimen unless representative cuttings are obtained for this purpose as in the case of undisturbed specimens. Indicate on the test report whether the water content sample was obtained before or after the shear test, as required in Section 9.1.2.

Note 6—Softer materials that will exhibit larger deformation at failure should be tested at a higher rate of strain. Conversely, stiff or brittle materials that will exhibit small deformations at failure should be tested at a lower rate of strain.

7.2. Make a sketch, or take a photo, of the test specimen at failure showing the slope angle of the failure surface if the angle is measurable.

7.3. A copy of a sample data sheet is included in the Appendix. Any data sheet can be used, provided the form contains all the required data.

8. CALCULATIONS

8.1. Calculate the axial strain, $\in_1$, to the nearest 0.1 percent, for a given applied load, as follows:

$$\in_1 = \Delta L / L_o \qquad (1)$$

where:

ΔL = length change of specimen as read from deformation indicator, mm (in.); and

L_o = initial length of test specimen, mm (in.).

8.2. Calculate the average cross-sectional area, A, for a given applied load, as follows:

$$A = A_o/(1 - \in_1) \qquad (2)$$

where:

A_o = initial average cross-sectional area of the specimen, mm^2 (in.^{2}); and

$\in_1$ = axial strain for the given load, percent.

8.3. Calculate the compressive stress, σ_c, to three significant figures, or nearest 1 kPa (0.01 ton/ft^2), for a given applied load, as follows:

$$\sigma_c = \frac{1000P}{A} \qquad (3)$$

where:

P = given applied load, N; and

A = corresponding average cross-sectional area m^2 (ft^2).

8.4. *Graph*—If desired, a graph showing the relationship between compressive stress (ordinate) and axial strain (abscissa) may be plotted. Select the maximum value of compressive stress, or the compressive stress at 15 percent axial strain, whichever is secured first, and report as the unconfined compressive strength, q_u. Whenever it is considered necessary for proper interpretation, include the graph of the stress-strain data as part of the data reported.

8.5. If the unconfined compressive strength is determined, the sensitivity, S_T, is calculated as follows:

$$S_T = \frac{q_u(\text{undisturbed specimen})}{q_u(\text{remolded specimen})} \qquad (4)$$

9. REPORT

9.1. The report should include the following:

9.1.1. Identification and visual description of the specimen, including soil classification, symbol, and whether the specimen is undisturbed, remolded, compacted, etc. Also include specimen identifying information, such as project, location, boring number, sample number, depth, etc.;

9.1.2. Initial dry density and water content (specify if the water content specimen was obtained before or after shear, and whether from cuttings or the entire specimen);

9.1.3. Degree of saturation (Note 7), if computed;

Note 7—The specific gravity determined in accordance with T 100 is required for calculation of the degree of saturation.

9.1.4. Unconfined compressive strength and shear strength;

9.1.5. Average height and diameter of specimen;

9.1.6. Height-to-diameter ratio;

9.1.7. Average rate of strain to failure, percent;

9.1.8. Strain at failure, percent;

9.1.9. Liquid and plastic limits, if determined, in accordance with T 88 and T 90;

9.1.10. Failure sketch or photo;

9.1.11. Stress-strain graph, if prepared;

9.1.12. Sensitivity, if determined;

9.1.13. Particle-size analysis, if determined, in accordance with T 88; and

9.1.14. *Remarks*—Note any unusual conditions or other data that would be considered necessary to properly interpret the results obtained; for example, slickensides, stratification, shells, pebbles, roots, or brittleness, the type of failure (that is, bulge, diagonal shear, etc.).

10. PRECISION AND BIAS

10.1. No method presently exists to evaluate the precision of a group of unconfined compression tests on undisturbed specimens due to specimen variability. Undisturbed soil specimens from apparently homogeneous soil deposits at the same location often exhibit significantly different strength and stress-strain properties.

10.2. A suitable test material and method of specimen preparation have not been developed for the determination of laboratory variances due to the difficulty in producing identical cohesive soil specimens. No estimates of precision for this test method are available.

Standard Method of Test for

Determination of Cement Content in Cement-Treated Aggregate by the Method of Titration

AASHTO Designation: T 211-90 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determination of Cement Content in Cement-Treated Aggregate by the Method of Titration

AASHTO Designation: T 211-90 (2008)

1. SCOPE

1.1. This method of test covers a procedure for determining cement content based upon the continuous neutralization of an aqueous solution from the cement-treated aggregate specimen for a specified time period. This is accomplished by adding sufficient acid to just neutralize the OH^- ion that is continuously being liberated during the hydration of the cement. The amount of acid used is directly proportional to the cement content of the treated base sample.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures, used in expressing the limiting value, in accordance with E 29, Using Significant Digits in Test Data to Determine Conformance with Specifications.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. Refer to R 16 for regulatory information for chemicals.

2. APPARATUS

2.1. A 100-mL titrating burette or other device permitting slow, easily controlled addition of acid.

2.2. A burette stand and burette clamp.

2.3. Four 1.9-L (2-qt) wide-mouth polyethylene containers (white).

2.4. Two 18.9-L (5-gal) plastic carboys equipped with siphons, neoprene or tygon tubing hose clamps, etc., for containing acid working solution and water (do not substitute glass containers for the plastic carboys).

2.5. Glass dropping bottle.

2.6. Four stainless steel stirring rods.

2.7. 9.5-mm sieve, 305-mm (12-in.) diameter.

2.8. 37.5-mm sieve, 305-mm (12-in.) diameter.

2.9. A balance or scale conforming to the requirements of M 231, Class G 2, and Class G 5.

3. REAGENTS

3.1. *Hydrochloric Acid (HCl) (Approximately 3 Normal)*—Pour approximately 11.4 L (3 gal) of water into an 18.9-L (5-gal) plastic carboy. Pour the contents of two full standard 2.7-kg (6-lb) bottles of concentrated reagent-grade HCl in the carboy. Stir or mix the solution vigorously for about 1 minute. Add tap water as necessary to bring the total volume of water and acid to 18.9 L (5 gal): then stir or mix the solution vigorously for another minute. Allow the acid solution to stand overnight; then remix it once again prior to using. Remix the acid solution once a week during use and also before using if the acid solution has been in storage for more than one week.

Note 1—The operator mixing the acid solution is required, for safety, to wear protective gloves, goggles, and aprons.

3.2. *Phenolphthalein Indicator Solution (1-Percent Solution)*—Dissolve 5 g of phenolphthalein powder U.S.P. in 250 mL of ethanol. Dilute with 250 mL of distilled water.

4. DETERMINATION OF A STANDARD CURVE

4.1. Use the particular aggregate, cement, and water from the project. Normally only one point is needed to establish the standard curve and this point is determined from duplicate tests on specimens containing 5 percent cement. However, if a small sample of untreated aggregate in water shows a red color on adding a few drops of phenolphthalein solution, indicating the presence of water soluble alkalis, then duplicate aggregate blank specimens should also be tested.

4.2. Determine a representative field moisture in percent for the cement-treated material from road moisture samples obtained after mixing.

4.3. Refer to Table 1 and select the mass of aggregate corresponding to the appropriate moisture content and 5 percent cement. This figure is the dry mass of untreated aggregate required to make a 5 percent calibration test specimen of 300 g. If the samples of untreated aggregate initially contain moisture, then adjust the mass of aggregate plus water to conform to the tabular values.

Table 1—Quantities of Materials for Calibration Specimens Containing 5-Percent Cement

Percent Moisture	Dry Mass of Aggregate, g	Volume of Water, mL	Mass of Cement, g
5	271	15	13.6
6	270	17	13.5
7	267	20	13.3
8	265	22	13.2
9	263	24	13.1
10	260	27	13.0
11	257	30	12.9
12	255	32	12.8
13	252	35	12.6
14	250	37	12.5
15	249	39	12.4
16	247	41	12.3
17	244	44	12.2
18	242	46	12.1
19	240	48	12.0
20	238	50	11.9

4.4. From the project records determine the average percentage of untreated aggregate passing the 9.5-mm sieve. This percentage passing the 9.5-mm sieve along with the portion retained on the 9.5-mm sieve will be the proportion used for the calibration specimens.

4.5. Remove and waste any aggregate in the sample of untreated material retained on the 37.5-mm sieve and then separate the sample on the 9.5-mm sieve. Recombine for duplicate calibration test specimens with the aggregate mass found in Section 4.3, and with the 9.5-mm sieve proportions found in Section 4.4.

4.6. Pour the weighed aggregate and cement (cement weighed to 0.1 g) into the 1.9-L (2-qt) plastic container and dry mix together thoroughly with a stainless steel stirring rod.

4.7. Add the amount of water specified in Table 1 and again mix thoroughly.

4.8. In order to correlate with the field testing operations, allow the mixture to stand in the covered plastic container for a period of time that corresponds to the time required to obtain a field treated sample, transport it to the testing location and prepare the 300 g test specimens.

4.9. Add 250 mL of tap water to each specimen and start timer.

4.10. Add two droppers full (approximately 40 drops) of phenolphthalein solution to each container. The water solution will normally turn red due to the presence of cement.

4.11. Determine the mass of each plastic container, including its contents, to the nearest 0.5 g.

4.12. Ten minutes after the addition of water, start adding the 3 Normal hydrochloric acid with a titrating burette while stirring continuously.

4.12.1. The initial amount of acid to be added is based upon the planned cement content of the mix and is determined from Figure 1.

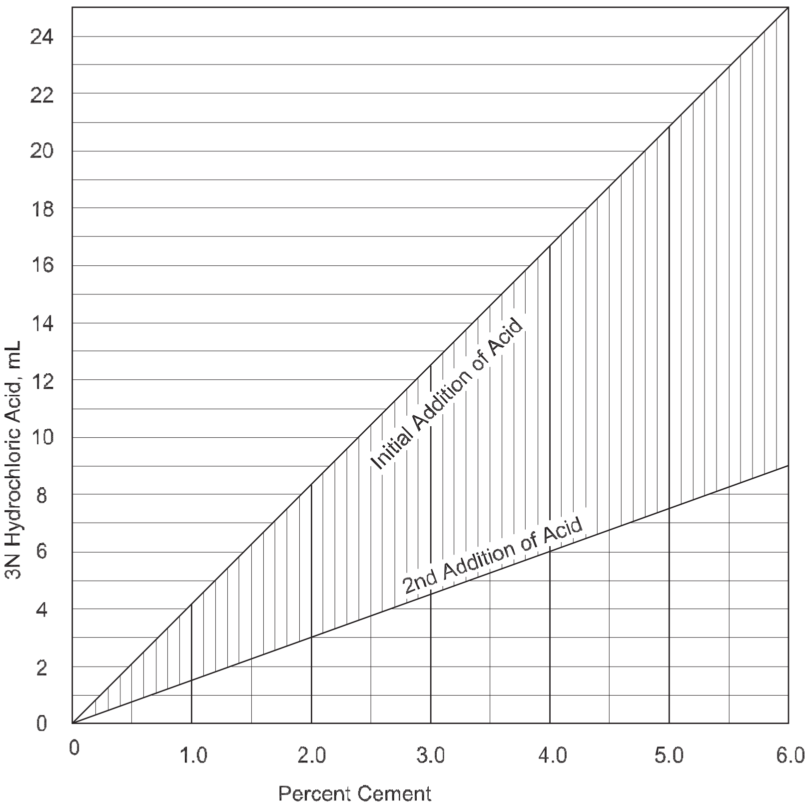

Figure 1—Constant Neutralization Procedure—Hydrochloric Acid Starting Quantities

4.12.1.1. *Example*: Suppose the planned cement content for a given project is 3.5 percent. Enter the abscissa of the chart in Figure 1 at 3.5 percent and find the intersection with the upper diagonal line. Reading from the ordinate to the nearest milliliter, it is noted that 15 mL of HCl is required. Use the titrating burette to measure and add the 15 mL of acid to the specimen in the plastic container. When the proper amount of acid is used, the red color in the solution will disappear.

4.12.2. When the red color starts to reappear, after the initial introduction of acid, use the burette to make a second addition of acid in the amount (mL) indicated by the lower diagonal line (at the planned cement content) of the chart in Figure 1.

4.13. After the first two additions of acid, make subsequent additions at random as soon as the red color reappears using only the minimum amounts necessary to cause the color to just disappear and maintain a neutral solution. This requires constant attention by the operator.

4.14. Besides the stirring accomplished during each introduction of acid, additional light stirring (for about three seconds) should be performed every minute with every fifth minute being devoted to deep stirring (for about six seconds), whether or not color is present.

4.15. Continue this procedure of adding acid and stirring until 1 hour after the initial addition of water to the specimen. Then reweigh the plastic container and contents to the nearest 0.5 g.

4.16. From the difference between the initial and final gross test specimen masses, calculate and record the total mass of hydrochloric acid used to neutralize the solution.

4.17. Plot the grams of acid used against percent cement for both duplicate 5 percent cement specimens (also aggregate blank specimens if tested). Draw a straight line from the origin of the chart (or the average of the duplicate blanks) to the average of the tests on the 5 percent specimens. This is the standard curve for determining the cement content of field mixed cement-treated specimens.

---

5. TEST PROCEDURE FOR FIELD SAMPLES

5.1. Secure one to four 3-kg field samples of the cement-treated aggregate. Remove and waste any aggregate retained on the 37.5-mm sieve. Separate sample on the 9.5-mm sieve and determine the proportion passing the 9.5-mm sieve on the basis of total sample mass including retained 37.5-mm material.

5.2. Recombine the retained and passing 9.5-mm portions for the 300-g test specimens in their "As received" proportions, place each specimen in a separate 1.9-L (2-qt) plastic container, and line the containers up along the front of the work bench. Follow steps in Sections 4.9 through 4.16.

5.3. Using the resulting mass of hydrochloric acid, determine the percentage of cement in the specimens from the standard curve established in Section 4.17.

5.4. Report cement content to the nearest 0.1 percent.

---

6. PRECAUTIONS

6.1. This test should not be performed by persons subject to "color blindness."

6.2. It is very important that the operator vigilantly maintain a neutral solution by repeatedly adding acid as soon as the pink color reappears.

6.3. After the first two additions of acid, use only the amount necessary to just eliminate the red color. Excess acid may attack the aggregates, particularly in the later phases when the amount of hydration products from the cement remaining in the mixture may be low.

Standard Method of Test for

Permeability of Granular Soils (Constant Head)

AASHTO Designation: T 215-70 (2007)
ASTM Designation: D 2434-68 (1994)$^{\epsilon 1}$

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Permeability of Granular Soils (Constant Head)

AASHTO Designation: T 215-70 (2007)
ASTM Designation: D 2434-68 (1994)$^{\in 1}$

AASHTO T 215-70 (2007) is identical to ASTM D 2434-68 (1994)$^{\in 1}$ except that all references to ASTM Standard D 422 contained in ASTM D 2434-68 (1994)$^{\in 1}$ shall be replaced with AASHTO Standard T 88.

Standard Method of Test for

One-Dimensional Consolidation Properties of Soils

AASHTO Designation: T 216-07
ASTM Designation: D 2435-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

One-Dimensional Consolidation Properties of Soils

AASHTO Designation: T 216-07
ASTM Designation: D 2435-04

1. SCOPE

1.1. This test method covers procedures for determining the magnitude and rate of consolidation of soil when it is restrained laterally and drained axially while subjected to incrementally applied controlled-stress loading. Two alternative procedures are provided as follows:

1.1.1. *Test Method A*—This test method is performed with constant load increment duration of 24 hours, or multiples thereof. Time-deformation readings are required on a minimum of two-load increments.

1.1.2. *Test Method B*—Time-deformation readings are required on all load increments. Successive load increments are applied after 100 percent primary consolidation is reached, or at constant time increments as described in Test Method A.

Note 1—The determination of the rate and magnitude of consolidation of soil when it is subjected to controlled-strain loading is covered by ASTM D 4186.

1.2. This test method is most commonly performed on undisturbed samples of fine grained soils naturally sedimented in water; however, the basic test procedure is applicable as well to specimens of compacted soils and undisturbed samples of soils formed by other processes such as weathering or chemical alteration. Evaluation techniques specified in this test method are generally applicable to soils naturally sedimented in water. Tests performed on other soils, such as compacted and residual (weathered or chemically altered) soils, may require special evaluation techniques.

1.3. It shall be the responsibility of the agency requesting this test to specify the magnitude and sequence of each load increment, including the location of a rebound cycle, if required, and, for Test Method A, the load increments for which time-deformation readings are desired.

Note 2—Time-deformation readings are required to determine the time for completion of primary consolidation and for evaluating the coefficient of consolidation, c_v. Since c_v varies with stress level and load increment (loading or unloading), the load increments with timed readings must be selected with specific reference to the individual project. Alternatively, the requesting agency may specify Test Method B wherein the time-deformation readings are taken on all load increments.

1.4. The values stated in SI units are to be regarded as the standard. The values stated in inch-pound units are approximate and given for guidance only. Reporting of test results in units other than SI shall not be regarded as nonconformance with this test method.

1.4.1. In the engineering profession, it is customary practice to use, interchangeably, units representing both mass and force, unless dynamic calculations ($F = Ma$) are involved. This implicitly combines two separate systems of units; that is, the absolute system and the gravimetric system. It is scientifically undesirable to combine two separate systems within a single standard. This test method has been written using SI units; however, inch-pound conversions are given in the gravimetric system, where the pound (lbf) represents a unit of force (weight). The use of balances or scales recording pounds of mass (lbm), or the recording of density in lb/ft^3, should not be regarded as nonconformance with this test method.

1.5. *This standard does not purport to address the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*—The definitions of terms used in this test method shall be in accordance with ASTM D 653.

4. SUMMARY OF TEST METHOD

4.1. In this test method, a soil specimen is restrained laterally and loaded axially with total stress increments. Each stress increment is maintained until excess pore water pressures are completely dissipated. During the consolidation process, measurements are made of change in the specimen height and these data are used to determine the relationship between the effective stress and void ratio or strain, and the rate at which consolidation can occur by evaluating the coefficient of consolidation.

5. SIGNIFICANCE AND USE

5.1. The data from the consolidation test are used to estimate the magnitude and rate of both differential and total settlement of a structure or earthfill. Estimates of this type are of key importance in the design of engineered structures and the evaluation of their performance.

5.2. The test results can be greatly affected by sample disturbance. Careful selection and preparation of test specimens is required to minimize disturbance.

5.3. Consolidation test results are dependent upon the magnitude of the load increments. Traditionally, the load is doubled for each increment resulting in a load-increment ratio of one. For undisturbed samples, this load procedure has provided data from which estimates of the preconsolidation pressure also referred to as the maximum past pressure, using established evaluation techniques, compare directly with field measurement. Other load schedules may be used to model particular field conditions or meet special requirements. For example, it may be desirable to inundate and load the specimen in accordance with the wetting or loading pattern expected in the field in order to best simulate the response. Smaller than standard load increment ratios may be desirable for soils that are highly sensitive or whose response is highly dependent on strain rate. The test method specified to estimate the preconsolidation pressure provides a simple technique to verify that one set of time readings are taken after the preconsolidation pressure. Several other evaluation techniques exist and may yield different estimates of the preconsolidation pressure. Therefore, the requesting agency may specify an alternate technique to estimate the preconsolidation pressure.

5.4. Consolidation test results are dependent upon the duration of each load increment. Traditionally, the load duration is the same for each increment and equal to 24 hours. For some soils, the rate of consolidation is such that complete consolidation (dissipation of excess pore pressure) will require more than 24 hours. The apparatus in general use does not have provisions for formal verification of pore pressure dissipation. It is necessary to use an interpretation technique that indirectly determines that consolidation is complete. This test method specifies two techniques; however, the requesting agency may specify an alternative technique and still be in conformance with this test method.

5.5. The apparatus in general use for this test method does not have provisions for verification of saturation. Most undisturbed samples taken from below the water table will be saturated. However, the time rate of deformation is very sensitive to degree of saturation and caution must be exercised regarding estimates for duration of settlements when partially saturated conditions prevail. The extent to which partial saturation influences the test results may be a part of the test evaluation and may include application of theoretical models other than conventional consolidation theory. Alternatively, the test may be performed using an apparatus equipped to saturate the specimen.

5.6. This test method uses conventional consolidation theory based on Terzaghi's consolidation equation to compute the coefficient of consolidation, c_v. The analysis is based upon the following assumptions:

5.6.1. The soil is saturated and has homogeneous properties;

5.6.2. The flow of pore water is in the vertical direction;

5.6.3. The compressibility of soil particles and pore water is negligible compared to the compressibility of the soil skeleton;

5.6.4. The stress-strain relationship is linear over the load increment;

5.6.5. The ratio of soil permeability to soil compressibility is constant over the load increment; and

5.6.6. Darcy's law for flow through porous media applies.

6. APPARATUS

6.1. *Load Device*—A suitable device for applying vertical loads or total stresses to the specimen. The device should be capable of maintaining specified loads for long periods of time with an accuracy of ±0.5 percent of the applied load and should permit quick application of a given load increment without significant impact.

Note 3—Load application generally should be completed in a time corresponding to 0.01 t_{100} or less. For soils where primary consolidation is completed in 3 minutes load application should be less than 2 seconds.

6.2. *Consolidometer*—A device to hold the specimen in a ring that is either fixed to the base or floating (supported by friction on periphery of specimen) with porous disks on each face of the specimen. The inside diameter of the ring shall be determined to a tolerance of 0.075 mm (0.003 in.). The consolidometer shall also provide a means of submerging the specimen, for transmitting the concentric vertical load to the porous disks, and for measuring the change in height of specimen.

6.2.1. *Minimum Specimen Diameter*—The minimum specimen diameter shall be 50 mm (2.00 in.). The diameter of the sample in the tube shall be greater than the diameter of the consolidation test ring. The diameter of the sample must be greater than the test ring to reduce sampling disturbance and prevent lateral displacement.

6.2.2. *Minimum Specimen Height*—The minimum initial specimen height shall be 12 mm (0.5 in.), but shall not be less than 10 times the maximum particle diameter.

Note 4—If large particles are found in the specimen after testing, include in the report this visual observation or the results of a particle-sized analysis in accordance with T 88 (except the minimum sample-sized requirement shall be waived).

6.2.3. *Minimum Specimen Diameter-to-Height Ratio*—The minimum specimen diameter-to-height ratio shall be 2.5.

Note 5—The use of greater diameter-to-height ratios is recommended. To minimize the effects of friction between the sides of the specimen and ring, a diameter-to-height ratio greater than four is preferable.

6.2.4. *Specimen Ring Rigidity*—The rigidity of the ring shall be such that, under hydrostatic stress conditions in the specimen, the change in diameter of the ring will not exceed 0.03 percent of the diameter under the greatest load applied.

6.2.5. *Specimen Ring Material*—The ring shall be made of a material that is noncorrosive in relation to the soil tested. The inner surface shall be highly polished or shall be coated with a low-friction material. Silicone grease or molybdenum disulfide is recommended; polytetrafluoroethylene is recommended for non-sandy soils.

6.3. *Porous Disks*—The porous disks shall be of silicon carbide, aluminum oxide, or similar noncorrosive material. The grade of the disks shall be fine enough to prevent intrusion of soil into the pores. If necessary, a filter paper (Note 6) may be used to prevent intrusion of the soil into the disks; however, the permeability of the disks, and filter paper, if used, must be at least one order of magnitude higher than that of the specimen.

Note 6—Whatman No. 54 filter paper has been found to meet requirements for permeability and durability.

6.3.1. *Diameter*—The diameter of the top disk shall be 0.2 to 0.5 mm (0.01 to 0.02 in.) less than the inside diameter of the ring. If a floating ring is used, the bottom disk shall have the same diameter as the top disk.

Note 7—The use of tapered disks is recommended, with the larger diameter in contact with the soil.

6.3.2. *Thickness*—Thickness of the disks shall be sufficient to prevent breaking. The top disk shall be loaded through a corrosion-resistant plate of sufficient rigidity to prevent breakage of the disk.

6.3.3. *Maintenance*—The disks shall be clean and free from cracks, chips, and nonuniformities. New porous disks should be boiled for at least 10 minutes and left in the water to cool to ambient temperature before use. Immediately after each use, clean the porous disks with a nonabrasive brush and boil to remove clay particles that may reduce their permeability. It is recommended that porous disks be stored in a jar with de-aired water between tests.

6.4. *Specimen Trimming Device*—A trimming turntable or a cylindrical cutting ring may be used for trimming the sample down to the inside diameter of the consolidometer ring with a minimum of disturbance. A cutter having the same inside diameter as the specimen ring shall attach to or be integral with the specimen ring. The cutter shall have a sharp edge, a highly polished surface, and be coated with a low-friction material. Alternatively, a turntable or trimming lathe may be used. The cutting tool must be properly aligned to form a specimen of the same diameter as that of the ring.

6.5. *Deformation Indicator*—To measure change in specimen height, with a readability of 0.0025 mm (0.0001 in.).

6.6. *Miscellaneous Equipment*—Including timing device with 1-second readability, distilled or demineralized water, spatulas, knives, and wire saws, used in preparing the specimen.

6.7. *Balances*, in accordance with T 265.

6.8. *Drying Oven*, in accordance with T 265.

6.9. *Water Content Containers*, in accordance with T 265.

6.10. *Environment*—Tests shall be performed in an environment where temperature fluctuations are less than ±4ºC (±7ºF) and there is no direct exposure to sunlight.

7. STANDARDIZATION

7.1. The measured vertical deformations must be corrected for apparatus flexibility whenever the calibration correction determined in Section 7.4 exceeds 5 percent of the measured deformation and in all tests where filter paper disks are used.

7.2. Assemble the consolidometer with a copper or hard steel disk of approximately the same height as the test specimen and at least 1 mm (0.04 in.) smaller in diameter than the ring, but no more than 5 mm smaller in diameter than the ring, in place of the sample. Moisten the porous disks. If filter papers are to be used (Section 6.3), they should be moistened and sufficient time (a minimum of 2 minutes) allowed for the moisture to be squeezed from them during each increment of the calibration process.

7.3. Load and unload the consolidometer as in the test and measure the deformation for each load applied. When filter papers are used, it is imperative that calibration be performed following the exact loading and unloading schedule to be used. This is due to the inelastic deformation characteristics of filter paper. Recalibration for tests without filter paper need be done only on an annual basis, or after replacement and reassembly of apparatus components.

7.4. At each load applied, plot or tabulate the corrections to be applied to the measured deformation of the test specimen. Note that the metal disk will deform also; however, the correction due to this deformation will be negligible for all but extremely stiff soils. If necessary, the compression of the metal disk can be computed and applied to the corrections.

8. SAMPLING

8.1. AASHTO T 207 and ASTM D 3550 cover procedures and apparatus that may be used to obtain undisturbed samples generally satisfactory for testing (Note 8). Specimens may also be trimmed from large undisturbed block samples fabricated and sealed in the field. Finally, remolded specimens may be prepared from bulk samples to density and moisture conditions stipulated by the agency requesting the test.

Note 8—Not all tube diameters specified may be of sufficient size for testing.

8.2. Undisturbed samples destined for testing in accordance with this test method shall be preserved, handled, and transported in accordance with the practices for Group C and D samples in ASTM D 4220. Bulk samples for remolded specimens should be handled and transported in accordance with the practice for Group B samples.

8.3. *Storage*—Storage of sealed samples should be such that no moisture is lost during storage; that is, no evidence of partial drying of the ends of the samples or shrinkage. Time of storage should be minimized, particularly when the soil or soil moisture is expected to react with the sample tubes.

8.4. The quality of consolidation test results diminishes greatly with sample disturbance. It should be recognized that no sampling procedure can ensure completely undisturbed samples. Therefore, careful examination of the sample is essential in selection of specimens for testing.

Note 9—Examination for sample disturbance, stones, or other inclusions, and selection of specimen location is greatly facilitated by x-ray radiography of the samples. (See ASTM D 4452.)

9. SPECIMEN PREPARATION

9.1. All possible precautions should be taken to minimize disturbance of the soil or changes in moisture and density during specimen preparation. Avoid vibration, distortion, and compression.

9.2. Prepare test specimens in an environment where soil moisture change during preparation is minimized.

Note 10—A high-humidity environment is usually used for this purpose.

9.3. Trim the specimen and insert it into the consolidation ring. When specimens come from undisturbed soil collected using sample tubes, the inside diameter of the tube shall be at least 5 mm (0.25 in.) greater than the inside diameter of the consolidation ring, except as noted in Sections 9.4 and 9.5. It is recommended that either a trimming turntable or cylindrical cutting ring be used to cut the soil to the proper diameter. When using a trimming turntable, make a complete perimeter cut, reducing the specimen diameter to the inside diameter of the consolidation ring. Carefully insert the specimen into the consolidation ring, by the width of the cut, with a minimum of force. Repeat until the specimen protrudes from the bottom of the ring. When using a cylindrical cutting ring, trim the soil to a gentle taper in front of the cutting edge. After the taper is formed, advance the cutter a small distance to form the final diameter. Repeat the process until the specimen protrudes from the ring.

9.4. Fibrous soils, such as peat, and those soils that are easily damaged by trimming, may be transferred directly from the sampling tube to the ring, provided that the ring has the same diameter as the sample tube.

9.5. Specimens obtained using a ring-lined sampler may be used without prior trimming, provided they comply with the requirements of ASTM D 3550 and this test method.

9.6. Trim the specimen flush with the plane ends of the ring. The specimen may be recessed slightly below the top of the ring, to facilitate centering of the top stone, by partial extrusion and trimming of the bottom surface. For soft to medium soils, a wire saw should be used for trimming the top and bottom of the specimen to minimize smearing. A straightedge with a sharp cutting edge may be used for the final trim after the excess soil has first been removed with a wire saw. For stiff soils, a sharpened straightedge alone may be used for trimming the top and bottom. If a small particle is encountered in any surface being trimmed, it should be removed and the resulting void filled with soil from the trimmings.

Note 11—If, at any stage of the test, the specimen swells beyond its initial height, the requirement of lateral restraint of the soil dictates the use of a recessed specimen or the use of a specimen ring equipped with an extension collar of the same inner diameter as the specimen ring. At no time should the specimen extend beyond the specimen ring or extension collar.

9.7. Determine the initial wet mass of the specimen, M_{T_o}, in the consolidation ring by measuring the mass of the ring with the specimen and subtracting the tare mass of the ring.

9.8. Determine the initial height, H_o, of the specimen to the nearest 0.025 mm (0.001 in.) by taking the average of at least four evenly spaced measurements over the top and bottom surfaces of the specimen using a dial comparator or other suitable measuring device.

9.9. Compute the initial volume, V_o, of the specimen to the nearest 0.25 cm^3 (0.015 in.^3) from the diameter of the ring and the initial specimen height.

9.10. Obtain two or three natural water content determinations of the soil in accordance with T 265 from material trimmed adjacent to the test specimen, if sufficient material is available.

9.11. When index properties are specified by the requesting agency, store the remaining trimmings taken from around the specimen and determined to be similar material in a sealed container for determination as described in Section 10.

10. SOIL INDEX PROPERTY DETERMINATIONS

10.1. The determination of index properties is an important adjunct to but not a requirement of the consolidation test. These determinations when specified by the requesting agency should be made on the most representative material possible. When testing uniform materials, all index tests may be performed on adjacent trimmings collected in Section 9.11. When samples are heterogeneous or trimmings are in short supply, index tests should be performed on material from the test specimen as obtained in Section 11.6, plus representative trimmings collected in Section 9.11.

10.2. *Specific Gravity*—The specific gravity shall be determined in accordance with T 100 on material from the sample as specified in Section 10.1. The specific gravity from another sample judged to be similar to that of the test specimen may be used for calculation in Section 12.2.5 whenever an accurate void ratio is not needed.

10.3. *Atterberg Limits*—The liquid limit shall be determined in accordance with T 89. The plastic limit and plasticity index shall be determined in accordance with T 90 using material from the sample as specified in Section 10.1. Determination of the Atterberg limits is necessary for proper material classification but is not a requirement of this test method.

10.4. *Particle-Sized Distribution*—The particle-sized distribution shall be determined in accordance with T 88 (except the minimum sample-sized requirement shall be waived) on a portion of the test specimen as obtained in Section 11.6. A particle-sized analysis may be helpful when visual inspection indicates that the specimen contains a substantial fraction of coarse-grained material, but is not a requirement of this test method.

11. PROCEDURE

11.1. Preparation of the porous disks and other apparatus will depend on the specimen being tested. The consolidometer must be assembled in such a manner as to prevent a change in water content of the specimen. Dry porous disks and filters must be used with dry, highly expansive soils and may be used for all other soils. Damp disks may be used for partially saturated soils. Saturated disks may be used when the specimen is saturated and known to have a low affinity for water. Assemble the ring with specimen, porous disks, filter disks (when needed), and consolidometer. If the specimen will not be inundated shortly after application of the seating load (Section 11.2), enclose the consolidometer in a loose-fitting plastic or rubber membrane to prevent change in specimen volume due to evaporation.

Note 12—In order to meet the stated objectives of this test method, the specimen must not be allowed to swell in excess of its initial height prior to being loaded beyond its preconsolidation pressure. Detailed procedures for the determination of one-dimensional swell or settlement potential of cohesive soils is covered by ASTM D 4546.

11.2. Place the consolidometer in the loading device and apply a seating pressure of 5 kPa (100 lbf/ft^2). Immediately after application of the seating load, adjust the deformation indicator and record the initial zero reading, d_o. If necessary, add additional load to keep the specimen from swelling. Conversely, if it is anticipated that a load of 5 kPa (100 lbf/ft^2) will cause significant consolidation of the specimen, reduce the seating pressure to 2 or 3 kPa (about 50 lbf/ft^2) or less.

11.3. If the test is performed on an intact specimen that was either saturated under field conditions or obtained below the water table, inundate shortly after application of the seating load. As inundation and specimen wetting occur, increase the load as required to prevent swelling. Record the load required to prevent swelling and the resulting deformation reading. If specimen inundation is to be delayed to simulate specific conditions, then inundation must occur at a pressure that is sufficiently large to prevent swell. In such cases, apply the required load and inundate the specimen. Take time deformation readings during the inundation period as specified in Section 11.5. In such cases, note in the test report the pressure at inundation and the resulting changes in height.

11.4. The specimen is to be subjected to increments of constant total stress. The duration of each increment shall conform to guidelines specified in Section 11.5. The specific loading schedule will depend on the purpose of the test, but should conform to the following guidelines. If the slope and shape of a virgin compression curve or determination of the preconsolidation pressure is required, the final pressure shall be equal to or greater than four times the preconsolidation pressure. In the case of overconsolidated clays, a better evaluation of recompression parameters may be obtained by imposing an unload-reload cycle after the preconsolidation pressure has been defined. Details regarding location and extent of an unload-reload cycle is the option of the agency requesting the test (Section 1.3), however, unloading shall always span at least two decrements of pressure.

11.4.1. The standard loading schedule shall consist of a load increment ratio (LIR) of one which is obtained by doubling the pressure on the soil to obtain values of approximately 12, 25, 50, 100, 200, etc. kPa (250, 500, 1000, 2000, 4000, etc. lbf/ft^2).

11.4.2. The standard rebound or unloading schedule should be selected by halving the pressure on the soil (that is, use the same increments of Section 11.4.1, but in reverse order). However, if desired, each successive load can be only one-fourth as large as the preceding load; that is, skip a decrement.

11.4.3. An alternative loading, unloading, or reloading schedule may be employed that reproduces the construction stress changes or obtains better definition of some part of the stress deformation (compression) curve, or aids in interpreting the field behavior of the soil.

Note 13—Small increments may be desirable on highly compressible specimens or when it is desirable to determine the preconsolidation pressure with more precision. It should be cautioned, however, that load increment ratios less than 0.7 and load increments very close to the preconsolidation pressure may preclude evaluation for the coefficient of consolidation, c_v, and the end-of-primary consolidation as discussed in Section 12.

11.5. Before each pressure increment is applied, record the height or change in height, d_f, of the specimen. Two alternative procedures are available that specify the time sequence of readings and the required minimum load duration. Longer durations are often required during specific load increments to define the slope of the characteristic straight-line secondary compression portion of the deformation versus log of time graph. For such increments, sufficient readings should be taken near the end of the pressure increment to define this straight-line portion. It is not necessary to increase the duration of other pressure increments during the test.

11.5.1. *Test Method A*—The standard load increment duration shall be 24 hours. For at least two load increments, including at least one load increment after the preconsolidation pressure has been exceeded, record the height or change in height, d, at time intervals of approximately 0.1, 0.25, 0.5, 1, 2, 4, 8, 15, and 30 minutes, and 1, 2, 4, 8, and 24 hours (or 0.09, 0.25, 0.49, 1, 4, 9 minutes, etc., if using Section 12.3.2 to present time-deformation data), measured from the time of each incremental pressure application. Take sufficient readings near the end of the pressure increment period to verify that primary consolidation is completed. For some soils, a period of more than 24 hours may be required to reach the end-of-primary consolidation (as determined in Section 12.3.1.1 or 12.3.2.3). In such cases, load increment durations greater than 24 hours are required. The load increment duration for these tests is usually taken at some multiple of 24 hours and should be the standard duration for all load increments of the test. The decision to use a time interval greater than 24 hours is usually based on experience with particular types of soils. If, however, there is a question as to whether a 24-hour period is adequate, a record of height or change in height with time should be made for the initial load increments in order to verify the adequacy of a 24-hour period. Load increment durations other than 24 hours shall be noted in the report. For pressure increments where time versus deformation data are not required, leave the load on the specimen for the same length of time as when time versus deformation readings are taken.

11.5.2. *Test Method B*—For each increment, record the height or change in height, d, at time intervals of approximately 0.1, 0.25, 0.5, 1, 2, 4, 8, 15, 30 minutes, and 1, 2, 4, 8, and 24 hours (or 0.09, 0.25, 0.49, 1, 4, 9 minutes, etc., if using Section 12.3.2 to present time deformation data), measured from the time of each incremental pressure application. The standard load increment duration shall exceed the time required for completion of primary consolidation as determined by Sections 12.3.1.1, 12.3.2.3 or a criterion set by the requesting agency. For each increment where it is impossible to verify the end of primary consolidation (for example, low LIR or rapid consolidation), the load increment duration shall be constant and exceed the time required for primary consolidation of an increment applied after the preconsolidation pressure and along the virgin compression curve. Where secondary compression must be evaluated, apply pressures for longer periods. The report shall contain the load increment duration for each increment.

Note 14—The suggested time intervals for recording height or change in height are for typical soils and load increments. It is often desirable to change the reading frequency to improve interpretation of the data. More rapid consolidation will require more frequent readings. For most soils, primary consolidation during the first load decrements will be complete in less time (typically one-tenth) than would be required for a load increment along the virgin compression curve; however, at very low stresses the rebound time can be longer.

11.6. To minimize swell during disassembly, rebound the specimen back to the seating load (5 kPa). Once height changes have ceased (usually overnight), dismantle quickly after releasing the final small load on the specimen. Remove the specimen and the ring from the consolidometer and wipe any free water from the ring and specimen. Determine the mass of the specimen in the ring and subtract the tare mass of the ring to obtain the final wet specimen mass, M_{T_f}. The most accurate determination of the specimen dry mass and water content is found by drying the entire specimen at the end of the test. If the soil sample is homogeneous and sufficient trimmings are available for the specified index testing (Section 9.11), then determine the final water content w_f, in accordance with T 265 and dry mass of solids, M_d, using the entire specimen. If the soil is heterogeneous or more material is required for the specified index testing, then determine the final water content, w_{f_p}, in accordance with T 265 using a small wedge shaped section of the specimen. The remaining undried material should be used for the specified index testing.

12. CALCULATION

12.1. Calculations as shown are based on the use of SI units. Other units are permissible, provided the appropriate conversion factors are used to maintain consistency of units throughout the calculations. See Section 1.4.1 for additional comments on the use of inch-pound units.

12.2. *Specimen Properties*:

12.2.1. Obtain the dry mass of the total specimen, K_d, by direct measurement or for the case where part of the specimen is used for index testing, calculate the dry mass as follows:

$$M_d = \frac{M_{T_f}}{1 + w_{f_p}} \qquad (1)$$

where:

M_{T_f} = moist mass of total specimen after test, g or kg; and

w_{f_p} = water content (decimal form) wedge of specimen taken after test.

12.2.2. Calculate the initial and final water content, in percent, as follows:

initial water content:

$$w_o = \frac{M_{T_o} - M_d}{M_d} \times 100 \qquad (2)$$

final water content:

$$w_f = \frac{M_{T_f} - M_d}{M_d} \times 100 \qquad (3)$$

where:

M_d = dry mass of specimen, g or kg; and

M_{T_o} = moist mass of specimen before test, g or kg.

12.2.3. Calculate the initial dry density of the specimen as follows:

$$\rho_d = \frac{M_d}{V_o} \qquad (4)$$

where:

ρ_d = dry density of specimen, g/cm^3 or kg/m^3; and

V_o = initial volume of specimen, cm^3 or m^3.

12.2.4. Calculate the dry unit weight of the specimen as follows:

$$\gamma_d = 9.81 \times \rho_d / 1000 \qquad (5)$$

where:

γ_d = dry unit weight, kN/m^3

ρ_d = dry density, kg/m^3

12.2.5. Compute the volume of solids as follows:

$$V_s = \frac{M_d}{G\rho_w} \qquad (6)$$

where:

G = specific gravity of the solids, and

ρ_w = density of water, 1.0 g/cm^3 or Mg/m^3.

12.2.6. Since the cross-sectional area of the specimen is constant throughout the test, it is convenient for subsequent calculations to introduce the term “equivalent height of solids,” defined as follows:

$$H_s = \frac{V_s}{A} \qquad (7)$$

where:

A = specimen area, cm^2 or mm^2.

12.2.7. Calculate void ratio before and after test as follows:

void ratio before test:

$$e_o = \frac{H_o - H_s}{H_s} \tag{8}$$

void ratio after test:

$$e_f = \frac{H_f - H_s}{H_s} \tag{9}$$

where:

H_o = initial specimen height, cm or mm; and

H_f = final specimen height, cm or mm.

12.2.8. Calculate the degree of saturation, in percent, before and after test as follows:

$$\text{initial degree of saturation: } S_o = \frac{M_{T_o} - M_d}{A\rho_w\left(H_o - H_s\right)} \times 100 \tag{10}$$

$$\text{initial degree of saturation: } S_f = \frac{M_{T_f} - M_d}{A\rho_w\left(H_f - H_s\right)} \times 100 \tag{11}$$

where:

M_{T_o}, M_{T_f}, and M_d = gram

A = cm^2

ρ_w = 1 g/cm^3

H_f and H_s = cm

12.3. *Time-Deformation Properties*—From those increments of load where time-deformation readings are obtained, two alternative procedures (Section 12.3.1 or 12.3.2) are provided to present the data, determine the end-of-primary consolidation, and compute the rate of consolidation. Alternatively, the requesting agency may specify a method of its choice and still be in conformance with this test method. The deformation readings may be presented as measured deformation, deformation corrected for apparatus compressibility, or converted to strain (Section 12.4).

12.3.1. Referring to Tables 1 and 2 (Figure 1), plot the deformation readings, *d*, versus the log of time (normally in minutes) for each increment of load.

12.3.1.1. First draw a straight line through the points representing the final readings that exhibit a straight-line trend and constant slope (C). Draw a second straight-line tangent to the steepest part of the deformation-log time curve (D). The intersection represents the deformation, d_{100}, and time, t_{100}, corresponding to 100 percent primary consolidation (E). Compression in excess of the above estimated 100 percent primary consolidation is defined as secondary compression.

12.3.1.2. Find the deformation representing 0 percent primary consolidation by selecting any two points that have a time ratio of 1 to 4. The deformation at the larger of the two times should be greater than one-fourth, but less than one-half of the total deformation for the load increment. The deformation corresponding to 0 percent primary consolidation is equal to the deformation at the smaller time, less the difference in deformation for the two selected times.

Load Increment (kPa)	d_f Corrected (mm)	$\Sigma\Delta H$ (mm)	Σ $\Sigma\Delta H/H_o$ (%)	H $(H_o - \Delta H)$ (mm)	e $(H - H_s)/H_s$

1.5077	3.8223	20.06	15.228	0.784	156	7.32 × 10-1

Figure 1—Void Ratio and Strain Information

12.3.1.3. The deformation, d_{50}, corresponding to 50 percent primary consolidation is equal to the average of the deformations corresponding to the 0 and 100 percent deformations. The time, t_{50}, required for 50 percent consolidation may be found graphically from the deformation-log time curve by observing the time that corresponds to 50 percent of the primary consolidation on the curve.

12.3.2. Referring to Figure 1, plot the deformation readings, d, versus the square root of time (normally in minutes) for each increment of load.

12.3.2.1. First draw a straight line through the points representing the initial readings that exhibit a straight-line trend. Extrapolate the line back to $t = 0$ and obtain the deformation ordinate representing 0 percent primary consolidation.

12.3.2.2. Draw a second straight line through the 0 percent ordinate so the abscissa of this line is 1.15 times the abscissa of the first straight line through the data. The intersection of this second line with the deformation-square root of time, curve is the deformation, d_{90}, and time t_{90}, corresponding to 90 percent primary consolidation.

12.3.2.3. The deformation at 100 percent consolidation is one-ninth more than the difference in deformation between 0 and 90 percent consolidation. The time of primary consolidation, t_{100}, may be taken at the intersection of the deformation-square root of time curve and this deformation ordinate. The deformation, d_{50}, corresponding to 50 percent consolidation is equal to the deformation at five-ninths of the difference between 0 and 90 percent consolidation.

12.3.3. Compute the coefficient of consolidation for each increment of load using the following equation and values appropriate to the chosen method of interpretation:

$$c_v = \frac{TH_{D50}^2}{t} \qquad (12)$$

where:

T = a dimensionless time factor: for method in Section 12.3.1, use 50 percent consolidation with $T = T_{50} = 0.197$; for method in Section 12.3.2, use 90 percent consolidation with $T = T_{90} = 0.848$,

t = time corresponding to the particular degree of consolidation, second or minute: for method in Section 12.3.1, use $t = t_{50}$; for method in Section 12.3.2, use $t = t_{90}$; and

$H_{D_{50}}$ = Length of the drainage path at 50 percent consolidation cm or m: for double-sided drainage, $H_{D_{50}}$ is half the specimen height at the appropriate increment; and for one-sided drainage, $H_{D_{50}}$ is the full-specimen height.

12.4. *Load-Deformation Properties*:

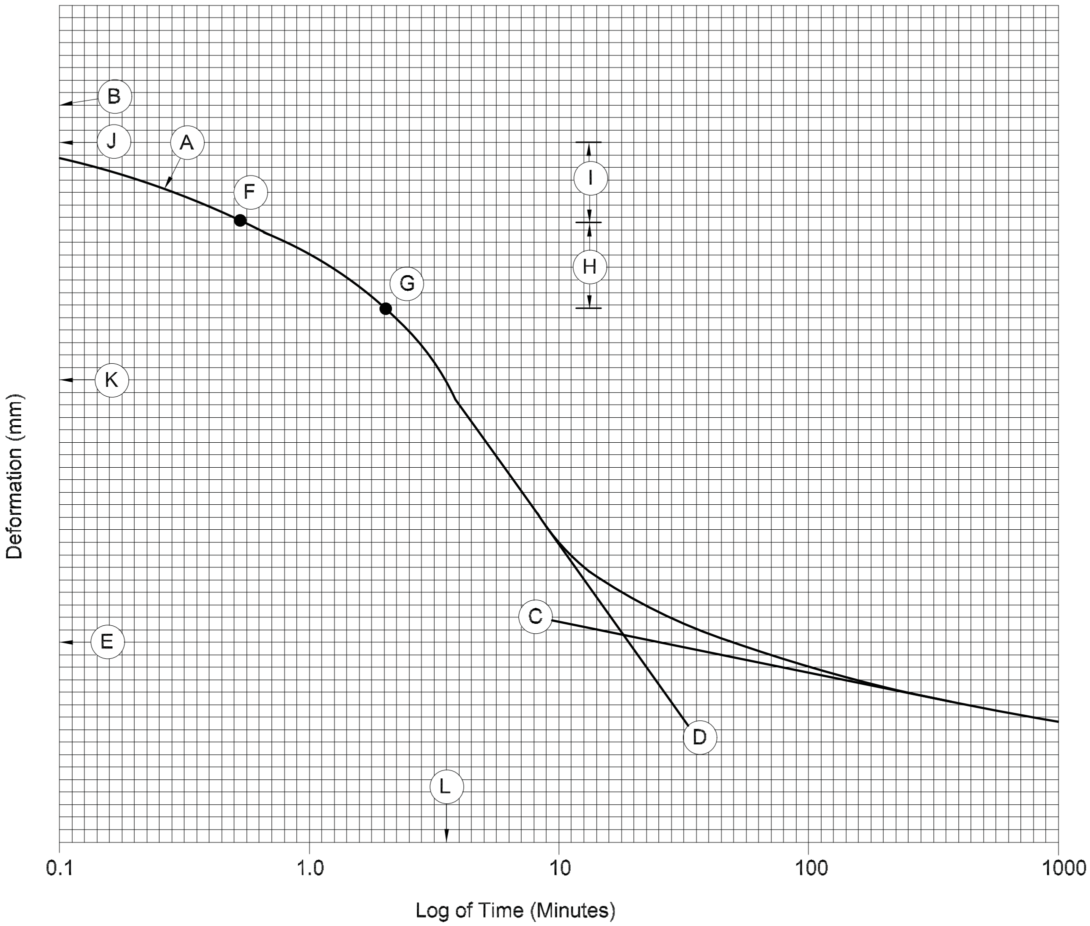
12.4.1. Tabulate the deformation or change in deformation, d_f, readings corresponding to the end of each increment and, if using Test Method B, corresponding to the end-of-primary consolidation, d_{100}.

12.4.2. Calculate the change in height, $\Delta H = d - d_0$, relative to the initial specimen height for each reading. If necessary, correct the deformation for the apparatus flexibility by subtracting the calibration value obtained in Section 9 from each reading.

12.4.3. Represent the deformation results in one of the following formats:

12.4.3.1. Calculate the void ratio as follows:

$$e = e_o - \frac{\Delta H}{H_s} \tag{13}$$



A	Time-deformation curve from data points
B	Deformation at time - 0 minutes
C	Extension of final linear portion of curve
D	Extension of steepest linear portion of curve
E	d_{100} Deformation at intersection of lines C and D
F	t_1 Selected point in time
G	t_2 time at four times t_1 (deformation at time t_2 should be less than 50% and larger than 25% of the total deformation for load increment)
H	Increment of deformation between times t_1 and t_2
I	Increment of deformation equal to F
J	d_0 Calculated initial deformation
K	d_{50} mean of d_0 and d_{100}
L	t_{50} time at d_{50}

Figure 2—Time Deformation Curve from Log-of-Time Method

12.4.3.2. Alternatively, calculate the vertical strain, in percent, as follows:

$$\in = \frac{\Delta H}{H_0} \times 100 \qquad (14)$$

12.4.4. Calculate the vertical stress as follows:

$$\sigma_v = \frac{P}{A} \times 10000 \qquad (15)$$

where:

σ_v = vertical stress, kPa;

P = applied load, kN; and

A = specimen area, cm^2.

12.4.5. Referring to Figure 2, plot the deformation results (void ratio or strain) corresponding to the end of each increment and, if using Test Method B, corresponding to the end-of-primary consolidation versus the logarithm of the pressure.

Note 15—In some cases, it may be preferable to present the load-deformation curve in arithmetic scale.

12.4.6. Referring to Figure 3, determine the value of the preconsolidation pressure using the following procedure:

Note 16—Any other recognized method of estimating preconsolidation pressure may also be used, provided the method is identified in the report. (See references.)

12.4.6.1. Estimate the point of maximum curvature on the consolidation curve (B).

12.4.6.2. Draw the tangent to the consolidation curve at this point (C), and a horizontal line through the point (D), both extended towards increasing values on the abscissa.

12.4.6.3. Draw the line bisecting the angle between these lines (E).

12.4.6.4. Extend the tangent to the steep, linear portion of the consolidation curve (virgin compression branch) (F) upwards to intersection with the bisector line (E). The pressure (G) (abscissa) corresponding to this point of intersection is the estimated preconsolidation pressure.

12.4.7. Complete evaluation often includes consideration of information not generally available to the laboratory performing the test. For this reason further evaluation of the test is not mandatory. Many recognized methods of evaluation are described in the literature. Some of these are discussed in the documents listed under References in Section 16.

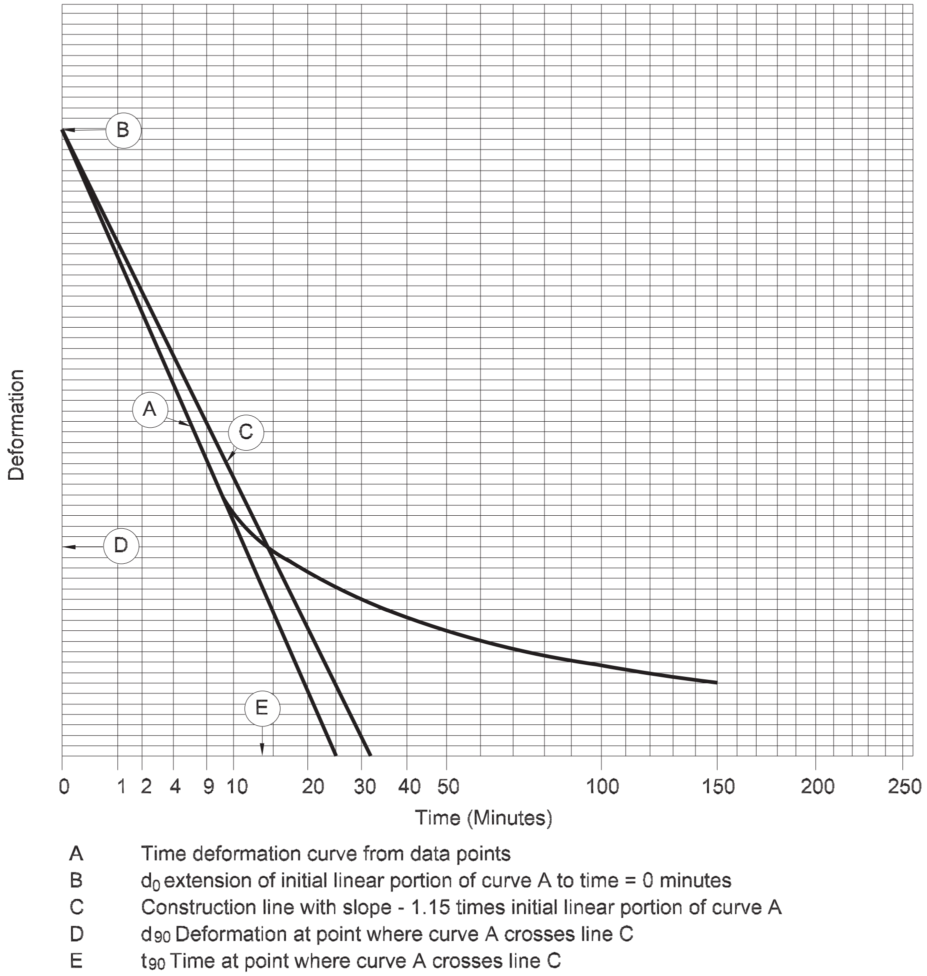


Figure 3—Time-Deformation Curve from Square Root of Time Method

13. REPORT

13.1. In addition to project name and location, boring number, sample number, and depth, report the following information:

13.1.1. Description and classification of the soil in accordance with ASTM D 2488 or ASTM D 2487 when Atterberg limit data are available. Specific gravity of solids, Atterberg limits, and the grain-sized distribution shall also be reported when available, plus the source of such information if other than measurements obtained on the test specimen. Also note occurrence and approximate size of isolated large particles.

13.1.2. *Soil Condition*:

13.1.2.1. Average water content of trimmings,

13.1.2.2. Initial and final water content of specimen,

13.1.2.3. Initial and final dry unit weight of specimen, 13.1.2.4. Initial and final void ratio of specimen,

13.1.2.5. Initial and final degree of saturation of specimen, and

13.1.2.6. Preconsolidation pressure.

13.1.3. *Test Procedure*:

13.1.3.1. Preparation procedure used relative to trimming; state whether the specimen was trimmed using a trimming turntable, trimmed using a cutting shoe, or tested directly in a ring from a ring lined sampler.

13.1.3.2. Condition of test (natural moisture or inundated, pressure at inundation).

13.1.3.3. Method of testing (A or B).

13.1.3.4. Test method used to compute coefficient of consolidation.

13.1.3.5. Listing of loading increments and decrements, and load increment duration, if differing from 24 hours; end of increment deformation results and, for Test Method B, end-of-primary deformation results and coefficient of consolidation. (See Tables 1 and 2.) All departures from the procedure outlined, including special loading sequences.

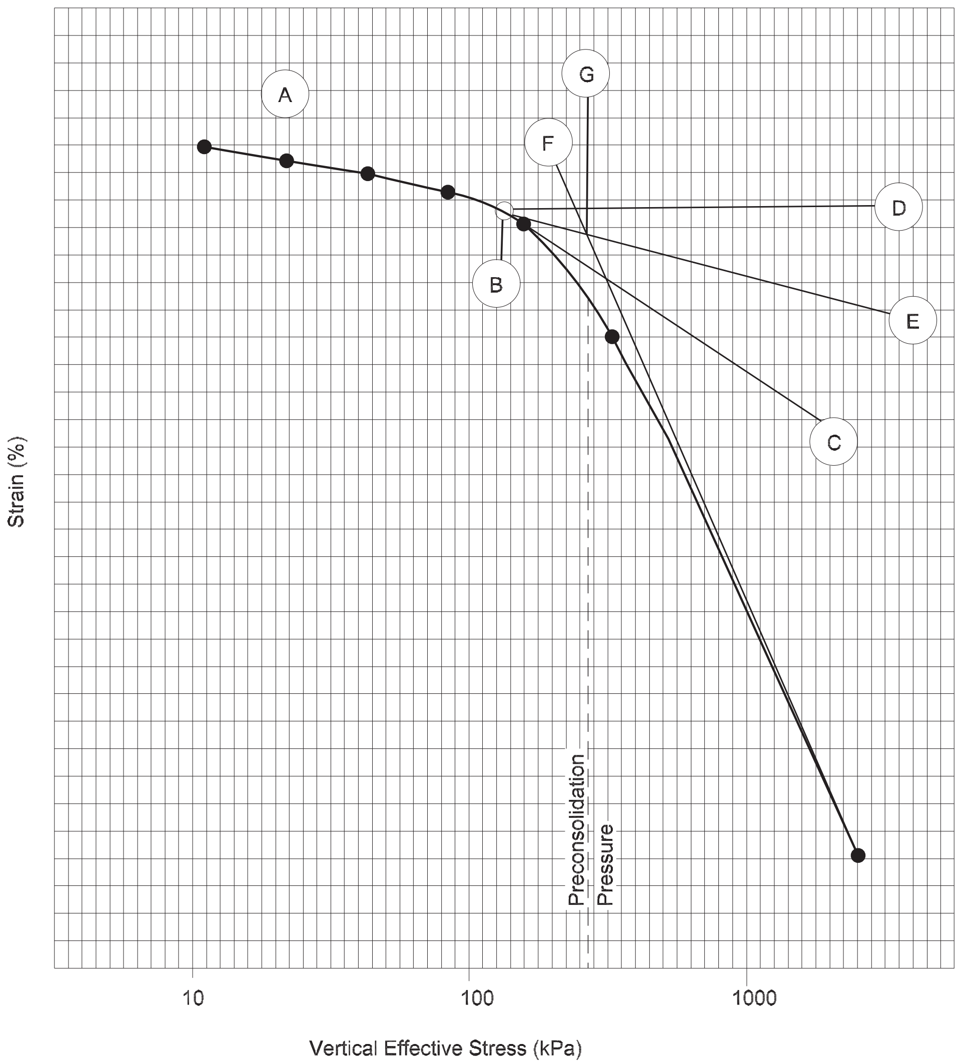
13.1.4. *Graphical Presentations*:

13.1.4.1. Graph of deformation versus log time (Figure 1) or square root of time (Figure 2) for those load increments where time rate readings were taken.

13.1.4.2. Graph of void ratio versus log of pressure curve or percent compression versus log of pressure curve. (See Figure 3.)

13.1.4.3. In cases where time rate of deformation readings have been taken for several load increments, prepare a graph of the log of coefficient of consolidation versus average void ratio or average percent compression for the respective load increments. (See Figure 4.) Alternatively, a graph of coefficient of consolidation or log of coefficient of consolidation versus log of average pressure may be used. If time rate readings were obtained for only two-load increments, simply tabulate the values of cv versus the average pressure for the increment.

Note 17—The average pressure between two-load increments is chosen because it is a convenient coordinate for plotting the result. Unless the rate of pore pressure dissipation is measured, it is not possible to determine the actual effective pressure at the time of 50 percent consolidation. Furthermore, some ambiguity may arise in cases where the test has been carried through one or more intermediate load-rebound cycles.



A Stress-strain curve from data points
B Point of maximum curvature
C Tangent line to curve at point B
D Horizontal line through point B
E Line bisecting angle between lines C and D
F Tangent to linear portion of curve in virgin compression range
G Intersection of lines E and F (vertical effective stress at point G equals the preconsolidation pressure)

Figure 4—Evaluation for Preconsolidation Pressure from Casagrande Method

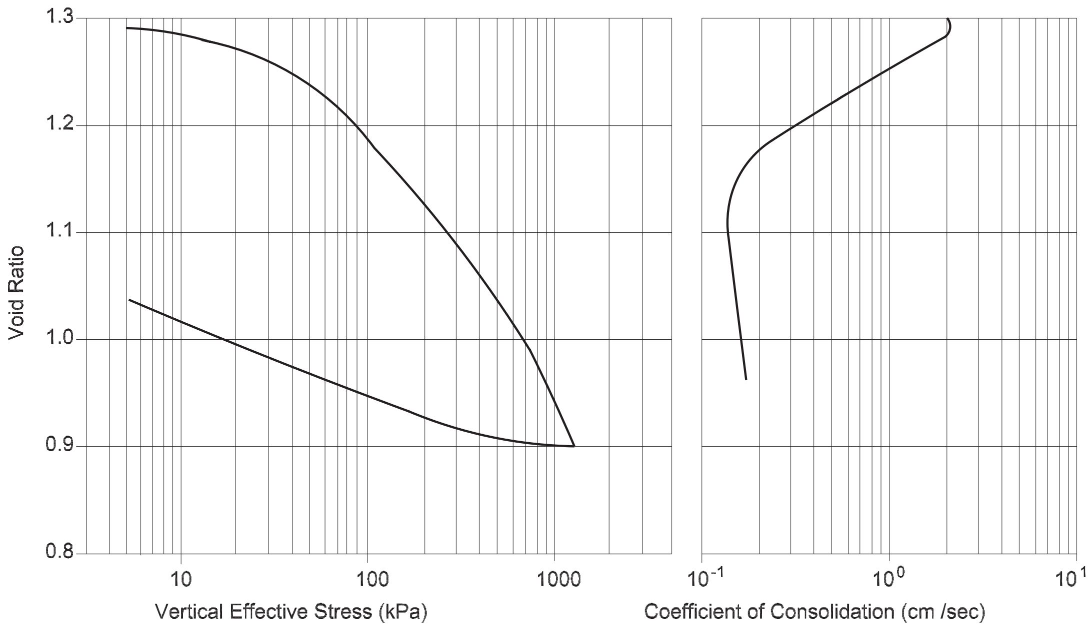


Figure 5—Example of Consolidation Test Summary Plots

14. PRECISION AND BIAS

14.1. *Statement of Precision*—Due to the nature of the soil materials tested by this test method, it is either not feasible or too costly at this time to produce multiple specimens that have uniform physical properties. Any variation observed in the data is just as likely to be due to specimen variation as to operator or laboratory testing variation.

14.2. *Statement of Bias*—There is no acceptable reference value for this test method; therefore, bias cannot be determined.

15. KEYWORDS

Standard Method of Test for

Determination of Moisture in Soils by Means of a Calcium Carbide Gas Pressure Moisture Tester

AASHTO Designation: T 217-02 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determination of Moisture in Soils by Means of a Calcium Carbide Gas Pressure Moisture Tester

AASHTO Designation: T 217-02 (2006)

1. SCOPE

1.1. This test method is intended to determine the moisture content of soils by means of a calcium carbide gas pressure moisture tester. The manufacturer's instructions shall be followed for the proper use of the equipment.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

Note 1—This method shall not be used on granular materials having particles large enough to affect the accuracy of the test—in general any appreciable amount retained on a 4.75-mm sieve. The super 200 D tester is intended to be used to test aggregate.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. Refer to R 16 for regulatory information for chemicals.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 265, Laboratory Determination of Moisture Content of Soils

2.2. *ASTM Standards*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. APPARATUS

3.1. *Calcium Carbide Pressure Moisture Tester*—A chamber with attached pressure gauge for the water content of specimens having a mass of at least 20 g (Figure 1).

3.2. *Balance*—Shall conform to M 231, Class G 2.

3.3. Two 31.75-mm (1.25-in.) steel balls.

3.4. Cleaning brush and cloth.

3.5. Scoop for measuring calcium carbide reagent.

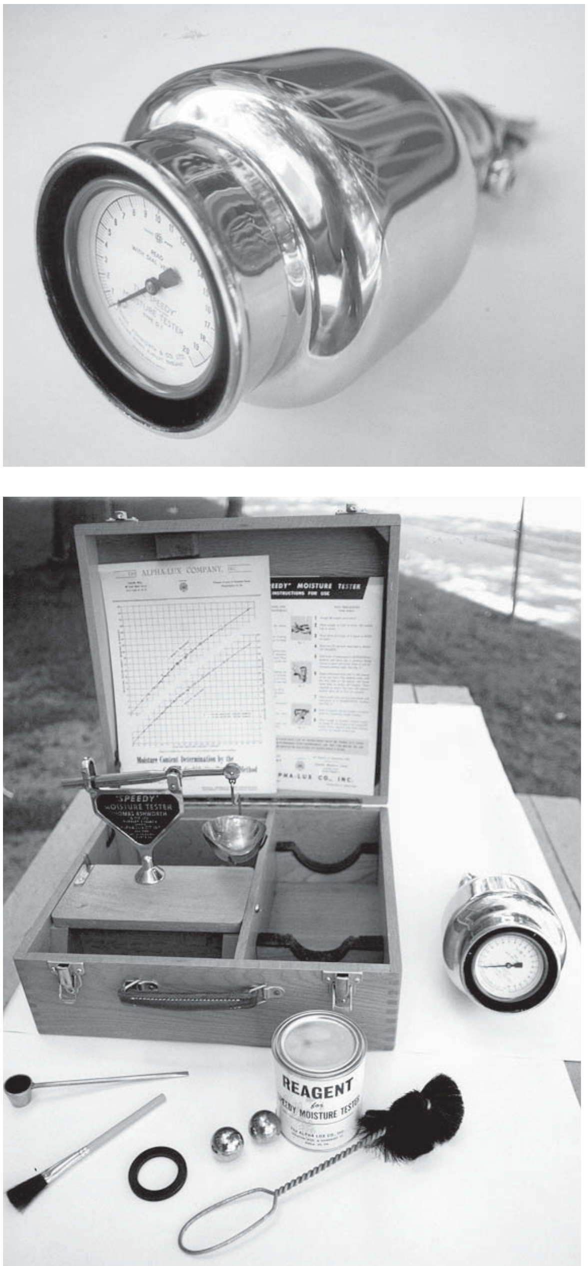

Figure 1—Calcium Carbide Gas Pressure Moisture Meter

4. MATERIAL

4.1. *Calcium carbide reagent.*

Note 2—The calcium carbide must be finely pulverized and should be of a grade capable of producing acetylene gas in the amount of at least 0.14 m^3/kg (2.25 ft^3/lb) of carbide.

Note 3—The “shelf life” of the calcium carbide reagent is limited, so it should be used according to the manufacturer’s recommendations.

5. PROCEDURE

5.1. When using the 20-g or 26-g tester, place three scoops (approximately 24 g) of calcium carbide in the body of the moisture tester. When using the super 200 D tester to test aggregate, place six scoops (approximately 48 g) of calcium carbide in the body of the moisture tester.

Note 4—Care must be exercised to prevent the calcium carbide from coming into direct contact with water.

5.2. Weigh a sample of the exact mass specified by the manufacturer of the instrument in the balance provided, and place the sample in the cap of the tester. When using the 20-g or 26-g sized tester, place two 31.75-mm (1.25-in.) steel balls in the body of the tester with the calcium carbide.

Note 5—Manufacturer’s instructions shall be followed for the use of steel balls, particularly when testing sand.

Note 6—If the moisture content of the sample exceeds the limit of the pressure gauge (12 percent moisture for aggregate tester or 20 percent moisture for soil tester), a one-half size sample must be used and the dial reading must be multiplied by 2. This proportional method is not directly applicable to the dry mass percent scale on the super 200 D tester.

5.3. With the pressure vessel in an approximately horizontal position, insert the cap in the pressure vessel and seal the unit by tightening the clamp, taking care that no carbide comes in contact with the soil until a complete seal is achieved.

5.4. Raise the moisture tester to a vertical position so the soil in the cap will fall into the pressure vessel.

5.5. Shake the instrument vigorously so all lumps will be broken up to permit the calcium carbide to react with all available free moisture. When steel balls are being used in the tester and when using the large tester to test aggregate, the instrument should be shaken with a rotating motion so the steel balls or aggregate will not damage the instrument or cause soil particles to become embedded in the orifice leading to the pressure diaphragm.

Note 7—Shaking should continue for at least 60 seconds with granular soils and for up to 180 seconds for other soils so as to permit complete reaction between the calcium carbide and the free moisture. Time should be permitted to allow dissipation of the heat generated by the chemical reaction.

5.6. When the needle stops moving, read the dial while holding the instrument in a horizontal position at eye level.

5.7. Record the sample mass and the dial reading.

5.8. With the cap of the instrument pointed away from the operator, slowly release the gas pressure. Empty the pressure vessel and examine the material for lumps. If the sample is not completely pulverized, the test should be repeated using a new sample. Clean the cap thoroughly of all carbide and soil before running another test.

Note 8—When removing the cap, care should be taken to point the instrument away from the operator to avoid breathing the fumes, and away from any potential source of ignition for the acetylene gas.

5.9. The dial reading is the percent of moisture by wet mass and must be converted to dry mass. With the super 200 D tester, the dial reading is the percent of moisture by dry mass and no further calculation is required.

6. CALCULATION

6.1. The percentage of moisture by dry mass of the soil may be determined from the correction curve (Figure 2).

6.2. A correction curve similar to Figure 2 is normally supplied with each moisture tester. Each moisture tester, however, should be checked for the accuracy of its gauge, and for the accuracy of its correction curve.

6.2.1. The accuracy of the moisture tester gauge should be checked by using a calibration kit (available from the manufacturer), equipped with a standard gauge. In case of discrepancy, the gauge on the tester should be adjusted to conform with the standard gauge.

6.2.2. The accuracy of the correction curve should be checked by comparing curve-corrected moisture contents to moisture contents of locally prepared soils determined using T 265. In case of discrepancy, develop a new correction curve based on moisture contents determined from T 265.

6.2.3. The range of the factory-supplied or laboratory-determined curves may be extended by additional testing.

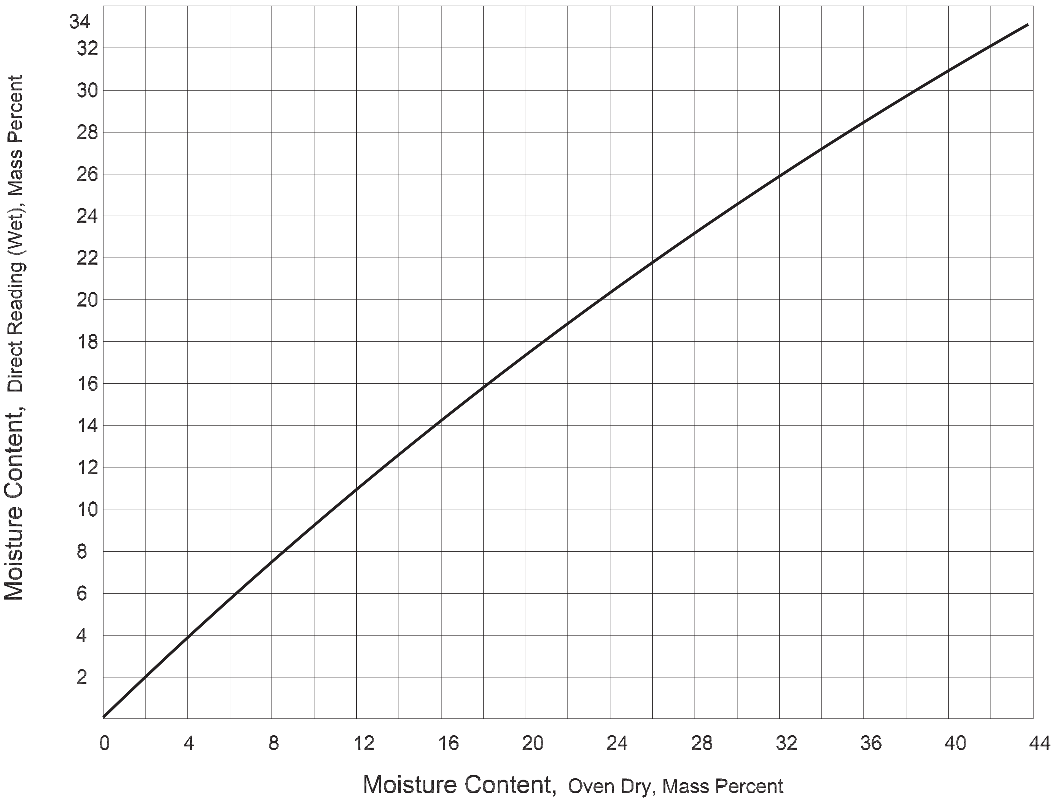

Figure 2—Correction Curve for Moisture Tester Reading (Example Only—Use the curve provided by the manufacturer with the specific apparatus, or a correction curve calibrated or extended for local soils at known moisture contents determined in accordance with Section 6.2.)

Note 9—It may be more convenient for field use of the apparatus to prepare a table of moisture tester readings versus oven-dry moisture content for the moisture tester.

6.3. Determine the percentage of moisture to the nearest whole percent.

Standard Method of Test for

Sampling Hydrated Lime

AASHTO Designation: T 218-86 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling Hydrated Lime

AASHTO Designation: T 218-86 (2008)

1. SCOPE

1.1. This method covers the procedure for sampling hydrated lime from various conveyors, points of shipment, and while in various states of storage.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. Refer to R 16 for regulatory information for chemicals.

2. APPARATUS

2.1. Apparatus shall consist of a 50-mm (2-in.) wide paint brush, 4 L (1 gal) buckets (or other container of approximately that capacity) with double seal friction lids (or other sealing method) and suitable lengths of sampling tubes such as 25-mm (1-in.) diameter and 2.5 m (8 ft) in length, and 19 mm ($^3/_4$ in.) in diameter and 1 m (3 ft) in length, with suitable diagonal cut on one end.

3. SAMPLING PROCEDURE FOR POWDERED LIME IN BULK

3.1. Being loaded or recently loaded into tank trucks, railway hopper cars, or box cars, take a representative 2-L (half-gal) portion of the powdered lime to be analyzed and place it in a 4-L (1-gal) bucket. Fit the bucket with a tight-fitting lid. Clean the lime from the groove before placing the lid; brushing with a 50-mm (2-in.) paint brush has been found to be satisfactory for this purpose.

Note 1—These sample buckets shall be only half filled with sample material so that subsequent mixing may take place within the bucket itself. Half filling the container will allow sufficient space to permit proper agitation during subsequent mixing operations. The sample bucket shall be dry and clean so as to prevent sample contamination.

3.1.1. Tank trucks or railroad cars being loaded with material shall be sampled during the loading operation by inserting the bucket into the flowing stream of material if conditions permit. The sampler should exercise due discretion in taking samples during the loading operation so that the total sample obtained is representative of the material. If material is being loaded from one or more bins or silos or from silo and plant production or various combinations, the composite sample contained in the bucket shall be representative of the composite material. Insofar as the possibility of poor mixing may exist, the sampler may at his or her discretion take separate samples of individual portions of material being loaded. This is particularly advisable where, in order to effect a complete load, material is being loaded from more than one plant source.

Note 2—If conveyors are being loaded in the rain, make every effort to ensure that the material contained in the sample bucket is typical of the material being shipped. In cases of suspected moisture difficulty, it is always advisable to rod the load with the long sampling tubes.

3.1.2. Trucks shall be rodded in three separate places from the top through the openings provided. Rod the center of the load and the two ends, rodding the material vertically or diagonally so as to obtain a composite 2-L (half-gal) portion of material that will be representative insofar as possible of the material.

3.1.3. If loading has been completed rather recently and weather conditions permit, "scoop" samples may be taken from the top of the loaded material and, depending upon the plant source of the material, the sampler may consider this sample to be representative. If the load is composed of one or more portions from more than one plant source, a "scoop" sample may be taken from the top of each portion during the loading operation and these samples may either be combined or submitted separately for analysis.

3.1.4. Added precautions are necessary in sampling railway hopper cars. The sampler should request assistance from plant personnel in attempting to sample material in hopper cars. From the standpoint of safety it is advisable that two people lift the heavy steel doors on as many openings as the sample requires be opened to allow for proper sampling. Should the level of material in the hopper car be too low to obtain a "scoop" sample with a minimum of hazard, then the material should be rodded in as many places as the sampler feels necessary, or the option of sampling from the loading spout with the assistance of plant personnel may be employed. Rodding the entire load in the prescribed fashion is the preferred method to be employed, but the sampler shall have the option of using any of the other methods described for such conditions should he/she feel the situation warrants employing such optional sampling procedures. With the exceptions noted the details and principles suggested for the sampling of tank trucks while being loaded, or recently loaded, also apply in the case of railway hopper cars under like conditions.

3.2. *In Storage Awaiting Shipment*—This procedure applies to material loaded and left standing awaiting shipment in what might be considered a modification of bin storage. These loads in so-called "truck-storage" should be sampled by rodding the material with the long 2.5-m (8-ft) sampling tube. The sampler shall decide if the trucks have been loaded recently enough to permit "scoop" sampling or if sufficient time has elapsed since loading to make it advisable to rod the material so as to obtain a representative "through" sample of the material. The sampler shall base all decisions concerning the optional forms of sampling on what he or she considers will yield a representative sample of the material being shipped within the practicalities of the situation at hand.

3.3. *At Job Site*—A representative 2-L (half-gal) portion of material should be taken by rodding the material in the rail car or tank truck (before unloading) in at least three positions, the center and on both ends. Use the long 2.5-m (8-ft) sampling tube.

Note 3—The material in rail cars should be sampled by rodding the material before unloading, thus preventing the possibility of material contamination after unloading and possibility of obtaining an otherwise unrepresentative composite sample. Due to varying conditions of storage, and the possibility of sample contamination due to moisture, exposure to air, etc., scoop samples are not recommended.

3.4. *At Loading Spouts Feeding from Plant Production, from Bin Storage or at Bagger Outlet Spouts Being Supplied by Either Plant Production or Bin Storage*—Make sure that a reasonable quantity of material has moved through the feed system so the possibility of contamination by material of long standing will be minimized. The 2-L (half-gal) sample should be taken from loaded bags rather than from the bagger outlet spout because sampling from the latter often tends to be nonrepresentative due to the presence of non-fresh or contaminated material in the outlet itself and the usual spillage that occurs in attempting to sample at the bagger outlet spout does not add to overall plant cleanliness.

Note 4—Samplers shall keep in mind that no plant equipment shall be operated by sampling personnel. In general, it should be the responsibility of the plant personnel to operate all equipment and to make the sample available in the sampler. Reasonable and safe sampling facilities shall be arranged for by the producer and provided wherever possible, provided such arrangements meet with the principles involved in obtaining a truly representative sample of the material shipped.

3.5. *From Loaded Silos or Storage Bins*—There is usually a considerable lack of mixing in the material contained in bulk hydrate storage bins. Stratification and flow patterns tend to occur and experience in attempting to correlate silo samples with samples obtained from rodded trucks loaded from such silos indicates poor correlation. Wherever possible, avoid taking silo or bin storage samples and concentrate the sampling on individual loads or shipments rather than taking composite samples of larger reservoirs which due to poor mixing or other conditions prevalent may contain portions of potentially unsatisfactory material which a composite sample might indicate to be satisfactory.

Note 5—Screw conveyors being supplied by either plant production or bin storage are dangerous sources for sampling material, and no attempt should be made to obtain material at such locations.

Note 6—Cumulative samples obtained by rodding should be thoroughly blended, after the container is tightly sealed, by repeatedly inverting and agitating the container.

4. SAMPLING PROCEDURE FOR BAGGED HYDRATED LIME

4.1. *From Warehouse Stock Consigned for Shipment*—If necessary, request that plant personnel make the material available to the sampler. Take care not to sample amongst bagged material that is stacked dangerously high. If necessary, the sampler should ask plant personnel to make available the sacks that he or she desires to sample. Choice of sacks should be made on the basis of obtaining a representative sample of the lot being shipped. If the entire lot consigned for an individual truck or group of trucks is from several different warehouse lots, the sampler may at his or her discretion take samples from the separate lots that comprise the whole. The sampler should use the short sampling rod and, through the sack loading spout, take sufficient diagonal roddings to insure a representative portion from each sack but not a sufficient quantity to materially reduce the poundage being supplied in any individual sack. For this reason and for the obvious reason of attempting to obtain a representative sample, it is suggested that at least four to six sacks from each lot to be inspected be sampled. These sampled lots may be combined to form one sample representing the individual truck or they may be submitted for analysis separately. Generally speaking at least six sacks should be sampled to represent each truck being shipped from consigned previously produced and stored, warehouse stock, to obtain the 2-L (half-gal) sample.

4.2. *From Bag Loads*—If the truck is partially loaded, the sampler may choose sacks at his or her discretion to effect a representative sample and may also sample floor stock consigned for the partially loaded truck so as to obtain a representative sample. The sampler may combine sampling from a partially loaded truck with material being produced by obtaining a sample at the bagger, but due to the usual spillage and interruption of plant activities, this bagger sampling option is not recommended. Rather than sampling at the bagger, it would be preferable to sample the bags being loaded on the truck or the loaded bags at various stages of the loading operation. This matter of which bags to sample should be at the discretion of the sampler; however, the sacks chosen for sampling should be selected from various points in the load so as to effect a representative sample. In sampling from loaded trucks and rail cars, the short sampling rod should be used to obtain a total of a 2-L (half-gal) sample from at least six sacks of material. Insert the sampling rod through the loading valve and take several through samples diagonally from each sack, taking care not to puncture the bottom or sides of the sack with the sharp sampling tube. (See Note 6.)

5. PRECISION

5.1. Since this method of sampling produces no numerical values, determination of the precision and accuracy is not applicable.

Standard Method of Test for

Testing Lime for Chemical Constituents and Particle Sizes

AASHTO Designation: T 219-87 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Testing Lime for Chemical Constituents and Particle Sizes

AASHTO Designation: T 219-87 (2008)

1. SCOPE

1.1. This test procedure is intended to serve as a reasonably accurate, fairly rapid means of determining the chemical limits of Type I hydrated lime and the particle size requirements of Types I and II hydrated lime on a routine basis.

Note 1—The chemical limits of Type II lime shall be determined in accordance with ASTM C 25.

1.2. The entire procedure, as well as the calculations it involves, is based on certain hypothetical assumptions. Lime products by their very nature contain many ingredients other than those mentioned or considered in the test procedure. For our purposes, only the principal constituents usually present are considered. This aids greatly in the simplification of the test procedure to the obvious loss of some degree of accuracy. All test values to be reported shall be rounded off to the first decimal place. *Example*: percent $Ca(OH)_2$ = 95.5 percent (rather than the 95.53 percent shown on the sample calculation sheets). The inherent accuracy obtainable through the use of this procedure is felt to be adequate for the purpose intended. The limitations of this test procedure, along with the object and intent of this same procedure, should be fully realized so that it may be evaluated as merely one approach to the problem of routine quality control on a quality basis.

1.2.1. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with E 29, Using Significant Digits in Test Data to Determine Conformance with Specifications.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. Refer to R 16 for regulatory information for chemicals.

---

3. APPARATUS

3.1. *Electric muffle furnace with temperature controlling device*—capable of sustained operation at a temperature of 1100 ± 11°C (2012 ± 20°F).

3.2. *Platinum crucible*—low-form wide bottom type, with reinforced rim and bottom, 30 mL-capacity.

3.3. *Metallic tongs for muffle furnace*—750 mm in length.

3.4. *Balances*—A general purpose balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231. The analytical balance shall conform to M 231, Class A.

3.5. *Beakers*—400-mL capacity.

3.6. *Buret*—100-mL capacity.

3.7. *Buret*—50-mL capacity of alkali resistant glass and fitted with a Teflon stopcock.

3.8. *Magnetic-type stirrer*—with stirring bars preferably of the Teflon-covered type.

3.9. *Stopwatch*—with 60 seconds long hand to indicate 0.2 seconds. The long hand is to complete one turn of the dial in 60 seconds. The watch should also have a short hand to register up to 30 minutes. Operation should preferably be by successive depressions of the crown to accomplish starting, stopping, and returning to zero.

3.10. *Sieves*—conforming to M 92 as follows: 3.35, 2.00, 0.600, and 0.075 mm.

3.11. *pH meter*—having an accuracy of 0.1 pH.

3.12. *pH meter electrode*—standard combination.

3.13. *Desiccator*.

---

4. REAGENTS

4.1. Reagent grade chemicals shall be used in all tests.

4.2. *Acid Potassium Phthalate*—(National Institute of Standards and Technology Standard Sample or equal).

4.3. *Bromphenol Blue*—tetrabromophenol sulfonphthalein.

4.4. *Hydrochloric Acid*.

4.5. *Phenolphthalein powder*.

4.6. *Potassium Biphthalate*—crystal primary standard. This reagent is satisfactory for use as a pH standard used in Section 5.5.

4.7. *Sodium Hydroxide*—50 percent solution.

5. PREPARATION OF SPECIAL SOLUTIONS

5.1. *Standardized Sodium Hydroxide Solution*:

5.1.1. This solution shall have a normality of 1.000 ± 0.015 when the normality of the solution is accurately determined by direct standardization against a National Institute for Standards and Technolgy Acidimetric Standard-Acid Potassium Phthalate. This acidimetric standard shall be used without prior crushing or drying. Once the standard sample bottle has been opened, it should be restoppered, sealed with plastic tape, and stored in a desiccator pending further use. For the purpose of this standardization, 8.1691 g of the prescribed acid potassium phthalate shall be considered as equivalent to 40.00 mL of 1.000 normal sodium hydroxide.

5.1.2. Prepare the desired volume of 1.0 normal sodium hydroxide by measuring out 52.3 mL of the 50 percent NaOH solution and dilute with distilled water to 1 L volume.

5.1.3. Standardize the sodium hydroxide solution by accurately determining the mass, to the nearest 0.1 mg, from 7.5 to 8.5 g of original acid potassium phthalate. Transfer the weighed material to a 400-mL beaker. Add 185 mL of carbon dioxide free distilled water at a temperature of 25 to 28°C (77 to 83°F) and stir the mixture gently until the crystals dissolve. The carbonate-free distilled water can be prepared by boiling 1 L of distilled water and cooling it to room temperature. Add five drops of prepared phenolphthalein indicator and titrate the prepared standard with the sodium hydroxide solution to be standardized. Titrate to a visual end point of light pink, which will persist for at least 60 seconds. Record the number of mL of sodium hydroxide solution required for the titration. Calculate the normality of the sodium hydroxide solution as follows:

$$N\ \text{NaOH} = \frac{\text{Mass of Acid Potassium Phthalate in g}}{\text{mL of NaOH Required} \times 0.204228} \qquad (1)$$

5.2. *Standardized Hydrochloric Acid Solution*—This solution shall have a normality of 1.000 ± 0.015 when the normality is accurately determined by direct comparison with the previously standardized sodium hydroxide. This solution is prepared by adding 86 mL of concentrated HCl to the distilled water such that the final volume is 1 L.

5.2.1. Determine the normality of the acid solution according to the following procedure: Transfer an approximate 40 mL portion of the acid solution to be standardized into a 400-mL beaker. Use a buret to deliver this volume and accurately record the volume delivered. Add 140 mL of distilled water plus five drops of the prepared phenolphthalein indicator to the contents of the beaker and proceed to titrate the contents of the beaker by adding from a buret some of the previously standardized sodium hydroxide. Titrate to a visual end point of light pink, which will persist for at least 60 seconds. Record the number of mL of sodium hydroxide solution required for the titration. Calculate the normality of the hydrochloric acid solution as follows:

$$N\ \text{HCl} = \frac{\text{mL of NaOH Required} \times N \text{ of NaOH Used}}{\text{mL of HCl used}} \qquad (2)$$

5.3. *Phenolphthalein Indicator Solution*—Prepare this solution by dissolving 0.5 g of powdered phenolphthalein, A.C.S. Grade, in 50 mL of absolute ethyl alcohol and add 50 mL of distilled water.

5.4. *Bromphenol Blue Indicator Solution*—Prepare this solution by dissolving 0.1 g of powdered bromphenol blue in 7.5 mL of 0.02 Normal NaOH and dilute the resulting solution to 250 mL.

5.5. *Potassium Hydrogen Phthalate Reference Solution (0.05 Molar)*—Prepare this solution by dissolving 10.21 g of potassium biphthalate crystal primary standard in distilled water and dilute to 1 L. It is necessary to dry the salt before use in preparing this solution.

5.6. *Color Reference Standard for Use with Bromphenol Blue Indicator Solution*—Transfer 2.0 mL of the prepared bromphenol blue indicator solution to a 400 mL tall-form titration beaker. Add 250 mL of the 0.05 Molar potassium hydrogen phthalate reference solution and then add from a 10-mL buret 1.86 mL of the 1.000 Normal NaOH solution. The resulting solution should be blue colored with a slight purple cast. This solution should be tightly stoppered and set aside to act as a visual color reference standard to be used for comparison purposes in the titration to pH 4.4. The end point of this solution when prepared as directed shall have a pH of 4.4 and be of the color described.

