INTRODUCTION

PART 1
SPECIFICATIONS

This Thirtieth Edition of Transportation Materials is published in two parts. Part 1 contains specifications for materials, and Part II includes methods of testing and specifications for testing equipment. Part 1 contains 162 materials specifications and 48 Standard Practices, of which most contain both English and Metric units of measure. Technical revisions were made in 26 of the standards since the Twenty-Ninth Edition, 14 standards were reconfirmed, six standards were updated, eight new standards were added, nine standards were discontinued, and one standard was deleted. A number of specifications were included in this publication at the request of the AASHTO Subcommittee on Bridges and Structures.

Many of these specifications agree with those of the American Society for Testing and Materials (ASTM). In all cases where the Association and ASTM standards are technically identical, or substantially identical with some changes, reference to the ASTM designation number is shown in the heading of the specification.

In past editions, AASHTO has printed ASTM standards which have been adopted by AASHTO and given an AASHTO designation. This was done under a long-standing copyright arrangement between AASHTO and ASTM. The Thirtieth Edition includes 32 AASHTO-approved ASTM specifications. These specifications appear in this edition as the actual ASTM specification preceded by a cover page with the AASHTO designation number. Any AASHTO exception to the ASTM specification is indicated on this cover page. The numerical order of the specifications has been retained. A list of the affected AASHTO specifications is included following the Table of Contents.

General jurisdiction over Association standards in this field rests with the AASHTO Highway Subcommittee on Materials, which has members representing each of the 50 States, the Commonwealth of Puerto Rico and the District of Columbia, that constitute the Member Departments of the Association, and the U.S. Department of Transportation. In addition, the Subcommittee has representation from several of its Associate Members, including the New Jersey Turnpike Authority, the Pennsylvania Turnpike Authority, and the Port Authority of New York and New Jersey. Also represented on the Subcommittee are most of the Association's International Associate members, including the Canadian Provinces of New Brunswick, the Northwest Territories, Nova Scotia, Ontario, and Saskatchewan.

Beginning in 1993 with the Sixteenth Edition, material specifications and test methods are published by AASHTO each year. Annual revisions are voted upon by the Association's 52 Member Departments prior to the publication of each new edition of this book, and if approved by at least two-thirds of the Member Departments, they are included in the edition as standards of the Association.

Comments regarding these specifications are welcomed and should be addressed to the Executive Director of AASHTO, 444 North Capitol Street, N.W., Suite 249, Washington, D.C. 20001. AASHTO's Web site and internet address is http://transportation.org.

INTRODUCTION

PART 2
METHODS OF SAMPLING AND TESTING

This Thirtieth Edition of Transportation Materials is published in two parts. Part 1 contains specifications for materials, and Part 2 includes methods of testing and specifications for testing equipment. Part 2 contains 215 test methods and equipment standards, of which most contain both U.S. Customary and Metric units of measure. Since the Twenty-Ninth Edition, technical revisions were made in 44 of the standards, 22 standards were reconfirmed, 1 standard was updated, 2 new standards were added, 2 standards were discontinued, and 5 standards were deleted. A number of specifications were included in this publication at the request of the AASHTO Subcommittee on Bridges and Structures.

Many of these standards agree with those of the American Society for Testing and Materials (ASTM). In all cases where the Association and ASTM standards are technically identical, or substantially identical with some changes, reference to the ASTM designation number is shown in the heading of the specification.

In past editions, AASHTO has printed ASTM standards which have been adopted by AASHTO and given an AASHTO designation. This was done under a long-standing copyright arrangement between AASHTO and ASTM. The Thirtieth Edition includes 22 AASHTO-approved ASTM test methods. These specifications appear in this edition as the actual ASTM specification preceded by a cover page with the AASHTO designation number. Any AASHTO exception to the ASTM specification is indicated on this cover page. The numerical order of the specifications has been retained. A list of the affected AASHTO specifications is included following the Table of Contents.

General jurisdiction over Association standards in this field rests with the AASHTO Highway Subcommittee on Materials, which has members representing each of the 50 States, the Commonwealth of Puerto Rico and the District of Columbia, that constitute the Member Departments of the Association, and the U.S. Department of Transportation. In addition, the Subcommittee has representation from several of its Associate Members, including the New Jersey Turnpike Authority, the Pennsylvania Turnpike Authority, and the Port Authority of New York and New Jersey. Also represented on the Subcommittee are most of the Association's International Associate members, including the Canadian Provinces of New Brunswick, the Northwest Territories, Nova Scotia, Ontario, and Saskatchewan.