6. TEST PROCEDURE

6.1. *Sample Preparation*:

6.1.1. Take a representative 2-L (half-gal) portion of the powdered lime to be analyzed and mix well by thoroughly shaking, inverting, etc., in a 4-L (1 gal) bucket fitted with a double friction-type lid.

6.1.2. The portion of material chosen for actual analysis shall be taken from the well-mixed material contained in the bucket. After each withdrawal, special precaution should be taken to replace the lid on the bucket so as to minimize atmospheric contamination of the material to be analyzed.

6.2. *Titrimetric Analysis of Various Alkaline Components of the Sample*:

6.2.1. *Titration to pH 8.3 with HCl*—Weigh out a 2.9 to 3.1-g portion of the well-mixed material contained in the bucket accurately to the third decimal place on an analytical-type balance. The weighed sample shall then be transferred quantitatively to a 400-mL beaker. Slowly add 150-mL of distilled water to the sample contained in the beaker and titrate immediately with approximately 1.0 normal hydrochloric acid to a prescribed end point of pH 8.3 using the pH meter. Gentle stirring of the mixture to be titrated shall be accomplished through the use of a magnetic-type stirrer. The first 50 mL of titrant may be added rather rapidly after which continued additions of titrant shall be made in "rapid drop-wise" fashion until a pH indication of nine or slightly less is obtained. A suitable rate for this "rapid drop-wise" addition has been found to be approximately 12 mL/min. After attaining a momentary pH indication of nine, or slightly less, proceed with the titration by adding titrant at the rate of approximately 2 mL/min. until the pH is in the vicinity of pH 8.5; then add acid in four-drop increments until the prescribed end point of 8.3 or of slightly less for 60 seconds is reached. The prescribed end point for this portion of the titration shall be taken to that point at which the addition of one two-drop increment of titrant produces a pH meter indication of 8.3 or slightly less than 8.3 when observed exactly 60 seconds after the addition of titrant. The first occurrence of such an end point in the normal course of the titration shall be considered as the end point for this portion of the analysis. The volume of titrant required to reach this end point should be recorded before proceeding with the further addition of HCl. The end point can also be obtained by taking a series of readings of pH vs. mL of HCl added and making a plot; the sharpest slope of the curve gives rise to the end point.

6.2.2. *Titration to "Measured Excess" of HCl*—After the pH 8.3 end point has been reached, continue to add hydrochloric acid titrant to the sample contained in the beaker to a point where a total of approximately 100 mL of titrant has been added to the sample since the beginning of the titration. The sample mixture contained in the titration beaker at this point shall be considered as containing a "measured excess" of hydrochloric acid. Record the total volume of acid added to the sample since the beginning of the titration before proceeding with the back-titration.

6.2.3. *Back-Titration to pH 4.4 with NaOH*—Titrate the sample mixture plus the "measured excess" of hydrochloric acid contained in the beaker with approximately 1.0 normal sodium hydroxide to a pH meter indication of 4.4 or of slightly greater than 4.4 when observed exactly 10 seconds after a one-drop addition of titrant. The first occurrence of such an end point in the normal course of the back-titration shall be taken to be the prescribed end point for this portion of the analysis. For an alternative method of obtaining the end point, see the last sentence in Section 6.2.1.

6.3. *Determination of Percent Loss on Ignition*—Weigh out 2.9 to 3.1 g, accurately to 0.1 mg, of the well-mixed material contained in the bucket. Transfer the material by means of a spatula directly from the bucket to a previously ignited and weighed platinum crucible, after which the crucible and sample portion that it contains shall be placed uncovered in an electric muffle furnace maintained at a temperature of 1100°C (2012°F) where it shall be allowed to remain for a required ignition period of 3 hours. After the sample has been ignited in this fashion, it should be removed from the furnace and placed on a piece of ceramic board for a period of 10 to 30 seconds prior to placing the crucible in a desiccator for further cooling. If several samples are being run simultaneously, it has been found expedient to remove all of the samples from the furnace, place them on the ceramic board and then proceed to place them in the desiccator. After they have been placed in the desiccator, replace the desiccator lid with a small opening. The heated air will expand through the opening for a period of several seconds after which the lid should be closed. The residue for the loss on ignition shall be allowed to cool for 30 minutes prior to the mass determination. The mass determination shall take place promptly after the cooling period so as to avoid possible contamination of the highly reactive quicklime residue. The actual mass determination of this residue shall be accomplished as rapidly as possible so as to prevent hydration of the residue due to exposure to the atmosphere. The mass determination shall be accurate to 0.1 mg.

7. SIEVE ANALYSIS

7.1. Weigh out two samples consisting of approximately 500 and 5 g portions of well-mixed material contained in the bucket.

7.1.1. Determine the mass of the 500 g portion to the nearest 0.1 g and then proceed in attempting to water-wash this material through each of the following sieves in the order listed. First, screen the material on the 3.35-, 2.00-, and 0.600-mm sieves. The wash water to be used for this purpose may be obtained from a piece of plastic tubing attached to a water faucet. The velocity of the wash water may be increased, if necessary, by pinching the tubing somewhat. In no case should the velocity of the stream of water being used to wash the residue be allowed to become sufficiently strong as to cause loss of sample over the sides of the sieve. The washing shall be continued until the water coming through each sieve is clear. If milkiness persists, the washing operation may be continued up to a maximum of 30 minutes. In no case shall the washing operation be continued past the point where the wash water appears clear. When the washing is complete, the residue on each sieve shall then be oven-dried at 100°C (212°F) for a period of 1 hour. After drying, the residue retained on each of the three sieves shall be transferred to separate tared weighing bottles in which the residues shall be cooled for 30 minutes and then the mass shall be determined separately on an analytical balance to the nearest 0.01 g. Use the cumulative masses to calculate the percentage retained on the various sieves on the basis of total dry mass of original sample taken before washing.

7.1.2. Residue on the 0.075-mm (No. 200) sieves shall be determined in accordance with T 192 except that a 5-g sample of lime rather than 1 g of cement shall be used and that a 0.075-mm (No. 200) sieve instead of the 0.045-mm (No. 325) sieve shall be used.

---

8. OPTIONAL INDICATOR METHOD FOR THE TITRIMETRIC ANALYSIS OF VARIOUS ALKALINE COMPONENTS OF THE SAMPLE

8.1. This method may be used in lieu of the prescribed pH meter method. However, for all reference tests, or in cases of dispute, the prescribed pH meter method shall be considered the official method to be used. In some cases, impurities such as aluminum compounds will prevent or hinder the appearance of the color change in the back-titration portion of the optional method. If such a difficulty is encountered with a particular sample, use the prescribed pH meter method. The procedure to be followed in employing this optional indicator method shall be exactly as outlined in the pH meter method with the following exceptions:

8.1.1. *Titration to Phenolphthalein End Point with HCl*—At the beginning of the titration to the phenolphthalein end point, add five drops of the prepared phenolphthalein indicator solution to the sample mixture and proceed with the titration by adding 50 mL of titrant rather rapidly, after which continued addition of titrant at the rate of approximately 12 mL/min shall be made in a "rapid dropwise" fashion to the point where the color of the solution changes temporarily from pink to clear. Before adding additional titrant, allow the pink color to return. At the return of the pink color, additional titrant should be added at the rate of approximately 2 mL/min until the color change appears imminent, then add acid in four-drop increments to where the pink coloration disappears for some 35 seconds. Then add two-drop increments until the prescribed end point of "failure to regain pink coloration for 60 seconds" is reached. The prescribed end point for this portion of the titration shall be taken to be that point at which the addition of one two-drop increment of titrant produces a condition in which the mixture in the titration beaker fails to regain its pink coloration when observed exactly 60 seconds after the last addition of titrant. The first occurrence of such an end point in the normal course of the titration shall be considered as the end point for this portion of the analysis. Once the prescribed end point has been reached, the further reappearance of pink color shall be ignored. The phenolphthalein end point shall be considered as being roughly equivalent to the pH 8.3 end point described in the official pH meter method of titration. For purposes of calculation, this phenolphthalein end point shall be considered to be the pH 8.3 end point when using this optional indicator method of titration. The volume of titrant required to reach this end point should be recorded before proceeding with the further addition of HCl.

8.1.2. *Titration to "Measured Excess" of HCl*—Consider the phenolphthalein end point as being the pH 8.3 end point and proceed to add a "measured excess" of hydrochloric acid by adding titrant to the 100-mL point and recording the total volume of acid added to the sample since the beginning of the titration before proceeding with the back-titration.

8.1.3. *Back-Titration to the Bromphenol Blue End Point with NaOH*—Add 2.0 mL of the bromphenol blue indicator to the sample mixture plus "measured excess" of HCl contained in the titration beaker. Proceed to titrate this mixture to the point where the color of the mixture changes from yellow to blue with a slight tinge of purple, and maintains this prescribed color of blue when observed exactly 10 seconds after a one-drop addition of titrant. The particular color of blue, which is prescribed as the end point for this portion of titration, should be visually color matched to the color standard that should be reserved for such comparison purposes. For the preparation of this color standard, refer to Section 5.6. The first occurrence of the prescribed end point in the normal course of the back-titration shall be taken to the bromphenol blue end point. For purposes of calculation, this bromphenol blue end point shall be considered to be the pH 4.4 end point when using this optional indicator method of back-titration.

9. CALCULATIONS

9.1. *Basic Data*:

9.1.1. *Chemical Constituents*:

$$\text{I} = \text{normality of acid used} \times \frac{54.08}{2000} \times 100$$

Note 2—I = factor derived by multiplying the normality of the acid used by the product of the mass weight of calcium oxide divided by 2000 (to convert to milli-equivalents) multiplied by 100 (so as to express the final unit to be calculated in percent). Example: In a case where the normality of the acid being used is 1.012 then the correct value for I = 1.012 × 2.804 = 2.838.

$$\text{II} = \text{normality of base used} \times \frac{56.08}{2000} \times 100$$

III = mL of acid to pH of 8.3,

IV = (I) × (III),

V = total mL of acid used,

Note 3—This volume of acid should approximate 100 mL and represents that volume of acid used in the titration to reach a pH of 8.3 plus that volume of acid added to insure a "measured excess" before proceeding with the prescribed "back-titration."

VI = (I) × (V),

VII = mL of base used in the "back-titration" to proceed from the point of "measured excess" to the prescribed end point of pH of 4.4,

VIII = (II) × (VII),

IX = (VI) – (VIII),

X = titration sample mass expressed in grams,

XI = "Loss on ignition" sample mass expressed in grams,

XII = "Loss on ignition" residual mass expressed in grams.

9.1.2. *Sieve Analysis*:

XIII = mass of the approximate 500-g sample (determined to the nearest 0.2 g) screened on the 3.35-mm sieve,

XIV = mass of the approximate 500-g sample (determined to the nearest 0.2 g) screened on the 2.00-mm sieve,

XV = mass of the approximate 500-g sample (determined to the nearest 0.2 g) screened on the 0.600-mm sieve,

XVI = mass of solids retained on the 3.35-mm sieve,

XVII = mass of solids retained on the 2.00-mm sieve, and

XVIII = mass of solids retained on the 0.600-mm sieve.

9.2. *Basic Calculations and Remarks*:

9.2.1. *Chemical Constituents*:

A = apparent hydrate alkalinity of the sample is indicated by titration and calculated as percent of CaO, Calculations:

$$\text{Percent CaO} = \frac{(IV)}{(X)}$$

B = carbonate alkalinity of the sample derived by titration and calculated as percent CaO,
Calculations:

$$\text{Percent CaO} = C - A$$

B′ = carbonate alkalinity of the sample derived by titration and calculated as percent $CaCO_3$,
Calculations:

$$\text{Percent } CaCO_3 = B \times (1.78479)$$

Note 4—1.78479 is a gravimetric factor used to convert percent CaO to percent $CaCO_3$.

C = total alkalinity of the sample calculated as percent CaO,
Calculations:

$$\text{Percent CaO} = \frac{(IX)}{(X)}$$

D = apparent hydrate alkalinity of the sample indicated by titration and expressed as percent $Ca(OH)_2$,
Calculations:

$$\text{Percent } Ca(OH)_2 = A \times (1.32126)$$

Note 5—1.32126 is a gravimetric factor used to convert percent CaO to percent $CA(OH)_2$.

E = carbonate alkalinity of the sample derived by titration and calculated as percent CO_2,
Calculations:

$$\text{Percent } Ca(OH)_2 = B \times (0.78479)$$

Note 6—0.78479 is a gravimetric factor used to convert percent CaO to percent CO_2.

F = loss on ignition of the sample when heated for 3 hours at 1100 °C (2012°F),
Calculations:

$$\text{Percent loss on ignition} = \frac{(XI - XII)}{(XI)} \times 100$$

Note 7—This equation is derived from the expression:

$$\text{Percent loss on ignition} = \frac{(\text{Sample Mass}) - (\text{Residue Mass})}{(\text{Sample Mass})} \times 100$$

For the purpose of this test procedure, *loss on ignition* shall be taken to be the sum of the losses due to "water of dehydration," "free water," and chemically combined carbon dioxide.

Water of Dehydration—that portion of the loss on ignition due to the loss of water resulting from the forced dehydration or disassociation of calcium hydroxide at elevated temperatures.

Free Water—the portion of the loss on ignition which is not accounted for by the loss due to "water of dehydration" plus the loss due to chemically combined carbon dioxide.

Total Water—that portion of the loss on ignition due to "water of dehydration" plus "free water."

G = "Total water" of the sample expressed as percent H_2O,
Calculations:

$$\text{Percent } H_2O = F - E$$

Note 8—This equation is derived from the assumption that at 1100°C, the principal losses to be encountered will be carbon dioxide and water, and that any gain in mass due to oxidation of other impurities such as sulfides to sulfates will be negligible. The basic assumption is that "total water" expressed as percent H_2O = (loss on ignition) – (carbonate alkalinity of the sample derived by titration expressed as percent CO_2).

H = apparent hydrate alkalinity of the sample indicated by the "total water" portion of the loss on ignition and expressed as percent $Ca(OH)_2$,
Calculations:

$$\text{Percent } Ca(OH)_2 = G \times (4.1128)$$

Note 9—4.1128 is a gravimetric factor used to convert percent H_2O to percent $Ca(OH)_2$.

I = corrected value for the hydrate alkalinity of the sample calculated as percent $Ca(OH)_2$,
Calculations:

$$\text{Percent } Ca(OH)_2 = H \text{ in Case I}$$

where $D > H$, then unhydrated lime is indicated as being present in the sample, = *D* or *H* in Case II

where $D = H$, then neither unhydrated lime nor "free water" is indicated as being present in the sample,= *D* in Case III

where $H > D$, then "free water" is indicated as being present in the sample.

Note 10—In instances in which this revised test procedure is used to arrive at a value for "hydrate alkalinity," mass percent $Ca(OH)_2$, then it is to be understood that it is to be the value "*I*" which shall be reported since this is the correct value for the hydrate alkalinity of the samples.

J = "Free water" of the sample calculated as percent H_2O,
Calculations:

$$\text{Percent } H_2O = \text{zero in Case I}$$

where $D > H$, then unhydrated lime is indicated as being present in the sample,= zero in Case II

where $D = H$, then neither unhydrated lime nor "free water" is indicated as being present in the sample, = $(H – D) \times (0.24314)$ in Case II

where $H > D$, then "free water" is indicated as being present in the sample.

Note 11—0.24314 is a gravimetric factor used to convert $Ca(OH)_2$ equivalents to H_2O equivalents.

K = unhydrated lime content of the sample calculated as percent CaO,
Calculations:

$$\text{Percent CaO} = (D - H) \times (0.75686) \text{ in Case I}$$

where $D > H$, then unhydrated lime is indicated as being present in the sample, = zero in Case II

where $D = H$, then neither unhydrated lime nor "free water" is indicated as being present in the sample, = zero in Case III

where $H > D$, then "free water" is indicated as being present in the sample.

Note 12—0.75686 = the conversion factor to convert $Ca(OH)_2$ equivalents to CaO equivalents.

L = "Inert matter" content of the sample calculated as percent inert matter,
Calculations:

Percent "inert matter" = $100 – (C + F)$.

Note 13—For the purpose of this test procedure, "inert matter" shall be defined as those sample constituents which by their chemical nature do not react under the conditions prescribed in acid titration nor do they volatilize under the conditions prescribed for the loss on ignition determination. It shall be assumed to consist essentially of acid insolubles plus possible metallic oxides.

9.2.2. *Sieve Analysis*—screen analysis on the sample expressed as mass percent of the total solids retained on the various sieves shall be calculated as follows:

$$M \;=\; \text{percent solids retained on the 3.35 – mm sieve} \frac{(\text{XVI})}{(\text{XIII})} \times 100$$

$$N \;=\; \text{percent solids retained on the 2.00 – mm sieve} \;=\; \frac{(\text{XVII})}{(\text{XIV})} \times 100,$$

$$O \;=\; \text{percent solids retained on the 0.600 – mm sieve} \;=\; \frac{(\text{XVIII})}{(\text{XV})} \times 100,$$

$$O' \;=\; \text{percent solids retained on the 0.075-mm sieve, and}$$

$$O' \;=\; R_c = [(R_s/5 \times 100 + C] \text{ (Note 14)}$$

Note 14—See T 192 for the definitions of variables R_c, R_s, and C. The value 100 is a constant in T 192 and the value five is used to correct the calculation in T 192 because a five-gram sample is used instead of a 1-gram sample.

Note 15—Sample calculations are given in Figure 1.

Figure 1—Sample Calculations

10. BASIC ASSUMPTIONS CONCERNING THE LOSS ON IGNITION PORTION OF TEST PROCEDURE

10.1. For the purpose of this test procedure, it shall be assumed that the loss in mass of sample during the loss on ignition portion of the test procedure is attributable solely to the volatilization of "free water," "water of dehydration," and of chemically combined carbon dioxide. The residue remaining in the platinum crucible, after the loss on ignition portion of the analysis, is assumed to be unhydrated calcium oxide plus "inert matter" that will not volatilize during the ignition at elevated temperatures nor react chemically during the acid titration of the principal alkaline constituents of the sample. This "inert matter" is usually termed "SiO_2," "acid insolubles," "combined metallic oxides," etc.

11. BASIC ASSUMPTIONS CONCERNING THE TITRATION PORTION OF THE TEST PROCEDURE

11.1. The titration portion of the analysis involved the assumption that the principal acid neutralizable alkaline constituents are calcium hydroxide, calcium oxide, and calcium carbonate. All of these constituents need not be present simultaneously, of course. This test procedure implies that under the conditions set forth for analysis, alkaline carbonates will not enter into the reaction during the first stage of titration (to the end point of 8.3). The "measured excess" of acid plus the back-titration with base is intended to cope with the bulk of the alkaline carbonates present and they are calculated as being present in the usual form of calcium carbonate. If unhydrated oxides are present in the sample, they will usually hydrate and/or react with the acid during the first state of titration (to the end point of 8.3) and will be calculated as calcium hydroxide. If they do not react under the conditions of the test, they will of course be considered as "inert matter" and calculated as such.

12. POSSIBLE PRESENCE OF MAGNESIUM COMPOUNDS

12.1. This entire test procedure is intended to be used in connection with the testing of a high-calcium-type lime hydrate. Magnesium compounds when present are assumed to be present to only a small degree and, as such, are either ignored or else calculated to the basis of calcium compounds. In instances where magnesium compounds are present to a significant degree, such a hydrate will usually encounter difficulty in meeting the requirements of the high-calcium-type lime specifications for which the particular test procedure was designed.

Standard Method of Test for

Determination of the Strength of Soil-Lime Mixtures

AASHTO Designation: T 220-66 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determination of the Strength of Soil-Lime Mixtures

AASHTO Designation: T 220-66 (2008)

1. SCOPE

1.1. This method provides for the determination of the unconfined compressive strength of soil-lime stabilization mixtures.

Note 1—Generally, an unconfined compressive strength of 690 kPa (100 psi) is satisfactory for the final course of base construction, and it is desirable that materials for such courses contain a minimum of 50 percent plus 0.425-mm (No. 40) material before treatment. Various soil materials may be treated for subbase, and, in such cases, the minimum suggested unconfined compressive strength is 345 kPa (50 psi).

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 216, Lime for Soil Stabilization

2.2. *ASTM Standard*:

- D 2216, Standard Test Methods for Laboratory Determination of Water (Moisture) Content of Soil and Rock by Mass

3. APARATUS

3.1. *Automatic Tamper*—A compaction device with base plate to hold 152 mm (6 in.) ID forming molds, equipped with 4.54-kg (10-lb) ram and adjustable height of fall. Ram fall is 457 mm (18 in.). The striking face of the ram is a 40-degree segment of a circle of 76-mm (3-in.) radius. Automatic tamper shall be furnished an extra base plate to hold the forming mold during specimen top finishing.

3.2. *Compaction Mold with Removable Collar*—Mold is 152 mm (6 in.) ID and 215 mm ($8^1/_2$ in.) high.

3.3. *Measuring Device for Specimen Height*—A micrometer dial assembly with a standard set of spacer blocks.

3.4. *Scale*, rated 18.1-kg (40-lb) capacity, sensitive to 0.0005 kg (0.001 lb).

3.5. *Press*, hydraulic, to extrude specimens from mold.

3.6. *Drying Oven*, controlled from 60 ± 5ºC (140 ± 9ºF) to 110 ± 5ºC (230 ± 9ºF).

3.7. *A Supply of Metal Pans*, wide and shallow, for mixing and drying materials, and a supply of rectangular stainless steel pans approximately 230 by 400 by 60 mm (9 by 16 by $2^{1}/_{4}$ in.) deep, equipped with porous spacer plates.

3.8. *Circular Porous Stones* slightly less than 152 mm (6 in.) in diameter and 51 mm (2 in.) high.

3.9. *Axial Cells*, lightweight stainless steel cylinders, 171 mm ($6^{3}/_{4}$ in.) ID and 305 mm (12 in.) high, fitted with standard air valve and straight, tubular rubber membrane 152 mm (6 in.) in diameter.

3.10. *Vacuum Pump*, 20 to 35 liters per minute (0.70 to 1.25 cfm), or aspirator.

3.11. *Air Compressor*, 4.7 to 7.1 L/s (10 to 15 cfm) with 230-L (60-gals) storage tank and controls, pressure regulators, gauges, and valves.

3.12. *Moist Room*, equipped with shelves and a constant pressure supply of air.

3.13. *Micrometer Dial Gauge*, calibrated to 0.02 mm (0.001 in.) with support to measure deflection of specimen.

3.14. *A supply of 2.27 and 4.54-kg (5 and 10-lb) Lead Surcharge Weights*.

3.15. *Calibrated Proving Ring or Other Continuous Force Measuring Device*, according to T 67 Verification of Testing Machines, except that an error of plus or minus 2 percent is allowed.

3.16. *Circumference Measuring Device*—A specially made metal tape measure.

3.17. *Screw Jack Press and Assembly* or other suitable testing press, with dial housing and two loading blocks.

3.18. *Sieves* with square openings of the following sizes conforming to the Standard Specification for Sieves for Testing Purposes (M 92) 75, 53, 50, 45, 31.5, 22.4, 16.0, 12.5, 9.5, 4.75, 2.00, 0.850, and 0.425-mm (3.0, 2.12, 2.00, 1.75, 1.25, $^{7}/_{8}$, $^{5}/_{8}$, $^{1}/_{2}$, $^{3}/_{8}$ in., No. 4, No. 10, No. 20, and No. 40) sieves.

3.19. *Mechanical Pulverizer* adjustable clearance rotating plate.

3.20. *Mechanical Sieve Shaker*—A laboratory size [0.014 m^3 ($^{1}/_{2}$ ft^3)] sieve shaker, convenient but not absolutely necessary, used for separating material for recombining specimens.

3.21. *A Supply of Small Tools and Accessories* such as wedgewood mortar and pestle, rubber covered pestle, rawhide hammer, spatulas, trowels, level, scoops, siphon tubes, sample containers, cardboard cartons, 510 by 510-mm (20 by 20-in.) filter papers, etc.

4. MATERIALS

4.1. A supply of lime, preferably meeting the requirements of M 216 for either Type I or II lime.

4.2. Good quality tap water.

5. SOIL PREPARATION

5.1. Select a 91-kg (200-lb) minimum representative sample for testing.

5.2. Spread the sample on a clean, dry floor to air-dry or use forced drafts of warm air.

5.3. The aggregations or hard lumps of clay in soils containing no appreciable amounts of coarse particles shall be crushed to pass the 2.00-mm (No. 10) sieve without breaking the coarse particles. The sample shall then be screened on the 0.850-mm (No. 20) sieve and the percentages retained and passing the 0.850-mm (No. 20) sieve determined.

5.4. Clays and other soils containing coarse particles shall be broken up to pass the 4.75-mm (No. 4) sieve without breaking the coarse particles. This may be done by means of a plastic mallet, rubber covered tamper, or similar hand tools. The material shall then be separated as follows:

5.4.1. Coarse particle materials (crushed stone, gravel, sand, and caliche) shall be dry-screened over the following suggested sieves: 45, 31.5, 22.4, 16, 9.5, 4.75, and 2.00 mm (1.75, 1.25, $^7/_8$, $^5/_8$, $^3/_8$ in., No. 4 and No. 10) to separate the various sizes of materials. Retain all material passing the 2.00-mm (No. 10) sieve. The material passing the 45-mm sieve (1.75-in.) is used in making specimens. Mix all minus 2.00-mm (No. 10) material on the floor until it is uniformly blended with respect to color, appearance, and moisture content.

5.5. Determine the mass of each size of material and compute the cumulative percentages retained on each sieve and the percent passing the 2.00-mm (No. 10) sieve. These values are not to be used as true sieve analysis, but are used to recombine individual specimens to ensure uniform graduation within each specimen.

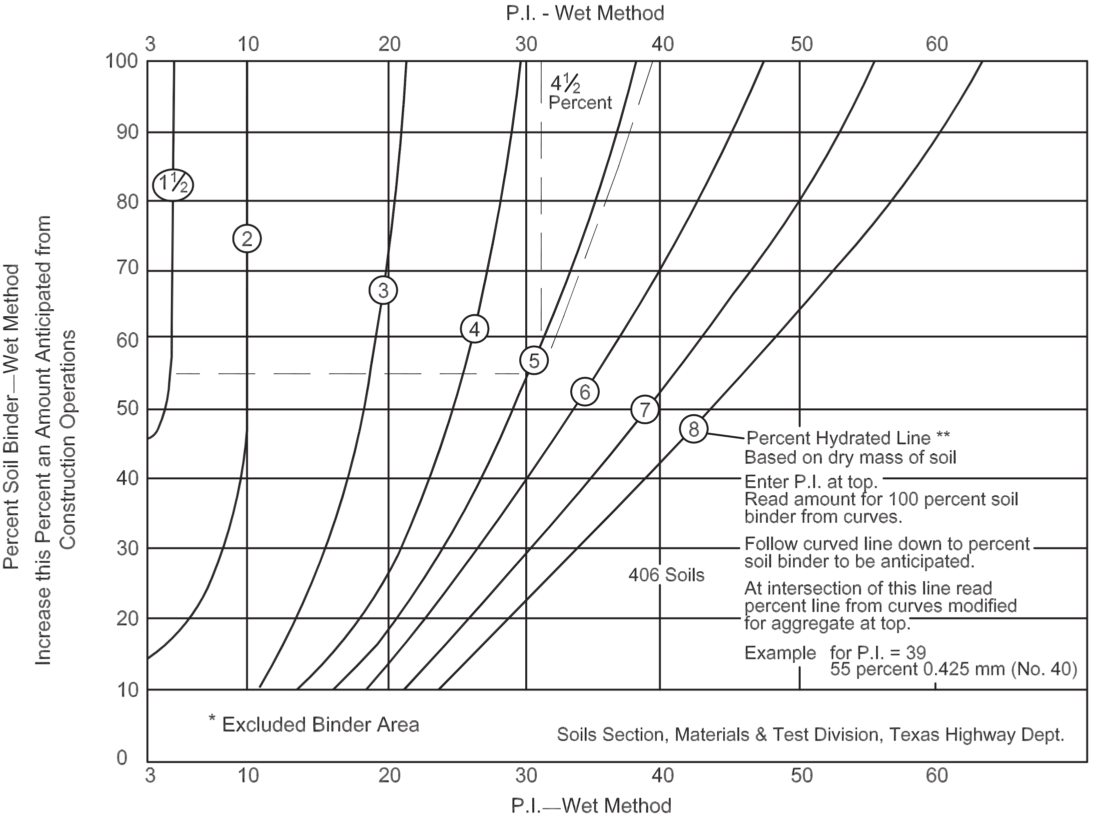
5.6. On the basis of the cumulative sieve size percentages obtained in Section 5.5 above, calculate and weigh out a 4.54-kg (10-lb) representative sample for sieve analysis and soil constants (Atterberg Limits). This 4.54-kg (10-lb) sample is prepared for testing by the wet method, T 146. Rolls, tumblers, or mills that might alter the coarse particles should not be used in this preparation. After preparation of the sample by the wet method, the following tests shall be performed in Table 1:

Table 1—Required Soils Tests

Mechanical Analysis	T 88
Liquid Limit, LL	T 89
Plastic Limit (PL) and Plasticity Index (PI)	T 90

6. SELECTION OF PERCENTAGE OF LIME

6.1. Enter plasticity index and percent minus 0.425 mm (No. 40), determined as in Section 4, of untreated soil on Figure 1, and determine the percentage of lime to add to the soil.



Percent Hydrated Line **
Based on dry mass of soil

Enter P.I. at top.
Read amount for 100 percent soil binder from curves.

Follow curved line down to percent soil binder to be anticipated.

At intersection of this line read percent line from curves modified for aggregate at top.

Example for P.I. = 39
55 percent 0.425 mm (No. 40)

Soils Section, Materials & Test Division, Texas Highway Dept.

* Exclude use of chart for materials with less than 10 %—No. 40 and cohesionless materials (P.I. less than 3).

** Percent of relatively pure lime usually 90% or more of Ce and/or Mg hydroxides and 85% or more of which pass the No. 200 sieve. Percentages shown are for stabilizing subgrades and base courses where lasting effects are desired. Satisfactory temporary results are sometimes obtained by the use of as little as ½ of above percentages. Reference to cementing strength is implied when such terms as "Lasting Effects" and "Temporary Results" are used.

Figure 1—Recommended Amounts of Lime for Stabilization of Subgrades and Bases (These percentages should be substantiated by approved testing methods on any particular soil material.)

7. PROCEDURE FOR DETERMINING OPTIMUM MOISTURE AND DENSITY

7.1. Determine the percent hygroscopic moisture in the soil using a representative sample of the soil according to ASTM Method D 2216. Estimate the mass of air-dry material that will, when wetted and compacted, fill the 152-mm (6-in.) ID mold to a height of 200 mm (8 in.). Using this estimated mass and the air dry screen analysis already obtained in preparing the large sample, compute the cumulative masses of each size to combine to make the 152-mm (6-in.) diameter by 200-mm (8-in.) high specimen. The amount of lime to use is the percentage from Section 5 and is based on the dry density of the soil.

7.2. Weigh up the material as calculated in Section 6.1. Keep the coarse particle fraction separate from (1) the passing 2.00-mm (No. 10) sieve material for flexible base, and (2) the clay lumps and passing 0.850-mm (No. 20) sieve for fine soils.

7.3. Calculate the mass of water to add on the basis of the dry soil and weigh into a tared sprinkling jar.

7.4. In preparing the soil-lime mixture for the moisture-density test, mix the lime with the portion of material passing the 2.00-mm (No. 10) sieve. Wet the plus 2.00-mm (No. 10) portion with some or all of the weighed quantity of water (depending on how little or how much plus 2.00-mm (No. 10) the sample contains) and stir and wet the coarse particles thoroughly. Let set until free water on surface has been absorbed.

Note 2—In clay soils or fine-grained soils, separate the material on the 0.850-mm (No. 20) sieve. Mix approximate proportionate amounts of the lime to be used with both fractions. Sprinkle the mixing water on the +0.850-mm (No. 20) fraction using most or all of the water required. Add in the –0.850-mm (No. 20) fraction and the remainder of water if any. Mix thoroughly and mold as above.

7.5. Pour the fine material passing the 2.00-mm (No. 10) or 0.850-mm (No. 20) sieve over the wet portion of the specimen and spread evenly. Use a trowel to cut grooves in the material allowing dry fines to fall toward the bottom of the pan; then mix until uniform. Take care not to lose any of the material and keep the mixing pan covered, when possible, to prevent loss of water by evaporation. In order to get uniform distribution of moisture in clay soils, pass the material through a 6.3-mm ($^1/_4$-in.) sieve.

7.6. Calculate and weigh out the material for one layer. This should be one-fourth of the mass of the wet mixture. Place this layer in the mold using putty knives, your hand, or convenient tools, keeping close watch in order to avoid segregation of rock sizes or fines. In base coarse materials or other coarse particle-type materials, place some excess fines, usually about 15 mm (0.5 in.) thick, loosely on the bottom flat surface, and then begin with large particles and other sizes, ending up with some fines to ensure a dense layer. Successive layers do not require as much fines as the 15-mm (0.5-in.) loose thickness in the first layer. This procedure ensures a smooth, tight bottom for each layer. Level the layer by hand or spatula, then use the spatula around the insides of the mold, spading the layer to intermix fines and coarse particles for a denser, more uniform layer. Do not tamp the loose material either by hand or any other hand tool, but compact the layer using a compactive effort of 50 accurately adjusted 457-mm (18-in.) drops of the 4.54-kg (10-lb) ram; determine the optimum moisture and maximum density for the soil-lime mixture. Keep the ram face clean of sticky or adhering material. Repeat this until all four layers are compacted.

7.7. After the last layer has been compacted, fasten the mold containing the specimen upon the top of the extra base plate and finish the top by means of various hand tools, such as a putty knife, or a lead, rawhide, or plastic mallet, and a circular steel plate with a smooth surface. Use the small level to check the surface of the specimen so that it will be plane and level with the top of the forming mold. Do not trim the specimen.

7.7.1. After the final layer has been compacted and while the hand finishing of the specimen is being done, the following type of blows (with hand hammers) shall be used after leveling, etc., to complete the hand finishing. (See Table 2.)

Table 2—Type of Blows

No. of 4.54-kg (10-lb), 457-mm (18-in.) Blows per Layer	Type of Hammer	No. of Blows and Description
15 to 20	0.45 to 0.90-kg (1 to 2-lb) hammer	2 to 4 light “pecking” blows
25	0.45 to 0.90-kg (1 to 2-lb) plastic 1.80 to 2.2-kg (4 to 5-lb) rawhide	5 to 10 light and 2 medium firm
50 and above	0.45 to 0.90-kg (1 to 2-lb) plastic 1.80 to 2.2-kg (4 to 5-lb) rawhide	5 to 10 light and 5 firm

7.8. Remove the mold from the base plate, determine the mass of the specimen in the mold to the nearest 0.5 g (0.001 lb), and measure the height, by means of the measuring device, to the nearest 0.02 mm (0.001 in.). Record the data.

7.9. Carefully center the specimen over a porous stone and place in the press to extrude molded specimens. Push the material on the bottom stone upward out of the mold.

7.10. Place the specimen in a large tared pan, break up material by hand or using convenient hand tools, and oven dry to constant mass at 110 ± 5ºC (230 ± 9ºF).

7.11. If necessary, adjust the mass of the material to obtain a 200-mm (8-in.) height of specimen, vary the amount of molding water, and repeat the above operations using individual batches for each specimen to obtain several points for a good moisture-density curve.

8. COMPACTION OF THE TEST SPECIMEN

8.1. Compact three specimens 152 mm (6 in.) in diameter and 200 mm (8 in.) in height at the optimum moisture and density found in Section 6. These lime-treated subgrade soil or flexible base specimens should be compacted as nearly identical as possible. The data for these specimens, as well as those obtained in the following test procedures, should be recorded on the test data sheet (Figure 2).

Figure 2—Compressive Strength Test Worksheet for Soil-Lime Mixes

9. CURING TEST SPECIMENS

9.1. Immediately after extruding the test specimens from the forming mold, with top and bottom porous stones in place, insert the specimens in a triaxial cell. Store the specimens at room temperature for a period of 7 days.

9.2. After moist curing, remove the cells and place the specimens in an air dryer and dry at a temperature not to exceed 60ºC (140ºF) for about 6 hours or until one-third to one-half of the molding moisture has been removed. All lime-treated soils are dried as given above even though a considerable amount of cracking may occur. Allow the specimen to cool for at least 8 hours before continuing the test.

9.3. Determine the mass and measure the specimens and subject them to capillarity for 10 days by the method described in Section 10.

10. SUBJECTING TEST SPECIMENS TO CAPILLARITY

10.1. Specimens are subject to capillarity for 10 days as follows:

10.1.1. Apply a vacuum to the axial cell and remove the cell from the specimen. Do not remove porous stones from specimens until after specimens have been tested. Cut a piece of filter paper, 250 by 510 mm (10 by 20 in.) in size, fold to 125 by 510 mm (5 by 20 in.) and make several cuts with scissors (jack-o'-lantern fashion). These cuts will prevent any restriction by the paper. Wrap the filter paper around the specimen and stones and fasten with a small piece of cellophane tape. Replace the cell.

10.2. Place the specimens into the rectangular pans provided for capillary absorption and adjust the water level on the lower porous stones to a distance of 13 mm (0.5 in.) below the bottom of the specimens.

10.3. Connect each cell to the air manifold and open the valve to apply a constant lateral pressure of 6.9 kPa (1 psi). Maintain this constant pressure throughout the period of absorption.

10.4. Place a suitable vertical surcharge load (which will depend upon the proposed use or location of the material in the roadway) on the top porous stone. For flexible base, use 3.45 kPa (0.5 psi) and for subgrade soils, use 6.90 kPa (1 psi) of the end area of the specimen. Consider the mass of the top porous stone as part of the surcharge mass.

11. PREPARING SPECIMENS FOR TESTING

11.1. Specimens subjected to 10 days of capillarity shall be prepared as follows:

11.1.1. Disconnect the air hose from the cell, remove the surcharge weight, and return the specimens to the laboratory for testing. Use a vacuum and deflate the rubber membrane to aid in removing the cell from the specimens, and discard the filter paper. If any appreciable material clings to the paper, carefully press it back into the available holes along the side of the specimen.

11.1.2. Determine the mass of the specimens and record their total mass after capillary absorption. Note that the wet mass of stones is obtained after the specimens are tested.

11.1.3. Measure the circumference of each specimen by means of the metal measuring tape. Measure the height of the specimen including the stones and enter on the data sheet as height over stones. Record the height of each stone.

11.2. Specimens that set overnight in cells shall be prepared as follows:

11.2.1. Use a vacuum and deflate the rubber membrane to aid in removing the cell from the specimens. Any material clinging to the membrane is pressed back into the available side holes or saved to place with the specimen when it is dried out.

11.2.2. Measure the specimen as in Section 11.1.3 and replace the cell.

12. TESTING SPECIMENS

12.1. In brief, the specimens are tested in compression while being subjected to their assigned constant lateral pressure. The motorized press is geared to travel at a rate of 3.3 to 3.8 mm (0.13 to 0.15 in.) per minute. Simultaneous readings of load and deformation shall be taken at intervals of 0.25-mm (0.01-in.) deformation until the specimen fails.

12.2. Disengage the worm gear drive and crank the press down far enough to have room to place the specimen, metal loading blocks, and the special bell dial housing in the press.

12.3. Center the specimen with the upper and lower metal loading blocks in place in the press. Adjust the deformation gauge in such a manner that it will be down against the center of the top spacer block and also compressed for almost the length of travel of the stem. The gauge must be placed in this position because the specimen moves away from the gauge during the compression. Set the dial of the deformation gauge to read zero.

12.4. Place the bell housing over the deformation gauge and adjust so that it does not touch the gauge or its mountings. At this point it should be noted that the compressive stress will necessarily be applied along a vertical line through the center of the ball that is mounted in the top of the bell housing. Since it is desirable to apply the compressive force along the vertical axis of the test specimen, shift the bell housing laterally to bring the ball directly over the axis of the specimen. Raise the press by means of the motor, then align and seat the ball on the bell housing into the socket in the proving ring. Then apply just enough pressure to obtain a perceptible reading on the proving ring gauge. Read the deformation gauge and record as deformation under dead load.

12.5. Connect the air line to the axial cell and apply lateral pressure to the specimen. The usual lateral pressures used for a series of tests are 0, 21, 34, 69, 103, and 138 kPa (0, 3, 5, 10, 15, and 20 psi). In cases where the load or stress is high (1207 to 1241 kPa (175 to 180 psi)) for the specimen tested at 103 kPa (15 psi) lateral pressure, use 48 kPa (7 psi) instead of 138 kPa (20 psi) for the last specimen. The lateral pressure applied by the air will tend to change the initial reading of the deformation gauge. As the air pressure is adjusted, start the motor momentarily to compress the specimen until the deformation gauge reads the same as recorded in Section 12.4. Read the proving ring gauge and enter in the load column opposite the initial deformation reading.

12.6. Turn on the motor and read the proving ring dial at each 0.25-mm (0.01-in.) deformation of the specimen. Continue reading until 60 readings have been taken, unless failure occurs earlier. Failure is reached when the proving ring dial readings remain constant or decrease with further increments of deformation. In testing specimens with coarse particles, the slipping and shearing of the coarse particles will cause temporary decreases in proving ring readings. The test shall be continued until true failure is reached. After 60 readings the cross-sectional area of the specimen has increased so that the subsequent small increase in load readings is little more than the increase in tension of the membrane acting as lateral pressure.

12.7. All of the above procedure applies to the unconfined specimen except that no air or axial cell is used. For materials that contain a large amount of coarse particles, compact and test two specimens at zero lateral pressure. Use the average of the test results unless large rocks appear to have created point bearings; in this case use the highest value.

---

13. CALCULATIONS AND GRAPHS

13.1. *Obtaining Dry Mass of Specimen and Stones*:

13.1.1. The specimen and stones are removed from the cell over a tared flat drying pan. Use a spatula to clean the material from the inside of the cell and the porous stones. Break up the specimen in the drying pan, taking care to lose none of the material, and place an identification tag in the pan.

13.1.2. Dry the material to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF) and determine the dry mass.

13.1.3. On specimens that have been subjected to capillarity overnight, determine the mass of the damp stones, dry at 60ºC (140ºF) to constant mass, and record the mass.

13.2. Calculate the volume in m^3 (ft^3) for 1 mm (1 in.) of height of the mold as follows:

$$V = \frac{\text{area of mold in mm}^2 \times 1\text{ mm}}{10^9} \tag{1}$$

or,

$$V = \frac{\text{area of mold in in.}^2 \times 1\text{ in.}}{1728} \tag{2}$$

13.3. Calculate the volume of the specimens as molded by multiplying the value obtained in Section 12.2 times the height of the specimen in mm (in.).

13.4. Calculate dry density as follows:

$$\text{Dry density} = \frac{\text{dry mass of specimen}}{\text{volume of specimen}} \tag{3}$$

13.5. Calculate compactive effort for a 50-mm (2-in.) layer expressed as J/m^3 (ft·lbf/ft^3):

Compactive effort (J/m^3) =

$$\frac{9.8\text{ m/s}^2}{1000\text{ mm/m}} \times \frac{\text{no. of blows} \times \text{mass of ram (kg)} \times \text{fall of ram (mm)}}{\text{volume of layer (value from Section 13.2} \times \text{layer thickness in mm)}} \tag{4}$$

or,

Compactive effort (ft·lbf/ft^3) =

$$\frac{1}{12\text{ in./ft}} \times \frac{\text{no. of blows} \times \text{mass of ram (lbm)} \times \text{fall of ram (in.)}}{\text{volume of layer (value from Section 13.2} \times \text{layer thickness in in.)}} \tag{5}$$

13.6. Calculate the percent molding moisture as follows:

$$\text{molding moisture, percent} = \frac{\text{mass of wet spec} - \text{mass of dry spec}}{\text{mass of dry spec}} \times 100 \tag{6}$$

13.7. Calculate percent moisture after specimens have been in capillarity, using the formula:

$$M_C = \frac{W_A - W_B - W_D}{W_D} \times 100 \tag{7}$$

where:

W_A = wet mass of specimen and stones after capillarity,

W_B = wet mass of stones, and

W_D = dry mass of specimen.

13.8. Calculate the values of strain and stress for each individual specimen from the following relations:

$$S = \frac{d}{h} \times 100 \tag{8}$$

where:

S = percent strain,

d = total vertical deformation at the given instant, and

h = the height of the specimen measured after specimen is removed from capillarity.

$$p = \frac{P}{A}\left(1 - \frac{S}{100}\right) \tag{9}$$

where:

p = the corrected vertical unit stress. A correction is necessary because the area of the cross section increases as the specimen is reduced in height. The assumption is made that the specimen deforms at constant volume.

P = the total vertical load on the specimen at any given deformation. It is the sum of the applied load measured by the proving ring, plus the dead weight of the upper stone, loading block, and dial housing.

A = the end area of the cylindrical specimen at the beginning of the test.

13.9. Plot a moisture-density curve (Figure 3).

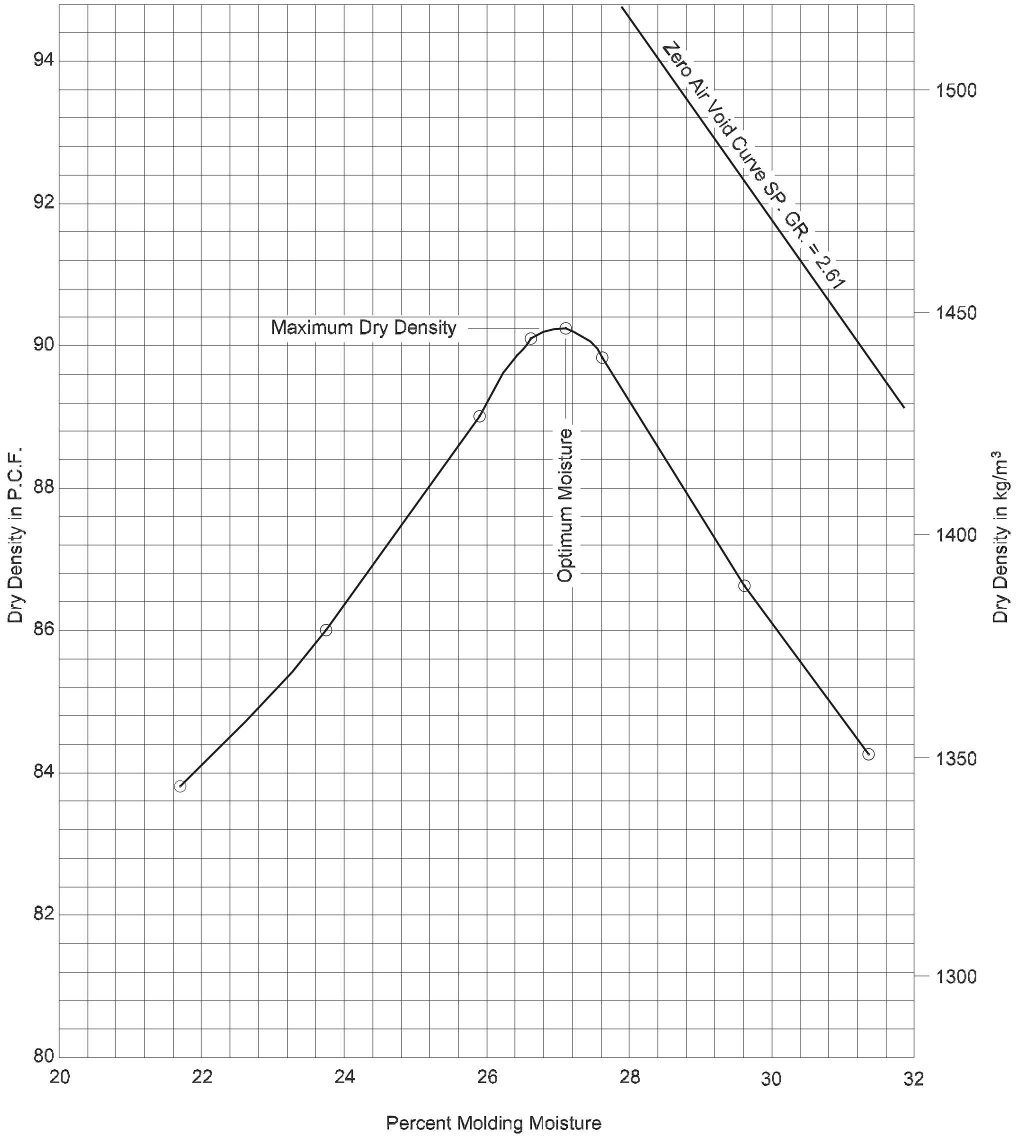

Figure 3—Moisture-Density Curve

14. REPORTING OF TEST RESULTS

14.1. Report the unconfined compressive strength values, density, moisture, and lime content as indicated in Figure 4. Use the average of the three specimen test values when reporting the unconfined compression test results.

Lab No.	Percent Lime Basis Dry Mass Soil	Dry Density kg/m^3 (lb/ft^3) Soil Lime	Compressive Strength kPa (psi)	Percent Moisture Absorbed	Optimum Moisture Soil Plus Lime

Washington, D.C. 20001

Standard Method of Test for

Repetitive Static Plate Load Tests of Soils and Flexible Pavement Components for Use in Evaluation and Design of Airport and Highway Pavements

AASHTO Designation: T 221-90 (2008)[1]
ASTM Designation: D 1195-93 (2004)

1. SCOPE

1.1. This test method covers a procedure for making repetitive static plate load tests on subgrade soils and compacted pavement components, in either the compacted condition or the natural state, and is to provide data for use in the evaluation and design of rigid and flexible-type airport and highway pavements.

1.2. The values stated in inch-pound units are to be regarded as the standard.

2. DEFINITIONS

2.1. *deflection*—the amount of downward vertical movement of a surface due to the application of a load to the surface.

2.2. *rebound deflection*—the amount of vertical rebound of a surface that occurs when a load is removed from the surface.

2.3. *residual deflection*—the difference between original and final elevations of a surface resulting from the application and removal of one or more loads to and from the surface.

3. APPARATUS

3.1. *Loading Device*—A truck or trailer or a combination of both a tractor-trailer, an anchored frame, or other structure loaded with sufficient weight to produce the desired reaction on the surface under test. The supporting points (wheels in the case of a truck or trailer) shall be at least 8 ft (2.44 m) from the circumference of the largest diameter bearing plate being used.

3.2. *Hydraulic Jack Assembly*—with a spherical bearing attachment, capable of applying and releasing the load in increments. The jack shall have sufficient capacity for applying the maximum load required, and shall be equipped with an accurately calibrated gauge that will indicate the magnitude of the applied load.

3.3. *Bearing Plates*—A set of circular steel bearing plates not less than 1 in. (25.4 mm) in thickness, machined so that they can be arranged in pyramid fashion to ensure rigidity, and having diameters ranging from 6 to 30 in. (152 to 762 mm). The diameters of adjacent plates in the pyramid arrangement shall not differ by more than 6 in. (152 mm) (Note 1).

Note 1—A minimum of four different plate sizes is recommended for pavement design or evaluation purposes. For evaluation purposes alone, a single plate may be used, provided that its area is equal to the tire-contact area corresponding to what may be considered as the most critical combination of conditions of wheel load and tire pressure. For the purpose of providing data indicative of bearing index (for example, the determination of relative subgrade support throughout a period of a year), a single plate of any selected size may be used.

3.4. *Dial Gauges*—two or more, graduated in units of 0.001 in. (0.02 mm) and capable of recording a maximum deflection of 1 in. (25 mm) or other equivalent deflection-measuring devices.

3.5. *Beam for Mounting Dial Gauges*—A beam upon which the dial gauges shall be mounted. The beam shall be a $2^1/_2$-in. (63.5-mm) standard black pipe or a 3 by 3 by $^1/_4$ in. (76 by 76 by 6-mm) steel angle, or equivalent. It shall be at least 18 ft (5.5 m) long and shall rest on supports located at least 8 ft (2.44 m) from the circumference of the bearing plate or nearest wheel or supporting leg. The entire deflection measuring system shall be adequately shaded from direct rays of the sun.

3.6. *Miscellaneous Tools*—including a spirit level, for preparation of the surface to be tested and for operation of the equipment.

4. PROCEDURE

4.1. Carefully center a bearing plate, of the selected diameter, under the jack assembly. Set the remaining plates of small diameter concentric with, and on top of, the bearing plate. Set the bearing plate level in a thin bed of a mixture of sand and plaster of paris, or plaster of paris alone, or of fine sand, using the least quantity of materials required for uniform bearing. To prevent loss of moisture from the subgrade during the load test, cover the exposed subgrade to a distance of 6 ft (1.83 m) from the circumference of the bearing plate with a tarpaulin or waterproof paper.

4.2. Where unconfined load tests are to be made at a depth below the surface, remove the surrounding material to provide a clearance equal to $1^1/_2$-plate diameters from the edge of the bearing plate. For confined tests, the diameter of the excavated circular area shall be just sufficient to accommodate the selected bearing plate.

4.3. Use a sufficient number of dial gauges, so located and fixed in position as to indicate the average vertical movement of the bearing plate. When using two dial gauges, they shall be set near each extremity of a diameter of the bearing plate, 1 in. (25.4 mm) from the circumference. When three gauges are employed, they shall be set at an angle of 120 degrees from each other, and equidistant from the circumference of the bearing plate. Each individual set of readings shall be averaged, and this value is recorded as the average settlement reading.

4.4. After the equipment has been properly arranged, and with all of the dead load (jack, plates, etc.) acting, seat the bearing plate and assembly by the quick application and release of a load sufficient to produce a deflection of not less than 0.01 in. (0.25 mm) nor more than 0.02 in. (0.51 mm), as indicated by the dial gauges. When the dial needles come to rest following the release of this load, reseat the plate by applying one-half of the recorded load producing the 0.01- to 0.02-in. (0.25- to 0.51-mm) deflection. When the dial needles have again come to rest, set each dial accurately at its zero mark.

Note 2—The use of additional dial gauges, placed on the surface of the material being tested at one-half, one, one-and-one-half, etc. bearing plate diameters from the edge of the bearing plate, is optional.

4.5. Apply a load giving a deflection of about 0.04 in. (1.02 mm), start a stopwatch, and maintain the same load constantly until the rate of deflection is 0.001 in. (0.03 mm) per minute or less for 3 successive minutes. Then completely release the load, and observe the rebound until the rate of recovery is 0.001 in. (0.03 mm) per minute or less, for 3 successive minutes. Apply and release the same load in this manner six times. Record the reading of the dial gauges resting on the bearing plate at the end of each minute; record the readings of the dial gauges set beyond the perimeter of the bearing plate just before the application, and just before the release of load, for each repetition. To ensure good contact between the gauges and the bearing plate or other surface on which they are resting, briefly buzz an electric bell attached to the deflection beam 10 seconds before the dial gauges are to be read.

4.6. Increase the load to give a deflection of about 0.2 in. (5.08 mm) and proceed as directed in Section 4.5.

4.7. Increase the load to give a deflection of about 0.4 in. (10.2 mm) and proceed as directed in Section 4.5.

4.8. In all cases, the standard end point shall be a rate of 0.001 in. (0.03 mm) per minute or less for 3 successive minutes.

4.9. From a thermometer suspended near the bearing plate, read and record the air temperature at half-hour intervals.

5. RECORD OF TESTS

5.1. In addition to the continuous listing of all load, deflection, and temperature data, as prescribed in Section 3, a record shall also be made of all associated conditions and observations pertaining to the test, including the following:

5.1.1. Date;

5.1.2. Time of beginning and completion of test;

5.1.3. List of personnel;

5.1.4. Weather conditions;

5.1.5. Any irregularity in routine procedure;

5.1.6. Any unusual conditions observed at the test site; and

5.1.7. Any unusual observations made during the test.

6. CALCULATION AND PLOTTING OF LOAD-DEFLECTION RELATIONSHIPS

6.1. For each repetition of each load, determine the deflection at which the rate of deflection is exactly 0.001 in. (0.03 mm) per minute. This is termed end-point deflection and can be determined with sufficient accuracy from visual inspection of the deflection data for each repetition of load recorded.

6.2. Correct the recorded loads, as read from the pressure gauge of each hydraulic jack employed, by means of the calibration curve for each jack and pressure gauge used.

6.3. Determine graphically the zero point corrections for both applied load and deflection. This requires taking into account the weight of the hydraulic jack, that of the pyramid of bearing plates, etc., and that of the corrected jack loads at which the dial gauges were set to zero at the beginning of the test.

6.4. Plot the corrected deflection at which the rate of deflection is exactly 0.001 in. (0.03 mm) per minute versus the number of repetitions of each corrected load. Similar graphs may be prepared in which corrected residual deflection and rebound deflection are plotted versus the number of repetitions of each corrected load.

7. PRECISION AND BIAS

7.1. The precision and bias of this test method for making repetitive static plate load tests on subgrade soils and flexible pavement components has not been determined. Soils and flexible pavement components at the same location may exhibit significantly different load-deflection relationships. No method presently exists to evaluate the precision of a group of repetitive plate load tests on soils and flexible pavement components due to the variability of these materials. The subcommittee is seeking pertinent data from users of this method that may be used to develop meaningful statements of precision and bias.

---

[1] This method is technically equivalent to ASTM D 1195-93 (2004).

Standard Method of Test for

Nonrepetitive Static Plate Load Test of Soils and Flexible Pavement Components for Use in Evaluation and Design of Airport and Highway Pavements

AASHTO Designation: T 222-81 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Nonrepetitive Static Plate Load Test of Soils and Flexible Pavement Components for Use in Evaluation and Design of Airport and Highway Pavements

AASHTO Designation: T 222-81 (2008)

1. SCOPE

1.1. This method covers the making of nonrepetitive static plate load test on subgrade soils and flexible pavement components, in either the compacted condition or the natural state, and is intended to provide data for use in the evaluation and design of rigid and flexible-type airport and highway pavements.

1.2. The values stated in SI units are to be regarded as the standard.

2. DEFINITIONS

2.1. *deflection*—the amount of downward vertical movement of a surface due to the application of a load to the surface.

2.2. *residual deflection*—the difference between original and final elevations of a surface resulting from the application and removal of one or more loads to and from the surface.

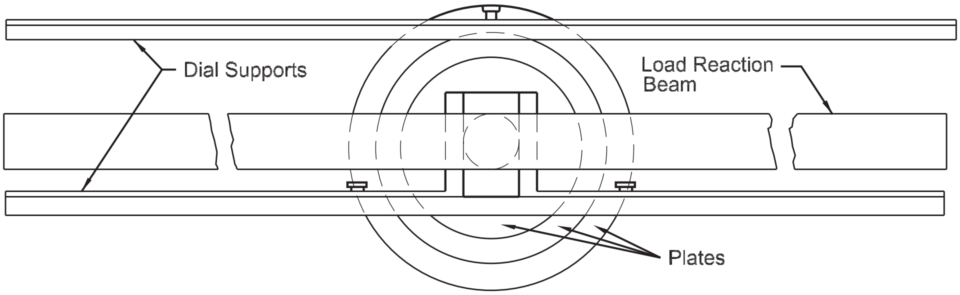
2.3. *rebound deflection*—the amount of vertical rebound of a surface that occurs when a load is removed from the surface.

3. APPARATUS

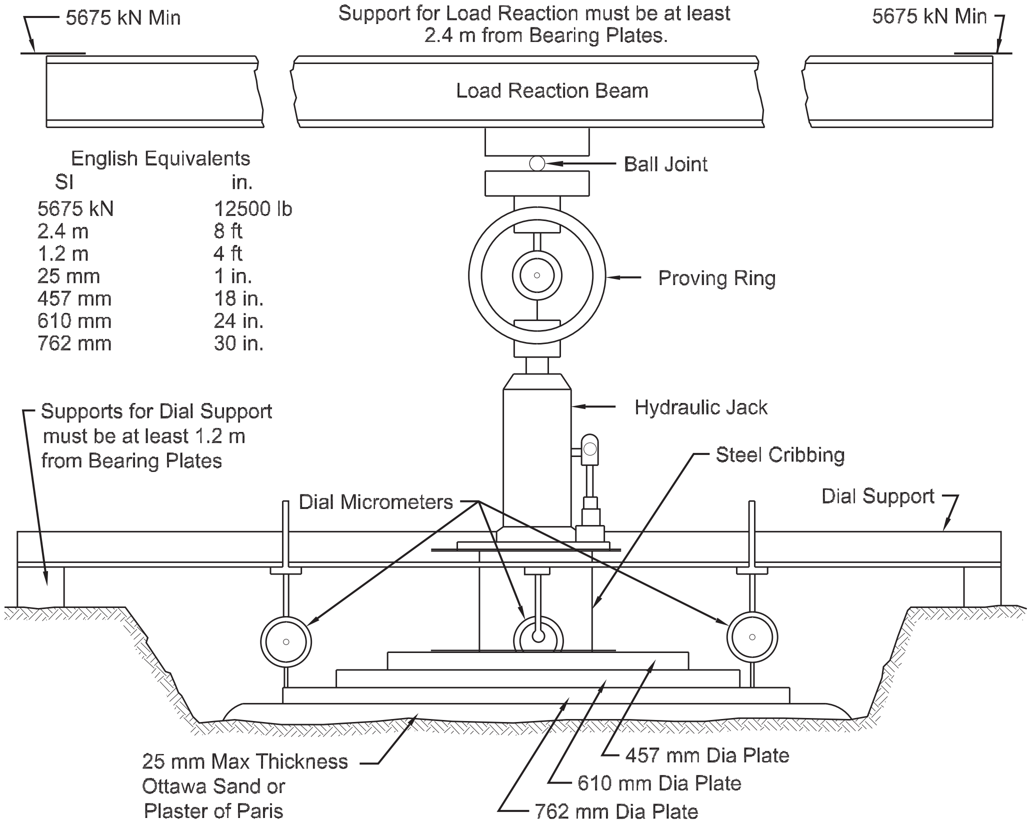
3.1. *Field Test Apparatus*—The required field test apparatus, part of which is shown in Figure 1, is as follows:

3.1.1. *Loading Device*—a truck or trailer, or a combination of both, a tractor trailer, an anchored frame, or other structure loaded with sufficient mass to produce the desired reaction on the surface under test. The supporting points (wheels in the case of a truck or trailer) shall be at least 2.4 m (8 ft) from the circumference of the largest diameter bearing plate being used. The dead load shall be at least 5675 kg (25000 lb).

3.1.2. *Hydraulic Jack Assembly*—with a spherical bearing attachment, capable of applying and releasing the load in increments. The jack shall have sufficient capacity for applying the maximum load required, and shall be equipped with an accurately calibrated gauge, or proving ring, that will indicate the magnitude of the applied load.



Plan



Elevation

Figure 1—Plate Bearing Test Equipment

3.1.3. *Bearing Plate*—A set of circular steel bearing plates not less than 25.4 mm (1 in.) in thickness, machined so that they can be arranged in pyramid fashion to ensure rigidity, and have diameters ranging from 152 to 762 mm (6 to 30 in.). The diameters of adjacent plates in the pyramid arrangement shall not differ by more than 152 mm (6 in.) (Note 1). Aluminum alloy No. 24ST plates 38 mm ($1^1/_2$ in.) thick may be used in lieu of steel plates.

Note 1—A minimum of four different plate sizes is recommended for pavement design or evaluation purposes. For evaluation purposes alone, a single plate may be used, provided that its area is equal to the tire-contact area corresponding to what may be considered as the most critical combination of conditions of wheel load and tire pressure. For the purpose of providing data indicative of bearing index (for example, the determination of relative subgrade support throughout a period of a year), a single plate of any selected size may be used.

3.1.4. *Dial Gauges*—Three or more, graduated in units of 0.02 mm (0.001 in.) and capable of recording an accumulated deflection of at least 25.4 mm (1 in.), or other equivalent deflection measuring devices.

3.1.5. *Deflection Beam*—Upon which the dial gauges shall be mounted. The beam shall be a 63.5 mm ($2^1/_2$ in.) standard black pipe or a 76 by 76 by 6 mm (3 by 3 by $^1/_4$ in.) steel angle, or equivalent. It shall rest on supports located at least 1.2 m (4 ft) from the circumference of the bearing plate or nearest wheel or supporting leg. The entire deflection measuring system shall be adequately shaded from direct rays of the sun and weather protected from rain, etc.

3.1.6. *Miscellaneous Tools*—Including a spirit level, for preparation of the surface to be tested and for operation of the equipment.

3.1.7. *Consolidometer Apparatus*—Necessary equipment for cutting an undisturbed specimen of the soil into a consolidometer test ring. Scales, oven, and miscellaneous tools for making moisture-content determination.

4. PROCEDURE

4.1. Where unconfined load tests are to be made, strip an area of the soil to be tested to the proposed elevation of the subgrade surface. The stripped area should be at least twice the diameter of the plates to eliminate surcharge or confining effects. If the subgrade is to be composed of fill material, construct a test embankment at least 762 mm (30 in.) in height using the proposed fill material compacted to the moisture content and density that will be required during construction. Clear the area to be tested of any loose materials and make it level. Extreme care should be taken not to disturb the soil in the test area, especially in granular material. For confined tests, the diameter of the excavated circular area shall be just sufficient to accommodate the selected bearing plate.

Carefully center a bearing plate of the selected diameter under the jack assembly. Set the remaining plates of smaller diameter concentric with, and on top of, the bearing plates. Set the bearing plate level in a thin bed of a mixture of sand and plaster of paris, of plaster of paris alone, or of fine sand, using the least quantity of materials required for uniform bearing. To prevent loss of moisture from the subgrade during the load test, cover the exposed subgrade to a distance of 2.0 m (6 ft) from the circumference of the bearing plate with a tarpaulin or waterproof paper.

4.2. Seat the 762-mm (30-in.) diameter bearing plate on the Ottawa sand or plaster of paris. Turning or working the plate back and forth will help to provide uniform seating of the plate. Center the 610-mm (24-in.) and 457-mm (18-in.) diameter plates on the 762-mm (30-in.) diameter plate, and center the hydraulic jack on the 457-mm (18-in.) diameter plate.

If cribbing is needed, crib between the top plate and the jack. If a steel proving ring is being used to measure load, it should be placed on top of the jack and the ball joint used between the proving ring and load reaction device. For safety reasons, shims should not be used between the ball joint and the reaction device. The load reaction device must be long enough so that its supports will be at least 2.4 m (8 ft) from the bearing plate. A steel beam between two loaded trucks provides a good load reaction device. Three dial gauges shall be used to measure deformation of the soil under load. Place these gauges so that the dial stems rest on the bottom 762-mm (30-in.) diameter plate not more than 6 mm ($^1/_4$ in.) from the outer edge, spaced 120 degrees apart. Fasten the gauges to a frame whose supports are at least 1.22 m (4 ft) from the edge of the 762-mm (30-in.) diameter plate.

4.3. Use one of the following initial procedures:

4.3.1. *Seating Procedure No. 1*—Seat the loading system and bearing plate by applying a load of 321 kg (707 lb), 6.9 kPa (1 psi) when the design thickness of the pavement will be less than 380 mm (15 in.) or a load of 642 kg (1414 lb), 13.8 kPa (2 psi) when the design thickness of the pavement is 380 mm (15 in.) or more. Allow the seating load to remain in place until practically complete deformation has taken place. Then take a reading on all three dial gauges, which will be used as the "zero" reading. The seating load is also considered to be the "zero" load. Cyclic loading under the seating load may be used to assure good seating of the apparatus and bearing plate.

4.3.2. *Seating Procedure No. 2*—After the equipment has been properly arranged, with all of the dead load (jacks, plates, etc.) acting, seat the bearing plate and assembly by the quick application and release of a load sufficient to produce a deflection of not less than 0.25 mm (0.01 in.) or more than 0.50 mm (0.02 in.) as indicated by the dials. When the dial needles come to rest following release of this load, reseat the plate by applying one half of the recorded load producing the 0.25- to 0.50-mm (0.01- to 0.02-in.) deflection. When the dial needles have then again come to rest, set each dial accurately at its zero mark.

4.4. Without releasing the seating load, Load Application Procedure No. 1 or 2 shall then be followed.

4.4.1. *Load Application Procedure No. 1*—Apply loads at a moderately rapid rate in uniform increments. The magnitude of each load increment shall be small enough to permit the recording of a sufficient number of load-deflection points to produce an accurate load-deflection curve (not less than six). After each increment of load has been applied, allow its action to continue until a rate of deflection of not more than 0.02 mm/min (0.001 in./min) has been maintained for 3 consecutive minutes. Record load and deflection readings for each load increment. Continue this procedure until the selected total deflection has been obtained, or until the load capacity of the apparatus has been reached, whichever occurs first. At this point, maintain the load until an increased deflection of not more than 0.02 mm/min (0.001 in./min) for 3 consecutive minutes occurs. Record the total deflection, after which release the load to that at which the dial gauges were set at zero, and maintain the zero-setting load until the rate of recovery does not exceed 0.02 mm (0.001 in.) for 3 consecutive minutes. Record the deflection at the zero-setting load.

Each individual set of readings shall be averaged, and this value is recorded as the average settlement reading.

4.4.2. Apply two load increments of 1605 kg (3535 lb), 34.5 kPa (5 psi) each with load increment being held until deformation averages less than 0.02 mm/min. (0.001 in./min) for 10 consecutive minutes. Read all three dial gauges at the end of each load increment. Following the completion of the 3210-kg (7070-lb), 69.0-kPa (10-psi) load increment, determine the average deflection by averaging the total movement between the "zero" and 69.0-kPa (10-psi) increment for each dial.

4.5. Compute a value of k'_u (uncorrected modulus of soil reaction) using the following formula:

$$k'_u = \frac{69.0\text{ kPa (10 psi)}}{\text{average deflection}} \qquad (1)$$

If the value of k'_u is less than 54.3 kPa/mm (200 psi/in.), the test is considered complete and the load may be released. Should the value of k'_u be 54.3 kPa/mm (200 psi/in.) or greater, apply load increments of 1605 kg (3535 lb) 34.5 kPa (5 psi) until a total load of 9630 kg (21210 lb) 207 kPa (30 psi) is reached, allowing each load increment to remain until the deformation averages less than 0.02 mm/min (0.001 in./min) for 10 consecutive minutes. Read all three dial gauges at the completion of each load increment.

4.6. Obtain an undisturbed sample of the foundation material for laboratory testing to determine the saturation correction to apply to the field test value. The undisturbed sample must be large enough to obtain two consolidometer specimens side by side (i.e., at the same elevation). Take the sample in a container suitable for sealing to preserve the moisture content until the laboratory correction tests can be performed. When the plate-bearing test is performed directly on cohesive subgrade material, obtain the undisturbed specimen from the foundation at the same elevation at which the test is performed, but alongside rather than under the plates. When the test is performed on a granular base coarse material which is underlaid by a cohesive material, and when the base coarse is less than 1.9 m (75 in.) in thickness, take the undisturbed sample from the cohesive material at the bottom of the base course.

4.7. From a thermometer suspended near the bearing plate, read and record the air temperature at 30-minute intervals.

5. RECORD THE TESTS

5.1. In addition to the continuous listing of all load, deflection, and temperature data, as prescribed in Section 3, a record shall also be made of all associated conditions and observations pertaining to the test, including the following:

5.1.1. Date;

5.1.2. Time of beginning and completion of test;

5.1.3. List of personnel;

5.1.4. Weather conditions;

5.1.5. Any irregularity in routine procedure;

5.1.6. Any unusual conditions observed at the test site; and

5.1.7. Any unusual observations made during the test.

6. CALCULATIONS AND PLOTTING OF LOAD DEFLECTION RELATIONSHIPS

6.1. When the k'_u value, as computed in Section 4.5, is less than 54.3 kPa/mm (200 psi/in.), load-deformation curves need not be prepared. However, when the k'_u value is 54.3 kPa/mm (200 psi/in.) or greater, it is necessary to plot the load-deformation curve and correct the curve for such things as poor seating of the plates, nonlinear load-deformation relations, or shear failure, the unit load (kPa (lb/in.^{2})) on the plate is plotted versus the average deflection for each load increment. The average deflection is the average of the three dial readings between the "zero" and the end of each load increment. When averaging the three dial gauge readings, the data should be carefully examined to ensure that a reasonable average is being computed. If the load-deformation relation does not plot a straight line passing through the origin, the curve is corrected, as shown in Figure 2. Generally, the load-deformation curve will approximate a straight line between the unit loads of 69.0 and 207 kPa (10 and 30 psi). The correction consists of drawing a straight line, parallel to the straight-line portion of the plotted curve, through the origin. When correcting the load-deformation curve, good engineering judgment will be required. If the curve is nonlinear through its length, the straight-line correction will be based on the average slope of the curve through at least three points in the region of the curve having the least curvature.

6.2. An uncorrected modulus of soil reaction k'_u is computed from the field test data using the formula:

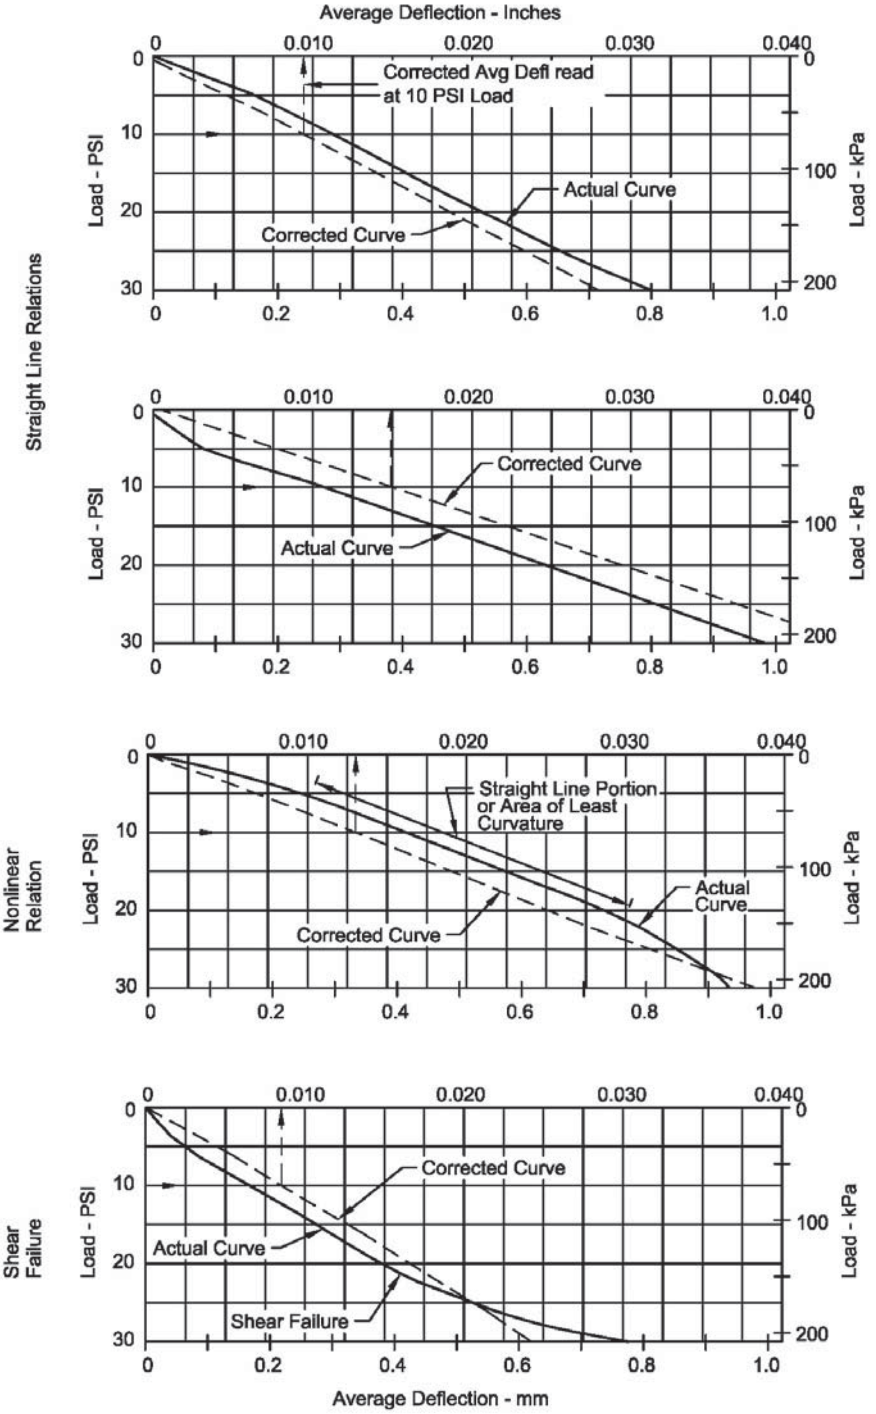
$$k'_u = \frac{69.0 \text{ kPa } (10 \text{ psi})}{\text{average deflection}} \tag{2}$$

When a load-deformation curve is unnecessary, as outlined in Section 6.1, the average deflection is the average of the total deflection recorded on each of the three gauges between the "zero" and the completion of the load increment. If a load deformation curve is required, the average deflection is read from the corrected curve as a load of 69.0 kPa (10 psi). The value of k'_u computed from the above formula must then be corrected for bending of the bearing plates and saturation of the soil as outlined in the following paragraphs:

6.3. There is a certain amount of bending in the bearing plates, even when a nest of plates is used. The bending results in a greater deflection at the center of the plate than at the rim where the deflections are measured. Since the modulus of soil reaction is actually a measurement of volume displacement under load, the lower deflection measured at the rim results in a k'_u value higher than actually exists. The amount of plate bending is related only to the strength of the soil being tested. Hence, for any one k'_u value, the correction to be made is always the same. This correction has been determined by test and is shown by the curve in Figure 3. The correction of k'_u is made by entering the plot in Figure 3 with the computed value of k'_u on the ordinate and projecting horizontally to the intersection of the plotted curve. The corrected value for the modulus of soil reaction (k'_u) is then determined by projecting vertically to the abscissa of the plot and reading the value.

6.4. The design of pavement is generally based upon the modulus of soil reaction when the soil is saturated. It is not feasible to saturate the soil in the field prior to the field test and seldom will the soil be in a saturated condition in its natural state. Therefore, the field test value must be corrected to reflect the value that will be obtained when the soil becomes saturated. Saturation correction is not normally required when evaluating pavements older than 3 years. Cohesionless soils are insensitive to saturation, and when the field test is performed on this type soil, the correction for saturation is not necessary. The most applicable method for correcting for saturation is through an adaption of the consolidation test. The correction test will be made on undisturbed specimens of the soil from the location of the field test. For the case where a field test is performed on the surface of a cohesionless base course material, but which is underlain by a cohesive soil, the saturation correction will be determined by tests on the underlying cohesive material.

The saturation correction factor is the ratio of the deformation of the consolidation specimen at the natural moisture content to the deformation in a saturated specimen under a 69.0-kPa (10-psi) loading. Two specimens of the undisturbed material are placed in a consolidometer. One specimen will be tested at the in situ moisture content, and the other specimen will be saturated after the seating load has been applied. Each specimen is then subjected to the same seating load (6.9 or 13.8 kPa (1 or 2 psi)) that was used for the field test. (See Section 4.3.1 or 4.3.2.) The seating load is allowed to remain on the in situ moisture-content specimen until all deformation occurs, at which time a "zero" reading is taken on the vertical deformation dial. Without releasing the seating load, an additional 69.0-kPa (10-psi) load is applied to the specimen and allowed to remain until all deformation has occurred. A final reading is then taken on the vertical deformation dial.



Note: Corrected Curve may lie above or below actual curve.

Figure 2—Correction of Load-Deformation Curve

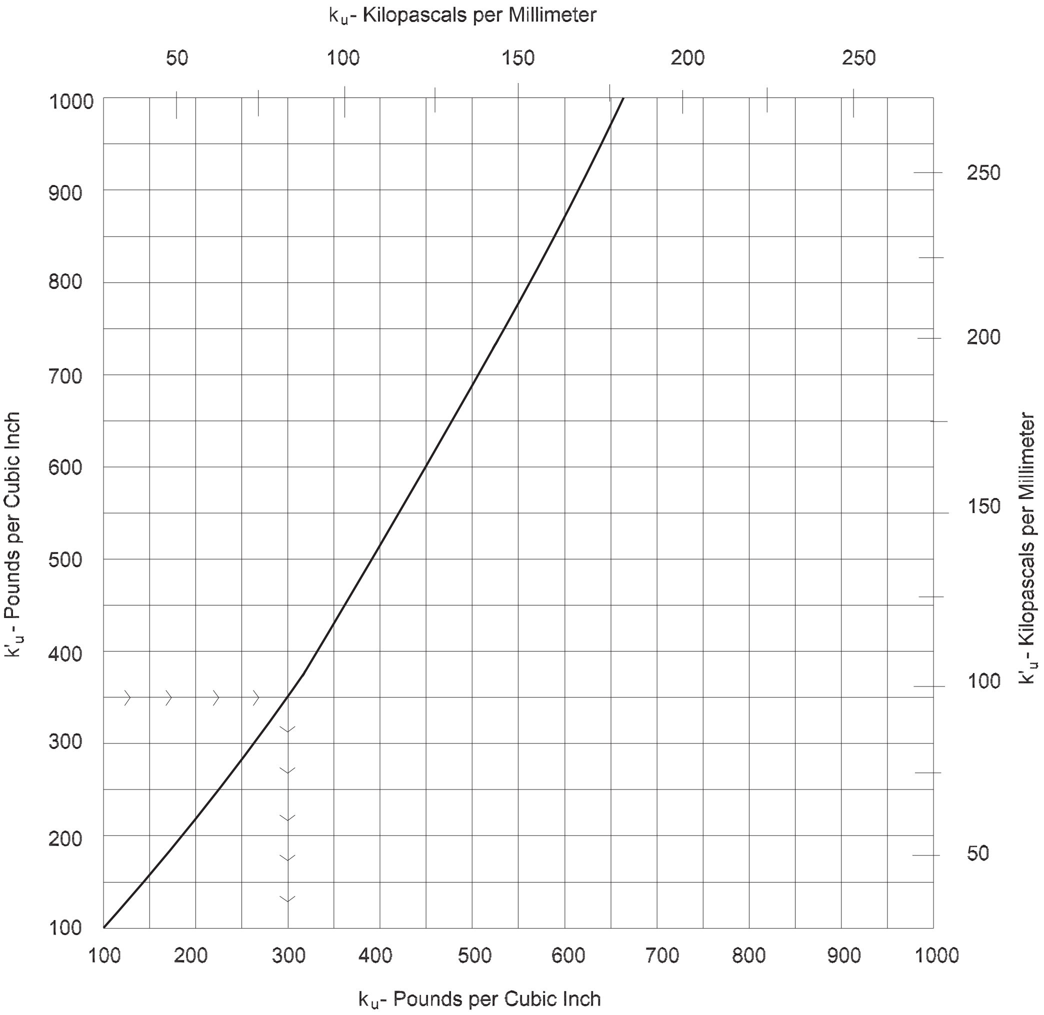


Figure 3—Correction of k'_u for Bending of the Plate

The other specimen is allowed to soak in the consolidometer under the seating load (6.9 or 13.8 kPa (1 or 2 psi)). After the specimen is saturated, a "zero" dial reading is obtained; then, without releasing the seating load, an additional 69.0-kPa (10-psi) load is applied. This load is allowed to remain on the specimen until all vertical deformation has occurred, after which a final reading on the dial is obtained. For soils of certain types, the specimen may swell under the seating load as it becomes saturated. Swelling of the material will result in extrusion of material above the top of the consolidometer ring, so that when the 69.0-kPa (10-psi) load is applied, the material may squeeze out over the ring rather than consolidate, which will lead to erroneous results. To prevent this, when dealing with a swelling-type soil or one that is suspected of being a swelling-type soil, the consolidometer ring will not be completely filled with soil. This can be accomplished by trimming the top of the specimen a sufficient amount, generally 1.6 mm ($^1/_{16}$ in.) to allow for the swelling. When the specimen for saturation is trimmed to allow for swelling, the specimen to be tested at the in situ moisture content will also be trimmed an equal amount so that the heights of the specimens will be equal at the beginning of the test.

The correction for saturation will be applied in proportion to the deformation of the two specimens under a unit load of 69.0 kPa (10 psi) as follows:

SI Units:

$$K = k_u \left[\frac{d}{d_s} + \frac{b}{1905} \left(1 - \frac{d}{d_s} \right) \right] \tag{3}$$

U.S. Customary Units:

$$K = k_u \left[\frac{d}{d_s} + \frac{b}{75} \left(1 - \frac{d}{d_s} \right) \right] \tag{4}$$

where:

K = corrected modulus of soil reaction, kPa (psi);

k_u = modulus of soil reaction uncorrected for saturation, kPa (psi);

d = deformation [mm (in.)] of a consolidometer specimen at in situ moisture content under a unit load of 69.0 kPa (10 psi);

d_s = deformation [mm (in.)] of saturated consolidometer specimen under a unit load of 69.0 kPa (10 psi); and

b = thickness of base course material, [mm (in.)].

Standard Method of Test for

Field Vane Shear Test in Cohesive Soil

AASHTO Designation: T 223-96 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Field Vane Shear Test in Cohesive Soil

AASHTO Designation: T 223-96 (2008)

1. SCOPE

1.1. This method covers the field vane test in soft, saturated, cohesive soils. Knowledge of the nature of the soil in which each vane test is to be made is necessary for assessment of the applicability and interpretation of the test.

1.2. The values stated in SI units are to be regarded as the standard.

2. SUMMARY OF METHOD

2.1. The vane shear test basically consists of placing a four-bladed vane in the undisturbed soil and rotating it from the surface to determine the torsional force required to cause a cylindrical surface to be sheared by the vane; this force is then converted to a unit shearing resistance of the cylindrical surface. It is of basic importance that the friction of the vane rod and instrument be accounted for; otherwise, the friction would be improperly recorded as soil strength. Friction measurements under no-load conditions (such as the use of a blank stem in place of the vanes, or a vane that allows some free rotation of the rod prior to loading) are satisfactory only provided that the torque is applied by a balanced moment that does not result in a side thrust. As torsional forces become greater during a test, a side thrust in the instrument will result in an increase in friction that is not accounted for by initial no-load readings. Instruments involving side thrust are not recommended. The vane rod may be of sufficient rigidity that it does not twist under full-load conditions; otherwise, a correction must be made for plotting torque-rotation curves.

3. APPARATUS

3.1. The vane shall consist of a four-bladed vane, as illustrated in Figure 1. Vane dimensions shall be as specified in Table 1. Sizes other than those specified in Table 1 shall be used only with the permission of the engineer in charge of the boring program. The ends of the vane may be tapered. (See Figure 1.) The penetrating edge of the vane blade shall be sharpened having an included angle of 90 degrees.

3.2. The vane shall be connected to the surface by means of steel torque rods. These rods shall have sufficient diameter such that their elastic limit is not exceeded when the vane is stressed to its capacity (Note 1). They shall be so coupled that the shoulders of the male and female ends shall meet to prevent any possibility of the coupling tightening when the torque is applied during the test. If a vane housing is used, the torque rods shall be equipped with well-lubricated bearings where they pass through the housing. These bearings shall be provided with seals to prevent soil from entering them.

The torque rods shall be guided so as to prevent friction from developing between the torque rods and the walls of casing or boring.

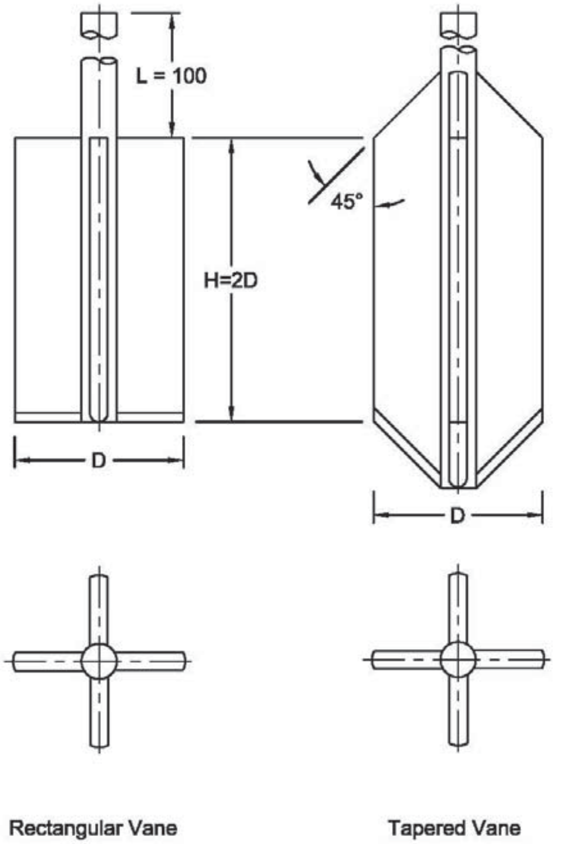

Figure 1—Geometry of Field Vane

Table 1—Recommended Dimensions of Field Vanes[a]

Minimum Casting Requirement		Diameter		Height		Thickness of Blade		Diameter of Vane Rod	
		mm	in.	mm	in.	mm	in.	mm	in.
	A	38.1	1.5	76.2	3	1.59	0.0625	12.7	0.5
Acker	B	50.8	2	102	4	1.59	0.0625	12.7	0.5
Type	N	63.5	2.5	127	5	3.18	0.125	12.7	0.5
	H	92.1	3.625	184	7.25	3.18	0.125	12.7	0.5
SGI[b]	H	55	2.17	110	4.33	2	0.078	11	0.43
Type	H	65	2.56	130	5.12	2	0.078	11	0.43
	B	50	1.97	110	4.33	2[d]	0.078	20	0.79
Nilcon[c]	N	65	2.56	130	5.12	2	0.078	20	0.79
Type	H	80	3.15	172	6.77	2	0.078	20	0.79

[a] Selection of the vane size is directly related to the consistency of the soil being tested; that is, the softer the soil, the larger the vane diameter.