Beginning in 1993 with the Sixteenth Edition, material specifications and test methods are published by AASHTO each year. Annual revisions are voted upon by the Association's 52 Member Departments prior to the publication of each new edition of this book, and if approved by at least two-thirds of the Member Departments, they are included in the edition as standards of the Association.

Standard Specification for

Fine Aggregate for Hydraulic Cement Concrete

AASHTO Designation: M 6-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Fine Aggregate for Hydraulic Cement Concrete

AASHTO Designation: M 6-08

1. SCOPE

1.1. This specification covers the quality and grading of fine aggregate for hydraulic cement concrete used in pavements or bases, highway bridges, and incidental structures.

1.2. This specification is for use by a contractor, concrete supplier, or other purchaser as part of the purchase document describing the material to be furnished.

Note 1—This specification is regarded as adequate to ensure satisfactory materials for most concrete. It is recognized that, for certain work or in certain regions, it may be either more or less restrictive than needed. For example, where aesthetics are important, more restrictive limits may be considered regarding impurities that would stain the concrete surface. The specifier should ascertain that aggregates specified are or can be made available in the area of the work, with regard to grading, physical, or chemical properties, or combination thereof.

1.3. This specification is also for use in project specifications to define the quality of aggregate, the nominal maximum size of the aggregate, and other specific grading requirements. Those responsible for selecting the proportions for the concrete mixture shall have the responsibility of determining the proportions of fine and coarse aggregate and the addition of blending aggregate sizes if required or approved.

1.4. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.5. The text of this standard references notes and footnotes that provide explanatory material. These notes (excluding those in tables and figures) shall not be considered as requirements of this standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 92, Wire-Cloth Sieves for Testing Purposes
- T 2, Sampling of Aggregates
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 21, Organic Impurities in Fine Aggregates for Concrete
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 71, Effect of Organic Impurities in Fine Aggregate on Strength of Mortar
- T 103, Soundness of Aggregates by Freezing and Thawing

- T 104, Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate
- T 112, Clay Lumps and Friable Particles in Aggregate
- T 113, Lightweight Pieces in Aggregate
- T 161, Resistance of Concrete to Rapid Freezing and Thawing
- T 303, Accelerated Detection of Potentially Deleterious Expansion of Mortar Bars Due to Alkali-Silica Reaction

2.2. *ASTM Standards*:

- C 227, Standard Test Method for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar-Bar Method)
- C 289, Standard Test Method for Potential Alkali-Silica Reactivity of Aggregates (Chemical Method)
- C 295, Standard Guide for Petrographic Examination of Aggregates for Concrete
- C 586, Standard Test Method for Potential Alkali Reactivity of Carbonate Rocks as Concrete Aggregates(Rock-Cylinder Method)
- C 1260, Standard Test Method for Potential Alkali Reactivity of Aggregates (Mortar-Bar Method)
- C 1293, Standard Test Method for Determination of Length Change of Concrete Due to Alkali-Silica Reaction
- STP 169D, *Significance of Tests and Properties of Concrete and Concrete-Making Materials*

---

3. ORDERING INFORMATION

3.1. The purchaser shall include the following information in the purchase order or contract when applicable:

3.1.1. Reference to this specification, M 6, and year of issue;

3.1.2. Whether the deleterious substances limits for Class A or Class B apply, and limits on other deleterious substances (Section 7.1 and Note 4);

3.1.3. If the sulfate soundness requirement is waived (Section 8.5);

3.1.4. In the case of the sulfate soundness test (Section 8.1), which salt is to be used; if none is stated, either sodium sulfate or magnesium sulfate may be used;

3.1.5. If the supplementary requirement for reactive aggregates applies (Section S1); and

3.1.6. Any exceptions or additions to this specification.

---

4. GENERAL REQUIREMENTS

4.1. Fine aggregate shall consist of natural sand or manufactured sand or combinations thereof, having hard, strong, durable particles.

4.2. Fine aggregate from different sources of supply shall not be mixed or stored in the same pile.

5. GRADING

5.1. Fine aggregate, when tested by means of laboratory sieves, shall conform to the requirements of Table 1, except as provided in Sections 5.2 and 5.3:

Table 1—Grading Requirements

Sieve	Mass, Percent Passing
9.5 mm ($^3/_8$ in.)	100
4.75 mm (No. 4)	95 to 100
2.36 mm (No. 8)	80 to 100
1.18 mm (No. 16)	50 to 85
600 µm (No. 30)	25 to 60
300 µm (No. 50)	10 to 30
150 µm (No. 100)	2 to 10

5.2. The minimum percent shown above for material passing the 300-µm (No. 50) and 150-µm (No. 100) sieves may be reduced to 5 and 0, respectively, if the aggregate is to be used in air-entrained concrete containing more than 237 kilograms of cement per cubic meter (400 lb/yd^3) or in non-air-entrained concrete containing more than 297 kilograms of cement per cubic meter (500 lb/yd^3) or if an approved mineral admixture is used to supply the deficiency in percent passing these sieves. Air-entrained concrete is here considered to be concrete containing air-entraining cement or an air-entraining agent and having an air content equal to or greater than 3.5 percent.