[b] This is a totally self-contained, portable vane shear unit, which is capable of providing its own cased hole. Where overburden is too stiff, casing is required for the 77-OD mm vane housing.

[c] This is a totally self-contained, portable shear unit, which is capable of being pushed directly into the soil. The vane is followed by a slip coupling during penetration, which provides for rod friction calibration before each test. Where overburden is too stiff, casing is required.

[d] This is the average thickness. Vane blades are tapered 2.5 mm (0.098 in.) at the shaft to 1.5 mm (0.059 in.) at the edge.

3.3. Torque shall be applied to the torque rods, thence to the vane. The accuracy of the torque reading should be such that it will produce a variation not to exceed ±1.2 kPa (25 lb/ft^2) shear strength.

3.4. It is preferable to apply torque to the vane with a geared drive. In the absence of a geared drive, it is acceptable to apply the torque directly by hand with a torque wrench or equivalent. The duration of the test should be controlled by the requirements of Section 4.3.

Note 1—If torque versus rotation curves are to be determined, it is essential that the torque rods be calibrated (prior to use in the field). The amount of rod twist (if any) must be established in degrees per meter (foot) per unit torque. This correction becomes progressively more important as the depth of the test increases and the calibration must be made at least to the maximum depth of testing anticipated.

4. PROCEDURE

4.1. In the case where a vane housing is used, advance the housing to a depth that is at least five vane housing diameters less than the desired depth of the vane tip. Where no vane housing is used, stop the hole in which the vane is lowered at a depth such that the vane tip may penetrate undisturbed soil for a depth of at least five times the diameter of the hole.

4.2. Advance the vane from the bottom of the hole or the vane housing in a single thrust to the depth at which the test is to be conducted. Take precautions to make sure no torque is applied to the torque rods during the thrust.

4.3. With the vane in position, apply the torque to the vane at a rate that should not exceed 0.1 degrees per second. This generally requires a time to failure of from 2 to 5 minutes, except in very soft clays where the time to failure may be as much as 10 to 15 minutes. In stiffer materials, which reach failure at small deformations, it may be desirable to reduce the rate of angular displacement so that a reasonable determination of the stress-strain properties can be obtained. During the rotation of the vane, hold it at a fixed elevation. Record the maximum torque. With apparatus with geared drives it is desirable to record intermediate values of torque at intervals of 15 seconds or at lesser frequency if conditions require.

4.4. Following the determination of the maximum torque, rotate the vane rapidly through a minimum of 10 revolutions; the determination of the remolded strength should be started immediately after completion of rapid rotation and in all cases within 60 seconds after the remolding process.

4.5. In the case where soil is in contact with the torque rods, determine the friction between the soil and the rod by means of torque tests conducted on similar rods at similar depths with no vane attached. Conduct the rod friction test at least once on each site; this shall consist of a series of torque tests at varying depths.

4.6. In apparatuses in which the torque rod is completely isolated from the soil, conduct a friction test with a blank rod (Note 2) at least once on each site to determine the magnitude of the friction of the bearings. In a properly functioning vane apparatus, this friction should be negligible.

4.7. Conduct undisturbed and remolded vane tests in cohesive soils only. Do not conduct the vane test in any soil that will permit drainage or dilates during the test period, such as sands or silts or in soils where stones or shells are encountered by the vane in such a manner as to influence the results.

Note 2—In some cases, it is not necessary to remove the vane for the friction test. As long as the vane is not in contact with the soil, that is, where it is retracted into a casing, the friction measurements are not affected.

5. CALCULATION

5.1. Calculate the shear strength of the soil in the following manner:

The turning moment required to shear the soil is as follows:

$$T = s \times K \tag{1}$$

where:

T = torque, kN·m (or lbf·ft);

s = shear strength of the clay kPa (or lbf/ft^2);

K = constant depending on dimensions and shape of the vane, m^3 (or ft^3).

5.2. Assuming the distribution of the shear strength is uniform across the ends of a cylinder and around the perimeter, calculate the value of *K* as follows:

SI Units:

$$K = \frac{\pi}{10^9} \times \frac{D^2 H}{2} \times \left[1 + \frac{D}{3H}\right] \tag{2}$$

U.S. Customary Units:

$$K = \frac{\pi}{1728} \times \frac{D^2 H}{2} \times \left[1 + \frac{D}{3H}\right] \tag{3}$$

where:

D = measured diameter of vane, mm (in.); and

H = measured height of vane, mm (in.).

It is important that these dimensions are checked periodically to ensure the vane is not distorted or worn.

5.3. If the ratio of length to breadth of the vane is 2:1, the value of *K* may be simplified in terms of the diameter so that it becomes the following:

SI Units:

$$K = \frac{3.66}{10^9} \times D^3 \tag{4}$$

U.S. Customary Units:

$$K = \frac{2.12}{10^3} \times D^3 \tag{5}$$

5.4. Since the value of *s* is required, it is more useful to write the equation as follows:

$$s = T \times K \tag{6}$$

where:

T = the torque, is measured so that *s* can be calculated.

5.5. For the tapered vane of Figure 1, the following modified equation may be used for the vane constant:

SI Units:

$$K = \frac{1}{10^9}\left[\pi D^3 + 0.37\left(2D^3 - d^3\right)\right] \tag{7}$$

U.S. Customary Units:

$$K = \frac{1}{1728}\left[\pi D^3 + 0.37\left(2D^3 - d^3\right)\right] \tag{8}$$

where:

d = rod diameter, mm (in.).

6. REPORT

6.1. For each vane test, record the following observations:

6.1.1. Date of test;

6.1.2. Boring number;

6.1.3. Size and shape of the vane (tapered or rectangular);

6.1.4. Depth of the vane tip;

6.1.5. Depth of the vane tip below the housing or bottom of the hole;

6.1.6. Maximum torque reading, and intermediate readings if required for the undisturbed test;

6.1.7. Time to failure of the test;

6.1.8. Rate of remolding;

6.1.9. Maximum torque reading for the remolded test; and

6.1.10. Notes on any deviations from standard test procedure.

6.2. In addition, record the following observations for the boring:

6.2.1. Boring number;

6.2.2. Location;

6.2.3. Location of the soil conditions;

6.2.4. Reference elevation;

6.2.5. Method of making the hole;

6.2.6. Description of the vane, that is, housed or not;

6.2.7. Description of the method of applying and measuring the torque;

6.2.8. Notes on the driving resistance;

6.2.9. Name of the drilling foreman; and

6.2.10. Name of the supervising engineer.

Standard Method of Test for

Correction for Coarse Particles in the Soil Compaction Test

AASHTO Designation: T 224-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Correction for Coarse Particles in the Soil Compaction Test

AASHTO Designation: T 224-10

1. SCOPE

1.1. This method describes a procedure for adjusting the densities of soil and soil aggregate mixtures to compensate for differing percentages of coarse particles retained on either the 4.75-mm (No. 4) or 19.0-mm ($^3/_4$-in.) sieve. This is necessary to adjust either the field wet density to a dry density of the material passing these sieves or the reverse, by adjusting the lab density to the field density when doing compaction control testing. Comparisons are made by comparing the field densities with the maximum dry density as determined by T 99 or T 180.

1.2. Two methods are available for correction: either lab to field or field to lab density. The method specified in Section 4.1 adjusts the compacted lab density to the field density. The method specified in Section 4.2 adjusts the field wet density to dry density of the fine fraction and compares its results with the compacted lab density.

1.3. This test method applies to soil mixtures that have 40 percent or less retained on the 4.75-mm (No. 4) sieve, when Method A or B of T 99 or T 180 is used, or mixtures that have 30 percent or less retained on the 19.0-mm ($^3/_4$-in.) sieve, when Method C or D of T 99 or T 180 is used. The material retained on these sieves shall be defined as oversize particles (coarse particles).

1.4. This method applies to soils with any percentage of oversize particles as specified in Section 1.3. However, the correction may not be of practical significance for soils with only a small percentage of oversize particles. The person or agency specifying this method shall specify a minimum percentage of oversize particles below which the method need not be applied. If a minimum percentage is not specified, this method shall be applied to samples with more than 5 percent by weight of oversize particles.

1.5. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off to the nearest 10 kg/m^3 (1 pcf), according to ASTM E 29.

1.6. The values stated in SI units are to be regarded as the standard.

3. OUTLINE OF METHOD

3.1. When Method A or Method B of T 99 or T 180 is employed, the total field wet density is compared with the dry density of the soil particles passing the 4.75-mm (No. 4) sieve.

3.2. When Method C or Method D of T 99 or T 180 is employed, the total field wet density is compared with the dry density of the soil particles passing the 19.0-mm ($^3/_4$-in.) sieve.

3.3. Significant figures are as follows:

3.3.1. Adjusted wet density of the fine material passing the 4.75-mm (No. 4) sieve, Methods A and B; or 19.0-mm ($^3/_4$-in.) sieve, Methods C and D; (D_f) 1 kg/m^3 (0.1 pcf).

3.3.2. Bulk specific gravity of the coarse material retained on the 4.75-mm (No. 4) sieve, Methods A and B; or 19.0-mm ($^3/_4$-in.) sieve, Methods C and D; (G_m) 0.01.

3.3.3. Percent by mass, of coarse and fine particles, of material retained and passing the 4.75-mm (No. 4) sieve, Methods A and B; or 19.0-mm ($^3/_4$-in.) sieve, Methods C and D; (P_c) and (P_f) 0.1 percent.

3.3.4. In-place (field) wet density of the total sample (D) 1 kg/m^3 (0.1 pcf).

4. ADJUSTMENT EQUATION

4.1. *Compacted Laboratory-Dry Density Corrected to Field-Dry Density*

4.1.1. This section corrects the laboratory density obtained by either T 99 or T 180 for the moisture content and density of the material retained on the 4.75-mm (No. 4) sieve, Methods A and B; or the material retained on the 19.0-mm ($^3/_4$-in.) sieve, Methods C and D. The maximum lab-dry density, adjusted for oversized particles and total moisture content, are compared with the field-dry density and field moisture content. This method is limited to field samples containing 40 percent or less for material retained on the 4.75-mm (No. 4) sieve, Methods A and B; or 30 percent or less of material retained on the 19.0-mm ($^3/_4$-in.) sieve, Methods C and D.

4.1.2. Determine the moisture content of the fine particles and oversize particles of the material used during compaction. The moisture contents can be determined by T 265, T 217, or T 255. The moisture content of the oversize material retained on the sieve can be assumed to be 2 percent for most construction applications. If the moisture content of the oversized material is generally known, substitute that moisture content in the calculations. It is recommended that if drying equipment is available, determine the actual moisture contents. Calculate the moisture contents according to the calculations specified in T 265.

4.1.3. Calculate the dry mass of the coarse and fine particles as follows:

$$M_D = M_M/(1+MC) \tag{1}$$

where:

M_D = mass of dry material (fine or oversize particles);

M_M = mass of moist material (fine or oversize particles); and

MC = moisture content of respective fine or oversize particles, expressed as a decimal.

4.1.4. Calculate the percentage of the fine particles and oversized particles by dry weight of the total sample as follows:

$$P_f = 100\ M_{DF}/(M_{DF} + M_{DC}) \tag{2}$$

and

$$P_C = 100\ M_{DC}/(M_{DF} + M_{DC}) \tag{3}$$

where:

P_f = percent of fine particles of sieve used, by weight;

M_{DF} = mass of dry particles;

M_{DC} = mass of oversize particles; and

P_C = percent of oversize particles of sieve used, by weight.

4.1.5. Calculate the corrected moisture content and corrected dry density of the total sample (combined fine and oversized particles) as follows:

$$MC_T = (MC_f P_f + MC_C P_C)/100 \tag{4}$$

where:

MC_T = corrected moisture content of the combined fine and oversize particles, expressed as a decimal;

MC_f = moisture content of the fine particles, expressed as a decimal;

P_f = percent of fine particles of sieve used, by weight;

MC_C = moisture content of the oversize particles, expressed as decimal; and

P_C = percent of oversize particles of sieve used, by weight.

and

$$D_d = 100\ D_f k/(D_f P_C + kP_f) \tag{5}$$

where:

D_d = corrected total dry density (combined fine and oversize particles), kg/m^3 (pcf);

D_f = dry density of the fine particles, kg/m^3 (pcf);

k = 1000 × Bulk Specific Gravity (G_m) (oven-dry basis) of coarse particles, kg/m^3; or 62.4 × Bulk Specific Gravity (G_m) (oven-dry basis) of coarse particles, pcf;

P_C = percent of oversize particles of sieve used by weight; and

P_f = percent of fine particles of sieve used, by weight.

Note 1—If the specific gravity has been determined, this value may be used in the calculations. Determine the Bulk Specific Gravity according to T 85. For most construction activities, the specific gravity can be assumed to be 2.60.

4.2. *Field-Wet Density Corrected to Compacted-Laboratory Density*:

4.2.1. The in-place total (field) wet density is corrected to a dry density of the sample passing the 4.75-mm (No. 4) sieve or the sample passing the 19.0-mm ($^3/_4$-in.) sieve. This adjusted dry density is compared with the maximum dry density obtained by methods T 99 or T 180.

4.2.2. Determine the moisture content of the total sample and for the material retained on the sieve used during compaction. Moisture content can be determined by T 265, T 217, or T 255. If using the nuclear moisture/density gauge, read the moisture content directly from the gauge for the total moisture content. The moisture content of the oversize material retained on the sieve can be assumed to be 2 percent for most construction applications. If the moisture content of the oversize material is generally known, substitute that moisture content in the calculations. It is recommended that if drying equipment is available, determine the actual moisture contents. Calculate the moisture contents according to the calculations specified in T 265.

4.2.3. Calculate the moisture content of the fine particles of the field sample as follows:

$$MC_f = (100\ MC_T - MC_C P_C)/P_f \qquad (6)$$

where:

MC_f = moisture content of the fine particles, expressed as a decimal;
MC_T = moisture content of total field sample, expressed as a decimal;
MC_C = moisture content of the oversize particles, expressed as a decimal;
P_c = percent of oversize particles of sieve used, by weight; and
P_f = percent of fine particles of sieve used, by weight.

4.2.4. Calculate the dry field density of the sample as follows:

$$D_d = D/(1 + MC_T) \qquad (7)$$

where:

D_d = dry field density of total sample, kg/m^3 (pcf);
D = total field wet density, kg/m^3 (pcf); and
MC_T = moisture content of total field sample, expressed as a decimal.

4.2.5. Calculate the dry field density of the fine particles of the field sample as follows:

$$D_f = D_d P_f/(100 - ((D_d P_C)/(k))) \qquad (8)$$

where:

D_f = adjusted dry density of the fine particles, kg/m^3 (pcf);
D_d = total field dry density, kg/m^3 (pcf);
P_f = percent of fine particles of sieve used, by weight;
P_C = percent of oversize particles of sieve used, by weight;
k = 1000 × Bulk Specific Gravity (G_m) (oven-dry basis) of coarse particles, kg/m^3; or 62.4 × Bulk Specific Gravity (G_m) (oven-dry basis) of coarse particles, pcf (Note 1).

5. PRECISION

5.1. Since this correction for coarse particles involves no testing but instead utilizes the results of other tests and mathematically combines the results, determination of the precision and accuracy is not applicable.

APPENDIX

X1. NOTES

X1.1. These methods, described for coarse particle correction, are applicable to one type of soil and soil aggregate material only. If the characteristic of the material changes, then a moisture density relationship (T 99 or T 180) test is performed to determine a new maximum density.

X1.2. T 272 describes the methods for determining different maximum densities of soil and soil-aggregate materials, which reveal certain similarities and trends characteristic of the material type and source.

X1.2.1. *Utilization of a Family of Curves*—When using the One Point Method (T 272), the percentage of oversized particles, when performing the density of soil and soil aggregate in-place, must be determined to adjust the T 99 or T 180 maximum density to compensate for this percentage.

Standard Method of Test for

Diamond Core Drilling for Site Investigation

AASHTO Designation: T 225-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Diamond Core Drilling for Site Investigation

AASHTO Designation: T 225-06

1. SCOPE

1.1. This method covers a procedure for diamond core drilling designing for securing intact samples of rock and some soils which are too hard to sample by soil sampling methods. This method is primarily for obtaining data for foundation and slope design and similar civil engineering purposes rather than for mineral development and mining.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 206, Penetration Test and Split-Barrel Sampling of Soils
- T 207, Thin-Walled Tube Sampling of Soils

2.2. *ASTM Standard*:

- D 5079, Standard Practices for Preserving and Transporting Rock Core Samples

3. EQUIPMENT

3.1. *A Rotary Drilling Machine*, capable of providing a rotary motion and hydraulically, or mechanically, actuated feed or thrust.

3.2. *A Water or Drilling Mud Pump*, or air compressor capable of delivering sufficient drilling fluid volume and pressure for the size of the hole to be drilled.

3.3. *Core Barrels* as required.

3.3.1. *A Single Tube* core barrel consists of a hollow tube with a threaded head at the upper end to fit the drill rod. The lower end of the barrel is fitted with a blank or set reaming shell, a core lifter, and a core bit.

3.3.2. *A Double Tube* core barrel (swivel-type) has a swiveling inner barrel that is contained in the core barrel suspended on a bearing hanger. Drilling fluid is routed between the inner and outer barrels. This method improves core recovery. More sophisticated double tubes are available having an inner tube which extends into the core bit, and the core lifter mounted inside the inner tube to protect cores of a soft or friable formation.

3.3.3. *Single Tube Type, WG Design*, consisting of a hollow steel tube, with a head at one end threaded for drill rod, and a threaded connection for a reaming shell and core bit at the other end. A core lifter, or retainer located within the core bit, is normal but may be omitted at the discretion of the geologist or engineer.

3.3.4. *Double Tube, Swivel-Type, WG Design*—An assembly of two concentric steel tubes joined and supported at the upper end by means of a ball or roller-bearing swivel arranged to permit rotation of the outer tube without causing rotation of the inner tube. The upper end of the outer tube, or removable head, is threaded for drill rod. A threaded connection is provided on the lower end of the outer tube for a reaming shell and core bit. A core lifter located within the core bit is normal but may be omitted at the discretion of the geologist or engineer.

3.3.5. *Double-Tube, Swivel-Type, WT Design*—is essentially the same as the double tube, swivel-type, WG design, except that the WT design has thinner tube walls, a reduced annular area between the tubes, and takes a larger core from the same diameter bore hole. The core lifter is located within the core bit.

3.3.6. *Double Tube, Swivel Type, WM Design*—is similar to the double tube, swivel-type, WG design, except that the inner tube is threaded at its lower end to receive a core lifter case that effectively extends the inner tube well into the core bit, thus minimizing exposure of the core to the drilling fluid. A core lifter is contained within the core lifter case on the inner tube.

3.3.7. *Double Tube Swivel-Type, Large-Diameter Design*—is similar to the double tube, swivel-type, WM design, with the addition of a ball valve to control fluid flow in all three available sizes and the addition of a sludge barrel to catch heavy cuttings on the two larger sizes. The large-diameter design double tube, swivel-type, core barrels are available in three-core-per hole sizes as follows: $2^3/_4$ in. (69.85 mm) by $3^7/_8$ in. (98.43 mm), 4 in. (101.6 mm) by $5^1/_2$ in. (139.7 mm), and 6 in. (152.4 mm) by $7^3/_4$ in. (196.85 mm). Their use is generally reserved for very detailed investigative work or where other methods do not yield adequate recovery.

3.3.8. *Double Tube, Swivel-Type, Retrievable Inner-Tube Method*—in which the core-laden inner-tube assembly is retrieved to the surface and an empty inner-tube assembly returned to the face of the borehole through the matching, large-bore drill rods without need for withdrawal and replacement of the drill rods in the borehole. The inner-tube assembly consists of an inner tube with removable core lifter case and core lifter at one end and a removable inner-tube head, swivel bearing, suspension adjustment, and latching device with release mechanism on the opposite end. The inner-tube latching device locks into a complementary recess in the wall of the outer tube such that the outer tube may be rotated without causing rotation of the inner tube and such that the latch may be actuated and the inner-tube assembly transported by appropriate surface control. The outer tube is threaded for the matching, large-bore drill rod and internally configured to receive the inner-tube latching device at one end and threaded for a reaming shell and bit, or bit only, at the other end.

3.3.9. *Longitudinally Split Inner Tubes*—As opposed to conventional cylindrical inner tubes, these allow inspection of, and access to, the core by simply removing one of the two halves. They are not standardized but are available for most core barrels, including many of the retrievable inner-tube types.

3.3.10. The size and design nomenclature shall be in accordance with the standards adopted by the Diamond Core Drill Manufacturers Association.

3.4. *Core Bits*—The core bits shall be set with diamonds, tungsten carbide, or similar hard materials appropriate to the hardness of the materials being drilled and shall be furnished in X- or M-design or equivalent as required. The sizes of the core barrels and bits shall be as given in Table 1.

Table 1—Sizes of Core Barrels[a]

Size	Hole, Diameter in.	Hole, Diameter mm	Core, Diameter in.	Core, Diameter mm
EWX, EWM	1.5	38.1	0.812	20.6
AWX, AWM	1.957	49.2	1.375	30.2
BWX, BWM	2.375	60.3	1.625	41.3
NWX, NWM	3	76.2	2.125	54.0
$2^{3}/_{4}$ by $3^{7}/_{8}$ in. (69.9 by 98.4 mm)	3.875	98.4	2.687	68.3
4 by $5^{1}/_{2}$ in. (102 by 140 mm)	5.5	140	3.937	100
6 by $7^{3}/_{4}$ in. (152 by 197 mm)	7.75	197	5.937	151

[a] As standardized by the Diamond Core Drill Manufacturers Assn., Bulletin No. 2. Other sizes may be specified, but should be so noted.

3.5. *Drive Pipe or Casing*—Standard weight or extra heavy pipe, as required by the nature of overburden or the drilling method, shall be furnished where necessary for driving through soils to bedrock. The casing or pipe shall have an inside diameter of sufficient size to accommodate the largest size core barrel to be employed. The inside of the casing or pipe shall be free of burrs and obstructions.

3.6. *Auxiliary Casing*—When it is necessary to case through formations already penetrated by the drill or when no drive casing has been employed, casing shall be provided with an outside diameter that will fit inside the hole and an inside diameter that will permit the use of the next smaller bit and core barrels. Standard sizes of casing are given in Table 2.

Table 2—Standard Sizes of Casing

Size	Outside Diameter in.	Outside Diameter mm	Inside Diameter in.	Inside Diameter mm	Will Fit Hole Drilled by:
EX	1.8125	46	1.5	38.1	AWX, AWM
AX	2.25	57.2	1.906	48.4	BWX, BWM
BX	2.875	73.0	2.187	60.3	NWX, NWM
NX	3.5	88.9	3.0	76.2	$2^{3}/_{4}$ by $3^{7}/_{8}$ in. (69.9 by 98.4 mm)

3.7. *Drill Rods*—The drill rods shall have an inside diameter that will permit the flow of drilling fluid through the rods in a quantity sufficient to provide an upward velocity of the fluid between the rod and the hole wall that will remove the cuttings effectively.

3.8. *Auxiliary Equipment*—Auxiliary equipment shall be furnished as required by the work including roller bits, fishtail bits, wrenches, equipment for mixing the drilling mud, hand tools, safety equipment, etc.

3.9. *Core Boxes*—Core boxes of wood or other durable material shall be provided for protection, transport, and storage of the cores. The boxes shall be provided with longitudinal spacers that will separate the core into compartments. Small blocks that fit snugly between the spacers shall be provided to secure core in place and/or fill space if the material recovered is insufficient to completely fill the box. The top of the core length, which corresponds to the shallowest depth, should be placed at one corner of the box and the core placed progressing downward in a continuous manner to the deepest depth, through the compartments toward the opposite corner. The top and bottom of the core length and each run shall be clearly indicated on the longitudinal spacers or blocks with waterproof marker. The top and bottom of the core length shall also be clearly indicated on the box cover, at the corresponding corners along with the core depths. Additional guidance regarding labeling and use of core boxes can be found in ASTM D 5079.

4. PROCEDURE

4.1. When formations are encountered that are too hard to be sampled by soil sampling methods, the core drilling procedure shall be used. A penetration of 1 in. (25 mm) or less for 50 blows (Notes 1 and 2) according to T 206 shall be considered as indicating that soil sampling methods are not applicable.

Note 1—When the subsurface investigation requires a sample for testing and identification for material that has a penetration-resistance between $N = 100$ specified in T 206 and 50 blows per inch, coring may be required. Materials such as very stiff clay or weathered shale bedrock can be sampled using core barrels such as the Denison-type Double Tube Core Barrel. The sampling can be enhanced by the use of air for the drilling medium and the use of bits with steel teeth hardfaced.

Note 2—The limit of 50 blows per in. (25.4 mm) may be increased if the core recoveries prove to be small and samples can be secured by the soil sampling method.

4.2. Firmly seat the casing on bedrock or hard material to prevent loose materials from entering the hole and to prevent the loss of drilling fluid. Level the surface of the rock or hard material when necessary by the use of a fishtail or other bits. If an open drill hole can be maintained without casing, the casing may be omitted. Bentonite mud is often effective in maintaining an open hole without the use of casing.

4.3. Begin the core drilling using the NWX or NWM double tube swivel-core barrel. The first core run will usually be 5 ft (1.52 m) because of nonuniform conditions at the soil rock contact (Note 3). The NWM barrel should be inspected prior to lowering into the hole to insure that the swivel is in good working order and rotating freely. The clearance between the inner barrel, when incorporated in the barrel, and the bit should be checked and adjusted if necessary to insure that the space between the bit and the inner barrel is sufficient so as not to restrict the flow of drilling fluid. Either type barrel should be inspected for dents or bends that impair rock recovery. The barrel should also be checked for material left in the barrel from previous drilling to insure the barrel is clean and unobstructed. The core retainer should be inspected, and if worn excessively or damaged, it should be replaced. The choice of bit setting shall be consistent with the type of material to be drilled. (Use extreme caution not to drop foreign material into the hole. Should an object be dropped into the hole and not be recoverable, abandon the hole and start a new one.) Inspect all drill rods to be used for straightness. If any rods display bends when rolled over a flat surface, they should not be used.

Note 3—In soft materials, a larger starting size may be specified; where local experience indicates satisfactory core recovery or where hard, sound materials are anticipated, a smaller size or the single-tube type may be specified in place of the NWX or NWM tube, and longer runs may be drilled.

4.4. Lower the barrel into the hole, using care to set the barrel on the formation to be drilled gently to prevent damage to the bit or buckling of the barrel. Measurement of barrel and rods to be used is essential; measurement shall be to the nearest 0.1 ft (30.5 mm). Log the depth when the barrel makes contact with the bottom of the hole. If the depth is more than 0.1 ft (30.5 mm) less than the depth logged from the previous run, there is probably loose material or core in the hole. Connect the drill chuck to the string of tools and connect the drilling fluid supply line. Prior to rotating, lift the string of tools slightly and start the circulation of the drilling fluid. Allow the fluid to circulate until a full-flow condition is reached. Lower the tools slowly to the bottom and seat the bit by slowly starting the rotation and slowly increasing the vertical pressure, maintaining full flow of the drilling fluid. When the bit is seated, adjust the vertical pressure and the rotation to achieve proper penetration in accordance with the formation being drilled (Note 4). Log the depth where the coring began to the nearest 0.1 ft (30.5 mm). If the flow of the drilling fluid is blocked during drilling, raise the bit slightly to allow the fluid flow to return. If the flow does not return, remove the drilling tools and correct the problem as necessary to maintain adequate flow of the drilling fluid. A judgment may be required when different types of material are encountered in a given run and recovery is less than 100 percent of the actual thickness of a given formation. To aid in making this judgment, the rate of penetration and the drilling fluid color and texture shall be monitored as drilling proceeds. The depths where changes are noted in the penetration rate and/or the color and/or texture of the cuttings in the return fluid are to be recorded for reference when this judgment is required. It may be desirable to retain samples of the cuttings contained in the return fluid at changes of color or texture or onset intervals.

Note 4—The life expectancy of the bit and the rate of penetration are dependent upon proper force on the bit and the peripheral velocity of the bit. The peripheral velocity should be as high as possible without causing undue strain on the drill rig or excessive vibration of the drilling tools. The force on the bit should be adjusted to match the information and the design of the bit. (For a given bit design, a softer formation would require less force than a harder formation.) It may be necessary to anchor the drill rig to obtain sufficient force on the bit.

4.5. After drilling a depth equivalent to the length of the barrel (not to exceed 10 ft (or 3.05 m) and minus any loose material noted during the seating of the barrel), remove the core barrel from the hole, and remove the core from the barrel. Place the core in the core box in such a manner that the top of the rock stratum will be located at one corner of the box as described in Section 3.9. When the run is greater than the length of the first compartment, the next compartment to the right is measured and temporarily marked at a point that will be equivalent to the difference between the length of the compartment and the length of the run measured from upper left to lower left. The first segment of rock removed from the core barrel (bottom of core run) shall be placed in the box so that the bottom of the core is either at the lower left end of the left compartment or at the temporary mark in the next compartment to the right. Each additional piece removed from the barrel shall be placed in the box one after another, orienting each piece of core with the direction of the box so that the upper stratum is to the upper and/or left of the box in respect to lower stratum. Proceed to place the core in the box from the lower end to the upper end as the core is removed from the barrel in such a manner that the top of the stratum falls in the upper left end of the left compartment as described in Section 2.9. When all of the core has apparently been removed from the barrel, check the barrel by inserting a rule into the core barrel and check the length to insure that all of the material has been removed. After all the material has been removed from the barrel, adjust the core in the box so that the pieces are consolidated together to represent as nearly as practical their in situ length, taking care to fit the broken pieces together in such a manner that will not cause a false measure of the recovered core. Measure the recovered core to the nearest 0.1 ft (30.5 mm) and record the recovery. After performing the measurement for core recovery, mark the depths of the top and bottom of the core and each noticeable gap in the formation by a spacer block clearly labeled. Wrap delicate cores or those which change materially upon drying in plastic film or seal in wax or both, when such treatment is considered necessary by the engineer. Subsequent core runs from the same project and hole shall continue this procedure with the top of the next run beginning at the bottom of the last proceeding run. Measure the length of the run from the end of the last run from upper to lower in the compartment, utilizing the next compartment to the right when the compartment will not accommodate the entire run, and mark the bottom of the run with a temporary marker. Place the first segment of rock removed from the core barrel (bottom of core run) at the newly established temporary mark. Place the core in the box as described previously.

4.6. When soft materials are encountered from a core run which produce less than 50 percent recovery changes in the type of barrel, a change to drilling procedure or soil sampling should be considered. If soil samples are desired, secure such samples in accordance with the procedures described in T 206 or T 207. Resume diamond core drilling when refusal materials are again encountered.

4.7. Since rock structure and the occurrence of seams, fissures, cavities, and broken areas are among the most important items to be detected and described, take special care to observe and record these features. If broken rock or cavities prevent the advance of the boring, (1) cement the hole or (2) ream and case, or (3) case and advance with the next smaller-sized core barrel, as the conditions warrant. Follow the same procedure where fissures are encountered which cause the loss of drilling fluid return (Notes 5 and 6).

Note 5—Whenever the drilling water loss indicates conditions of engineering or geologic importance, the procedure for advancing the boring will be as determined by the engineer.

Note 6—Other optional procedures are as follows: (1) In soft, seamy, or otherwise unsound rock, where core recovery may be difficult, the M-design core barrels may be specified; (2) In hard sound rock where a high percentage of core recovery is anticipated, the single tube core barrel may be employed.

5. REPORT

5.1. *The report shall include the following*:

5.1.1. Project identification, boring number, location, and driller;

5.1.2. Elevation of the ground surface;

5.1.3. Elevation of ground water, including dates and times measured;

5.1.4. Elevations (or depths) at which drilling water return was lost;

5.1.5. Size and design of core barrel used. Size and length of all casing and any movements of the casing;

5.1.6. Length of each core run and the length or percentage, or both, of the core recovered;

5.1.7. Description of the rock in each run;

5.1.8. Structure including stratification, angle of dip, cavities, fissures, and any other observations that could give information on these features;

5.1.9. Depth, thickness, and apparent nature of the filling in each cavity or soft seam in the rock;

5.1.10. Depth of sample cuttings retained from the drilling fluid;

5.1.11. Any changes in the character of the drilling fluid; and

5.1.12. Date of beginning and end of boring.

Standard Method of Test for

Triaxial Compressive Strength of Undrained Rock Core Specimens without Pore Pressure Measurements

AASHTO Designation: T 226-90 (2008)
ASTM Designation: D 2664-86

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Triaxial Compressive Strength of Undrained Rock Core Specimens without Pore Pressure Measurements

AASHTO Designation: T 226-90 (2008)
ASTM Designation: D 2664-86

1. SCOPE

1.1. This test method covers the determination of the strength of cylindrical rock specimens in an undrained state under triaxial compression loading. The test provides data useful in determining the strength and elastic properties of rock, namely: shear strengths at various lateral pressures, angle of internal friction (angle of shearing resistance), cohesion intercept, and Young's modulus. It should be observed that this method makes no provision for pore pressure measurements. Thus the strength values determined are in terms of total stress, that is not corrected for pore pressures.

1.2. The values stated in inch-pound units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:[1]

- D 4543, Standard Practices for Preparing Rock Core as Cylindrical Test Specimens and Verifying Conformance to Dimensional and Shape Tolerances
- E 4, Standard Practices for Force Verification of Testing Machines
- E 122, Standard Practice for Calculating Sample Size to Estimate, With Specified Precision, the Average for a Characteristic of a Lot or Process

3. SIGNIFICANCE AND USE

3.1. Rock is known to behave as a function of the confining pressure. The triaxial compression test is commonly used to stimulate the stress conditions under which most underground rock masses exist.

4. APPARATUS

4.1. *Loading Device*—A suitable device for applying axial load to the specimen. It shall be of sufficient capacity to apply load at a rate conforming to the requirements set forth in Section 7.2.

It shall be verified at suitable time intervals in accordance with the procedures given in ASTM E 4, Verification of Testing Machines, and comply with the requirements prescribed therein.

4.2. *Pressure-Maintaining Device*—A hydraulic pump, pressure intensifier,[2] or other system of sufficient capacity to maintain constant the desired lateral pressure, σ_3.

4.3. *Triaxial Compression Chamber*[3]—An apparatus in which the test specimen may be enclosed in an impermeable flexible membrane; placed between two hardened platens, one of which shall be spherically seated; subjected to a constant lateral fluid pressure; and then loaded axially to failure. The platens shall be made of tool steel hardened to a minimum of Rockwell 58 HRC, the bearing faces of which shall not depart from plane surfaces by more than 0.0005 in. (0.013 mm) when the platens are new and which shall be maintained within a permissible variation of 0.001 in. (0.025 mm). In addition to the platens and membrane, the apparatus shall consist of a high-pressure cylinder with overflow valve, a base, suitable entry ports for filling the cylinder with hydraulic fluid and applying the lateral pressure, and hoses, gauges, and valves as needed.

4.4. *Deformation Measuring Device*—High-grade dial micrometers or other measuring devices graduated to read to 0.0001 in. (0.0025 mm); and accurate within 0.0001 in. (0.0025 mm); in any 0.0010 in. (0.025 mm) range, and within 0.0002 (0.005 mm) in any 0.0100 in. (0.25 mm) range shall be provided for measuring axial deformation due to loading. These may consist of micrometer screws, dial micrometers, or linear variable differential transformers securely attached to the high pressure cylinder.

4.4.1. Electrical resistance strain gauges applied directly to the rock specimen in the axial direction may also be used. In addition, the use of circumferentially applied strain gauges will permit the observation of data necessary in the calculation of Poisson's ratio. In this case two axial (vertical) gauges should be mounted on opposite sides of the specimen at mid-height and two circumferential (horizontal) gauges similarly located around the circumference, but in the direction perpendicular to the axial gauges.

4.5. *Flexible Membrane*[4]—A flexible membrane of suitable material to exclude the confining fluid from the specimen, and that shall not significantly extrude into abrupt surface pores. It should be sufficiently long to extend well onto the platens and when slightly stretched be of the same diameter as the rock specimen.

5. SAMPLING

5.1. The specimen shall be selected from the cores to represent a true average of the type of rock under consideration. This can be achieved by visual observations of mineral constituents, grain sizes and shape, and partings and defects such as pores and fissures.

6. TEST SPECIMENS

6.1. *Preparation*—The test specimens shall be prepared in accordance with ASTM D 4543.

6.2. Moisture condition of the specimen at time of test can have a significant effect upon the indicated strength of the rock. Good practice generally dictates that laboratory tests be made upon specimens representative of field conditions. Thus, it follows that the field moisture condition of the specimen should be preserved until time of test. On the other hand, there may be reasons for testing specimens at other moisture contents including zero. In any case, the moisture content of the test specimens should be tailored to the problem at hand and reported in accordance with Section 9.1.6.

7. PROCEDURE

7.1. Place the lower platen on the base. Wipe clean the bearing faces of the upper and lower platens and of the test specimen, and place the test specimen on the lower platen. Place the upper platen on the specimen and align properly. Fit the flexible membrane over the specimen and platens and install rubber or neoprene O-rings to seal the specimen from the confining fluid. Place the cylinder over the specimen, ensuring proper seal with the base, and connect hydraulic pressure lines. Position the deformation measuring device and fill the chamber with hydraulic fluid. Apply a slight axial load, approximately 25 lbf (111 N), to the triaxial compression chamber by means of the loading device in order to properly seat the bearing parts of the apparatus. Take an initial reading on the deformation device. Slowly raise the lateral fluid pressure to the predetermined test level and at the same time apply sufficient axial load to prevent the deformation measuring device from deviating from the initial reading. When the predetermined test level of fluid pressure is reached, note and record the axial load registered by the loading device. Consider this load to be the zero or starting load for the test.

7.2. Apply axial load continuously and without shock until the load becomes constant, or reduces, or a predetermined amount of strain is achieved. Apply the load in such a manner as to produce a strain rate as constant as feasible throughout the test. Do not permit the strain rate at any given time to deviate by more than 10 percent from that selected. The strain rate selected should be that which will produce failure of a similar test specimen in unconfined compression, in a test time of between 2 and 15 minutes. The selected strain rate for a given rock type shall be adhered to for all tests in a given series or investigation (Note 1). Maintain constant the predetermined confining pressure throughout the test and observe and record readings of deformation as required.

Note 1—Results of tests by other investigators have shown that strain rates within this range will provide strength values that are reasonably free from rapid loading effects and reproducible within acceptable tolerances.

Note 2—If the specimen diameter is not the same as the piston diameter through the chamber, a correction must be applied to the measured load to account for differences in area between the specimen and the loading piston where it passes through the seals into the chamber.

7.3. To make sure that no testing fluid has penetrated into the specimen, the specimen membrane shall be carefully checked for fissures or punctures at the completion of each triaxial test. If in question, weigh the specimen before and after the test.

8. CALCULATIONS

8.1. The following calculations and graphical plots shall be made:

8.1.1. A stress difference versus axial strain curve shall be constructed (Note 3). Stress difference is defined as the maximum principal axial stress, σ_1, minus the lateral pressure, σ_3. The value of the lateral pressure, σ_3, shall be indicated on the curve.

Note 3—Because total deformation is recorded during the test, suitable calibration for apparatus deformation must be made. This may be accomplished by inserting into the apparatus a steel cylinder having known elastic properties and observing differences in deformation between the assembly and steel cylinder throughout the loading range. The apparatus deformation is then subtracted from the total deformation at each increment of load in order to arrive at specimen deformation, from which the axial strain of the specimen is computed.

8.1.2. Mohr stress circles shall be constructed on an arithmetic plot with shear stresses as ordinates and normal stresses as abscissas. At least three triaxial compression tests, each at a different confining pressure, shall be made on the same material to define the envelope to the Mohr stress circles.

Note 4—Because of the heterogeneous nature of rock and the scatter in results often encountered, it is considered good practice to make at least three tests of essentially identical specimens at each confining pressure or single tests at nine different confining pressures covering the range investigated. Individual stress circles shall be plotted and considered in drawing the envelope.

8.1.3. A "Best-Fit," smooth curve (the Mohr envelope) shall then be drawn approximately tangent to the Mohr circles as in Figure 1. The figure shall also include a brief note indicating whether a pronounced failure plane was or was not developed during the test and the inclination of this plane with reference to the plane of major principal stress.

Note 5—If the envelope is a straight line, the angle the line makes with the horizontal shall be reported as the angle of interval friction ϕ (or the slope of the line as tan ϕ depending upon preference), and the intercept of this line at the vertical axis reported as the cohesion intercept, *C*. If the envelope is not a straight line, values of ϕ (or tan ϕ) should be determined by constructing a tangent to the Mohr circle for each confining stress at the point of contact with the envelope, and the corresponding cohesion intercept noted.

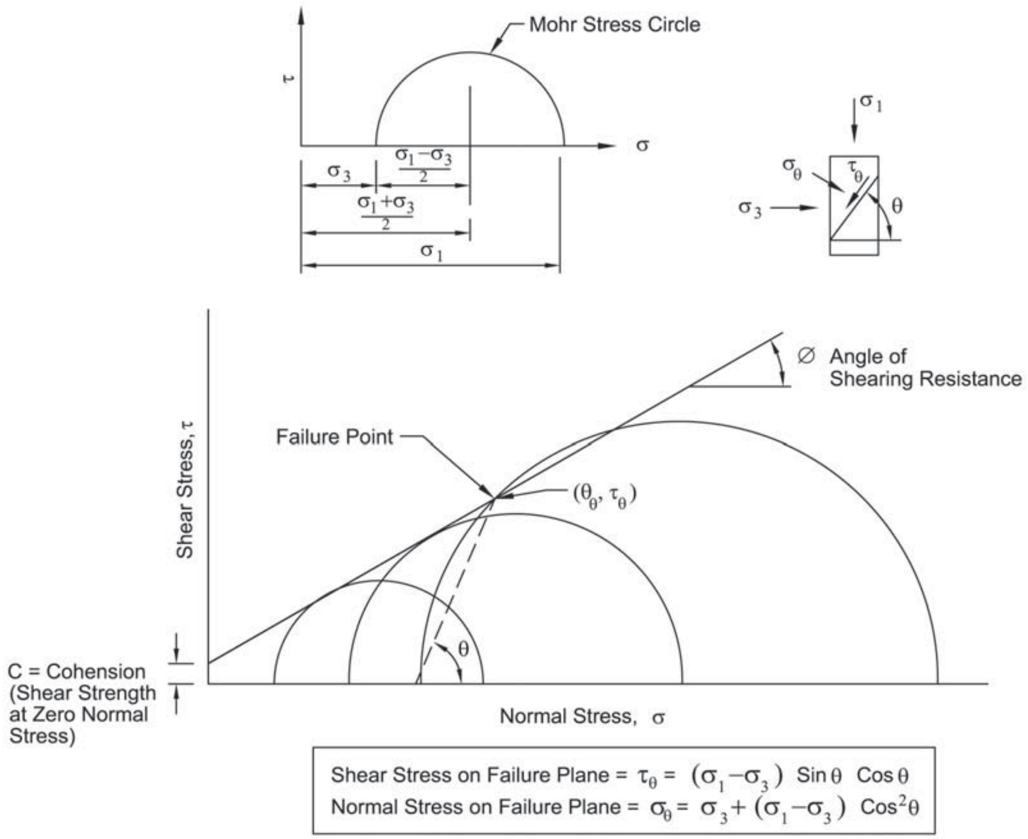

Figure 1—Typical Mohr Stress Circles

9. REPORT

9.1. In addition to the plots discussed in Section 8, Calculations, the report should include the following:

9.1.1. Sources of the specimen including project name and location, and if known, storage environment. The location is frequently specified in terms of the borehole number and depth of specimen from collar of hole.

9.1.2. Physical description of the specimen including rock type; location and orientation of apparent weakness planes, bedding planes, and schistosity; large inclusions of inhomogeneities, if any.

9.1.3. Dates of sampling and testing.

9.1.4. Specimen diameter and length, conformance with dimensional requirements.

9.1.5. Rate of loading or deformation or strain rate.

9.1.6. General indication of moisture condition of the specimen at time of test such as: as-received, saturated, laboratory air-dry, or oven dry. It is recommended that the moisture condition be more precisely determined when possible and reported as either water content or degree of saturation.

9.1.7. Type and location of failure. A sketch of the fractured specimen is recommended.

Note 6—If it is a ductile failure and $\sigma_1 - \sigma_3$ is still increasing when the test is terminated, the maximum strain at which $\sigma_1 - \sigma_3$ is obtained shall be clearly stated.

10. PRECISION AND BIAS

10.1. An interlaboratory study was conducted in which six laboratories each tested five specimens of three different rocks, three confining pressure and four replications. The specimens were prepared by a single laboratory from a common set of samples and randomly distributed to the testing laboratories for testing. The study was carried out in accordance with ASTM E 691. Details of the study are given in ISR Research Report "Interlaboratory Testing Program for Rock Properties (ITP/RP) Round Two," 1994. Tables 1 through 3 give the repeatability (within a laboratory) and reproducibility (between laboratories) for the method at confining pressure of 10, 25, and 40 MPa.

10.1.1. The probability is approximately 95 percent that two test results obtained in the same laboratory on the same material will not differ by more than the repeatability limit. Likewise, the probability is approximately 95 percent that two test results obtained in different laboratories on the same material will not differ by more than the reproducibility limit.

Table 1—Compressive Strength (MPa) at 10 MPa Confining Pressure

	Berea Sandstone	Tennessee Marble	Barre Granite
Average Value	127	173	282
Repeatability	5.29	32.2	13.5
Reproducibility	22.5	38.3	25.7

Table 2—Compressive Strength (MPa) at 25 MPa Confining Pressure

	Berea Sandstone	Tennessee Marble	Barre Granite
Average Value	179	206	366
Repeatability	8.69	43.3	22.5
Reproducibility	34.7	51.8	31.0

Table 3—Compressive Strength (MPa) at 40 MPa Confining Pressure

	Berea Sandstone	Tennessee Marble	Barre Granite
Average Value	215	237	N/A
Repeatability	7.95	42.4	N/A
Reproducibility	52.0	73.5	N/A

11. KEYWORDS

11.1. Compression strength; compression testing; loading tests; rock; triaxial compression.

[1] Available from ASTM, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959.

[2] A pressure intensifier as described by Leonard Obert in U.S. Bureau of Mines Report of Investigations No. 6332, "An Inexpensive Triaxial for Testing Mine Rock," has been found to fulfill the above requirements.

[3] Assembly and detail drawings of an apparatus that meets these requirements and that is designed to accommodate $2^1/_8$-in. (54-mm) diameter specimens and operate at a lateral fluid pressure of 10000 psi (69 MPa) are available from ASTM Headquarters, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959. Request Adjunct No. 12-426640-00.

[4] Neoprene rubber tubing of $^1/_{16}$ in. (1.588 mm) wall thickness and of 40 to 60 Durometer hardness, Shore Type A or various sizes of bicycle inner tubing, have been found generally suitable for this purpose.

Standard Method of Test for

Determination of Lime Content in Lime-Treated Soils by Titration

AASHTO Designation: T 232-90 (2008)

American Association of State Highway and Transportation Officials

Washington, D.C. 20001

Standard Method of Test for

Determination of Lime Content in Lime-Treated Soils by Titration

AASHTO Designation: T 232-90 (2008)

1. SCOPE

1.1. A method of test is described for determining the percentage of lime in soils or aggregates that have been treated with hydrated lime. It is based on the continuous neutralization of an aqueous solution from the lime-treated specimen for a specified time period. This is accomplished by adding sufficient acid to just neutralize the lime which is continuously being dissolved during the test. The amount of acid used is directly proportional to the lime content of the specimen.

1.2. The following applies to all specified limits in this standard: For the purpose of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with E 29, Using Significant Digits in Test Data to Determine Conformance with Specifications. (This test has a statement pertaining to significant figures.) (No statistical data are available.)

1.3. The values stated in SI units are to be regarded as the standard.

1.4. Refer to R 16 for regulatory information for chemicals.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests

2.2. *ASTM Standard*:
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. APPARATUS

3.1. A 100-mL titrating buret or other device permitting slow, easily controlled addition of acid, with stand and clamp.

3.2. Ten 1.9-L (2-quart) wide-mouth polyethylene containers (white).

3.3. Two 18.9-L (5-gal) plastic carboys, equipped with siphons, neoprene or tygon tubing, hose clamps, etc., for dispensing acid-working solution and water.

3.4. Glass (or plastic) dropping bottle.

3.5. *Four stirring rods*—of stainless steel or other suitable material.

3.6. *Sieves*—37.5-mm and 9.5-mm sieves conforming to the requirements of the Specification for Wire-Cloth Sieves for Testing Purposes (M 92).

Note 1—Although sieves in 203-mm (8-in.) frames are satisfactory, a 9.5-mm sieve in 305-mm (12-in.) frame may be more suitable for separating the field samples (Sections 5.4 and 8.3).

3.7. *Balances*—The balances shall conform to M 231, Class G 5 and Class G 2.

3.8. *Four plastic beakers*, having a minimum capacity of 500 mL.

3.9. A 200-mL glass beaker.

3.10. Four 50-mL graduates.

3.11. *Fluorescent light*, one 915 mm (36 in.) long, or two 457 mm (18 in.) long.

4. REAGENTS

4.1. *Hydrochloric Acid (HCl) (Approximately 3 Normal)*—Pour approximately 11.4 L (3 gal) of water into an 18.9-L (5-gal) plastic carboy. Pour the contents of two full standard 2.7-kg (6-lb) bottles of concentrated reagent-grade HCl in the carboy. Stir or mix the solution vigorously for about 1 minute. Add tap water as necessary to bring the total volume of water and acid to 18.9 L (5 gal); then stir or mix the solution vigorously for another minute. Allow the acid solution to stand overnight; then remix it once again prior to using. Remix the acid solution once a week during use and also before using if the acid solution has been in storage for more than 1 week.

4.2. *Phenolphthalein Indicator Solution (1 Percent Solution)*—Dissolve 5 g of phenolphthalein (U.S.P.) in 250 mL of 95 percent ethyl alcohol. Dilute with 250 mL of distilled water.

4.3. *Polyacrylamide (Flocculating Agent) Stock Solution*—Mix 0.5 g of polyacrylamide (such as “separan” NP-10 by Dow Chemical Company) with 1000 mL of distilled water in a glass beaker. Stir frequently and allow to stand until no precipitates are visible. Prepare a fresh solution weekly.

5. MATERIALS FOR CALIBRATION TEST SPECIMENS

5.1. Two specimens with 1 percent less than the planned lime content and two specimens with 1 percent more than the planned lime content for the project must be tested and the data used in preparing a lime titration calibration curve. Aggregate, lime, and water to be used in the field project shall be used in preparing the calibration specimens. The moisture content of the specimens should be representative of that to be used for the lime-treated material on the project.

5.2. From Table 1, select the mass of aggregate corresponding to the appropriate lime and moisture content. This is the mass of dry untreated aggregate required to prepare calibration test specimens of 300 g. If the sample of untreated aggregate initially contains moisture, adjust the mass of moist aggregate to yield the correct mass of dry material. A correction is also made in the water measurement in Section 5.6 for the water contained in the moist aggregate.

Table 1—Quantities of Materials for Calibration Specimens Containing Various Percentages of Lime

		1% Lime		2% Lime		3% Lime		4% Lime		5% Lime		6% Lime		7% Lime	
Moisture Content, Percent	Water, mL	Dry Mass Agg., g	Lime, g	Dry Mass Agg., g	Lime, g	Dry Mass Agg., g	Lime, g	Dry Mass Agg., g	Lime, g	Dry Mass Agg., g	Lime, g	Dry Mass Agg., g	Lime, g	Dry Mass Agg., g	Lime, g

5.3. From the project records, determine the average percentage of untreated aggregate passing the 37.5-mm sieve and retained on the 9.5-mm sieve. These percentages will be used for proportioning the calibration specimens.

5.4. Remove and waste any aggregate in the sample of untreated material retained on the 37.5-mm sieve and separate the sample on the 9.5-mm sieve. Recombine for duplicate calibration test specimens with the aggregate mass found in Section 5.2, and with the 9.5-mm sieve proportions found in Section 5.3.

5.5. Select the required amount of lime from Table 1 and determine the mass to the nearest 0.1 g.

5.6. Measure in a glass graduate, the required amount of water (corrected as in Section 5.2) in mL, given in Table 1.

6. CALIBRATION CURVE

6.1. Each test operator must establish two calibration curves at least once each day; one for a 4 or 5-hour curing time, for use with field samples that are completely mixed and tested during the same day; and one for a 24-hour curing time, for use with field samples that are tested on the next day after mixing. If there is a change in acid, lime, aggregate or water, new curves must be established after the change.

Note 2—Less correction will be needed and the results will be more accurate if similar curing times are used for calibration test and field sample tests.

Note 3—A new calibration curve should be established when a fresh batch of diluted acid solution is prepared and when the source of the aggregate or water is changed. The calibration curve for each curing time should be checked when there is a suspected change in character of aggregate specimen or water from the same source.

6.2. For each specimen, pour the weighed aggregate and lime from Sections 5.4 and 5.5, respectively, into the 1.9-L (2-quart) plastic container and mix thoroughly with stirring rod.

6.3. Add the quantity of water measured in Section 5.6 and mix thoroughly. The time that the water is added is considered the start of the curing period.

6.4. Place the 1.9-L (2-quart) containers in a row on the table that is to be used for the testing, leave the samples uncovered, and allow to cure for the times given in Section 6.1.

6.5. Just prior to expiration of the curing time in Section 6.1, prepare the polyacrylamide solution as follows: behind each testing specimen, place a plastic beaker into which has been measured 200 mL of tap water and 50 mL of the polyacrylamide stock solution (prepared from Section 4.3); also for each test specimen, determine the mass of a glass graduate, add to it 50 mL of the polyacrylamide stock solution and record the net mass to the nearest 0.1 g.

6.6. At the end of the curing period, the constant neutralization test is performed as follows:

6.6.1. Start the timer and add the mixed water and polyacrylamide stock solution to the first specimen. Add the liquid to successive specimens at intervals of 120 seconds.

6.6.2. Add two full droppers (approximately 40 drops) of phenolphthalein solution to each container. The water will normally turn red due to the presence of lime.

6.6.3. Determine the mass of each plastic container including its contents to the nearest 0.1 g.

6.6.4. Place the fluorescent light behind the plastic containers.

6.6.5. At 8 minutes after the addition of the mixed water and polyacrylamide stock solution to the first specimen (Section 6.6.1), start adding 3 Normal HCl to this specimen from a buret while stirring continuously. Only enough acid is added to cause the red color to just disappear. Similarly, add acid to successive specimens at 120-second intervals; that is, at timer readings of 10, 12, and 14 minutes for the second, third, and fourth specimens, respectively, or a series.

6.6.6. When the red color starts to reappear after the initial introduction of acid, use the buret to make a second addition of acid in the amount (mL) necessary to cause the color to just disappear. Subsequent additions of acid are made as necessary to cause the color to just disappear.

Note 4—**Caution**—Stir lightly. Vigorous stirring at this time will cause the flocculated particles to disperse, making it difficult to see the end point.

6.6.7. In addition to the stirring accomplished during each introduction of acid, stir lightly for about 3 seconds of every minute and for about 6 seconds of every fifth minute, whether or not color is present. Perform the stirring in a circular and zigzag pattern across the bottom of the plastic container. Be careful to avoid the possibility of leaving any deposit of unneutralized lime in the center of the container.

6.6.8. At the end of 25 minutes after adding the initial amount of mixed water and polyacrylamide stock solution to the first sample, stir the sample vigorously, add the additional 50 mL of polyacrylamide stock solution (Section 6.5), and continue the test. Repeat this procedure with each of the specimens allowing a 120-second interval between specimens. This will require timer readings of 27, 29, and 31 minutes, respectively, for the second, third, and fourth specimens of a series.

6.6.9. Continue the procedure of adding acid and stirring until 38 minutes have elapsed since the initial addition (Section 6.6.1) of mixed water and polyacrylamide stock solution to the first specimen. Then reweigh the plastic container contents to the nearest 0.1 g. Repeat this procedure with each of the specimens allowing 120-second intervals between specimens. This will require readings of 40, 42, and 44 minutes, respectively, for the second, third, and fourth specimens of a series.

6.6.10. Using the difference between the initial mass (determined in Section 6.6.3) plus the additional mass of polyacrylamide stock solution (determined in Section 6.5) and the final test specimen masses (determined in Section 6.6.9), calculate and record the total mass of hydrochloric acid (HCl) used to neutralize the solution; then determine the average mass of HCl used for each pair of test specimens.

6.7. Plot the average mass of HCl used (Section 6.6.10) against the percent lime used in the paired specimens. Draw a straight line between the two points. This is the calibration curve for determining the lime content of field-mixed lime-treated specimens (Figure 1).

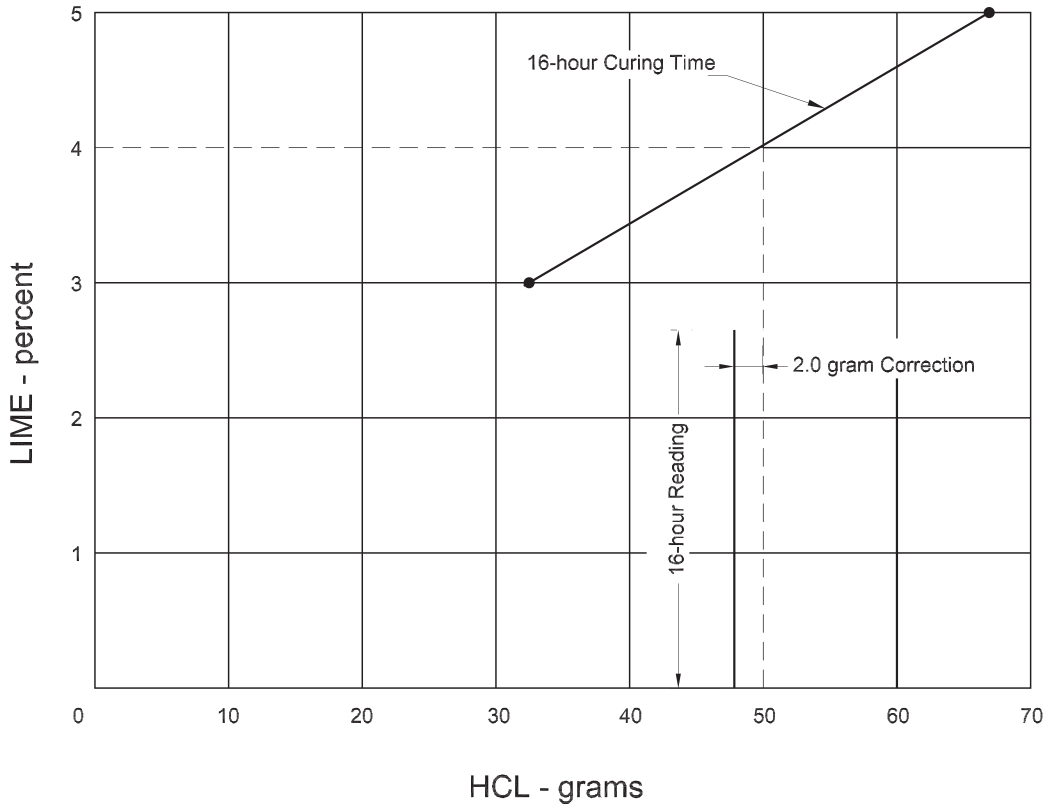

Figure 1—Lime Titration Calibration Curve

7. CURING TIME CORRECTION CURVE

7.1. Since it will normally be impossible to select lime-treated samples from the field project that have been cured for the same time as the specimens used in preparing the calibration curve, preparation of a correction curve is necessary.

7.2. Using the aggregate, lime, and water from the field project, prepare 10 specimens at the planned lime content. Preparation of the required quantities of materials shall be as in Section 5, and mixing shall be as in Sections 6.2 and 6.3.

7.3. Test the specimens in pairs at approximate curing times of 1, 3, 7, 24, and 48 hours to establish a curing time curve as shown in Figure 2. Leave the samples uncovered during the curing period.

Note 5—The test is very sensitive to curing time during the first hour after mixing. Therefore, it is advisable not to perform the first tests until at least 1 hour after mixing.

7.4. At the end of each of the curing times given in Section 7.3, perform the constant neutralization test on two of the specimens, using the procedure described in Section 6.6.

7.5. Plot the grams of HCl used against the curing time to establish the correction curve (Figure 2).

Note 6—The curing time correction needs to be established only once for a project unless there is a change in aggregate or lime source.

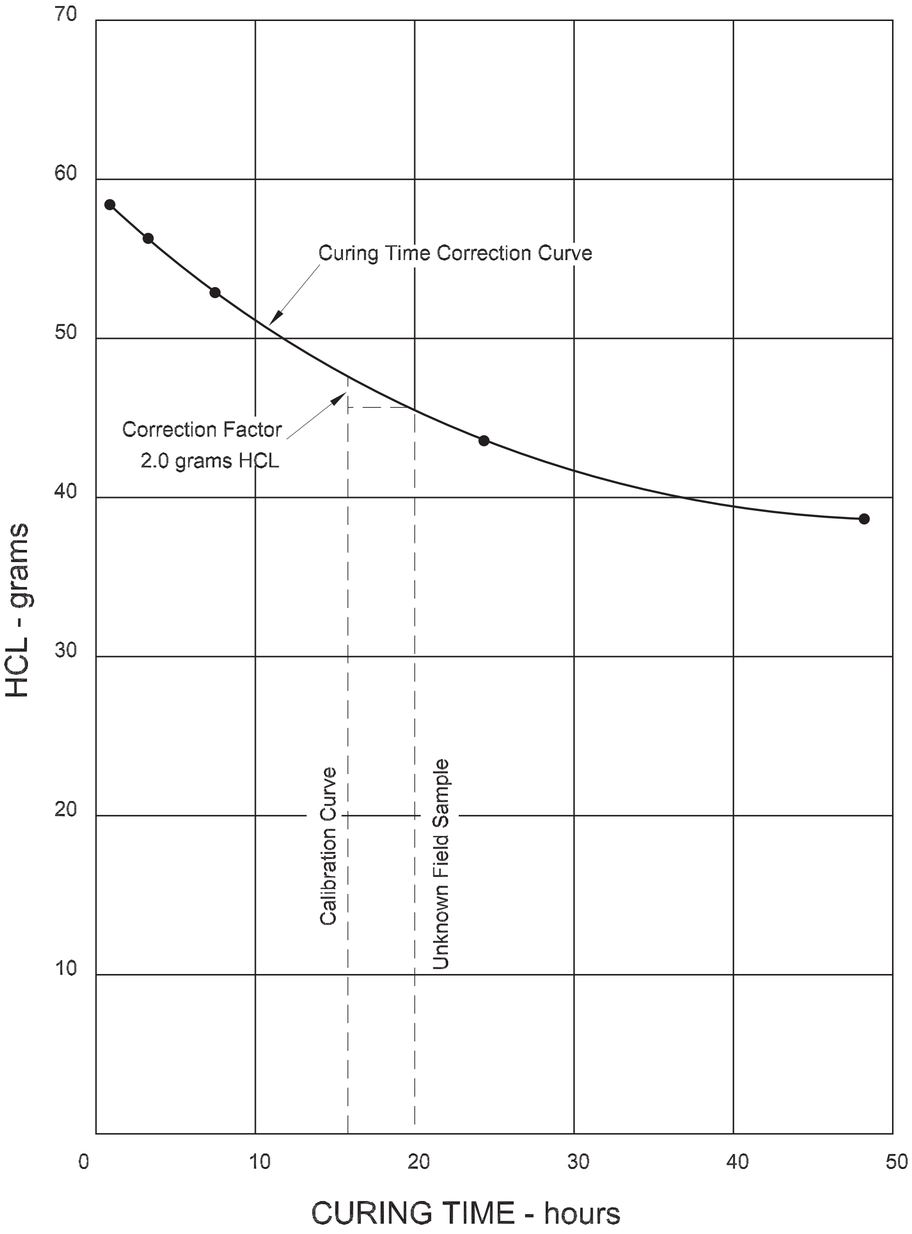

Figure 2—Curing Time Correction Curve

8. TEST PROCEDURE FOR FIELD SAMPLES

8.1. Secure one to four field samples of the lime-treated aggregate, with each sample having a mass of approximately 3000 g. Determine the mass of the sample to the nearest 1.0 g.

8.2. Remove any waste and aggregate retained on the 37.5-mm sieve.

8.3. Separate sample on the 9.5-mm sieve and determine the proportion retained and passing the 9.5-mm sieve on the basis of total sample mass including retained 37.5-mm material.

8.4. Prepare 300-g test specimens in the same proportions of retained and passing 9.5-mm material as contained in the original 3000-g sample. The retained 9.5-mm material is made up of passing 37.5-mm and retained 9.5-mm material to represent all the retained 9.5-mm material including the retained 37.5-mm material.

8.5. Perform the constant neutralization test in accordance with Section 6.6.

8.6. Determine the correction factor in grams of acid between the curing time for the calibration and field samples from the curing time correction curve (Figure 2). Apply a plus correction factor if the curing time of the field sample is greater than the curing time of the calibration samples. Apply a minus correction factor if the curing time of the field sample is less than the curing time of the calibration samples.

Note 7—The curing time for a field sample begins with the time for mixing and includes the time required for sampling the mixture, for transporting the sample to the testing location, and for preparing the 300 g test specimens.

8.7. Apply the correction factor to the grams of HCl required for neutralization. (See Section 6.6.10.)

8.8. From the calibration curve, determine the percent lime (Figure 1).

9. CALCULATIONS

9.1. Assume the following data:

9.1.1. The curing time correction curve was established using the planned lime content (Figure 2).

9.1.2. The calibration curve was established with a 16-hour curing time (Figure 1).

9.1.3. The field sample had a 20-hour curing time.

9.1.4. The titration of the field sample required 48.0 g of acid.

9.2. Plot the curing time for the calibration and field sample against the curing time correction curve, as shown in Figure 2. For this field sample, the correction is +2.0 g. Apply this correction to the grams of acid required to titrate the field sample (48 + 2.0 = 50.0 g of acid). Apply the 50.0 g of acid to the calibration curve (Figure 1). Then, the calculated lime content is 4.0 percent (Figure 1).

10. PRECAUTIONS

10.1. This test should not be performed by persons subject to color blindness.

10.2. It is very important that the operator vigilantly maintain a neutral solution by repeatedly adding acid as soon as the pink color reappears.

10.3. Use only the amount of hydrochloric acid (HCl) necessary to just eliminate the red color. Excess acid may attack the aggregates, particularly in the later phases when the amount of lime remaining in the mixture is low.

10.4. This test should not be performed in direct sunlight or at any location where there is a steady air movement over the containers. The amount of evaporation caused by exposure to air currents or sunlight can affect test data.

10.5. Glass carboys should not be substituted for plastic carboys described in the test apparatus, and all containers having acids or solutions made from them should be clearly labeled.

10.6. Exercise extreme care in handling the concentrated solutions of HCl and also exercise care in the use of the diluted solutions of HCl, as it can be harmful to the eyes, skin, or clothing. If this chemical is splashed in the eyes, on the skin, or on the clothing, flush the affected areas immediately with liberal quantities of water.

10.7. When handling acids, personnel should wear chemical protective gloves, goggles, and aprons.

10.8. Phenolphthalein has been known to cause allergic symptoms in humans and has a powerful laxative effect. It can be toxic. Exposed personnel who are sensitive to it should wear protective clothing, if necessary, to avoid bodily contact. Do not ingest.

Standard Method of Test for

Density of Soil In-Place by Block, Chunk, or Core Sampling

AASHTO Designation: T 233-02 (2006)

American Association of State Highway and Transportation Officials

Standard Method of Test for

Density of Soil In-Place by Block, Chunk, or Core Sampling

AASHTO Designation: T 233-02 (2006)

1. SCOPE

1.1. This method of test is intended to determine the density of cohesive soil in the natural state, compacted cohesive soil, and stabilized soil by measuring the weight and volume of undisturbed samples.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. Refer to R 16 for regulatory information for chemicals.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 217, Determination of Moisture in Soils by Means of a Calcium Carbide Gas Pressure Moisture Tester

2.2. *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

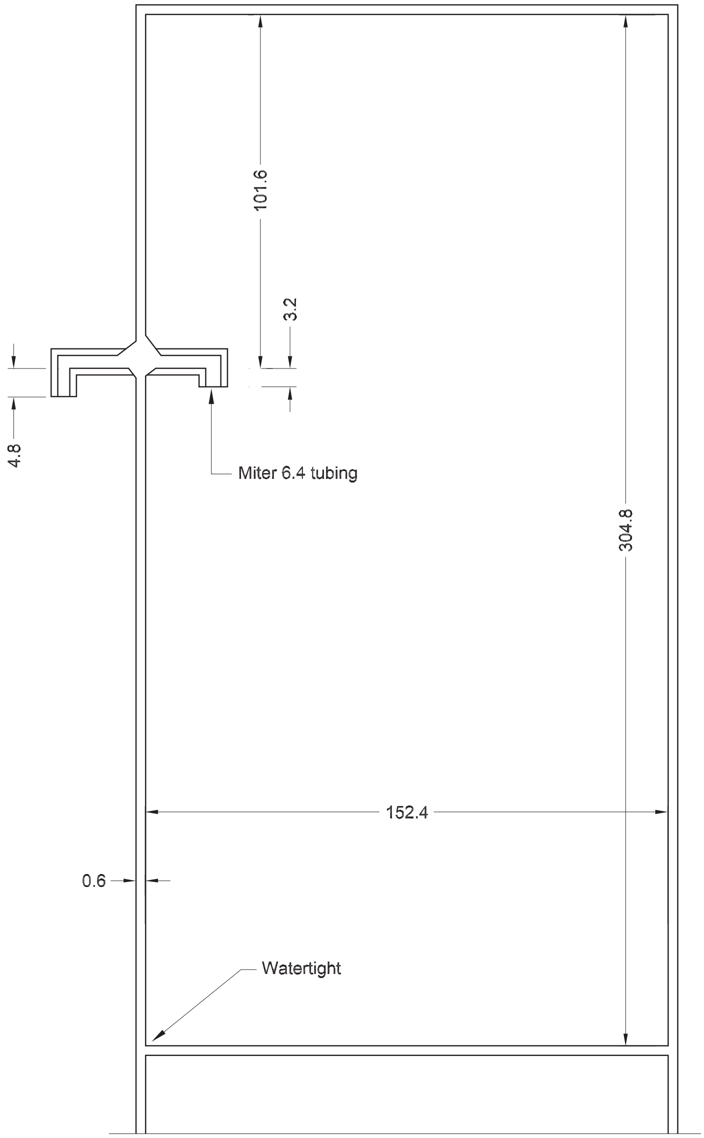
3. APPARATUS AND MATERIALS

3.1. *Sampling Tools*—Trowel, thick-blade spatula, knife, small spade suitable for removing sample, or a coring device suitable for obtaining an undisturbed sample. Diamond and Carborundum saws may be used.

3.2. *Balances and Scales*—A balance or scale conforming to the requirements of M 231, Class G 20. Also, a balance conforming to the requirements of M 231, Class G 2.

3.3. *Water Bath*, for immersing the paraffin-coated sample in water while on the holder under the balance, equipped with an overflow outlet for maintaining a constant water level.

3.4. *Volume Measuring Device*—An overflow, volumetric displacement apparatus as shown in Figure 1, or similar.



Note: All dimensions are shown in millimeters unless otherwise noted. (See Table 1 for dimensional equivalents.)

Figure 1—Volumetric Displacement Apparatus

Table 1—Dimensional Equivalents

mm	in.
304.8	12
152.4	6
101.6	4
6.4	$^1/_4$
4.8	$^3/_{16}$
3.2	$^1/_8$
0.6	26 gauge

Note 1—The volume-measuring device is not needed if the suspension apparatus with holder (Section 3.2) and water bath (Section 3.3) is used.

3.5. *Oven*—An oven, stove, or other suitable equipment for drying soil samples for moisture content determination.

3.6. *Containers*—Containers for moisture content samples, made of metal or other suitable material, and with close-fitting lids to prevent loss of moisture prior to or during mass determinations.

Note 2—The moisture content may also be determined in accordance with T 217.

3.7. *Coating Material*—Paraffin and a kettle or other container suitable for melting paraffin and dipping samples.

4. SAMPLING

4.1. Obtain a sample of the soil or stabilized soil by marking the area from which the desired sample is to be cut and digging the soil or stabilized soil from around it with a sharp tool, such as a trowel, spatula, knife, or small spade. Exercise care in digging around the sample to prevent disturbance of the soil structure. Sample the depth of the layer for which the density is desired. The minimum size of the untrimmed sample should be slightly greater than shown in Table 2, so as to provide for final trimming (Section 5.2).

Table 2—Minimum Density-Sample Volumes and Minimum Moisture Content Samples Based on Maximum Size of Particle

Maximum Particle Size		Minimum Sample Volume		Minimum Moisture Content Sample
mm	Alternate	cm^3	ft^3	g
4.75	No. 4 Sieve	710	0.025	100
12.7	$^1/_2$ in.	1415	0.050	250
25.0	1 in.	2125	0.075	500
50	2 in.	2850	0.100	1000
63	$2^1/_2$ in.	3550	0.125	1500

4.2. Other suitable methods of obtaining the undisturbed sample include drilling with a coring device and cutting with a diamond or Carborundum saw.

5. PROCEDURE

5.1. After removal of the undisturbed sample, take a representative moisture sample from the wall of the hole or from the trimmings obtained in cutting the undisturbed sample, place in a container, determine the mass to the nearest 0.1 g, dry to constant mass, and determine the moisture content. The minimum size of the moisture content sample, based on the maximum particle size, is given in Table 2.

5.2. Trim any loose material from the undisturbed sample and determine the mass of the sample to the nearest 1.0 g. The minimum sample volume, after trimming, is given in Table 2.

5.3. Immerse the undisturbed sample in melted paraffin, being careful that the sample is completely coated. Allow the paraffin coating to cool, and then determine the mass of the coated sample to the nearest 1.0 g. The gain in mass represents the mass of paraffin and the volume of the coating is calculated using the density of paraffin.

5.4. The volume of the paraffin-coated sample in water shall be determined by one of the following methods:

5.4.1. Determine the mass of the paraffin-coated sample submerged in the water bath described in Section 3.3 and record the mass to the nearest 1.0 g. Determine the volume of the sample in accordance with Section 6.2.

5.4.2. Fill the volume measuring device (Figure 1) with water above the overflow. Permit the excess water to drain. Immerse the coated sample and determine the mass of the displaced water to the nearest 1.0 g. Determine the volume of the sample in accordance with Section 6.2.

Note 3—Kerosene or another suitable liquid may be used instead of water in the water bath (Section 3.3) to avoid the necessity for (1) coating the undisturbed sample with paraffin (Section 5.3) prior to immersion (Section 5.4) and (2) making a correction for the volume of the paraffin coating.

6. CALCULATIONS

6.1. Calculate the moisture content as follows:

$$w = \frac{A - B}{B - C} \times 100 \tag{1}$$

where:

w = percentage of moisture in the sample, based on dry mass of soil;

A = mass of container and wet soil;

B = mass of container and dry soil; and

C = mass of container.

6.2. Calculate the in-place density (dry unit mass), D, of the soil, in kg/m^3, as follows:

$$I = \frac{F - E}{D_p} \tag{2}$$

$$J = \frac{F - G}{D_m} = \frac{H}{D_m} \tag{3}$$

$$V = J - I \tag{4}$$

$$D = \frac{(1000)D_w}{1 + \frac{w}{100}} \tag{5}$$

For determining D in lb/ft^3 use:

$$D = \frac{(62.43)\,D_w}{1 + \frac{w}{100}} \qquad (6)$$

where:

E = mass of soil sample in grams;
F = mass of paraffin-coated sample in grams;
G = mass of submerged paraffin-coated sample in grams;
H = mass of displaced water in grams;
I = volume of paraffin in cubic centimeters;
J = volume of paraffin-coated soil sample in cubic centimeters;
V = volume of soil sample in cubic centimeters;
D_p = density of paraffin in grams per cubic centimeter;
D_m = density of water in grams per cubic centimeter;
D_w = wet density of soil in grams per cubic centimeter;
D = in-place density of soil in kg/m^3 (lb/ft^3); and
w = moisture content of soil, in percent.

Standard Method of Test for

Direct Shear Test of Soils under Consolidated Drained Conditions

---

AASHTO Designation: T 236-08[1]
ASTM Designation: D 3080-72 (2003)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Direct Shear Test of Soils under Consolidated Drained Conditions

AASHTO Designation: T 236-08[1]
ASTM Designation: D 3080-72 (2003)

1. SCOPE

1.1. This method describes procedures for determining the consolidated drained shear strength of a soil material in direct shear. The test may be conducted in either a single shear or in a double shear, as shown in Figure 1. The direct shear test is well-suited to a consolidated drained test because the drainage paths through the test specimen are short, thereby allowing excess pore pressures to be dissipated fairly rapidly. The test can be made on all soil material,[2] and on undisturbed or remolded samples.

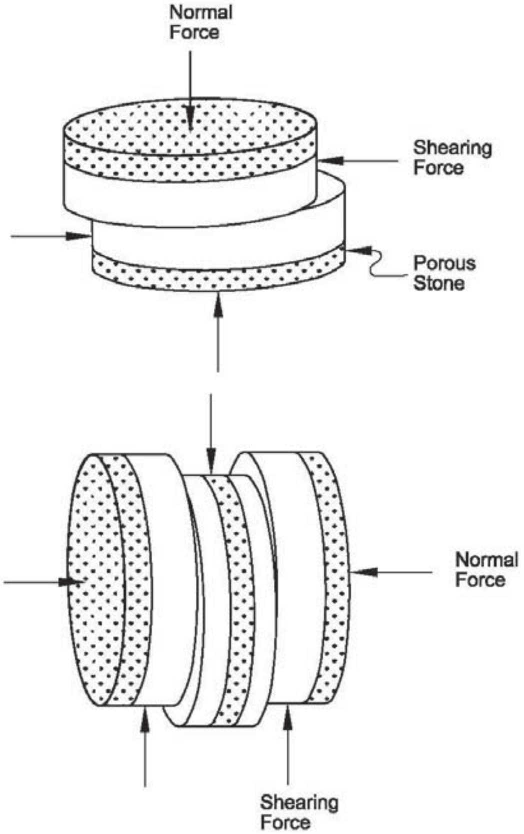


Figure 1—Test Specimens in (a) Single and (b) Double Shear

1.2. The test results are applicable to field situations where complete consolidation has occurred under the existing overburden and failure is reached slowly so that excess pore pressures are dissipated. The test is also useful in determining the shearing resistance along recognizable weak planes within the soil material.

Note 1—If failure is forced to occur on or near a horizontal plane at the middle of the specimen, it may not necessarily occur along the weakest plane, thereby overestimating shear strength parameters. Only when weak plane(s) are recognizable within the soil mass or interfaces between dissimilar materials are being tested, and the plane or interface at question is placed within the limits of the forced failure zone, can the shear resistance along these planes or interfaces be evaluated. The usefulness of direct shear test results was discussed in the Symposium on Direct Shear Testing of Soils; the proceedings appear in ASTM Special Technical Publication 131.

1.3. The test is not suited to the development of exact stress-strain relationships nor for evaluating any other associated quantities such as moduli within the test specimen because of the non-uniform distribution of shearing stresses and displacements. The slow rate of displacement provides for dissipation of excess pore pressures, but it also permits plastic flow of soft cohesive soils. Care should be taken that the testing conditions represent those being investigated.

1.4. The values stated in SI units are to be regarded as the standard.

2. SUMMARY OF METHOD

2.1. The method consists of (a) placing the test specimen in the direct shear device, (b) applying a predetermined normal stress, (c) providing for drainage or wetting of the test specimen, (d) consolidating the specimen under the normal stress, (e) unlocking the frames that hold the test specimen, and (f) applying a shearing force to shear the specimen (Figures 1 and 2). Generally three or more specimens are tested, each under a different normal stress to determine the effects upon shear resistance and displacement. The range in normal stresses should be appropriate for the soil conditions being investigated.

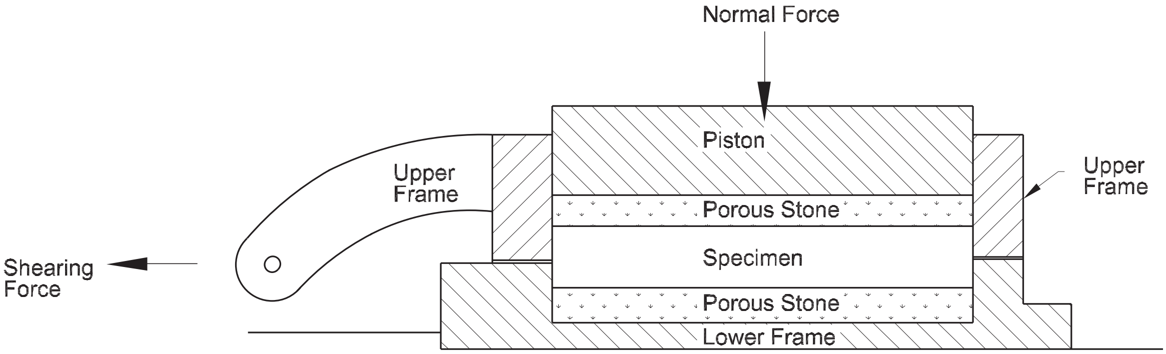

Figure 2—Typical Direct Shear Box for Single Shear

3. APPARATUS

3.1. *Shear Device*—A device (square or circular) to hold the specimen securely between two porous stones in such a way that torque cannot be applied to the specimen. The shear device shall provide means for applying a normal stress to the faces of the specimen, for measuring change in thickness of the specimen, for permitting drainage of water through the porous stones, and for submerging the specimen in water. The device shall be capable of applying a shearing force to shear the specimen along a predetermined shear plane (single shear) or shear planes (double shear) parallel to the faces of the specimen. The frames that hold the specimen shall be sufficiently rigid to prevent their distortion during shearing. The various parts of the shear device shall be made of material not subject to corrosion by substances within the soil or soil moisture.

3.2. *Porous Stones*—The porous stones shall consist of silicon carbide, aluminum oxide, or metal that is not susceptible to corrosion by soil substances or soil moisture. The proper grade of stone depends upon the soil being tested. The stone should be coarse enough to develop adequate interlock with the specimen and fine enough to prevent excessive intrusion of the soil into the pores. Exact criteria for this have not been established. For normal soil testing, medium grade stones with a permeability of about 0.5 to 1 mm/s are appropriate.

3.3. *Loading Devices*:

3.3.1. Device for applying the normal force shall be capable of applying the specified force quickly, without exceeding it, and capable of maintaining it with an accuracy of ±1 percent for the duration of the test.

3.3.2. Device for applying the shear force. The capabilities will depend upon whether a controlled-displacement test or controlled-stress test is used. The former is generally preferred because the ultimate stress as well as the maximum stress can be determined. Controlled displacement equipment shall be capable of shearing the specimen at a uniform rate of displacement, with less than ±5 percent deviation, and should permit adjustment of the rate of displacement over a relatively wide range. The rate depends upon the consolidation characteristics of the soils.[3] The rate is usually maintained with a motor and gear box arrangement and the shear force is determined by a force indicating device such as a proving ring. Controlled-stress equipment, if used, should be capable of applying the shear force in increments to the specimen in the same manner and to the same degree of accuracy as that described under Section 3.3.1.

3.4. *Calibration Disk*—A metal disk having a thickness equal to the desired test specimen and about 5 mm smaller in diameter.

3.5. *Moisture Room* for storing samples as well as for preparing samples where moisture loss during preparation does not exceed 0.5 percent.

3.6. *Trimmer or Cutting Ring* for trimming oversized samples to the inside dimensions of the shear box with a minimum of disturbance. An exterior jig may be needed to maintain the succession of rings—two or three—in axial alignment.

3.7. *Balance* sensitive to 0.1 g or to 0.1 percent of the specimen mass.

3.8. *Displacement Indicators* to measure change in thickness of the test specimen, with a sensitivity to 0.002 mm (0.0001 in.), and to measure horizontal displacement with a sensitivity of 0.02 mm (0.001 in.).

3.9. *Drying Oven* that can be maintained at 110 ± 5ºC (230 ± 9ºF).

3.10. *Containers*—Suitable containers made of material resistant to corrosion and not subject to change in mass or disintegration on repeated heating and cooling. Containers shall have close-fitting lids to prevent loss of moisture from samples before initial mass determination and to prevent absorption of moisture from the atmosphere following drying and before final mass determination. One container is needed for each moisture content determination.

3.11. *Equipment for Remolding or Compacting Specimens*.

3.12. *Miscellaneous Equipment*, including a timing device with a second hand, distilled or demineralized water, spatulas, knives, straightedge, wire saws, etc., used in preparing the sample.

4. CALIBRATION

4.1. The calibration step is necessary in order to determine the deformation of the testing device when subjected to consolidation load. For each consolidation step, the corresponding device deformation will be subtracted from the observed deformation so that only deformations due to sample consolidation will be reported at the end of each consolidation step. Calibration of the testing device must be performed when the device is originally placed in service as well as whenever any of its components are changed. An annual calibration, at a minimum, should be performed.

4.2. Assemble the single shear direct shear device with the calibration disk used in place of the test specimen. The calibration disk should be a copper or hard steel disk of approximately the same height as the test specimen and at least 1 mm (0.04 in.) but no more than 5 mm (0.20 in.) smaller in diameter than the ring.

Note 2—The double shear device will require two calibration disks.

4.3. Position and adjust the normal displacement indicator so it can be used to measure either consolidation or swell from the "calibration disk" reading. Record the zero or "no load" reading.

4.4. Apply increments of normal force up to the equipment limitations and record both the applied normal force and the normal displacement indicator reading for future reference in determining the thickness of the test specimen and compression within the test apparatus itself. Remove the applied normal force in reverse sequence of the applied force and again record the normal displacement indicator readings and normal force. Calculate the average of the two recorded deformation values corresponding to each value of applied normal loading sequences (loading and unloading). Plot the average deformation of the device as a function of the applied load. As indicated in Section 4.1, this information will be used in determining the thickness of the test specimen and its compression within the testing device at the end of each consolidation loading step.

4.5. Remove the calibration disk.

Note 3—Other equally accurate methods for calibrating the apparatus are acceptable.

5. SAMPLE PREPARATION

5.1. If an undisturbed sample is used, it should be large enough to provide a minimum of three similar specimens. Prepare the specimens so that moisture loss is negligible. Trim oversized specimens to the inside diameter of the direct shear device and to the length of the trimmer. Extreme care shall be taken in preparing undisturbed specimens of sensitive soils to prevent disturbance of their natural structure. Determine the initial mass of the specimen for subsequent use in determining initial moisture content.

5.2. If specimens of compacted soil are used, they shall be compacted to the moisture content and unit weight as prescribed in the test request. They may be compacted directly in the shear device, in a mold of equal dimensions and extruded into the shear device, or in a larger mold and trimmed as in Section 5.1.

5.3. Minimum specimen diameter for circular specimens, or width of rectangular (square) specimens, shall be approximately 50 mm (2.00 in.). For undisturbed samples, the diameter of the sampling tube shall be greater than the specimen diameter to reduce disturbance in the specimen and prevent lateral displacement (Note 4).

Note 4—The diameter of undisturbed test specimens cut from tube samples should be at least 6 mm (0.25 in.) less than the diameter of the sampling tube to minimize disturbance caused by sampling.

5.4. Minimum specimen thickness shall be approximately 13 mm (0.5 in.), but not less than six times the maximum grain diameter.

5.5. Minimum specimen diameter-to-thickness ratio shall be 2:1. For square or rectangular specimens, the minimum width-to-thickness ratio shall also be 2:1.

6. PROCEDURE

6.1. Assemble the shear box with the frames aligned and locked in position.

A light coating of grease between the frames may be used to ensure watertightness during consolidation and reduce friction during shear.

Teflon® spacers or Teflon®-coated surfaces may also be used to reduce friction during shear. Carefully insert the test specimen. Connect the loading devices. Position and/or activate the displacement indicators for measuring shear deformation and changes in specimen thickness. Determine the initial thickness of the specimen.

Note 5—The decision to dampen the porous stones before insertion of the specimen and before application of the normal force depends upon the problem under study. For undisturbed samples from below the water table, the porous stones are usually dampened. For swelling soils, wetting should probably follow application of the normal force to prevent swell not representative of field conditions.

6.2. Consolidate each test specimen under the appropriate normal force. As soon as possible after applying the initial normal force, fill the water reservoir to a point above the top of the specimen. Maintain this water level during the consolidation and subsequent shear phases so that the specimen is at all times effectively submerged. Allow the specimen to drain and consolidate under the desired normal force or increments thereof prior to shearing. During the consolidation process, record the normal displacement readings before each increment of normal force is applied and at appropriate times.[4] Plot the normal displacement readings against elapsed time. Allow each increment of normal force to remain until primary consolidation is complete. The final increment should equal the previous normal force developed and should produce the specified normal stress.

Note 6—The normal force used for each of the three or more specimens will depend upon the information required. Application of the normal force in one increment may be appropriate for relatively firm soils. For relatively soft soils, however, several increments may be necessary to prevent damage to the specimen. The initial increment will depend upon the strength and sensitivity of the soil. This force should not be so large as to squeeze the soil out of the device.

6.3. *Shear the Specimen*—After consolidation is complete, unlock the frames and separate them slightly (0.64 mm [0.025 in.]) so the specimen can be sheared. Apply the shearing force and shear the specimen slowly to ensure complete dissipation of excess pore pressure. The following guide for total elapsed time to failure (t_f) may be useful in determining rate of loading:

$t_f = 50\ t_{50}$

where:

t_{50} = time required for the specimen to achieve 50 percent consolidation under the normal force.