5.3. The fine aggregate shall have not more than 45 percent passing any sieve and retained on the next consecutive sieve of those shown in Section 5.1, and its fineness modulus shall be not less than 2.3 nor more than 3.1.

5.4. Fine aggregate failing to meet the sieve analysis and fineness modulus requirements of Sections 5.1, 5.2, or 5.3, may be accepted provided that concrete made with similar fine aggregate from the same source has an acceptable performance record in similar concrete construction; or, in the absence of a demonstrable service record, provided that it is demonstrated that concrete of the class specified, made with the fine aggregate under consideration, will have relevant properties at least equal to those of concrete made with the same ingredients with the exception that a reference fine aggregate be used which is selected from a source having an acceptable performance record in similar concrete construction.

Note 2—Fine aggregate that conforms to the grading requirements of a specification, prepared by another organization such as a state transportation agency, which is in general use in the area, should be considered as having a satisfactory service record with regard to those concrete properties affected by grading.

Note 3—Relevant properties are those properties of the concrete, which are important to the particular application being considered. STP 169D provides a discussion of important concrete properties.

6. UNIFORMITY OF GRADING

6.1. For continuing shipments of fine aggregate from a given source, the fineness modulus shall not vary more than 0.20 from the base fineness modulus. The base fineness modulus shall be that value that is typical of the source. If necessary, the base fineness modulus may be changed when approved by the purchaser.

Note 4—The base fineness modulus should be determined from previous tests, or if no previous tests exist, from the average of the fineness modulus values for the first 10 samples (or all preceding samples if less than 10) on the order. The proportioning of a concrete mixture may be dependent on the base fineness modulus of the fine aggregate to be used. Therefore, when it appears that the base fineness modulus is considerably different from the value used in selecting proportions for the concrete mixture, a suitable adjustment in the mixture may be necessary.

7. DELETERIOUS SUBSTANCES

7.1. The amount of deleterious substances shall not exceed the following limits: (See Table 2.)

Table 2—Deleterious Substances Limits

	Class A, Max Mass, percent	Class B, Max Mass, percent
Clay lumps and friable particles	3.0	3.0
Coal and lignite	0.25	1.0
Material finer than 75-µm (No. 200) sieve:		
a. In concrete subject to surface abrasion not more than	2.0	4.0
b. All other classes of concrete, not more than	3.0	5.0
Other deleterious substances (such as shale, alkali, mica, coated grains, and soft and flaky particles)	Note 5	Note 5

Note 5—The purchaser or specifier, due to knowledge of the requirements of the work and the constituents of locally available aggregate, should insert appropriate requirements when needed.

7.2. *Organic Impurities*:

7.2.1. Fine aggregate shall be free of injurious amounts of organic impurities. Except as herein provided, aggregates subjected to the test for organic impurities and producing a color darker than the standard shall be rejected.

7.2.2. A fine aggregate failing in the test may be used, provided that the discoloration is due principally to the presence of small quantities of coal, lignite, or similar discrete particles.

7.2.3. A fine aggregate failing in the test may be used, provided that, when tested for the effect of organic impurities on strength of mortar, the relative strength at seven days calculated in accordance with T 71 is not less than 95 percent.

7.3. Fine aggregate used in concrete that will be subject to wetting, extended exposure to humid atmosphere, or contact with moist ground shall not contain any components that are known to be reactive with soluble alkalies from the concrete paste in an amount sufficient to cause deleterious expansion of mortar or concrete without the accompanying use of some form of remediation in the concrete which is known to prevent deleterious expansion due to alkali-silica reactivity. The method chosen for prevention of ASR in any one situation will depend on the materials available for remediation, the relative effectiveness of the available materials in preventing excessive expansion due to alkali-silica reactivity, and the reactivity of the aggregate intended for use in the concrete. (See Supplementary Requirement S1 and Appendix X1.)

8. SOUNDNESS

8.1. Except as provided in Sections 8.2 through 8.5, fine aggregate subjected to five cycles of the soundness test shall have a weighted average loss not greater than 10 percent when sodium sulfate is used or 15 percent when magnesium sulfate is used.