Note 7—If the normal displacement versus square root of time is used, t_{50} can be calculated from the time to complete 90 percent consolidation using the following expression:

$$t_{50} = \frac{t_{90}}{4.28}$$

where:

t_{90} = time required for the specimen to achieve 90 percent consolidation under the specified normal force.

4.28 = constant, relates displacement and time factors at 50 and 90 percent consolidation.

Note 8—If the material exhibits a tendency to swell, the soil must be saturated with water and must be permitted to achieve equilibrium under an increment of normal stress large enough to counteract the swell tendency before the minimum time to failure can be determined. The time-consolidation curve for subsequent normal stress increments is then valid for use in determining t_f.

Note 9—Some soils, such as dense sands and over-consolidated clays, may not exhibit well defined time-settlement curves. Consequently, the calculation of t_f may produce an inappropriate estimate of the time required to fail the specimen under drained conditions. For over-consolidated clays that are tested under normal stresses less than the soil's pre-consolidation pressure, it is suggested that a time to failure be estimated using a value of t_{50} equivalent to one obtained from normal consolidation time-settlement behavior. For clean, dense sands that drain quickly, a value of 10 minutes may be used for t_f. For dense sands with more than 5 percent fines, a value of 60 minutes may be used for t_f. If an alternative value of t_f is selected, the rationale for the selection shall be explained with the test results.

Note 10—The screws used for separating the frames should be retracted so they are not in contact with the lower frame before the shear force is applied. Also remove the pins or screws used for locking the frames together

Note 11—In a controlled-displacement test, the rate of displacement (d_r mm/min or in./min) may be determined approximately by dividing the estimated shear (lateral) deformation (d_f mm or in.) at maximum shear stress by the computed time to failure (t_f):

$$d_r = \frac{d_f}{t_f}$$

The magnitude of the estimated shear (lateral) displacement at failure is dependent on many factors, among them the type and the stress history of the soil. As a guide, use $d_f = 12$ mm (0.5 in.) if the material is normally or lightly over-consolidated fine-grained soil, otherwise use $d_f = 5$ mm (0.2 in.).

6.3.1. Compute the percent relative shear (lateral) displacement for each shear force reading.

6.3.2. Continue the test until the shear stress becomes essentially constant or until a shear deformation of 10 percent of original diameter has been reached. In a controlled-stress test, begin with shearing force increments equal to about 10 percent of the estimated maximum. Permit at least 95 percent consolidation before applying the next increment. When 50 to 70 percent of the estimated failure force has been applied to the specimen, reduce the increment to one-half the initial size or 5 percent of the estimated maximum shear stress. As failure is approached, use a series of increments equal to one-fourth the initial increment. Record the applied shear force and the shear and normal deformations at convenient intervals. A continuous buildup of shearing force would be preferable.

6.4. At the completion of the test, remove the entire specimen from the shear box, oven-dry it in accordance with T 265, Laboratory Determination of Moisture Content of Soils, and weigh it to determine the mass of solids.

7. CALCULATIONS

7.1. Measure initial moisture content, specific gravity, mass, and volume of the total specimen.

7.2. Based on these measured quantities, compute initial void ratio, wet and dry densities, and initial degree of saturation of the sample.

7.3. Calculate shear stress data (maximum shear stress, normal stress at failure, actual displacement rates, etc.).

7.4. Void ratio after consolidation, as well as after the shear test, is desirable.

7.5. Final degree of saturation.

8. REPORT

8.1. Description of type of shear device used in the test and components serial or lab numbers, if available. List also the PIN (Project Identification Number) and its exact location (county and municipality, route number, and mile marker).

8.2. Identification and description of sample, including tube or jar number, depth of retrieval, whether soil is undisturbed, remolded, compacted, or otherwise prepared, and noting any unusual features such as stratification and soil structure.

8.3. Initial moisture content and degree of saturation,

8.4. Dry mass (mass of solids), initial wet and dry density.

8.5. Initial sample dimensions (thickness, width, length, diameter, etc.).

8.6. All basic test data including normal stress, shear displacements and corresponding shear resistance values, specimen thickness changes, and specimen final dimensions. Include Atterberg limits and grain size data, if available.

8.7. Plot of maximum shear stress versus normal stress. For each test specimen, a plot of shear stress and specimen thickness change versus shear displacement.

8.8. Plot of nominal shear stress versus percent shear (lateral) displacement.

8.9. Plots of log of time or square root of time versus deformation of those load increments where t_{50} was determined in the time to failure calculations.

8.10. Final degree of saturation, final moisture content, final wet density (unit weight), final dry density (unit weight).

8.11. Departure from the procedure outlined, such as special loading sequences or special wetting requirements.

Standard Method of Test for

Measurements of Pore Pressures in Soils

AASHTO Designation: T 252-09

INTRODUCTION

The principal reasons for measuring pore pressures in highway construction are:

1. to monitor strength increases during construction;
2. to estimate remaining settlements after construction; and
3. to determine existing pore pressures in landslides.

This method consists of installing the pore water pressure measuring device in a soil layer at a point determined by detailed knowledge of the field conditions and theoretical evaluation of the need required. Pore pressure measurement may be made by determining the total pore pressure at the point or determining the differential pore pressure at that point relative to the surrounding normal groundwater table. The data are usually reduced to “excess” pore pressure, which is the difference between the measured pore pressure and the “normal” pore pressure under the general groundwater table for the area at the time of reading.

Interpretation of pore pressure measurements in the field are complicated by the variability both vertically and horizontally in the soils. Therefore, interpretation of any pore pressure measurement can be misleading if the complete soil profile, loading history, and detailed soil parameters are not adequately known.

1. SCOPE

1.1. This method covers procedures for determining field pore pressure measurements in the natural soils.

1.1.1. This does not include methods of pore pressure measurement in the laboratory or field installations in dams.

1.2. The values stated in SI units are to be regarded as the standard.

2. APPARATUS

2.1. *Open System*—The following equipment may be used to obtain pore pressure in soils of relatively high (Note 1) permeability:

Note 1—This equipment is also satisfactory for low-permeability soils.

2.1.1. A simple open observation well consisting of an open hole supported by plastic or metal casing if necessary.

2.1.2. A standard well point installation which consists of a screened well point on the end of standard pipe. Various screen lengths and openings are available for use in different situations.

2.1.3. The open well "Casagrande"-type (Hydraulic) piezometer which consists of a porous tip connected to a small diameter riser tube surrounded by filter (Ottawa) sand (100 percent passing 0.850-mm (No. 20) sieve, 100 percent retained on 0.425-mm (No. 40) sieve) and sealed in the bottom of a drilled hole. The tips are available in various sizes and porosities and may be made of ceramic filter stone, porous plastic, or porous metals. The riser tube may be plastic and for convenience in reading should have an inside diameter no smaller than 6.35 mm ($^1/_4$ in.).

2.2. *Closed Systems*—The following equipment may be used to obtain pore pressure in soils of low permeability (Note 2):

Note 2—This equipment is also satisfactory for high-permeability soils.

2.2.1. *Closed Casagrande-Type Piezometer*—This consists of a porous tip (as in Section 2.1.3) sealed into a soil layer and connected to the ground surface by a fluid filled tube (or tubes) connected to a gauge. The porous tip is installed at the bottom of a drilled hole and surrounded by filter (Ottawa) sand (100 percent passing 0.850-mm (No. 20) sieve, 100 percent retained on 0.425-mm (No. 40) sieve). The tubing may be 6.35 to 12.7 mm ($^1/_4$ to $^1/_2$ in.) or larger-diameter plastic or flexible metal. Clean water should be used to fill the tube. Where freezing is a problem, consider using a pneumatic or electrically operated piezometer. A Bourdon tube-type compound gauge (of sufficient capacity to accommodate the expected pore pressure change) should be used. The gauge should be calibrated for the conditions under which it will be used (position, temperature, etc.). This type system measures the differential water pressure between the surrounding groundwater table and the pressure within the soils system.

2.2.2. *Pneumatic Piezometer*—This consists of a pneumatic pressure transducer in a plastic or stainless steel case with a porous (ceramic, plastic, or metal) opening to allow the pore water to reach the transducer diaphragm. Two small-diameter plastic air leads are connected to the transducer. A supply of compressed air, bottle compressed, or liquified gas (clean and without moisture) is required to operate the transducer. An air pressure gauge of sufficient capacity to record the existing pressure at the depth of the piezometer tip plus the expected pore pressure is needed.

2.2.3. *Electrically Operated Piezometer*—This consists of a calibrated diaphragm (with a strain gauge attached) sealed in a plastic or stainless steel case, with one side open to the pore water through a porous filter. The strain gauge attached to the diaphragm may be resistance type or vibrating wire type. Pore pressure is obtained by use of an electrical readout system compatible with the type of strain gauge used.

3. INSTALLATION PROCEDURES

3.1. *Driven or Drilled in-Type Installations*:

3.1.1. *Open-Well Piezometers*:

3.1.1.1. *Open Hole*—Drive standard pipe (with disposable point) of suitable size and strength to reach the soil layer in which pore pressure is to be obtained. Pull back the pipe a sufficient distance to obtain pore pressure response and cap the pipe with a vented cap.

3.1.1.2. *Wellpoint*—Drive standard pipe (with suitable wellpoint attached) of suitable size and strength to reach the soil layer in which the pore pressure is obtained. The wellpoint may be of any size, length, and screen opening suitable for the soil in which it is installed. However, the largest diameter of the wellpoint shall not be greater than the diameter of the pipe coupling above it. Insert a suitable flexible hose through the pipe and into the wellpoint. Pump clean water through the hose to clean the wellpoint (and screen). Flushing should continue for about 5 minutes after the water flows clean out of the top of the pipe. Remove the hose and install a vented cap on the pipe.

3.1.1.3. *Low-Volume Change Wellpoint*—A small-diameter 9.5 to 12.7-mm ($^3/_8$ to $^1/_2$ in.) plastic tube is firmly sealed (by mechanical coupling or suitable glue) to a suitable wellpoint. The seal must be strong enough to withstand the total pore pressure without allowing leakage into the drive pipe. The wellpoint is attached to a standard pipe of sufficient size and strength to reach the soil layer in which pore pressure is to be measured. The pipe threads for the first 6.1 m (20 ft) of pipe shall be sealed with a suitable pipe sealing compound to prevent leakage through the pipe joints. The plastic tube is threaded through the pipe sections during driving. After driving, the tube is suspended (with sufficient tension to keep the tube straight) from the top of the pipe, and the pipe capped with a vented cap.

3.1.2. *Closed-System Piezometers*:

3.1.2.1. Closed-system piezometers may be driven into the proper soil layer in a manner similar to Section 3.1.1.3 above. Special filters and points may be used for special situations. Connections to standard pipe or standard drill rods are acceptable provided the seals are watertight for the pore pressures used and the diameter of the point does not exceed the diameter of the drill rod or the drive pipe. For Casagrande-type piezometers, the point and enough tubing to reach the ground surface shall be completely filled with clean water before start of driving. The upper end of the tube shall be sealed to prevent entrance or loss of water from the system during driving. No tubing connectors should be used in the vertical (Riser) tube.

3.1.2.2. *Surface Connections*—Closed-system piezometers which are to be extended vertically through the embankment fill may be extended in any manner suitable for the type of piezometer being installed provided that (1) adequate protection is provided, and (2) there is a method of recalibrating the pore pressure reading with each extension. Closed-system piezometers with remote readout shall be installed in the following manner:

- Excavate a trench 610 mm (2 ft) deep by 305 mm (1 ft) wide from the piezometer location to the readout protection box. The bottom of the trench shall be 610 mm (2 ft) min below future construction (ditches, pipes, etc.).
- The top of the drive pipe shall be removed to a point at least 1.52 m (5 ft) below ground surface. The tube (or leads) shall be centered over the pipe for at least 305 mm (1 ft) as sand is placed in the hole. The tube (or leads) shall then be coiled in a spiral approximately 610 mm (2 ft) diameter upwards to the bottom of a trench approximately 610 mm (2 ft) below ground surface as sand is placed loosely around it.
- The horizontal leads shall be layered in a zigzag pattern in the trench on a bed of 152 mm (6 in.) of clean sand. When more than one tube or lead is used in a trench, the lines shall not cross.
- All horizontal tubes or wires shall be checked for continuity, leakage, etc., before final connections are made to the vertical piezometer leads. If possible, the leads or tubes should be in one continual length with no connections, from the piezometer tip to the readout protection box.
- All electrical leads shall be immersed in clear water and the resistance checked. If there is any change in resistance upon immersion, the leads shall be discarded and replaced.
- The air leads for pneumatic piezometers shall be immersed in clear water and checked for leaks under pressures exceeding the expected pore pressure. Also, the air leads shall be flushed with high pressure air to clear any dust or moisture from the leads before final connections are made. The air used for flushing should come from a tank which holds only filtered air and which has been bled for excess moisture.
- The horizontal tubes for hydraulic piezometers shall be vacuum tested to 70 kPa (10 psi) of vacuum prior to filling the tubes with colored water. There shall be two horizontal tubes with

T connection to the vertical riser from the piezometer tip. The tubes shall be completely filled with colored fluid with the tubes in a configuration such that any air bubbles that occur during filling can be seen and removed. The preferable way of filling is to immerse one end in the colored fluid, seal the T at the rise with a plug, and apply a vacuum to the free end of the horizontal tube. Care must be taken to prevent the formation of air bubbles during filling operations. Once the tube is completely filled with fluid, the connections should be made at the readout box. The vertical riser from the piezometer tip shall then be filled with water and the plug removed from the horizontal tube T, and the connection between the vertical riser and the horizontal tubes shall be made underwater. The elevation of the T and the readout gauge must be determined prior to backfilling the trench.

3.2. *Piezometers Installed in Drill Holes*:

3.2.1. The following additional equipment is required for installation of drilled-in piezometers:

3.2.1.1. A tamping hammer, made of a 610-mm (2-ft) length of seamless steel tubing, 41.3-mm ($1^5/_8$-in.) O.D. and 15.9-mm ($^5/_8$-in.) I.D. or cast bronze of the same dimensions and having a mass of at least 11.3 kg (25 lb). These dimensions are for a 50.8-mm (2-in.) I.D. casing. Larger hammer dimensions are required for larger casing sizes. At the upper end, a loop of 3.2-mm ($^1/_8$-in.) diameter galvanized airplane cable should be firmly attached to the hammer and to a grooved ring. The inside surface of the hammer should be smooth and all edges that touch the tubing should be rounded. This hammer should be supplied with a 41.3-mm ($1^5/_8$-in.) diameter disc 12.7-mm ($^1/_2$-in.) thick which can be firmly attached to the bottom. This disc shall have a slot in the center (of suitable size to accommodate the size tubing or leads used) with rounded edges. This hammer-cable assembly is used for the following purposes:

- To tamp the bentonite layers and thereby assure a watertight seal between the casing and the risers.
- To center the risers while the bentonite seal is being tamped into place.
- To measure depths at various stages of the installation.

3.2.1.2. Galvanized preformed airplane cable 6.35-mm ($^1/_4$-in.) diameter of sufficient length to permit installation on the deepest piezometers. This should be securely fastened to one end of a snap-type swivel hook. Mark the cable at 1.52-m (5-ft) intervals, starting at the bottom face of the hammer.

3.2.1.3. A tripod and sheave for operating the tamping hammer.

3.2.1.4. Drive sample drilling equipment.

3.2.1.5. Ottawa sand or a thoroughly washed sand passing the 0.850-mm (No. 20) sieve and retained on 0.425-mm (No. 40) sieve.

3.2.1.6. Bentonite balls about 12.7 mm ($^1/_2$ in.) in diameter, which are formed at a water content somewhat above the plastic limit but below the sticky limit (i.e., at a putty-like consistency) rolled in talcum powder to prevent sticking, and stored in glass jars to protect them from drying, or the commercial pellets.

3.2.1.7. Rounded pebbles approximately 12.7 mm ($^1/_2$ in.) in diameter.

3.2.2. Drive casing, 50.8-mm (2-in.) I.D. or larger, to the approximate elevation of the bottom of the piezometer cell. The bottom 3.05-m (10-ft)-long section must be in one piece, without joints or couplings, and it is not to have a drive shoe on the lower end. The casing may be advanced by any means, except for the final 6.1 m (20 ft) of penetration. It shall then be advanced in 1.52-m (5-ft) increments, and the casing must be washed out after each 1.52-m (5-ft) advance. The casing shall be kept filled with water at all times and no washing below the casing will be permitted.

3.2.2.1. Obtain a spoon sample of the material for 305 mm (12 in.) below the bottom of the casing and deliver the samples in sealed jars to the engineer. Drive the casing 305 mm (12 in.) below the piezometer cell elevation and clean out the remaining soil to the bottom of the casing. Replace the water in the casing with clear water by reversing the flow of the pump and using the jet pipe as the intake, with the lower end of the pipe held a few centimeters above the bottom of the casing. Keep the casing filled with clean water and continue the operation until the return water becomes clear.

3.2.2.2. Pull the casing up 305 mm (1 ft) and pour clean sand into the casing to fill up the 305-mm (1-ft) hole. The top of the sand should be measured by a sounding device. Lower the assembly into the casing until the piezometer cell rests on the sand, and center the cell by lowering the tamping hammer to the top of the cell.

3.2.2.3. *Pneumatic piezometers*—Connect the air leads (in one continuous unspliced length, to extend 3.05 m (10 ft) above the ground surface) to the piezometer cell. The system should be checked for leaks and the air leads labeled or color coded before installation. The cell and readout gauge should be checked for accuracy by measuring the pore pressure (equal to the head of water in the casing) at several depths between the top of the casing and the installation depth. The leads should then be plugged to prevent entrance of dirt during the remainder of the installation.

- For electric piezometers: Connect the electric leads (in one continuous unspliced length to extend to 3.05 m (10 ft) above the ground surface) to the piezometer cell with watertight connections. The leads should be color coded or labeled before installation. The accuracy of the piezometer cell shall be checked as in Section 3.2.2.3 above.
- For hydraulic piezometers: Saturate the porous tip and fill the riser tube (in one continuous unspliced length to extend to 3.05 m (10 ft) above the ground surface) with clean water by immersing the porous tip in clean water and applying a vacuum to the tube. The tube should be checked for air bubbles and the top plugged. The porous tip shall only be removed from the clean water while being transferred to the filled casing.

3.2.3. Pull the casing up so that the bottom of the casing is 305 mm (1 ft) above the bottom of the cell (Note 3) and, at the same time, slowly (Note 4) pour a measured volume of clean sand into the casing so that the sand fills the space around the piezometer tip and to approximately 762 mm ($2^1/_2$ ft) above the bottom of the casing. Maintain tension on the tubing but do not permit any vertical movements of the piezometer tip.

Note 3—In areas where large foundation settlements are expected (over 914 mm (3 ft), the casing is not pulled above the piezometer tip, or the bottom of the casing can be perforated.

Note 4—If sand is poured too fast, it could fill the pipe such that when the pipe is pulled back, the tip would also move.

3.2.4. Form a 25.4-mm (1-in.) thick layer of 12.7-mm ($^1/_2$-in.) diameter pebbles on top of the sand in the casing and apply 20 blows to the pebble layer with a 152-mm (6-in.) drop of the hammer per blow.

3.2.5. Form a bentonite seal of five layers of bentonite balls, each 76.2-mm (3-in.)-thick layer placed and compacted as follows, while maintaining a constant tension on the tubing or leads.

3.2.5.1. Lower the water 76.2 mm (3 in.) below the top of the casing.

3.2.5.2. Drop bentonite balls individually into the casing until the water rises to the top of the casing and allow sufficient time for the balls to reach the bottom (about 1 minute for each 3.05 m (10 ft) of depth).

3.2.5.3. Drop enough 12.7-mm ($^1/_2$-in.)-diameter pebbles into the casing to form a layer 25.4-mm (1-in.) thick and allow sufficient time for the pebbles to reach the bottom.

3.2.5.4. Slip the tamping hammer over the plastic tubing and, keeping tensions on the tubing, apply 20 blows to the pebble layer with a 152-mm (6-in.) drop of the hammer per blow.

3.2.5.5. Repeat this procedure until a five-layer seal is formed. Whenever the tamper does not move freely, it should be immediately withdrawn and cleaned.

3.2.6. Pour enough sand into the casing to form a 610-mm (2-ft) layer of sand; cover with pebbles and compact with 20 blows of the hammer.

3.2.7. Repeat step in Section 3.2.5, forming another bentonite seal.

3.2.8. Disconnect the top section of the casing, so that the top of the casing is at least 1.52 m (5 ft) below the ground surface. This can be done by having the upper sections of casing tightened to a lesser degree than the lower sections of casing. Fill at least 3.05 m (10 ft) of the remainder of the casing with sand.

Note 5—An alternative to this would be complete withdrawal of the casing. In the event that it is decided to completely withdraw the casing, the following alterations will be necessary: casing must be pulled up enough to allow filling the space around the piezometer tip and to approximately 762 mm ($2^1/_2$ ft) above the piezometer tip (Section 3.2.3). Then the casing must be pulled up enough to allow forming the first five-layer bentonite seal (Sections 3.2.4 through 3.2.5.5), then pulled up enough to allow placing the 610-mm (2-ft) layer of sand atop the bentonite seal (Section 3.2.6), then pulled up enough to allow forming the second five-layer bentonite seal (Section 3.2.7). After completing the second bentonite seal, pull the casing up 305 mm (1 ft), add sand, and apply 20 blows with a 152-mm (6-in.) drop of the hammer per blow. Repeat 305 mm at a time until 1.52 m (5 ft) of sand has been placed above the second bentonite seal. Completely withdraw the casing.

Note 6—An alternative to forming the two five-layer bentonite seals is to backfill the piezometer hole with a flexible cement/bentonite grout.

3.2.9. Surface connections are made identical to those used for the driven installations for closed-system piezometers under Section 3.1.2.2.

3.3. *Pressed or Pushed in-Type Installation*:

3.3.1. Drill through any granular soil or very stiff clay overlying the clay layer in which the tip is to be installed with a casing or auger of a larger diameter than the drill rod or pipe to which the tip will be attached.

3.3.2. Fill the piezometer and enough tubing to extend from the tip elevation to above the ground surface with water.

3.3.3. Slowly press (use two pipe wrenches, hydraulic jack, etc.) the piezometer tip attached to drill rod or flush joint pipe into the clay, maintaining a slight flow of water through the tip with a small pump until within 6.1 m (20 ft) of tip elevation. At this point, disconnect the pump and continue pressing piezometer to desired tip elevation. Each time a section of drill rod must be added, the pump is disconnected and the end of the tubing plugged while tubing is threaded through next section of drill rod. This should be done as expeditiously as possible.

4. INTERPRETATION OF DATA

4.1. *Corrections to Pore Pressure Readings*:

4.1.1. *Open-well piezometers—water filled*:

4.1.1.1. The excess pore pressure is the difference between the elevation of the water in the well and the general water table elevation.

4.1.2. *Closed-system hydraulic Casagrande-type piezometers*.

4.1.2.1. The excess pore pressure is determined using the gauge reading and adding the differential water pressure between the elevation of the gauge and the elevation of the surrounding groundwater table.

4.1.3. *Pneumatic and electrical piezometers*—Most of these devices measure the total water pressure at a point, and therefore, the excess pore pressure in the soil is determined by subtracting the difference in elevation between the piezometer tip and the surrounding groundwater table from the gauge reading.

4.2. *Data Interpretation*:

4.2.1. Pore pressure measurements in soils are usually used to estimate the gain in shear strength or the settlement remaining under known conditions of loading. Since pore pressures are only an indirect measure of these characteristics, much care is needed to interpret the results with accuracy. The following information should be considered when interpreting pore pressures:

4.2.2. The total applied load and the rate of loading.

4.2.3. *The seasonal fluctuations of the surrounding groundwater table*—Observation wells (shallow and open-well piezometers) are required in the surrounding area. This is necessary where tidal waters are encountered. The number and location depends on the surrounding terrain.

4.2.4. The actual distribution of pore pressures in the soil deposit being monitored—both vertical and horizontal. This usually requires three or more piezometers at different levels and three or more at different distances from the center of loading.

4.2.5. *The soil parameters for the deposit being monitored*—This is usually obtained from extensive laboratory testing of undisturbed soil samples.

5. SPECIAL PROBLEMS

5.1. The following special problems occur with sufficient frequency to warrant discussion:

5.2. *Gas Lock*:

5.2.1. In many organic soils, the gas generated around the piezometer tip is sufficient to block entrance of the pore water through the filter into the measuring device. Where this is expected to be a problem, special piezometers are available with flushing devices to remove the gas from the piezometer tip.

5.3. *Large Settlements*:

5.3.1. In areas where large foundation settlements occur, numerous problems have developed.

5.3.1.1. Crimping of the riser tubes below the end of a permanent casing installation. This is eliminated by installing the piezometer inside the casing.

5.3.1.2. *Crimping of the riser at the top of the permanent casing*—This is eliminated by removing the top section of casing to about 1.52 m (5 ft) below ground surface and backfilling with sand.

5.3.1.3. *Stretching of the horizontal leads*—This is acceptable for most installations provided that no connections are made in the horizontal leads and the leads are made of materials having yield before rupture. Stretching of electrical leads may adversely affect the calibration of the circuits giving erroneous readings.

5.4. *Electronic Variations*:

5.4.1. The accuracy of electrical pore pressure measuring units may depend on the changes in temperature, elongation of the lead wires, and changes in diaphragm characteristics. Maintaining calibration is very difficult over long periods of time. Some special piezometer cells are available which reduce these problems.

5.5. *Closed System*:

5.5.1. Hydraulic piezometers often lose accuracy because of leaks in the tubing or gas generation (dissolved air). These conditions can be reduced by using “de-aired” water. Once air is in the system, it must be removed before accurate readings can be obtained. To remove the air, the two horizontal leads must be flushed with a different colored fluid (water) by applying a vacuum to one lead and providing a continuous fluid supply to the other lead. Air leaks on the readout device can be repaired, but air leaks underground can generally not be located or repaired.

Standard Method of Test for

Determining Expansive Soils

AASHTO Designation: T 258-81 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Expansive Soils

AASHTO Designation: T 258-81 (2008)

1. SCOPE

1.1. This standard covers a method to determine if a soil is expansive and methods to predict the amount of swell.

Note 1—Methods that are being used by various agencies to control the amount of swell are given in the appendix.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 87, Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test
- T 89, Determining the Liquid Limit of Soils
- T 90, Determining the Plastic Limit and Plasticity Index of Soils
- T 99, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop
- T 100, Specific Gravity of Soils
- T 216, One-Dimensional Consolidation Properties of Soils
- T 273, Soil Suction

3. DETECTING EXPANSIVE SOILS

3.1. The potential expansiveness of a soil may be determined by using the Atterberg Limits of the soil and the natural soil suction.

3.2. Using AASHTO Test Methods, the Liquid Limit (LL), the Plasticity Index (PI) and the soil suction at natural water content (τ_{nat}) are determined on a soil. From Table 1, determine how potentially expansive the soil is using the Liquid Limit, Plasticity Index, and the soil suction at natural water content.

Table 1—Determining Degree of Expansion in Soil

Degree of Expansion	LL	PI	τ_{nat}, tsf
High	>60	>35	>383 kPa
Marginal	50–60	25–35	144 to 383 kPa
Low	<50	<25	<144 kPa

4. DETERMINING THE AMOUNT OF SWELL

4.1. The amount of swell to be expected in a stratum is determined by one of the following described methods. Where more exacting determination of the amount of swell is needed, the Overburden

Swell Test Procedure should be used. Due to the length of time and costs required to perform the Overburden Swell Test, an empirical procedure called the Potential Vertical Rise Method may be used to estimate the swell where conditions do not require the more exact determination.

4.2. *Overburden Swell Test and Prediction Procedure*:

4.2.1. *Method 1*—Prepare an undisturbed sample for consolidation testing according to the procedure in T 216. Extreme care should be taken to prevent moisture loss during the preparation stage. From the sample trimmings, determine the field moisture content and the specific gravity of the soil. The field moisture is determined as a percentage of the mass of oven-dried soil and shall be calculated as follows:

$$\text{Percentage of Moisture} = \frac{\text{Mass of Water}}{\text{Mass of Oven} - \text{Dried Soil}} \times 100 \qquad (1)$$

The specific gravity of the soil is determined as outlined in T 100. After the sample has been placed in the consolidometer, a load equal to the existing overburden pressure is applied on the sample. This load shall be maintained until the dial gage of the extensometer indicates that all adjustment to the applied load has ceased. During the application of this load and adjustment period, extreme care must be exercised to prevent desiccation. It is extremely important not to lose any moisture from this sample. This may be accomplished by covering the consolidometer with moist cotton. This loading procedure returns the sample, as closely as possible, to the actual field void ratio and field condition since extrusion allows undisturbed samples to immediately rebound elastically. Actual field conditions are defined as Point One (1) in Figure 1. The sample is then inundated and allowed to reach an equilibrium as indicated by the dial gage of the extensometer. This condition then is defined as Point Two (2) in Figure 1. The sample then is unloaded to the desired pressure, in decrements of load that a laboratory normally uses, thus producing a swell curve from Point Two (2) to Point Three (3) in Figure 1. From this point (Point 3, Figure 1), a normal consolidation-rebound test is conducted as outlined in T 216. The swell-curves form approximately straight lines on a semi-log plot; therefore, the No-Volume Change pressure is determined by extrapolating the swell curves between Points 2 and 3 until it intersects the Field Void Ratio as Point Four (4). The Field Void Ratio (e_f) is determined as follows:

$$e_f = \frac{\text{Percent Field Moisture} \times \text{Specific Gravity}}{\text{Percent Saturation}} \qquad (2)$$

4.2.2. *Method II*—This method is presented because there may be a need to expedite the work and the existing overburden load may be so small that obtaining swell curves directly may be meaningless. This method may be used only after running several tests by Method I and finding that the slope of the rebound curve, Points Five (5) and Six (6), is substantially the same as the slope of the swell curve, Points Two (2) and Three (3). Method II is the same as Method I to the point where the sample is inundated and the total swell is recorded. At this point, a normal consolidation-rebound load sequence is followed to produce the desired curves. Since the slope of the rebound and swell curves is substantially the same, the swell curve can be produced by passing a curve through Point Two (2), Figure 1 that is parallel to the rebound curve. The intersection of this curve with the Field Void Ratio gives the point of No-Volume Change or maximum swell pressure potential.

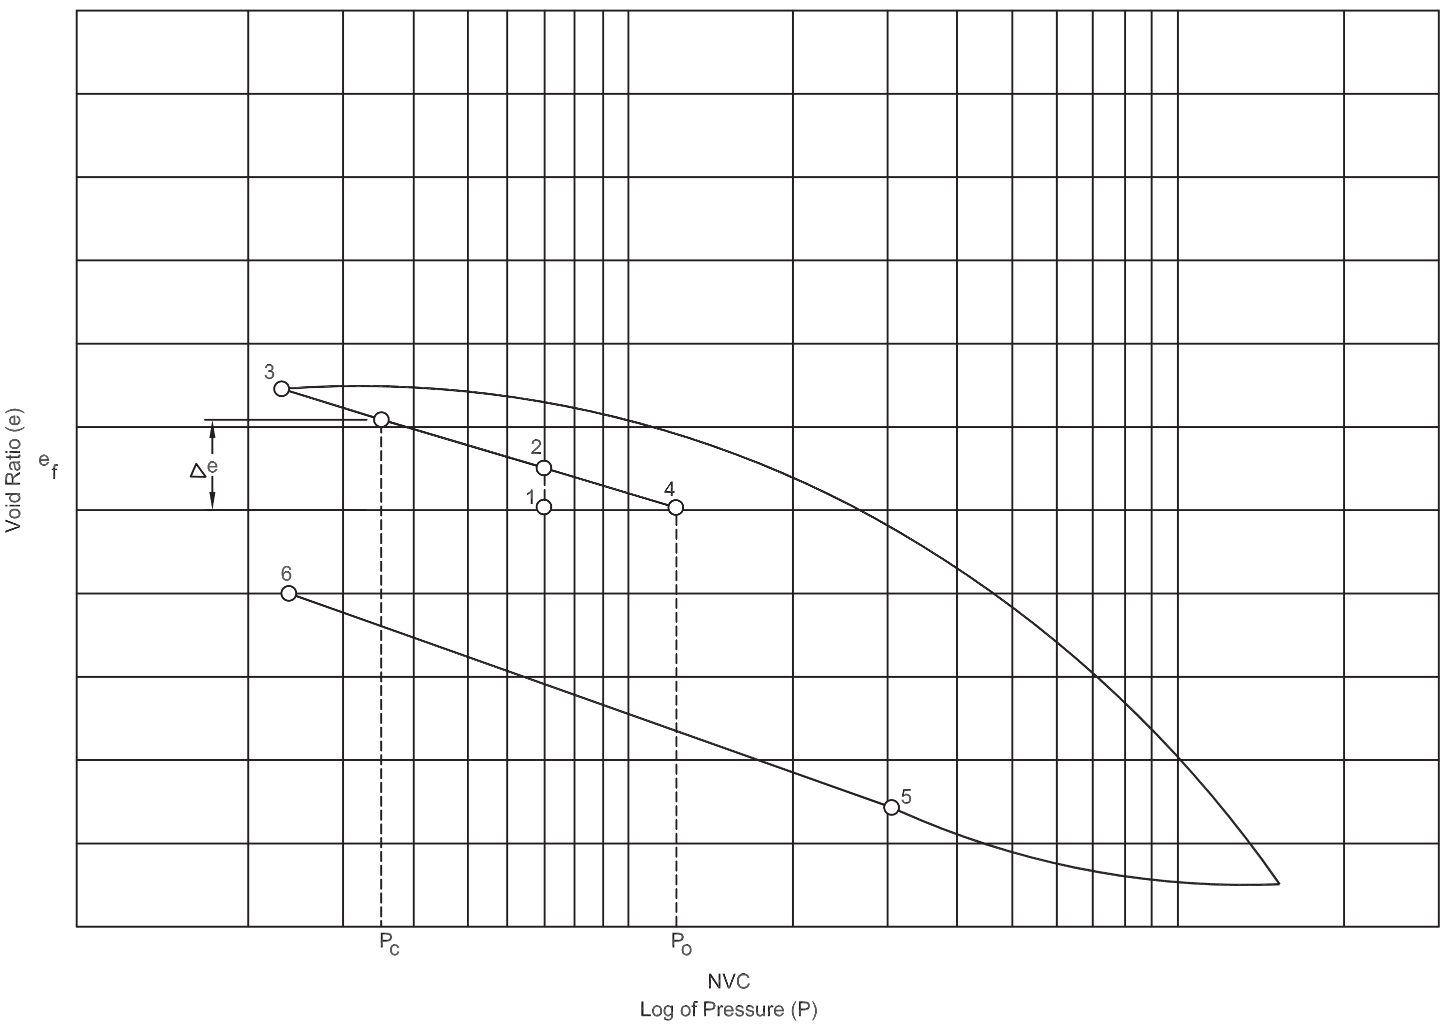

Figure 1—Design Example of Void Ratio Versus Log of Pressure

4.2.3. *Calculations*—Calculation for the amount of swell to be expected in a stratum can be made as follows:

$$S = \frac{eH}{1 + e_f} \tag{3}$$

where:

S = amount of swell in mm (in.),

e = difference in void ratio between existing overburden pressure (no-volume change load) and the desired overburden pressure,

H = thickness of stratum in mm (in.), and

e_f = field void ratio.

4.3. *Potential Vertical Rise (PVR) Test and Prediction Procedure*:

4.3.1. For this procedure, it is necessary to know the moisture content of each layer sampled. It is preferable that moisture samples be taken at the time of sampling. These moisture samples can be taken from cores that have been moisture sealed.

4.3.2. When cores have been taken, determine the wet density by trimming the cores to make right circular cylinders, measuring height and diameter, to the nearest 0.25 mm, determining the mass to the nearest estimated 0.5 g and calculating. When cuttings only are taken during sampling, use a wet density of 2002 kg/m^3, which is usually a reasonable value.

4.3.3. From representative portions of the cuttings or cores, determine the Liquid Limit, Plasticity Index, and percent soil binder [minus 0.425-mm (No. 40) sieve] in the soil layers. Record these results on Table 3 at the appropriate layer.

													Total PVR = 61.4[a]			
[b]6.0–9.6	131 to 214	80	25.0	39.6	33.9	Avg	100	54	12.6	16.0	123.9	135.6	11.7	1.00	1.00	11.7

[a] 2002 Kilograms per cubic meter wet density assumed for all layers. When greater accuracy is desired, use $\frac{2002}{\text{Actual Wet Density of Soil, kg/m}^3}$ as the modifier.

[b] Note: Since the 3.6-m layer from 6.0–9.6 m is uniform, the PVR may be determined in one reading by using the "top of the layer" as 131 kPa (as in 0.6-m layers) and reading the bottom of the layer at 214 kPa load as in the 9.0–9.6m layer. Readings of 123.9 mm and of 135.6 mm, respectively, or a difference of 11.7 mm will be obtained, which is the summation of increments (differences) as shown above for the bottom 3.6 m.

When layers of expensive clays of less than 0.6 m exist (example 1.2–1.4), it is preferable to enter the abscissa on the proper swell curve at 1.2 and 1.4 curve and use the difference in the respective ordinate readings as the unmodified swell in the 0.2-m thick layer.

[c] See example in Figure 2.

4.3.4. Beginning with the top layer at the surface of the ground from the drilling log (Table 2), start compilation of Table 3. Determine whether the layers are "wet," "dry," or "average."

Note 2—It has been determined that 0.2 LL + 9 is the "dry" condition from which little shrinkage is experienced, but where volumetric swell potential is greatest. It is the minimum moisture content swelling clays usually dry to 0.47 LL + 2, or "wet" condition, corresponds to the maximum capillary absorption by laboratory tests on specimens molded at optimum moisture and surcharged with a 7-kPa load. This is also analogous to moisture contents found beneath old pavements and other lightweight structures. This is the "optimum" condition.

4.3.5. Using Figure 2 and the wet, dry, or average moisture condition, find the PI of the first soil layer on the abscissa. Move vertically upwards to the appropriate swell curve (dry, average, or wet) and read the percent volumetric change on the ordinate. This percent volumetric change was determined for 7-kPa surcharge.

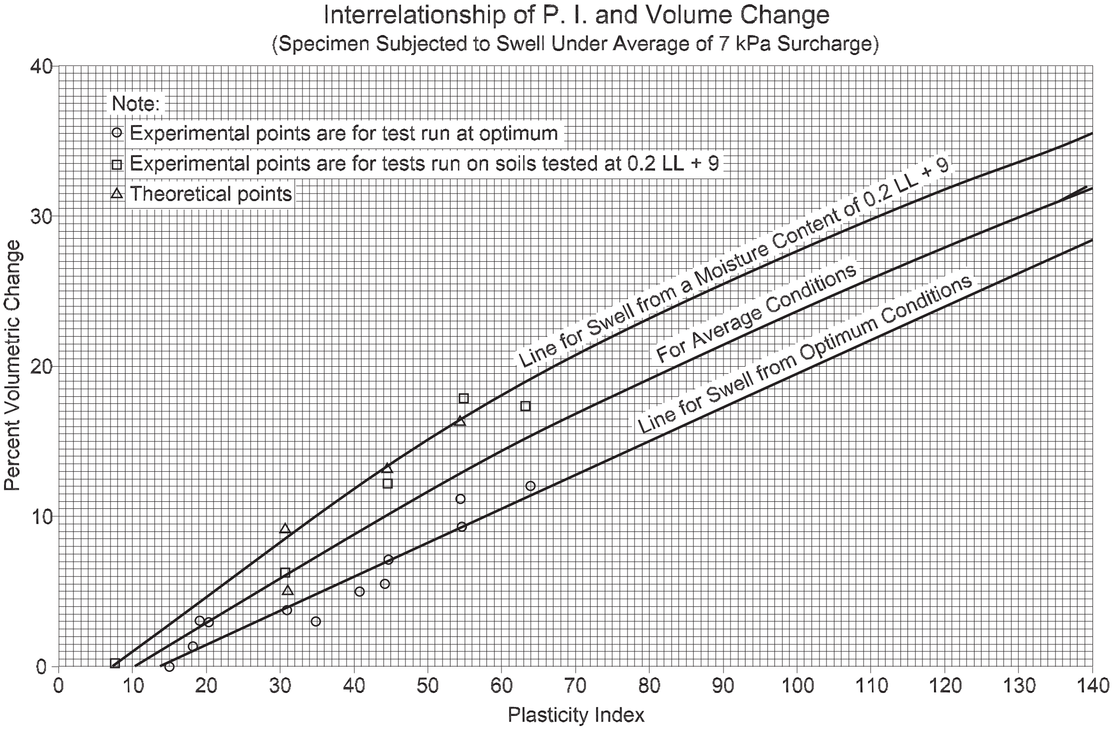

Figure 2—Interrelationship of Plasticity Index and Volume Change

Note 3—The PVR versus Load Curves in Figures 3 and 4 are for free swelling clays under no load and are based on a wet density of soil of 2002 kg/m^3. In order to use the curves in Figures 3 and 4, it has been determined that under the conditions of free swell and the percent volumetric swell at 7-kPa surcharge given in Figure 2, the following relationship exists:

Percent volumetric swell @

No load = percent volumetric swell @ [7 kPa (1 psi)] × (1.07) + 2.6

Example: From Figure 2, the swell @ 7 kPa = 10

Percent at no load or free swell = 10 × (1.07) + 2.6 = 10.7 + 2.6 = 13.3

These curves may have to be penciled in on Figures 3 or 4 for accurate readings.

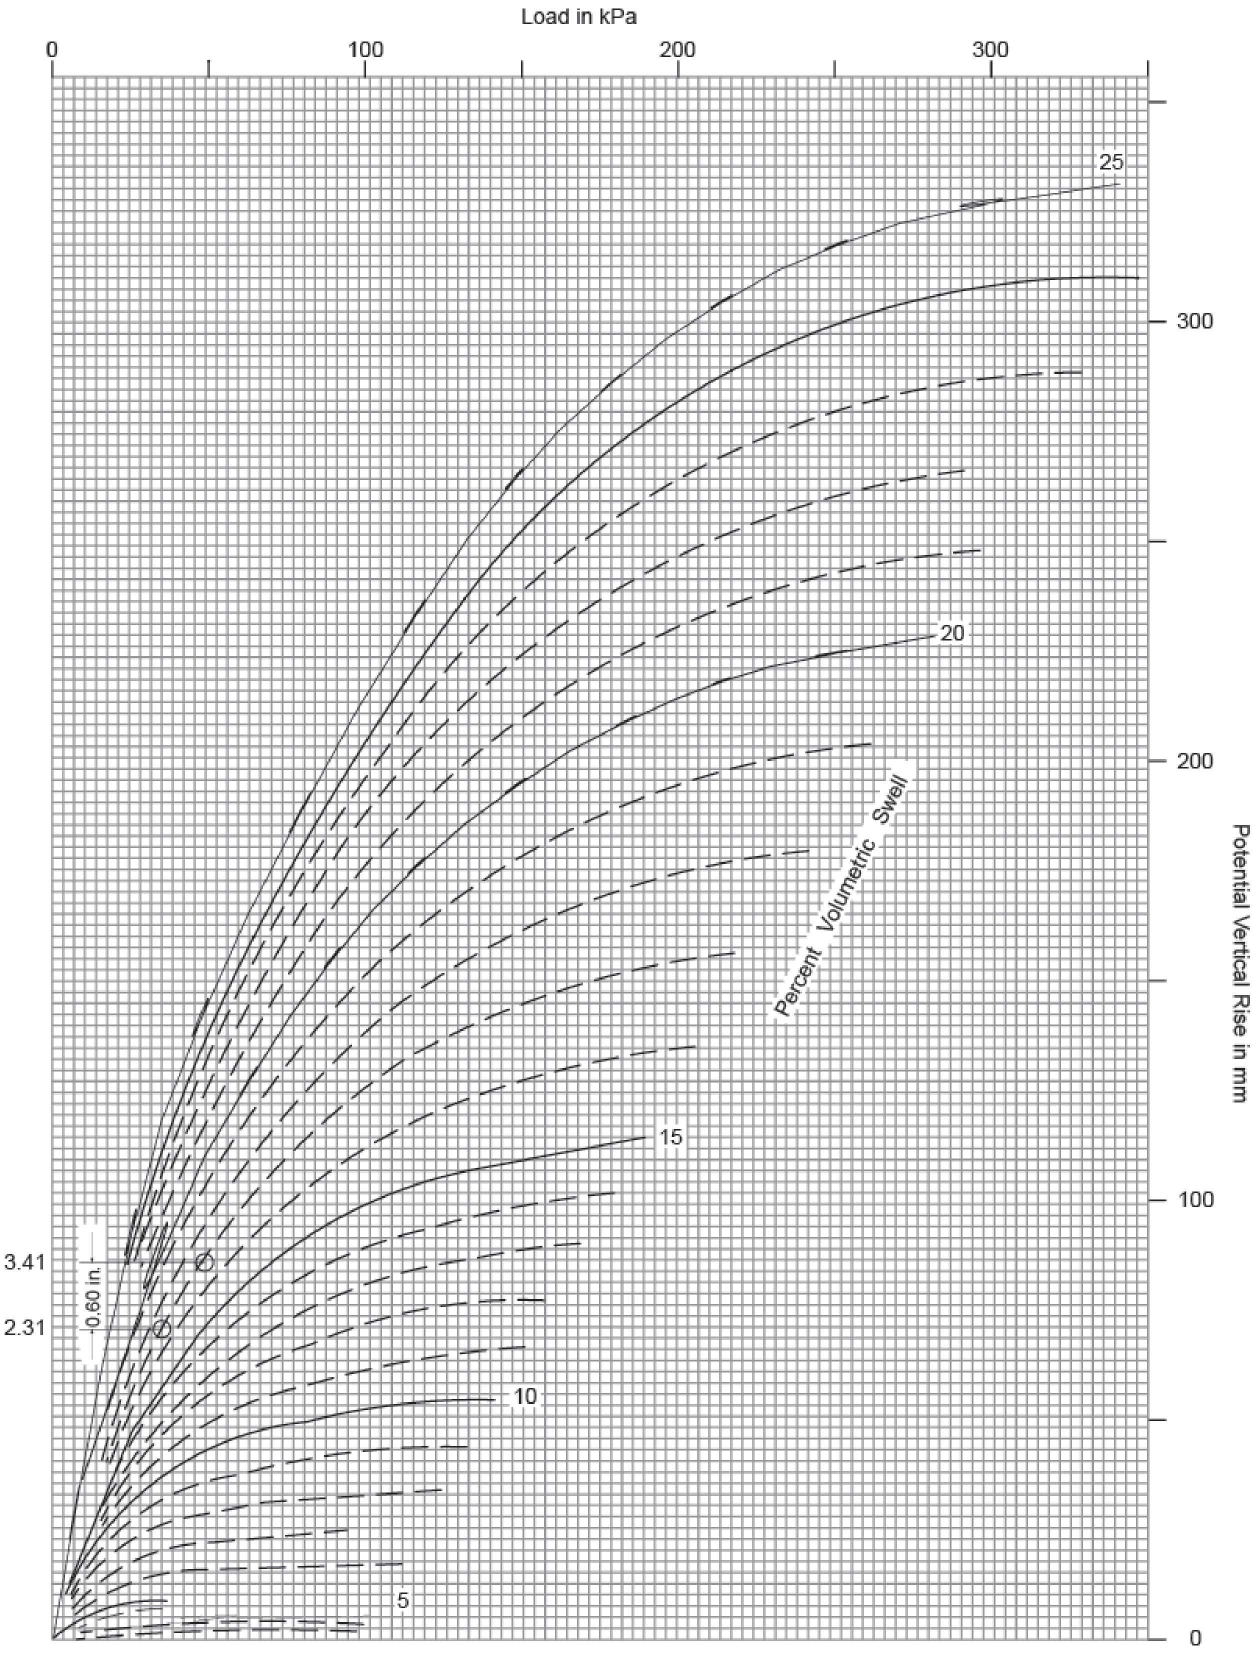

Figure 3—Potential Vertical Rise Versus Load Curves for Free Swelling Clays

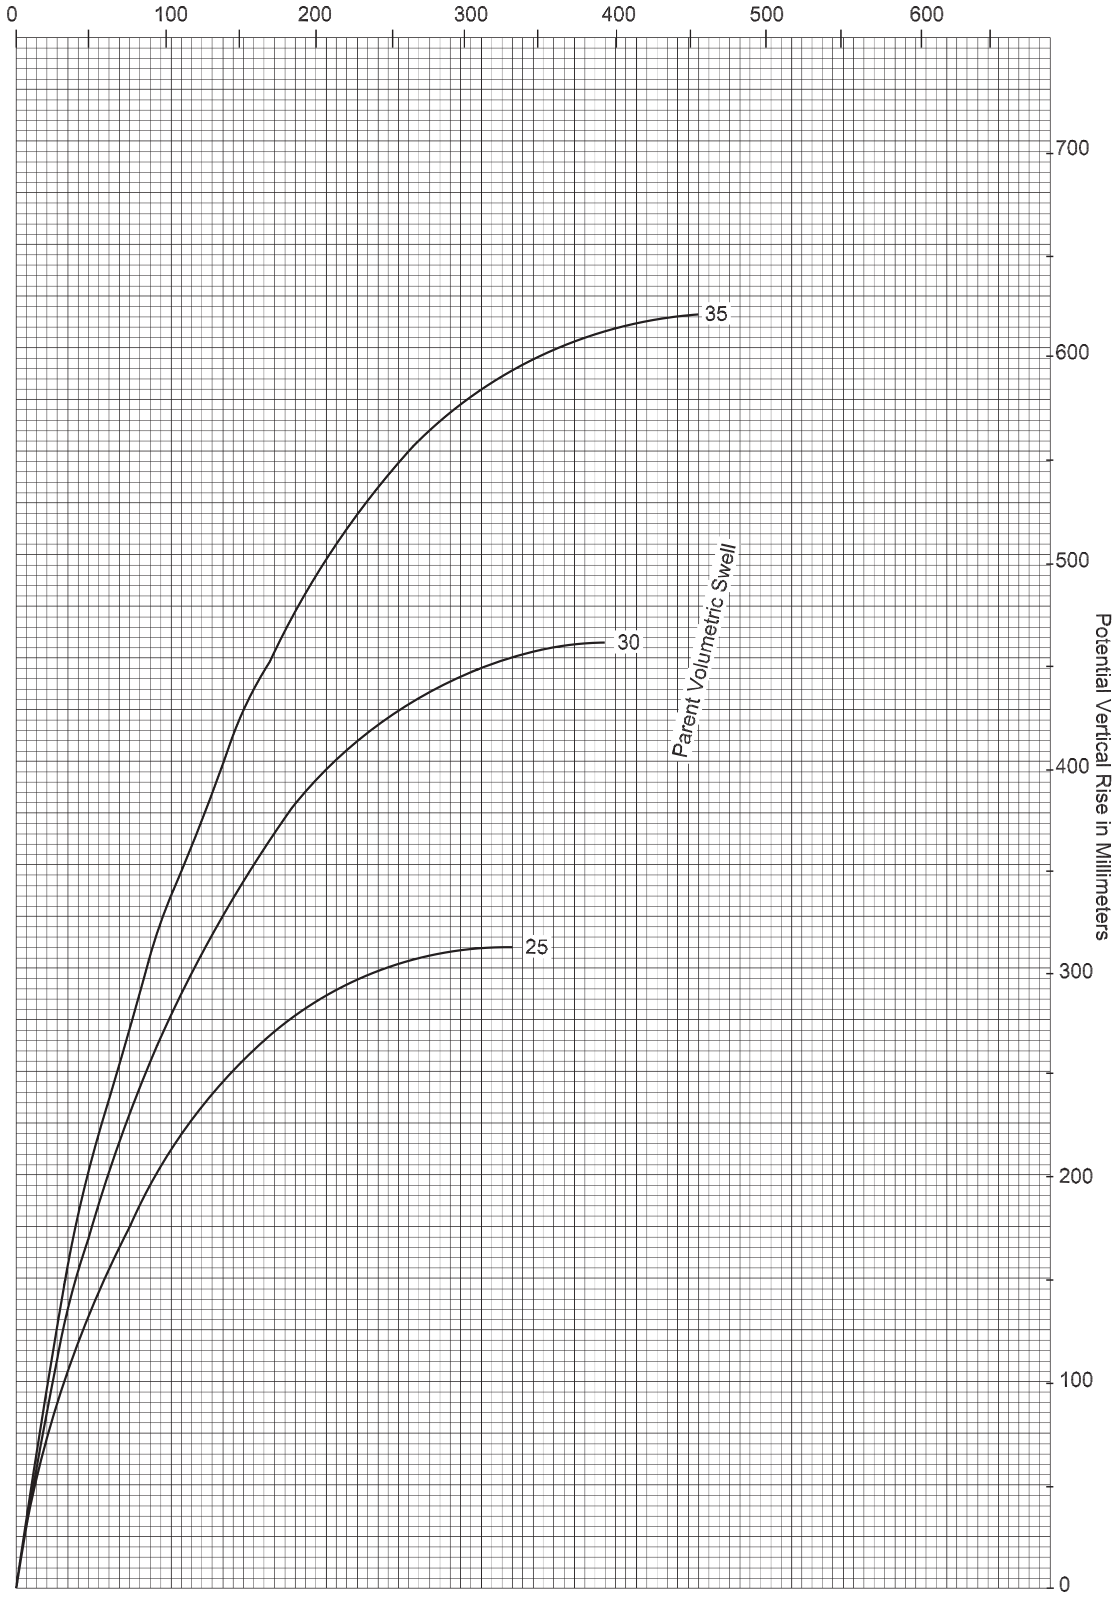

Figure 4—Potential Vertical Rise Versus Load Curves for Free Swelling Clays

4.3.6. In calculating the potential vertical rise, it is convenient or preferable to use 0.6-m elements or layers, provided the moisture contents and the log of the hole will permit. The use of 0.6-m layers and the assumption of 2002 kg/m^3 wet density, which is usually a reasonable wet density, make the tabulation simpler. The modification caused by using 2002 kg/m^3 rather than 2307 kg/m^3 for 7 kPa per meter has already been incorporated into the curves on Figures 3 and 4. Where wet densities vary from 2002 kg/m^3 and greater accuracy is desired, a modification factor should be applied to that layer equivalent to 2002 divided by the actual wet density.

Note 4—In the 0.6-m layer at the surface, the "average" load in the layer is 7 kPa; likewise, in the 0.6 to 1.2-m layer, the kPa load is 14 kPa for the top 0.6 m plus one-half of the 0.6 to 1.2-m layer, or 21 kPa total. Therefore, the average load in any 0.6-m layer is the average depth of the layer (subject to the correction factor as described above).

4.3.7. Using the percent minus 0.425-mm (No. 40) sieve column, PVR subsequently determined shall be modified as follows:

- Use zero swell where the percent minus 0.425 mm is less than 25 percent.
- Multiply the swell obtained for the layer by the percent minus 0.425 mm when the percentage exceeds 25 percent.

4.3.8. Then using Figure 2, determine the percent Volumetric Swell in the first layer (0 to 0.6 m). Since this swell is determined using 7 kPa surcharge, it must be modified for free swell, or no surcharge, as given in Note 3. Using Figures 3 and 4, and the percent free swell curve, just determined, begin to compile the swell in the layer.

- In the 0 to 0.6-m layer, read the ordinate (PVR) at the 7 kPa load from the swell curve and record on Table 3 as "bottom of layer."
- From the curve, read the "top of the layer" load of zero in the case of this layer, and record on Table 3.
- The difference in these two readings is the PVR in the first 0.6-m layer, subject to modification for density correction from Section 4.3.6 and for soil binder (minus 0.425-mm) correction from Section 4.3.7.

4.3.9. Take the 0.6 to 1.2-m layer and determine the percent Volumetric Swell by modifying the value determined from Figure 2. On this percent Volumetric Swell curve, or a sketched-in pencil curve if the line is not actually on Figures 3 or 4, read the PVR on the ordinate corresponding to 21 kPa (bottom of layer) and record on Table 3. Read the ordinate corresponding to 7 kPa (top of layer) from the same curve and record. The difference in the two readings is the swell in the 0.6 to 1.2-m layer subject to any density or soil binder (minus 0.425-mm) modifications.

4.3.10. Continue determination of PVR in each 0.6-m layer until each swelling layer has been determined as shown by the curves on Figures 3 and 4. Each curve should level out and indicate no difference when PVR is read from that curve. (Actually the swell is negligible or zero anywhere beyond the end of any given curve as shown on these two figures.) Thicker layers may be used in this calculation where they consist of uniform soil having a similar PI and moisture contents.

4.3.11. Check each layer for modification for density factor and soil binder.

4.3.12. Add the PVR in all layers to obtain the total PVR for the site.

Note 5—Table 3 has been calculated for no loading due to the structure. When unit loadings due to the structure are known, then simply add it in "Average load, kPa," and increase each figure in the column by the amount of the structure unit load, but note that the swell will be reduced because of increased loading.

4.3.13. To report the test results, submit a copy of Table 3 with appropriate job and site identifications.

Note 6—Often, during design, it is necessary to estimate PVR without knowing moisture contents anticipated at the time of construction. In cases of this kind, the design and planning of a job should influence the choice of line on Figure 2 to be selected for use. If the project exists in an arid to semiarid climate and the plans and specifications do not provide for moisture-density control or preservation of moisture, it is suggested that the line for 0.2 LL + 9 be used. If the plans and specifications do require moisture-density control and moisture preservation, the average line may be used.

In high rainfall areas, the average line may be used where moisture preservation is provided for, but if moisture-density-control and moisture preservation are provided for, the lower line (0.47 LL + 2) on Figure 1 may be used.

The term *moisture preservation* refers to the use of *blanket sections* with wide shoulders consisting of granular materials, stabilized soils, or where asphalt membranes are applied for this purpose.

APPENDIX

(Nonmandatory Information)

X1. PREVENTION OR REMEDIAL METHODS PRESENTLY BEING USED TO CONTROL THE AMOUNT OF SWELL

X1.1. All preventive methods are directed to keeping the moisture content of swelling soils constant. Without moisture change, these soils are generally stable. Four possible methods are as follows:

X1.1.1. *Membranes*—The most widely used membrane is a catalytically blown asphalt that is generally placed completely across the subgrade to the bottom of side ditches and up the back slope to a vertical distance of 457 mm. There are other waterproof membranes that have been used in the same mode as the asphalts. The most popular of these is a plastic sheet with joints sealed by some means such as liquid asphalts.

X1.1.2. *Ponding*—Ponding has been used successfully in soils that had fissures and cracks. The idea is to obtain all the swell possible before paving. Generally, lime stabilization is used in conjunction with ponding to provide a work platform and an impermeable barrier to prevent desiccation.

X1.1.3. *Lime Treatment*—It appears that lime continues to be the most effective and widely used additive for reducing swelling characteristics of expansive clays. In addition to conventional shallow mix-in-place or batch mix surface treatment drill-hole lime, LSPI, and deep-plow techniques have been used successfully. The benefits from drill-hole lime are the increase in moisture content of the surrounding subgrade and stress relief of lateral expansive pressures. The benefits obtained from Lime Slurry Pressure Injection (LSPI) are attributed to prewetting, development of soil-lime moisture barriers, and the formation of limited quantities of soil-lime reaction products.

X1.1.4. *Mix and Compact*—The mixing and compaction of the subgrade to various depths with moisture-compaction control has been effective. Generally, compaction is specified to be 95 percent of T 99. The moisture specified is optimum or above.

Note X1—The determination of PVR in deep-cut sections or deep side-hill cuts presents a special case of this test method. In the case of these two conditions, the material is surcharged in such a manner that the movement from swell is mostly in one direction, and in some high rainfall areas could be greater than that obtained by use of these procedures.

Note X2—When layers of expansive clays of less than 0.6 m exist (example: 1.2 to 1.4 m), it is preferable to enter the abscissa on the proper swell curve at 1.2 and 1.4, respectively, and use the difference in the respective ordinate readings as the unmodified swell in the 0.2-m thick layer.

Note X3—At optimum conditions, the following relationships are valid from Figure 2:

1. Percent volumetric swell @ 7 kPa surcharge = 0.217 (PI) – 2.9
2. Percent free swell = 0.232 (PI) – 0.5.

Standard Method of Test for

Laboratory Determination of Moisture Content of Soils

AASHTO Designation: T 265-93 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Laboratory Determination of Moisture Content of Soils

AASHTO Designation: T 265-93 (2008)

1. SCOPE

1.1. This method covers the laboratory determination of the moisture content of soils.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with E 29, Using Significant Digits in Test Data to Determine Conformance with Specifications.

2. DEFINITION

2.1. *moisture or water content of a soil*—the ratio, expressed as a percentage, of the mass of water in a given mass of soil to the mass of the solid particles. Practical application is to determine the mass of water removed by drying the moist soil to a constant mass in a drying oven controlled at 110 ± 5ºC (230 ± 9ºF) and to use this value as the mass of water in the given soil mass. The mass of soil remaining after oven-drying is used as the mass of the solid particles.

3. APPARATUS

3.1. *Drying Oven*—Thermostatically controlled, preferably of the forced-draft type, capable of being heated continuously at a temperature of 110 ± 5ºC (230 ± 9ºF).

3.2. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

3.3. *Containers*—Suitable containers made of material resistant to corrosion and not subject to change in mass or disintegration on repeated heating and cooling. Containers shall have close-fitting lids to prevent loss of moisture from samples before initial weighing and to prevent absorption of moisture from the atmosphere following drying and before final weighing. One container is needed for each moisture content determination.

4. TEST SAMPLE

4.1. Select a representative quantity of moist soil in the amount indicated in the method of test. If no amount is indicated, the minimum mass of the sample shall be in accordance with the following table:

Maximum Particle Size	Minimum Mass of Sample, g
0.425-mm (No. 40) sieve	10
4.75-mm (No. 4) sieve	100
12.5-mm (1/2 in.)	300
25.0-mm (1 in.)	500
50-mm (2 in.)	1000

5. PROCEDURE

5.1. Weigh a clean, dry container with its lid and place the moisture content sample in the container. Replace the lid immediately and weigh the container, including the lid and the moist sample. Remove the lid and place the container with the moist sample in the drying oven maintained at a temperature of 110 ± 5ºC (230 ± 9ºF) and dry to a constant mass (Notes 1 and 2). Immediately upon removal from the oven, place the lid and allow the sample to cool to room temperature. Weigh the container including the lid and the dried sample (Notes 3 and 4).

Note 1—Checking every moisture content sample to determine that it is dried to a constant mass is impractical. In most cases, drying of a moisture content sample overnight (15 or 16 hours) is sufficient. In cases where there is doubt concerning the adequacy of overnight drying, drying should be continued until the mass after two successive periods of drying indicates no change in mass. Samples of sand may often be dried to constant mass in a period of several hours. Since dry soil may absorb moisture from wet samples, dried samples should be removed before placing wet samples in the oven.

Note 2—Oven-drying at 110 ± 5ºC (230 ± 9ºF) does not result in reliable moisture content values for soil containing gypsum or other minerals having loosely bound water from hydration or for soil containing significant amounts of organic material. Reliable moisture content values for these soils can be obtained by drying in an oven at approximately 60ºC (140ºF), or by vacuum desiccation at a pressure of approximately 10 mm Hg and at a temperature not lower than 23ºC (73ºF).

Note 3—A container without a lid may be used provided the moist sample is weighed immediately after being taken, and provided the dried sample is weighed immediately after being removed from the oven or after cooling in a desiccator.

Note 4—Moisture content samples should be discarded and should not be used in any other tests.

6. CALCULATION

6.1. Calculate the moisture content of the soil as follows:

$$w = \left[\left(\text{mass of moisture}\right)/\left(\text{mass of oven-dry soil}\right)\right] \times 100 = \left[\left(W_1 - W_2\right)/\left(W_2 - W_c\right)\right] \times 100 \quad (1)$$

where:

w = moisture content, percent;

W_1 = mass of container and moist soil, g;

W_2 = mass of container and oven-dried soil, g; and

W_c = mass of container, g.

6.2. Calculate the percent of moisture content to the nearest 0.1 percent.

Standard Method of Test for

Determination of Organic Content in Soils by Loss on Ignition

---

AASHTO Designation: T 267-86 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determination of Organic Content in Soils by Loss on Ignition

AASHTO Designation: T 267-86 (2008)

1. SCOPE

1.1. The "Loss on Ignition" method for the determination of organic content is most applicable to those materials identified as peats, organic mucks, and soils containing relatively undecayed or undecomposed vegetative matter or fresh plant materials such as wood, roots, or grass, or carbonaceous materials such as lignite, coal, etc. This method determines the quantitative oxidation of organic matter in these materials and gives a valid estimate of organic content. The Wet Combustion method (T 194) is recommended when it is desired to determine the humus-like easily oxidized organic material to provide information relating to the suitability of a soil for plant growth.

1.2. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 87, Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test
- T 194, Determination of Organic Matter in Soils by Wet Combustion

2.2. *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. APPARATUS

3.1. *Oven*—Drying oven capable of maintaining temperatures of 110 ± 5°C (230 ± 9°F). Gravity, instead of blower convection, may be necessary when drying lightweight material.

3.2. *Balance*—The balance shall have sufficient capacity and conform to M 231, Class G 1.

3.3. *Muffle Furnace*—The furnace shall be capable of maintaining a continuous temperature of 455 ± 10°C (833 ± 18°F) and have a combustion chamber capable of accommodating the designated container and sample. A pyrometer recorder shall indicate the temperature while in use.

3.4. *Crucibles or Evaporating Dishes*—High silica, alundum, porcelain, or nickel crucibles of 30 to 50-mL capacity or Coors porcelain evaporating dishes approximately 100-mm top diameter.

3.5. *Desiccator*—A desiccator of sufficient size containing an effective desiccant.

3.6. *Containers*—Suitable rustproof metal, porcelain, glass, or plastic-coated containers.

3.7. *Miscellaneous Supplies*—Asbestos gloves, tongs, spatulas, etc.

4. SAMPLE PREPARATION

4.1. A representative sample with a mass of at least 100 g shall be taken from the thoroughly mixed portion of the material passing the 2.00-mm (No. 10) sieve that has been obtained in accordance with T 87.

4.2. Place the sample in a container and dry in the oven at 110 ± 5°C (230 ± 9°F) to constant mass. Remove the sample from the oven, place in the desiccator, and allow to cool.

Note 1—This sample can be allowed to remain in the oven until ready to proceed with the remainder of the test.

5. IGNITION PROCEDURE

5.1. Select a sample with a mass of approximately 10 to 40 g, place into tared crucibles or porcelain evaporating dishes, and determine the mass to the nearest 0.01 g.

Note 2—Sample masses for lightweight materials such as peat may be less than 10 g but should be of sufficient amount to fill the crucible to at least $^3/_4$ depth. A cover may initially be required over the crucible during the initial phase of ignition to decrease the possibility of the sample being “blown out” from the container.

5.2. Place the crucible or dish containing the sample into the muffle furnace for 6 hours at a temperature of 455 ± 10°C. Remove the sample from the furnace, place into the desiccator, and allow to cool.

5.3. Remove the cooled sample from the desiccator and determine the mass to the nearest 0.01 g.

6. CALCULATION

6.1. The organic content shall be expressed as a percentage of the mass of the oven-dried soil and shall be calculated as follows:

$$\text{Percent Organic Matter} = \frac{A-B}{A-C} \times 100 \qquad (1)$$

where:

A = mass of crucible or evaporating dish and oven-dried soil, before ignition;

B = mass of crucible or evaporating dish and oven-dried soil, after ignition; and

C = mass of crucible or evaporating dish, to the nearest 0.01 g.

6.2. Calculate the percentage of organic content to the nearest 0.1 percent.

Standard Method of Test for

Family of Curves - One-Point Method

AASHTO Designation: T 272-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Family of Curves - One Point Method

AASHTO Designation: T 272-10

1. SCOPE

1.1. These methods of tests are for the rapid determination of the maximum density and optimum moisture content of a soil sample utilizing a family of curves and a one-point determination.

1.2. One-point determinations are made by compacting the soil in a mold of a given size with a 2.5-kg (5.5-lb) rammer dropped from a height of 305 mm (12 in.). Four alternate procedures are provided as follows:

- *Method A*—A 101.6-mm (4-in.) mold; soil material passing a 4.75-mm (No. 4) sieve. Sections 5 and 6.
- *Method B*—A 152.4-mm (6-in.) mold; soil material passing a 4.75-mm (No. 4) sieve. Sections 7 and 8.
- *Method C*—A 101.6-mm (4-in.) mold; soil material passing a 19.0-mm ($^3/_4$ in.) sieve. Sections 9 and 10.
- *Method D*—A 152.4-mm (6-in.) mold; soil material passing a 19.0-mm ($^3/_4$ in.) sieve. Sections 11 and 12.

1.3. The methods described herein correspond to the methods in T 99 and must be chosen accordingly; that is, when moisture-density relationships as determined by Method C of T 99 are used to form the family of curves, then Method C described in this procedure must be used for the one-point determination (Note 1).

Note 1—Direct reference to T 99 is made throughout these test methods, and most terminology, apparatus, and procedures are the same.

1.4. In addition, the concepts described herein are applicable to one-point determinations and moisture-density relationships as specified in T 180, with appropriate apparatus and method used as required.

1.5. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with the rounding-off method of ASTM E 29.

1.6. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

2.2. *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. DEFINITION

3.1. A family of curves is a group of typical soil moisture-density relationships determined using T 99, which reveal certain similarities and trend characteristic of the soil type and source. Soils sampled from one source will have many different moisture-density curves, but if a group of these curves are plotted together, certain relationships usually become apparent. In general, it will be found that higher unit mass soils assume steeper slopes with maximum dry densities at lower optimum moisture contents, while the lower unit mass soils assume flatter, more gently sloped curves with higher optimum moisture contents (Figure 1).

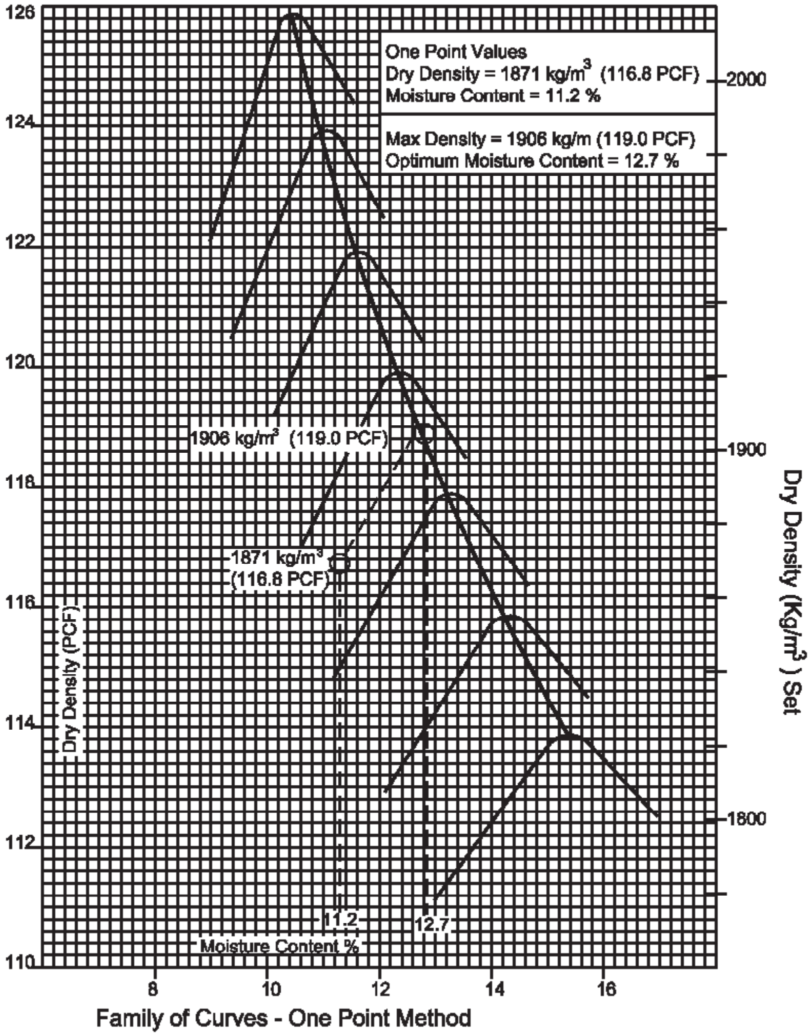

Figure 1—Example of Curves

4. APPARATUS

4.1. See T 99, Section 3.

METHOD A

5. SAMPLE

5.1. See T 99, Section 4.

6. PROCEDURE

6.1. Thoroughly mix the selected representative sample with sufficient water to dampen approximately 4 percentage points below optimum moisture content. Greater accuracy in the determination of the maximum density will result as the moisture content used approaches optimum moisture content. Moisture content of the sample should never exceed the optimum water content.

6.2. Form a specimen by compacting the prepared soil in the 101.6-mm (4-in.) mold (with collar attached) in three approximately equal layers to give a total compacted depth of about 125 mm (5 in.). Compact each layer by 25 uniformly distributed blows from the rammer dropping free from a height of 305 mm (12 in.) above the elevation of the soil when a sleeve-type rammer is used, or from 305 mm (12 in.) above the approximate elevation of compacted soil when a stationary mounted type of rammer is used. During compaction, the mold shall rest firmly on a dense, uniform, rigid, and stable foundation (Note 2).

Note 2—Each of the following has been found to be a satisfactory base on which to rest the mold during compaction of the soil: a block of concrete, with a mass not less than 91 kg (200 lb) supported by a relatively stable foundation; a sound concrete floor; and for field application, such surfaces as are found in concrete box culverts, bridges, and pavements.

6.2.1. Following compaction, remove the extension collar, carefully trim the compacted soil even with the top of the mold by means of the straightedge, and determine the mass of the mold and moist soil in kilograms to the nearest 5 grams, or determine the mass in pounds to the nearest 0.01 pounds. For molds conforming to tolerances given in T 99 and masses recorded in kilograms, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 1060, and record the result as the wet density, W_1, in kilograms per cubic meter, of compacted soil. For molds conforming to tolerances given in T 99 and masses recorded in pounds, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 30, and record the result as the wet density, W_1, in pounds per cubic foot, of compacted soil. For used molds out of tolerance by no more than 50 percent (T 99), use the factor for the mold as determined in accordance with T 19M/T 19.

6.3. Remove the material from the mold and slice vertically through the center. Take a representative sample of the material from one of the cut faces, determine the mass immediately, and dry in an oven at 110 ± 5ºC (230 ± 9ºF) for at least 12 hours, or to a constant mass to determine the moisture content. The moisture sample shall have a mass not less than 100 grams.

METHOD B

7. SAMPLE

7.1. Select the representative sample in accordance with Section 5, except that it shall have a mass of approximately 7 kg (16 lb).

8. PROCEDURE

8.1. Follow the same procedure as described for Method A in Section 6, except for the following: Form a specimen by compacting the prepared soil in the 152.4-mm (6-in.) mold (with collar attached) in three approximately equal layers to give a total compacted depth of about 125 mm (5-in.), each layer being compacted by 56 uniformly distributed blows from the rammer. For molds conforming to tolerances given in T 99 and masses recorded in kilograms, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 471, and record the result as the wet density, W_1, in kilograms per cubic meter of compacted soil. For molds conforming to tolerances given in T 99 and masses recorded in pounds, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 13.33, and record the result as the wet density, W_1, in pounds per cubic foot, of the compacted soil. For used molds out of tolerance by no more than 50 percent (T 99), use the factor for the mold as determined in accordance with T 19M/T 19.

METHOD C

9. SAMPLE

9.1. If the soil sample is damp when received from the field, dry it until it becomes friable under a trowel. Drying may be in air or by use of a drying apparatus such that the temperature does not exceed 60ºC (140ºF). Then thoroughly break up the aggregations in such a manner as to avoid reducing the natural size of individual particles.

9.2. Sieve an adequate quantity of the representative pulverized soil over the 19.0-mm sieve. Discard the coarse material, if any, retained on the 19.0-mm sieve (Note 3).

Note 3—The discarded coarse material may be utilized in T 224.

9.3. Select a representative sample having a mass of approximately 5 kg (12 lb) or more of the soil prepared as described in Sections 9.1 and 9.2.

10. PROCEDURE

10.1. Thoroughly mix the selected representative sample with sufficient water to dampen it to approximately 4 percentage points below optimum moisture content. Greater accuracy in the determination of the maximum density will result as the moisture content used approaches the optimum moisture content.

10.2. Form a specimen by compacting the prepared soil in the 101.6-mm (4-in.) mold (with collar attached) in three approximately equal layers to give total compacted depth of about 125 mm

(5 in.). Compact each layer by 25 uniformly distributed blows from the rammer dropping free from a height of 305 mm (12 in.) above the elevation of the soil when a sleeve-type rammer is used or from 305 mm (12 in.) above the approximate elevation of each finely compacted layer when a stationary mounted type rammer is used. During compaction, the mold shall rest firmly on a dense, uniform, rigid, and stable foundation (Note 2).

10.2.1. Following compaction, remove the extension collar and carefully trim the compacted soil even with the top of the mold by means of the straightedge. Holes developed in the surface by removal of coarse material shall be patched with smaller-size material. Determine the mass of the mold and moist soil in kilograms to the nearest 5 g, or determine the mass in pounds to the nearest 0.01 pounds. For molds conforming to tolerances given in T 99 and masses recorded in kilograms, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 1060, and record the result as the wet density, W_1, in kilograms per cubic meter of compacted soil. For molds conforming to tolerances given in T 99 and masses recorded in pounds, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 30, and record the result as the wet density, W_1, in pounds per cubic foot, of compacted soil. For used molds out of tolerance by no more than 50 percent (T 99), use the factor for the mold as determined in accordance with Section 8 (Calibration of Measure) of T 19M/T 19.

10.3. Remove the material from the mold and slice vertically through the center. Take a representative sample of the material from one of the cut faces, determine the mass immediately, and dry to a constant mass using a drying apparatus described in T 99 to determine the moisture content. The moisture sample shall have a mass no less than 500 g.

METHOD D

11. SAMPLE

11.1. Select the representative sample in accordance with Section 9.3 except that it shall have a mass of approximately 11 kg (25 lb).

12. PROCEDURE

12.1. Follow the same procedure as described for Method C in Section 10, except for the following: Form a specimen by compacting the prepared soil in the 152.4-mm (6-in.) mold (with collar attached) in three approximately equal layers to give a total compacted depth of about 125 mm (5 in.), each layer being compacted by 56 uniformly distributed blows from the rammer. For molds conforming to tolerances given in T 99 and masses recorded in kilograms, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 471, and record the result as the wet density, W_1, in kilograms per cubic meter, of compacted soil. For molds conforming to tolerances given in T 99 and masses recorded in pounds, multiply the mass of the compacted specimen and the mold, minus the mass of the mold, by 13.33, and record the result as the wet density, W_1, in pounds per cubic foot, of the compacted soil. For used molds out of tolerance by no more than 50 percent (T 99), use the factor for the mold as determined in accordance with Section 8 (Calibration of Measure) of T 19M/T 19.

CALCULATIONS AND REPORT

13. CALCULATIONS

13.1. See T 99, Section 12.

14. MAXIMUM DENSITY AND OPTIMUM MOISTURE CONTENT DETERMINATION

14.1. The calculations in Section 13.1 shall be made to determine the moisture content and corresponding oven-dry mass (density) in kilograms per cubic meter (pounds per cubic foot) of the compacted specimen. The dry density (unit mass) of the soil shall be plotted as ordinate and the corresponding moisture content as the abscissa to define one-point within or on the family of curves (Figure 1).

14.2. If the one-point falls on one of the curves in the family of curves, the maximum dry density and optimum moisture content defined by that curve shall be used (Note 4).

14.3. If the one-point falls within the family but not on a curve, a new curve shall be drawn through the plotted one-point parallel and in character with the nearest existing curve in the family of curves. The maximum dry density and optimum moisture content as defined by the new curve shall be used (Note 4).

Note 4—If the one-point plotted within or on the family of curves does not fall in the 80 to 100 percent of optimum moisture range, compact another specimen, using the same material, at an adjusted moisture content that will place the one-point within this range.

14.3.1. If the family of curves is such that the profile of a new curve to be drawn through a one-point is not well defined or in any way questionable, then a full moisture-density relationship shall be made for the soil in question to correctly define the new curve and verify the applicability of the family of curves (Note 5).

Note 5—New curves drawn through plotted one-point determinations shall not become a permanent part of the family of curves until verified by a full moisture-density relationship.

15. REPORT

15.1. The report shall include the following:

15.1.1. The method used (Method A, B, C, or D).

15.1.2. The optimum moisture content as a percentage to the nearest whole number.

15.1.3. The maximum density to the nearest 0.5 kg/m^3 (1.0 lb/ft^3).

15.1.4. In Methods C and D, indicate if the material retained on the 19.0-mm sieve was removed or replaced.

15.1.5. Type of face if other than 50.8-mm (2-in.) circular.

Note 6—Inherent variability of soils places limitations on this method of test. The person using this test method must realize this and become thoroughly familiar with the material being tested. Knowledge of the AASHTO Soil Classification System and ability to recognize the gradation of soils are requirements for this work.

APPENDIX—DEVELOPING A MOISTURE-DENSITY FAMILY OF CURVES

The purpose of the family of curves is to represent the average moisture-density characteristics of the material. The family must, therefore, be based on moisture-density relationships that adequately represent the entire mass range and all types of material for which the family is to be used. It may be that particular soil types have moisture-density relationships that differ considerably and cannot be represented on one general family of curves; in this case, a separate family may be developed. Also, moisture-density relationships for material of widely varying geologic origins should be carefully examined to determine if separate families are required.

When a small number of moisture-density relationships are being used to develop a family of curves, plot the point representing the maximum density and optimum moisture content for each relationship on a single sheet of graph paper. Draw a smooth curve as close as possible to connect all the points. This line will define the maximum density and optimum moisture content of the material represented by this family of curves. At 1-kg (2-lb) increments, draw moisture-density curves with slopes similar to the slopes of the original moisture-density relationships. Slopes should gradually steepen, going from low to high maximum density material.

When a great number of moisture-density relationships are available, the above procedure can be modified by using average values. Tabulate the maximum density, optimum moisture content, and slope for all moisture-density relationships in each 1-kg (2-lb) increment of density. Average the maximum densities and optimum moisture contents for each increment and plot these values. As before, draw a smooth curve as close as possible to connect all the points. Determine the average slope for each increment, and at each 1-kg (2-lb) increment, draw a moisture-density curve using this average slope value. A computer may be used to accomplish this work.

The accuracy of a family of curves can be checked by comparing the maximum density and optimum moisture content from an individual moisture-density relationship with that obtained using the One-Point Method and family of curves. A point representing 80 percent of optimum moisture content is taken from the individual moisture-density relationship and used as described in the One-Point Method to determine the maximum density and optimum moisture content from the family of curves. These values are compared with the values from the individual moisture-density relationship. The difference represents the maximum variance expected when the One-Point Method and family of curves are used for material represented by that individual moisture-density relationship. This comparison should be made for all types of material over the mass range of the family. Based on these results, some adjustments may be necessary to the family, and/or it may be recognized that the family is not applicable to some types of material. Families based on relatively few moisture-density relationships will generally require the closest scrutiny, since it can be expected that a larger number of relationships will give better average conditions.

Standard Method of Test for

Soil Suction

AASHTO Designation: T 273-86 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Soil Suction

AASHTO Designation: T 273-86 (2008)

1. SCOPE

1.1. This method covers the procedure for determining total soil suction force using thermocouple psychrometers. The test results of this method are to be used in conjunction with T 258.

1.2. The thermocouple psychrometer measures the relative humidity in the soil by a technique called Peltier cooling. By causing a small direct current of approximately four to eight milliamperes to flow through the thermocouple junction for approximately 15 seconds in the correct direction, this junction will cool and water will condense on it when the dewpoint temperature is reached. Condensation of this water inhibits further cooling of the junction and the voltage difference developed between the thermocouple and the reference junctions can be measured using a microvoltmeter. With proper calibration, the thermocouple psychrometer output in microvolts can be coverted directly to soil suction in convenient units of pressure. Typical thermocouple psychrometer output voltages vary from less than one microvolt for relative humidities close to 100 percent or total soil suction less than 95.76 kPa (1 tsf) to about 25 microvolts for relative humidities of about 95 percent or total soil suctions of about 5746 kPa (60 tsf).

1.3. The following applies to all specified limits in this standard: For the purposes of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

1.4. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 207, Thin-Walled Tube Sampling of Soils
- T 233, Density of Soil In-Place by Block, Chunk, or Core Sampling
- T 258, Determining Expansive Soils

2.2. *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. DEFINITIONS

3.1. *matrix suction*—the matrix suction is the result of clay mineral surface attractive forces for water and cations (i.e., ion hydration) and the surface tension effects of water in soil. The matrix suction is both water content and surcharge pressure dependent.

3.2. *osmotic suction*—the osmotic suction arises from the presence of soluble salts in the pore water of the soil and is the result of the difference in the ion concentration between the pore water and the clay particles double-layer water. Osmotic suction is independent of water content and surcharge pressure.

3.3. *soil suction*—soil suction is a quantity that can be used to characterize the effect of moisture on the volume and strength properties of soils; that is, soil suction quantitatively describes the interaction between soil particles and water, which determines the physical behavior of the soil mass. Soil suction, expressed in units of pressure, is a measure of the pulling force exerted on water by the soil mass.

3.4. *total soil suction*—total soil suction, as determined by this method of test, is the force responsible for soil water retention and is the sum of the matrix and osmotic components.

4. APPARATUS

4.1. *Microvoltmeter*—Minimum range of 30 microvolts and readable to the nearest 0.01 microvolt.

4.2. *Milliammeter*—Minimum range 0 to 25 milliammeters.

4.3. *Thermocouple Psychrometers*—WESCOR Model PT 51-10, or equal.

4.4. *Polystyrene Thermal Containers*—Chest or box insulated with at least 38.1 mm (1.5 in.) of foamed polystyrene. One container approximately 304.8 mm by 304.8 mm by 381 mm (12 in. by 12 in. by 15 in.) will accommodate six samples.

4.5. *Sample Containers*—0.5 L (1-pint) metal sample containers with interior coated with melted wax to prevent corrosion. One-half liter paint cans are satisfactory.

4.6. *Rubber Stoppers*—Size $13^1/_2$ rubber stoppers with an approximately 6-mm (0.25-in.) diameter hole through the center.

4.7. *Electrical Supplies*—Switch box, selector switches, electrical connectors, two 1.5-volt dry cell batteries, and a 1 K ohm variable potentiometer.

4.8. *Calibration Standards*—Minimum of three WESCOR Osmolality Standards (290, 1000, and 1800 mOs/kg) (Note 1). Standard sodium chloride solutions of various molalities may be prepared in the laboratory.

4.9. *Stopwatch*.

4.10. *Tare Containers*.

4.11. *Specimen Cutting Equipment*—wire saw, knife, bandsaw, etc.

4.12. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

Note 1—mOs/kg is the abbreviation for milliosmos per kilogram.

5. ASSEMBLING EQUIPMENT

5.1. The assembled apparatus is as shown in Figure 1. The apparatus should be assembled to accommodate multiple samples to be tested simultaneously. The wiring diagram shown in Figure 2 permits the testing of twelve samples simultaneously by utilizing a 12-position selector switch.

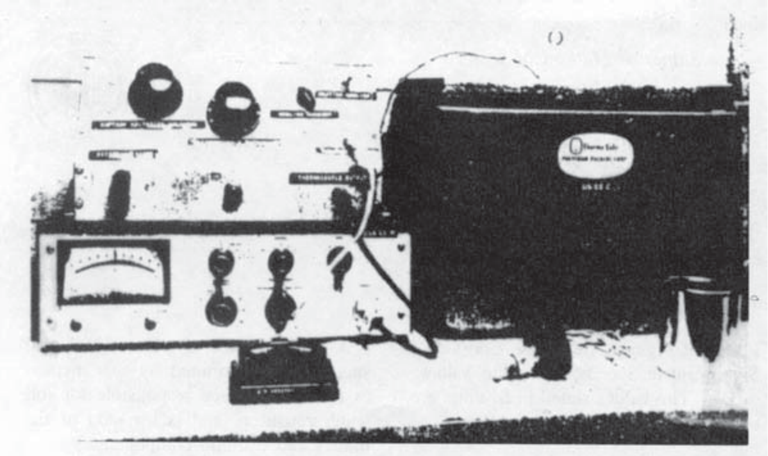

Figure 1—Soil Suction Apparatus

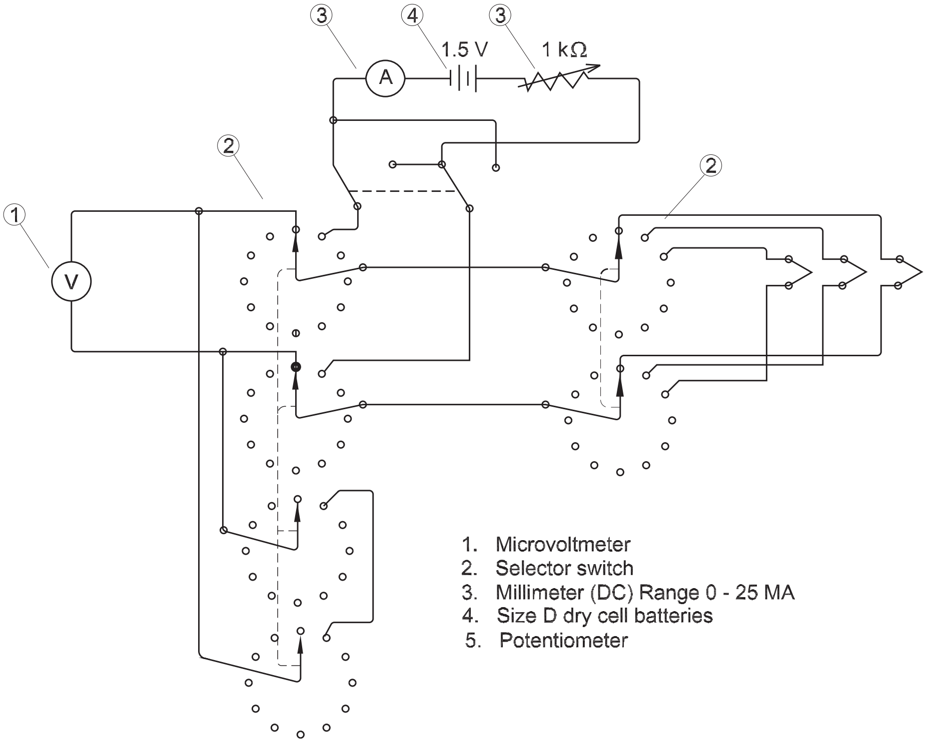

Figure 2—Wiring Diagram for Soil Suction Apparatus

5.2. The thermocouple psychrometer wires are fed through an approximately 12-mm (0.5-in.) diameter hole in the center of the thermal container cover. The thermocouple psychrometer wires are then fed through the hole in the rubber stoppers so the psychrometer tips extend approximately 25 mm (1 in.) from the bottom (small diameter end) of the stopper. The protective sheathing around the psychrometer tip must form an airtight seal in the hole in the rubber stopper.

5.3. The milliammeter, dry-cell batteries, and the variable potentiometer form the cooling circuit.

5.4. The electrical connectors are affixed to the psychrometer wires for easy connection to the switch box.

5.5. The switches are wired so the output voltages (temperature and soil suction) can be monitored on each of the psychrometers in turn.

5.6. The rubber stoppers are placed in the metal sample containers, which are placed in the thermal containers to minimize temperature variations. The temperature inside the thermal container is monitored by a thermometer placed through the container cover.

5.7. The equipment should be kept in a room where ambient temperature variations are minimal.

6. CALIBRATION OF EQUIPMENT

6.1. Place a small piece of filter paper (type and grade variable) in the bottom of each sample container along with 3 mL of the calibration standard. A minimum of three calibration standard concentrations should be used to adequately define the calibration line (i.e., 290, 1000, and 1800 mOs/kg).

6.2. Seal the sample containers, containing the standards, with the rubber stopper psychrometers installed and place them in the thermal containers. Allow the temperature to come to equilibrium, which requires approximately 24 hours.

6.3. After the temperature has come to equilibrium, begin taking temperature (millivolt) and soil suction (microvolt) output readings at least three times per day until the output readings stabilize. A cooling current of 8 mA is applied to the psychrometer for 15 seconds prior to reading the soil suction output reading. Time to stabilization varies with concentrations of the calibration standard but will generally be in the range of 7 to 10 days.

6.4. Obtain at least three stable output readings on each standard. Perform the following calculations on the average of the three readings.

6.4.1. Convert the thermocouple voltage output (millivolts) to temperature (ºC), using the equation in Section 9.1.

6.4.2. Convert the psychrometer (soil suction) voltage output, E_T (microvolts) to the equivalent output at the calibration temperature of 25ºC, E_{25}, using the equation in Section 9.2.

6.4.3. Calculate the equivalent moisture retention force or suction according to one of the following:

SI Units:

Multiply each concentration by 2.509 (i.e., 1800 mOs/kg × 2.509 = 4516 kPa).

U.S. Customary Units:

Multiply each concentration by 2.62×10^{-2} (i.e., 1800 mOs/kg × 0.0262 = 47.2 tsf).

6.5. Plot the calibration curve for each psychrometer using E_{25} (microvolts) as the abscissa and the soil suction, τ, kPa (tsf), for each calibration standard as the ordinate. Typical thermocouple psychrometer calibration curves (Figure 3) are linear and can be expressed using the following equation:

$$\text{Soil Suction, } \tau, \text{ kPa } (\text{or tsf}) = mE_{25} - n, \qquad (1)$$

where:

m = slope of the calibration curve, and

n = y-intercept of the calibration curve.

The slope of the calibration curve will always be positive and the y-intercept should be equal to or less than zero. The calibration curve is good for the useful life of the thermocouple psychrometer; however, under normal use, an annual check of the calibration by at least one point will assure that the equipment is operating properly.

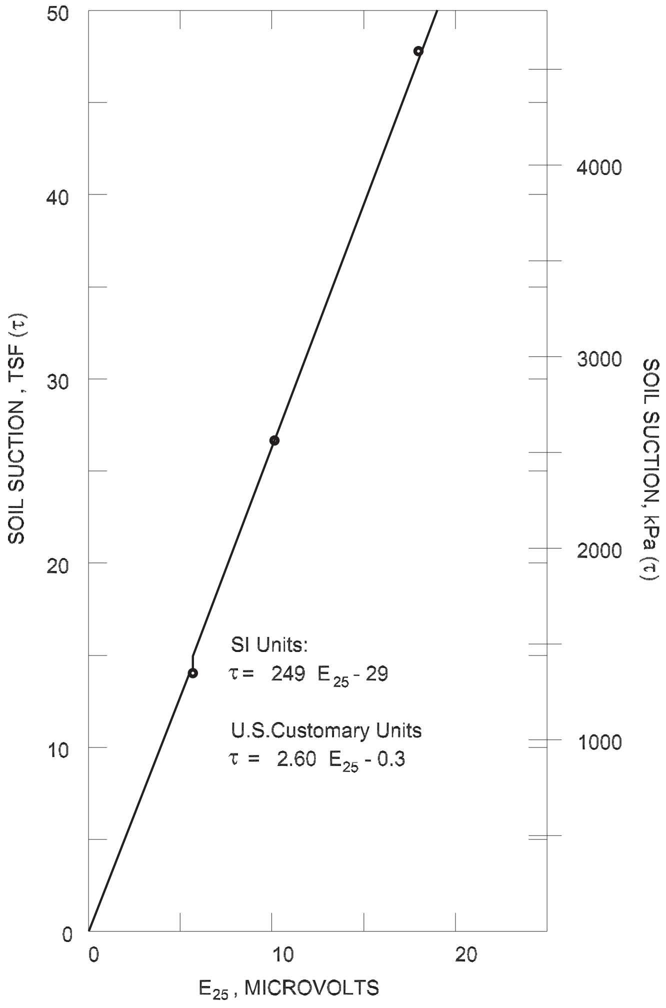

Figure 3—Typical Thermocouple Psychrometer Calibration Line

7. SAMPLING

7.1. Undisturbed samples shall be obtained, sealed, and protected in accordance with T 207.

8. TEST PROCEDURE

8.1. Set up apparatus according to Section 5.

8.2. Cut the sample selected for testing into nine (9) cubes approximately 38.1 mm by 38.1 mm (1.5 in. by 1.5 in.).

8.3. Place two of the specimens directly into the metal sample containers, seal with the rubber stoppers containing the thermocouple psychrometers, and place in the thermal containers. These two specimens represent the natural conditions of the soil.

8.4. The remaining seven specimens, depending on their natural water contents, are either wetted with varying amounts of distilled water or dried at room temperature for varying lengths of time to establish a range of water content conditions. For example, consider a soil that appears relatively dry (i.e., well below the plastic limit): To establish the necessary water content range, three of the specimens should be dried at room temperature (i.e., 1, 2, and 4 hours, respectively, would be reasonable times) and the remaining four specimens should be wetted with distilled water (i.e., 0.5, 1, 2, and 4 mL, respectively, would be reasonable amounts).

8.4.1. Place the specimen to be wetted into the metal sample containers; add varying amounts of water to the specimens as described above. Immediately seal the wetted specimens with the rubber stoppers containing the thermocouple psychrometers and place them in the thermal containers.

8.4.2. Allow the remaining specimens to dry at room temperature for varying lengths of time as described above. Place each dried specimen into the metal sample container and seal with a rubber stopper containing a thermocouple psychrometer and place in the thermal container.

8.5. Allow the specimens to come to equilibrium in the sealed containers. Temperature equilibrium is attained within a few hours after placing the cover of the thermal container. Equilibrium of the relative humidity of the air measured by the psychrometer and the relative humidity in the soil specimen is usually obtained within 48 to 72 hours.

8.6. Using the appropriate switch, read and record the temperature output of the thermocouple psychrometer in millivolts.

8.7. Change the switch from thermocouple to psychrometer, set the meter to zero, apply a cooling current of approximately 8 mA for 15 seconds, then read and record the psychrometer output in microvolts. The cooling currents and times should be identical to those used to determine the calibration curves.

8.8. Repeat Sections 8.6 and 8.7 for each of the thermocouple psychrometers in the equipment setup.

8.9. After the readings are completed, remove the specimens from the containers. Determine the dry density (volume displacement method) and the water content of each specimen in accordance with T 233. (A suggested data sheet that assures correct collection of the required data is shown in Figure 4.)

Figure 4—Suggested Data Sheet for Collection of Soil Suction Data

9. DATA REDUCTION AND INTERPRETATION

9.1. Convert the thermocouple voltage output (millivolts) to temperature (ºC) using the following equation:

$$T,\ ^\circ\mathrm{C}\ = \frac{\text{Output in Millivolts}}{0.0395\ \text{Millivolts}/^\circ\mathrm{C}} \qquad (2)$$

9.2. Convert the psychrometer voltage output, E_τ (microvolts) to the equivalent output at the calibration temperature of 25ºC, E_{25}, using the following equation:

$$E_{25} = \frac{E_\tau}{0.325 + 0.027T} \qquad (3)$$

9.3. Determine the Soil Suction, τ, of each individual specimen by entering the respective psychrometer calibration curve with E_{25} and reading the corresponding soil suction. The soil suction may also be calculated using the respective psychrometer calibration equation (Section 6).

9.4. Plot the soil suction (ordinate, log scale) versus the water content (abscissa) on a semilog plot to establish the log soil suction versus water content relationship, Figure 5, which is linear and can be expressed using the following equation:

$$\log\ \tau = A - Bw, \qquad (4)$$

where:

A = y-intercept;

B = slope; and

w = water content, percent.

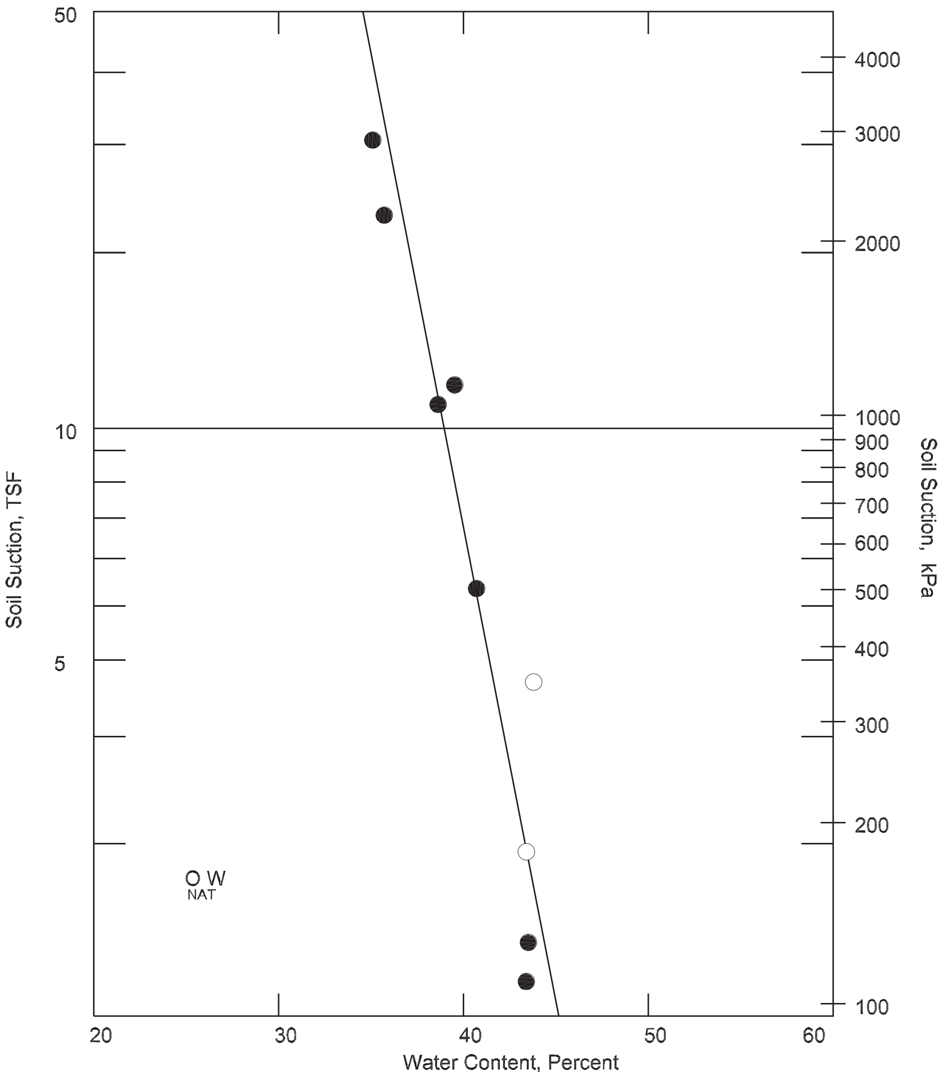

Figure 5—Typical Soil Suction Versus Water Content

9.4.1. All of the data points are used to establish the *τ–w* relationship. The points representing natural conditions should be identified on the plot. If some variation occurs at the upper or lower end of the curve because the limits of the measurement range are approached, the data points between soil suction values of 200 kPa (2 tsf) and 2000 kPa (20 tsf) should be used to establish the *τ–w* relationship.

9.4.2. The slope, *B*, of the line is determined by calculating the inverse of the change in water content over one cycle of the log scale.

9.4.3. The intercept, *A,* is calculated by applying the equation $\log \tau = A - Bw$, at a soil suction equal to 100 kPa (1 tsf) and solving for *A*.

9.5. Determine the specific volume of each specimen that is the inverse of its dry density. Plot the specific volume of each specimen (ordinate) versus its water content (abscissa), as in Figure 6.

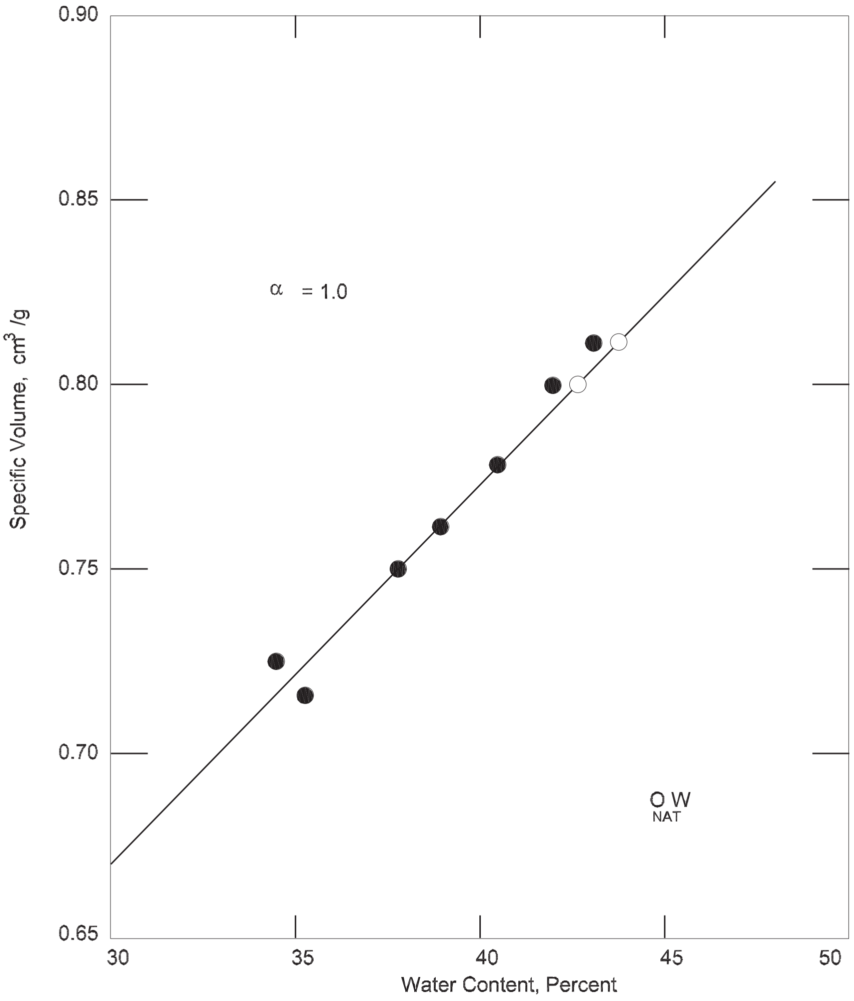

Figure 6—Typical Specific Volume vs. Water Content

9.6. Determine the volumetric compressibility factor, α, of the soil, which is the slope of the specific volume versus water content curve. The volumetric compressibility factor relates the change in volume to a corresponding change in water content. Occasionally, the slope of the curve may indicate an α greater than one, in which case α should be taken as one since the compressibility factor cannot be greater than one.

Standard Method of Test for

Determining Minimum Laboratory Soil Resistivity

AASHTO Designation: T 288-91 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Minimum Laboratory Soil Resistivity

AASHTO Designation: T 288-91 (2008)

1. SCOPE

1.1. This test method covers the laboratory determination for the minimum resistivity of a soil.

1.2. The principal use of this test method is to determine a soil's corrosivity and thereby identify the conditions under which the corrosion of metals in soil may be sharply accentuated. This standard is divided into two parts. The first part involves obtaining and preparing the sample to size for testing, and the second part describes the test method for determining the minimum laboratory soil resistivity.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

PART I—INITIAL PREPARATION OF TEST SAMPLES

3. SCOPE

3.1. This method covers the dry preparation of soil and soil-aggregate samples, as received from the field, for soil resistivity determination.

3.2. The following applies to all specified limits in this standard: for the purpose of determining conformance with these specifications, an observed value or calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

4. APPARATUS

4.1. *Balance*—The balance shall have sufficient capacity and be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

4.2. *Drying Apparatus*—Any suitable device capable of drying samples at a temperature not exceeding 60ºC (140ºF).

4.3. *Sieves*—A series of the following sizes: 6.3 mm ($^1/_4$ in.), 4.75 mm (No. 4), 2.00 mm (No. 10), and pan as required for preparing the sample for the minimum soil resistivity test. The sieves shall conform to M 92, Wire-Cloth Sieves for Testing Purposes (Note 1).

4.4. *Pulverizing Apparatus*—Either a mortar and rubber-covered pestle or any device suitable for breaking up the aggregations of soil particles without reducing the size of the individual grains of soil (Note 2).

4.5. *Sample Splitter*—A suitable riffle sampler or sample splitter for proportional splitting of the sample and capable of obtaining representative portions of the sample without appreciable loss of fines. The width of the container used to feed the riffle sampler splitter should be equal to the total combined width of the riffle chutes. Proportional splitting of the sample on a canvas cloth is also permitted.

Note 1—The sieve sizes that have an opening size of 6.3 mm ($^1/_4$ in.) or larger shall conform to the requirements specified in M 92, excluding column No. 7. This exclusion permits the use of heavier screens in non-standard frames that are larger than the 203.2 mm (8 in.) round frames.

Note 2—Other types of apparatus are satisfactory if the aggregations of soil particles are broken up without reducing the size of the individual grains.

5. SAMPLE SIZE

5.1. The amount of soil material required to perform the minimum soil resistivity test is as follows:

Test	Approx Mass (g)	Sieve Size Finer Than:
Resistivity	1500	2.00 mm (No. 10)

6. INITIAL PREPARATION OF TEST SAMPLES

6.1. The sample as received from the field shall be dried in air or a drying apparatus not exceeding 60ºC (140ºF). A representative test sample of the amount required to perform the minimum soil resistivity test shall then be obtained with the sampler, or by splitting or quartering. The aggregations of soil particles shall then be broken up in the pulverizing apparatus until the aggregation of soil particles is separated into individual grains in such a way as to avoid reducing the natural size of the individual particles (Note 3).

Note 3—Samples dried in an oven or other drying apparatus at a temperature not exceeding 60ºC (140ºF) are considered to be air dried.

6.2. The portion of the dried sample selected for minimum soil resistivity testing shall be separated into fractions by one of the following methods:

6.2.1. *Alternate Method Using 2.0-mm (No. 10) Sieve*—The dried sample shall be separated into two fractions using a 2.00-mm sieve. The fraction retained on the sieve shall be ground with a pulverizing apparatus until the aggregations of the soil particles are broken into separate grains. The ground soil shall then be separated into two fractions using the 2.00-mm sieve.

6.2.2. *Alternate Method Using 4.75-mm and 2.00-mm (No. 4 and No. 10) Sieves*—The dried sample shall first be separated into two fractions using a 4.75-mm sieve. The fraction retained on this sieve shall be ground with a pulverizing apparatus until the aggregations of soil particles are broken into separate grains and again separated on the 4.75-mm sieve. The fraction passing the 4.75-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for testing shall be obtained. This split-off portion shall then be separated on the 2.00-mm sieve, and processed as in Section 6.2.1.

6.2.3. *Alternate Method Using 6.3-mm and 2.00-mm ($^1/_4$ in. and No. 10) Sieves*—The dried sample shall first be separated into two fractions using a 6.3-mm sieve. The fraction retained on this sieve shall be ground with a pulverizing apparatus until the aggregations of soil particles are broken into separate grains and again separated on the 6.3-mm sieve. The fraction passing the 6.3-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for testing shall be obtained. This split-off portion shall then be separated on the 2.00-mm sieve, and processed as in Section 6.2.1.

PART 2—MINIMUM SOIL RESISTIVITY DETERMINATION

7. SCOPE

7.1. This method covers the laboratory procedure for determining the minimum resistivity of soil samples. The values obtained from this method are relatable to the corrosion potential that a soil may exhibit.

8. APPARATUS AND MATERIALS

8.1. *Resistivity Meter*—An alternating current (AC) meter or a 12-volt direct current (DC) meter utilizing a Wien Bridge (AC bridge) with a phase sensitive detector and a square wave inverter that produces a nominal alternating signal at 97 Hz. (Note 4).

8.2. 100, 200, 500, and 900-ohm resistors with a 1 percent tolerance.

8.3. *Soil Box*—See Figure 1 and Figure 2.

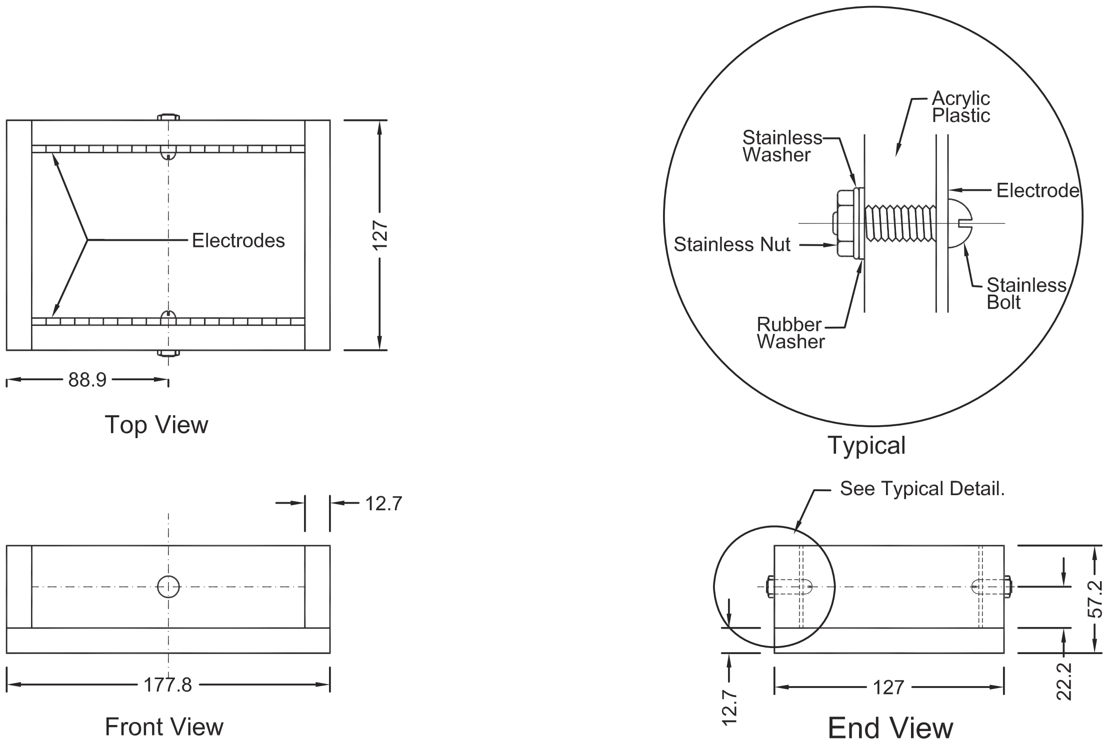
8.4. 2.00-mm (No. 10) sieve conforming to the requirements of M 92.

8.5. Mixing Pans (non-corrosive; e.g., stainless steel, plastic, etc.).

8.6. Graduated cylinder, 100 mL capacity.

8.7. Distilled water or deionized water that has a resistivity greater than 20000 (ohm) × (cm).

8.8. Straightedge, 305 mm (12 in.) length.

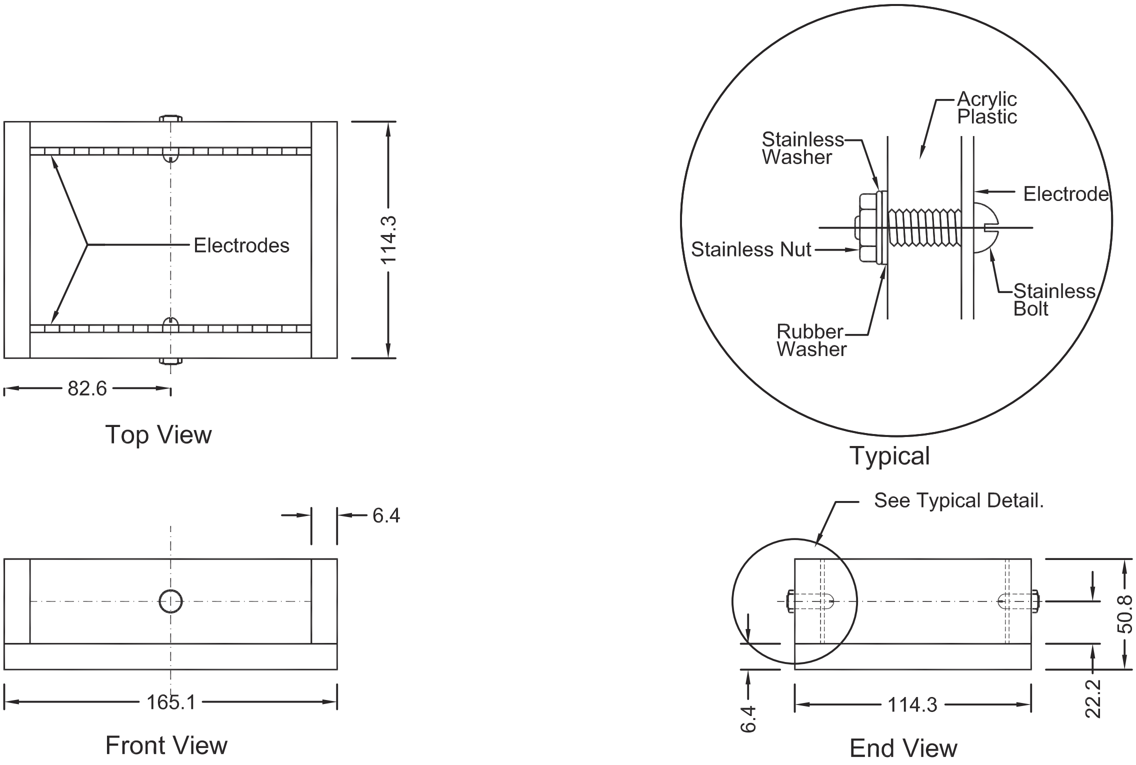


Materials

Bottom - 1 Pc 177.8 mm x 127 mm x 12.7 mm
Ends - 2 Pcs 127 mm x 44.45 mm x 12.7 mm
Sides - 2 Pcs 152.4 mm x 44.45 mm x 12.7 mm
Electrodes - 2 Pcs 0.9-mm stainless steel 152.4 mm x 44.45 mm
2 Each - M 4 x 0.5 x 19.0 mm (or longer)
Round head stainless steel
machine bolt with rubber
washer and stainless steel
washer and nut

Note: All dimensions in millimeters.

Figure 1—Soil Box for Laboratory Resistivity Determination (Not to Scale)



Materials

Bottom - 1 Pc 165.1 mm x 114.3 mm x 6.4 mm
Ends - 2 Pcs 114.3 mm x 44.45 mm x 6.4 mm
Sides - 2 Pcs 152.4 mm x 44.45 mm x 6.4 mm
Electrodes - 2 Pcs 0.9-mm stainless steel 152.4 mm x 44.45 mm
2 Each - M 4 x 0.5 x 19.0 mm (or longer)
Round head stainless steel
machine bolt with rubber
washer and stainless steel
washer and nut

Note: All dimensions in millimeters.

Figure 2—Soil Box for Laboratory Resistivity Determination (Not to Scale)

9. CALIBRATION OF RESISTIVITY METER

9.1. *Calibrate resistivity meter (follow manufacturer's instructions)*:

9.1.1. Zero the resistivity meter by clamping the two leads together, and adjusting the meter (if necessary).

9.1.2. Connect the leads of the resistivity meter to the 100-ohm resistor and read the meter. Repeat this process with the 200, 500, and 900-ohm resistors.

9.1.3. If the readings are within 10 percent of the resistance of the resistor, the meter is functioning satisfactorily.

10. SOIL RESISTIVITY DETERMINATION

10.1. Select the material for testing in accordance with T 248 and separate on a 2.00-mm (No. 10) sieve. Approximately 1500 grams of the material passing the 2.00-mm (No. 10) sieve will be required for testing.

10.2. Add 150 mL of distilled water to the prepared soil. Mix the sample thoroughly and cover the test sample with a damp cloth and allow the sample to stabilize until equilibrium has been reached, or allow to cure a minimum of 12 hours.

10.3. Zero the meter as per manufacturer's instructions.

10.4. Clean the soil box thoroughly with distilled water.

10.5. Thoroughly mix and place the sample in the soil box in layers and compact (moderate compaction with the fingers is sufficient). Trim off the excess material with the straightedge.

10.6. Measure the resistance and calculate the resistivity of the soil in accordance with the instructions furnished with the meter and record the test value.

10.7. Remove and retain the soil from the box, add 100 mL of distilled water to the sample, and mix thoroughly. Clean the soil box with distilled water prior to performing the next test.

10.8. Repeat the process of placing, compacting the soil in the box, then measure the resistance and calculate the soil resistivity (Note 5).

10.9. Repeat the steps in Sections 10.4 to 10.8 until a minimum value can be determined.

10.10. The minimum value is used for computing the minimum soil resistivity and reporting (Note 6).

11. REPORT

11.1. The minimum soil resistivity value determined above should be reported in units of (ohm) × (cm).

11.2. The Minimum Soil Resistivity utilizing the typical soil box is:

$$\text{Minimum Soil Resistivity} = \left[\text{minimum reading }\left(\text{ohms}\right)\right] \times \left[6.67\text{ cm}\right] \qquad (1)$$

(See Note 7.)

Note 4—Most resistance meters without an inverting circuit allow the sample under test to polarize during measurement causing the reading to vary (i.e., drift).

Note 5—In some soils, the minimum soil resistivity occurs when the specimen is in a slurry condition. When this occurs, it is necessary to thoroughly mix the soil slurry and then pour the slurry water into the soil box until full. If the soil box doesn't reach its capacity with the addition of the slurry water, add just enough of the mixed soil into the box until the soil box is filled; then take the reading.

Note 6—The minimum soil resistivity can occur at any moisture content.

Note 7—Multiplying Constant for each Soil Box is derived by:

$$\frac{\text{Surface Area of One Electrode}\left(\text{cm}^2\right)}{\text{Measured Average Distance between Electrodes}\left(\text{cm}\right) = \dfrac{\text{cm}^2}{\text{cm}} = \text{cm}} \qquad (2)$$

Typical Soil Box

$$\frac{15.24\ \text{cm} \times 4.445\ \text{cm}}{10.16\ \text{cm}} = 6.67\ \text{cm} \qquad (3)$$

The soil box may be constructed of either 6.4 or 12.7 mm ($^1/_4$ or $^1/_2$ in.) acrylic plastic. If other size soil boxes are used, it will be necessary to determine the correct multiplier. It should also be noted that it may be necessary to prepare extra soil for testing to fill the soil box.

12. PRECISION AND BIAS

12.1. Data not available at this time.

Standard Method of Test for

Determining pH of Soil for Use in Corrosion Testing

AASHTO Designation: T 289-91 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining pH of Soil for Use in Corrosion Testing

AASHTO Designation: T 289-91 (2008)

1. SCOPE

1.1. This test method describes procedures and apparatus for determining a pH value for corrosion testing by use of a pH meter.

1.2. The principal use of the test is to supplement soil-resistivity measurements and thereby identify conditions under which the corrosion of metals in the soil may be sharply accentuated. This standard is divided into two parts. The first part involves obtaining and preparing the sample to size for testing. The second part describes the test method for determining the pH of soil.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standard*:
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

PART I—INITIAL PREPARATION OF TEST SAMPLES

3. SCOPE

3.1. This method covers the dry preparation of soil and soil-aggregate samples for determining a soil's pH.

3.2. The following applies to all specified limits in this standard: For the purpose of determining conformance with these specifications, an observed value or calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

4. APPARATUS

4.1. *Sieves*—A series of sieves of the following sizes: 6.3 mm ($^1/_4$ in.), 4.75 mm (No. 4), 2.00 mm (No. 10), and a pan. The sieve shall conform to M 92, Sieves for Testing Purposes (Note 1).

4.2. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

4.3. *Drying Apparatus*—Any suitable device capable of drying samples at a temperature not exceeding 60ºC (140ºF).

4.4. *Pulverizing Apparatus*—Either a mortar and rubber-covered pestle or any device suitable for breaking up the aggregations of soil particles without reducing the size of the individual grains (Note 2).

4.5. *Sample Splitter*—A suitable riffle sampler or sample splitter for proportional splitting of the sample and capable of obtaining representative portions of the sample without appreciable loss of fines. The width of the container used to feed the riffle sampler splitter should be equal to the total combined width of the riffle chutes. Proportional splitting of the sample on a canvas cloth is also permitted.

Note 1—The sieve sizes that have an opening size of 6.3 mm ($^1/_4$ in.) or larger shall conform to the requirements specified in M 92, excluding Column No. 7. The exclusion of Column 7 permits the use of heavier screens in nonstandard frames that are larger than the 203.2 mm (8 in.) round frames.

Note 2—Other types of apparatus are satisfactory if the aggregations of soil particles are broken up without reducing the size of the individual grains.

5. SAMPLE SIZE

5.1. The amount of soil material required to perform the test is as follows:

Test	Approx Mass (g)	Sieve Size Finer Than:
pH	100	2.00 mm (No.10)

6. INITIAL PREPARATION OF TEST SAMPLES

6.1. The sample as received shall be in a moist condition for pH testing purposes. If the sample is too wet, it may be dried to a moist condition in air or a drying apparatus not exceeding 60ºC (140ºF) prior to sample selection (Note 3). A representative test sample to perform the pH test shall then be obtained with the sampler, or by splitting or quartering as per T 248.

Note 3—Samples dried in an oven or other drying apparatus at a temperature not exceeding 60ºC (140ºF) are considered to be air dried.

6.2. The portion of the sample selected for pH testing shall be separated into fractions by one of the following methods:

6.2.1. *Alternate Method Using 2.00-mm (No. 10) Sieve*—The sample shall be separated into two fractions using a 2.00-mm sieve. The fraction retained on the sieve shall be ground with a pulverizing apparatus until the aggregations of soil particles are broken into separate grains. The ground soil shall then be separated into two fractions using the 2.00-mm sieve.

6.2.2. *Alternate Method Using 4.75-mm and 2.00-mm (No. 4 and No. 10) Sieves*—The sample shall first be separated into two fractions using a 4.75-mm sieve. The fraction retained on this sieve shall be ground with a pulverizing apparatus until the aggregations of soil particles are broken into separate grains and again separated on the 4.75-mm sieve. The fraction passing the 4.75-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for testing shall be obtained. This split-off portion shall then be separated on the 2.00-mm sieve and processed as in Section 6.2.1.

6.2.3. *Alternate Method Using 6.3-mm and 2.00-mm ($^1/_4$-in. and No. 10) Sieves*—The sample shall first be separated into two fractions using a 6.3-mm sieve. The fraction retained on this sieve shall be ground with a pulverizing apparatus until the aggregations of soil particles are broken into separate grains and again separated on the 6.3-mm sieve. The fraction passing the 6.3-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for testing shall be obtained. This split-off portion shall then be separated on the 2.00-mm sieve and processed as in Section 6.2.1.

PART 2—DETERMINATION OF SOIL PH

7. SCOPE

7.1. This section describes the procedure for determining soil pH.

8. APPARATUS

8.1. *pH Meter*—suitable for laboratory or field analysis, with either one or two electrodes.

8.2. A 50 mL wide-mouth glass beaker or other suitable container with a watch glass for cover. If lightweight material is to be tested, it may be necessary to increase the beaker size up to a maximum of 250 mL.

8.3. *Standard Buffer Solutions of Known pH Values*—standards to be used are pH of 4.0, 7.0, and 10.0.

8.4. Distilled water.

8.5. A teaspoon or small scoop.

8.6. A thermometer capable of reading 25 ± 10º C, to the nearest 0.1ºC.

8.7. *Sieves*—A 2.00 mm (No. 10) for preparing the sample and a pan. The sieve shall conform to M 92, Wire-Cloth Sieves for Testing Purposes.

8.8. A glass stirring rod.

9. PROCEDURE

9.1. Of the material selected for testing, place a mass of 30.0 ± 0.1 grams of soil into the glass beaker or other suitable container.

9.2. Add 30.0 ± 0.1 grams of distilled water to the soil sample. Stir to obtain a soil slurry and then cover with a watch glass.

9.3. The sample must stand for a minimum of 1 hour, stirring every 10 to 15 minutes. This is to allow the pH of the soil slurry to stabilize.

9.4. Measure the temperature of the sample and adjust the temperature controller of the pH meter to that of the sample temperature. This adjustment should be done just prior to testing. On meters with an automatic temperature control, follow the manufacturer's instructions.

9.5. Standardize the pH meter by means of the standard solutions provided. Temperature and adjustments must be performed as stated under Section 9.4 (see Note 4).

9.6. Immediately before immersing the electrode(s) into the sample, stir well with a glass rod. Place the electrode(s) into the soil slurry solution and gently turn the beaker or container to make good contact between the solution and the electrode(s). DO NOT place the electrode(s) into the soil; place them only into the soil slurry solution (see Note 5).

9.7. The electrode(s) require immersion for 30 seconds or longer in the sample before reading to allow the meter to stabilize. If the meter has an auto-read system, it will automatically signal when stabilized.

9.8. Read and record the pH value to the nearest tenth of a whole number. If the pH meter reads to the hundredth place, it is necessary to round off the result in accordance with the rounding-off method in ASTM E 29.

9.9. Rinse off the electrode(s) well with distilled water, then dab lightly with tissues to remove any film formed on the electrode(s). **Caution**—Do not wipe the electrode(s) as this may result in polarization of the electrode(s) and consequent slow response (see Note 6).

Note 4—To standardize the pH meter, use the 7.0 pH buffer standard solution plus the other standard solution that is nearest the estimated pH value of the sample to be tested. If the manufacturer's instructions indicate a method other than that noted above, then those instructions must be followed.

Note 5—When immersing electrode(s) into the glass beaker or container, care should be taken not to hit the bottom or side, causing damage to the electrode(s).

Note 6—If polarization does occur, as indicated by a slow response, rinse the electrode(s) and dab lightly again.

10. PRECAUTIONS

10.1. Periodically check for damage to the electrode(s).

10.2. The electrode tip should be kept moist during storage. Follow the manufacturer's instructions.

11. REPORT

11.1. As specified in Section 9.8, report the pH value to the nearest tenth of a whole number in accordance with ASTM E 29.

12. PRECISION AND BIAS

12.1. Data are not available at this time.

Standard Method of Test for

Determining Water-Soluble Sulfate Ion Content in Soil

AASHTO Designation: T 290-95 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Water-Soluble Sulfate Ion Content in Soil

AASHTO Designation: T 290-95 (2007)

1. SCOPE

1.1. This test method covers the determination of the water-soluble sulfate ion content in soil. This standard is divided into two parts. The first part specifies the procedure for sampling and preparing the sample to size for testing. The second part delineates two test procedures (Methods A or B) for the determination of the sulfate ion content in soils. The selection of the method is dependent on the concentration of sulfate ion and the accuracy desired. Two methods are given as follows:

	Section
Method A:	
(Gravimetric Method)	(1 to 7) and (8 to 16)
Method B:	
(Turbidimetric Method)	(1 to 7) and (17 to 26)

1.2. Method A is a primary measure of sulfate ion. Method B is less time-consuming, but often more liable to interference than Method A. It is particularly useful in the lower sulfate range and can be used as a screening test. This method is directly applicable over the range of 10 to 100 mg/kg.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standards*:
- D 859, Standard Test Method for Silica in Water
- D 1129, Standard Terminology Relating to Water
- D 1193, Standard Specification for Reagent Water
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 60, Standard Practice for Analysis of Metals, Ores, and Related Materials by Molecular Absorption Spectrometry

- E 275, Standard Practice for Describing and Measuring Performance of Ultraviolet and Visible Spectrophotometers

3. DEFINITIONS

3.1. For definitions of terms used in these methods, refer to ASTM D 1129.

PART I—INITIAL PREPARATION OF TEST SAMPLES

4. SCOPE

4.1. This method covers the dry preparation of soil and soil-aggregate samples, as received from the field, for use in determining the sulfate ion content in soils.

4.2. The following applies to all specified limits in this standard: For the purpose of determining conformance with these specifications, an observed value or calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

5. APPARATUS

5.1. The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass or better, and conform to the requirements of M 231.

5.2. *Drying Apparatus*—Any suitable device capable of drying samples at a temperature not exceeding 60ºC (140ºF).

5.3. *Sieves*—A series of sieves of the following sizes: 6.3 mm ($^1/_4$ in.), 4.75 mm (No. 4), 2.00 mm (No. 10), and a pan. The sieve shall conform to M 92, Wire-Cloth Sieves for Testing Purposes (Note 1).

Note 1—The sieve sizes that have an opening size of 6.3 mm ($^1/_4$ in.) or larger shall conform to the requirements specified in M 92, excluding Column No. 7. This exclusion permits the use of heavier screens in non-standard frames that are larger than the 203.2 mm (8 in.) round frames.

5.4. *Pulverizing Apparatus*—Either a mortar and rubber-covered pestle or any device suitable for breaking up the aggregations of soil particles without reducing the size of the individual grains (Note 2).

Note 2—Other types of apparatus are satisfactory if the aggregations of soil particles are broken up without reducing the size of the individual grains.

5.5. *Sample Splitter*—A suitable riffle sampler or sample splitter for proportional splitting of the sample and capable of obtaining representative portions of the sample without appreciable loss of fines. The width of the container used to feed the riffle sampler splitter should be equal to the total combined width of the riffle chutes. Proportional splitting of the sample on a canvas cloth is also permitted.

6. SAMPLE SIZE

6.1. The amount of soil material required to perform the individual test is as follows:

Test	Approx Mass (g)	Sieve Size Finer Than:
Sulfates	250	2.00 mm (No. 10)

7. INITIAL PREPARATION OF TEST SAMPLES

7.1. The sample as received from the field may be dried in air or a drying apparatus not exceeding 60ºC (140ºF) prior to sample selection (Note 3). A representative test sample of the amount required to perform the tests shall then be obtained with the sampler, or by splitting or quartering. The aggregations of soil particles shall then be broken up in the pulverizing apparatus in such a way as to avoid reducing the natural size of the individual particles.

Note 3—Samples dried in an oven or other drying apparatus at a temperature not exceeding 60ºC (140ºF) are considered to be air dried.

7.2. The portion of the sample selected for sulfate testing shall be separated into fractions by one of the following methods:

7.2.1. *Alternate Method Using 2.00-mm (No. 10) Sieve*—The dried sample shall be separated into two fractions using a 2.00-mm sieve. The fraction retained on the sieve shall be ground with the pulverizing apparatus until the aggregation of soil particles is separated into individual grains. The ground soil shall then be separated into two fractions using the 2.00-mm sieve.

7.2.2. *Alternate Method Using 4.75-mm and 2.00-mm (No. 4 and No. 10) Sieves*—The dried sample shall first be separated into two fractions using a 4.75-mm sieve. The fraction retained on this sieve shall be ground with a pulverizing apparatus until the aggregations of soil particles are broken into separate grains and again separated on the 4.75-mm sieve. The fraction passing the 4.75-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for testing shall be obtained. This split-off portion shall then be separated on the 2.00-mm sieve and processed as in Section 7.2.1.

7.2.3. *Alternate Method Using 6.3-mm and 2.00-mm ($^1/_4$ in. and No. 10) Sieves*—The dried sample shall first be separated into two fractions using a 6.3-mm sieve. The fraction retained on this sieve shall be ground with a pulverizing apparatus until the aggregations of soil particles are broken into separate grains and again separated on the 6.3-mm sieve. The fraction passing the 6.3-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for testing shall be obtained. This split-off portion shall then be separated on the 2.00-mm sieve and processed as in Section 7.2.1.

PART 2—DETERMINATION OF SULFATE CONTENT

8. METHOD A—GRAVIMETRIC METHOD (SECTIONS 8 TO 16)

8.1. *Scope*:

8.2. This method is utilized to determine the amount of water-soluble sulfate ion in soil. It is directly applicable to samples containing approximately 20 to 100 mg/kg of sulfate ion. It can be extended to higher or lower ranges by adjusting the sample size.

8.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all the safety concerns associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

9. SUMMARY OF METHOD

9.1. Sulfate ion is precipitated and the mass determined as barium sulfate after removal of silica and other insoluble matter.

10. INTERFERENCES

10.1. Sulfites and sulfides may oxidize and precipitate with the sulfate. Turbidity caused by silica or other insoluble material would interfere if allowed to be present, but removal of such interference is provided in this method.

10.2. Other substances tend to be occluded or adsorbed on the barium sulfate, but these do not significantly affect the precision and accuracy of the method.

11. PURITY OF REAGENTS

11.1. Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

11.2. Unless otherwise indicated, references to water shall be understood to mean Type II reagent water conforming to ASTM D 1193. In addition, reagent water used for these methods shall be sulfate-free.

12. REAGENTS

12.1. *Ammonium Hydroxide (sp gr 0.90)*—Concentrated ammonium hydroxide (NH_4OH).

12.2. *Barium Chloride Solution (100 g/L)*—Dissolve 100 g of barium chloride ($BaCl_2{\cdot}2H_2O$) in water and dilute to 1 L.

12.3. *Hydrochloric Acid (1 + 9)*—Mix one volume of hydrochloric acid (HCl, sp gr 1.19) with nine volumes of water.

12.4. *Hydrofluoric Acid (48 to 51 percent)*—Concentrated hydrofluoric acid (HF).

12.5. *Methyl Orange Indicator Solution (0.5 g/L)*—Dissolve 0.05 g of methyl orange in water and dilute to 100 mL.

12.6. *Nitric Acid (sp gr 1.42)*—Concentrated nitric acid (HNO_3).

12.7. *Picric Acid (saturated aqueous solution)*.

12.8. *Silver Nitrate Solution (100 g/L)*—Dissolve 10 g of silver nitrate ($AgNO_3$) in water and dilute to 100 mL.

12.9. *Sulfuric Acid (sp gr 1.84)*—Concentrated sulfuric acid (H_2SO_4).

---

13. TEST PROCEDURE

13.1. Weigh 100 g of the soil sample for testing. Put the test sample into a 500-mL Erlenmeyer flask.

13.2. Add 300 mL of distilled water. Stopper the flask and shake the mix.

13.3. Centrifuge the sample; if the sample exhibits turbidity, filter the sample through a 0.45 micron membrane filter. A drop of concentrated nitric acid may be added, if needed, to precipitate finely divided suspended matter (Note 4).

13.4. Pipet 30.0 mL, or measure a quantity of the clear sample containing sulfate ion equivalent to 20 to 50 mg of barium sulfate ($BaSO_4$) into a 250 mL beaker. Adjust the volume by evaporation, or dilution with water, to approximately 200 mL. Adjust the acidity of the sample to the methyl orange end point and add 10 mL excess HCl (1 + 9). If a quantity other than 30 mL is used, substitute the volume of the aliquot into the calculation in place of 30 mL.

Note 4—Silica may be removed before applying this method by dehydration with HCl or perchloric acid ($HClO_4$) in accordance with the respective procedures in ASTM D 859. In this case, the ignition described in Section 13.8 need not be done in a platinum crucible.

13.5. Measure into the beaker a quantity of the clear sample containing sulfate ion equivalent to 20 to 50 mg of barium sulfate ($BaSO_4$). Adjust the volume by evaporation or dilution with water to approximately 200 mL. Adjust the acidity of the sample to the methyl orange end point and add 10 mL excess of HCl (1 + 9).

13.6. Heat the acidified solution to boiling and slowly add to it 5 mL of hot $BaCl_2$ solution (Note 5). Keep the temperature just below boiling until the liquid has become clear and the precipitate has settled out completely. In no case shall this settling period be less than 2 hours.

Note 5—Faster precipitation and a coarser precipitate can be obtained by adding 10 mL of saturated picric acid solution and boiling the sample 5 minutes before adding $BaCl_2$.

13.7. Filter the suspension of $BaSO_4$ on a fine, ashless filter paper and wash the precipitate with hot water until the washings are substantially free of chlorides, as indicated by testing the last portion of the washings with $AgNO_3$ solution (Note 6). Avoid excessive washing. If any $BaSO_4$ passes through the filter, pour the filtrate through the paper a second time (Note 7).

Note 6—Do not attempt to obtain a completely negative test for chloride. Discontinue washing when no more than a faint opalescence is produced in the test. Using a small amount of ashless filter paper pulp in the suspension will aid in filtration and reduce the tendency for $BaSO_4$ to pass through the filter.

Note 7—If the filtrate is poured through the paper a second time, $AgNO_3$ must not be present in the filtrate.

13.8. Place the filter paper and contents in a tared platinum crucible (Note 4), and char and consume the paper slowly without flaming. Ignite the residue at approximately 800ºC for one hour, or until it is apparent that all carbon has been consumed.

13.9. Add a drop of H_2SO_4 and a few drops of HF, and evaporate under a hood to expel silica as silicon tetrafluoride (SiF4). Reignite at about 800ºC, cool in a desiccator, and determine the mass of the $BaSO_4$.

14. CALCULATION

14.1. Calculate the concentration of sulfate ion (SO_4) in milligrams per kilogram, as follows:

$$\text{Sulfate, mg/kg} = (W \times 411500)/S \qquad (1)$$

where:

W = grams of $BaSO_4$ and

S = grams of sample used, e.g.,

$$\frac{100 \text{ g soil}}{S} = \frac{300 \text{ mL water}}{30 \text{ mL aliquot}}$$

$$S = 10 \text{ g}$$

14.2. *Sulfate Ion Content in Soil*:

$$(\text{mg/kg moisture free}) = [\text{Sulfates (mg/kg as determined above)} \times 100]/(100 - \text{percent moisture}) \qquad (2)$$

15. REPORT

15.1. Report the sulfate content as computed in Section 14.2 on a moisture-free basis in units of milligrams per kilogram (mg/kg). Report this value to the nearest whole number in accordance with the rounding-off method ASTM E 29.

16. PRECISION AND BIAS

16.1. Data are not available at this time.

METHOD B—TURBIDIMETRIC METHOD (SECTIONS 17 TO 26)

17. SCOPE

17.1. This method is intended for rapid routine or control tests for the water-soluble sulfate ion in soil where extreme accuracy and precision are not required. It is directly applicable over the range of 10 to 100 mg/kg of sulfate ion (SO_4).

18. SUMMARY OF METHOD

18.1. Sulfate ion is converted to a barium sulfate suspension under controlled conditions. Glycerin solution and a sodium chloride solution are added to stabilize the suspension and minimize interferences. The resulting turbidity is determined by a photoelectric colorimeter or spectrophotometer and compared to a curve prepared from standard sulfate solutions.

19. INTERFERENCES

19.1. Insoluble suspended matter in the sample must be removed. Dark colors that cannot be compensated for in the procedure interfere with the measurement of suspended barium sulfate ($BaSO_4$).

19.2. Although other ions normally found in water do not appear to interfere, the formation of the barium sulfate suspension is very critical. This method is more suitable as a control procedure where concentration and type of impurities present in the water are relatively constant. Determinations that are in doubt should be checked by Method A in some cases, or by the procedure suggested in Note 10.

20. APPARATUS

20.1. *Photometer*—A filter photometer or spectrophotometer suitable for measurements between 350 and 425 nm, the preferable wavelength range being 380 to 400 nm. The cell for the instrument should have a light path through the sample of approximately 40 mm, and should hold about 50 mL of sample. Filter photometers and photometric practices prescribed in this method shall conform to ASTM E 60; spectrophotometers shall conform to ASTM E 275.

21. REAGENTS

21.1. *Barium Chloride*—Crystals of barium chloride ($BaCl_2 \cdot 2H_2O$) screened to 20 to 30-mesh.

21.2. *Glycerin Solution (1 + 1)*—Mix one volume of glycerin with one volume of water.

Note 8—A stabilizing solution containing sodium carboxymethylcellulose (10 g/L) may be used instead of the glycerin solution.

21.3. *Sodium Chloride Solution (240 g/L)*—Dissolve 240 g of sodium chloride (NaCl) in water containing 20 mL of concentrated hydrochloric acid (HCl, sp gr 1.19), and dilute to 1 L with water. Filter the solution if turbid.

21.4. *Sulfate, Standard Solution (1 mL = 0.100 mg SO_4)*—Dissolve 0.1479 g of anhydrous sodium sulfate (Na_2SO_4) in water, and dilute with water to 1 L in a volumetric flask. Standardize by the procedure prescribed in Section 13.

22. CALIBRATION

22.1. Follow the procedure given in Section 23, using appropriate amounts of the standard sulfate solution prepared in accordance with Section 21.4, and prepare a calibration curve showing sulfate ion content in mg/L plotted against the corresponding photometer readings (Note 9). Prepare standards by diluting with water 0.0, 2.0, 5.0, 10.0, 15.0, 20.0, 30.0, 40.0, and 50.0 mL of standard sulfate solution to 50-mL volumes in volumetric flasks. These solutions will have sulfate ion concentrations of 0.0, 4.0, 10.0, 20.0, 30.0, 40.0, 60.0, 80.0, and 100.0 mg/L (ppm), respectively.

Note 9—A separate calibration curve must be prepared for each photometer and a new curve must be prepared if it is necessary to change the cell, lamp, or filter, or if any other alterations of instrument or reagents are made. Check the curve with each series of tests by running two or more solutions of known sulfate concentrations.

23. TEST PROCEDURE

23.1. Weigh 100 g of the soil sample for testing. Put the test sample into a 500-mL Erlenmeyer flask.

23.2. Add 300 mL of distilled water. Stopper the flask and shake the mix.

23.3. Centrifuge the sample; if the sample exhibits turbidity then filter the sample through a 0.45 micron membrane filter. A drop of concentrated nitric acid may be added, if needed, to precipitate finely divided suspended matter (Note 4).

23.4. Pipet into a 200-mL beaker 50 mL of the clear sample containing between 0.5 and 5 mg of sulfate ion (Note 10). Dilute to 50 mL with water, if required, and add 10.0 mL of glycerin solution (Note 8) and 5.0 mL of NaCl solution. If less than 50 mL of sample is used, use the appropriate dilution factor.

Note 10—The solubility of $BaSO_4$ is such that difficulty may be experienced in the determination of sulfate concentrations below 10 mg/kg. This can be overcome by concentrating the sample or by adding 5 mL of standard sulfate solution (1 mL = 0.100 mg SO_4) to the sample before diluting to 50 mL. This will add 0.5 mg SO_4 to the sample, which must be subtracted from the final result.

23.5. Fill a 40-mm sample cell with sample solution, wipe it with a clean, dry cloth, and place it in the cell compartment. Set the colorimeter to zero absorbance (100 percent transmission) for a blank. This compensates for any acid-insoluble matter that has not been filtered out, or for color present, or for both.

23.6. Pour the sample solution from the cell back into the beaker and add, with stirring, 0.3 g of $BaCl_2 \cdot 2H_2O$ crystals (Note 11). Continue gently stirring the solution for 60 seconds. Let it stand for 4 minutes, and stir again for 15 seconds. Fill the sample cell as before, and immediately make a reading with the photometer.

Note 11—The stirring should be at a constant rate in all determinations. The use of a magnetic stirrer has been found satisfactory for this purpose.

23.7. If interferences are suspected, dilute the sample with an equal volume of water and determine the sulfate concentration again. If the value so determined is one-half that in the undiluted sample, interferences may be assumed to be absent.

24. CALCULATION

24.1. Convert the photometer readings obtained with the sample to mg/L sulfate ion (SO_4) by use of the calibration curve described in Section 22.

$$\text{Sulfate Ion Content in Soil}\left(\text{mg/kg not corrected for moisture}\right) = \frac{50\ \text{mL solution}\ \left(\text{ppm curve}\right)}{S} \qquad (3)$$

where:

S = grams of samples used, e.g.,

$$\frac{100}{S} = \frac{300\ \text{mL water}}{50\ \text{mL aliquot}}$$

$$S = 16.6666\ \text{g}$$

24.2. *Sulfate Ion Content in Soil*:

(mg/kg moisture free) = [Sulfates (mg/kg with moisture) × 100]/
(100 – percent moisture) *(4)*

25. REPORT

25.1. Report the sulfate content as computed in Section 24.2 on a moisture-free basis in units of milligram per kilogram (mg/kg). Report this value to the nearest whole number in accordance with the rounding-off method in ASTM E 29.

26. PRECISION AND BIAS

26.1. Data are not available at this time.

Standard Method of Test for

Determining Water-Soluble Chloride Ion Content in Soil

AASHTO Designation: T 291-94 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Water-Soluble Chloride Ion Content in Soil

AASHTO Designation: T 291-94 (2008)

1. SCOPE

1.1. This test method describes the procedures for sampling and testing a soil for chloride ion content. This standard is divided into two parts. The first part specifies the procedure for sampling and preparing the sample to size for testing. The second part delineates two test procedures (Methods A or B) for the determination of the water-soluble chloride ion content in soil. Two methods are given as follows:

	Section
Method A:	
(Mohr Titration Method)	(1 to 7) and (8 to 16)
Method B:	
(pH/mV Meter Method)	(1 to 7) and (17 to 28)

1.2. Method A is based upon the Mohr procedure for determining chloride ion with silver nitrate. Method B utilizes a pH/mV Meter. By comparing the mV readings to the calibration curve, determine the chloride ion content.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standards*:

- D 1129, Standard Terminology Relating to Water
- D 1193, Standard Specification for Reagent Water
- D 2777, Standard Practice for Determination of Precision and Bias of Applicable Test Methods of Committee D19 on Water
- D 3370, Standard Practices for Sampling Water from Closed Conduits
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. DEFINITIONS

3.1. For definitions of terms used in this test method, refer to ASTM D 1129.

PART 1—INITIAL PREPARATION OF TEST SAMPLES

4. SCOPE

4.1. This method covers the dry preparation of soil and soil-aggregate samples, as received from the field, for use in determining the chloride content.

4.2. The following applies to all specified limits in this standard: For the purpose of determining conformance with these specifications, an observed value or calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with ASTM E 29.

5. APPARATUS

5.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

5.2. *Drying Apparatus*—Any suitable device capable of drying samples at a temperature not exceeding 60ºC (140ºF).

5.3. *Sieves*—A series of sieves of the following sizes: 6.3-mm ($^1/_4$-in.), 4.75-mm (No. 4), 2.00-mm (No. 10) sieve, and a pan. The sieve shall conform to M 92, Wire-Cloth Sieves for Testing Purposes (Note 1).

Note 1—The sieve sizes that have an opening size of 6.3 mm ($^1/_4$ in.) or larger shall conform to the requirements specified in M 92, excluding Column No. 7. This exclusion permits the use of heavier screens in non-standard frames that are larger than the 203.2 mm (8 in.) round frames.

5.4. *Pulverizing Apparatus*—Either a mortar and rubber-covered pestle or any device suitable for breaking up the aggregations of soil particles without reducing the size of the individual grains (Note 2).

Note 2—Other types of apparatus are satisfactory if the aggregations of soil particles are broken up without reducing the size of the individual grains.

5.5. *Sample Splitter*—A suitable riffle sampler or sample splitter for proportional splitting of the sample and capable of obtaining representative portions of the sample without appreciable loss of fines. The width of the container used to feed the riffle sampler splitter should be equal to the total combined width of the riffle chutes. Proportional splitting of the sample on a canvas cloth is also permitted.

6. SAMPLE SIZE

6.1. The amount of soil material required to perform the individual test is as follows:

Test	Approx Mass (g)	Sieve Size Finer Than:
Chlorides	250	2.00 mm (No. 10)

7. INITIAL PREPARATION OF TEST SAMPLES

7.1. The sample as received from the field may be dried in air or a drying apparatus not exceeding 60ºC (140ºF) prior to sample selection (Note 3). A representative test sample of the amount required to perform the tests shall then be obtained with the sampler, or by splitting or quartering. The aggregations of soil particles shall then be broken up in the pulverizing apparatus in such a way as to avoid reducing the natural size of the individual particles.

Note 3—Samples dried in an oven or other drying apparatus at a temperature not exceeding 60ºC (140ºF) are considered to be air dried.

7.2. The portion of the sample selected for chloride testing shall be separated into fractions by one of the following methods:

7.2.1. *Alternate Method Using 2.00-mm (No. 10) Sieve*—The dried sample shall be separated into two fractions using a 2.00-mm sieve. The fraction retained on this sieve shall be ground with the pulverizing apparatus until the aggregation of soil particles is separated into individual grains. The ground soil shall then be separated into two fractions using the 2.00-mm sieve.

7.2.2. *Alternate Method Using 4.75-mm and 2.00-mm (No. 4 and No. 10) Sieves*—The dried sample shall be separated into two fractions using a 4.75-mm sieve. The fraction retained on this sieve shall be ground with the pulverizing apparatus until the aggregation of soil particles is separated into individual grains and again separated on the 4.75-mm sieve. The fraction passing the 4.7-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for testing shall be obtained. This split-off portion shall then be separated on the 2.00-mm sieve and processed as in Section 7.2.1.

7.2.3. *Alternate Method Using 6.3-mm and 2.00-mm ($^1/_4$-in. and No. 10) Sieves*—The dried sample shall be separated into two fractions using a 6.3-mm sieve. The fraction retained on this sieve shall be ground with the pulverizing apparatus until the aggregations of soil particles are separated into individual grains and again separated on the 6.3-mm sieve. The fraction passing the 6.3-mm sieve shall be mixed thoroughly and, by the use of the sampler or by splitting and quartering, a representative portion adequate for testing shall be obtained. This split-off portion shall then be separated on the 2.00-mm sieve and processed as in Section 7.2.1.

PART 2—DETERMINATION OF WATER-SOLUBLE CHLORIDE ION CONTENT BY MOHR TITRATION METHOD (METHOD A)

8. SCOPE

8.1. This method covers the test procedure for the determination of water-soluble chloride content of soils.

8.2. Samples containing from 10 to 150 mg/kg of chloride can be analyzed by this test method. These levels are achieved by dilution as described in the test method.

8.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

9. SUMMARY OF METHOD

9.1. This test method is based upon the Mohr procedure for determining chloride ion with silver nitrate. The chloride reacts with the silver ion before any silver chromate forms, due to the lower solubility of silver chloride. The potassium chromate indicator reacts with excess silver ion to form a red silver chromate precipitate. The end point is the appearance of the first permanent orange color.

9.2. This test method is suitable for analyzing solutions with a pH between 6.0 and 8.5.

10. INTERFERENCES

10.1. Sulfide, bromide, iodide, thiocyanate, cyanide, phosphate, sulfite, carbonate, hydroxide, and iron interfere in this test method. Sulfide, sulfite, and thiosulfate can be removed with a peroxide treatment, but usually no attempt is made to remove bromide and iodide because they are usually present in insignificant quantities compared to chloride. If necessary, the pH can be raised and the hydroxides of several metals, including iron, can be filtered off. Iron, barium, lead, and bismuth precipitate with the chromate indicator.

11. APPARATUS

11.1. Buret, 25 mL capacity.

11.2. Hot plate.

11.3. Magnetic stirrer and TFE-fluorocarbon-coated stirring bars.

11.4. Buret, 50 mL capacity, 0.1 mL gradations.

11.5. Pipets, 1, 5, 10, 25, 30, and 50 mL.

11.6. Beaker, 250 mL.

11.7. Erlenmeyer flask, 500 mL.

11.8. Centrifuge with tubes capable of holding at least 50 mL.

11.9. Phydrion papers covering pH 1 through 11 in 1 pH units. A pH meter is preferable, if available.

11.10. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

12. REAGENTS

12.1. *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specification of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

12.2. *Nitric Acid Solution (1 + 19)*—Add one volume of HNO_3 (sp. gr. 1.42) to 19 volumes of water.

12.3. *Purity of Water*—Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to ASTM D 1193, Type III.

12.4. *Silver Nitrate Solutions*:

12.4.1. Silver nitrate solution (1 mL of solution is equivalent to 1 mg of chloride). Dissolve 4.79 grams of $AgNO_3$ in distilled water. Dilute to one liter. Add one drop concentrated nitric acid (HNO_3) and dilute to 1 L in a volumetric flask. The HNO_3 will eliminate any precipitation of silver hydroxide that would change the concentration. Standardize against sodium chloride (NaCl). Store in an amber-brown bottle to protect the solution from light.

12.4.2. *Silver Nitrate Solution, Standard (equivalent to 2 mg Cl/mL)*—For chloride concentrations slightly higher than specified in Section 12.4.1, this is a more concentrated standard. Dissolve 9.5834 g of $AgNO_3$ in approximately 700 mL of water. Add one drop concentrated nitric acid (HNO_3) and dilute to 1 L in a volumetric flask. Standardize against sodium chloride (NaCl). Store in an amber-brown bottle to protect the solution from light.

12.4.3. *Silver Nitrate Solution, Standard (equivalent to 5 mg Cl/mL)*—For chloride concentrations higher than specified in Section 12.4.2, dissolve 23.9582 g of $AgNO_3$ in approximately 700 mL of water. Add one drop concentrated nitric acid (HNO_3) and dilute to 1 L in a volumetric flask. The HNO_3 will eliminate any precipitation of silver hydroxide which would change the concentration. Standardize against sodium chloride (NaCl) by procedure described below. Store in an amber-brown bottle to protect the solution from light.

12.5. *Sodium Chloride Solution*:

12.5.1. Dry 2 to 6 g of high purity (minimum 99.5 percent) sodium chloride crystals at 110 ± 5ºC for 1 hour and cool in a desiccator to room temperature.

12.5.2. Weigh 1.6484 g of the NaCl crystals. Transfer the crystals into a 1-L volumetric flask, dissolve, dilute, and mix well. A quantity of 1 mL of this solution provides 1 mg of Cl.

12.5.3. A 0.2 mL blank can be utilized or determine the indicator blank by substituting 100 mL of reagent grade water for the sample and perform the following:

12.5.3.1. Check the pH with a meter, if available, or with phydrion paper. If the pH is in the range of six through eight, proceed immediately to the step in Section 12.5.3.2. If the pH is below six, add sodium bicarbonate to adjust to the above range; if the pH is above eight, add nitric acid to adjust to the above range.

12.5.3.2. Add two drops of potassium chromate solution.

12.5.3.3. Titrate with silver nitrate solution until the indicator begins to turn from yellow to red.

12.5.3.4. Indicator blank is the volume of $AgNO_3$ required to the end point. Record this value as the blank.

12.5.4. The titre (T) of the silver nitrate solution is given in the following equation:

$$T = \frac{\text{mg CL used}}{\text{mL AgNO}_3\text{ required} - \text{Blank}} \qquad (1)$$

12.5.5. If the titre (T) of the solutions are not exactly 1.0, 2.0, or 5.0 mg of Cl per mL $AgNO_3$, it may be desirable to dilute the solutions if they are too concentrated or add more silver nitrate if they are too weak. In either case, restandardize the resulting solution.

12.6. *Potassium or Sodium Chromate, Indicator Solution*—Prepare a 5 percent solution (5 g/100 mL) and adjust the pH to 7.0 with HNO_3 (1 + 19) or $NaHCO_3$ powder described in Sections 12.2 and 12.7.

12.7. *Sodium Bicarbonate ($NaHCO_3$)*—Powder to adjust the sample pH to 8.3.

12.8. *Standardization of Silver Nitrate Solutions*:

12.8.1. Pipet 25 mL aliquots of NaCl solution to standardize the $AgNO_3$ solution (1 mg Cl/mL) and dilute to 100 mL with water. For the higher concentrations use 50 mL aliquots of the NaCl solution to standardize the $AgNO_3$ solution (2 mg Cl/mL) and dilute to 100 mL with water. Use 100 mL of the NaCl solution to standardize the more concentrated $AgNO_3$ solution (5 mg of Cl/mL).

12.8.2. Add 1 mL of 5 percent indicator solution (see Section 12.6), 1 g of sodium bicarbonate powder, and titrate to the appearance of a permanent orange color preceding a red precipitate. The analyst must practice this titration to become familiar with this color.

13. TEST PROCEDURE

13.1. Weigh 100 g of soil into a 500-mL Erlenmeyer flask. Add 300 mL of distilled water. Stopper and shake vigorously for 20 seconds. After 1 hour repeat shaking. Centrifuge the sample. If the sample exhibits turbidity, then filter the sample through a 0.45 micron membrane filter.

13.2. Check the pH and titrate a 30 mL aliquot for chlorides as follows:

13.2.1. Check the pH with a meter, if available, or with phydrion paper. If the pH is in the range of six through eight, proceed immediately to the step in Section 13.2.2. If the pH is below six, add sodium bicarbonate to adjust to the above range; if the pH is above 8, add nitric acid to adjust to the above range.

13.2.2. Add two drops of potassium chromate solution.

13.2.3. Titrate with silver nitrate solution until the indicator begins to turn from yellow to red. If the titration is over 30 mL, take a smaller sample so as to keep the titration under this value. Dilute any smaller sample to about 50 mL with distilled water before titrating.

13.2.4. Record the volume of $AgNO_3$ required to the end point and calculate the chloride content.

13.2.5. Deduct the 0.2 blank or the blank volume as determined in Section 12.5.5.

14. CALCULATIONS

14.1. Calculate the chloride content as follows:

$$\text{Chloride content (mg/kg)} = (\text{mL } AgNO_3 \text{ used} - \text{B}) \times \text{T} \times 1000/S \qquad (2)$$

where:

T = titre, mg Cl/mL of $AgNO_3$;

B = indicator blank, 0.2 or as determined in Section 12.5.5; and

S = g of sample titrated as diluted in steps described in Sections 13.1 and 13.2, e.g.:

$$\frac{100 \text{ g soil}}{S} = \frac{300 \text{ mL water}}{30 \text{ mL aliquor}}$$

$$S = 10 \text{ gr}$$

14.2. Chloride content on a moisture-free basis: Determine percent moisture by drying at 110 ± 5°C and adjust above result as:

Chloride content mg/kg (moisture-free basis) = [mg/kg (as received) × 100]/
(100 – percent moisture)

15. REPORT

15.1. The chloride content will be reported as in Section 14.2 on a moisture-free basis in milligrams per kilogram (mg/kg). This result will be reported to the nearest whole number in accordance with ASTM E 29.

16. PRECISION AND BIAS

16.1. Data are not available at this time.

DETERMINATION OF WATER-SOLUBLE CHLORIDE ION CONTENT UTILIZING A PH/MV METER (METHOD B)

17. SCOPE

17.1. This method covers the test procedure and apparatus for the determination of water-soluble chloride ion content of soils by the use of a pH/mV meter equipped with chloride ion electrode(s).

17.2. Samples containing from 10 to 1000 mg/kg of chloride can be analyzed by this test method. The range is based on the calibration curve that is developed (Note 5).

17.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

18. SUMMARY OF METHOD

18.1. This test method utilizes a pH/mV meter equipped with chloride ion selective electrode(s). This apparatus can be used directly to measure concentrations after the addition of mV ionic strength adjustment buffer to sample(s) and standards. This procedure brings all solutions to the same ionic strength so the activity coefficients are equal in all cases. The activity of an ion is a function of the change and concentration of all ions present.

19. INTERFERENCES

19.1. Sulfide, bromide, iodide, thiocyanate, cyanide, phosphate, sulfite, carbonate, hydroxide, and iron interfere in this test method. Sulfide, sulfite, and thiosulfate can be removed with a peroxide treatment, but usually no attempt is made to remove bromide and iodide because they are usually present in insignificant quantities compared to chloride.

20. APPARATUS

20.1. pH/mV Meter.

20.2. Electrodes.
(a) Reference Electrode Ag/AgCl Double Junction.
(b) Chloride Electrode.

20.3. Centrifuge with tubes capable of holding at least 50 mL.

20.4. *Glassware, Assorted*—As required in the procedure.

20.5. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

20.6. *Drying Apparatus*—An oven capable of drying samples at a temperature of 110 ± 5ºC.

21. REAGENTS/SOLUTIONS

21.1. *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specification of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

21.1.1. 4 M KC1 Solution saturated with AgCl (purchased, reference electrode internal chamber fill solution).

21.1.2. 1 M KNO_3 Solution. Dissolve 101.11 g of reagent grade potassium nitrate in deionized water and dilute to 1 liter. (Reference electrode external chamber fill solution).

21.1.3. 0.2 M potassium nitrate (KNO_3) buffer. Dissolve 20.22 g of potassium nitrate in deionized water and dilute to 1 liter (Note 4).

Note 4—Other strengths of the buffer solution may be substituted in lieu of the 0.2 M buffer. However, it should be noted that the buffer solution being substituted must be used to develop the calibration curve as well as for performing the test.

21.1.4. *Potassium Chloride Stock Solution*—Dry the potassium chloride in an oven at 110 ± 5ºC for a minimum of 12 hours and allow to cool in a desiccator before determining the mass. Dissolve 2.103 g of reagent potassium chloride in deionized water and dilute to 1 liter (Note 5). This produces a stock solution of 1000 mg/L.

Note 5—Other strengths of stock solution may be prepared that will span the range of the material being tested.

21.1.5. *Standard Solutions*—Standard solutions are prepared by diluting potassium chloride stock solution.

22. SAMPLE PREPARATION

22.1. Select a representative portion of the material passing the 2.00-mm (No. 10) sieve and dry a minimum of 12 hours at 110 ± 5ºC.

22.2. To 100 g of the prepared soil, add 100 mL of deionized water and agitate for 15 minutes on a small paint shaker. If less vigorous means of agitation is used, a longer period of time is necessary.

22.3. Centrifuge a 50-mL portion of the mixture at approximately 10000 r/min for 10 to 15 minutes and then transfer 20 mL or 25 mL aliquot into a 100-mL beaker. If the sample is turbid, then filter the sample through a 0.45 micron membrane filter.

23. CALIBRATION OF METER-MILLIVOLT MEASUREMENT

23.1. *Calibrate the pH/mV Meter*—Follow the instructions supplied with the meter and the electrodes.

24. PROCEDURE

24.1. *Preparation of Calibration Curves*:

24.1.1. Calibration solutions should be prepared by serial dilution of the potassium chloride stock solution. The range of the standards should be from 10 to 1000 mg/L. Solutions of other strengths may be prepared that span the range of the material being tested.

24.1.2. Standards and samples should be ionic strength buffered.

24.1.3. Construct a calibration graph on semi-log paper by plotting the value of the concentration standards on the long axis (mg/L) versus the mV reading obtained with these standards on the linear axis. (Ion selective electrodes give a logarithmic response to the activities of ions rather than to their concentrations. With the addition of an ionic strength adjustment buffer, the electrodes can be used directly to measure concentrations or millivolts.)

25. CHLORIDE CONCENTRATION MEASUREMENT

25.1. Transfer an aliquot (25 mL to 40 mL) of liquid from the centrifugation of the sample into a 100-mL beaker.

25.2. Buffer the samples (or standards) by the addition of an equal volume of the 0.2 M KNO_3 solution (one to one by volume).

25.3. Rinse the electrodes with deionized water and blot off excess liquid.

25.4. Immerse the electrodes into the solution—stir gently.

25.5. Allow the electrodes to remain in the solution until the meter reading stabilizes. Refer to the instructions supplied with the meter and the electrode(s).

25.6. After stabilization, read and record the displayed reading (see manufacturer's operating instructions).

25.7. Before removing the electrode(s) from the solution refer to the proper operating instructions supplied with the meter and electrode(s) so as not to damage the meter.

25.8. Remove the electrodes from the solution, rinse, and blot dry.

25.9. Consult the calibration curve to determine the concentration to which the displayed value in mV corresponds.

26. PRECAUTIONS

26.1. Periodically check the electrodes for any damage.

26.2. The temperature of the solution used to develop the calibration curve must be the same temperature as the sample being tested.

27. REPORT

27.1. Report the values (mg/kg) to the nearest whole number in accordance with ASTM E 29.

28. PRECISION AND BIAS

28.1. Data are not available at this time.

Standard Method of Test for

Unconsolidated, Undrained Compressive Strength of Cohesive Soils in Triaxial Compression

AASHTO Designation: T 296-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Unconsolidated, Undrained Compressive Strength of Cohesive Soils in Triaxial Compression

AASHTO Designation: T 296-10

1. SCOPE

1.1. This test method covers the determination of unconsolidated strength and stress-strain relationships for a cylindrical specimen of either an undisturbed or remolded cohesive soil sheared undrained in compression at a constant rate of axial deformation (strain controlled).

1.2. The test method provides for the calculation of total stresses on, and axial compression of, the test specimen by measurement of axial load and axial deformation.

1.3. The test provides data useful in determining strength and deformation properties of cohesive soils much as Mohr strength envelopes and Young's modulus.

1.4. The determination of strength envelopes and the development of relationships to aid in interpreting and evaluating test results are left to the engineer or office requesting the test.

1.5. The values stated in SI units are to be regarded as standard.

1.6. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*—The definitions of terms used in this test method shall be in accordance with Terminology D 653.

3.2. *Description of Terms Specific to This Standard*:

3.2.1. *failure*—the stress condition at failure for a test specimen. Failure is often taken to correspond to the maximum principal stress difference (maximum deviator stress) attained or the principal stress difference (deviator stress) at 15 percent axial strain, whichever is obtained first during the performance of a test. Depending on soil behavior and field application, other suitable failure criteria may be defined, such as the principal stress difference (deviator stress) at a selected axial strain other than 15 percent.

3.2.2. *principal stress difference (deviator stress)*—the difference in magnitude between the major principal stress and minor principal stress; in a triaxial compression test, the stress due to the axial load that is applied in excess of the confining pressure.

3.2.3. *total stress,* σ—the total force per unit area acting within a soil mass. It is the sum of neutral and effective stresses ($\sigma' + \mu$).

4. SIGNIFICANCE AND USE

4.1. The strength in this test is measured under undrained conditions and is applicable to field conditions where soils are subjected to a change in stress without time for consolidation to take place (unconsolidated condition), and the field stress conditions are similar to those in the tests.

4.2. The shear strength determined from the test expressed in terms of total stresses or effective stresses is commonly used in embankment stability analyses, earth pressure calculations, and foundation design.

5. APPARATUS

5.1. The requirements for equipment needed to perform satisfactory tests are given in the following sections.

5.2. *Axial Loading Device*—The axial compression device may be a screw jack driven by an electric motor through a geared transmission, a hydraulic or pneumatic loading device, or any other compression device with sufficient capacity and control to provide the rate of axial strain (loading) described in Section 8.2.6. The rate of advance of the loading device should not deviate by more than ±1 percent from the selected value. Vibration due to the operation of the loading device shall be sufficiently small to not cause dimensional changes in the specimen or to produce changes in pore-water pressure when the drainage valves are closed.

Note 1—A loading device may be judged to produce sufficiently small vibrations if there are no visible ripples in a glass of water placed on the loading platform when the device is operating.

5.3. *Axial Load-Measuring Device*—The axial load-measuring device may be a load ring, electronic load cell, hydraulic load cell, or any other load-measuring device capable of the accuracy prescribed in this paragraph and may be a part of the axial loading device. The axial load-measuring device shall be capable of measuring the axial load to an accuracy of within ±1 percent of the axial load at failure. If the load-measuring device is located inside the triaxial compression chamber, it shall be insensitive to horizontal forces and to the magnitude of the chamber pressure.

5.4. *Triaxial Compression Chamber*—The triaxial chamber must be able to withstand a chamber pressure equal to the sum of the effective confining pressure and back pressure. It shall consist of a top plate and a baseplate separated by a cylinder. The cylinder may be constructed of any material capable of withstanding the applied pressures. It is desirable to use a transparent material or have a cylinder provided with viewing ports so the behavior of the specimen may be observed. The top plate shall have a vent valve such that air can be forced out of the chamber as it is filled. The baseplate shall have an inlet through which pressure liquid is supplied to the chamber.

Note 2—Although the confining fluid for this test is typically a liquid, compressed air or other gases may be successfully used. Use of air or other gases is a safety concern, however, about which the user must be aware and take reasonable safeguards.

5.5. *Axial Load Piston*—The piston passing through the top of the chamber and its seal must be designed so the variation in axial load due to friction does not exceed 0.1 percent of the axial load at failure and so there is negligible lateral bending of the piston during loading.

Note 3—The use of two linear ball bushings to guide the piston is recommended to minimize friction and maintain alignment.

Note 4—A minimum piston diameter of one-sixth the specimen diameter has been used successfully in many laboratories to minimize lateral bending.

5.6. *Chamber Pressure Control Device*—The chamber pressure control device shall be capable of applying and controlling pressure to within 2 kPa (±0.25 psi) for chamber pressures less than 200 kPa (28 psi) and to within ±1 percent for chamber pressures greater than 200 kPa (28 psi). The device may consist of self-compensating mercury pots, pneumatic pressure regulator, or any other device capable of applying and controlling pressures to the required tolerances.

5.7. *Chamber Pressure Measurement Device*—The chamber pressure measuring device shall be capable of measuring pressures to the tolerances given in Section 5.6. It may be a Bourdon gauge, pressure manometer, electronic pressure transducer, or any other device capable of measuring pressures to the stated tolerances.

5.8. *Deformation Indicator*—The vertical deformation of the specimen is usually determined from the travel of the piston acting on the top of the specimen. The piston travel shall be measured with an accuracy of at least ±0.02 percent of the initial specimen height. The deformation indicator shall have a travel range of at least 20 percent of the initial height of the specimen and may be a dial indicator, linear variable differential transformer (LVDT), extensiometer, or other measuring device meeting the requirements for accuracy and range.

5.9. *Specimen Cap and Base*:

5.9.1. *For Total Stress Determination*—An impermeable rigid cap and base shall be used to prevent drainage of the specimen. The specimen cap and base shall be constructed of a noncorrosive impermeable material and each shall have a circular plane surface of contact with the specimen and a circular cross section. The weight of the specimen cap shall produce an axial stress on the specimen of less than 1 kN/m^2 (0.145 psi). The diameter of the cap and base shall be equal to the initial diameter of the specimen. The specimen base shall be coupled to the triaxial compression chamber so as to prevent lateral motion or tilting and the specimen cap shall be designed to receive the piston such that the piston-to-cap contact area is concentric with the cap. The specimen cap during shear shall not tilt more than 5 degrees. The cylindrical surface of the specimen base and cap that contacts the membrane to form a seal shall be smooth and free of scratches.

Note 5—The stress produced by the specimen cap can exceed 1 kN/m^2 (0.145 psi) provided the test data is corrected for the effects of that stress.

5.10. *Rubber Membrane*—The rubber membrane used to encase the specimen shall provide reliable protection against leakage. To check a membrane for leakage, the membrane shall be placed around a cylindrical form, sealed at both ends with rubber O-rings, subjected to a small air pressure on the inside, and immersed in water. If air bubbles appear from any point on the membrane it shall be rejected. To offer minimum restraint to the specimen, the unstretched membrane diameter shall be between 90 and 95 percent of that of the specimen. The membrane thickness shall not exceed 1 percent of the diameter of the specimen. The membrane shall be sealed to the specimen cap and base with rubber O-rings for which the unstressed inside diameter is between 75 and 85 percent of the diameter of the cap and base, or by other means that will provide a positive seal. An equation for correcting the principal stress difference (deviator stress) for the effect of the stiffness of the membrane is given in Section 10.4.3.

5.11. *Specimen-Size Measurement Devices*—Devices used to determine the height and diameter of the specimen shall measure the respective dimensions to within ±0.1 percent of the total dimension and shall be constructed such that their use will not disturb the specimen.

Note 6—Circumferential measuring tapes are recommended over calipers for measuring the diameter.

5.12. *Recorders*—Specimen behavior may be recorded manually or by electronic digital or analog recorders. If electronic recorders are used, it shall be necessary to calibrate the measuring devices through the recorder using known input standards.

5.13. *Sample Extruder*—Hand-operated, mechanical, and hydraulic extruders are acceptable provided the device (1) is capable of extruding the soil core from the sampling tube in the same direction of travel in which the sample entered the tube, (2) has a length of travel at least equal to the required untrimmed test length of the sample and permits the extrusion to occur in one operation without resetting the piston or extrusion mechanism, (3) can be operated at a relatively uniform rate, and (4) causes negligible disturbance of the sample.

5.14. *Weighing Device*—The specimen weighing device shall determine the mass of the specimen to an accuracy of within ±0.05 percent of the total mass of the specimen.

5.15. *Testing Environment*—The shear portion of the test shall be performed in an environment where temperature fluctuations are less than ±4ºC (±7.2ºF) and there is no direct contact with sunlight.

5.16. *Miscellaneous Apparatus*—Specimen trimming and carving tools including a wire saw, steel straightedge, miter box, and vertical trimming lathe, apparatus for preparing compacted specimens, membrane and O-ring expander, water content cans, and data sheets shall be provided as required.

6. TEST SPECIMEN PREPARATION

6.1. *Specimen Size*—Specimens shall be cylindrical and have a minimum diameter of 3.3 cm (1.3 in.). The height-to-diameter ratio shall be between 2 and 2.5. The largest particle size shall be smaller than one-sixth the specimen diameters. If, after completion of a test, it is found based on visual observation that oversize particles are present, indicate this information in the report of test data (Section 11.1.20).

Note 7—If oversize particles are found in the specimen after testing, a particle-size analysis may be performed in accordance with ASTM D 422 to confirm the visual observation and the results provided with the test report (Section 11.1.4).

6.2. *Undisturbed Specimens*—Prepare undisturbed specimens from large undisturbed samples or from samples secured in accordance with T 207 or other acceptable undisturbed tube sampling procedures and preserved and transported in accordance with the practices for Group C samples in ASTM D 4220. Specimens obtained by tube sampling may be tested without trimming except for cutting the end surfaces plane and perpendicular to the longitudinal axis of the specimen, provided soil characteristics are such that no significant disturbance results from sampling. Handle specimens carefully to minimize disturbance, changes in cross section, or change in water content. If compression or any type of noticeable disturbance would be caused by the extrusion device, split the sample tube lengthwise or cut the tube in suitable sections to facilitate removal of the specimen with minimum disturbance. Prepare trimmed specimens, in an environment such as a controlled high-humidity room where soil water content change is minimized. Where removal of pebbles or crumbling resulting from trimming causes voids on the surface of the specimen, carefully fill the voids with remolded soil obtained from the trimmings. Where the sample condition permits, a vertical trimming lathe that will accommodate the total sample may be used as an aid in preparing the specimen to the required diameter. After obtaining the desired diameter, place the specimen in a miter box and cut the specimen to the final length with a wire saw or other suitable device. Trim the surfaces with the steel straightedge. Perform one or more water content determinations on material trimmed from the specimen in accordance with ASTM D 2216. Determine the mass and dimensions of the specimen using the devices described in Sections 5.13 and 5.16. A minimum of three height measurements (120° apart) and at least three diameter measurements at the quarter points of the height shall be made to determine the average height and diameter of the specimen.

6.3. *Remolded Specimens*—Prepare the specimen by first thoroughly working the previously undisturbed specimen, which has been tested and is still encased in the rubber membrane, with the fingers. Then reform the specimen by forming within a mold having dimensions such that the remolded specimen dimensions will be equal to those of the undisturbed specimen. Exercise care to avoid entrapping air in the specimen. This will aid in obtaining a uniform unit mass, in remolding to the same void ratio as the undisturbed specimen, and in preserving the natural water content of the soil.

6.4. *Compacted Specimens*—Prepare specimens using the compaction method, predetermined water content, and unit mass prescribed by the individual assigning the test. Compacted specimens may be prepared by compacting material in at least six layers, using a pressing or kneading action, into a split mold of circular cross section having dimensions meeting the requirements of Section 6.1. Material required for the specimen shall be batched by thoroughly mixing soil with sufficient water to produce the desired water content. After batching, store the material in a covered container for at least 16 hours prior to compaction. Specimens may be molded to the desired density by either: (1) kneading or tamping each layer until the accumulative mass of the soil placed in the mold is compacted to a known volume or (2) by adjusting the number of layers, the number of tamps per layer, and the force per tamp. Scarify the top of each layer prior to the addition of material for the next layer. The tamper used to compact the material shall have an area in contact with the soil equal to or less than one-half the area of the mold. After a specimen is formed, with the ends perpendicular to the longitudinal axis, remove the mold and determine the mass and dimensions of the specimen using the devices described in Sections 5.13 and 5.16. Perform one or more water content determinations on excess material used to prepare the specimen in accordance with ASTM D 2216.