8.2. Fine aggregate failing to meet the requirements of Section 8.1 may be accepted, provided that concrete of comparable properties, made from similar aggregate from the same source, has given satisfactory service when exposed to weathering similar to that to be encountered.

8.3. Fine aggregate not having a demonstrable service record and failing to meet the requirements of Section 8.1 may be accepted, provided it gives satisfactory results in concrete subjected to freezing and thawing tests. (See T 161.)

8.4. Fine aggregate failing to meet the requirements given in Section 8.1 may, at the option of the purchaser or specifier, be subjected to an alternate freezing and thawing test of unconfined aggregate and may be accepted provided it gives satisfactory results.

Note 6—The purchaser or specifier should determine the details of the evaluation and criteria for determining satisfactory performance in Sections 8.2, 8.3, and 8.4.

8.5. The requirements for soundness given in Section 8.1 may be waived in the case of aggregate for use in structures or portions of structures not exposed to weathering.

9. METHODS OF SAMPLING AND TESTING

9.1. Sampling and testing of fine aggregate shall be in accordance with the following methods of the American Association of State Highway and Transportation Officials:

9.1.1. *Sampling*—T 2;

9.1.2. *Sieve Analysis and Fineness Modulus*—T 27;

9.1.3. *Clay Lumps and Friable Particles*—T 112;

9.1.4. *Lightweight Pieces in Aggregate*—T 113, using a liquid of 2.0 specific gravity to remove the particles of coal and lignite; only material that is brownish-black, or black, shall be considered coal or lignite; coke shall not be classed as coal or lignite.

9.1.5. *Materials Finer than 75 µm (No. 200)*—T 11;

9.1.6. *Organic Impurities*—T 21;

9.1.7. *Effect of Organic Impurities on Strength*—T 71;

9.1.8. *Sulfate Soundness*—T 104;

9.1.9. *Soundness (Unconfined Freezing and Thawing)*—T 103; and

9.1.10. *Freezing and Thawing of Concrete*—T 161.

SUPPLEMENTARY REQUIREMENT

The following supplementary requirement applies only when specifically stated in the order or contract.

S1. REACTIVE AGGREGATE

S1.1. *Potential Reactivity of Siliceous Aggregates*—Alkali-silica reactions shall be mitigated either by a performance specification as given in S1.1.1 or a prescriptive specification as given in S1.1.2:

S1.1.1. *Performance Type*—One of the following options shall be used:

S1.1.1.1. Obtain a service record of the aggregate in a service condition at least as severe as that in which it is intended to be used, with similar cementitious materials having similar alkali content. If satisfactory, no mitigation is necessary.

S1.1.1.2. Test the aggregate in accordance with T 303, ASTM C 1260, or ASTM C 1293. If the expansion is less than 0.10 percent at 14 days after initial reading when tested in accordance with T 303 or ASTM C 1260, or less than 0.04 percent at 1 year with ASTM C 1293, no mitigation is necessary.

S1.1.1.3. If reactive aggregates are used, testing shall be performed using the proposed materials (aggregates, cementitious, and supplementary materials) in proportions to be used on the project according to the selected test method(s). Selection of appropriate test methods to evaluate mitigation effectiveness shall be based on the procedure's ability to identify behavior of materials that correlate well with field performance. An example of a test that has been used to evaluate deleterious expansion and effectiveness of mitigation is T 303.

S1.1.1.4. If specified, T 303 test shall be used with the pozzolan or slag or blended cements to detect the potential for deleterious expansion. The test shall be performed by using 440 grams of the proposed blended cementitious materials, in the proportion to be used on the project, and 990 grams of the combined aggregates, in the proportions to be used on the project. For acceptance using T 303, the expansion shall not exceed 0.10 percent at 14 days.

S1.1.2. *Prescriptive Type*—Use of prescriptive methods may not be adequate to prevent Alkali-silica reactions for every combination of materials in all service environments. Limits and properties established in prescriptive methods utilized by an agency should be based on proven field performance of locally available materials. One of the following options shall be used:

S1.1.2.1. Select aggregates with proven field performance when similar cementitious materials having similar alkali content are used.

S1.1.2.2. Use varying percentage of pozzolan or slag for different levels of alkali content of cement.

S1.1.2.3. Use lithium salts at a dosage rate of 1:1 $LiOH.H_2O$: equivalent Na_2O in the portland cement.