Note 8—It is common for the unit mass of the specimen after removal from the mold to be less than the value based on the volume of the mold. This occurs as a result of the specimen swelling after removal of the lateral confinement due to the mold.

Note 9—Experience indicates that it is difficult to compact, handle, and obtain valid results with specimens that have a degree of saturation that is greater than about 90 percent.

7. MOUNTING SPECIMEN

7.1. *Preparations*—Before mounting the specimen in the triaxial chamber, make the following preparations:

7.1.1. If deemed necessary, check the rubber membrane for leaks. (See Section 5.11.)

7.1.2. Place the membrane on the membrane expander or, if it is to be rolled onto the specimen, roll the membrane on the cap or base.

7.1.3. Attach the pressure-control device to the chamber base.

7.2. Place the rubber membrane around the specimen and seal it at the cap and base with two rubber O-rings or other positive seal at each end. A thin coating of silicon grease on the vertical surfaces of the cap and base will aid in sealing the membrane.

8. PROCEDURE

8.1. *For total stress determination*:

8.1.1. With the specimen encased in the rubber membrane, which is sealed to the specimen cap and base and positioned in the chamber, assemble the triaxial chamber. Bring the axial load piston into contact with the specimen cap several times to permit proper seating and alignment of the piston with the cap. When the piston is brought into contact the final time, record the reading on the deformation indicator. During this procedure, take care not to apply an axial stress to the specimen exceeding approximately 0.5 percent of the estimated compressive strength. If the mass of the piston is sufficient to apply an axial stress exceeding approximately 0.5 percent of the estimated compressive strength, lock the piston in place above the specimen cap after checking the seating and alignment and keep locked until application of the chamber pressure.

8.1.2. Place the chamber in position in the axial loading device. Be careful to align the axial loading device, the axial load-measuring device, and the triaxial chamber to prevent the application of a lateral force to the piston during testing. Attach the pressure-maintaining and measurement device and fill the chamber with the confining liquid. Adjust the pressure-maintaining and measurement device to the desired chamber pressure and apply the pressure to the chamber fluid. If it is determined to be necessary to stabilize the specimen under the chamber pressure prior to application of the axial load, wait approximately 10 minutes after applying chamber pressure before continuing the test.

Note 10—In some cases the chamber will be filled and the chamber pressure applied before placement in the axial loading device.

Note 11—Make sure the piston is locked or held in place by the axial loading device before applying the chamber pressure.

Note 12—The purpose of the waiting period is to allow the specimen to stabilize under the chamber pressure prior to application of the axial load.

8.1.3. If the axial load-measuring device is located outside of the triaxial chamber, the chamber pressure will produce an upward force on the piston that will react against the axial loading device. In this case, start the test with the piston slightly above the specimen cap, and before the piston comes in contact with the specimen cap, either: (1) measure and record the initial piston friction and upward thrust of the piston produced by the chamber pressure and later correct the measured axial load, or (2) adjust the axial load-measuring device to compensate for the friction and thrust. If the axial load-measuring device is located inside the chamber, it will not be necessary to correct or compensate for the uplift force acting on the axial loading device or for piston friction. In both cases record the initial reading on the deformation indicator when the piston contacts the specimen cap.

8.1.4. Apply the axial load to produce axial strain at a rate of approximately 1 percent/min for plastic materials and 0.3 percent/min for brittle materials that achieve maximum deviator stress at approximately 3 to 6 percent strain. At these rates, the elapsed time to reach maximum deviator stress will be approximately 15 to 20 minutes. Continue the loading to 15 percent axial strain, except loading may be stopped when the deviator stress has peaked, then dropped 20 percent, or the axial strain has reached 5 percent beyond the strain at which the peak in deviator stress occurred.

8.1.5. Record load and deformation values at about 0.1, 0.2, 0.3, 0.4, and 0.5 percent strain; then at increments of about 0.5 percent strain to 3 percent; and, thereafter, at every 1 percent. Take sufficient readings to define the stress-strain curve; hence, more frequent readings may be required in the early stages of the test and as failure is approached.

Note 13—Alternate intervals for the readings may be used provided sufficient points are obtained to define the stress-strain curve.

8.1.6. For completion of the total stress determination, proceed to Section 9 and applicable portions of Section 10.

9. REMOVING SPECIMEN

9.1. When shear is completed, perform the following steps:

9.1.1. Remove the axial load and reduce the chamber and back pressures to zero.

9.1.2. With the specimen drainage valves remaining closed, quickly remove the specimen from the apparatus so the specimen will not have time to absorb water from the porous discs.

9.1.3. Remove the rubber membrane and determine the water content of the total specimen in accordance with the procedure outlined in ASTM D 2216. (Free water remaining on the specimen after removal of the membrane should be blotted away before obtaining the water content.) In cases where there is insufficient material from trimmings for index property tests, that is, where specimens have the same diameter as the sampling tube, the mass of the specimen should be determined prior to removing material for index property tests and a representative portion of the specimen used to determine its final water content. Prior to placing the specimen (or portion thereof) in the oven to dry, sketch a picture or take a photograph of the specimen showing the mode of failure (shear plane, bulging, etc.).

10. CALCULATIONS

10.1. *Initial Specimen Properties*—Using the dry mass of the total specimen, calculate and record on the appropriate data sheet the initial water content, volume of solids, initial void ratio, initial degree of saturation, and initial dry unit mass. Calculate the specimen volume from values measured in Section 6.2 or 6.3. Calculate the volume of solids by dividing the dry mass of the specimen by the specific gravity of the solids (Note 14) and dividing by the density of water. Calculate the void ratio by dividing the volume of voids by the volume of solids where the volume of voids is assumed to be the difference between the specimen volume and the volume of the solids. Calculate dry density by dividing the dry mass of the specimen by the specimen volume.

Note 14—The specific gravity of solids can be determined in accordance with Test Method T 100 or it may be assumed based on previous test results.

10.2. Calculate the axial strain, $\in$ (expressed as a decimal), for a given applied axial load, as follows:

$$\in = \Delta L/L_o \qquad (1)$$

where:

ΔL = change in length of specimen as read from deformation indicator, and

L_o = initial length of test specimen minus any change in length prior to loading.

10.3. Calculate the average cross-sectional area, A, for a given applied axial load as follows:

$$A = A_o/(1 - \in) \qquad (2)$$

where:

A_o = initial average cross-sectional area of the specimen, and

$\in$ = axial strain for the given axial load (expressed as a decimal).

Note 15—In the event that the application of the chamber pressure results in a change in the specimen length, A_o should be corrected to reflect this change in volume. Frequently, this is done by assuming that lateral strains are equal to vertical strains. The diameter after volume change would be given by $D = D\sigma\ (1 - \Delta L/L)$.

10.4. For determination of total stress:

10.4.1. Calculate the principal stress difference (deviator stress), $\sigma_1 - \sigma_3$, for a given applied axial load as follows:

$$\sigma_1 - \sigma_3 = P/A \qquad (3)$$

where:

P = measured applied axial load (corrected for uplift and piston friction; if required, see Section 8.2.5.1.3), and

A = corresponding average cross-sectional area.

10.4.2. *Stress-Strain Curve*—Prepare a graph showing the relationship between principal stress difference (deviator stress) and axial strain, plotting deviator stress as ordinate and axial strain (in percent) as abscissa. Select the compressive strength and axial strain at failure in accordance with the definitions in Sections 3.2.3 and 3.2.6.

10.4.3. *Correction of Strength Due to Stiffness of Rubber Membrane*—Assuming units are consistent, the following equation, or other acceptable equations, shall be used to correct the principal stress difference or deviator stress for the effect of the rubber membrane if the error in principal stress difference due to the stiffness of the membrane exceeds 5 percent:

$$\Delta(\sigma_1 - \sigma_3) = \frac{4E_m t \in_1}{D} \quad (4)$$

where:

$\Delta(\sigma_1 - \sigma_3)$ = correction to be subtracted from the measured principal stress difference,

D = $\sqrt{\frac{4A}{\pi}}$ = diameter of specimen,

E_m = Young's modulus for the membrane material,

t = thickness of the membrane, and

$\in_1$ = axial strain.

10.4.3.1. The Young's modulus of the membrane material may be determined by hanging a 12.5-mm (0.5-in.) wide strip of membrane over a thin rod, placing another rod along the bottom of the hanging membrane, and measuring the force per unit strain obtained by stretching the membrane. The modulus value may be computed using the following equation assuming units are consistent:

$$E_m = \frac{FL}{A_m \Delta L} \quad (5)$$

where:

E_m = Young's modulus of the membrane material,

F = force applied to stretch the membrane,

L = unstretched length of the membrane,

A_m = twice the initial thickness of the membrane multiplied by the width of the membrane strip, and

ΔL = change in length of the membrane due to application of F.

A typical value of E_m for latex membrane is 200 psi (1400 kPa).

Note 16—The effect of the stiffness of the membrane on the lateral stress is usually assumed to be negligible.

Note 17—The correction for rubber membranes is based on simplified assumptions concerning their behavior during shear. Their actual behavior is complex and there is not a consensus on more exact corrections.

10.4.4. Calculate the major and minor principal total stresses at failure as follows:

σ_3 = minor principal total stress = chamber pressure, and

σ_1 = major principal total stress = deviator stress at failure plus chamber pressure.

10.4.4.1. Calculate the initial degree of saturation of the test specimen using the initial mass and dimensions.

Note 18—The specific gravity determined in accordance with Test Method T 100 is required for calculation of the degree of saturation, or an assumed value may be used provided it is noted in the test report that an assumed value was used.

11. REPORT

11.1. The report shall include the following (as applicable):

11.1.1. Identification data and visual description of specimen, including soil classification and whether the specimen is undisturbed, compacted, or otherwise prepared.

11.1.2. Values of plastic limit and liquid limit, if determined in accordance with Test Methods T 89 and T 90.

11.1.3. Value of specific gravity of solids and notation if the value was determined in accordance with Test Method T 100 or assumed.

11.1.4. Particle-size analysis, if determined in accordance with ASTM D 422.

11.1.5. Initial specimen dry unit weight, void ratio, water content, and percent saturation.

11.1.6. Initial height and diameter of specimen.

11.1.7. Failure criterion used.

11.1.8. The value of the principal stress difference (deviator stress) at failure and the values of the effective minor and major principal stresses at failure.

11.1.9. Axial strain at failure, percent.

11.1.10. Rate of strain, percent/min.

11.1.11. Stress-strain curve as described in Section 10.4.2.

11.1.12. Failure sketch or photograph of the specimen.

11.1.13. Remarks and notations regarding any unusual conditions or other information necessary to properly interpret the results obtained, including any departures from the procedure outlined.

12. PRECISION AND BIAS

12.1. The variability of soil and resultant inability to determine a true reference value prevent development of a meaningful statement of bias. Data are being evaluated to determine the precision of this test method. In addition, the subcommittee is seeking pertinent data from users of this test method.

13. KEYWORDS

13.1. Back pressure saturation; unconsolidated-undrained triaxial compression test; effective stress; pore pressure; shear strength; strength envelope; total stress.

Standard Method of Test for

High-Strain Dynamic Testing of Piles

AASHTO Designation: T 298-99 (2006)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

High-Strain Dynamic Testing of Piles

AASHTO Designation: T 298-99 (2006)[1]

1. SCOPE

1.1. This test method covers the procedure for testing vertical or batter piles individually to determine the force and velocity response of the pile to an impact force applied axially by a pile-driving hammer to the top of the pile. This test method is applicable to deep foundation units that function in a manner similar to foundation piles, regardless of their method of installation, provided that they are receptive to high-strain impact testing. These elements can include drilled shafts, micropiles, and continuous flight auger cast piles.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. For a specific precautionary statement, see Note 7.

Note 1—High-strain dynamic testing requires a strain at impact which is representative of a force in the pile having the same order of magnitude, or greater, than the ultimate pile-soil resistance.

Note 2—This standard method may be applied to the high-strain dynamic testing of piles with the use of only force or strain transducers and/or acceleration, velocity or displacement transducers as long as the test results clearly state how the testing deviates from the standard, i.e., what combination of instruments was used.

Note 3—A suitable follower may be required for testing existing cast-in-place concrete piles. This follower should have an impedance within 50 percent of the impedance of the pile. However, additional caution and analysis may be required if the impedance is not within 10 percent.

Note 4—For mandrel-driven piles, the mandrel may be instrumented in a similar way to a driven pile. However, results from a mandrel that is more than two pieces, one that has joints, will require additional analysis.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- C 469, Standard Test Method for Static Modulus of Elasticity and Poisson's Ratio of Concrete in Compression[2]
- D 198, Standard Test Methods of Static Tests of Lumber in Structural Sizes[3]
- D 653, Standard Terminology Relating to Soil, Rock, and Contained Fluids[4]
- D 1143, Standard Test Methods for Deep Foundations Under Static Axial Compressive Load[4]

3. TERMINOLOGY

3.1. Except as defined in Section 3.2, the terminology used in this test method conforms with Terminology ASTM D 653.

3.2. *Descriptions of Terms Specific to This Standard*:

3.2.1. *capblock*—the material inserted between the hammer striker plate and the drive cap on top of the pile (also called the hammer cushion).

3.2.2. *cushion*—the material inserted between the drive cap and top of the pile (also called the pile cushion).

3.2.3. *impact event*—the period of time during which the pile is moving in a positive and/or negative direction of penetration due to a single impact force application. (See Figure 1.)

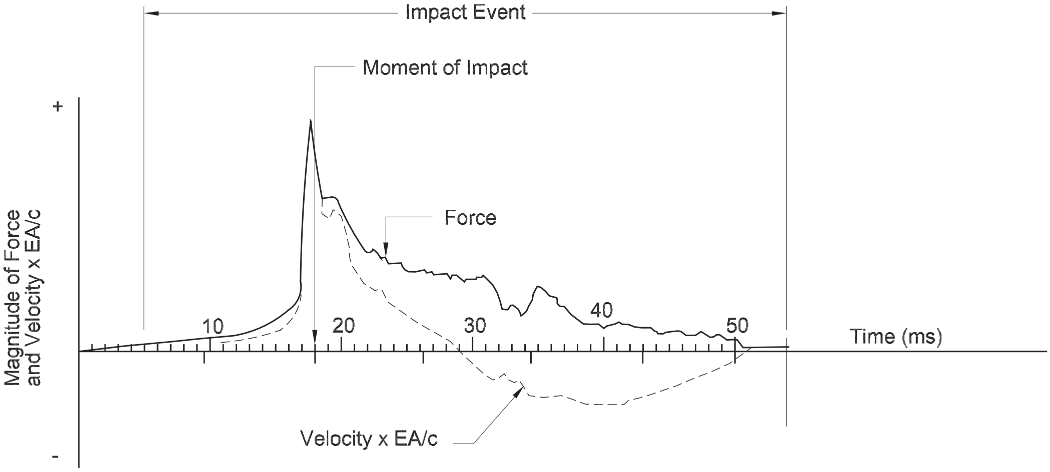

Figure 1—Typical Force and Velocity Traces Generated by the Apparatus for Obtaining Dynamic Measurements

3.2.4. *moment of impact*—the first moment of time after the start of the impact event when the acceleration is zero, i.e., first major velocity peak. (See Figure 1.)

3.2.5. *strain wave speed (or wave speed)*—the speed with which a strain wave propagates through a pile. It is a property of the pile material.

3.2.6. *particle velocity*—the velocity of a particle in the pile as a strain wave passes by.

3.2.7. *pile impedance*—indicates the resistance a pile has to a sudden change in velocity. It can be calculated by multiplying Young's Modulus of Elasticity by the cross-sectional area and dividing the product by the strain wave speed (proportionality constant):

$$Z = AE/c = \rho cA \quad (1)$$

where:

Z = impedance,

A = cross-sectional area,

E = Young's Modulus of Elasticity,

c = wave speed of the pile, and

ρ = unit mass density of the pile material.

3.2.8. *restriking*—the redriving of a previously driven pile after a waiting period of from 15 minutes to 30 days or more. The length of the waiting period is dependent upon the type of pile and the soil.

3.2.9. *transducer attachment area (TAA)*—an extension of non-driven elements used to attach the instruments the minimum distance from the top of the column. The minimum length of the TAA is two element diameters. This length can be achieved by using a buildup to extend the column height and/or by excavation of the soil, from around the existing column.

4. SIGNIFICANCE AND USE

4.1. This test method is used to provide data on strain or force and acceleration, velocity or displacement of a pile under impact force. The data may be used to estimate the bearing capacity and the integrity of the pile, as well as hammer performance, pile stresses, and soil dynamics characteristics such as soil damping coefficients and quake values.

5. APPARATUS

5.1. *Apparatus for Applying Impact Force*:

5.1.1. *Impact Force Application*—Any conventional pile-driving hammer or similar device is acceptable for applying the impact force. The hammer or device should be capable of generating:

- A net measurable pile penetration, or
- An estimated mobilized static resistance in the bearing strata which, for a minimum period of three minute, exceeds to a sufficient degree the working load assigned to the pile, as judged by the engineer.

The device shall be positioned so that the impact is applied axially to the head of the pile and concentric with the pile. For non-driven piles the concrete should be level with or above any casing. The top should be fitted with a cushioning material with a thickness of 50 to 150 mm. The final thickness shall be determined from a wave equation study. A steel striker plate, minimum thickness of 50 mm, and an area between 70 and 90 percent of the shaft area, but not less than the area of the impact weight.

Note 5—If protruding reinforcing bars are present, the contractor has the option to incorporate the reinforcing bars inside the TAA, or use a pedestal follower (see Note 3).

5.2. *Apparatus for Obtaining Dynamic Measurements*:

5.2.1. *Measurement Transducer Requirements*—The apparatus shall include transducers that are capable of independently measuring strain and acceleration versus time at a specific location along the pile axis during the impact event. The transducers should have a natural frequency in excess of 2000 Hz once they are attached to the pile. A minimum of two each of these devices shall be attached securely to the pile so that they do not slip. Bolt-on, glue-on or weld-on transducers are acceptable. The transducers shall have been calibrated to an accuracy of two percent throughout the applicable measurement range. If damage is suspected during use, the transducers shall be replaced or recalibrated.

5.2.2. *Location of Transducers*—The measurement transducers shall be located at equal radial distances on diametrically opposite sides of the pile. They shall be located the same axial distance from the bottom of the pile, so that measurements are not affected by bending of the pile. When near the upper end of the pile, they shall be attached at least one and one-half pile diameters from the head; where practicable this distance should be three diameters. When testing large diameter piles or non-driven elements it is recommended to use four transducers, if practicable. Attaching transducers to a TAA, created with a casing, will require cutting windows in the casing to access the concrete. The windows should be a minimum of 15 cm square. This is illustrated in Figures 4 through 7.

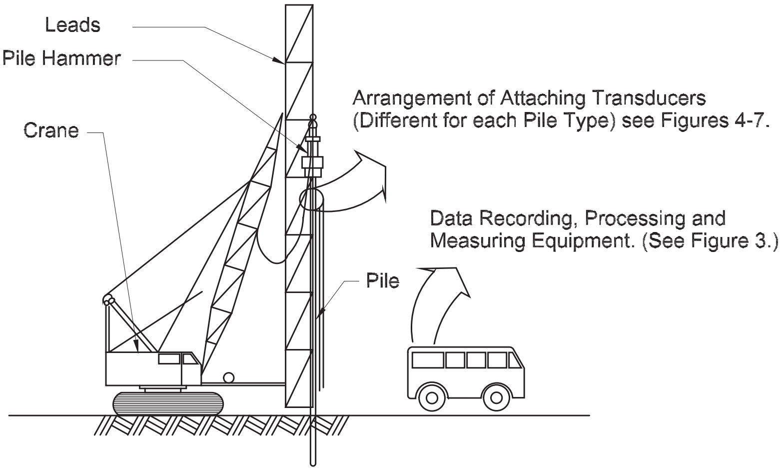

Figure 2—Typical Arrangement for High-Strain Testing

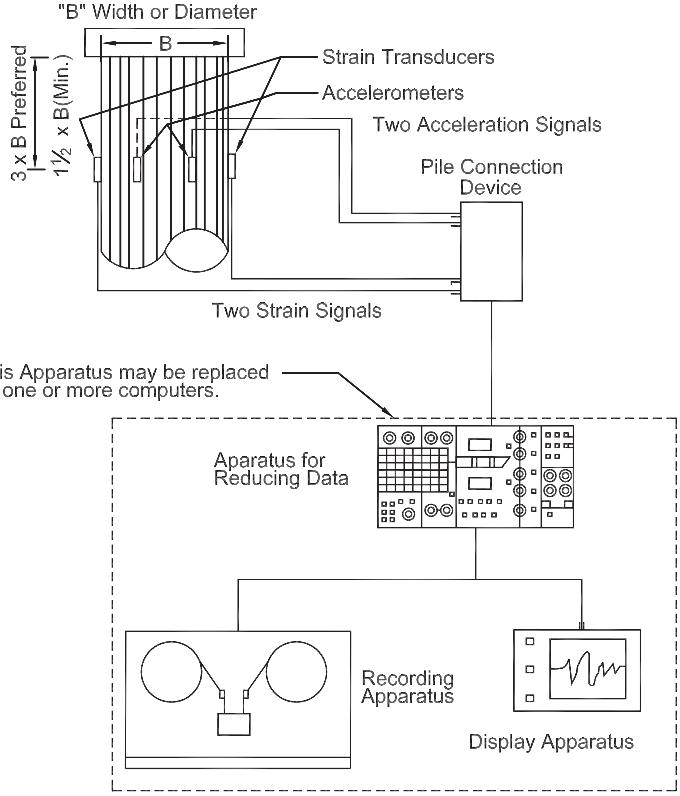

Figure 3—Schematic Diagram of Apparatus for Dynamic Monitoring of Piles

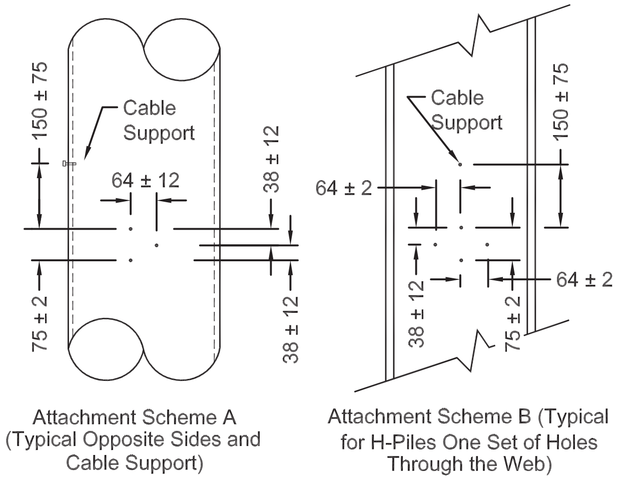

Note: All dimensions shown in millimeters unless otherwise noted.

Figure 4—Instrument Attachment Schemes and Dimensions

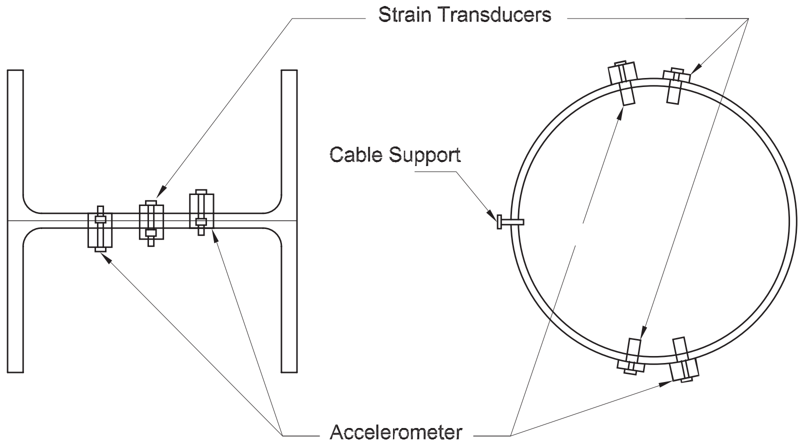

Figure 5—Typical Attachment for H-Piles and Pipe Piles

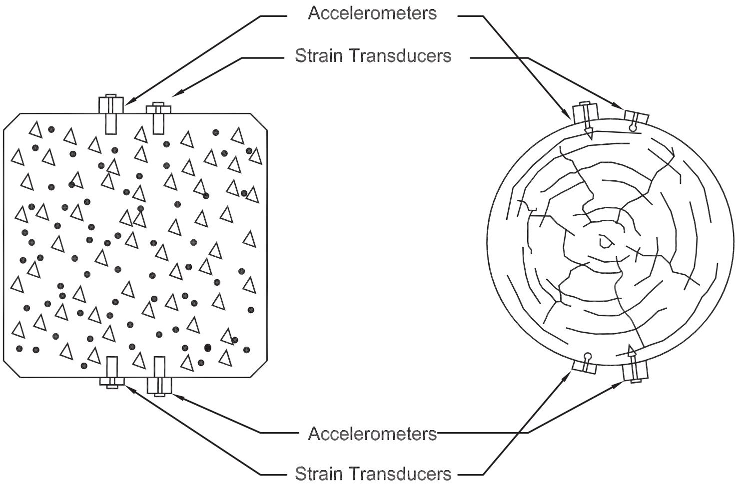

Figure 6—Typical Attachment for Concrete and Timber Piles

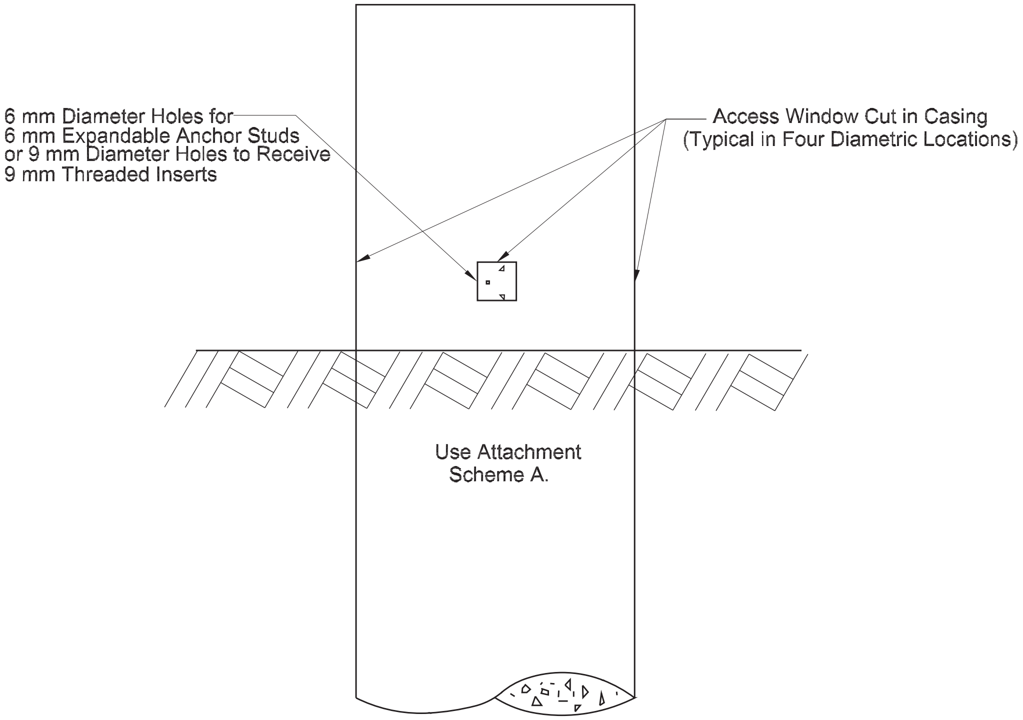

Figure 7—Typical Arrangement for Attaching Transducers to a Non-Driven Pile

5.2.3. *Force or Strain Transducers*—The strain transducers shall have a linear output over the range of possible pile strains. The measured strain shall be converted to force using the pile cross-section area and dynamic modulus of elasticity at the measuring location. The dynamic modulus of elasticity may be assumed to be 200 to 207 GPa for steel. The dynamic modulus of elasticity for concrete and wood piles may be calculated from the wave speed determined as indicated in Section 6.2. The dynamic modulus of elasticity is equal to the product of the strain wave speed squared and the unit weight of the pile divided by gravity.

$$E = c^2 \gamma / g = c^2 \rho \qquad (2)$$

where:

E = dynamic modulus of elasticity,

c = wave speed of pile,

γ = unit weight of pile material,

g = gravity, and

ρ = unit mass density of the pile material.

Alternatively, the dynamic modulus of elasticity may be estimated from the static modulus of elasticity by measurement during a compression test in accordance with ASTM C 469 and D 198, for concrete and wood, respectively.

5.2.3.1. Force measurements also can be made by a force transducer, an instrumented unit, placed between the pile head and the driving hammer, although it should be recognized that such a transducer may alter the dynamic characteristics of the driving system. Force transducers shall have an impedance between 50 percent and 200 percent of the pile impedance. The output signal must be linearly proportional to the axial force, even under eccentric load application. The connection between the force transducers and the pile shall have the smallest possible mass and least possible cushion necessary to prevent damage.

5.2.4. *Acceleration, Velocity, or Displacement Transducers*—Velocity data shall be obtained with accelerometers, provided the signal can be processed by integration in the apparatus for reducing data. The accelerometers shall be linear to at least 1000 g and 1000 Hz for satisfactory results on concrete and timber piles. For steel piles, it is advisable to use accelerometers that are linear up to 2000 g and 2000 Hz. Either ac or dc accelerometers can be used. If ac devices are used, the resonant frequency shall be above 50,000 Hz and the time constant shall be at least 1.0 second. Alternatively, velocity or displacement transducers may be used to obtain velocity data, provided they are equivalent in performance to the specified accelerometers.

5.3. *Signal Transmission*—The signals from the transducers shall be transmitted to the apparatus for recording, reducing, and displaying the data (see Section 5.4) by means of a cable or equivalent. The means of signal transmission shall limit electronic or other interference to less than three percent of the maximum signal expected. The signals arriving at the apparatus shall be linearly proportional to the measurements at the pile over the frequency range of the equipment.

5.4. *Apparatus for Recording, Reducing, and Displaying Data*:

5.4.1. *General*—The signals from the transducers (see Section 5.2) during the impact event shall be transmitted to an apparatus for recording, reducing, and displaying data to allow determination of the force and velocity versus time. It may be desirable to also determine the acceleration and displacement of the pile head, and the energy transferred to the pile. The apparatus shall include an oscilloscope, oscillograph, or LCD screen for displaying the force and velocity traces; a tape recorder, digital disk, or equivalent for obtaining a record for future analysis; and a means to reduce the data. The apparatus for recording, reducing, and displaying data shall have the capability of making an internal calibration check of strain, acceleration, and time scales. No error shall exceed two percent of the maximum signals expected. A typical schematic arrangement for this apparatus is illustrated in Figure 3.

5.4.2. *Recording Apparatus*—Signals from the transducers shall be recorded electronically in either analog or digital form so that frequency components have a low pass cut-off frequency of 1500 Hz (–3 dB). When digitizing, the sample frequency shall be at least 5000 Hz for each data channel.

5.4.3. *Apparatus for Reducing Data*—The apparatus for reducing signals from transducers shall be an analog or digital computer capable of at least the following functions:

5.4.3.1. *Force Measurements*—The apparatus shall provide signal conditioning, amplification, and calibration for the force measurements system. If strain transducers are used (see Section 5.2.3), the apparatus shall be able to compute the force. The force output shall be continuously balanced to zero except during the impact event.

5.4.3.2. *Velocity Data*—If accelerometers are used (see Section 5.2.4), the apparatus shall integrate the acceleration over time to obtain velocity. If displacement transducers are used, the apparatus shall differentiate the displacement over time to obtain velocity. If required, the apparatus shall zero the velocity between impact events and shall adjust the velocity record to account for transducers' zero drift during the impact event.

5.4.3.3. *Signal Conditioning*—The signal conditioning for force and velocity shall have equal frequency response curves to avoid relative phase shifts and relative amplitude differences.

5.4.4. *Display Apparatus*—Signals from the transducers specified in Section 5.2 shall be displayed by means of an apparatus, such as an oscilloscope, oscillograph, or LCD screen on which the force and the product of velocity and impedance versus time can be observed for each hammer blow. This apparatus may receive the signals from the transducers directly or after they have been processed by the apparatus for reducing the data. The apparatus shall be adjustable to reproduce a signal having a duration of between 5 and 160 ms. Both the force and velocity data can be reproduced for each blow and the apparatus shall be capable of holding and displaying the signal from each selected blow for a minimum period of 30 seconds.

6. PROCEDURE

6.1. *General*—Record applicable project information (Section 7). Attach the transducers (see Section 5.2) to the pile, perform the internal calibration check and take the dynamic measurements for the impacts during the interval to be monitored together with routine observations of penetration resistance. Determine properties during initial driving. The recommended minimum for determining dynamic properties is 10 blows. However, concrete piles in an easy driving condition may preclude striking the pile this many times. If a restrike is necessary to determine the bearing capacity of the piling, the data from the first one or two blows should normally be used to determine the bearing capacity of the piling. The force and velocity versus time signals may be reduced by the apparatus for reducing data or by a computer or may be reduced manually to calculate the developed force, velocity, acceleration, displacement, and energy over the impact event.

6.2. *Determination of Strain Wave Speed for Concrete and Wood Piles (See Figure 8)*—Wave speeds should be determined for each concrete or timber pile tested. The strain wave speed should be determined from the impact event if a tensile reflection wave from the pile toe is clearly identified. Alternatively, place the pile on supports or level ground free and clear from neighboring piles and obstructions. Attach accelerometer to one end of the pile and strike the end of the pile with a sledge hammer of suitable weight. Take care not to damage or dent the pile. Record (see Section 5.4.2) and display (see Section 5.4.4) the accelerometer signal. Measure the time between acceleration peaks of as many cycles of reflection as possible. However, the first impact should not be counted. Divide this time by the appropriate travel length of the strain waves during this interval to determine the wave speed.

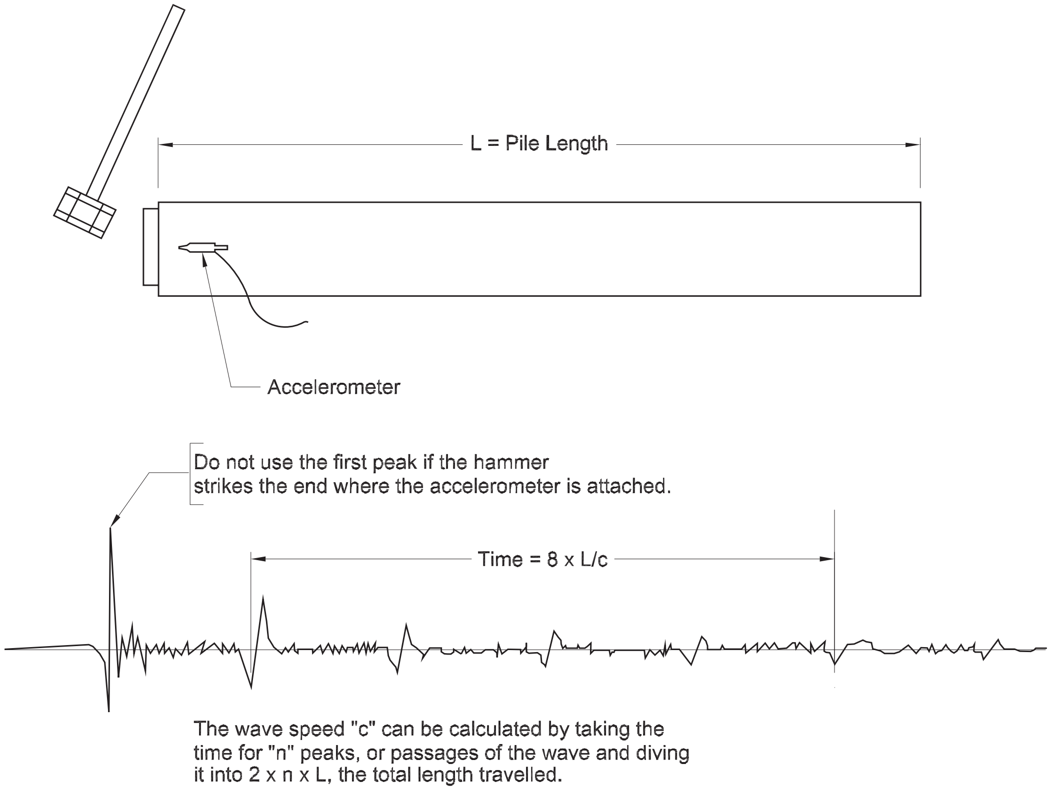

Figure 8—Wave Speed Determination for Concrete and Timber Piles

6.3. *Preparation*—Mark the piles clearly at appropriate intervals. Attach the transducers securely to the piles by bolting, gluing, or welding. For pile materials other than steel, determine the wave speed (see Section 6.2). Position the apparatus for applying the impact force so that the force is applied axially and concentrically with the pile. Set up the apparatus for recording, reducing, and displaying data so that it is operational and the force and velocity signals are zeroed.

6.4. *Taking Measurements*—Record the number of impacts for a specific penetration. For drop hammers and single acting diesel and air/steam hammers, record the drop of the ram or ram travel length. For double-acting diesel hammers, measure the bounce chamber pressure and, for double-acting steam or compressed-air hammers, measure the steam or air pressure in the pressure line to the hammer. For all movements record the number of blows per minute delivered by the hammer. Take, record, and display a series of force and velocity measurements. Compare the force and the product of velocity and impedance (see Section 3.2.7) at the moment of impact.

Note 6—If the dynamic measurements are to be used for bearing capacity computations, take the dynamic measurements during restriking of the pile at time periods sufficiently long after the end of initial driving to allow pore water pressure and soil strength changes to occur. The capacity of the pile is the pile-soil resistance. It does not address pile settlement due to underlying compressible layers.

Note 7—**Warning**: Before approaching a pile being driven, check that no material or other appurtenances can break free and jeopardize the safety of people in the vicinity.

6.5. *Data Quality Checks*—For confirmation of data quality, periodically compare the force and the product of the velocity and pile impedance at the moment of impact for proportionality agreement. The force and the product of velocity and pile impedance versus time should be checked for consistency and proportionality over a series of selected and generally consecutive impact events.

Consistent and proportional signals from the force or strain transducers and the acceleration, velocity, or displacement transducers are the result of the transducer systems and the apparatus for recording, reducing, and displaying data being properly calibrated. If the signals are not in proportionality agreement, investigate the cause and correct the situation if necessary. If the cause is determined to be a transducer, it must be recalibrated before further use. Perform internal calibration checks at the beginning and end of each data set.

Note 8—For purposes of calibration, the apparatus for obtaining dynamic measurements and the apparatus for recording, reducing, and displaying data can be placed in three categories:
(a) Those which can be checked by the user.
(b) Those which can be checked and calibrated by the user.
(c) Those which can only be checked and calibrated by the manufacturer.

It is recommended that types a and b be checked before each trip to a site and calibrated as necessary. It is recommended that type c apparatus be calibrated at least once every two years.

6.6. *Analysis of Measurements*:

6.6.1. Obtain force and velocity from the readout of the apparatus for reducing data (see Section 5.4.3) or from the display apparatus (see Section 5.4.4). Record the impact force and velocity and the maximum and minimum forces for the selected representative blows. Obtain the maximum acceleration directly from the accelerometer signal or by differentiation of the velocity versus time record. Obtain the displacement from the pile-driving record or from the displacement transducer, if used in accordance with Section 5.2.4, or by integration of the velocity versus time record. Obtain the maximum energy transferred to the location of the transducers.

6.6.2. The recorded data may be subjected to analysis by a computer. The results of the analysis may include an assessment of integrity of the pile, the driving system performance, and the maximum dynamic driving stresses. The results may also be used for evaluation of static soil resistance and its distribution on the pile at the time of the testing. Such further use of the data is a matter of proper engineering judgment.

Note 9—Normally, there is better correlation between mobilized resistance and bearing capacity where there is a measurable net penetration per impact. In a majority of cases, blow counts should not exceed 35 blows per decimeter, so as to achieve the best correlation.

Note 10—Evaluation of static soil resistance and its distribution can be based on a variety of analytical methods and is the subject of individual engineering judgment. The input into the analytical methods may or may not result in the dynamic evaluation matching static load test data. It is desirable and sometimes necessary to calibrate the result of the dynamic analysis with those of a static pile load test carried out according to ASTM D 1143.

7. REPORT

7.1. The report of the dynamic testing shall include all the following information, as applicable to the type of pile being tested. Any required information that could not be obtained should be indicated in the testing report as “not available.”

7.1.1. *General*:

7.1.1.1. Project identification;

7.1.1.2. Project location;

7.1.1.3. Test site location;

7.1.1.4. Log of nearest test boring;

7.1.2. *Pile Installation Equipment*:

7.1.2.1. Make and model of the equipment used for either driving or drilling the test pile(s) and/or the testing of the pile(s).

7.1.2.2. Weight of hammer and ram;

7.1.2.3. Rated and actual stroke of ram;

7.1.2.4. Rated energy of hammer;

7.1.2.5. Rated capacity of boiler or compressor;

7.1.2.6. Type, dimensions, and stiffness values of hammer cushion and pile cushion;

7.1.2.7. Weight and dimensions of drive cap;

7.1.2.8. Description of the lead type (fixed, semifixed, or swinging); and

7.1.2.9. Description of any special installation equipment such as followers, mandrels, augering, or jetting.

7.1.3. *Test Piles*:

7.1.3.1. Identification and location of test pile(s),

7.1.3.2. Working load and safety factor (or required ultimate resistance) of pile(s),

7.1.3.3. Type and dimensions of pile(s) including cross-sectional area, length, and diameter (as a function of the length for timber and composite piles),

7.1.3.4. Description of pile tip reinforcement or protection,

7.1.3.5. Description and location of splices, if applicable.

7.1.3.6. Description of special coating used, if applicable.

7.1.3.7. Which piles were vertical or batter,

7.1.3.8. Degree of batter,

7.1.3.9. For concrete piles, cast-in-place pipe piles (tested after filling) and drilled shafts:

- dates that the test piles were cast or installed
- design concrete strength
- description of internal reinforcement used in test pile (size, length, number longitudinal bars, arrangement, spiral, or tie steel)

- condition of precast piles including spalled areas, cracks, head surface, and straightness of piles
- the effective prestress, if applicable

7.1.3.10. For steel piles:

- steel grade
- yield strength
- type of pile (seamless or spiral welded pipe, with wall thickness of pipe or H section)

7.1.3.11. For timber piles:

- general quality of the test pile(s) including type of timber, occurrence of knots, splits, checks and shakes, and straightness of pile(s)
- the density of the material
- preservative treatment, if any
- description of banding, if any

7.1.4. *Pile Installation*:

7.1.4.1. Date driven (installed),

7.1.4.2. Date concreted (cast-in-place),

7.1.4.3. Cause and duration of interruptions in pile installation, and,

7.1.4.4. Notation of any unusual occurrences during installation,

7.1.4.5. For drilled shafts or micropiles:

- nominal size of auger or casing used
- volume of concrete or grout placed in the pile (volume versus depth, if available)
- a description of special installation procedure such as casing installation or removal
- grout pressure used, if applicable

7.1.4.6. For driven piles:

- when hammer and pile cushions were replaced, if applicable
- description of pre-excavation or jetting (depth, size, pressure, duration)
- driving records, including blow counts, hammer stroke, and/or operating level, especially for final penetration and/or restrike

7.1.5. *Dynamic Testing*:

7.1.5.1. Description, calibration data, and date of calibration of all components of the apparatus for obtaining dynamic measurements and apparatus for recording, reducing, and displaying data,

7.1.5.2. Date tested,

7.1.5.3. Test pile identification,

7.1.5.4. The modulus of elasticity, density, and wave speed of test pile, and how determined, 7.1.5.5. Where in the sequence of pile-driving operations the test was carried out, such as end of initial driving, beginning of restrike,

7.1.5.6. Length of pile, as being driven, the length embedded and the length below apparatus for obtaining dynamic measurements,

7.1.5.7. Penetration resistance during dynamic testing,

7.1.5.8. The range, average, and standard deviation of the measurements of maximum and minimum compression force,

7.1.5.9. The range, average, and standard deviation of the impact velocity data,

7.1.5.10. The range, average, and standard deviation of the measurements of maximum acceleration,

7.1.5.11. The range, average, and standard deviation of the measurements of final penetration of the pile,

7.1.5.12. The range, average, and standard deviation of the maximum and final energy data,

7.1.5.13. Which one-dimensional wave theory was used for the analysis of the pile driving; give reference (i.e., program name and version),

7.1.5.14. The variable entered into the wave theory, such as damping, quake, and resistance,

7.1.5.15. When applicable, the computed soil resistance acting on the pile at the time of testing and how computed, and

7.1.5.16. Comments on the integrity of the pile.

Note 11—Data on the forces, velocity, acceleration, penetration, and energy can be recorded at any point of interest during the pile driving. The standard deviation of these values should be calculated for a minimum of 20 consecutive hammer blows.

8. PRECISION AND BIAS

8.1. *Precision*—The precision of the procedure in this test method for direct measurements of strain and acceleration is difficult to determine because of the variability of the pile-driving hammer and the materials in which the pile is located. Information is being gathered on the precision of the procedure.

8.2. *Bias*—No justifiable statement of bias can be made on the procedure in this test method because there are no standard values to which the measured values can be referenced.

---

[1] Except for Section 5.2, this standard is in general conformance to ASTM D 4945.

Standard Method of Test for

Progressing Auger Borings for Geotechnical Explorations

AASHTO Designation: T 306-98 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Progressing Auger Borings for Geotechnical Explorations

AASHTO Designation: T 306-98 (2006)

1. SCOPE

1.1. This practice covers equipment and procedures for the use of earth augers in geotechnical subsurface explorations.

1.2. This procedure is applicable in soils that permit auger drilling to obtain representative or *in situ* samples and when information concerning resistance to driving casing or drive pipe is not necessary.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 206, Penetration Test and Split-Barrel Sampling of Soils
- T 207, Thin-Walled Tube Sampling of Soils

3. SIGNIFICANCE AND USE

Auger borings provide a simple method of soil investigations and sampling. They are used for collecting representative, split-spoon or undisturbed tube samples, determining groundwater levels, observing changes in earth strata, and setting of slope inclinometers. Depths of auger investigations are, however, limited by groundwater conditions, soil characteristics, and the equipment used.

4. APPARATUS AND DEFINITIONS

4.1. *Hand-Operated Augers for Obtaining Soil Samples*:

4.1.1. *helical augers*—small lightweight augers generally available in sizes from 25.4 through 76.2 mm (1 through 3 in.) in diameter.

4.1.1.1. *spiral type*—a flat, thin metal strip, machine twisted to a spiral configuration of uniform pitch having at one end, a sharpened or hardened point, with a means of attaching a shaft or extension at the opposite end.

4.1.1.2. *ship type*—similar to a carpenter's wood bit. It is generally forged from steel and machined to the desired size and configuration. It is normally provided with sharpened and hardened nibs at the point end and with an integral shaft extending through its length for attachment of a handle or extension at the opposite end.

4.1.2. *open tubular augers*—ranging in size from 38 through 200 mm (1.5 through 8 in.) in diameter and having the common characteristic of appearing tubular when viewed from the digging end.

4.1.2.1. *orchard-barrel type*—a tube having cutting lips or nibs hardened and sharpened on one end to penetrate the formation and an adaptor fitting for an extension or handle on the opposite end.

4.1.2.2. *open-spiral type*—a flat, thin metal strip that has been helically wound around a circular shank to form a spiral in which the flat faces of the strip are parallel to the axis of the augered hole. The lower helix edges are hard-faced to improve wear characteristics. The drive end is fitted with an adaptor for extension.

4.1.2.3. *closed-spiral type*—nearly identical to the open-spiral type, except the pitch of the helically wound spiral is much less than that of the open-spiral type.

4.1.3. *post-hole augers*—generally 50 through 200 mm (2 through 8 in.) in diameter, and having a means of blocking the escape of soil from the auger.

4.1.3.1. *clam-shell type*—consisting of two halves, hinged to allow opening and closing for alternatively digging and retrieving. Generally, it is not used deeper than about 1.5 m (5 ft).

4.1.3.2. *Iwan type*—consisting of two tubular steel segments, connected at the top to a common member to form a nearly complete tube, but with diametrically opposed openings. It is connected at the bottom by two radial blades pitched to serve as cutters, which also block the escape of contained soil. Attachment of handle or extension is at the top connector.

4.2. *Machine-Operated Augers for Obtaining Disturbed Soil Samples*:

4.2.1. *continuous-flight augers*—a boring device that has a solid center shank with a flat, metal strip helically wound around itself to form a continuous spiral or flight to bore into and convey or store cut soil. The drive end is fitted with a socket for applying power. The cutting head is affixed with replaceable carbide teeth of various styles to penetrate hard soil formations.

Auger sections generally come in 0.6- and 1.5-m (2- and 5-ft) lengths with other lengths available on special request. When coupled together, the sections provide a continuous flight to convey the soil throughout the full length of the borehole.

4.2.1.1. *available sizes*—generally, these augers come in nominal sizes ranging from 100- through 300-mm (4- through 12-in.) outside diameter.

4.3. *Machine-Operated Augers for Obtaining Split-Barrel and Tube Samples*:

4.3.1. *continuous hollow-stem augers*—basically the same as Continuous Flight Augers except the center shank is a hollow tube whose inside diameter is large enough to allow the passage of split barrel and tube samplers.

4.3.1.1. *available sizes*—inside diameters shall be 57, 82, and 95 mm (2.25, 3.25, and 3.75 in.). Additional and larger sizes are acceptable, provided the sampler clearance requirement of Section 4.3.1.2 is met.

4.3.1.2. Sampler clearance shall be such that no sampler or core barrel will be operated in or through a hollow-stem auger whose bore diameter is less than 108 percent of the sampler outside diameter.

4.3.1.3. The hollow-stem auger may be advanced and sampling or coring conducted by any power-operated drilling machine having sufficient torque and ram range to rotate and force the auger to the desired depth, provided the machine is equipped with the accessory equipment needed to take the required sample or core.

4.4. *Casing (when needed)*—Pipe of slightly larger diameter than the auger used.

4.5. *Accessory Equipment*—Labels, field log sheets, sample jars, sealing wax, sample bags, and other necessary tools and supplies.

5. DRILLING PROCEDURES

5.1. *Progressing Hand- and Machine-Operated Solid Shaft Auger Borings*:

5.1.1. Progress the boring by rotating and advancing the auger the desired distance into the soil. If continuous flight augers are not used, withdraw the auger from the hole and remove the soil for examination and tests. Return the empty auger into the hole and repeat the procedure. Continue the sequence until the required depth is reached.

5.1.2. Casing is required in unstable soil in which the borehole fails to stay open, and especially when the boring is extended below the groundwater level. The inside diameter of the casing must be slightly larger than the diameter of the auger used. The casing shall be driven to a depth not greater than the top of the next sampling location and shall be cleaned out by means of the auger. The auger can then be inserted into the borehole and turned below the bottom of the casing to obtain a sample.

5.1.3. The continuous flight auger can be used both for boring the hole and for bringing up disturbed samples of the soil encountered. The structure of a cohesive soil is completely destroyed and the moisture content may be changed by the auger. The samples may be contaminated with soils from the overlying strata, especially when the cohesive soil is overlain by a sand and casing has not been placed through the sandy strata. Seal all samples in a jar or other airtight container and label appropriately. If more than one type of soil is picked up in the sample, prepare a separate container for each type of soil.

5.1.4. *Field Observations*—Record complete groundwater information in the field logs. Where casing is used, measure groundwater levels before and after the casing is pulled. In sands, determine the water level at least 30 minutes after boring completion; in silts, after at least 24 hours. In clays, no accurate water level determination is possible unless pervious seams are present. As a precaution, however, water levels in clays should be checked after at least 24 hours.

5.2. *Progressing Machine-Operated, Hollow-Stem Auger Borings*:

5.2.1. *Method A*:

Advance the hollow-stem auger with plug or pilot bit in place to the desired sampling depth. Retract the plug or pilot bit by withdrawing the center drill rods. Remove the plug or pilot bit from the drill rods and replace with the desired sampling or coring tool. Lower and seat the sampling tool through the hollow-stem auger into the exposed undisturbed material at the bottom of the hole. Proceed with the sampling operation by rotating, pressing, or driving in accordance with the standard or approved method governing use of the particular sampling tool. Retract the loaded sampler by withdrawing the center rods. Replace the sampler with the plug or pilot bit and return to the bottom of the hole. Add an additional auger and lock the plug or pilot bit in place and advance the hollow-stem auger to the next desired sample depth. Repeat the sequence for each sample desired.

5.2.2. *Method B*:

Advance the hollow-stem auger with plug or pilot bit in place to the desired sampling depth. Retract the plug by reeling in the wire line and attached in-hole hammer and auger plug. Remove the auger plug from the in-hole hammer and replace it with the desired drive sampler. Lower the wire line and attached in-hole hammer and sampler through the hollow-stem to seat the sampler into the exposed undisturbed material at the bottom of the hole. Proceed with the sampling operation in accordance with the standard or approved method governing use of the sampler and hammer. Free the loaded sampler by overaugering until the auger mouth is at the sampler shoe depth, or by bumping back. Retrieve the sampler by reeling in the wire line and attached in-hole hammer and sampler. Remove the sampler from the hammer and replace with the auger plug or pilot bit or, in the case of continuous sampling, with another sampler. Lower the in-hole hammer with plug or sampler attached and again advance the auger or begin sampling as appropriate to the incremental or continuous sampling being conducted. Repeat or continue the sequence to the desired completion.

5.2.3. *Method C*:

5.2.3.1. The small hollow-stem auger, approximately 57 mm (2.25 in.) or less, may be used without the plug or pilot bit. When so used, a plug of soil may be expected to form at the mouth of the auger. This plug will seldom exceed 100 to 150 mm (4 to 6 in.) in thickness. Samplers can normally be pressed or driven through this plug. However, the plug of soil then becomes the upper part of the sample. Accordingly, samplers for use in the hollow-stem auger should be fitted with spoil reservoirs or spoil barrels, if the auger is to be used without a plug or pilot bit.

5.2.3.2. The hollow-stem auger may be utilized with a constantly positive liquid head within the center tube of the auger when working without the center plug. Liquid may be water or drilling mud weighted as necessary to preclude entry of saturated free-flowing formation into the auger. Care shall be taken to avoid blow out of the formation by excessive pressure or weight of liquid in the center tube. Normally weighted liquid shall be introduced into the auger only by gravity flow and only as necessary to maintain the level within the auger center tube above the formation water level. Sampling within the liquid-filled auger shall be conducted in the normal manner prescribed for use of the particular sampler in a liquid-filled borehole.

5.2.3.3. In the event of inflow of the formation into the auger from loss of positive internal head or other cause, the center tube is to be washed out in the same manner as prescribed for casing cleanout. Sampling may then be conducted as prescribed for use of the particular sampler in the liquid-filled borehole; however, the boring report should always indicate that loss of formation occurred before sampling was conducted.

Note 1—The inflow of cohesionless materials into the bottom of any type of borehole normally results in the loosening of natural material at or below the bottom, and thus a sample or *N* value taken may not be truly representative of the undisturbed condition of the material.

6. REPORTING

6.1. The data obtained in Section 5 shall be recorded in the field logs and shall include the following:

6.1.1. Date of start and completion of boring.

6.1.2. Identifying number of boring.

6.1.3. Reference datum including direction and distance of boring relative to reference line of project or other suitable reference points.

6.1.4. Type and size of auger used in boring.

6.1.5. Depth of changes in strata.

6.1.6. Description and classification of soil in each major stratum.

6.1.7. Groundwater elevation and location of seepage zones, when found.

6.1.8. Condition of augered hole upon removal of auger, that is, whether the hole remains open or the sides cave in, when such can be observed.

6.2. In addition, the data obtained in Section 6.2 shall be reported as required in accordance with T 206 and/or T 207.

7. PRECISION AND BIAS

7.1. This standard provides qualitative data only; hence, precision and bias are not applicable.

Standard Method of Test for

Determining the Resilient Modulus of Soils and Aggregate Materials

AASHTO Designation: T 307-99 (2007)

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Determining the Resilient Modulus of Soils and Aggregate Materials

AASHTO Designation: T 307-99 (2007)

1. SCOPE

1.1. This method covers procedures for preparing and testing untreated subgrade soils and untreated base/subbase materials for determination of resilient modulus (M_r) under conditions representing a simulation of the physical conditions and stress states of materials beneath flexible pavements subjected to moving wheel loads.

1.2. The methods described are applicable to undisturbed samples of natural and compacted subgrade soils, and to disturbed samples of subgrade soils and untreated base/subbase prepared for testing by compaction in the laboratory.

1.3. In this method, stress levels used for testing specimens for resilient modulus are based upon the location of the specimen within the pavement structure. Samples located within the base and subbase are subjected to different stress levels as compared to those specimens that are from the subgrade. Generally, specimen size for testing depends upon the type of material based upon the gradation and the plastic limit of the material as described in a later section.

1.4. The value of resilient modulus determined from this procedure is a measure of the elastic modulus of untreated base and subbase materials and subgrade soils recognizing certain nonlinear characteristics.

1.5. Resilient modulus values can be used with structural response analysis models to calculate the pavement structural response to wheel loads, and with pavement design procedures to design pavement structures.

1.6. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Note 1—Test specimens and equipment described in this method may be used to obtain other useful and related information such as the Poisson's ratio and rutting characteristics of subgrade soils and base/subbase materials. Procedures for obtaining these are not covered in this standard.

3. TERMINOLOGY

3.1. *untreated granular base and subbase materials*—these include soil-aggregate mixtures and naturally occurring materials. No binding or stabilizing agent is used to prepare untreated granular base or subbase layers. These materials may be classified as either Type 1 or Type 2 as subsequently defined in Sections 3.3 and 3.4.

3.2. *subgrade*—subgrade soils are prepared and compacted before the placement of subbase and/or base layers. These materials may be classified as either Type 1 or Type 2 as subsequently defined in Sections 3.3 and 3.4.

3.3. *Material Type 1*—for the purposes of resilient modulus testing, Material Type I includes all untreated granular base and subbase material and all untreated subgrade soils that meet the criteria of less than 70 percent passing the 2.00-mm (No. 10) sieve and less than 20 percent passing the 75-µm (No. 200) sieve, and that have a plasticity index of 10 or less. Soils classified as Type 1 will be molded in a 150-mm diameter mold.

3.4. *Material Type 2*—for the purpose of resilient modulus testing, Material Type 2 includes all untreated granular base/subbase and untreated subgrade soils not meeting the criteria for material Type 1 given in Section 3.3. Thin-walled tube samples of untreated subgrade soils fall into this Type 2 category.

3.5. *resilient modulus of untreated materials*—the modulus of an untreated material is determined by repeated load triaxial compression tests on test specimens of the untreated material samples. Resilient modulus (M_r) is the ratio of the amplitude of the repeated axial stress to the amplitude of the resultant recoverable axial strain.

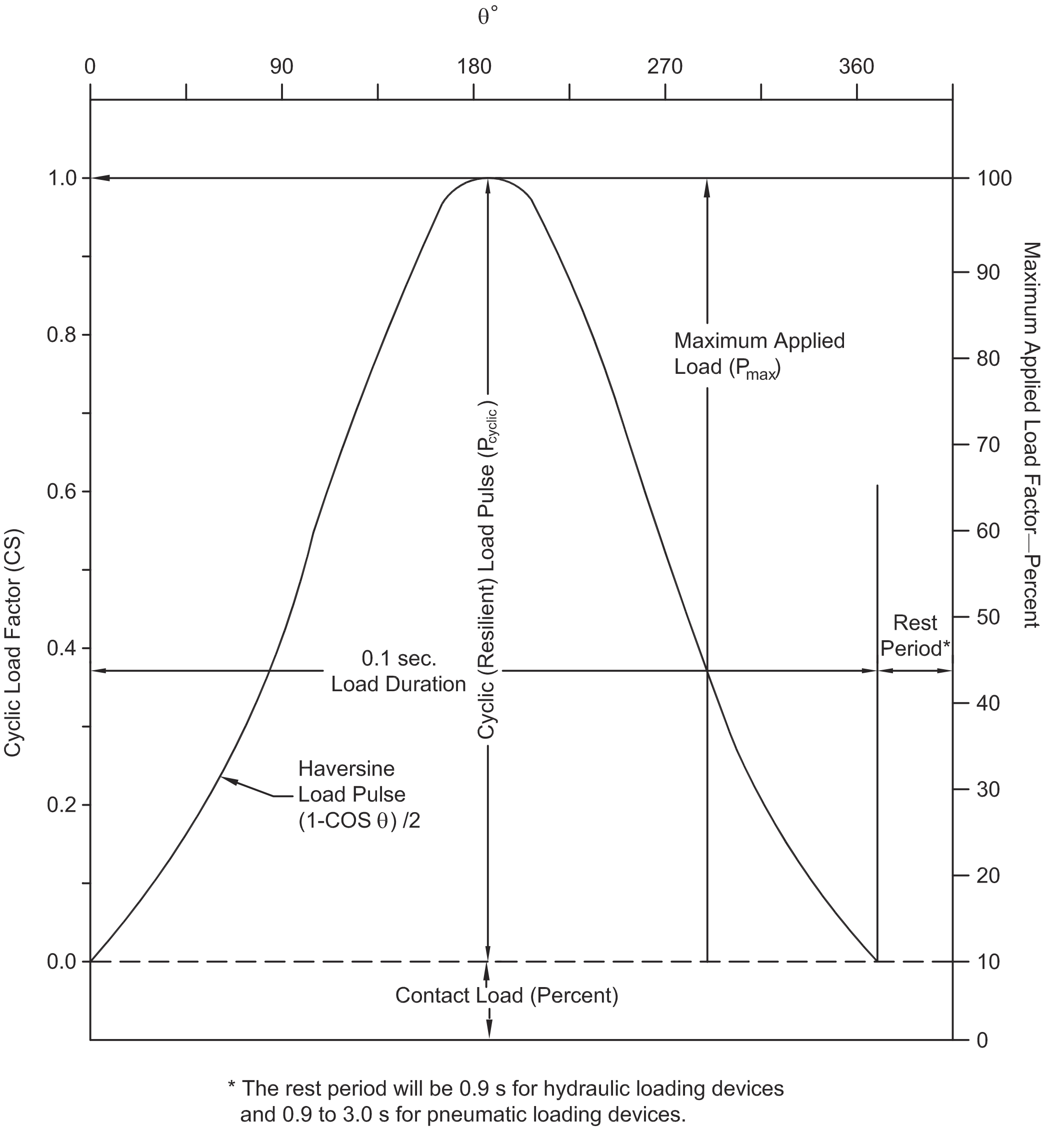
3.6. *haversine-shaped load form*—the required load pulse form. The load pulse is in the form $(1 - \cos \theta)/2$ as shown in Figure 1.

3.7. *maximum applied axial load* ($P_{\max}$)—the total load applied to the sample, including the contact and cyclic (resilient) loads.

$$P_{\text{max}} = P_{\text{contact}} + P_{\text{cyclic}} \qquad (1)$$

3.8. *contact load* (P_{contact})—vertical load placed on the specimen to maintain a positive contact between the specimen cap and the specimen.

$$P_{\text{contact}} = 0.1P_{\text{max}} \qquad (2)$$



* The rest period will be 0.9 s for hydraulic loading devices and 0.9 to 3.0 s for pneumatic loading devices.

Figure 1—Definition of Resilient Modulus Terms Cyclic Axial Load (Resilient Vertical Load, P_{cyclic})—Repetitive Load Applied to a Test Specimen

$$P_{\text{cyclic}} = P_{\text{max}} - P_{\text{contact}} \qquad (3)$$

3.9. *maximum applied axial stress* (S_{max})—the total stress applied to the sample including the contact stress and the cyclic (resilient) stress.

$$S_{\text{max}} = P_{\text{max}}/A \qquad (4)$$

where:

A = initial cross-sectional area of the specimen.

3.10. *cyclic axial stress* (resilient stress, S_{cyclic})—Cyclic (resilient) applied axial stress.

$$S_{\text{cyclic}} = P_{\text{cyclic}}/A \tag{5}$$

3.11. *contact stress* (S_{contact})—axial stress applied to a test specimen to maintain a positive contact between the specimen cap and the specimen.

$$S_{\text{contact}} = P_{\text{contact}}/A \tag{6}$$

Also,

$$S_{\text{contact}} = 0.1S_{\text{max}} \tag{7}$$

3.12. S_3 is the total radial stress; that is, the applied confining pressure in the triaxial chamber (minor principal stress).

3.13. e_r is the resilient (recovered) axial deformation due to S_{cyclic}.

3.14. $\in_r$ is the resilient (recovered) axial strain due to S_{cyclic}.

$$\in_r = e_r/L \tag{8}$$

where:

L = original specimen length.

3.15. Resilient Modulus (M_r) is defined as $S_{\text{cyclic}}/\in_r$.

3.16. Load duration is the time interval the specimen is subjected to a cyclic stress (usually 0.1 s).

3.17. Cycle duration is the time interval between the successive applications of a cyclic stress (usually 1.0 to 3.1 s, depending on type of loading device. See Section 6.2).

4. SUMMARY OF METHOD

4.1. A repeated axial cyclic stress of fixed magnitude, load duration (0.1 s), and cycle duration (1.0 to 3.1 s) is applied to a cylindrical test specimen. During testing, the specimen is subjected to a dynamic cyclic stress and a static-confining stress provided by means of a triaxial pressure chamber. The total resilient (recoverable) axial deformation response of the specimen is measured and used to calculate the resilient modulus.

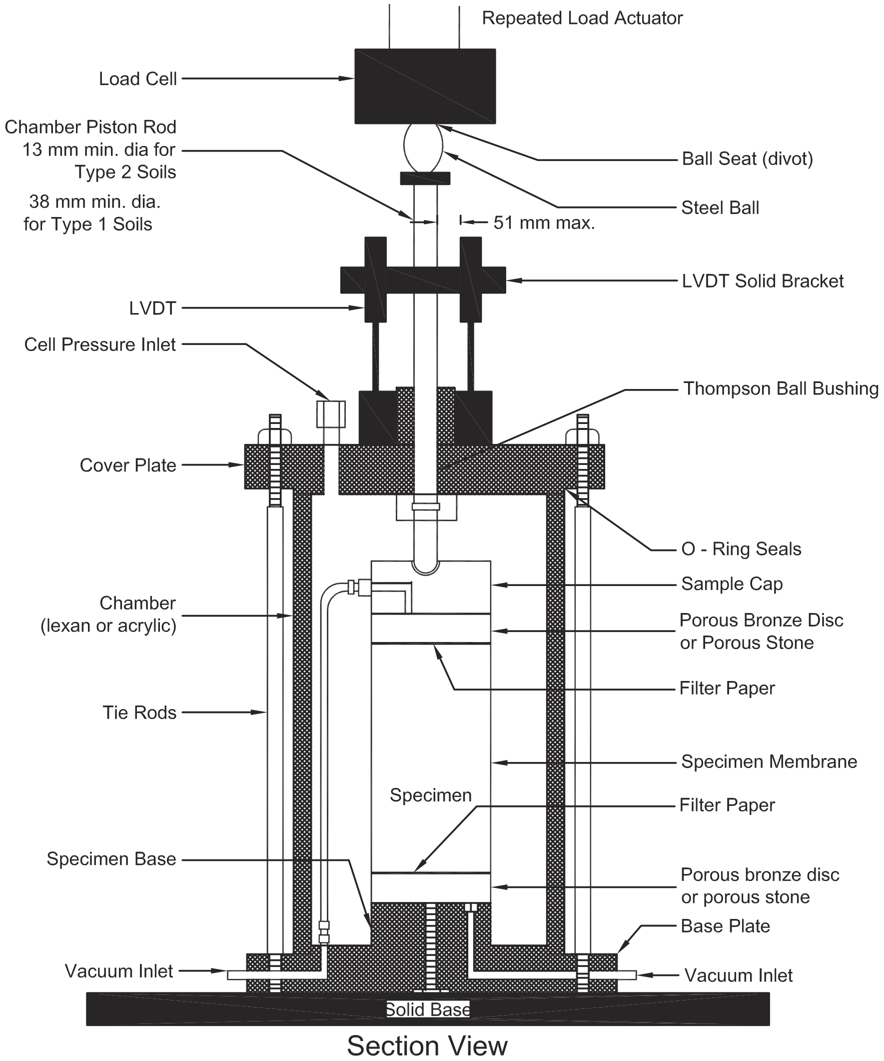
5. SIGNIFICANCE AND USE

5.1. The resilient modulus test provides a basic relationship between stress and deformation of pavement materials for the structural analysis of layered pavement systems.

5.2. The resilient modulus test provides a means of characterizing pavement construction materials, including subgrade soils, under a variety of conditions (i.e., moisture, density, etc.) and stress states that simulate the conditions in a pavement subjected to moving wheel loads.

6. APPARATUS

6.1. *Triaxial Pressure Chamber*—The pressure chamber is used to contain the test specimen and the confining fluid during the test. A typical triaxial chamber suitable for use in resilient testing of soils is shown in Figure 2. The deformation is measured *externally* with two spring-loaded linear variable differential transducers (LVDT) as shown in Figure 2.



Note: LVDT tips shall rest on the triaxial cell itself or on a plate/bracket that is rigidly attached to the triaxial cell.

Figure 2—Typical Triaxial Chamber with Eternal LVDTs and Load Cell (Not to Scale)

6.1.1. Air shall be used in the triaxial chamber as the confining fluid.

6.1.2. The chamber shall be made of polycarbonate, acrylic or other suitable “see through” material to facilitate the observation of the specimen during testing.

6.2. *Loading Device*—The loading device shall be a top-loading, closed loop, electrohydraulic or electropneumatic testing machine with a function generator that is capable of applying repeated cycles of haversine-shaped load pulse of the following durations.

Type of Loading Device	Load Pulse (s)	Rest Period (s)
pneumatic	0.1	0.9 to 3.0
hydraulic	0.1	0.9

6.2.1. The haversine-shaped load pulse shall conform to Section 3.6. All preconditioning and testing shall be conducted using a haversine-shaped load pulse. The system-generated haversine waveform and the response waveform shall be displayed to allow the operator to adjust the gains to ensure that they coincide during preconditioning and testing.

6.3. *Load and Specimen Response Measuring Equipment*:

6.3.1. The axial load-measuring device should be an electronic load cell located between the actuator and the chamber piston rod as shown in Figure 2. The following load-cell capacities are required:

Specimen Dia. (mm)	Max. Load Cap. (kN)	Req. Accuracy (N)
71	2.2	±4.5
100	8.0	±10.0
152	22.24	±22.24

The above requirements for load capacity and accuracy are approximately linear when plotted versus specimen cross-section area. Requirements for load cells used with other specimen diameters should be approximately on the same linear relationships.

Note 2—During periods of resilient modulus testing, the load cell shall be monitored and checked once every 2 weeks or after every 50 resilient modulus tests with a calibrated proving ring to assure that the load cell is operating properly. An alternative to using a proving ring is to insert an additional calibrated load cell and independently measure the load applied by the original load cell to ensure accurate loadings. Additionally, the load cell shall be checked at any time if the laboratory's in-house QA/QC testing indicates non-compliance or there is a suspicion of a load-cell problem. Resilient modulus testing shall not be conducted if the testing system is found to be out of calibration or if the load cell does not meet the manufacturer's tolerance requirements stated above for accuracy, whichever of the two is of the higher accuracy.

6.3.2. Test chamber pressures shall be monitored with conventional pressure gages, manometers, or pressure transducers accurate to 0.7 kPa.

6.3.3. *Axial Deformation*—Measuring system for all materials shall consist of 2 LVDTs fixed to opposite sides of the piston rod outside the test chamber as shown in Figure 2. These two transducers shall be located equidistant from the piston rod and shall bear on hard, fixed surfaces, which are perpendicular to the LVDT axis. Spring-loaded LVDTs are required. The following LVDT ranges are required:

Specimen Dia. (mm)	Range (mm)
71	±1
100	± 2.5
152	±6

Both LVDTs shall meet the following minimum specifications:

- *Linearity*, ±0.25 percent of full scale
- *Repeatability*, ±1 percent of full scale

- *Minimum Sensitivity*, 2 mv/v (AC) or 5 mv/v (DC)

The above requirement for range is approximately linear when plotted vs. specimen cross-section area. Requirements for LVDTs used with other specimen diameters are approximately on the same linear relationships. A digital or other type of deformation measurement system with equivalent linearity and repeatability specifications may be used in place of LVDTs.

6.3.3.1. A positive contact between the vertical LVDTs and the surface on which the tips of the transducers rest shall always be maintained during the test procedure. In addition, the two LVDTs shall be wired so that each transducer can be read and reviewed independently and the results averaged for calculation purposes.

Note 3—Misalignment or dirt on the shaft of the transducer can cause the "sticking" of the shafts of the LVDT. The laboratory technician shall depress and release each LVDT prior to each test to assure that there is no sticking. An acceptable cleaner/lubricant (as specified by the manufacturer) shall be applied to the transducer shafts on a regular basis.

6.3.3.2. The response of the LVDTs shall be checked daily with the laboratory's in-house QA/QC program. Additionally, the LVDTs shall be calibrated every 2 weeks, or after every 50 resilient modulus tests, whichever comes first, using a micrometer with compatible resolution or a set of specially machined gauge blocks. Resilient modulus testing shall not be conducted if the LVDTs do not meet the manufacturer's tolerance requirements for accuracy.

6.3.4. Suitable signal excitation, conditioning, and recording equipment are required for simultaneous recording of axial load and deformations. The signal shall be clean and free of noise. Use shielded cables for connections. If a filter is used, it shall have a frequency that cannot attenuate the signal. The LVDTs shall be wired separately so each LVDT signal can be monitored independently. A minimum of 200 data points from each LVDT shall be recorded per load cycle.

6.4. *Specimen Preparation Equipment*—A variety of equipment is required to prepare undisturbed samples for testing and to obtain compacted specimens that are representative of field conditions. Use of different methods of compaction is necessary to prepare specimens of different materials and to simulate desired field conditions. See Annexes A, B, and C for specimen preparation (Annex A), specimen compaction equipment and compaction procedures for Type 1 (Annex B), and Type 2 materials (Annex C or Appendix A), respectively.

6.5. Equipment for trimming test specimens from undisturbed thin-walled tube samples of subgrade soils shall be as described in T 296.

6.6. *Miscellaneous Apparatus*—This includes calipers, micrometer gauge, steel rule calibrated to 0.5 mm, rubber membranes 0.25 to 0.79 mm thick, rubber O-rings, vacuum source with bubble chamber and regulator, membrane expander, porous stones (subgrade), porous bronze discs (base/subbase), scales, moisture content cans, and report forms, as required.

6.7. *System Calibration and Periodic Checks*—The entire system (transducer, conditioning, and recording devices) shall be calibrated every 2 weeks or after every 50 resilient modulus tests using the laboratory's in-house QA/QC program. Daily and other periodic checks of the system shall also be performed in accordance with the laboratory's in-house QA/QC program.

7. PREPARATION OF TEST SPECIMENS

7.1. *Specimen Size*—The following guidelines, based on the sieve analysis test results, shall be used to determine the test specimen size.

7.1.1. Use 71-mm or 86-mm diameter specimens for tests on undisturbed cohesive specimens of Type 2 materials. For Type 1 materials, or compacted specimens of Type 2 materials, select mold sizes to fabricate specimens of a minimum diameter equal to five times the maximum particle size. If the maximum particle size exceeds 25 percent of the largest mold diameter available, these particles will be scalped. Length for all specimens will be at least two times the diameter.

7.2. *Undisturbed Subgrade Soil Specimens*—Undisturbed subgrade soil specimens are trimmed and prepared. The natural moisture content, *w,* of the tube sample shall be determined after triaxial resilient modulus testing following the procedure outlined in T 265, and recorded in the test report.

7.2.1. To be suitable for testing, a specimen of sufficient length, being at least twice the diameter of the specimen, shall be cut from the tube sample. The specimen shall be free from defects. Such defects include cracks in the specimen, broken corners that cannot be repaired during preparation, or presence of particles much larger than that typical for the material. For example, the presence of plus 19.0 mm stones in a fine-grained soil or presence of “foreign objects” such as large roots, wood particles, organic material, and gouges due to gravel hanging on the edge of the tube constitute damaged specimens that are unacceptable.

7.3. *Laboratory Compacted Specimens*—Reconstituted test specimens of both Type 1 and Type 2 materials shall be prepared to approximate the *in situ* wet density, Υ_w, and moisture content, *w*. These laboratory-compacted specimens shall be prepared for all unbound granular base and subbase material and for all subgrade soils for which undisturbed tube specimens could not be obtained.

7.3.1. *Moisture Content*—The moisture content of the laboratory-compacted specimen shall be the *in situ* moisture content obtained in the field using T 310. If data are not available on *in situ* moisture content, then refer to Section 7.3.3. The moisture content of the laboratory-compacted specimen shall not vary by more than ±1.0 percent for Type 1 materials or ±0.5 percent for Type 2 materials from the *in situ* moisture content obtained.

7.3.2. *Compacted Density*—The density of the compacted specimen shall be the in-place wet density obtained in the field using T 310 or T 191. If these data are not available on *in situ* density, then refer to Section 7.3.3. The wet density of the laboratory-compacted specimen shall not vary by more than ±3 percent of the in-place wet density for that layer.

7.3.3. If either the *in situ* moisture content or the in-place density data are not available, then use the percentage of maximum dry density and the corresponding optimum moisture content by T 99 or T 180 as is specified by the individual testing or transportation agency. The moisture content of the laboratory-compacted specimen shall not vary by more than ±1.0 percent for Type 1 materials or ±0.5 percent for Type 2 materials from the target moisture content. Also, the wet density of the laboratory-compacted specimen shall not vary by more than ±3 percent of the target wet density.

Example: If the desired density is 1950 kg/m^3 and the desired moisture content is 8.0 percent for a Type 1 material, then a moisture content between 7.0 and 9.0 percent would be acceptable. For the same desired moisture content and density for a Type 2 material, acceptable moisture contents are between 7.5 and 8.5 percent. Acceptable densities for either material are between 1892 and 2009 kg/m^3.

7.3.4. *Sample Reconstitution*—Reconstitute the specimen for Type 1 and Type 2 materials in accordance with the provisions given in Annex A. The target moisture content and density to be used in determining needed material quantities are given in Section 7.3. Annex A provides guidelines for reconstituting the material to obtain a sufficient amount of material to prepare the appropriate specimen type at the designated moisture content and density. After this step is completed, specimen compaction can begin.

7.4. *Compaction Methods and Equipment for Reconstituting Specimens*:

7.4.1. *Compacting Specimens for Type 1 Materials*—The general method of compaction for Type 1 materials will be that of Annex B.

7.4.2. *Compacting Specimens for Type 2 Materials*—The general method of compaction for Type 2 materials will be that of Annex C or Appendix A. If it is desired to investigate specimen density gradient, the method is that of Appendix B.

7.4.3. The prepared specimens shall be protected from moisture change by applying the triaxial membrane and testing within 5 days of completion. Prior to storage, and directly after removal from storage, weigh the specimen to determine if there was any moisture loss. If moisture loss exceeds 1 percent for Type 1 materials or 0.5 percent for Type 2 materials, then the prepared specimen will not be tested. However, a new specimen will be needed to be prepared for testing. Material from the specimens not tested may be reused.

8. PROCEDURE—RESILIENT MODULUS TEST FOR SUBGRADE SOILS

8.1. The procedure described in this section is used for undisturbed or laboratory-compacted specimens of subgrade soils. This can include specimens of 150-mm diameter or Type 2 specimens of 70 mm diameter.

8.2. *Assembly of Triaxial Chamber*—Specimens trimmed from undisturbed samples and laboratory-compacted specimens are placed in the triaxial chamber and loading apparatus in the following steps:

8.2.1. Place a moist porous stone and moist paper filter on the top of the specimen base of the triaxial chamber as shown in Figure 2.

8.2.2. Carefully place the specimen on the porous stone. Place the membrane on a membrane expander, apply vacuum to the membrane expander, then carefully place the membrane on the specimen and remove the vacuum and the membrane expander. Seal the membrane to the pedestal (or bottom plate) with an O-ring or other pressure seal.

8.2.3. Place a moist paper filter and the top platen containing a moist porous stone on the specimen, fold up the membrane, and seal it to the top platen with an O-ring or some other pressure seal.

8.2.4. If the specimen has been compacted or stored inside a rubber membrane and the porous stones and sample are already attached to the rubber membrane in place, Sections 8.2.1, 8.2.2, and 8.2.3 are omitted. Instead, the “specimen assembly” is placed on the base plate of the triaxial chamber.

8.2.5. Connect the specimen’s bottom drainage line to the vacuum source through the medium of a bubble chamber. Apply a vacuum of 7 kPa. If bubbles are present, check for leakage caused by poor connections, holes in the membrane, or imperfect seals at the cap of the base. The existence of an airtight seal ensures that the membrane will remain firmly in contact with the specimen. Leakage through holes in the membrane can frequently be eliminated by coating the surface of the membrane with liquid rubber latex or by using a second membrane.

8.2.6. When leakage has been eliminated, disconnect the vacuum supply and place the chamber on the base plate and the cover plate on the chamber. Insert the loading piston and obtain a firm connection with the load cell. Tighten the chamber tie rods firmly.

8.2.7. Slide the assembly apparatus into position under the axial loading device. Positioning of the chamber is extremely critical in eliminating all possible side forces in the piston rod. Couple the loading device to the triaxial chamber piston rod.

8.3. *Conduct the Resilient Modulus Test*—The following steps are required to conduct the resilient modulus test on a subgrade specimen that has been installed in the triaxial chamber and placed under the loading frame.

8.3.1. Open all drainage valves leading into the specimen to atmospheric pressure. This will simulate drained conditions. Simulation of undrained conditions will require saturation of specimens. Such procedures are not contained in this method.

8.3.2. If it is not already connected, connect the air pressure supply line to the triaxial chamber and apply the specified pre-conditioning confining pressure of 41.4 kPa to the test specimen. A contact stress of 10 percent ± 0.7 kPa of the maximum applied axial stress during each sequence number shall be maintained.

8.3.2.1. Loads applied to the top of the triaxial cell piston rod must be adjusted to apply stresses shown in Table 1 after accounting for a net upward or downward resultant calculated as follows:

$$F = (A \times P) - W \qquad (9)$$

where:

F = resultant force,

A = piston rod cross-section area,

P = confining pressure, and

W = weight of piston rod and exterior-mounted specimen deformation measurement system.

Table 1—Testing Sequence for Subgrade Soil

Sequence No.	Confining Pressure, S_3		Max. Axial Stress, $S_{\max}$		Cyclic Stress, S_{cyclic}		Constant Stress, $0.1S_{\max}$		No. of Load Applications
	kPa	psi	kPa	psi	kPa	psi	kPa	psi

12	13.8	2	27.6	4	24.8	3.6	2.8	0.4	100
13	13.8	2	41.4	6	37.3	5.4	4.1	0.6	100
14	13.8	2	55.2	8	49.7	7.2	5.5	0.8	100
15	13.8	2	68.9	10	62.0	9.0	6.9	1.0	100

Note: Load sequences 14 and 15 are not to be used for materials designed as Type 1.

8.3.3. *Conditioning*—Begin the test by applying a minimum of 500 repetitions of a load equivalent to a maximum axial stress of 27.6 kPa and corresponding cyclic stress of 24.8 kPa using a haversine-shaped load pulse with durations as described in Section 6.2. If the sample is still decreasing in height at the end of the conditioning period, stress cycling shall be continued up to 1000 repetitions prior to testing as outlined in sequence No. 0, Table 1.

Note 4—The laboratory/technician shall conduct appropriate QA/QC comparative checks of the individual deformation output from the two vertical transducers during the conditioning phase of each resilient modulus test in order to recognize specimen misplacement and misalignment. During the preconditioning phase, the two vertical deformation curves shall be viewed to ensure that acceptable vertical deformation ratios are being measured. The vertical deformation ratio R_v is defined as $R_v = Y_{\max}/Y_{\min}$, where $Y_{\max}$ equals the larger of the two vertical deformations and $Y_{\min}$ equals the smaller of the two vertical deformations. Every effort shall be made to achieve R_v values of 1.10 or less. Acceptable R_v values are 1.30 or less. If unacceptable vertical deformation ratios are obtained (i.e., R_v is greater than 1.30), then the test shall be discontinued and specimen placement/alignment difficulties alleviated. Once acceptable vertical deformation values are obtained, then the test shall be continued to completion. It is emphasized that the specimen alignment is critical for proper resilient modulus results. This note also applies to Section 9.3.3.

8.3.3.1. The above stress sequence constitutes sample conditioning; that is, the elimination of the effects of the interval between compaction and loading and the elimination of initial loading versus reloading. This conditioning also aids in minimizing the effects of initially imperfect contact between the sample cap and the test specimen.

8.3.3.2. If the total vertical permanent strain reaches 5 percent during conditioning, the conditioning process shall be terminated. For recompacted samples, a review shall be conducted of the compaction process to identify any reason(s) why the sample did not attain adequate compaction. If this review does not provide an explanation, the material shall be refabricated and tested a second time. If the sample again reaches 5 percent total vertical permanent strain during preconditioning, then the test shall be terminated and a notation added to the report form.

8.3.4. *Testing Specimen*—The testing is performed following the loading sequence shown in Table 1. Begin by decreasing the maximum axial stress to 13.8 kPa (Sequence No. 1, Table 1) and set the confining pressure to 41.4 kPa.

8.3.5. Apply 100 repetitions of the corresponding cyclic axial stress using a haversine-shaped load pulse with durations as described in Section 6.2. Record the average recovered deformations for each LVDT separately for the past five cycles on the Report Form C4.1 (Table C3.1).

8.3.6. Increase the maximum axial stress to 27.6 kPa (Sequence No. 2) and repeat Step 8.3.5 at this new stress level.

8.3.7. Continue the test for the remaining load sequences in Table 1 (3 to 15), recording the vertical recovered deformation. If at any time the permanent strain of the sample exceeds 5 percent, stop the test and report the result on the appropriate worksheet.

8.3.8. After completion of the resilient modulus test procedure, check the total vertical permanent strain the specimen was subjected to during the resilient modulus portion of the test procedure. If the total vertical permanent strain did not exceed 5 percent, and if strength information is desired, continue with the quick shear test procedure (Section 8.3.9). If the total vertical permanent strain exceeds 5 percent, the test is completed. No additional testing is to be conducted on the specimen, other than in Section 8.3.11.

8.3.9. *Quick Shear Test*—Apply a confining pressure of 27.6 kPa to the specimen. Apply a load so as to produce an axial strain at a rate of 1 percent per minute under a strain-controlled loading procedure. Continue loading until either (1) the load values decrease with increasing strain, (2) 5 percent strain is reached, or (3) the capacity of the load cell is reached. Data from the internally mounted deformation transducer in the actuator shaft and from the load cell shall be used to record specimen deformation and loads at a maximum of 3-s intervals.

8.3.10. At the completion of the triaxial shear test, reduce the confining pressure to zero and remove the sample from the triaxial chamber.

8.3.11. Remove the membrane from the specimen and use the entire specimen to determine moisture content in accordance with T 265.

8.3.12. Plot the stress-strain curve for the specimen for the triaxial shear test procedure.

9. PROCEDURE—RESILIENT MODULUS TEST FOR BASE/SUBBASE MATERIALS

9.1. The procedure described in this section applies to all unbound granular base and subbase materials. This can include specimens classified as Type 1 or Type 2 material.

9.2. *Assembly of the Triaxial Chamber*—When compaction is completed, place the porous bronze disc and specimen cap on the top surface of the specimen. Roll the rubber membrane off the rim of the mold and over the sample cap. If the sample cap projects above the rim of the mold, the membrane shall be sealed tightly against the cap with the O-ring seal. If it does not, the seal can be applied later. Install the specimen in the triaxial chamber as in Sections 8.2.1 through 8.2.7.

9.2.1. Connect the chamber pressure supply line and apply a confining pressure of 103.4 kPa.

9.2.2. Remove the vacuum supply from the vacuum saturation inlet and open the top and bottom head drainage ports to atmospheric pressure.

9.3. *Conduct the Resilient Modulus Test*—After the test specimen has been prepared and placed in the loading device as described in Section 8.2.1, the following steps are necessary to conduct the resilient modulus testing:

9.3.1. If not already done, adjust the position of the axial loading device or triaxial chamber base support as necessary to couple the load-generation device piston and the triaxial chamber piston. The triaxial chamber piston should bear firmly on the load cell. A contact stress of 10 percent ±0.7 kPa of the maximum applied axial stress during each sequence number shall be maintained.

9.3.1.1. Loads applied to the top of the triaxial cell piston rod must be adjusted to apply the stresses shown in Table 2 after accounting for a net upward or downward resultant calculated as follows:

$$F = (A \times P) - W \qquad (10)$$

where:

F = resultant force,

A = piston rod cross-section area,

P = confining pressure, and

W = weight of piston rod and exterior-mounted specimen deformation measurement system.

Table 2—Testing Sequences for Base/Subbase Materials

Sequence No.	Confining Pressure, S_3		Max. Axial Stress, $S_{\max}$		Cyclic Stress, S_{cyclic}		Constant Stress, $0.1S_{\max}$		No. of Load Applications
	kPa	psi	kPa	psi	kPa	psi	kPa	psi	
0	103.4	15	103.4	15	93.1	13.5	10.3	1.5	500–1000
1	20.7	3	20.7	3	18.6	2.7	2.1	0.3	100
2	20.7	3	41.4	6	37.3	5.4	4.1	0.6	100
3	20.7	3	62.1	9	55.9	8.1	6.2	0.9	100
4	34.5	5	34.5	5	31.0	4.5	3.5	0.5	100
5	34.5	5	68.9	10	62.0	9.0	6.9	1.0	100
6	34.5	5	103.4	15	93.1	13.5	10.3	1.5	100
7	68.9	10	68.9	10	62.0	9.0	6.9	1.0	100
8	68.9	10	137.9	20	124.1	18.0	13.8	2.0	100
9	68.9	10	206.8	30	186.1	27.0	20.7	3.0	100
10	103.4	15	68.9	10	62.0	9.0	6.9	1.0	100
11	103.4	15	103.4	15	93.1	13.5	10.3	1.5	100
12	103.4	15	206.8	30	186.1	27.0	20.7	3.0	100
13	137.9	20	103.4	15	93.1	13.5	10.3	1.5	100
14	137.9	20	137.9	20	124.1	18.0	13.8	2.0	100
15	137.9	20	275.8	40	248.2	36.0	27.6	4.0	100

9.3.2. Adjust the recording devices for the LVDTs and load cell as needed.

9.3.3. *Conditioning*—Set the confining pressure to 103.4 kPa and apply a minimum of 500 repetitions of a load equivalent to a maximum axial stress of 103.4 kPa and corresponding cyclic axial stress of 93.1 kPa according to sequence 0, Table 2, using a haversine-shaped load pulse with durations as described in Section 6.2. If the sample is still decreasing in height at the end of the conditioning period, stress cycling shall be continued up to 1000 repetitions prior to testing.