APPENDIX

(Nonmandatory Information)

X1. METHODS FOR EVALUATING POTENTIAL REACTIVITY OF AN AGGREGATE

X1.1. A number of methods for detecting potential reactivity have been proposed. However, they do not provide quantitative information on the degree of reactivity to be expected or tolerated in service. Therefore, evaluation of potential reactivity of an aggregate should be based upon judgment and on the interpretation of test data and examination of concrete structures containing a combination of fine and coarse aggregates and cements for use in the new work. Results of the following tests will assist in making the evaluation:

X1.1.1. *ASTM C 295*—Certain materials are known to be reactive with the alkalies in cements. These include the following forms of silica: opal, chalcedony, tridymite, and cristobalite; intermediate to acid (silica-rich) volcanic glass such as is likely to occur in rhyolite, andesite, or dacite; and certain constituents of some phyllites. Determination of the presence and quantities of these materials by petrographic examination is helpful in evaluating potential alkali reactivity. Some of these materials render an aggregate deleteriously reactive when present in quantities as little as 1.0 percent or even less.

X1.1.2. *ASTM C 289*—In this test, aggregates represented by points lying to the right of the solid line of Figure 2 of Method C 289 usually should be considered potentially reactive.

X1.1.2.1. If R_c exceeds 70, the aggregate is considered potentially reactive if S_c is greater than R_c.

X1.1.2.2. If R_c is less than 70, the aggregate is considered potentially reactive if S_c is greater than $35 + (R_c/2)$.

X1.1.2.3. These criteria conform to the solid line curve given in Figure 2 of Method C 289. The test can be made quickly and, while not completely reliable in all cases, can provide helpful information, especially where results of the more time-consuming tests are not available.

X1.1.3. *ASTM C 227*—The results of this test, when made with a high-alkali cement, furnish information on the likelihood of harmful reactions occurring. The alkali content of the cement should be substantially above 0.6 percent (preferably above 0.8 percent) expressed as sodium oxide. Combinations of aggregate and cement, which have produced excessive expansions in this test, usually should be considered potentially reactive. While the line of demarcation between nonreactive and reactive combinations is not clearly defined, expansion is generally considered to be excessive if it exceeds 0.05 percent at three months or 0.10 percent in six months. Expansions greater than 0.05 percent at three months should not be considered excessive where the six-month expansion remains below 0.10 percent. Data for the three-month tests should be considered only when six-month results are not available.

X1.1.3.1. In addition to its usefulness in research, this test method has been found useful in the selection of aggregates of the so-called “sand-gravel” type found mainly in some parts of Kansas, Nebraska, and Iowa, which contain very little coarse material, generally 5 to 15 percent retained on the 4.75-mm (No. 4) sieve. Much work has been done on the problems of using these aggregates successfully in concrete and is reported in summary in the “Final Report of Cooperative Tests of Proposed Tentative Method of Test for Potential Volume Change of Cement-Aggregate

Combinations," Appendix to *Committee C-9 Report*, Proceedings, ASTM, Volume 54, 1954, p. 356. It indicates that cement-aggregate combinations tested by this procedure in which expansion equals or exceeds 0.200 percent at an age of 1 year may be considered unsatisfactory for use in concrete exposed to wide variations of temperature and degree of saturation with water. In that geographical region, the problem has been reduced through the use of partial replacement of the "sand-gravel" with limestone coarse aggregate.

X1.1.4. *Potential Reactivity of Carbonate Aggregates*—The reaction of the dolomite in certain carbonate rocks with alkalies in hydraulic cement paste has been found to be associated with deleterious expansion of concrete containing such rocks as coarse aggregate. Carbonate rocks capable of such reaction possesses a characteristic texture and composition. The characteristic texture is that in which large crystals of dolomite are scattered in a finer-grained matrix of calcite and clay. The characteristic composition is that in which the carbonate portion consists of substantial amounts of both dolomite and calcite, and the acid-insoluble residue contains a significant amount of clay. Except in certain areas, such rocks are of relatively infrequent occurrence and seldom make up a significant proportion of the material present in a deposit of rock being considered for use in making aggregate for concrete. ASTM C 586 has been successfully used in (1) research and (2) preliminary screening of aggregate sources to indicate the presence of material with a potential for deleterious expansions when used in concrete.

Standard Specification for

Mineral Filler for Bituminous Paving Mixtures

AASHTO Designation: M 17-07
ASTM Designation: D 242-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Mineral Filler for Bituminous Paving Mixtures

AASHTO Designation: M 17-07

ASTM Designation: D 242-04

AASHTO M 17-07 is identical to ASTM D 242-04 except for the following provisions:

1. All references to the ASTM standards contained in ASTM D 242-04, listed in the following table, shall be replaced with the corresponding AASHTO standard:

Referenced Standards

ASTM	AASHTO
C 183	T 127
D 546	T 37
D 4318	T 90

2. Add a new Section 4.3 after Section 4.2 that contains the following:

   "Fly ash used as a mineral filler shall have a maximum loss on ignition of 12 percent."

3. Add a new Section 5.5 after Section 5.4 that contains the following:

   "Determine the loss on ignition of fly ash according to ASTM C 311."

Standard Specification for

Fine Aggregate for Bituminous Paving Mixtures

AASHTO Designation: M 29-03 (2007)
ASTM Designation: D 1073-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Fine Aggregate for Bituminous Paving Mixtures

AASHTO Designation: M 29-03 (2007)

ASTM Designation: D 1073-06

1. SCOPE

1.1. This specification covers fine aggregate for use in bituminous paving mixtures.

1.2. This specification is intended to describe material from a single supplier. When material from two or more suppliers is to be blended to produce a grading to meet requirements as described in a specification for bituminous paving mixtures, the grading requirements of Table 1 of this specification need not apply.

Table 1—Grading Requirements for Fine Aggregates

	Amounts Finer Than Each Laboratory Sieve (Square Openings), Mass, %				
Sieve Size	Grading No. 1	Grading No. 2	Grading No. 3	Grading No. 4	Grading No. 5
9.5 mm ($^3/_8$ in.)	100	—	—	100	100
4.75 mm (No. 4)	95 to 100	100	100	80 to 100	80 to 100
2.36 mm (No. 8)	70 to 100	75 to 100	95 to 100	65 to 100	65 to 100
1.18 mm (No. 16)	40 to 80	50 to 74	85 to 100	40 to 80	40 to 80
600 μm (No. 30)	20 to 65	28 to 52	65 to 90	20 to 65	20 to 65
300 μm (No. 50)	7 to 40	8 to 30	30 to 60	7 to 40	7 to 46
150 μm (No. 100)	2 to 20	0 to 12	5 to 25	2 to 20	2 to 30
75 μm (No. 200)	0 to 10	0 to 5	0 to 5	0 to 10	—

1.3. The values stated in SI units are to be regarded as the standard. Inch-pound units, shown in parentheses, are for information only.

Note 1—When obtaining materials from two or more suppliers that do not meet the gradings in Table 1 and that are to be blended, it is recommended that the specifying or the ordering agency specify the alternative gradings to be supplied.

2. REFERENCED DOCUMENTS

- T 90, Determining the Plastic Limit and Plasticity Index of Soils
- T 104, Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate

2.2. *ASTM Standards*:

- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates
- D 8, Standard Terminology Relating to Materials for Roads and Pavements
- D 3665, Standard Practice for Random Sampling of Construction Materials
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. For definitions regarding aggregate types, see ASTM C 125 and D 8.

4. ORDERING INFORMATION

4.1. Orders for material under this specification shall include the following:

4.1.1. Reference to this specification, M 29, and year of issue;

4.1.2. Grading (Section 6.2 and Table 1), or alternate grading designated by the purchaser;

4.1.3. Supplementary requirement for sulfate soundness, if required, including salt to be used (Section S1); and

4.1.4. Any exceptions or additions to this specification.

5. GENERAL CHARACTERISTICS

5.1. Fine aggregate is aggregate passing the 9.5-mm ($^3/_8$-in.) sieve and almost entirely passing the 4.75-mm (No. 4) sieve. It shall consist of natural sand, or of sand prepared from stone, or of crushed blast-furnace slag, or gravel, or combinations thereof. It shall consist of hard, tough grains, free of injurious amounts of clay, loam, or other deleterious substances.

6. PHYSICAL REQUIREMENTS

6.1. To determine conformance to this specification, each value for grading (and sulfate soundness, when required) shall be rounded to the nearest 1 percent, and each value for plasticity index shall be rounded to 0.1 unit, both according to the rounding off method of ASTM E 29.

6.2. *Grading*—The grading of the fine aggregate shall conform to the grading in Table 1 for the grading number specified in the order, or other grading designated by the purchaser.

6.3. *Grading Variability Limits*—For continuing shipments of fine aggregate from a given source, the fineness modulus shall not vary more than 0.25 from the base fineness modulus. The base fineness modulus shall be that value that is typical of the source, and shall be determined from previous tests, or if no previous tests exist, from the average of the fineness modulus values for the first 10 samples (or all preceding samples if less than 10) on the order. If necessary, the base fineness modulus may be changed when approved by the purchaser.

Note 2—The proportioning of a bituminous mixture may be dependent on the base fineness modulus of the fine aggregate to be used. Therefore, when it appears that the base fineness modulus is considerably different from the value used in the bituminous mixture, a suitable adjustment in the mixture may be necessary.