9.3.3.1. The above stress sequence constitutes sample conditioning; that is, the elimination of the effects of the interval between compaction and loading and the elimination of initial loading versus reloading. This conditioning also aids in minimizing the effects of initially imperfect contact between the sample cap and base plate and the test specimen. The drainage valves should be open to atmospheric pressure throughout the resilient modulus testing. This will simulate drained conditions. Simulation of undrained conditions will require saturation of specimens. Such procedures are not contained in this method.

9.3.3.2. If the total vertical permanent strain reaches 5 percent during conditioning, the conditioning process shall be terminated. A review shall be conducted of the compaction process to identify any reason(s) why the sample did not attain adequate compaction. If this review does not provide an explanation, the material shall be refabricated and tested a second time. If the sample again reaches 5 percent total vertical permanent strain during preconditioning, then the test shall be terminated and a notation added to the report form.

9.3.4. *Testing Specimen*—The testing is performed following the loading sequences in Table 2 using a haversine-shaped load pulse as described above. Decrease the maximum axial stress to 21.0 kPa and set the confining pressure to 21.0 kPa (Sequence No. 1, Table 2).

9.3.5. Apply 100 repetitions of the corresponding cyclic stress using a haversine-shaped load pulse with durations as described in Section 6.2. Record the average recovered deformations for each LVDT separately for the past five cycles on the report form.

9.3.6. Continue with sequence No. 2 increasing the maximum axial stress to 41.0 kPa and repeat Step 8.2.2.5 at this new stress level.

9.3.7. Continue the test for the remaining load sequences in Table 2 (sequences 3 to 15), recording the vertical recovered deformation. If at any time the total vertical permanent strain deformation exceeds 5 percent, stop the test and make a notation on the report form.

9.3.8. After completion of the resilient modulus test procedure, check the total vertical permanent strain that the specimen was subjected to during the resilient modulus portion of the test procedure. If the total vertical permanent strain did not exceed 5 percent, and if strength information is desired, continue with the quick shear test procedure (Section 9.3.9). If the total vertical permanent strain exceeds 5 percent, the test is completed. No additional testing is to be conducted on the specimen, other than in Section 9.3.11.

9.3.9. *Quick Shear Tests*—Apply a confining pressure of 34.5 kPa to the specimen. Apply a load so as to produce an axial strain at a rate of 1 percent per minute under a strain-controlled loading procedure. Continue loading until either (1) the load values decrease with increasing strain, (2) 5 percent strain is reached, or (3) the capacity of the load cell is reached. Data from the internally mounted deformation transducer in the actuator shaft and from the load cell shall be used to record specimen deformation and loads at a maximum of 3-s intervals.

9.3.10. At the completion of the triaxial shear test, reduce the confining pressure to zero and remove the sample from the triaxial cell.

9.3.11. Remove the membrane from the specimen and use the entire sample to determine the moisture content in accordance with T 265.

9.3.12. Plot the stress-strain curve for the specimen for the triaxial shear test procedure.

10. CALCULATIONS

10.1. Perform the calculations to obtain resilient modulus values using the tabular arrangement shown on Report Form C4.1 (Table C3.1). The resilient modulus value is computed for each of the past five cycles of each load sequence. These values are subsequently averaged on the data sheet.

11. REPORT

11.1. *The report shall consist of the following*:

11.1.1. Report Form C4.1 (Table C3.1).

11.1.2. Report Form C4.2 (Table C3.2) (recompacted specimens) or Report Form C4.3 (Table C3.3) (thin-walled tube specimens).

11.2. *The following general information is to be recorded on all of the Report Forms*:

11.2.1. The specimen identification, the material type (Type 1 or Type 2), and test date.

11.3. *Report the following information on the appropriate data sheet*:

11.3.1. Report Form C4.2 (Table C3.2) shall be used to record general information concerning the specimen being tested. This form shall be completed only for those specimens that are recompacted from bulk samples. This form shall not be used to record information for thin wall tube samples.

11.3.1.1. *Item 4*—Record a "Y" (Yes) or "N" (No) to denote whether the sample reached a 5 percent total vertical permanent strain during the conditioning stage of the test procedure (Sections 8.3.3 and 9.3.3). Also, note with a "Y" (Yes) or "N" (No) whether or not the sample reached 5 percent total vertical permanent strain during the testing sequence. Record the number of test sequences completed, either partially or completely, for the given sample.

11.3.1.2. *Item 5*—Record the specimen dimensions and perform the area and volume calculations.

11.3.1.3. *Item 6*—Record the compaction masses as outlined in Annex B (Type 1) or Annex C or Appendix A (Type 2).

11.3.1.4. *Item 7*—Record the *in situ* moisture content/density values used as the basis for compaction of the specimen as per Sections 7.3.1 and 7.3.2. These values were obtained from nuclear methods in the field. If these values are not available, record the optimum moisture content, maximum dry density, and 95 percent maximum dry density values used as the basis for compaction of the specimen as per Section 7.3.3.

11.3.1.5. *Item 8*—Record the moisture content of the compacted material as per Section B1.3.16 (Type 1) or Sections C1.3.12 or D1.6.3 (Type 2). Record the moisture content of the material after the resilient modulus test as per Section 8.3.11 (Subgrade) or Section 9.3.11 (Base/Subbase). Also, record the target density used for specimen recompaction.

11.3.1.6. *Item 9*—Record the results and accompanying information for the quick-shear test procedure as per Section 8.3.9 (Subgrade) or Section 9.3.9 (Base/Subbase).

11.3.2. Report Form C4.3 (Table C3.3) shall be used to record general information concerning the specimen being tested. This form shall be completed only for thin-walled tube specimens. This form shall not be used to record information for recompacted samples.

11.3.2.1. *Item 4*—Record the approximate distance from the top of the subgrade to the top of the specimen (if known).

11.3.2.2. *Item 5*—Record a "Y" (Yes) or "N" (No) to denote whether the sample reached 5 percent total vertical permanent strain during the preconditioning stage of the test procedure (Sections 8.3.3 and 9.3.3). Also, note with a "Y" (Yes) or "N" (No) whether or not the sample reached a 5 percent total vertical permanent strain during the testing sequence. Record the number of test sequences completed, either partially or completely, for the given sample.

11.3.2.3. *Item 6*—Record the specimen dimensions and perform the area and volume calculations. Record the mass of the specimen.

11.3.2.4. *Item 7*—Record the moisture content (*in situ*) prior to resilient modulus testing. Record the moisture content at the completion of resilient modulus testing as per Section 8.3.11. Record the wet and dry density of the thin-walled tube samples.

11.3.2.5. *Item 8*—Record the results and accompanying information for the quick-shear test procedure as per Section 8.3.9 (Subgrade).

11.3.3. Record the test data for each specimen in a format similar to Report Form C4.1 (Table C3.1) and attach with Report Form C4.2 (Table C3.2) or Report Form C4.3 (Table C3.3). The following information shall be recorded on Report Form C4.1 (Table C3.1):

11.3.3.1. *Column 1*—Record the chamber confining pressure for the testing sequence. Only one entry need be made for the past five load cycles. This entry should correspond exactly with the confining pressure levels shown in Table 1 (Subgrade) or Table 2 (Base/Subbase).

11.3.3.2. *Column 2*—Record the nominal axial cyclic stress for the testing sequence. Only one entry need be made for the past five load cycles. This entry should correspond exactly with the nominal axial cyclic stress required in Table 1 (Subgrade) or Table 2 (Base/Subbase).

11.3.3.3. *Columns 4 through 9*—Record the actual applied loads and stresses for each of the past five load cycles as shown on the worksheet.

11.3.3.4. *Columns 10 through 12*—Record the recoverable axial deformation of the sample for each LVDT independently for each of the past five load cycles. Average the response from the two LVDTs and record this value in Column 12. This value will be used to calculate the axial strain of the material.

11.3.3.5. *Column 13*—Compute the axial strain for each of the past five load cycles. This value is computed by dividing Column 12 by the original length of the specimen, L_o, which was recorded on Report Form C4.2 (Table A3.2) (recompacted specimens) or Report Form C4.3 (Table C3.3) (thin-walled tube specimens).

11.3.3.6. *Column 14*—Compute the resilient modulus for each of the past five load cycles. This value is computed by dividing Column 8 by Column 13.

11.3.3.7. *Average*—Compute the average of the past five load cycles for each column.

11.3.3.8. *Standard Deviation*—Compute the standard deviation of the values for each column for the past five load cycles using the equation:

$$s = \sqrt{\frac{\sum\left(x_i - \bar{x}\right)^2}{n-1}} = \sqrt{\frac{\sum x_i^2 - \frac{\left(\sum x_i\right)^2}{n}}{n-1}} \qquad (11)$$

ANNEX A—SAMPLE PREPARATION

(Mandatory Information)

A1. SCOPE

A1.1. The following procedure provides guidelines for reconstituting the material to be tested so as to produce a sufficient amount of material needed to prepare the appropriate sample type (Type 1 or Type 2 sample) at the designated moisture content and density.

A1.1.1. *Sample Conditioning*—If the sample is damp when received from the field, dry it until it becomes friable. Drying may be in air or by use of a drying apparatus as long as the temperature does not exceed 60ºC. Then thoroughly break up the aggregations in such a manner as to avoid reducing the natural size of individual particles. Moderate pressure using a rubber-covered implement to push the particles through a 4.75-mm (No. 4) sieve has been found to be adequate to break down clay lumps.

A1.1.2. *Sample Preparation*—Determine the moisture content, w_1, of the sample as per T 265. The mass of the moisture content specimen shall be at least 200 g for samples with a maximum particle size smaller than the 4.75-mm (No. 4) sieve and at least 500 g for samples with a maximum particle size greater than the 4.75-mm (No. 4) sieve.

A1.1.2.1. Determine the appropriate total volume V of the compacted specimen to be prepared. The total volume must be based on a height of the compacted specimen slightly greater than that required for resilient testing to allow for trimming of the specimen ends, if necessary. Compacting to a height/diameter ratio of 2.1 to 2.2 will provide adequate material for this purpose.

A1.1.2.2. Determine the mass of oven-dry soil solids W_s required to obtain the desired dry density γ_d and moisture content w as follows:

$$W_s = 453.59\ \gamma_d\ V \qquad (A1.1)$$

where:

W_s = mass of oven-dry solids, g;

γ_d = desired dry density, lb/ft^3; and

V = total volume of compacted specimen, ft^3.

A1.1.2.3. Determine the mass of the dried sample, W_{ad}, with the moisture content, w_1, required to obtain W_s plus an additional amount, W_{as}, of at least 500 g to provide material for the determination of moisture content at the time of compaction.

$$W_{ad} = (W_s + W_{as})(1 + w_1/100) \qquad (A1.2)$$

where:

W_{ad} = mass of sample at water content w_1, g;

W_{as} = mass of moisture content specimen (usually 500 g), g; and

w_1 = water content of prepared material, percent.

A1.1.2.4. Determine the mass of water (W_{aw}) required to change the water content from the existing water content, w_1, to the desired compaction water content, w. (See Section 7.3.3)

$$W_{aw} = (W_s + W_{as})[(w - w_1)/100] \qquad (A1.3)$$

where:

W_{aw} = mass of water needed to obtain water content, w, g; and

w = desired water content of compacted material, percent.

A1.1.2.5. Place a sample of mass W_{ad} into a mixing pan.

A1.1.2.6. Add the mass of water (w_{aw}) needed to change the water content from w_1 to w, to the sample in small amounts and mix thoroughly after each addition.

A1.1.2.7. Place the mixture in a plastic bag. Seal the bag, place it in a second bag and seal it. Cure the sample for 16 to 48 hours, determine the mass of the wet soil and container to the nearest gram and record this value on Report Form C4.2 (Table A3.2).

A1.1.2.8. The material is now ready for compaction.

ANNEX B—VIBRATORY COMPACTION OF TYPE 1 AND TYPE 2 SOILS

(Mandatory Information)

B1. SCOPE

B1.1. Soils will be recompacted using a split mold and vibratory compaction. Select mold sizes to fabricate specimens of a minimum diameter equal to five times the maximum particles size. If the maximum particle size exceeds 25 percent of the largest mold diameter available, these particles shall be scalped. Length of all specimens will be at least two times the diameter.

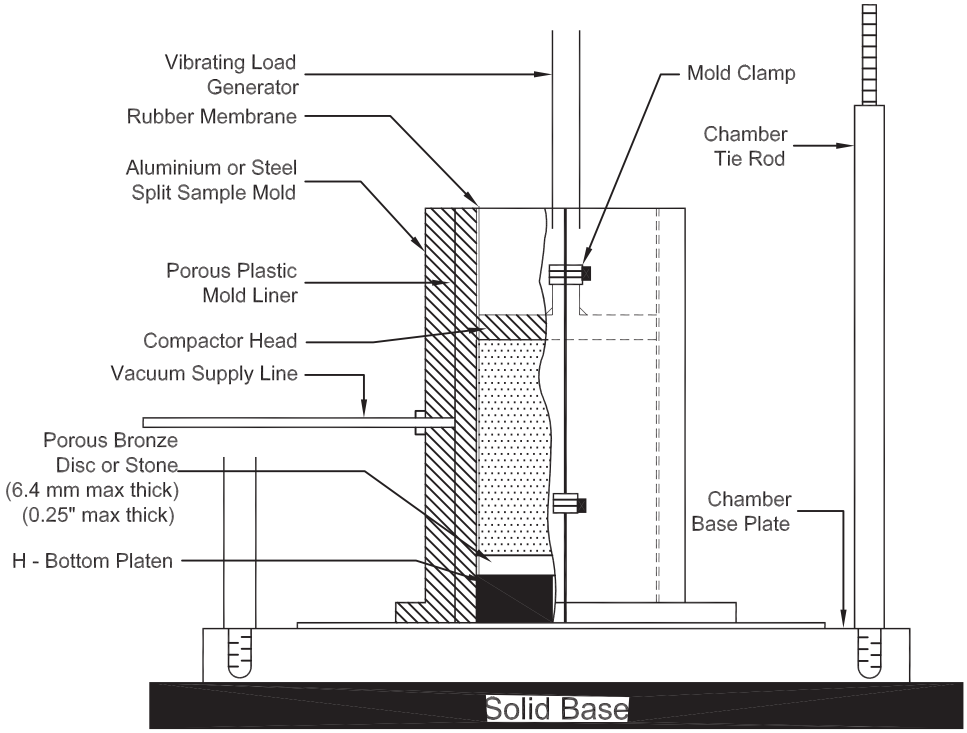
B1.2. Specimens shall be compacted in six lifts in a split mold mounted on the base of the triaxial cell as shown in Figure B2.1. Compaction forces are generated by a vibratory impact hammer without kneading action powered by air or electricity and of sufficient size to provide the required laboratory densities while minimizing damage to the sample membrane.

B2. APPARATUS

B2.1. A split mold, with an inside diameter of 152 mm, having a minimum height of 381 mm (or a sufficient height to allow guidance of the compaction head for the final lift).

B2.2. *Vibratory Compaction Device*—Vibratory compaction shall be provided using electric rotary or demolition hammers with a rated input of 750 to 1250 watts and capable of 1800 to 3000 blows per minute.

B2.3. The compactor head shall be at least 13-mm thick and have a diameter of not less than 146 mm.



Note: Compactor head should be 6.35 ± 0.5 mm (0.25 ± 0.02 in.) smaller than specimen diameter.

Figure B2.1—Typical Apparatus for Vibratory Compaction of Type 1 Untreated Materials

B3. PROCEDURE

B3.1. For removable platens, tighten the bottom platen into place on the triaxial cell base. It is essential that an airtight seal is obtained and that the bottom platen interface constitutes a rigid body because calculations of strain assume zero movement of the bottom platen under load.

B3.2. Place the two porous stones and the top platen on the bottom platen. Determine the total height of the top and bottom platens and stones to the nearest 0.25 mm.

B3.3. Remove the top platen and bronze disc, if used. Measure the thickness of the rubber membrane with a micrometer.

B3.4. Place the rubber membrane over the bottom platen and lower bronze disc. Secure the membrane to the bottom platen using an O-ring or other means to obtain an airtight seal.

B3.5. Place the split mold around the bottom platen and draw the membrane up through the mold. Tighten the split mold firmly in place. Exercise care to avoid pinching the membrane.

B3.6. Stretch the membrane tightly over the rim of the mold. Apply a vacuum to the mold sufficient to draw the membrane in contact. If wrinkles are present in the membrane, release the vacuum, adjust the membrane, and reapply the vacuum. The use of a porous plastic forming jacket line helps to ensure that the membrane fits smoothly inside the mold. The vacuum is maintained throughout the compaction procedure.

B3.7. Measure, to the nearest 0.25 mm, the inside diameter of the membrane-lined mold and the distance between the top of the lower porous stone and the top of the mold.

B3.8. Determine the volume, V, of the specimen to be prepared using the diameter determined in Step B3.7 and a value of height between 305 to 318 mm.

B3.9. Determine the mass of material, at the prepared water content, to be compacted into the volume, V, to obtain the desired density.

B3.10. For 152-mm diameter specimens (specimen height of 305 mm) six layers of 50 mm per layer are required for the compaction process. Determine the mass of wet soil, W_L, required for each layer.

$$W_L = W_t / N \qquad (B3.1)$$

where:

W_t = total mass of test specimen to produce the appropriate density, and

N_t = number of layers to be compacted.

B3.11. Place the total required mass of soil for all lifts, W_{ad}, into a mixing pan. Add the required amount of water, W_{aw}, and mix thoroughly.

B3.12. Determine the mass of the wet soil and the mixing pan.

B3.13. Place the amount of wet soil, W_L, into the mold. Avoid spillage. Using a spatula, draw soil away from the inside edge of the mold to form a small mound at the center.

B3.14. Insert the vibrator and vibrate the soil until the distance from the surface of the compacted layer to the rim of the mold is equal to the distance measured in B3.7 minus the thickness of the layer selected in Step B3.10. This may require removal and reinsertion of the vibrator several times until experience is gained in gauging the vibration time that is required.

B3.15. Repeat Steps B3.13 and B3.14 for each new layer after first scarifying the top surface of the previous layer to a depth of 6.4 mm. The measured distance from the surface of the compacted layer to the rim of the mold is successively reduced by the layer thickness selected in Step B3.10. The final surface shall be a smooth horizontal plane. As a recommended final step where porous bronze discs are used, the top plate shall be placed on the sample and seated with the vibrator head. If necessary, due to degradation of the first membrane, a second membrane can be applied to the sample at the conclusion of the compaction process.

B3.16. When the compaction process is completed, determine the mass of the mixing pan and the excess soil. This mass subtracted from the mass determined in Step B3.12 is the mass of the wet soil used (mass of specimen). Verify the compaction water, W_c, of the excess soil using care in covering the pan of wetted soil during compaction to avoid drying and loss of moisture. The moisture content of this sample shall be conducted using T 265.

B3.17. Proceed with Section 9 of this method.

Note B1—As an alternative for soils lacking in cohesion, a mold with the membrane installed and held by vacuum, as in Appendix B, may be used.

ANNEX C—COMPACTION OF TYPE 2 SOILS

(Mandatory Information)

C1. SCOPE

C1.1. This method covers the compaction of Type 2 soils for use in resilient modulus testing.

C1.2. The general method of compaction of Type 2 soils will be that of static loading (a modified version of the double plunger method). If testable thin-walled tubes are available, specimens shall not be recompacted.

C1.3. The process is one of compacting a known mass of soil to a volume that is fixed by the dimensions of the mold assembly. The minimum mold diameter shall be 71 mm. Select mold sizes to fabricate specimens of a minimum diameter equal to five times the maximum particle size. If the maximum particle size exceeds 25 percent of the largest mold diameter available, these particles shall be scalped. Length of all specimens will be at least two times the diameter. A typical mold assembly is shown in Figure C3.1. As an alternative for soils lacking in cohesion, a mold with the membrane installed and held by vacuum, as in Annex B, may be used. Several steps are required for static compaction, as follows in Section C3 of this Annex and as illustrated in Figures C3.2 to C3.6.

C2. APPARATUS

C2.1. The apparatus is as shown in Figure C3.1.

C3. PROCEDURE

C3.1. Five layers of equal mass shall be used to compact the specimens using this procedure. Determine the mass of wet soil, W_L, to be used per layer where $W_L = W_t/5$.

C3.2. Place one of the spacer plugs into the specimen mold.

C3.3. Place the mass of soil, W_L, determined in Step C3.1, into the specimen mold. Using a spatula, draw the soil away from the edge of the mold to form a slight mound in the center.

C3.4. Insert the second plug and place the assembly in the static loading machine. Apply a small load. Adjust the position of the mold with respect to the soil mass, so the distances from the mold ends to the respective spacer plugs are equal. Soil pressure developed by the initial loading will serve to hold the mold in place. By having both spacer plugs reach the zero volume change simultaneously, more uniform layer densities are obtained.

C3.5. Slowly increase the load until the plugs rest firmly against the mold ends. Maintain this load for a period of not less than 1 minute. The amount of soil rebound depends on the rate of loading and load duration. The slower the rate of loading and the longer the load is maintained, the less the rebound (Figure C3.2).

Note C1—To obtain uniform densities, extreme care must be taken to center the first soil layer exactly between the ends of the specimen mold. Checks and any necessary adjustments should be made after completion of Steps C3.4 and C3.5.

Note C2—Use of compaction by measuring the plunger movements to determine that the desired volume has been reached for each layer is an acceptable alternative to the use of the spacer plugs.

C3.6. Decrease the load to zero and remove the assembly from the loading machine.

C3.7. Remove the loading ram. Scarify the top surface of the compacted layer to a depth of 3.2 mm and put the mass of wet soil, W_L, for the second layer in place and form a mound. Add a spacer plug of the height shown in Figure C3.3.

C3.8. Slowly increase the load until the plugs rest firmly against the top of the mold end. Maintain load for a period of not less than 1 minute (Figure C3.3).

C3.9. Remove the load, flip the mold over, and remove the bottom plug keeping the top plug in place. Scarify the bottom surface of layer one and put the mass of wet soil W_L for the third layer in place and form a mound. Add a spacer ring of the height shown in Figure C3.4.

C3.10. Place the assembly in the loading machine. Increase the load slowly until the spacer plugs firmly contact the ends of the specimen mold. Maintain this load for a period of not less than 1 minute.

C3.11. Follow the steps presented in Figures C3.5 and C3.6 to compact the remaining two layers.

C3.12. After compaction is completed, determine the moisture content of the remaining soil using T 265. Record this value on Report Form C4.2 (Table C3.2).

C3.13. Using the extrusion ram, press the compacted soil out of the specimen mold and into the extrusion mold. Extrusion should be done slowly to avoid impact loading the specimen.

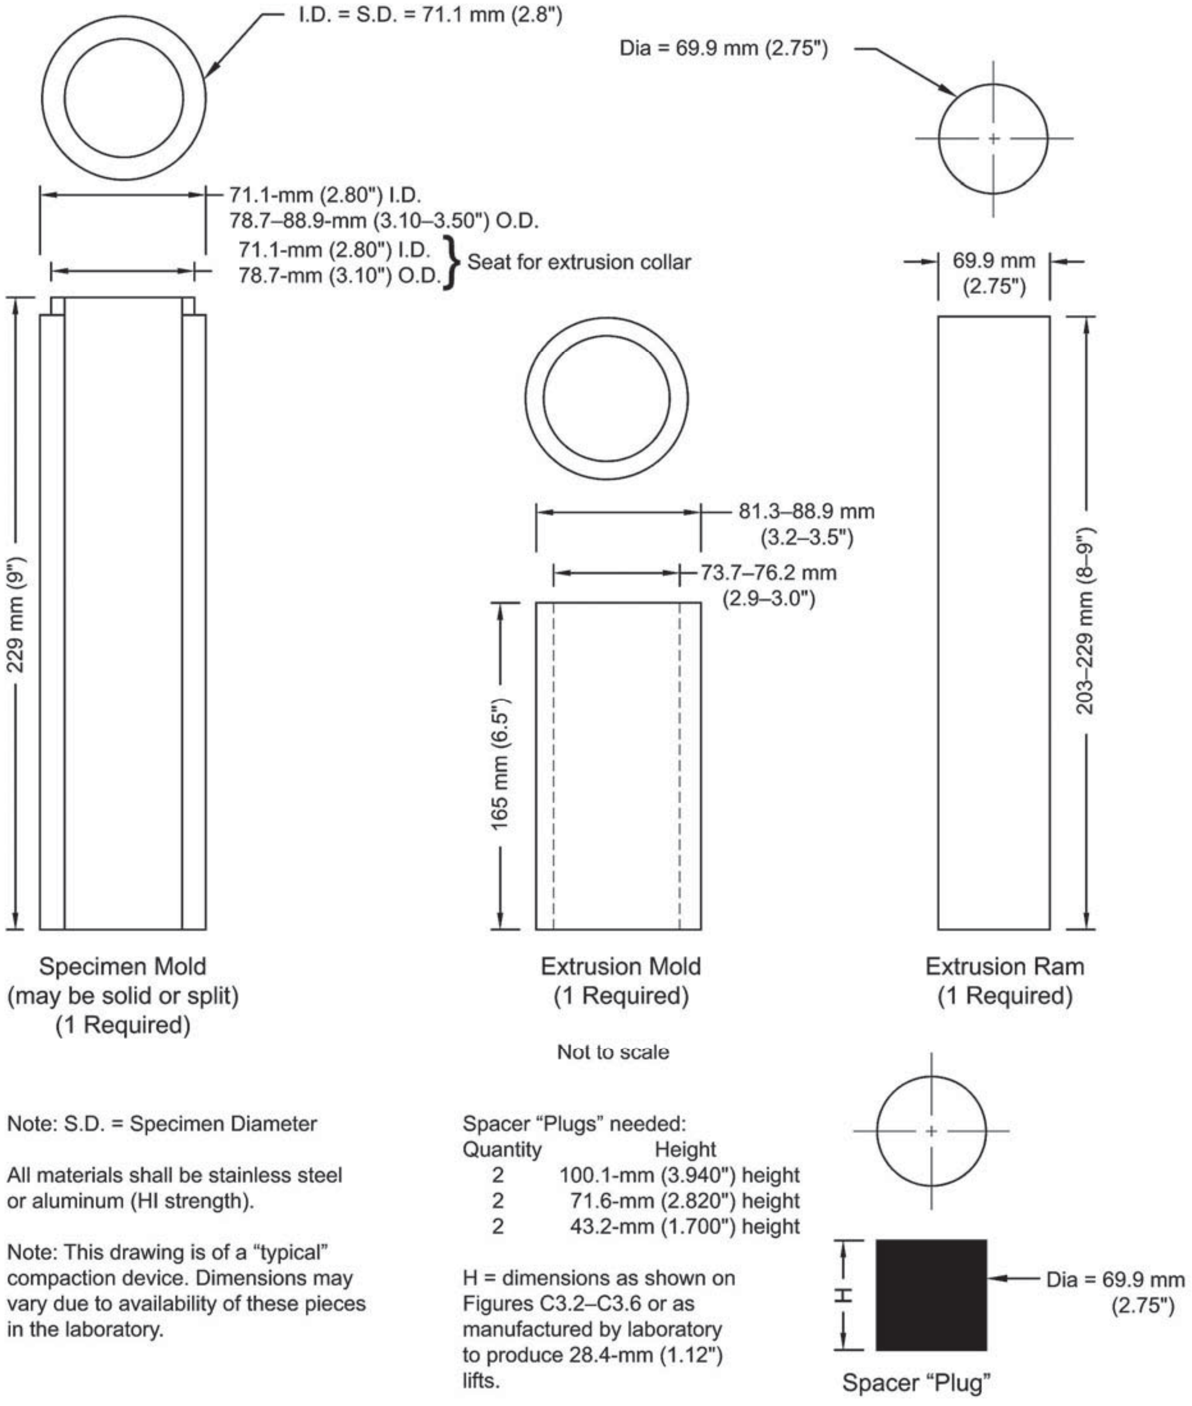
C3.14. Using the extrusion mold, carefully slide the specimen off the ram onto a solid end platen. The platen should be circular with a diameter equal to that of the specimen and have a minimum thickness of 13 mm. Platens shall be of a material that will not absorb soil moisture.

C3.15. Determine the mass of the compacted specimen to the nearest gram. Measure the height and diameter to the nearest 0.25 mm. Record these values on Report Form C4.1 (Table C3.1).

C3.16. Place a platen similar to the one used in Step C3.13 on top of the specimen.

C3.17. Using a vacuum membrane expander, place the membrane over the specimen. Carefully pull the ends of the membrane over the end platens. Secure the membrane to each platen using O-rings or other means to provide an airtight seal.

C3.18. Proceed with Section 8 of this method.



Note: S.D. = Specimen Diameter

All materials shall be stainless steel or aluminum (HI strength).

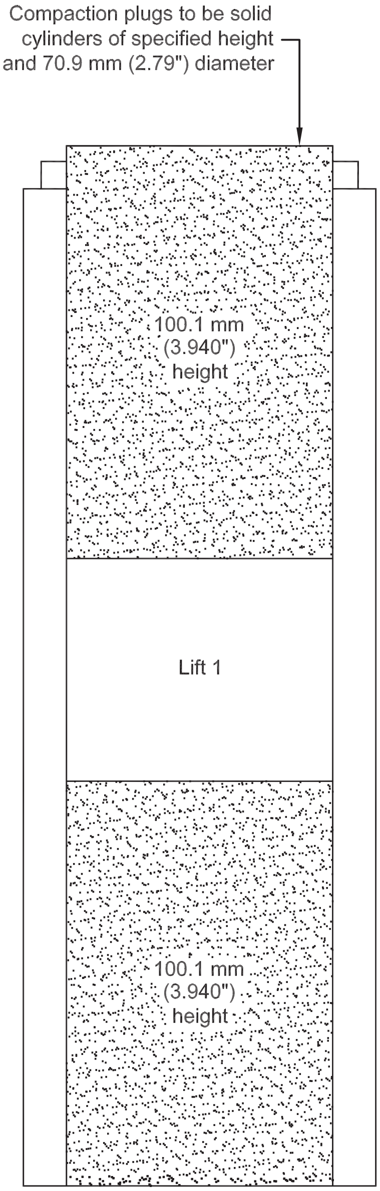
Note: This drawing is of a "typical" compaction device. Dimensions may vary due to availability of these pieces in the laboratory.

Spacer "Plugs" needed:

Quantity	Height
2	100.1-mm (3.940") height
2	71.6-mm (2.820") height
2	43.2-mm (1.700") height

H = dimensions as shown on Figures C3.2–C3.6 or as manufactured by laboratory to produce 28.4-mm (1.12") lifts.

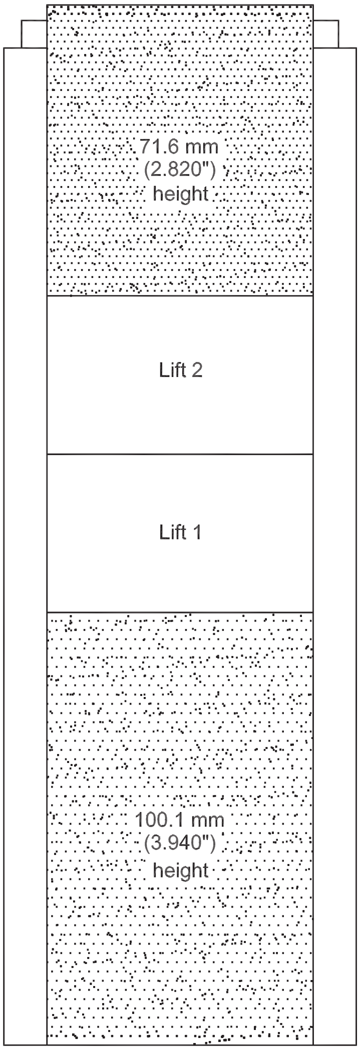
Figure C3.1—Typical Apparatus for Static Compaction of Type 2 Materials



Step 3.5—Lift 1:

- * Measure correct wet weight of soil to use for a layer.
- * Place in mold, spade.
- * Insert plugs of given height.
- * Double plunge until plugs are flush with top and bottom of mold.
- * Remove top plug.
- * Scarify the exposed surface of Lift 1.
- * Proceed with next step.

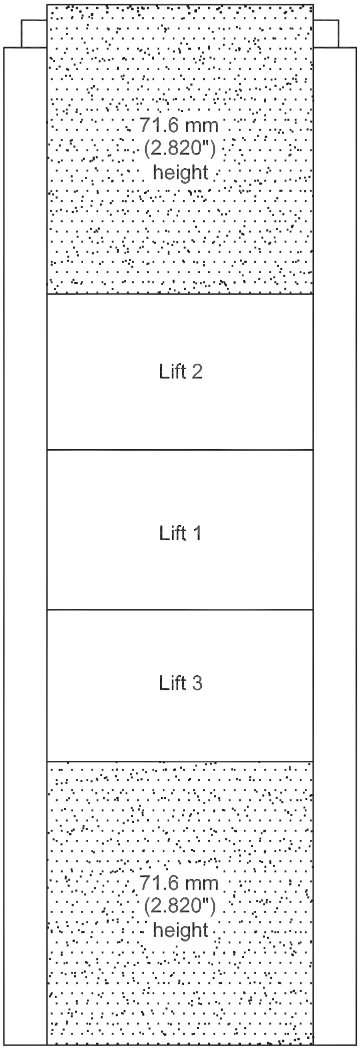
Figure C3.2—Compaction of Type 2 Soil, Lift 1



Step 3.7—Lift 2:

* Measure correct wet weight of soil to use for a layer.
* Place in mold, spade.
* Insert 71.6 mm (2.820") plug.
* Plunge until plugs are flush with top and bottom of mold.
* Flip mold over and remove 100.1 mm (3.940") plug, keeping the 71.6 mm (2.820") plug in place.
* Scarify the exposed surface of Lift 1.
* Proceed with next step.

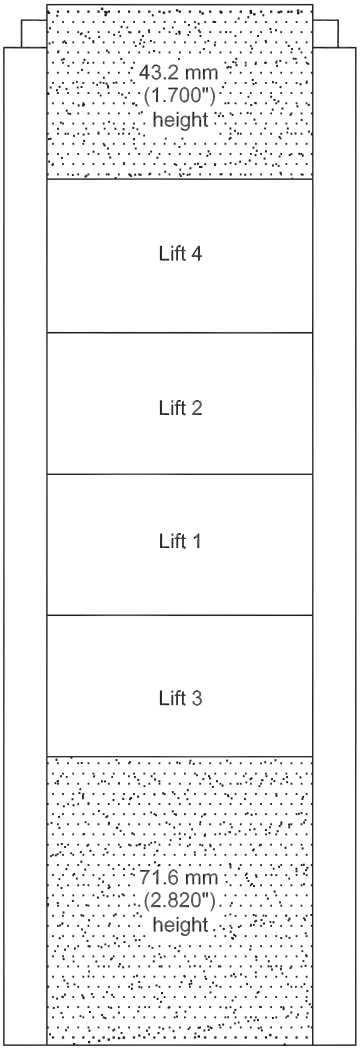
Figure C3.3—Compaction of Type 2 Soil, Lift 2



Step 3.9—Lift 3:

- * Measure correct wet weight of soil to use for a layer.
- * Place in mold, spade.
- * Insert 71.6 mm (2.820") plug.
- * Plunge until plugs are flush with top and bottom of mold.
- * Flip mold over and remove 71.6 mm (2.280") plug, from the top of Lift 2, keeping the 71.6 mm (2.820") plug (on Lift 3) in place.
- * Scarify the exposed surface of Lift 2.
- * Proceed with next step.

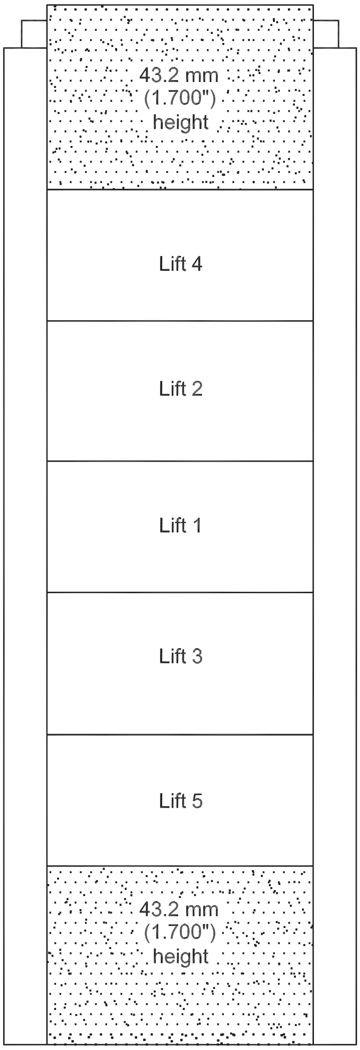
Figure C3.4—Compaction of Type 2 Soil, Lift 3



Step 3.11—Lift 4:

* Measure correct wet weight of soil to use for a layer.
* Place in mold, spade.
* Insert 43.2 mm (1.700") plug.
* Plunge until plugs are flush with top and bottom of mold.
* Flip mold over and remove 71.6 mm (2.820") plug, keeping the 43.2 mm (1.700") plug in place.
* Scarify the exposed surface of Lift 3.
* Proceed with next step.

Figure C3.5—Compaction of Type 2 Soil, Lift 4



Step 3.13—Lift 5:

* Measure correct wet weight of soil to use for a layer.
* Place in mold, spade.
* Insert 43.2 mm (1.700") plug.
* Plunge until plugs are flush with top and bottom of mold.
* Extrude compacted sample from mold using extruding apparatus or extrusion mold.
* Place in rubber membrane.
* Test for M_r.

Figure C3.6—Compaction of Type 2 Soil, Lift 5

APPENDIX A—KNEADING COMPACTION OF TYPE 2 SOILS

(Nonmandatory Information)

X1. SCOPE

X1.1. This method covers kneading compaction of Type 2 soils for use in resilient modulus testing.

X1.2. Specimens shall be compacted in five lifts (layers) in a split mold. Either a pneumatic manual compactor or a hydraulic mechanical compactor provides the compactive effort. The number of tamps per lift and the compaction pressure are constant for all lifts. The compaction pressure is adjusted to achieve the required laboratory density.

X2. SIGNIFICANCE AND USE

X2.1. Kneading compaction will yield a structure in Type 2 soils that is characteristically obtained by field compaction methods. Thus, when compacted dry of the optimum moisture content, the soil structure is mostly flocculated; and when compacted wet of the optimum, it is mostly dispersed.

X2.2. This procedure may result in a gradient of soil density within the specimen, which may affect the resilient modulus, M. Where it is important to achieve a uniform density in all specimen layers, the procedure described in Appendix B should be used.

X3. APPARATUS

X3.1. *Test Specimen Mold*—A split mold with a removable collar, as shown in Figure X6.1, shall be used. The minimum mold inside diameter shall be 71 mm. The mold shall have a minimum inside diameter not less than five times the maximum particle size. The trimmed length of all specimens shall be at least two times the diameter.

Note X1—As an alternative for soils lacking in cohesion, a mold with the membrane installed and held by vacuum, as described in Annex B, may be used.

X3.2. *Manual Compactor*—A pneumatic manual compactor, as shown in Figure X6.2, may be used. The volume of the air reservoir shall be a minimum of 200 times the volume of the compactor at full piston extension. The compactor rod shall be threaded to receive tamping feet of various diameters from 13 to 19 mm. The reservoir pressure regulator and gauge shall be capable of adjusting and reading air pressure from zero to 400 kPa. Calibration shall be checked annually using a calibrated proving ring or load cell.

Note X2—This device is modeled after the Harvard miniature compactor. A pneumatically operated compactor is preferred to a spring-loaded compactor due to the more consistent compactive effort and reduced operator variability.

X3.3. *Mechanical Compactor*—A hydraulic mechanical compactor capable of applying a foot pressure from 250 to 2000 kPa and meeting the requirements of T 190 may be used. When a mechanical compactor is used, the split mold inside diameter shall be chosen as required to work with the compactor, provided that the requirements of Section X3.1 are met.

X4. MANUAL COMPACTION PROCEDURE

X4.1. Specimen material shall be prepared in accordance with Annex A. If the maximum particle size exceeds 25 percent of the mold inside diameter, the oversize particles shall be scalped. The specimen will be fabricated 6 to 8 mm over height to allow trimming to a square end. Increase the quantity of material prepared to allow for the trimming.

X4.2. Specimens shall be compacted in five lifts of equal mass. Determine the mass of soil, W_L, required for each lift according to:

$$W_L = W_T/5 \qquad (X4.1)$$

where:

W_T = total mass of test specimen to produce the target density, including the allowance for trimming.

Note X3—In most cases, the target density will be determined by field conditions. Where this is not the case, an appropriate target density can be determined by performing a laboratory moisture-density test according to the procedure of T 99 or T 180.

X4.3. Adjust the air reservoir pressure to the level to be used in the first trial. Thread the desired diameter tamper foot onto the compactor piston. Determine the required number of tamps for one coverage of each lift according to Table X4.1.

Table X4.1—Number of Tamps for One Coverage of a Lift-Manual Procedure

Specimen Diameter	Tamper Foot Diameter			
	13 mm	15 mm	17 mm	19 mm
71 mm	30	22	17	14
86 mm	44	33	26	20
102 mm	62	46	36	29
152 mm	137	103	80	64

Note X4—Maintaining a database of compaction variables, soil types and moisture-density conditions will assist with selection of starting air pressure to achieve the desired specimen density.

X4.4. Place the mass of wet soil, W_L, for one lift in the mold. Using a spatula, draw the soil away from the edge of the mold to form a slight mound in the center.

X4.5. Holding the compactor vertically, apply the required number of tamps to the soil. Tamps should be distributed evenly over the specimen cross section. Each tamp should be applied slowly with just enough force to move the piston approximately 5 to 10 mm in the compactor.

Note X5—**Caution**: The piston should not be moved all the way to the end of the compactor, as this will cause an unregulated force to be applied.

X4.6. Lightly scarify the top surface of the compacted lift to a depth of 3 mm prior to placing soil in the mold for the next lift.

X4.7. Repeat Steps X4.5 and X4.6 until five lifts have been compacted. Continue with Section X6.1.

X5. MECHANICAL COMPACTION PROCEDURE

X5.1. Specimen material shall be prepared and weighed in accordance with Sections X4.1 and X4.2.

X5.2. Adjust the foot pressure to the level to be used in the first trial.

X5.3. Place the mass of wet soil, W_L, for one lift in the mold. Using a spatula, draw the soil away from the edge of the mold to form a slight mound in the center.

X5.4. Apply one revolution of tamps to the first lift (normally five to seven tamps per revolution, according to T 190) to achieve one coverage over the specimen cross section.

X5.5. Lightly scarify the top surface of the compacted lift to a depth of 3 mm prior to placing soil in the mold for the next lift.

X5.6. Repeat Steps X5.3 through X5.5 until five lifts have been compacted.

X6. SPECIMEN TRIMMING AND CALCULATIONS

X6.1. Remove the collar and carefully screed off the specimen to the top of the mold. Small depressions in the screeded surface, caused by removal of larger particles, shall be filled with fines. Remove the split mold from the base and the mold halves from the specimen.

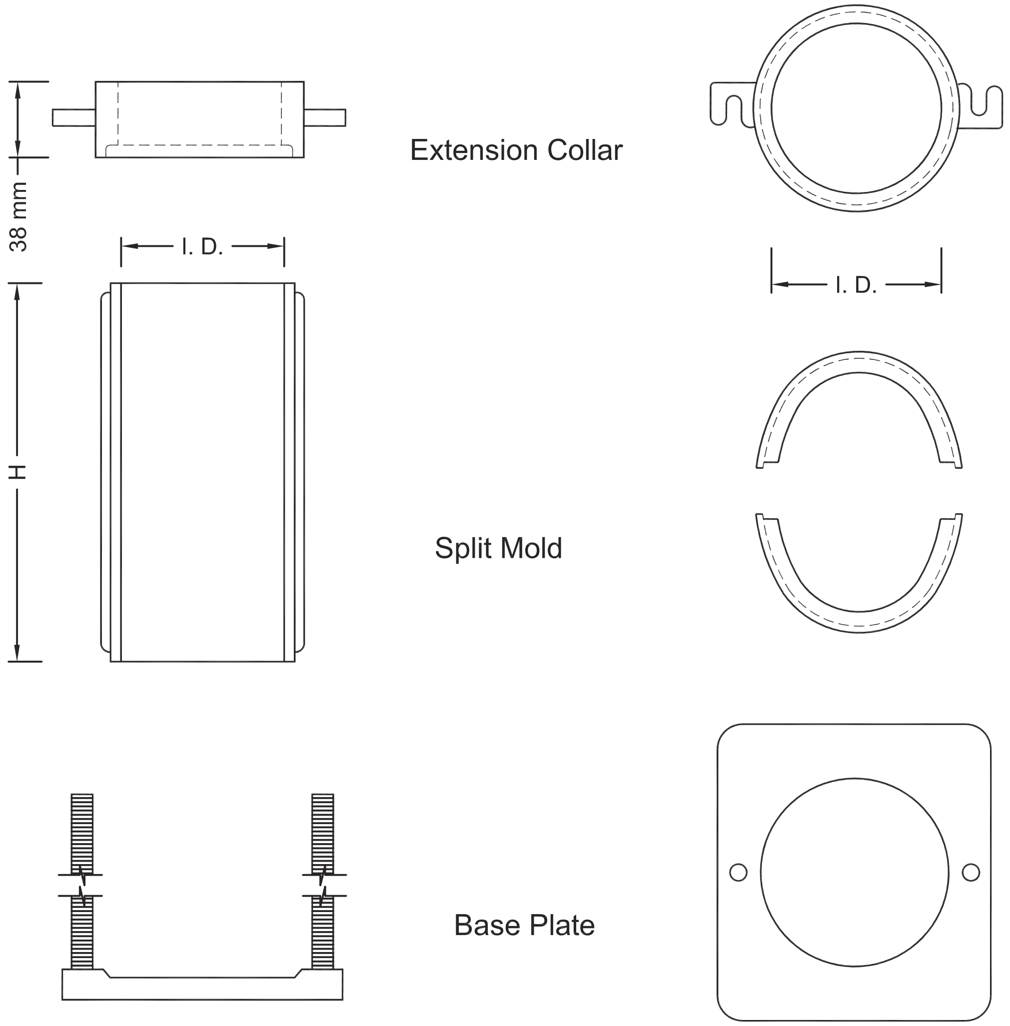
X6.2. Determine and record the mass of the entire specimen to the nearest gram. Use a tabular form, as in Figure X6.2, to record the data.

X6.3. Determine and record the moisture content of the remaining soil according to T 265.

X6.4. Calculate and record the average bulk (wet) density of the entire specimen, γ_s. If the average density differs from the target density by *less* than the tolerance allowed in Section 7.3.2 or 7.3.3, then proceed with Section 7.4.3 of this method.

X6.5. If the average density differs from the target density by *more* than the tolerance allowed in Section 7.3.2 or 7.3.3, then the compaction pressure shall be adjusted to increase or decrease the average density toward the target density. Repeat X4 or X5.

Note X6—If a sufficient quantity of material is available, it is preferable to use new material for each subsequent specimen. If the old material is reused, this will have an effect on the structure of subsequently compacted specimens.



Notes: 1. Mold halves are connected with 2 hose clamps.
2. H = I.D. × 2

Figure X6.1—Specimen Mold

Figure X6.3—Kneading Compaction of Type 2 Soils

APPENDIX B—OBTAINING A UNIFORM DENSITY IN TYPE 2 SOILS

(Nonmandatory Information)

X7. SCOPE

X7.1. This method provides procedures for measuring and minimizing or eliminating density gradients in a specimen of Type 2 soil for use in resilient modulus testing.

X7.2. Specimens shall be compacted in five lifts (layers) in a density gradient mold. Kneading compaction (Appendix A) shall be used. The number of tamps per lift shall be adjusted for each lift to avoid imparting a density gradient to the specimen.

X8. SIGNIFICANCE AND USE

X8.1. A specimen fabricated in layers, with each lift receiving equal compactive effort, will typically exhibit a density gradient with the first lift compacted being more dense than the last. To measure this effect, the density gradient mold is used to determine the density of each lift. A trial and error process is used to adjust the compactive effort for each lift until the desired specimen density is obtained with a minimum gradient.

X8.2. Density gradients can occur with kneading (Appendix A), static double plunger (Annex C), or vibratory (Annex B) compaction methods. The density gradient mold can be used in conjunction with any of the three compaction methods to measure density gradients from top to bottom within the specimen.

X8.3. For the most accurate characterization of resilient modulus, the density gradient within the test specimen should be minimized. The test specimen should have a structure that closely approximates the one that will be obtained in field compaction. The use of kneading compaction can help to achieve the proper structure.

X9. APPARATUS

X9.1. *Density Gradient Mold*—The density gradient mold is shown in Figure X10.1. This is a split mold with the inside milled to receive five interchangeable solid rings that have been permanently numbered from one through five. The ring I.D. shall be equal to the mold I.D. The mold height and diameter shall be the same as those used in preparing specimens for resilient modulus testing (Appendix A).

X9.2. *Compactor*—To measure the density gradient (using Section X10), the same type of compactor shall be used as is used in preparing specimens for resilient modulus testing, as described in Annex B, Annex C, or Appendix A. To minimize the density gradient (using Section X11), either a manual or a mechanical kneading compactor, as described in Appendix A, shall be used.

X10. PROCEDURE FOR COMPACTING SPECIMENS TO MEASURE DENSITY GRADIENTS

X10.1. Specimen material shall be prepared in accordance with Annex A. If the maximum particle size exceeds 25 percent of the mold inside diameter, the oversize particles shall be scalped. The specimen will be fabricated 6 to 8 mm over height to allow trimming to a square end. Increase the quantity of material prepared to allow for the trimming.

X10.2. Specimens shall be compacted to the same diameter, and using the same apparatus and procedure, as is used in preparing specimens for resilient modulus testing, as described in Annex B, Annex C, or Appendix A.

X10.3. Remove the collar and carefully screed off the specimen to the top of the mold. Small depressions in the screeded surface, caused by removal of larger particles, shall be filled with fines. Remove the split mold from the base and the mold halves from the specimen. Leave the five rings on the specimen.

X10.4. Determine and record the net mass of the entire specimen to the nearest gram. To do this, subtract the mass of the rings from the mass of the specimen with rings attached.

X10.5. Determine and record the moisture content of the remaining soil according to T 265.

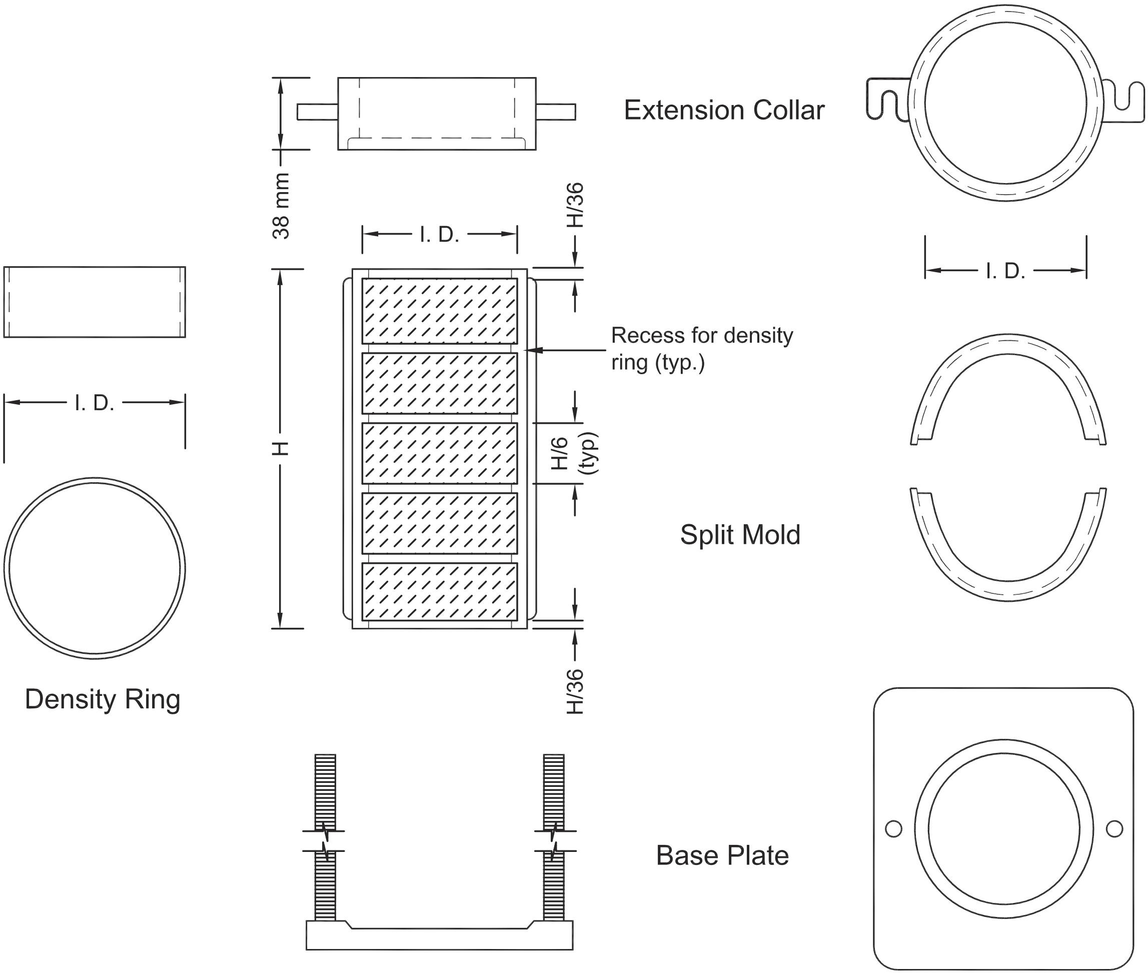
X10.6. Using a hacksaw or other abrasive device, carefully cut the specimen into five pieces. Each cut should be made midway between the rings. Screed off each piece to form square ends at the top and bottom of each ring. Small depressions in the screeded surface, caused by removal of larger particles, shall be filled with fines.

X10.7. Determine and record the net mass of each numbered piece to the nearest gram. Use a tabular form, as in Figure X10.2, to record the data.

X10.8. Determine and record the moisture content of each numbered piece.

X10.9. Calculate and record the average bulk (wet) density of the entire specimen, γ_s, and the densities of each of the five pieces, γ_1 to γ_5.

X10.10. If the maximum difference between the density of each individual piece and the average density is 1.0 percent or less, report the density gradient as being uniform. If the maximum difference between the density of each individual piece and the average density is more than 1.0 percent, report the density gradient as being non-uniform.



Notes: 1. L = Specimen ht. + Collar ht. – Layer HL + 12 mm
2. Minimum Reservoir Volume = 200 × Compactor Volume
3. Minimum gauge accuracy is 0.5 kPa.
4. Compactor air cylinder is rolling diaphragm type.

Figure X10.2—Check for Density Gradient

X11. PROCEDURE FOR COMPACTING TEST SPECIMENS TO ACHIEVE A UNIFORM DENSITY

X11.1. Follow the procedure in Sections X10.1 through X10.9, using either the manual or mechanical kneading compaction procedure (Appendix A).

Note X7—The requirement in Appendix A that the number of tamps per lift be constant is waived. However, it is recommended that the number of tamps per lift be constant for each lift in the first trial specimen in order to establish that a density gradient does exist.

X11.2. If the average bulk density differs from the target density by more than the tolerance allowed in Section 7.3.2 or 7.3.3, then the compaction pressure shall be adjusted, holding the number of tamps per lift constant, to increase or decrease the average density toward the target density. Repeat Step X11.1.

X11.3. After the target average density is achieved, check the density uniformity according to Section X10. If the density is non-uniform, hold the compaction pressure constant and adjust the number of tamps per lift until a uniform density gradient is achieved.

Note X8—If a sufficient quantity of material is available, it is preferable to use new material for each subsequent specimen. If the old material is reused it will have an effect on the structure of subsequently compacted specimens.

X11.4. Use the compaction pressure and number of tamps per lift thus determined to prepare specimens for resilient modulus testing using the procedure in Appendix A.

Standard Method of Test for

In-Place Density and Moisture Content of Soil and Soil-Aggregate by Nuclear Methods (Shallow Depth)

AASHTO Designation: T 310-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

In-Place Density and Moisture Content of Soil and Soil-Aggregate by Nuclear Methods (Shallow Depth)

AASHTO Designation: T 310-10

1. SCOPE

1.1. This test method describes the procedure for determining the in-place density and moisture of soil and soil-aggregate by use of nuclear gauge. The density of the material may be determined by either direct transmission, backscatter, or backscatter/air-gap ratio method. The moisture of the material is determined only from measurements taken at the surface of the soil (i.e., backscatter).

1.2. *Density*—The total or wet density of soil and soil-rock mixtures is determined by the attenuation of gamma radiation where the source or detector is placed at a known depth up to 300 mm (12 in.) while the detector(s) or source remains on the surface (Direct Transmission Method) or the source and detector(s) remain on the surface (Backscatter Method).

1.2.1. The density in mass per unit volume of the material under test is determined by comparing the detected rate of gamma radiation with previously established calibration data.

1.3. *Moisture*—The moisture content of the soil and soil-rock mixtures is determined by thermalization or slowing of fast neutrons where the neutron source and the thermal neutron detector both remain at the surface.

1.3.1. The water content in mass per unit volume of the material under test is determined by comparing the detection rate of thermalized or slow neutrons with previously established calibration data.

1.4. *SI Units*—The values stated in SI units are to be regarded as the standard. The inch-pound equivalents may be approximate. It is common practice in the engineering profession to concurrently use pounds to represent both a unit of mass (lbm) and of force (lbf). This implicitly combines two systems of units, that is, the absolute system and the gravitational system.

1.4.1. This standard has been written using the absolute system for water content (kilograms per cubic meter) in SI units. Conversion to the gravitational system of unit weight in lbf/ft^3 may be made. The recording of water content in pound-force per cubic foot should not be regarded as nonconformance with this standard, although the use is scientifically incorrect.

1.4.2. In the English system, the pound (lbf) represents a unit of force (weight). However, the use of balances or scales recording pounds of mass (lbm) or recording of density (lbm/ft^3) should not be regarded as nonconformance with this standard.

1.5. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and* *health practices and determine the applicability of regulatory limitations prior to use.* See Section 6, Hazards.

3. SIGNIFICANCE

3.1. The test method described is useful as a rapid, nondestructive technique for the in-place determination of the wet density and water content of soil and soil-aggregate.

3.2. The test method is used for quality control and acceptance testing of compacted soil and rock for construction and for research and development. The nondestructive nature allows for repetitive measurements at a single test location and statistical analysis of the results.

3.3. *Density*—The fundamental assumptions inherent in the methods are that Compton scattering is the dominant interaction and that the material under test is homogeneous.

3.4. *Moisture*—The fundamental assumptions inherent in the test method are that the hydrogen present is in the form of water as defined by ASTM D 2216 and that the material under test is homogeneous.

3.5. Test results may be affected by chemical composition, sample heterogeneity, and to a lesser degree, material density and the surface texture of the material being tested. The technique also exhibits spatial bias in that the gauge is more sensitive to water contained in the material in close proximity to the surface and less sensitive to water at deeper levels.

---

4. INTERFERENCES

4.1. *In-Place Density Interferences*:

4.1.1. The chemical composition of the sample may affect the measurement, and adjustments may be necessary.

4.1.2. The gauge is more sensitive to the density of the material in close proximity to the surface in the Backscatter Method.

Note 1—The nuclear gauge density measurements are somewhat biased to the surface layers of the soil being tested. This bias has largely been corrected out of the Direct Transmission Method, and any remaining bias is insignificant. The Backscatter Method is still more sensitive to the material within the first several inches from the surface. Density measurements with direct transmission is the preferred method.

4.1.3. Oversize rocks or large voids in the source-detector path may cause higher or lower density determination. Where lack of uniformity in the soil due to layering, rock, or voids is suspected, the test site should be excavated and visually examined to determine if the test material is representative of the full material in general, and if rock correction is required.

4.1.4. The sample volume is approximately 0.0028 m^3 (0.10 ft^3) for the Backscatter Method and 0.0057 m^3 (0.20 ft^3) for the Direct Transmission Method when the test depth is 150 mm (6 in.). The actual sample volume is indeterminate and varies with the gauge and the density of the material. In general, the higher the density, the smaller the volume.

4.1.5. Other radioactive sources must not be within 10 m (30 ft) of the gauge in operation.

4.2. *In-Place Moisture Content Interferences*:

4.2.1. The chemical composition of the sample may dramatically affect the measurement and adjustments may be necessary. Hydrogen in forms other than water, as defined by ASTM D 2216, and carbon will cause measurements in excess of the true value. Some chemical elements, such as boron, chlorine, and minute quantities of cadmium, will cause measurements lower than the true value.

4.2.2. The water content determined by this test method is not necessarily the average water within the volume of the sample involved in the measurement. The measurement is heavily influenced by the water content of the material closest to the surface. The volume of soil and rock represented in the measurement is indeterminate and will vary with the water content of the material. In general, the greater the water content of the material, the smaller the volume involved in the measurement. At 160 kg/m^3 (10 lb/ft^3), approximately 50 percent of the typical measurement results from the water content of the upper 50 to 75 mm (2 to 3 in.).

4.2.3. Other neutron sources must not be within 10 m (30 ft) of the gauge in operation.

5. APPARATUS

5.1. *Nuclear Density/Moisture Gauge*—While exact details of construction of the gauge may vary, the system shall consist of:

5.1.1. A sealed source of high-energy gamma radiation such as cesium or radium.

5.2. *Gamma Detector*—Any type of gamma detector such as a Geiger-Mueller tube(s).

5.3. *Fast Neutron Source*—A sealed mixture of a radioactive material such as americium, radium, or californium-252 and a target material such as beryllium.

5.4. *Slow Neutron Detector*—Any type of slow neutron detector such as boron trifluoride or helium-3 proportional counter.

5.5. *Reference Standard*—A block of material used for checking gauge operation, correction of source decay, and to establish conditions for a reproducible reference count rate.

5.6. *Site Preparation Device*—A plate, straightedge, or other suitable leveling tool which may be used for planing the test site to the required smoothness, and in the Direct Transmission Method, guiding the drive pin to prepare a perpendicular hole.

5.7. *Drive Pin*—A pin not to exceed the diameter of the rod in the Direct Transmission gauge by more than 6 mm ($^1/_4$ in.), or as recommended by the gauge manufacturer, used to prepare a hole in the material under test for inserting the rod.

5.7.1. A slide hammer, with a drive pin attached, may also be used both to prepare a hole in the material to be tested and to extract the pin without distortion to the hole.

5.8. *Drive Pin Extractor*—A tool that may be used to remove the drive pin in a vertical direction so that the pin will not distort the hole in the extraction process.

6. HAZARDS

6.1. The gauge utilizes radioactive materials that may be hazardous to the health of the users unless proper precautions are taken. Users of the gauge must become familiar with applicable safety procedures and government regulations.

6.2. Effective user instructions together with routine safety procedures, such as source leak tests, recording and evaluation of film badge data, etc., are a recommended part of the operation and storage of this gauge.

7. CALIBRATION

7.1. Calibration of the gauge will be in accordance with Annexes A1 and A2. (See also ASTM D 7013).

8. STANDARDIZATION

8.1. All nuclear density/moisture gauges are subject to long-term aging of the radioactive sources, detectors, and electronic systems, which may change the relationship between count rates and the material density and water content. To offset this aging, gauges are calibrated as a ratio of the measurement count rate to a count rate made on a reference standard or to an air-gap count (for the backscatter/air-gap ratio method). The reference count rate should be in the same or higher order of magnitude than the range of measurement count rates over the useful range of the gauge.

8.2. Standardization of the gauge on the reference standard is required at the start of each day's use and a permanent record of these data shall be retained. The standardization shall be performed with the gauge at least 10 m (30 ft) away from other nuclear density/moisture gauges and clear of large masses of water or other items which may affect the reference count rates. Standard counts should be taken in the same environment as the actual measurement counts.

8.2.1. Turn on the gauge and allow for stabilization according to the manufacturer's recommendations. If the gauge is to be used either continuously or intermittently during the day, it is best to leave it in the "power on" condition to prevent having to repeat the stabilization (refer to manufacturer recommendations). This will provide more stable, consistent results.

8.2.2. Using the reference standard, take at least four repetitive readings at the normal measurement period and obtain the mean. If available on the gauge, one measurement of four or more times the normal period is acceptable. This constitutes one standardization check.

Use the procedure recommended by the gauge manufacturer for determining compliance with the gauge calibration curves. Without specific recommendations for the gauge manufacturer, use the procedure in Section 8.2.3.

8.2.3. If the mean of the four repetitive readings is outside the limits set by Equation 1, repeat the standardization check. If the second standardization check satisfies Equation 1, the gauge is considered in satisfactory operating condition. If the second standardization check does not satisfy Equation 1, the gauge should be checked and verified according to Annexes A1 and A2, Sections A1.8 and A2.5. If the verification shows that there is no significant change in the calibration curve, a new reference standard count, N_o, should be established. If the verification check shows that there is a significant difference in the calibration curve, repair and recalibrate the gauge.

$$N_s = N_o \pm 1.96\sqrt{(N_o/F)} \qquad (1)$$

where:

N_s = value of current standardization count;

N_o = average of the past four values of N_s taken for prior usage; and

F = factory pre-scale factor (contact gauge manufacturer for the factor).

9. PROCEDURE

9.1. Select a test location where the gauge will be at least 150 mm (6 in.) away from any vertical mass. If closer than 600 mm (24 in.) to a vertical mass, such as in a trench, follow gauge manufacturer correction procedures.

9.2. *Prepare the test site in the following manner*:

9.2.1. Remove all loose and disturbed material and additional material as necessary to expose the top of the material to be tested.

Note 2—The spatial bias should be considered in determining the depth at which the gauge is to be seated.

9.2.2. Prepare a horizontal area sufficient in size to accommodate the gauge by planing the area to a smooth condition so as to obtain maximum contact between the gauge and material being tested.

9.2.3. The maximum void beneath the gauge shall not exceed 3 mm ($^1/_8$ in.). Use native fines or fine sand to fill the voids and smooth the surface with a rigid plate or other suitable tool. The depth of the filler should not exceed approximately 3 mm ($^1/_8$ in.).

Note 3—The placement of the gauge on the surface of the material to be tested is critical to the successful determination of density. The optimum condition is total contact between the bottom surface of the gauge and the surface of the material being tested. When optimal conditions are not present, correct surface irregularities by the use of sand or similar filler material. The total area filled should not exceed 10 percent of the bottom area of the gauge. Several trial seatings may be required to achieve these conditions.

9.3. Turn on and allow the gauge to stabilize (warm up) according to the manufacturer's recommendations (see Section 8.2.1).

9.4. *Backscatter or Backscatter/Air-Gap Ratio Method of In-Place Nuclear Density and Moisture Content*:

9.4.1. Seat the gauge firmly.

9.4.2. Keep all other radioactive sources at least 10 m (30 ft) away from the gauge to avoid affecting the measurement.

9.4.3. Set the gauge into the Backscatter (BS) position (see Note 4).

9.4.4. Secure and record one or more 1-minute readings (see Note 5). When using the backscatter/air-gap ratio method, follow the manufacturer's instructions regarding gauge setup. Take the same number of readings for the normal measurement period in the air-gap position as in the standard backscatter position. Determine the air-gap ratio by dividing the counts per minute obtained in the air-gap position by the counts per minute obtained in the standard position. Many gauges have built-in provisions for automatically calculating the air-gap ratio and wet density.

9.4.5. Determine the in-place wet density by use of the calibration curve previously established or read the gauge directly if so equipped.

9.4.6. *Direct Transmission Method of In-Place Nuclear Density and Moisture Content:*

9.4.6.1. Select a test location where the gauge in test position will be at least 150 mm (6 in.) away from any vertical projection.

9.4.7. Make a hole perpendicular to the prepared surface using the guide and the hole-forming device (Section 5). The hole shall be a minimum of 50 mm (2 in.) deeper than the desired measurement depth and of an alignment that insertion of the probe will not cause the gauge to tilt from the plane of the prepared area.

9.4.8. Mark the test area to allow the placement of the gauge over the test site and to allow the alignment of the source rod to the hole. Follow manufacturer recommendations if applicable.

9.4.9. Remove the hole forming device carefully to prevent the distortion of the hole, damage to the surface, or loose material to fall into the hole.

9.4.10. Place the gauge on the material to be tested, making sure of maximum surface contact as described above.

9.4.11. Lower the source rod into the hole to the desired test depth. Pull gently on the gauge in the direction that will bring the side of the probe to face the center of the gauge so that the probe is in intimate contact with the side of the hole in the gamma measurement path.

Note 4—As a safety precaution, do not extend a rod containing radioactive sources out of its shielded position prior to placing on the test site. Always align the gauge so as to allow placing the rod directly into the test hole from the shielded position.

9.4.12. Keep all other radioactive sources at least 10 m (30 ft) away from the gauge to avoid affecting the measurement.

9.4.13. If the gauge is so equipped, set the depth selector to the same depth as the probe before recording the automated (gauge computed densities, moisture contents, and weights) values.

9.4.14. Secure and record one or more 1-minute readings (see Note 5).

9.4.15. Determine the in-place wet density by use of the calibration curve previously established or read the gauge directly if so equipped.

Note 5—The gauge may be rotated about the axis of the probe to obtain additional readings.

10. CALCULATION OF RESULTS

10.1. If dry density is required, the in-place water content may be determined by using the nuclear methods described herein, gravimetric samples and laboratory determination, or other approved instrumentation.

10.1.1. If the water content is determined by nuclear methods, use the gauge readings directly, or subtract the kg/m^3 (lbm/ft^3) of moisture from the kg/m^3 (lbm/ft^3) of wet density, and obtain dry density in kg/m^3 (lbm/ft^3).

10.1.2. If the water content is determined by other methods, and is in the form of percent, proceed as follows:

$$d = \frac{100}{100 + w}(m) \tag{2}$$

where:

d = dry density in kg/m^3 (lbm/ft^3);

m = wet density in kg/m^3 (lbm/ft^3); and

w = water as a percent of dry mass.

10.2. *Percent Density:*

10.2.1. It may be desired to express the in-place density as a percentage of some other density, for example, the laboratory densities determined in accordance with T 99 and T 180. This relation can be determined by dividing the in-place density by the laboratory density and multiplying by 100. Calculations for determining relative density are provided in ASTM D 4253 or D 4254. Corrections for oversize material, if required, should be performed in accordance with T 224 or ASTM D 4718.

10.2.2. If representative samples of material are to be taken for purposes of correlation with other test methods or rock correction, the volume measured can be approximated by a 200-mm (8-in.)-diameter cylinder located directly under the center line of the radioactive source and detector(s). The height of the cylinder to be excavated will be the depth setting of the source rod when using the Direct Transmission method or approximately 75 mm (3 in.) when using the Backscatter method.

10.2.3. An alternate to the correction for oversize particles that can be used with mass density methods or minimal oversize situations involves multiple tests. Three tests may be taken at adjacent locations and the results averaged to get a representative value.

Comparisons need to be made to evaluate whether the presence of a single large rock or void in the soil is producing unrepresentative values of density. Whenever values obtained are questionable, the test volume site should be excavated and visually examined.

11. REPORT

11.1. The report shall include the following:

11.1.1. Standardization and adjustment data for the date of the tests.

11.1.2. Make, model, and serial number of the test gauge.

11.1.3. Name of the operator(s).

11.1.4. Date of last instrument calibration or calibration verification.

11.1.5. Test site identification.

11.1.6. Visual description of material tested.

11.1.7. Test mode (backscatter or direct transmission) and test depth (if applicable).

11.1.8. Wet and dry densities in kg/m^3 or unit weights in lb/ft^3.

11.1.9. Water content in percent of dry mass or dry unit weight.

11.1.10. Any adjustments made in the reported values and reasons for adjustments (i.e., offset, oversize particles, etc.).

12. PRECISION AND BIAS

12.1. *Precision*:

12.1.1. *Wet Density*—Criteria for judging the acceptability of wet density test results obtained by this test method are given in Table 1. The figure in Column 3 represents the standard deviations that have been found to be appropriate for the materials tested in Column one. The figures given in

Column 4 are the limits that should not be exceeded by the difference between the results of two properly conducted tests. The figures given are based upon an inter-laboratory study in which five test sites containing soils, with wet densities as shown in Column 2, were tested by eight different devices and operators. The wet density of each test site was determined three times by each device.

Table 1—Results of Statistical Analysis (Wet Density)[a]

	Soil Type (Column 1)	Average, lb/ft^3 (kg/m^3) (Column 2)	Standard Deviation (Column 3)	Acceptable Range of Two Results,[b] lb/ft^3 (kg/m^3) (Column 4)
Single-Operator Precision				
Direct Transmission:				
	CL	114.7 (1837.3)	0.34 (5.45)	0.94 (15.06)
	SP	120.9 (1936.6)	0.27 (4.32)	0.74 (11.85)
	ML	130.1 (2084.0)	0.46 (7.37)	1.28 (20.50)
Backscatter:				
	ML	124.6 (1995.9)	1.21 (19.38)	3.39 (54.30)
Multilaboratory Precision				
Direct Transmission:				
	CL	114.7 (1837.3)	0.66 (10.57)	1.86 (29.79)
	SP	120.9 (1936.6)	0.68 (10.89)	1.91 (30.59)
	ML	130.1 (2084.0)	0.77 (12.23)	2.15 (34.44)
Backscatter:				
	ML	124.6 (1995.9)	2.38 (38.12)	6.67 (106.84)

[a] The data used to establish the density and moisture content precision statements are contained in ASTM Research Report RR:D18-1004. Similar soil types using other classification systems should reflect similar precision values.

[b] Two separate readings at a singular site with constant gate orientation and settings.

12.1.2. *Moisture Content*—Criteria for judging the acceptability of the moisture content results obtained by this test method are given in Table 2. The value in Column 2 is in the units actually measured by the nuclear gauge. The figures in Column 3 represent the standard deviations that have been found to be appropriate for the materials tests in Column 1. The figures given in Column 4 are the limits that should not be exceeded by the difference between the results of two properly conducted tests. The figures given are based upon an inter-laboratory study in which five test sites containing soils, with moisture content as shown in Column 2, were tested by eight different devices and operators. The moisture content of each test site was determined three times by each device.

Table 2—Results of Statistical Analysis (Moisture Content)

	Soil Type (Column 1)	Average, lb/ft^3 (kg/m^3) (Column 2)	Standard Deviation (Column 3)	Acceptable Range of Two Results,[a] lb/ft^3 (kg/m^3) (Column 4)
Single-Operator Precision				
	CL	12.1 (193.8)	0.35 (5.6)	0.97 (15.5)
	SP	18.7 (299.5)	0.46 (7.4)	1.29 (20.7)
	ML	19.6 (314.0)	0.35 (5.6)	0.99 (15.8)
Multilaboratory Precision				
	CL	12.1 (193.8)	0.52 (8.3)	1.44 (23.1)
	SP	18.7 (299.5)	0.75 (12.0)	2.10 (33.6)
	ML	19.6 (314.0)	0.58 (9.3)	1.63 (26.1)

[a] Two separate readings at a singular site with constant gauge orientation and settings.

12.2. *Bias*:

12.2.1. There are no accepted reference values for these test methods; therefore, bias cannot be determined.

13. KEYWORDS

13.1. Compaction test; construction control, density; moisture content; nuclear methods; quality control; water content.

ANNEXES

(Mandatory Information)

A1. WET DENSITY CALIBRATION AND VERIFICATION

A1.1. *Calibration*—Newly acquired gauges shall be calibrated initially. Existing gauges shall be calibrated after repairs that may affect the gauge geometry. Existing gauges shall be calibrated to re-establish calibration curves, tables, or equivalent coefficients if the gauge does not meet the specified tolerances in the verification process. If the owner does not establish a verification procedure, the gauge shall be calibrated at a minimum frequency of 24 months.

A1.2. *Verification*—Existing gauges shall be verified at a minimum frequency of 12 months. The verification process and resultant tolerances obtained over the depths that the gauge shall be formally recorded and documented. If the verification process indicates a variance beyond the specified tolerances, the gauge shall be calibrated.

A1.3. The calibration response of the gauge shall be within ±16 kg/m^3 (±1.0 lb/ft^3) on the blocks on which the gauge was calibrated. This calibration may be done by the manufacturer, the user, or an independent vendor. Nuclear gauge response is influenced by the chemical composition of measured materials. This response must be taken into account in establishing the assigned standard block density. The blocks used for calibration shall be capable of generating a general and reliable curve covering the entire density range of materials tested in the field. The density of these standard blocks shall be determined to an accuracy of ±0.2 percent.

A1.4. Sufficient data shall be taken on each density standard block to ensure a gauge count precision (see Annex A3) of at least one half the gauge count precision required for field use assuming field use measurement of 1-minute duration and 4-minute duration used for calibration, or an equivalent relationship. The data may be presented in the form of a graph, table, equation coefficients, or stored in the gauge, to allow converting the count rate data to density.

A1.5. The method and test procedures used in establishing the calibration count rate data shall be the same as those used for obtaining the field count rate data.

A1.6. The material type, actual density, or assigned standard block density of each calibration standard used to establish or verify the gauge calibration shall be stated as part of the calibration data for each measurement depth.

A1.7. The standards should be sufficient in size to not change the count rate if enlarged in any dimension.

Note A1—Minimum surface dimensions of approximately 610 mm by 430 mm (24 by 17 in.), have proven satisfactory. For the Backscatter Method, a minimum depth of 230 mm (9 in.) is adequate, while for the Direct Transmission Method the depth should be at least 50 mm (2 in.) deeper than the deepest rod penetration depth. A larger surface area should be considered for the backscatter air-gap method. For blocks with width and length smaller than the sizes specified, follow block manufacturers' recommendations for proper installation and use.

A1.8. The most successful standards that have been established for calibration have been made of magnesium, aluminum, aluminum/magnesium, granite, and limestone. These standards have been used in combination with each other, with historical curve information, and with other prepared block(s) to produce accurate and reliable calibration.

A1.8.1. Standards of soil, rock, and concrete that have stable characteristics for reproducibility and uniformity are difficult to prepare. These standards may be of use for specialty verification or field calibration where local site material chemistry or background situation require special adaptation.

A1.9. *Verify an existing calibration* by taking a sufficient number of counts at each measurement depth on one or more blocks of established density to ensure the accuracy of the existing calibration within ±32 kg/m^3 (±2.0 lb/ft^3) at each measurement depth.

A1.9.1. Sufficient data shall be taken to ensure a gauge count precision of at least one half the gauge count precision required for field use assuming field use measurement of 1-minute duration and 4-minute duration used for calibration, or an equivalent relationship.

A1.9.2. Calibration blocks, which are used for calibration of the gauge, or prepared block(s), which are capable of generating a general and reliable curve covering the range of densities of the materials to be tested in the field, can be used to verify the gauge calibration.

A1.9.2.1. Blocks prepared of soil, rock, concrete, asphalt, and engineered blocks that have characteristics of reproducible uniformity may be used, but care must be taken to minimize changes in density and water content over time.

A1.9.2.2. Density values of prepared blocks shall be determined to an accuracy of ±0.5 percent at each measurement depth.

A1.9.3. The assigned block density for each calibration depth used to verify the gauge calibration shall be stated as part of the verification data.

A2. WATER CONTENT CALIBRATION AND VERIFICATION

A2.1. *Calibration*—Newly acquired gauges shall be calibrated initially. Existing gauges shall be calibrated after repairs that may affect the gauge geometry. Existing gauges shall be calibrated to re-establish calibration curves, tables, or equivalent coefficients if the gauge does not meet the specified tolerances in the verification process. If the owner does not establish a verification procedure, the gauge shall be calibrated at a minimum frequency of 24 months.

A2.2. *Verification*—Existing gauges shall be verified at a minimum frequency of 12 months. The verification process and resultant tolerances obtained over the depths the gauge shall be formally recorded and documented. If the verification process indicates a variance beyond the specified tolerances, the gauge shall be calibrated.

A2.3. The calibration response of the gauge shall be within ±16 kg/m^3 (±1.0 lb/ft^3) on the blocks on which the gauge was calibrated. This calibration may be done by the manufacturer, the user, or an independent vendor. The blocks used for calibration should be capable of generating a general curve covering the entire water content range of the materials to be tested in the field. The calibration curve can be established using counts and water contents of standard blocks, previous factory curve information, or historical data. Due to the effect of chemical composition, the calibration supplied by the manufacturer with the gauge will not be applicable to all materials. It shall be accurate for silica and water; therefore, the calibration must be verified and adjusted, if necessary, in accordance to Section A2.5.

A2.4. Calibration standards may be established using any of the following methods. Prepared containers or standards must be large enough to not change the observed count rate if made larger in any dimension.

Note A2—Dimensions of approximately 610-mm long by 460-mm wide by 360-mm deep (approximately 24 in. by 18 in. by 14 in.) have proven satisfactory. For blocks with width and length smaller than the sizes specified, follow block manufacturers' recommendations for proper installation and use.

A2.4.1. Prepare a homogeneous standard of hydrogenous materials having an equivalent water content determined by comparison (using a nuclear gauge) with a saturated silica sand standard prepared in accordance with Section A.2.4. Metallic blocks used for wet density calibration, such as magnesium or aluminum, are convenient zero water content standard.

A2.4.2. Prepare containers of compacted material with a percent water content determined by oven dry (ASTM D 2216) and a wet density calculated from the mass of the material and the inside dimensions of the container. The water content may be calculated as follows:

$$M_m = \frac{\rho \times w}{100 + w} \qquad (A2.1)$$

where:

M_m = water content, kg/m^3 or lbm/ft^3;

ρ = wet (total) density, kg/m^3 or lbm/ft^3; and

w = water content, percent of dry mass.

A2.4.3. Where neither of the previous calibration standards are available, the gauge may be calibrated by using a minimum of four selected test sites in an area of a compaction project where material has been placed at several different water contents. The test sites shall represent the range of water contents over which the calibration is to be used. At least four replicate nuclear measurements shall be made at each test site. The density at each site shall be measured by making four closely spaced determinations with calibrated equipment in accordance with AASHTO T 191 or ASTM D 2937. The water content of each of the density tests shall be determined by ASTM Test Method D 2216. Use the mean value of the replicate readings as the calibration point value for each site.

A2.5. *Calibration Adjustments*:

A2.5.1. The calibration of newly acquired or repaired gauges shall be verified and adjusted prior to use. Calibration curves shall be checked prior to performing tests on materials that are distinctly different from material types previously used in obtaining or adjusting the calibration. Sample materials may be selected by either Section A2.5.1.1 or Section A2.5.1.2. The amount of water shall be within ±2 percent of the water content established as optimum for compaction. Determine the water content in kg/m^3 or lb/ft^3 by Equation A2.1. A microwave oven or direct heater may be utilized for drying materials which are not sensitive to temperature, in addition to the methods listed in Section A2.4.3. A minimum of four comparisons is required and the mean of the observed differences used as the correction factor.

A2.5.1.1. Container(s) of compacted material taken from the test site may be prepared in accordance with Section A2.4.2.

A2.5.1.2. Test site(s) or the compacted material may be selected in accordance with Section A2.4.3.

A2.5.2. The method and test procedures used in obtaining the count rate to establish the error must be the same as those used for measuring the water content of the material to be tested.

A2.5.3. The mean value of the difference between the moisture content of the test samples as determined in Section A2.5.1.1 or Section A2.5.1.2 and the values measured with the gauge shall be used as a correction to measurements made in the field. Some gauges utilizing a microprocessor may have provision to input a correction factor that is established by the relative values of water content as a percentage of dry density, thus eliminating the need to determine the difference in mass units of water.

A2.6. *Verify an existing calibration* by taking sufficient number of counts on one or more blocks of established water content to ensure the accuracy of the existing calibration within ±16 kg/m^3 (±1 lb/ft^3). The water content block(s) should be prepared in accordance with Sections A2.4.1 and A2.4.2.

A2.6.1. Sufficient data shall be taken to ensure a gauge count precision (see Annex A3) of at least one half the gauge count precision required for field use assuming field use measurement of 1-minute duration and 4-minute duration used for calibration, or an equivalent relationship.

A2.6.2. Calibration blocks used to establish calibration parameters and prepared block(s) that are capable of generating a general and reliable curve covering the range of densities of the materials that are to be tested in the field can be used to verify calibration.

A2.6.3. Prepared block(s) that have characteristics of reproducible uniformity may be used, but care must be taken to minimize changes in density and water content over time.

A2.6.4. The assigned water content of the block(s) used for verification of the gauge shall be stated as part of the verification data.

A3. GAUGE COUNT PRECISION

A3.1. Gauge count precision is defined as the change in density or water content that occurs corresponding to a one standard deviation change in the count due to the random decay of the radioactive source. The density of the material and time period of the count must be stated. It may be determined using calibration data (Equation A3.1) or Sections A3.2 and A3.3.

A3.2. Determine the gauge count precision of the system, P, from the slope of the calibration curve, S, and the standard deviation, σ, of the signals (detected gamma rays or detected neutrons) in counts per minute (cpm), as follows:

$$P = \sigma / S \qquad (A3.1)$$

where:

P = precision;

σ = standard deviation, cpm; and

S = slope, $cpm/kg/m^3$ ($cpm/lb/ft^3$).

Note A3—Displayed gauge counts may be scaled. Contact the manufacturer to obtain the appropriate pre-scale factor.

A3.3. *Density*—Determine the slope of the calibration curve at the 2000-kg/m^3 (125-lb/ft^3) point in counts per minute per kilogram per cubic meter (counts per minute per pound per cubic foot). Determine the standard deviation of a minimum of 20 per pound repetitive readings of 1 minute each (gauge is not moved after seating for the first count) taken on material having a density of 2000 ± 80 kg/m^3 (125.0 ± 5.0 lb/ft^3). The value of P is typically less than 10 kg/m^3 (0.6 lb/ft^3) in the backscatter method and 5 kg/m^3 (0.3 lb/ft^3) in the direct transmission method at 6-in. depth.

A3.4. *Moisture*—Where the slope of the calibration curve is determined at the 160-kg/m^3 (10-lb/ft^3) point and the standard deviation is determined from a minimum of 20 repetitive readings of 1 minute each (the gauge is not moved after the first count) taken on material having a moisture content of 160 ± 10 kg/m^3 (10.0 ± 0.6 lb/ft^3) the value of P is typically less than 4.8 kg/m^3 (0.30 lb/ft^3).

Standard Method of Test for

Grain-Size Analysis of Granular Soil Materials

AASHTO Designation: T 311-00 (2010)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Grain-Size Analysis of Granular Soil Materials

AASHTO Designation: T 311-00 (2010)

1. SCOPE

1.1. This method covers the determination of the particle size distribution of granular soil material. This method utilizes the 6.3-mm sieve size for separation purposes. However, the sample tester may use an alternative sieve size (i.e., 4.75 mm, 2.00 mm, etc.). In this case, the alternative sieve size used must replace the 6.3-mm size throughout this procedure.

1.2. Specifications for granular soil material, which reference this method, usually contain grading requirements that include both coarse and fine fractions in sizes between 100 mm and 0.075 mm.

1.3. *The standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes (Excluding Column 7 in Table No. 1)
- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates

2.2. *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. SUMMARY OF METHOD

3.1. A weighed sample of dry granular soil material is separated through a series of sieves with progressively smaller openings. Particle size distribution is determined by weighing the material retained on each of the sieves and dividing these weights by the total dry weight of the sample. This method requires drying, washing, and a series of separations.

4. SIGNIFICANCE AND USE

4.1. This method is used primarily to determine the gradation of granular soil material for use as fill material in subbase, pipe, or structural backfill. Granular soil material used in these applications generally necessitates a well-graded material. This results in samples that contain material that is retained on a wide range of sieve sizes. The results are used to determine the compliance of grain size distribution of granular soil material with applicable specification requirements, and to provide the necessary data in order to determine the acceptability of this select granular material for the stated uses. This procedure is intended for use in quality assurance testing where large numbers of samples are processed.

5. APPARATUS

5.1. *Platform Scale*—The platform scale shall conform to the requirements of M 231 for the class of general purpose scale required for the principal sample weight being tested.

5.2. *Balance*—The balance shall conform to the requirements of M 231 for the class of general purpose balance required for the sample weight of fine granular material being tested.

5.3. *Sieves*—The sieves shall be mounted on substantial frames constructed in a manner that will prevent loss of material during sieving. Suitable sieve sizes shall be selected to furnish the information required by the specifications covering the material to be tested. The sieves shall conform to M 92 (Note 1).

Note 1—It is recommended that sieves mounted in frames larger than standard 203-mm diameter frames be used for testing coarse aggregate. Also, it may be desirable to use a heavy duty screen meeting the required opening tolerances but with a larger wire diameter.

5.4. *Mechanical Sieve Shaker*—A mechanical sieve shaker, if used, shall impact a vertical or lateral and vertical motion to the sieve, causing the particles thereon to bounce and turn so as to present different orientations to the sieving surface. The sieving action shall be such that the criterion for adequacy of sieving described in Section 7.4 is met in a reasonable time period.