6.4. *Plasticity Index*—The plasticity index of the fraction passing the 425-µm sieve (No. 40) shall not exceed 4.0.

7. METHODS OF SAMPLING AND TESTING

7.1. The aggregate shall be sampled and the properties enumerated in this specification shall be determined in accordance with the following methods:

7.1.1. *Sampling*—T 2;

7.1.2. *Random Sampling*—ASTM D 3665;

7.1.3. *Grading*—T 27 and T 11, Procedure B;

7.1.4. *Fineness Modulus*—T 27; and

7.1.5. *Plasticity Index*—T 89 and T 90.

8. KEYWORDS

8.1. Aggregate; bituminous paving; fine aggregate; paving mixtures.

SUPPLEMENTARY REQUIREMENT

The following supplementary requirement shall apply only when specified by the purchaser in the contract or order.

S1. SULFATE SOUNDNESS

S1.1. The fine aggregate, when subjected to five cycles of the soundness test according to T 104, shall have a weighted loss of not more than 15 percent when sodium sulfate is used or 20 percent when magnesium sulfate is used. If the salt to be used is not stated by the purchaser, the fine aggregate shall be acceptable if it meets the requirements when tested with either salt.

Standard Specification for

Sizes of Aggregate for Road and Bridge Construction

AASHTO Designation: M 43-05 (2009)[1]
ASTM Designation: D 448-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Sizes of Aggregate for Road and Bridge Construction

AASHTO Designation: M 43-05 (2009)[1]

ASTM Designation: D 448-08

1. SCOPE

1.1. This specification defines aggregate size designations and ranges in mechanical analyses for standard sizes of coarse aggregate and screenings for use in the construction and maintenance of various types of highways and bridges.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- T 2, Sampling of Aggregates
- T 27, Sieve Analysis of Fine and Coarse Aggregates

3. SIGNIFICANCE AND USE

3.1. Some contract documents specify certain aggregate sizes for specific uses or may suggest one or more of these sizes as appropriate for the preparation of various end-product mixtures. In some cases, closer limits on variability of the aggregate grading are required.

4. MANUFACTURE

4.1. The standard sizes of aggregate described in this classification are manufactured by means of any suitable process used to separate raw material into the desired size ranges. Production of standard sizes by blending two or more different components is also permitted.

5. STANDARD SIZES

5.1. Standard sizes of coarse aggregate shall comply with the sizes given in Table 1. All sizes shall be determined by means of laboratory sieves having square openings and conforming to M 92.

6. BASIS OF CLASSIFICATION

6.1. Classification is based upon the size number and size ranges shown in Table 1 with the aggregate sampled in accordance with T 2 and tested for grading by T 27.