Note 2—Use of a mechanical sieve shaker is recommended when the size of the sample is 20 kg or greater, and may be used for smaller samples, including fine granular material. Excessive time (more than approximately 5 minutes) to achieve adequate sieving may result in degradation of the sample. The same mechanical sieve shaker may not be practical for all sizes of samples, since the large sieving area needed for practical sieving of a large nominal size coarse granular material very likely could result in loss of a portion of the sample if used for a smaller sample of coarse granular or fine granular material.

5.5. *Oven*—An oven of appropriate size capable of maintaining a uniform temperature of 110 ± 5ºC.

5.6. *Miscellaneous*—Spoons, spatulas, brushes, and containers (non-corroding and not subject to weight change).

6. SAMPLING AND PREPARATION

6.1. Sample the aggregate in accordance with T 2.

6.2. *Sample Size*:

6.2.1. For granular construction items, the sample(s) shall be transported to the testing facility in a clean, approved container. Assure that the sample size meets a minimum mass requirement of 20 kg.

6.2.2. For materials other than granular construction items, i.e., design testing, the sample(s) shall be transported to the testing facility in a clean, approved container and be large enough to be representative of the material being tested. In general, the larger the nominal maximum particle size is, the larger the sample should be in order to be considered representative. The following may be considered a guide (not a requirement) for sample masses on particle size:

Nominal Maximum Particle Size	Sample Mass
50 mm	20 kg
19 mm	7 kg
6.3 mm	1 kg

7. PROCEDURE

Note 3—Due to ease of operation, the following Procedure, Calculation, and Sieve Analysis Data Sheet utilizes a 6.3-mm sieve for separation. Depending on the sample type and size, or the tester's preference, or both, alternative sieve sizes can be used for separation (i.e., 4.75 mm, 2.00 mm). When an alternative sieve size is used, then that size must replace the 6.3-mm size as outlined in this method. In addition, a new Sieve Analysis Data Sheet must be developed for the alternative sieve size utilized.

7.1. Screen the sample on a 6.3-mm sieve in order to divide it into plus 6.3-mm and minus 6.3-mm portions. If an excessive amount of silt or clay adheres to the plus 6.3-mm material, it should be screened again after additional drying. If the sample does not have any plus 6.3-mm particles, proceed in accordance with Section 7.4.

Note 4—During this initial and subsequent sieving, care should be exercised to prevent "overloading" the 6.3 mm and any other sieve. This condition exists when an excessive amount of soil is placed on the sieve, leaving an insufficient amount of sieve openings for the material to pass through. To avoid "overloading," the sample must be divided into smaller portions and sieved separately.

Note 5—In some soils a significant amount of the particles will adhere together and form silt or clay balls, or both, that may be mistaken for plus 6.3-mm particles. Care must be taken to ensure that such balls pass through the 6.3-mm screen. It may be necessary to run a wood mallet over the material on the screen for this purpose; but be careful not to pulverize the actual particles or damage the sieve.

7.2. Once the plus 6.3-mm portion has fully dried (to the point where there is no visible sign of moisture), weigh the sample to the nearest 5 g and record this value (line A).

Note 6—Prior to weighing the plus 6.3-mm portion, check for particles larger than 100 mm. Remove such material and weigh it to the nearest 5 g and make a note of it on the data sheet. These particles should not be included in the test. (See Figures 1 and 2.)

REMARKS

TESTED BY: DATE: CHECKED BY: DATE:

Figure 2—Sample Completed Sieve Analysis Data Sheet

7.3. Sieve the material retained on the 6.3-mm sieve during initial separation of coarse and fine material. The series of sieves used shall comply with the particle size requirements of the material being tested. The sieves shall be arranged such that the largest opening sieve is on top, with the sizes progressively decreasing. The last sieve shall be the 6.3 mm, followed by a "pan." During the sieving process, some additional material will pass through the 6.3-mm sieve into the "pan." Weigh this "pan" material to the nearest 5 g and record on line B of the data sheet. Incorporate this material to the minus 6.3-mm material obtained in Section 7.1. Weigh the material retained on each sieve to the nearest 5 g and record these values in Column 1 of the data sheet. Sum the values in Column 1 and record this value at the bottom of the column. Compute the total mass of plus 6.3-mm material by subtracting line B from line A, and record this value on line C.

Note 7—If the sieving is performed using a mechanical shaker, the sieves shall be shaken no less than 3 minutes and no more than 5 minutes. If performed manually, the sieve shall be shaken no less than 5 minutes. Very often particles will get stuck in the openings of a sieve. Such material shall be removed from the openings and weighed as being retained on that sieve. Do not force particles through the sieves.

7.4. Weigh the portion of the minus 6.3-mm sample to the nearest 5 g and record this value on the data sheet (line D). Immediately mix the portion of minus 6.3-mm sample thoroughly. By quartering or using a sample splitter, obtain a minimum 500 g sample of this material, and place it into a container of known weight for a moisture content determination. The weight of the container and the weight of the soil and container should be recorded respectively to the nearest 0.1 g (lines J and H). Dry the sample to a constant mass as noted below. After drying, allow the sample to cool and re-weigh it to the nearest 0.1 g and record (line I).

Note 8—If the sample being tested is a recycled material, or if it contains any bituminous material (asphalt, etc.), it shall be dried to a *constant weight* by air drying or in an oven not exceeding 60ºC.

Note 9—If a hot plate or stove is used, place the container holding the sample on a pan containing a thin layer of sand to prevent spattering and/or fracturing of the soil particles during the drying process.

Note 10—If an oven is used, maintain the temperature of the sample at 110º ± 5ºC for a minimum of 12 hours or until it maintains a constant weight.

Note 11—When a sample contains less than 500 g of minus 6.3-mm particles, moisture content and gradation may be performed on the smaller amount only if the sample is considered to be representative.

7.5. Obtain a 300 ± 5 g portion of the moisture content sample (from Section 7.4) and record this mass to the nearest 0.1 g (line N). Wash this sample on a 0.075-mm sieve to remove all material finer than the 0.075-mm sieve from the sample. It is suggested to wash the sieve sample over a white basin to make it easier to see when the wash water is clean. After the sample is thoroughly washed, carefully transfer the sample from the sieve to a container for drying. Dry the sample in accordance with the provisions of Section 7.4. Weigh the dried sample to the nearest 0.1 g and record this value (line O).

Note 12—Examine the 0.075-mm sieve prior to each washing to determine its condition. Replace the sieve if any holes or cracks are noticed in the solder or mesh, or if the sieve's mesh is stretched excessively. A new 0.075-mm sieve should be washed with soap and water prior to initial use.

Note 13—The 0.075-mm sieves are delicate. Fingertips may be used to agitate the sample during washing, but do not apply pressure to the mesh itself.

Note 14—Do not allow water to overflow or splash out of the sieve. This may cause a loss of material and lead to inaccurate results. Tapping the side of the sieve will help break the surface tension as well as eliminate clogging.

7.6. Sieve the dry washed sample remaining from Section 7.5. The series of sieves used shall comply with the particle size requirements of the material being tested. The sieves shall be arranged such that the largest mesh sieve is on top, with the mesh sizes progressively decreasing. The last sieve should be the 0.075 mm, followed by a "pan." Weigh the material retained on each sieve and the "pan," and record the weights to the nearest 0.1 g in Column 5. Sum the values (Column 5) of the masses retained on each sieve and pan, and record this value at the bottom of that column.

8. CALCULATION

8.1. Calculate the mass of minus 6.3-mm material for moisture content.

8.1.1. Determine the moisture content.

Compute the mass of water by subtracting line *I* from line *H* and record this value on line *K*. Compute the mass of dry material by subtracting line *J* from line *I* and record this value on line *L*. Compute moisture content by dividing mass of water (line K) by the mass of dry material (line L) and multiplying this value by 100 and record to the nearest 0.1 percent on line *M*.

$$\text{\% Moisture Content:} \quad M = \frac{H - I}{I - J} \times 100 \qquad (1)$$

8.1.2. Compute the dry mass of the minus 6.3-mm material.

Divide the total mass of minus 6.3-mm material (line D) by the quantity 1 plus the moisture content (line M) divided by 100 and record this value on line *E*.

$$\text{Mass of Dry minus 6.3 mm:} \quad E = \frac{D}{1 + \left(\frac{M}{100}\right)} \qquad (2)$$

8.2. Compute the total dry mass of the sample.

Compute the total dry mass by adding the dry mass of the plus 6.3-mm material (line C) to the dry mass of the minus 6.3-mm material (line E) and record this value on line *F*.

Total Dry Mass, $F = C + E$ *(3)*

8.3. Compute the particle size distribution of plus 6.3-mm material.

8.3.1. Compute the percent retained.

Divide the mass retained on each sieve (in Column 1) by the total dry mass of the sample (line F). Multiply each value by 100 and record the results to the nearest 0.1 percent in Column 2 opposite the respective sieve. Sum the values in Column 2 and record this value at the bottom of Column 2.

8.3.2. Compute the percent of total sample passing.

The smallest sieve in which all of the sample passes will have 100 percent total sample passing. For the rest of the sieve sizes, compute the percent total sample passing by subtracting the percent retained (in Column 2) from the percent of total sample passing computed for the previous sieve size. This makes it necessary to work from the top down. Record each of the values computed to the nearest 0.1 percent in Column 3 of the data sheet. For checking specification criteria, round the values in Column 3 to the nearest 1 percent and record these values in Column 4.

8.4. Compute the particle size distribution of minus 6.3-mm material.

8.4.1. Compute the percent retained.

Divide the mass retained on each sieve (in Column 5) by the mass of the minus 6.3-mm sample prior to washing (line N). Multiply each value by 100 and record the results to the nearest 0.1 percent in Column 6. Sum the values in Column 6 and record this value at the bottom of the column.

8.4.2. Compute the percent passing based on minus 6.3-mm material.

Subtract the percent retained, on the largest sieve used on the minus 6.3-mm material, from 100 percent to determine the percent for that sieve. For the rest of the sieves, compute the percent sample passing by subtracting the percent retained from the percent sample passing computed for the previous sieve size. Record these values as percents to the nearest 0.1 percent in Column 7.

8.4.3. Compute the percent passing based on total mass.

Multiply the percents passing, computed in Section 8.4.2. (Column 7), by the percent of the total sample passing the 6.3-mm sieve, (last value in Column 3), for each sieve size. Divide each value by 100 to get percent and record to the nearest 0.1 percent in Column 8. For checking specification criteria, round the values in Column 8 to the nearest 1 percent and record these values in Column 9.

9. CHECKS AND BALANCES

9.1. Check the computed percent retained.

9.1.1. For the plus 6.3-mm material:

The total mass retained (Total of Column 1) divided by the total dry mass of the sample (line F) and multiplied by 100, should be no more than ±0.2 percent from the sum of the percents retained (Total of Column 2).

9.1.2. For the minus 6.3-mm material:

The total mass retained (Total of Column 5) minus the "pan" material, divided by the mass of dry minus 6.3-mm material before wash (line N) and multiplied by 100, should be no more than ±0.2 percent from the sum of the percents retained (Total of Column 6).

9.2. Check the computed percent passing.

9.2.1. For the plus 6.3-mm material:

The sum of the percent retained (Total of Column 2) plus the percent of total sample passing the 6.3-mm sieve (last value of Column 3) must equal 100 percent.

9.2.2. For the minus 6.3-mm material:

The sum of the percent retained (Total of Column 6) plus the percent passing the 0.075-mm sieve, based on minus 6.3 mm, (last value of Column 7) must equal 100 percent.

As an aid to the user of this volume, the following tabulation shows equivalencies between AASHTO and ASTM specifications. Where an asterisk (*) follows the ASTM number, there is a difference between the two specifications. These differences are explained in the endnote accompanying each individual specification.

AMERICAN ASSOCIATION OF STATE HIGHWAY AND TRANSPORTATION OFFICIALS

EXECUTIVE COMMITTEE
2009–2010

President: Larry L. "Butch" Brown, Sr., Mississippi
Vice President: Susan Martinovich, P.E., Nevada
Secretary/Treasurer: Carlos Braceras, Utah

Regional Representatives:

Region I	Joseph Marie, Connecticut, One-Year Term Gabe Klein, District of Columbia, Two-Year Term
Region II	Dan Flowers, Arkansas, One-Year Term Mike Hancock, Kentucky, Two-Year Term
Region III	Nancy J. Richardson, Iowa, One-Year Term Thomas K. Sorel, Minnesota, Two-Year Term
Region IV	Paula Hammond, Washington, One-Year Term Amadeo Saenz, Jr., Texas, Two-Year Term

Immediate Past President: Allen Biehler, P.E., Pennsylvania
Executive Director: John C. Horsley, Washington, DC

AMERICAN ASSOCIATION OF STATE HIGHWAY AND TRANSPORTATION OFFICIALS

HIGHWAY SUBCOMMITTEE ON MATERIALS

2009–2010

Grant Levi, NORTH DAKOTA, Chairman
Mark Felag, RHODE ISLAND, Vice Chairman
Jack Springer, FHWA, Secretary

ALABAMA
Larry Lockett, Materials and Tests Engineer, Alabama Department of Transportation
3700 Fairground Road
Montgomery, AL 36110

Lynn Wolfe, Testing Engineer

ALASKA
Michael San Angelo, State Materials Chief Materials Engineer, Alaska Department of Transportation and Public Facilities
5800 E. Tudor Road
Anchorage, AK 99507-1286

R. Scott Gartin, State Quality Assurance Engineer

ARIZONA
James Delton, Assistant State Engineer, Materials Group, Arizona Department of Transportation
1221 North 21st Avenue
Phoenix, AZ 85007

Paul Burch, Quality Assurance Engineer

Julie Kliewer, District Engineer, Phoenix Construction

ARKANSAS
Michael Benson, Engineer of Materials Division, Arkansas State Highway and Transportation Department
P.O. Box 2261
Little Rock, AR 72203

Emanuel Banks, Assistant Chief Engineer, Operations

Ralph J. Hall, Assistant to the Director

CALIFORNIA
Phil Stolarski, Division of Materials Engineering and Testing Services, California Department of Transportation
5900 Folsom Boulevard
Sacramento, CA 95819-4612

COLORADO
Jim Zufall, Materials and Geotechnical Branch Manager, Colorado Department of Transportation
4670 Holly Street, Unit A
Denver, CO 80216-6408

CONNECTICUT
Ravi V. Chandran, Director of Research and Materials, Connecticut Department of Transportation
280 West Street
Rocky Hill, CT 06067-3502

Wayne Blair, Assistant Director of Materials Testing

DELAWARE
James T. Pappas, III, Chief Materials and Research Engineer, Delaware Department of Transportation
P.O. Box 778
Dover, DE 19903-0778

Maureen Kelley, Geotechnical Engineer

DISTRICT OF COLUMBIA
Wasi U. Khan, Chief, QA/QC Materials Division, District of Columbia Department of Transportation
2000 14th Street, N.W., Room N-401
Washington, DC 20009

FLORIDA
Thomas O. Malerk, Director, Office of Materials, Florida Department of Transportation
5007 N.E. 39th Avenue
Gainesville, FL 32609-2604

GEORGIA
Georgene M. Geary, State Materials and Research Administrator, Georgia Department of Transportation
15 Kennedy Drive
Forest Park, GA 30297

Richard Douds, Office of Materials and Research

Donald Wishon, Project Review Engineer

HAWAII
JoAnne Nakamura, Bituminous Engineer, Materials Testing and Research Branch, Hawaii Department of Transportation
2530 Likelike Highway
Honolulu, HI 96819

Gerry Carnate, Structural Materials Engineer

IDAHO
Jeff Miles, Materials Engineer, Idaho Transportation Department
P.O. Box 7129
Boise, ID 83707-1129

ILLINOIS
David L. Lippert, Chief of Materials and Physical Research, Illinois Department of Transportation
126 E. Ash Street
Springfield, IL 62704-4766

Matt Mueller, Engineer of Tests

INDIANA
Ronald P. Walker, Chief, Division of Materials and Tests, Indiana Department of Transportation
120 S. Shortridge Road
Indianapolis, IN 46219

IOWA
James Berger, Director, Office of Materials, Iowa Department of Transportation
800 Lincoln Way
Ames, IA 50010

KANSAS
Richard E. Kreider Jr., Chief, Bureau of Materials and Research, Kansas Department of Transportation
Dwight D. Eisenhower State Office Building, 700 S.W. Harrison Street
Topeka, KS 66603-3754

KENTUCKY
William Broyles, Director, Division of Materials, Kentucky Transportation Cabinet
1227 Wilkinson Boulevard
Frankfort, KY 40601-1226

Allen H. Myers, Asphalt Branch Manager

LOUISIANA
Luanna Cambas, Materials Engineer Administrator, Louisiana Department of Transportation and Development
5080 Florida Boulevard
Baton Rouge, LA 70806

MAINE
Bruce A. Yeaton, Testing Engineer, Maine Department of Transportation
16 State House Station
Augusta, ME 04333-0016

MARYLAND
Timothy E. Smith, Director, Office of Materials and Technology, Maryland State Highway Administration
7450 Traffic Drive, Building #4
Hanover, MD 21076

Woodrow L. Hood, Materials Management Division Chief

Mark Wolcott, Deputy Director, Office of Materials Technology

MASSACHUSETTS
John E. Grieco, Director of Research and Materials, Massachusetts Department of Transportation,
400 D Street
South Boston, MA 02110

MICHIGAN
John F. Staton, Materials Engineer, Construction and Technology Division, Michigan Department of Transportation
8885 Ricks Road,
P.O. Box 30049
Lansing, MI 48909

MINNESOTA
Keith L. Shannon, Director, Office of Materials and Road Research, Minnesota Department of Transportation
1400 Gervais Avenue, Mailstop 645
Maplewood, MN 55109

Curt Turgeon, Pavement Engineer

MISSISSIPPI
James A. Williams, State Materials Engineer, Mississippi Department of Transportation
P. O. Box 1850
Jackson, MS 39215-1850

Mike O'Brien, Assistant State Materials Engineer

MISSOURI
William Stalcup, Physical Laboratory Director, Missouri Department of Transportation
P.O. Box 270
Jefferson City, MO 65102

David D. Ahlvers, State Construction and Materials Engineer

David B. Nichols, Director of Program Delivery

MONTANA
Matt Strizich, Materials Engineer, Montana Department of Transportation
P.O. Box 201001
Helena, MT 59620-1001

NEBRASKA
Mostafa Jamshidi, Materials and Research Engineer, Nebraska Department of Roads
P.O. Box 94759
Lincoln, NE 68509

NEVADA
Reid Kaiser, Chief Materials Engineer, Nevada Department of Transportation
1263 S. Stewart Street
Carson City, NV 89712

NEW HAMPSHIRE
Alan D. Rawson, Administrator, Bureau of Materials and Research, New Hampshire Department of Transportation
P.O. Box 483-5, Hazen Drive
Concord, NH 03302-0483

Scott Leslie, Data Collection Supervisor

NEW JERSEY
Eileen Sheehy, Manager, Bureau of Materials, New Jersey Department of Transportation
P.O. Box 607
Trenton, NJ 08625-0607

NEW MEXICO
Bryce Simons, Materials Testing, Engineer, New Mexico Department of Transportation
P.O. Box 1149
Santa Fe, NM 87504-1149

NEW YORK
Robert L. Sack, Director, Office of Technical Services, New York State Department of Transportation
50 Wolf Road
Albany, NY 12232

Donald A. Streeter, Concrete Section Program Manager

Robert A. Burnett, Director, Geotechnical Engineering Bureau

NORTH CAROLINA
Christopher A. Peoples, State Materials and Test Engineer, North Carolina Department of Transportation
1563 Mail Service Center
Raleigh, NC 27699

Jack E. Cowsert, State Materials Quality Engineer

NORTH DAKOTA
Ron Horner, Materials and Research Engineer, North Dakota Department of Transportation
300 Airport Road
Bismarck, ND 58504

OHIO
Lloyd M. Welker, Jr., Administrator, Office of Materials Management, Ohio Department of Transportation
1600 W. Broad Street
Columbus, OH 43223

OKLAHOMA
Reynolds H. Toney, Materials Engineer, Oklahoma Department of Transportation
200 N.E. 21st Street
Oklahoma City, OK 73105-3299

Scott Seiter, Assistant Materials Engineer

OREGON
Cole F. Mullis, Construction Quality Control Engineer, Oregon Department of Transportation
800 Airport Road, S.E.
Salem, OR 97301

PENNSYLVANIA
Timothy Ramirez, Engineer of Tests, Pennsylvania Department of Transportation
1118 State Street,
P.O. Box 2926
Harrisburg, PA 17105-2926

Revisions for 30th Edition of Standard Specifications for Transportation Materials and Methods of Sampling and Testing—Part 2

The balloted technical and editorial changes listed below are also indicated in the specifications by a change bar in the left margin. Non-balloted editorial changes do not receive a change bar.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
T 11-05 (2009)	Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing	1c	Reconfirmed in 2009.
T 21-05 (2009)	Organic Impurities in Fine Aggregates for Concrete	1c	Reconfirmed in 2009.
T 22-10	Compressive Strength of Cylindrical Concrete Specimens	3c	Revised extensively.
T 30-10	Mechanical Analysis of Extracted Aggregate	2c	Revised the requirements for mechanical washing.
T 32-10	Sampling and Testing Brick	4a	Updated to reference ASTM C 67-09.
T 42-10	Preformed Expansion Joint Filler for Concrete Construction	4e	Revised to maintain equivalency with ASTM D 545-08.
T 67-08	Standard Practices for Force Verification of Testing Machines	4f	Deleted in 2009.
T 68-05	Tension Testing of Metallic Materials	4f	Deleted in 2009.
T 68M/T 68-09	Tension Testing of Metallic Materials	4f	Discontinued in 2009.
T 70-08	Brinell Hardness of Metallic Materials	4f	Deleted in 2009.
T 72-10	Saybolt Viscosity	2a	Revised extensively.
T 78-10	Distillation of Cutback Asphaltic (Bituminous) Products	2a	Revised extensively.
T 80-08	Rockwell Hardness and Rockwell Superficial Hardness of Metallic Materials	4f	Deleted in 2009.
T 84-10	Specific Gravity and Absorption of Fine Aggregate	1c	Revised Section 13.1.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
T 85-10	Specific Gravity and Absorption of Coarse Aggregate	1c	Revised Section 10.1.
T 88-10	Particle Size Analysis of Soils	1a	Revised reference to dispersing agent in Section 8.3.
T 89-10	Determining the Liquid Limit of Soils	1a	Revised to specify at what stage the samples should be taken.
T 92-97 (2009)	Determining the Shrinkage Factors of Soils	1a	Reconfirmed in 2009.
T 97-10	Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)	3c	Revised to maintain equivalency with ASTM C 78-08.
T 99-10	Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop	1b	Revised to include information on what to do with discarded coarse material.
T 111-10	Mineral Matter or Ash in Asphalt Materials	2b	Revised to clarify procedure discussed in Section 6.3.
T 119M/T 119-10	Slump of Hydraulic Cement Concrete	3b	Revised to maintain equivalency with ASTM C 143/C 143M-08.
T 131-10	Time of Setting of Hydraulic Cement by Vicat Needle	3a	Revised to maintain equivalency with ASTM C 191-08.
T 132-87 (2009)	Tensile Strength of Hydraulic Cement Mortars	3a	Reconfirmed in 2009.
T 134-05 (2009)	Moisture-Density Relations of Soil-Cement Mixtures	1b	Reconfirmed in 2009.
T 135-97 (2009)	Wetting-and-Drying Test of Compacted Soil-Cement Mixtures	1b	Reconfirmed in 2009.
T 136-97 (2009)	Freezing-and-Thawing Tests of Compacted Soil-Cement Mixtures	1b	Reconfirmed in 2009.
T 140-97 (2009)	Compressive Strength of Concrete Using Portions of Beams Broken in Flexure	3c	Reconfirmed in 2009.
T 141-05 (2009)	Sampling Freshly Mixed Concrete	3b	Reconfirmed in 2009.
T 152-10	Air Content of Freshly Mixed Concrete by the Pressure Method	3b	Revised to maintain equivalency with ASTM C 231-08c.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
T 154-10	Time of Setting of Hydraulic Cement Paste by Gillmore Needles	3a	Revised to maintain equivalency with ASTM C 266-08.
T 164-10	Quantitative Extraction of Asphalt Binder from Hot Mix Asphalt (HMA)	2c	Revised the requirements for drying the test specimen and added definition of term.
T 165-02 (2006)	Effect of Water on Compressive Strength of Compacted Bituminous Mixtures	2d	Discontinued in 2009.
T 166-10	Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens	2c	Revised the precision and bias statement.
T 167-10	Compressive Strength of Hot Mix Asphalt	2d	Revised.
T 170-00 (2009)	Recovery of Asphalt Binder from Solution by Abson Method	2c	Reconfirmed in 2009.
T 177-10	Flexural Strength of Concrete (Using Simple Beam with Center-Point Loading)	3c	Revised to maintain equivalency with ASTM C 293-08.
T 178-10	Portland-Cement Content of Hardened Hydraulic-Cement Concrete	3c	Revised.
T 179-05 (2009)	Effect of Heat and Air on Asphalt Materials (Thin-Film Oven Test)	2b	Reconfirmed in 2009.
T 180-10	Moisture-Density Relations of Soils Using a 4.54-kg (10-lb) Rammer and a 457-mm (18-in.) Drop	1b	Revised to harmonize with T 99.
T 188-05 (2009)	Evaluation by Freezing and Thawing of Air-Entraining Additions to Hydraulic Cement	3b	Reconfirmed in 2009.
T 193-10	The California Bearing Ratio	1a	Revised to clarify procedure discussed in Section 8.5.
T 199-00 (2009)	Air Content of Freshly Mixed Concrete by the Chace Indicator	3b	Reconfirmed in 2009.
T 201-10	Kinematic Viscosity of Asphalts (Bitumens)	2b	Revised so that the temperature tolerances for the bath are less restrictive.
T 202-10	Viscosity of Asphalts by Vacuum Capillary Viscometer	2b	Revised so that the temperature tolerances for the bath are less restrictive.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
T 208-10	Unconfined Compressive Strength of Cohesive Soil	1a	Revised to clarify the procedure for extruding the sample.
T 209-10	Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)	2c	Revised extensively.
T 210-10	Aggregate Durability Index	1c	Revised to remove reference to the Tyler sieve shaker that is no longer available.
T 224-10	Correction for Coarse Particles in the Soil Compaction Test	1b	Revised to include information on dealing with discarded coarse material.
T 231-05 (2009)	Capping Cylindrical Concrete Specimens	3c	Reconfirmed in 2009.
T 235-96 (2004)	Bearing Capacity of Soil for Static Load on Spread Footings	1b	Deleted in 2009.
T 237-05 (2009)	Testing Epoxy Resin Adhesive	4c	Reconfirmed in 2009.
T 244-10	Mechanical Testing of Steel Products	4f	Revised to maintain equivalency with ASTM A 370-09a.
T 246-10	Resistance to Deformation and Cohesion of Hot Mix Asphalt (HMA) by Means of Hveem Apparatus	2d	Revised.
T 247-10	Preparation of Test Specimens of Hot Mix Asphalt (HMA) by Means of California Kneading Compactor	2d	Revised.
T 250-05 (2009)	Thermoplastic Traffic Line Material	4c	Reconfirmed in 2009.
T 260-97 (2009)	Sampling and Testing for Chloride Ion in Concrete and Concrete Raw Materials	3c	Reconfirmed in 2009.
T 271-83 (2009)	Density of Plastic and Hardened Portland Cement Concrete In-Place by Nuclear Methods	3c	Reconfirmed in 2009.
T 272-10	Family of Curves—One-Point Method	1b	Revised to include information on dealing with discarded coarse material.
T 276-10	Measuring Early-Age Compression Strength and Projecting Later-Age Strength	3c	Revised.
T 296-10	Unconsolidated, Undrained Compressive Strength of Cohesive Soils in Triaxial Compression	1a	Revised to clarify the procedure for extruding the sample.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
T 299-93 (2009)	Rapid Identification of Alkali-Silica Reaction Products in Concrete	3c	Reconfirmed in 2009.
T 302-05 (2009)	Polymer Content of Polymer-Modified Emulsified Asphalt Residue and Asphalt Binders	2a	Reconfirmed in 2009.
T 308-10	Determining the Asphalt Binder Content of Hot Mix Asphalt (HMA) by the Ignition Method	2c	Revised to expand methods to determine correction factors.
T 309M/T 309-10	Temperature of Freshly Mixed Hydraulic Cement Concrete	3b	Revised to include additional types of thermometers.
T 310-10	In-Place Density and Moisture Content of Soil and Soil-Aggregate by Nuclear Methods (Shallow Depth)	1b	Revised the Annex.
T 311-00 (2010)	Grain-Size Analysis of Granular Soil Materials	1a	Reconfirmed in 2010.
T 313-10	Determining the Flexural Creep Stiffness of Asphalt Binder Using the Bending Beam Rheometer (BBR)	2b	Revised to change the composition of the Glycerol-Talc Mixture.
T 315-10	Determining the Rheological Properties of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)	2b	Revised to provide guidance on Section 13.
T 316-10	Viscosity Determination of Asphalt Binder Using Rotational Viscometer	2b	Revised Section 9.1.
T 326-05 (2009)	Uncompacted Void Content of Coarse Aggregate (As Influenced by Particle Shape, Surface Texture, and Grading)	1c	Reconfirmed in 2009.
T 331-10	Bulk Specific Gravity and Density of Compacted Hot Mix Asphalt (HMA) Using Automatic Vacuum Sealing Method	2c	Revised extensively.
T 336-10	Coefficient of Thermal Expansion of Hydraulic Cement Concrete	3c	Revised.
T 339-10	Analysis of Structural Steel Coatings for Isocyanate Content	4c	Revised.
T 340-10	Determining Rutting Susceptibility of Hot Mix Asphalt (HMA) Using the Asphalt Pavement Analyzer (APA)	2d	Adopted TP 63 as full standard T 340-10.
T 341-10	Determination of Compression Capacity for Profile Wall Plastic Pipe by Stub Compression Loading	4b	Adopted new test method based upon recommendation in NCHRP Report 631.

Standard Specification for

Reclaimed Concrete Aggregate for Use as Coarse Aggregate in Hydraulic Cement Concrete

AASHTO Designation: MP 16-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Reclaimed Concrete Aggregate for Use as Coarse Aggregate in Hydraulic Cement Concrete

AASHTO Designation: MP 16-10

1. SCOPE

1.1. This specification covers coarse aggregate derived from reclaimed concrete for use in hydraulic cement concrete. The specification is not intended for use when lightweight, high-density, or other specialty concrete applications are required. When aggregate materials are properly processed and manufactured to the requirements of this specification, combined and mixed in accordance with the appropriate requirements, and placed, consolidated, and cured properly, a concrete structure of acceptable strength and durability can be produced. Introducing reclaimed concrete aggregate into concrete, however, requires the use of quality control and quality assurance procedures to ensure that deleterious materials that might be present in the reclaimed concrete aggregate will not adversely impact the quality of the concrete product.

1.2. Best practice applications for using reclaimed concrete aggregate in concrete shall consist of concrete pavements, cement-treated base courses, sidewalks, median barriers, curbings, and other non-structural applications.

Note 1—Caution should be exercised if reclaimed concrete aggregate is considered for use in structural applications. The presence of deleterious materials and the variability in the source concrete may produce inconstant volumetric properties and affect the properties of the concrete produced. Two properties of concern include dimensional stability and creep.

1.3. Since reclaimed concrete aggregate is a recycled material, various state and local jurisdiction laws and regulations may be applicable. The user of this specification is cautioned to contact state and local environmental and other local regulators to determine what requirements are appropriate.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 43, Sizes of Aggregate for Road and Bridge Construction
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- T 2, Sampling of Aggregates
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 19M/T 19, Bulk Density (“Unit Weight”) and Voids in Aggregate
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 85, Specific Gravity and Absorption of Coarse Aggregate
- T 96, Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine

- T 103, Soundness of Aggregates by Freezing and Thawing
- T 104, Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate
- T 112, Clay Lumps and Friable Particles in Aggregate
- T 113, Lightweight Pieces in Aggregate
- T 161, Resistance of Concrete to Rapid Freezing and Thawing
- T 260, Sampling and Testing for Chloride Ion in Concrete and Concrete Raw Materials
- T 299, Rapid Identification of Alkali-Silica Reaction Products in Concrete
- T 303, Accelerated Detection of Potentially Deleterious Expansion of Mortar Bars Due to Alkali-Silica Reaction
- T 327, Resistance of Coarse Aggregate to Degradation by Abrasion in the Micro-Deval Apparatus

2.2. *ASTM Standards*:

- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates
- C 227, Standard Test Method for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar-Bar Method)
- C 289, Standard Test Method for Potential Alkali-Silica Reactivity of Aggregates (Chemical Method)
- C 295, Standard Guide for Petrographic Examination of Aggregates for Concrete
- C 342, Standard Test Method for Potential Volume Change of Cement Aggregate Combinations
- C 586, Standard Test Method for Potential Alkali Reactivity of Carbonate Rocks as Concrete Aggregates (Rock-Cylinder Method)
- C 856, Standard Practice for Petrographic Examination of Hardened Concrete
- C 1293, Standard Test Method for Determination of Length Change of Concrete Due to Alkali-Silica Reaction
- D 6928, Standard Test Method for Resistance of Coarse Aggregate to Degradation by Abrasion in the Micro-Deval Apparatus

3. TERMINOLOGY

3.1. The definitions of concrete and concrete aggregate terms used in this specification are provided in ASTM C 125. The term “reclaimed concrete aggregate,” as used in this specification, shall mean coarse aggregate material derived from the crushing, processing, and classification of hydraulic cement concrete construction debris recovered from roadways, sidewalks, buildings, bridges, and other sources.

4. ORDERING INFORMATION

4.1. The purchaser or specifier shall include the following information in the purchase order or contract documents:

4.1.1. Reference to this specification and year of issue,

4.1.2. Grading to be furnished (AASHTO Size No.) (Section 6.1),

4.1.3. Soundness testing requirement (Section 7.2), 4.1.4. Class designation of aggregate (Table 1),

4.1.5. Whether the restriction on reactive materials applies (Section 7.3),

4.1.6. Additional testing requirements, and

4.1.7. Any exceptions or additions to this specification.

5. SAMPLING

5.1. Sample reclaimed concrete aggregate in accordance with T 2.

6. GRADING AND PROPORTIONS

6.1. Coarse reclaimed concrete aggregate tested in accordance with T 27 shall conform to the coarse aggregate gradation requirements prescribed in M 43 for the size number specified in the contract documents.

Note 2—Generally, there is no reason that reclaimed concrete aggregate should have gradation requirements that differ from natural or conventional aggregate materials.

Note 3—The ranges shown in M 43 are, by necessity, very wide in order to accommodate nationwide conditions. For quality control of any specific operation, a producer should develop an average gradation for the particular source and production facilities, and control the gradation within reasonable tolerances from this average. Where coarse aggregate sizes numbers 357 or 467 are used, the aggregate should be furnished in at least two separate sizes.

7. PHYSICAL PROPERTIES

7.1. Reclaimed concrete aggregate shall have a maximum Los Angeles abrasion loss of 50 percent, measured in accordance with T 96.

Note 4—T 327, Micro-Deval, may be required in lieu of T 96 if the specifying agency has experience with the procedure and has established limits.

7.2. Reclaimed concrete aggregate soundness testing shall be conducted in accordance with T 104 at 5 cycles. The maximum limit for soundness shall be 12 percent if sodium sulfate is used and 18 percent if magnesium sulfate is used.

Note 5—Reclaimed concrete aggregate can be susceptible to sulfate attack when tested for soundness using sodium sulfate or magnesium sulfate solutions, resulting in higher than expected soundness loss values (particularly when sodium sulfate solution is used in the test procedure). Sulfate solution test methods (T 104) should be applied if local experience has shown these methods to be acceptable; however, alternative approaches may be used.

7.3. Reclaimed concrete aggregate for use in concrete that will be subjected to in-service wetting, extended exposure to humid atmosphere, or contact with moist ground shall not contain any materials that are reactive with alkali components in the cement in an amount sufficient to cause excessive expansion of mortar or concrete. Except, if such materials are present in injurious amounts, the coarse aggregate may be used with the addition of a material that has been shown to prevent harmful expansion due to the alkali-aggregate reaction. Alkali reactivity shall be tested in accordance with T 303 when alkali-silica reaction is suspected, in accordance with ASTM C 586 when alkali-carbonate reaction is suspected.

Note 6—If the source and history of the reclaimed concrete aggregate are known and no reactive failures were present in the source concrete, testing for reactive expansion may not be necessary. However, unless a precise history is known, the source concrete may have not been exposed to all elements required to cause reactive expansion, and the reclaimed concrete aggregate may be reactive. See Appendix X2 for a discussion of alternative test methods. Mitigation methods found to work with natural reactive aggregates may not be effective with potentially expansive RCA. Aggregate that gave satisfactory performance in the original concrete may not continue to do so when used as RCA in new concrete. Consider the contribution of alkali from the RCA in addition to the alkali from the new hydraulic cement.

7.4. Reclaimed concrete aggregate for use in concrete that will be subjected to freeze-thaw action shall not contain aggregate components that expand and result in D-cracking of the concrete. When potential D-cracking is suspected, the reclaimed concrete aggregate shall be tested in accordance with T 161.

Note 7—In areas where D-cracking is a significant problem and agencies have developed equivalent test methods, local methods of testing may be used. Acceptance criteria for T 161 and equivalent methods should be based on local criteria that have been developed to address the issue of D-cracking.

7.5. Reclaimed concrete aggregate shall meet the flat and elongated particle requirements of the specifying jurisdiction.

7.6. Reclaimed concrete aggregate shall be tested in accordance with T 85 to establish the specific gravity and absorption. For specific gravity, the total variability of tests from minimum value to maximum value shall not exceed 0.100; and for absorption, the total variability of tests from minimum value to maximum value shall not exceed 0.8 percent.

Aggregates that have specific gravity and absorption values that fall outside of these limits shall be stockpiled separately, and the limits stated above shall apply to the new stockpile.

Note 8—Testing of specific gravity and absorption may not be necessary during production of aggregate if the reclaimed concrete is from one source with known aggregate properties.

Note 9—Coarse reclaimed concrete aggregate may contain air-entrained concrete mortar and, therefore, may be highly absorptive and can exhibit low and highly variable specific gravity values. Utilizing highly absorptive aggregates (coarse and fine) that do not exhibit consistent specific gravity values in hydraulic cement concrete can adversely affect the weighing and batching process in the concrete production operation. Further discussions of this issue are presented in Appendix X1.

8. DELETERIOUS SUBSTANCES

8.1. Reclaimed concrete aggregate shall not contain clay lumps and friable particles, chert, coal and lignite, or other deleterious substances that exceed the maximum allowable amounts listed in Table 1 when tested in accordance with T 112, T 113, and ASTM C 295.

Table 1—Limits for Deleterious Substances and Physical Property Requirements of Reclaimed Coarse Aggregate for Concrete

	Maximum Allowable Percent[a]				
Class Designation[b]	Clay Lumps and Friable Particles	Chert (Less Than 2.40 sp gr SSD)[c]	Sum of Clay Lumps, Friable Particles, and Chert (Less Than 2.40 sp gr SSD)[c]	Other Deleterious Substances[d]	Coal and Lignite
A	2.0	3.0	2.0	0.3	0.2
B	3.0	5.0	3.0	0.3	0.2
C	3.0	8.0	5.0	0.3	0.2

[a] The engineer may supplement the requirements of Table 1 by placing limits on the amount of deleterious substances or physical properties in accordance with local experience and practice.

[b] Aggregate conforming to the requirements for the various classes designated in Table 1 should generally be suitable for the following uses:

Typical Uses (Suggested)	Weathering Exposure	Class of Aggregate
Concrete pavements, cement-treated base courses, sidewalks, median barriers, curbings, and other non-structural applications	Severe	A
	Moderate	B
	Negligible	C

The purchaser or specifier must indicate the class of aggregate to be furnished as the degree of weathering exposure is not precisely defined.

[c] These limitations apply only to aggregate in which chert appears as an impurity. They are not applicable to gravels that are predominantly chert. Limitations on the soundness of such aggregate must be based on service records in the environment in which it is used.

[d] Other deleterious substances include adherent fines, vegetable matter, plastics, plaster, paper, gypsum board, metals, fabrics, wood, brick, tile, glass, and bituminous materials. The percentage of these materials shall be determined in accordance with ASTM C 295 or other equivalent method approved by the specifying jurisdiction.

Note 10—The presence of deleterious materials in aggregates used in the production of hydraulic cement concrete could adversely affect concrete setting time, strength, or both, and could also induce expansive reactions that could result in premature deterioration of the concrete structure. As a result, strict quality control and quality assurance procedures are required to ensure that reclaimed concrete aggregate material used as coarse aggregate in the production of concrete will not adversely affect the quality of the concrete product.

8.2. Reclaimed concrete aggregate shall not contain more than 1.5 percent by mass of material finer than the 75-µm (No. 200) sieve in accordance with T 11.

8.3. Reclaimed concrete aggregate, when sampled and tested according to T 260, shall not contain chloride ion in excess of 0.6 lb per cubic yard of concrete.

9. QUALITY CONTROL

9.1. If the contractor/supplier wishes to use reclaimed concrete aggregate, or combinations of reclaimed concrete aggregate and other approved aggregate materials, a request shall be made to the engineer for approval. The percentage of combined materials shall be established as part of a pre-submitted blended aggregate combination. At the engineer’s discretion, revised hydraulic cement concrete mix designs shall be required when percentages of materials change.

Note 11—A revised concrete mix design is recommended when percentages of materials change. The reclaimed concrete aggregate will likely have a different specific gravity and absorption than the virgin aggregate.

9.2. The contractor/supplier of recycled concrete aggregate shall develop and implement a quality control plan for aggregate production.

9.2.1. The quality control plan shall detail the production procedures, testing methods, and testing frequencies that will be used to ensure that recycled concrete aggregate meets the requirements of this specification.

9.2.2. The quality control plan will detail the production procedures and methods to ensure consistent production of aggregate from reclaimed concrete.

9.2.3. Detail methods to ensure that reclaimed concrete source materials are not contaminated with extraneous solid waste or hazardous materials. Methods and criteria for examining reclaimed concrete materials prior to use should be established.

9.3. Stockpiling will be required to assist in qualitatively and quantitatively identifying the presence of deleterious materials. Stockpiling can also be used as a means to qualitatively assess the uniformity of the material. The stockpile may represent all or part of the material to be used on a project and should be constructed in a manner that will minimize segregation and permit visual examination and representative sampling of the material.

9.4. If reclaimed concrete aggregate is blended with other approved aggregates, this shall be accomplished by mechanical interlock blending or belt blending to ensure uniform proportioning.

Note 12—Other methods of blending shall be permissible if it can be demonstrated through sampling and testing that the alternate blending method will prevent segregation.

9.5. Reclaimed concrete aggregate shall be saturated with water for a time period that is sufficient to saturate all particles, prior to introducing the reclaimed concrete aggregate into a concrete mix, by means of a water sprinkling system or another approved method. At the time of batching, the reclaimed concrete aggregate shall contain water in excess of the saturated surface dry condition. Provision shall also be made for the free drainage of excess water.

APPENDIXES

(Nonmandatory Information)

X1. SPECIFIC GRAVITY AND WATER ABSORPTION

X1.1. The specific gravity of reclaimed concrete aggregate from different sources can be expected to vary. Such fluctuations in specific gravity properties are undesirable in a concrete aggregate material. Since concrete is batched on the principle of weighing the components, the effect on the volume of material measured when the specific gravity varies may be significant. These potential variations can affect the yield of the mix, the cement factor, and the engineering properties of the concrete mixture.

X1.1.1. A technique to control the variability of specific gravity properties of reclaimed concrete aggregate is to use the source approval method. In this approach, the state or other jurisdiction specifies what materials within the limits of the project are suitable for recycling into reclaimed concrete aggregate. The concrete to be recycled generally contains aggregate from one source, where little variation in specific gravity can be expected.

X1.1.2. An alternative to the source approval approach is for the engineer to monitor the physical properties of the fresh concrete, including yield, to determine if specific gravity variations result in property changes. Standard practices of adjusting batch weights to correct yield should be followed. A ±3.0 percent variation in yield should require batch weight adjustments.

X1.2. Reclaimed concrete aggregate can be expected to exhibit higher and more variable water absorption properties than conventional aggregates. This is due to the presence of a highly absorptive mortar component of the original concrete material adhering to the aggregate particles.

X1.2.1. The primary effect on the quality of the concrete manufactured using aggregate with high water absorptive properties is to draw the free water that is present in the mortar of the fresh concrete into the pore structure of the aggregate. The net effect of this process is to reduce the water in the mortar, thus resulting in an early setting of the concrete and an early loss in workability.

X1.2.2. Since the fine portion (material passing the 2.36-mm (No. 8) sieve) of reclaimed concrete aggregate will contain the predominant fraction of high-absorption material in the recycled concrete aggregate, eliminating the fine portion from the source material can be utilized as a means to mitigate this problem.

X1.2.3. High-absorption problems can be further mitigated by requiring that coarse reclaimed concrete aggregate contains water in excess of the saturated surface dry condition prior to mixing it with cement and water. During this process, steps must also be taken to ensure that excess water readily drains from the reclaimed concrete aggregate material. This process ensures that the internal voids in the aggregate particles are filled with water at the time of batching of the concrete, eliminating any additional water demand.

X2. METHODS FOR EVALUATING POTENTIAL REACTIVITY OF AN AGGREGATE

X2.1. A number of methods for detecting potential reactivity have been proposed. However, they do not provide quantitative information on the degree of reactivity to be expected or tolerated in service. Therefore, the evaluation of the potential reactivity of an aggregate must be based upon judgment and on the interpretation of test data and examination of concrete structures containing a combination of fine and coarse aggregates and cements for use in the new work. For the test methods listed in this appendix, note that the required aggregate gradation shall be obtained by crushing the coarse RCA intended for use in the concrete. Fine aggregate produced from initial processing of the reclaimed concrete has been found to inaccurately represent the reactivity of the coarse RCA. A listing of suggested test methods follows:

X2.1.1. *T 299*—This rapid test method is intended to be used in conjunction with other tests to determine the presence of alkali-silica reaction (ASR) products in hardened concrete. A solution of uranyl acetate is applied to the fractured surface of hardened concrete. The reagent reacts with the sodium- and potassium-rich ASR gel present on the fractured surface of the concrete in such a manner that the uranium ions are absorbed by these gels. If sodium- and potassium-rich ASR gels are present on the fractured surface of the uranyl-acetate treated concrete, the areas in which the gel is concentrated will effloresce a bright yellow-green. However, both expansive and non-expansive sodium- and potassium-rich ASR gels will effloresce after exposure to a uranyl-acetate solution. This test, therefore, can only be used as an indicator that ASR may be present. A positive test then indicates that further evaluation is required. If sodium silicates are present, the light will effloresce. The use of this test method may be restricted by local environmental requirements because of the use of a uranyl-acetate solution.

X2.1.2. *T 303*—In this 16-day test, hardened mortar bars consisting of portland cement and the crushed suspect aggregate are subjected to submersion in a standard sodium hydroxide solution. The specimens are measured both before and after the 16-day submersion in the solution. If the specimens expand more than 0.10 percent, there is a strong probability that reactive aggregates are present.

X2.1.3. *ASTM C 295*—Certain materials are known to be reactive with the alkalis in cements. These include the following forms of silica: opal, chalcedony, tridymite, and cristobalite; intermediate to acid (silica-rich) volcanic glass such as is likely to occur in rhyolite, andesite, or dacite; and certain constituents of some phyllites. Determination of the presence and quantities of these materials by petrographic examination is helpful in evaluating potential alkali reactivity. Some of these materials render an aggregate deleteriously reactive when present in quantities as small as 1.0 percent.

X2.1.4. *ASTM C 289*—This test method covers chemical determination of the potential reactivity of an aggregate with alkalis in concrete as indicated by the amount of reaction during 24 h at 80°C between 1N sodium hydroxide solution and aggregate that has been crushed and sieved to pass a 300-µm (No. 50) sieve and be retained on a 150-µm (No. 100) sieve. Test results from ASTM C 289, which indicate that the aggregate is non-reactive, should not be used as a final determination that the aggregate is indeed non-reactive. Many aggregates which react very slowly to cause deleterious expansion from alkali-silica reactivity have tested as non-reactive in ASTM C 289. In addition to ASTM C 289, the aggregate should be subjected to at least one of the following additional tests: T 303, ASTM C 295, or ASTM C 1293.

X2.1.5. *ASTM C 342*—This test method is intended primarily for research concerning the potential expansion of cement-aggregate combinations subjected to variations of temperature and water saturation during storage under prescribed conditions of test.

X2.1.6. *ASTM C 586*—The reaction of the dolomite in certain carbonate rocks with alkalis in hydraulic cement paste has been found to be associated with the deleterious expansion of concrete containing such rocks as coarse aggregate. Carbonate rock capable of such reactions possess a characteristic texture and composition. The characteristic texture is that in which large crystals of dolomite are scattered in a finer grained matrix of calcite and clay. The characteristic composition is that in which the carbonate portion consists of substantial amounts of both dolomite and calcite, and the acid-insoluble residue contains a significant amount of clay. This method has been successfully used in (1) research and (2) preliminary screening of aggregate sources to indicate the presence of material with a potential for deleterious expansions when used in concrete.

X2.1.7. *T 161*—This test method applies freeze-thaw cycling to hardened concrete samples. The object of the test is to determine the potential of the aggregate used in the concrete to expand as a result of freeze-thaw action.

X2.1.8. *ASTM C 856*—An effective method of determining the nature of aggregate materials to react with alkali components of hydraulic cement to form alkali-silica reaction products is to perform a petrographic analysis of hardened concrete. The suspect concrete material is cut with a diamond saw into slices that are called thin sections. The thin sections are then studied with a petrographic microscope to determine if a reaction has taken place.

X2.1.9. *ASTM C 227*—A relatively long test in which mortar bars containing the test aggregate and cement are stored in sealed containers at 100°F for periods up to six months, or more. Test is relatively slow and allows potentially deleterious aggregate or cement-aggregate combinations to pass.

Standard Practice for

Determining Aggregate Source Shape Values from Digital Image Analysis Shape Properties

AASHTO Designation: PP 64-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Determining Aggregate Source Shape Values from Digital Image Analysis Shape Properties

AASHTO Designation: PP 64-10

1. SCOPE

1.1. This standard covers the determination of aggregate source and source blend shape characteristics using gradation analysis and shape properties determined by means of digital image analysis.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 85, Specific Gravity and Absorption of Coarse Aggregate
- TP 81, Determining Aggregate Shape Properties by Means of Digital Image Analysis

3. TERMINOLOGY

3.1. *aggregate size*—material retained on a given sieve size after passing the next larger sieve.

3.1.1. *fine aggregate*—aggregate material passing 4.75-mm (No. 4) sieve. Sieve sizes are 2.36 mm (No. 8), 1.18 mm (No. 16), 0.60 mm (No. 30), 0.30 mm (No. 50), 0.15 mm (No. 100), and 0.075 mm (No. 200).

3.1.2. *coarse aggregate*—aggregate material retained on 4.75-mm (No. 4) sieve. Sieve sizes are 25.0 mm (1 in.), 19.0 mm ($^3/_4$ in.), 12.5 mm ($^1/_2$ in.), 9.5 mm ($^3/_8$ in.), and 4.75 mm (No. 4).

3.2. *Shape Properties for Each Retained Sieve (x)*:

3.2.1. *gradient angularity* (*GA*)—applies to both fine and coarse aggregate sizes and is related to the sharpness of the corners of two-dimensional images of aggregate particles. The gradient angularity quantifies changes along a particle boundary with higher gradient values indicating a more angular shape. Gradient angularity has a relative range of zero to 10000 with a perfect circle having a value of zero.

Gradient Angularity:

$$GA = \frac{1}{\frac{n}{3} - 1} \sum_{i=1}^{n-3} \left| \theta_i - \theta_{i+3} \right| \quad (1)$$

where:

θ = angle of orientation of the edge points

n = the total number of points

i = denoting the *i*th point on the edge of the particle

3.2.2. *texture (or micro-texture) (TX)*—applies to coarse aggregate sizes only and describes the relative smoothness or roughness of surface features less than approximately 0.5 mm in size that are too small to affect the overall shape. Texture has a relative scale of zero to 1000 with a smooth polished surface approaching a value of zero.

$$TX = \frac{1}{3N} \sum_{i=1}^{3} \sum_{j=1}^{N} \left(D_{i,j}(x, y) \right)^2 \quad (2)$$

where:

D = decomposition function

n = decomposition level

N = total number of coefficients in an image

i = 1, 2, or 3 for detailed images

j = wavelet index

x, y = location of the coefficients in transformed domain

3.2.3. *sphericity (SP)*—applies to coarse aggregate sizes only and describes the overall three-dimensional shape of a particle. Sphericity has a relative scale of zero to one. A sphericity value of one indicates a particle has equal dimensions (cubical).

$$SP = \sqrt[3]{\frac{d_S \times d_I}{d_L^2}} \quad (3)$$

where:

d_S = particle shortest dimension

d_I = particle intermediate dimension

d_L = particle longest dimension

3.2.4. *Form 2D*—Applies to fine aggregate sizes only and is used to quantify the relative form from 2-dimensional images of aggregate particles. Form 2D has a relative scale of 0 to 20. A perfect circle has a Form 2D value of zero.

$$\text{Form 2D} = \sum_{\theta=0}^{\theta=360-\Delta\theta} \left[\frac{R_{\theta+\Delta\theta} - R_\theta}{R_\theta} \right] \quad (4)$$

where:

R_θ = the radius of the particle at an angle of θ

$\Delta\theta$ = the incremental difference in the angle

3.2.5. *flat* ***and*** *elongated*—those particles having a ratio of longest dimension to shortest dimension greater than a specified value.

Aggregate particle dimensions in an *x, y, z* coordinate system:

d_S = particle shortest dimension

d_I = particle intermediate

d_L = particle longest dimension

Flatness Ratio (*S/L*): $Flatness = \frac{d_S}{d_I}$ (5)

Elongation Ratio (*I/L*): $Elongation = \frac{d_I}{d_L}$ (6)

Flat and Elongated Value (*F&E*): $L / S = \frac{d_L}{d_S}$ (7)

3.2.6. *flat* ***or*** *elongated*—those particles having a ratio of intermediate dimension to shortest dimension or longest dimension to intermediate dimension greater than a specified value.

Flat ***or*** Elongated (*F* or *E*): $\frac{d_I}{d_S}$ or $\frac{d_L}{d_I} >$ Ratio (i.e., 1, 2, 3…) (8)

3.2.7. $\%Pass_x$ = Percent passing sieve *x*.

3.2.8. $\%R_x$ = Percent retained on sieve *x* (passing sieve *x* + 1).

4. SIGNIFICANCE AND USE

4.1. Shape, angularity, and surface texture of aggregates have been shown to directly affect the engineering properties of highway construction materials such as hot mix asphalt concrete, portland cement concrete, and unbound aggregate layers. This standard is used to characterize the combined shape values for an aggregate source from the individual particle shape properties determined by digital image analysis from TP 81. The aggregate shape characterization includes Gradient Angularity, Form 2D, Sphericity, Texture, and Flat and Elongated value.

Note 1—The National Cooperative Highway Research Program Report 555 provides background information relevant to characterizing aggregate shape, texture, and angularity.

4.2. This practice may be used to characterize the shape characteristics of single source aggregate materials and multiple source aggregate material blends.

5. PROCEDURE

5.1. Determine the aggregate sample grading according to T 27 and the amount finer than 75 µm according to T 11.

5.2. Determine the aggregate sample specific gravities according to T 84 and T 85.

5.3. Determine the material sample shape values for Form 2D, Gradient Angularity, Sphericity, Form Ratios (*F&E*, *F* or *E*), and Texture according to TP 81.

6. CALCULATIONS—SINGLE SOURCE

6.1. The material sample is typically characterized by individual evaluation of material retained on each sieve size, passing the next larger sieve. For the purpose of calculating the combined shape values, consider any sizes that contain inadequate percent retained mass to achieve minimum particle count to have the same shape value as the average of the next larger or the next smaller size, whichever is present.

6.2. Calculate the Percent Retained for the aggregate sample on each sieve using the T 27 results:

Sieve Sizes (*x*):

Coarse: 25.0 mm (1 in.), 19.0 mm ($^3/_4$ in.), 12.5 mm ($^1/_2$ in.), 9.5 mm ($^3/_8$ in.), 4.75 mm (No. 4)

Fine: 2.36 mm (No. 8), 1.18 mm (No. 16), 0.60 mm (No. 30), 0.30 mm (No. 50), 0.15 mm (No. 100), 0.075 mm (No. 200)

Percent Passing:

$\%\text{Pass}_x$ = Percent passing sieve *x*

Percent Retained:

$\%R_x$ = Percent retained on sieve *x*

$$\%R_x = \%\text{Pass}_{x+1} - \%\text{Pass}_x$$

6.3. Calculate average particle size, volume, and surface area for each sieve size *x* for unit mass.

For the purposes of shape characterization, volume and surface area of an average particle is estimated by using a cubical shape with side dimensions estimated by the average of the retained sieve and next larger sieve dimension.

Average Particle Size: $D_x = \frac{(\text{Sieve}_x + \text{Sieve}_{x+1})}{2}$ (mm)

Average Particle Surface Area (cubical): $PSA_x = 6 \times D_x{}^2$ (mm^2)

Average Particle Volume (cubical): $V_x = D_x{}^3$ (mm^3)

6.4. Calculate number of particles per sample unit mass for each sieve size from the size distribution of T 27 and the respective specific gravities from T 84 and T 85.

Number of particles per sieve size: $\# P_x = \frac{\%R_x \times 1000}{G_{sb} \times V_x}$

Note 2—A mass of one is assumed in Eq 13. This calculation determines the weighting factor applied to each sieve size for a material sample; therefore, actual mass is not required.

6.5. Calculate total particle surface area for each sieve size per sample unit mass:

Particle Surface Area (each sieve *x*) (mm^2): $SSA_x = PSA_x \times \# P_x$

6.6. Calculate Sample Surface Area (per unit mass):

Total Surface Area (mm^2): $TSA = \sum_{x=0.075}^{25.0} SSA_x$

Coarse Surface Area (mm^2): $CSA = \sum_{x=4.75}^{25.0} SSA_x$

Fine Surface Area (mm^2): $FSA = \sum_{x=0.075}^{2.36} SSA_x$

6.7. Calculate Sample Particles Count (per unit mass):

Total Particles: $\#TP = \sum_{x=0.075}^{25.0} \#P_x$

\# Coarse Particles: $\#CP = \sum_{x=4.75}^{25.0} \#P_x$

\# Fine Particles: $\#FP = \sum_{x=0.075}^{2.36} \#P_x$

6.8. Calculate Sample Gradient Angularity (weighted by surface area):

Fine Gradient Angularity: $FGA = \frac{1}{FSA} \sum_{x=0.075}^{2.36} \left[SSA_x \times GA_x \right]$

Coarse Gradient Angularity: $CGA = \frac{1}{CSA} \sum_{x=4.75}^{25.0} \left[SSA_x \times GA_x \right]$

Overall Gradient Angularity: $GA = \frac{1}{TSA} \sum_{x=0.075}^{25.0} \left[SSA_x \times GA_x \right]$

6.9. Calculate Sample Fine Aggregate Form 2D (weighted by surface area):

$$\text{Form 2D} = \frac{1}{FSA} \sum_{x=0.075}^{2.36} \left[SSA_x \times 2D_x \right]$$

6.10. Calculate Sample Coarse Aggregate Texture (weighted by surface area):

$$TX = \frac{1}{CSA} \sum_{x=4.75}^{25.0} \left[SSA_x \times TX_x \right]$$

6.11. Calculate Sample Coarse Aggregate Sphericity (weighted by particle count):

$$SP = \frac{1}{\#CP} \sum_{x=4.75}^{25.0} \left[\#P_x \times SP_x \right]$$

6.12. Calculate Sample Sphericity Range Distribution (weighted by particle count):

Percent of Particles with Sphericity ≤ 0.3:

$$SP(0.3) = \frac{1}{\#CP}\sum_{x=4.75}^{25.0}\left[\#P_x \times SP(0.3)_x\right]$$

Percent of Particles with Sphericity $0.3 < SP \leq 0.7$:

$$SP(0.7) = \frac{1}{\#CP}\sum_{x=4.75}^{25.0}\left[\#P_x \times SP(0.7)_x\right]$$

Percent of Particles with Sphericity $0.7 < SP \leq 1.0$:

$$SP(1.0) = \frac{1}{\#CP}\sum_{x=4.75}^{25.0}\left[\#P_x \times SP(1.0)_x\right]$$

6.13. Calculate sample weighted percentages of coarse aggregate Flat ***and*** Elongated Values (weighted by mass fraction) at the following ratios: ≥1:1, >2:1, >3:1, >4:1, >5:1

% $d_L/d_S \geq 1$: $\%L/S(\geq 1) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%L/S(\geq 1)_x}{100}\right]$

% $d_L/d_S > 2$: $\%L/S(> 2) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%L/S(> 2)_x}{100}\right]$

% $d_L/d_S > 3$: $\%L/S(> 3) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \cdots \%L/S(> 3)_x}{100}\right]$

% $d_L/d_S > 4$: $\%L/S(> 4) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%L/S(> 4)_x}{100}\right]$

% $d_L/d_S > 5$: $\%L/S(> 5) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%L/S(> 5)_x}{100}\right]$

6.13.1. Calculate the sample weighted percentages of Coarse Aggregate Flat ***or*** Elongated (weighted by mass fraction) at the following ratios: ≥1:1, >2:1, >3:1, >4:1, >5:1

% d_I/d_S or $d_L/d_I \geq 1$: $\%\left(F \text{ or } E\right)(\geq 1) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%\left(F \text{ or } E\right)(\geq 1)_x}{100}\right]$

% d_I/d_S or $d_L/d_I > 2$: $\%\left(F \text{ or } E\right)(> 2) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%\left(F \text{ or } E\right)(> 2)_x}{100}\right]$

% d_I/d_S or $d_L/d_I > 3$: $\%\left(F \text{ or } E\right) > 3) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%\left(F \text{ or } E\right)(> 3)_x}{100}\right]$

% d_I/d_S or $d_L/d_I > 4$: $\%\left(F \text{ or } E\right)(> 4) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%\left(F \text{ or } E\right)(> 4)_x}{100}\right]$

% d_I/d_S *or* d_L/d_I > 5: $$\%\left(F \text{ or } E\right)(>5) = \sum_{x=4.75}^{25.0}\left[\frac{\%R_x \times \%\left(F \text{ or } E\right)(>5)_x}{100}\right]$$

7. CALCULATIONS—MULTIPLE SOURCE BLEND

7.1. Use the calculations in this section to estimate the shape characteristics of multiple material source blends. Each source must be sampled and characterized according to Section 6 calculations.

7.2. Determine Blend Composition Percentages:

$\%AS_n$ = Percent Aggregate Source n

$$\sum_{i=1}^{n}\%AS_i = 100$$

where:

n = number of aggregate sources

7.3. Calculate Blend Surface Area:

Blend Total Surface Area (each sieve):

$$SSA_{\text{Blend}\_x} = \sum_{i=1}^{n}\sum_{x=0.075}^{37.5}\left[\frac{\%AS_i \times SSA_{ix}}{100}\right]$$

where:

x = 0.075 to 25.0 mm

n = number of aggregate sources

Total Surface Area Blend (all sieves x = 0.075 to 25.0 mm)

$$TSA_{\text{Blend}} = \sum_{x=0.075}^{25.0} SSA_{\text{Blend}\_x}$$

Coarse Surface Area Blend (sieve x = 4.75 to 25.0):

$$CSA_{\text{Blend}} = \sum_{x=4.75}^{25.0} SSA_{\text{Blend}\_x}$$

Fine Surface Area Blend (sieve x =0.075 to 2.36):

$$FSA_{\text{Blend}} = \sum_{x=0.075}^{2.36} SSA_{\text{Blend}\_x}$$

7.4. Calculate number of particles per blend unit mass for each sieve size:

$$\#P_{\text{Blend}\_x} = \sum_{i=1}^{n}\sum_{x=0.075}^{25.0}\left[\frac{\%AS_i \times \#P_{ix}}{100}\right]$$

7.5. Calculate number of particles per blend unit mass:

Total Particle Count Blend:

$$\#TP_{\text{Blend}} = \sum_{x=0.075}^{25.0} \#P_{\text{Blend}\_x}$$

Coarse Particles Blend:

$$\#CP_{\text{Blend}} = \sum_{x=4.75}^{25.0} \#P_{\text{Blend}\_x}$$

Fine Particles Blend:

$$\#FP_{\text{Blend}} = \sum_{x=0.075}^{2.36} \#P_{\text{Blend}\_x}$$

7.6. Calculate Blend Gradient Angularity for each size x = 0.075 to 25.0 mm and combined (weighted by surface area):

$$GA_{\text{Blend}\_x} = \frac{1}{SSA_{\text{Blend}\_x}}\left[\sum_{i=1}^{i}\left[\frac{\%AS_i \times SSA_{ix} \times GA_{ix}}{100}\right]\right]$$

Blend Fine Gradient Angularity:

$$FGA_{\text{Blend}} = \frac{1}{FSA_{\text{Blend}}}\left[\sum_{x=0.075}^{2.36}\left[SSA_{\text{Blend}\_x} \times GA_{\text{Blend}\_x}\right]\right]$$

Blend Coarse Gradient Angularity:

$$CGA_{\text{Blend}} = \frac{1}{CSA_{\text{Blend}}}\left[\sum_{x=4.75}^{25.0}\left[SSA_{\text{Blend}\_x} \times GA_{\text{Blend}\_x}\right]\right]$$

Blend Overall Gradient Angularity:

$$GA_{\text{Blend}} = \frac{1}{TSA_{\text{Blend}}}\left[\sum_{x=0.075}^{25.0}\left[SSA_{\text{Blend}\_x} \times GA_{\text{Blend}\_x}\right]\right]$$

7.7. Calculate Blend Fine Aggregate Form 2D for each sieve size x = 0.075 to 2.36 mm and combined (weighted by surface area):

$$\text{Form 2D}_{\text{Blend}\_x} = \frac{1}{SSA_{\text{Blend}\_x}}\left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times SSA_{ix} \times 2D_{ix}}{100}\right]\right]$$

Blend Form 2D:

$$\text{Form 2D}_{\text{Blend}} = \frac{1}{FSA_{\text{Blend}}}\left[\sum_{x=0.075}^{2.36}\left[SSA_{\text{Blend}\_x} \times 2D_{\text{Blend}\_x}\right]\right]$$

7.8. Calculate Blend Texture for each sieve size x = 4.75 to 25.0 mm and combined (weighted by coarse aggregate surface area):

$$TX_{\text{Blend}\_x} = \frac{1}{SSA_{\text{Blend}\_x}}\left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times SSA_{ix} \times TX_{ix}}{100}\right]\right]$$

Blend Texture:

$$TX_{\text{Blend}} = \frac{1}{CSA_{\text{Blend}}}\left[\sum_{x=4.75}^{25.0}\left[SSA_{\text{Blend}\_x} \times TX_{\text{Blend}\_x}\right]\right]$$

7.9. Calculate Average Blend Sphericity for each sieve size x = 4.75 to 25.0 mm and blend (weighted by coarse particle count):

$$SP_{\text{Blend}\_x} = \frac{1}{\#P_{\text{Blend}\_x}}\left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \#P_{ix} \times SP_{ix}}{100}\right]\right]$$

Blend Sphericity:

$$SP_{\text{Blend}} = \frac{1}{\#CP_{\text{Blend}}}\left[\sum_{x=4.75}^{25.0}\left[\#P_{\text{Blend}\_x} \times SP_{\text{Blend}\_x}\right]\right]$$

7.10. Calculate Blend Sphericity Distribution for each sieve size x = 4.75 to 25.0 mm and blend (weighted by coarse particle count):

Percent of Particles with Sphericity ≤ 0.3 (Blend):

$$SP(0.3)_{\text{Blend}\_x} = \frac{1}{\#P_{\text{Blend}\_x}}\left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \#P_{ix} \times SP(0.3)_{ix}}{100}\right]\right]$$

$$SP(0.3)_{\text{Blend}} = \frac{1}{\#CP_{\text{Blend}}}\left[\sum_{x=4.75}^{25.0}\left[\#P_{\text{Blend}\_x} \times SP(0.3)_{\text{Blend}\_x}\right]\right]$$

Percent of Particles with Sphericity 0.3 < SP ≤ 0.7 (Blend):

$$SP(0.7)_{\text{Blend}\_x} = \frac{1}{\#P_{\text{Blend}\_x}}\left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \#P_{ix} \times SP(0.7)_{ix}}{100}\right]\right]$$

$$SP(0.7)_{\text{Blend}} = \frac{1}{\#CP_{\text{Blend}}}\left[\sum_{x=4.75}^{25.0}\left[\#P_{\text{Blend}\_x} \times SP(0.7)_{\text{Blend}\_x}\right]\right]$$

Percent of Particles with Sphericity 0.7 < SP ≤ 1.0 (Blend):

$$SP(1.0)_{\text{Blend}\_x} = \frac{1}{\#P_{\text{Blend}\_x}}\left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \#P_{ix} \times SP(1.0)_{ix}}{100}\right]\right]$$

$$SP(1.0)_{\text{Blend}} = \frac{1}{\#CP_{\text{Blend}}}\left[\sum_{x=4.75}^{25.0}\left[\#P_{\text{Blend}\_x} \times SP(1.0)_{\text{Blend}\_x}\right]\right]$$

7.11. Calculate combined Flat *and* Elongated Values for each sieve size x = 4.75 to 25.0 mm and blend (weighted by mass fraction):

% $d_L/d_S \geq 1$ (Blend):

$$\%L/S(\geq 1)_{\text{Blend}\_x} = \left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \%R_{ix} \times \%L/S(\geq 1)_{ix}}{100^2}\right]\right]$$

$$\%L/S(\geq 1)_{\text{Blend}} = \left[\sum_{x=4.75}^{25.0}\left[\%L/S(\geq 1)_{\text{Blend}\_x}\right]\right]$$

% $d_L/d_S > 2$ (Blend):

$$\%L/S(>2)_{\text{Blend}\_x} = \left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \%R_{ix} \times \%L/S(>2)_{ix}}{100^2}\right]\right]$$

$$\%L/S(>2)_{\text{Blend}} = \left[\sum_{x=4.75}^{25.0}\left[\%L/S(>2)_{\text{Blend}\_x}\right]\right]$$

% $d_L/d_S > 3$ (Blend):

$$\%L/S(>3)_{\text{Blend}\_x} = \left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \%R_{ix} \times \%L/S(>3)_{ix}}{100^2}\right]\right]$$

$$\%L/S(>3)_{\text{Blend}} = \left[\sum_{x=4.75}^{25.0}\left[\%L/S(>3)_{\text{Blend}\_x}\right]\right]$$

% $d_L/d_S > 4$ (Blend):

$$\%L/S(>4)_{\text{Blend}\_x} = \left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \%R_{ix} \times \%L/S(>4)_{ix}}{100^2}\right]\right]$$

$$\%L/S(>4)_{\text{Blend}} = \left[\sum_{x=4.75}^{25.0}\left[\%L/S(>4)_{\text{Blend}\_x}\right]\right]$$

% $d_L/d_S \leq 5$ (Blend):

$$\%L/S(>5)_{\text{Blend}\_x} = \left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \%R_{ix} \times \%L/S(>5)_{ix}}{100^2}\right]\right]$$

$$\%L/S(>5)_{\text{Blend}} = \left[\sum_{x=4.75}^{37.5}\left[\%L/S(>5)_{\text{Blend}\_x}\right]\right]$$

7.12. Calculate Flat *or* Elongated Values for each sieve size *x* = 4.75 to 25.0 mm and blend (weighted by mass fraction):

% d_I/d_S *or* $d_L/d_I \geq 1$ (Blend):

$$\%\left(F \text{ or } E\right)(\geq 1)_{\text{Blend}\_x} = \left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \%R_{ix} \times \%\left(F \text{ or } E\right)(\geq 1)_{ix}}{100^2}\right]\right]$$

$$\%\left(F \text{ or } E\right)(\geq 1)_{\text{Blend}} = \left[\sum_{x=4.75}^{25.0}\left[\%\left(F \text{ or } E\right)(\geq 1)_{\text{Blend}\_x}\right]\right]$$

% d_I/d_S *or* $d_L/d_I > 2$ (Blend):

$$\%\left(F \text{ or } E\right)(>2)_{\text{Blend}\_x} = \left[\sum_{i=1}^{n}\left[\frac{\%AS_i \times \%R_{ix} \times \left(F \text{ or } E\right)(>2)_{ix}}{100^2}\right]\right]$$

$$\%\left(F\ \text{or}\ E\right)(>2)_{\text{Blend}}=\left[\sum_{x=4.75}^{25.0}\left[\%\left(F\ \text{or}\ E\right)(>2)_{\text{Blend}\_x}\right]\right]$$

% d_I/d_S *or* $d_L/d_I > 3$ (Blend):

$$\%\left(F\ \text{or}\ E\right)(>3)_{\text{Blend}\_x}=\left[\sum_{i=1}^{n}\left[\frac{\%AS_i\times\%R_{ix}\times\%\left(F\ \text{or}\ E\right)(>3)_{ix}}{100^2}\right]\right]$$

$$\%\left(F\ \text{or}\ E\right)(>3)_{\text{Blend}}=\left[\sum_{x=4.75}^{25.0}\left[\%\left(F\ \text{or}\ E\right)(>3)_{\text{Blend}\_x}\right]\right]$$

% d_I/d_S *or* $d_L/d_I > 4$ (Blend):

$$\%\left(F\ \text{or}\ E\right)(>4)_{\text{Blend}\_x}=\left[\sum_{i=1}^{i}\left[\frac{\%AS_i\times\%R_{ix}\times\%\left(F\ \text{or}\ E\right)(>4)_{ix}}{100^2}\right]\right]$$

$$\%\left(F\ \text{or}\ E\right)(>4)_{\text{Blend}}=\left[\sum_{x=4.75}^{25.0}\left[\%\left(F\ \text{or}\ E\right)(>4)_{\text{Blend}\_x}\right]\right]$$

% d_I/d_S or $d_L/d_I > 5$ (Blend):

$$\%\left(F\ \text{or}\ E\right)(>5)_{\text{Blend}\_x}=\left[\sum_{i=1}^{n}\left[\frac{\%AS_i\times\%R_{ix}\times\%\left(F\ \text{or}\ E\right)(>5)_{ix}}{100^2}\right]\right]$$

$$\%\left(F\ \text{or}\ E\right)(>5)_{\text{Blend}}=\left[\sum_{x=4.75}^{25.0}\left[\%\left(F\ \text{or}\ E\right)(>5)_{\text{Blend}\_x}\right]\right]$$

8. REPORT

8.1. *Report the following information*:

8.1.1. Project name.

8.1.2. Date of the analysis.

8.1.3. Material sample identifications: type, source, size, gradation.

8.1.4. Number of particles analyzed for each size.

8.1.5. Material shape property mean and standard deviation. Graphical representations of the property distributions may be included.

8.2. A sample report format is presented in Appendix X1.

9. PRECISION AND BIAS

9.1. *Precision*—This practice uses data generated from other testing methods to generate cumulative information, therefore the precision of the values generated in this practice are established by the precision of the standards used to collect the raw data.

9.2. *Bias*—The research required to determine the bias of this procedure has not been conducted.

10. KEYWORDS

10.1. Aggregate; angularity; consensus property; elongation; form; shape; texture.

APPENDIX

Standard Practice for

Determining the Reactivity of Concrete Aggregates and Selecting Appropriate Measures for Preventing Deleterious Expansion in New Concrete Construction

AASHTO Designation: PP 65-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Determining the Reactivity of Concrete Aggregates and Selecting Appropriate Measures for Preventing Deleterious Expansion in New Concrete Construction

AASHTO Designation: PP 65-10

1. SCOPE

1.1 This practice describes approaches for identifying potentially deleteriously reactive aggregates and selecting appropriate preventive measures to minimize the risk of expansion when such aggregates are used in concrete. Both alkali-silica reactive and alkali-carbonate reactive aggregates are covered. Preventive measures for alkali-silica reactive aggregates include avoiding the reactive aggregate, limiting the alkali content of the concrete, using blended cement, using supplementary cementitious materials, using lithium nitrate as an admixture, or a combination of these measures. Preventive measures for alkali-carbonate reactive rocks are limited to avoiding the reactive aggregate.

1.2 The values stated in SI units are the preferred standard.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

3. TERMINOLOGY

3.1 *accelerated mortar bar test (AMBT)*—test method used to determine aggregate reactivity (T 303) or to evaluate the effectiveness of measures to prevent deleterious expansion when reactive aggregates are used (ASTM C 1567).

3.2 *alkali-aggregate reaction (AAR)*—chemical reaction in either mortar or concrete between alkalis (sodium and potassium) present in the concrete pore solution and certain constituents of some aggregates; under certain conditions, deleterious expansion of concrete or mortar may result. Two types of AAR are considered in this standard practice; these are alkali-carbonate reaction (ACR) and alkali-silica reaction (ASR).

3.3 *alkali-carbonate reaction (ACR)*—the reaction between the alkalis (sodium and potassium) present in the concrete pore solution and certain carbonate rocks, particularly argillaceous calcitic dolomite and argillaceous dolomitic limestone, present in some aggregates; the products of the reaction may cause deleterious expansion and cracking of concrete.

3.4 *alkali-silica reaction (ASR*)—the reaction between the alkalis (sodium and potassium) present in the concrete pore solution and certain siliceous rocks or minerals, such as opaline chert, strained quartz, and acidic volcanic glass, present in significant quantities in some aggregates; the products of the reaction may cause deleterious expansion and cracking of concrete.

3.5 *class of structure*—in this guideline structures are classified on the basis of the severity of the consequences should ASR occur.

3.6 *concrete prism test (CPT)*—test method (ASTM C 1293) used to determine aggregate reactivity or to evaluate the effectiveness of measures to prevent deleterious expansion when reactive aggregates are used. Another version of this test, ASTM C 1105, can be used with a limited alkali content to determine the potential for alkali-carbonate reactivity.

3.7 *deleterious expansion*—term used to describe an increase in volume that is sufficient to cause cracking of the concrete or result in other problems (e.g., misalignment of adjacent components, closing of joints, etc.).

3.8 *deleteriously reactive*—term used to define aggregates that undergo chemical reactions in concrete that subsequently result in deleterious expansion of the concrete.

3.9 *equivalent alkali,* Na_2Oe—calculated from the sodium (Na_2O) and potassium oxide (K_2O) as follows: $Na_2Oe = Na_2O + 0.658 \times K_2O$.

3.10 *non-deleteriously reactive*—term used to define aggregates with no reactive constituents or minor amounts of reactive constituents that may exhibit some small amount of reaction without producing significant damage to the concrete.

3.11 *preventive measures*—termed used to describe strategies for suppressing damaging expansion due to alkali-aggregate reaction (AAR).

3.12 *supplementary cementitious material (SCM)*—term used to describe cementitious materials other than portland cement (i.e., pozzolans and slag).

4. SIGNIFICANCE AND USE

4.1 This practice describes a procedure for evaluating aggregate reactivity and determining measures to prevent deleterious expansion due to alkali-aggregate reaction (AAR).

4.2 Following this practice will not completely eliminate the possibility of deleterious expansion occurring in new construction; rather the practice provides various approaches for minimizing the risk of AAR to a level acceptable to the owner.

4.3 Aggregate reactivity is determined on the basis of one or more of the following: field performance, petrographic examination, or the expansion testing of mortars or concrete, or both.

4.4 If the aggregate is deemed to be non-deleteriously reactive, it can be accepted for use in concrete with no further consideration of preventive measures (assuming that the physical properties of the aggregate render it suitable for use).

4.5 If the aggregate is found to be deleteriously reactive, it must then be determined whether the reaction is of the alkali-carbonate or alkali-silica type.

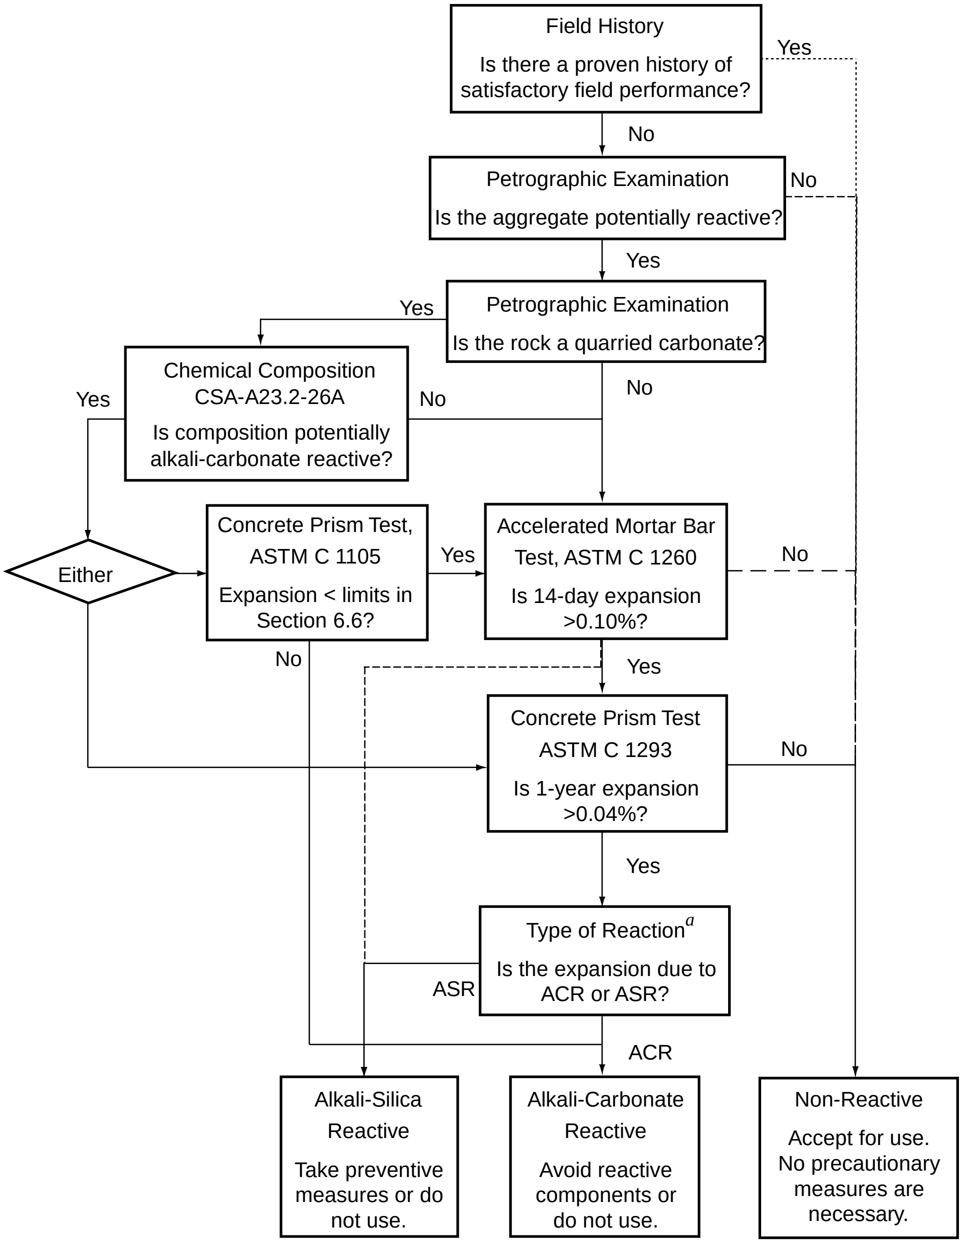
4.6 If the aggregate is alkali-silica reactive, the aggregate may be either rejected for use or accepted with an appropriate preventive measure. There are a number of options for minimizing the risk of expansion with alkali-silica reactive rocks. This practice allows for preventive measures to be evaluated on the basis of performance testing or to be selected prescriptively from a list of options based on previous experience. The level of prevention required is a function of the reactivity of the aggregate, the class of structure, the nature of the exposure conditions, the availability of alkali in the system, the type of material used for prevention, and the level of risk the owner is willing to accept.

4.7 If the aggregate is alkali-carbonate reactive, the aggregate must be rejected for use. There are no proven measures for effectively preventing damaging expansion with alkali-carbonate reactive rocks, and such materials should not be used in concrete without selective quarrying or processing to limit the reactive components to acceptable levels.

4.8 In the approach outlined here, the level of testing varies depending on the level of risk that is acceptable to the owner. For example, in regions where occurrences of AAR are rare or where the aggregate sources in use have a long history of good field performance, it may be reasonable to continue to rely on the previous field history without subjecting the aggregates to laboratory tests. However, in regions where AAR problems are known and where the reactivity of aggregates is known to vary from source to source, it may be necessary to implement a rigorous testing regime to establish the potential aggregate reactivity and evaluate preventive measures.

5. GENERAL APPROACH

5.1 The flow chart in Figure 1 shows the sequence of testing and decisions that has to be made when evaluating a source of aggregate for potential AAR. It is recommended that the following sequence of testing is followed to determine aggregate reactivity: consideration of field performance history, petrographic examination, accelerated mortar bar testing, and concrete prism testing. If the rock is a quarried carbonate, additional tests are required to determine the potential for alkali-carbonate reaction (as shown in Figure 1). Some agencies may adopt one or more of these test procedures depending on prior experience with AAR and the acceptable level of risk of AAR in new construction.



[a] The type of reaction only needs to be determined after the concrete prism test if the aggregate being tested is a quarried carbonate that has been identified as being potentially alkali-carbonate reactive by chemical composition in accordance with test method CSA A23.2-26A.

The solid lines show the preferred approach. However, some agencies may want to reduce the amount of testing and accept a higher level of risk, and this can be achieved by following the direction of the hashed lines.

Figure 1—Sequence of Laboratory Tests for Evaluating Aggregate Reactivity

5.2 Appropriate preventive measures can be selected either by performance testing using the accelerated mortar bar test or concrete prism test, or by using prescribed measures that have been developed based on previous experience and published research data. The level of prevention prescribed is a function of the class of the structure, the reactivity of the aggregate, the alkali content of the portland cement, the composition of the material used for prevention, the exposure conditions, and the level of risk the owner is willing to accept.

Note 1—If desired, performance testing can be conducted on the aggregate with preventive measures, without first establishing aggregate reactivity.

6. DETERMINING AGGREGATE REACTIVITY

6.1 *Field Performance History*:

6.1.1 The long-term field performance history of an aggregate can be established by consulting the available documentation (e.g., specifications and construction files) and conducting a survey of existing structures that were constructed using the same or similar (i.e., from the same geological environment) aggregate source. As many structures as practical should be included in the survey, and these structures should, where possible, represent different types of construction (pavements, sidewalks, curb and gutter, elements of bridges, barrier walls, and even non-transportation structures). The following information should be collected for each structure: (1) *age*—structures should be at least 10 years old and preferably more than 15 years old as deleterious expansion due to AAR can take more than 10 years to develop; (2) *cement content and alkali content* of the cement used during construction; (3) use and type of *supplementary cementitious materials* during construction; (4) *exposure condition*—availability of moisture, use of deicing chemicals; and (5) presence and type of *symptoms of distress* due to AAR or other causes.

6.1.2 Cores should be taken from a representative number of these structures and petrographic examinations conducted in accordance with ASTM C 856 to establish the following: (1) the presence or not of evidence of deleterious expansion due to AAR, (2) the aggregate used in the structures surveyed is close in mineralogical composition to that of the aggregate currently being produced, and (3) the presence and an estimate of the quantity of supplementary cementitious materials.

6.1.3 If the results of the field survey indicate that the aggregate is non-deleteriously reactive, the aggregate may be used in new construction provided that the new concrete is not produced with a higher alkali loading, a lower amount of or different supplementary cementitious materials, or more aggressive exposure condition than the structures included in the survey.

6.1.4 If field performance indicates that an aggregate source is deleteriously reactive, laboratory expansion testing is required to determine the level of aggregate reactivity and to evaluate prevention measures.

Note 2—There is a certain level of risk associated with accepting aggregates solely on the basis of field performance due to difficulties in establishing unequivocally that the materials and proportions used are similar to those to be used in new construction. For example, petrographic examination can only estimate the quantity of pozzolans and slag to the nearest 10 percent or so and is not able to determine the composition of the material (e.g., Class F versus Class C fly ash). The presence of very finely divided pozzolans (silica fume) cannot be detected using a petrographic examination.

6.2 *Petrographic Examination*:

6.2.1 Petrographic examination of aggregates should be conducted in accordance with ASTM C 295. Petrography can reveal useful information about the composition of an aggregate, including the identification and approximate quantification of reactive minerals.

6.2.2 Petrography may be used to classify an aggregate as potentially reactive, but expansion testing is required to determine the extent of potential reactivity and appropriate levels of prevention.

6.2.3 Quarried carbonate rocks should be tested to determine the chemical composition and the potential for alkali-carbonate reaction in accordance with Section 6.3.

Note 3—Aggregates may be accepted as non-deleteriously-reactive solely on the basis of petrography, but there is certain level of risk associated with such a decision as some reactive phases may not be routinely detected by optical microscopy (e.g., finely dispersed cryptocrystalline silica found in some siliceous limestone).

6.3 *Determination of Potential Alkali-Carbonate Reactive Rocks by Chemical Composition*:

6.3.1 If the aggregate being assessed is a quarried carbonate rock, the potential for alkali-carbonate reaction may be assessed on the basis of its chemical composition using the test method CSA A23.2-26A. This test involves the determination of the lime (CaO), magnesia (MgO), and alumina (Al_2O_3) content of the rock, and determining where the composition of the rock falls on a plot of CaO/MgO ratio versus the Al_2O_3 content, as shown in Figure 2.