Table 1—Standard Sizes of Processed Aggregate

Size Number	Nominal Size, Square Openings	Amounts Finer Than Each Laboratory Sieve (Square Openings), Mass, percent														
		100 mm (4 in.)	90 mm ($3^1/_2$ in.)	75 mm (3 in.)	63 mm ($2^1/_2$ in.)	50 mm (2 in.)	37.5 mm ($1^1/_2$ in.)	25.0 mm (1 in.)	19.0 mm ($^3/_4$ in.)	12.5 mm ($^1/_2$ in.)	9.5 mm ($^3/_8$ in.)	4.75 mm (No. 4)	2.36 mm (No. 8)	1.18 mm (No. 16)	300 µm (No. 50)	150 µm (No. 100)
1	90 to 37.5 mm ($3\,^1/_2$ to $1\,^1/_2$ in.)	100	90 to 100	—	25 to 60	—	0 to 15	—	0 to 5	—	—	—	—	—	—	—
2	63 to 37.5 mm ($2\,^1/_2$ to $1\,^1/_2$ in.)	—	—	100	90 to 100	35 to 70	0 to 15	—	0 to 5	—	—	—	—	—	—	—
24	63 to 19.0 mm ($2\,^1/_2$ to $^3/_4$ in.)	—	—	100	90 to 100	—	25 to 60	—	0 to 10	0 to 5	—	—	—	—	—	—
3	50 to 25.0 mm (2 to 1 in.)	—	—	—	100	90 to 100	35 to 70	0 to 15	—	0 to 5	—	—	—	—	—	—
357	50 to 4.75 mm (2 in. to No. 4)	—	—	—	100	95 to 100	—	35 to 70	—	10 to 30	—	0 to 5	—	—	—	—
4	37.5 to 19.0 mm ($1\,^1/_2$ to $^3/_4$ in.)	—	—	—	—	100	90 to 100	20 to 55	0 to 15	—	0 to 5	—	—	—	—	—
467	37.5 to 4.75 mm ($1\,^1/_2$ to No. 4)	—	—	—	—	100	95 to 100	—	35 to 70	—	10 to 30	0 to 5	—	—	—	—
5	25.0 to 12.5 mm (1 to $^1/_2$ in.)	—	—	—	—	—	100	90 to 100	20 to 55	0 to 10	0 to 5	—	—	—	—	—
56	25.0 to 9.5 mm (1 to $^3/_8$ in.)	—	—	—	—	—	100	90 to 100	40 to 85	10 to 40	0 to 15	0 to 5	—	—	—	—
57	25.0 to 4.75 mm (1 to No. 4)	—	—	—	—	—	100	95 to 100	—	25 to 60	—	0 to 10	0 to 5	—	—	—
6	19.0 to 9.5 mm ($^3/_4$ to $^3/_8$ in.)	—	—	—	—	—	—	100	90 to 100	20 to 55	0 to 15	0 to 5	—	—	—	—
67	19.0 to 4.75 mm ($^3/_4$ to No. 4)	—	—	—	—	—	—	100	90 to 100	—	20 to 55	0 to 10	0 to 5	—	—	—
68	19.0 to 2.36 mm ($^3/_4$ to No. 8)	—	—	—	—	—	—	100	90 to 100	—	30 to 65	5 to 25	0 to 10	0 to 5	—	—
7	12.5 to 4.75 mm ($^1/_2$ to No. 4)	—	—	—	—	—	—	—	100	90 to 100	40 to 70	0 to 15	0 to 5	—	—	—
78	12.5 to 2.36 mm ($^1/_2$ to No. 8)	—	—	—	—	—	—	—	100	90 to 100	40 to 75	5 to 25	0 to 10	0 to 5	—	—
8	9.5 to 2.36 mm ($^3/_8$ to No. 8)	—	—	—	—	—	—	—	—	100	85 to 100	10 to 30	0 to 10	0 to 5	—	—
89	9.5 to 1.18 mm ($^3/_8$ to No. 16)	—	—	—	—	—	—	—	—	100	90 to 100	20 to 55	5 to 30	0 to 10	0 to 5	—
9	4.75 to 1.18 mm (No. 4 to No. 16)	—	—	—	—	—	—	—	—	—	100	85 to 100	10 to 40	0 to 10	0 to 5	—
10	4.75 mm (No. 4 to 0)[a]	—	—	—	—	—	—	—	—	—	100	85 to 100	—	—	—	10 to 30

[a] Screening.

7. KEYWORDS

7.1. Coarse aggregate; standard sizes; classification.

---

[1] This specification is technically equivalent to ASTM D 448-08.

Standard Specification for

Aggregate for Masonry Mortar

AASHTO Designation: M 45-06[1]
ASTM Designation: C 144-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Aggregate for Masonry Mortar

AASHTO Designation: M 45-06[1]
ASTM Designation: C 144-04

1. SCOPE

1.1. This specification covers aggregate for use in masonry mortar.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 6, Fine Aggregate for Hydraulic Cement Concrete
- T 2, Sampling of Aggregates
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 21, Organic Impurities in Fine Aggregates for Concrete
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 71, Effect of Organic Impurities in Fine Aggregate on Strength of Mortar
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 104, Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate
- T 112, Clay Lumps and Friable Particles in Aggregate
- T 113, Lightweight Pieces in Aggregate

2.2. *ASTM Standard*:
- C 270, Standard Specification for Mortar for Unit Masonry

3. MATERIAL

3.1. Aggregate for use in masonry mortar shall consist of natural sand or manufactured sand. Manufactured sand is the product obtained by crushing stone, gravel, or air-cooled iron blast-furnace slag specially processed to ensure suitable particle shape as well as gradation.

4. GRADING

4.1. Aggregate for use in masonry mortar shall be graded within the following limits, depending upon whether natural sand or manufactured sand is to be used. (See Table 1.)

Table 1—Aggregate Grading Limits

	Percent Passing	
Sieve Size	Natural Sand	Manufactured Sand
4.75 mm (No. 4)	100	100
2.36 mm (No. 8)	95 to 100	95 to 100
1.18 mm (No. 16)	70 to 100	70 to 100
600 µm (No. 30)	40 to 75	40 to 75
300 µm (No. 50)	10 to 35	20 to 40
150 µm (No. 100)	2 to 15	10 to 25
75 µm (No. 200)	0 to 5	0 to 10

4.2. The aggregate shall not have more than 50 percent retained between any two consecutive sieves of those listed in Section 4.1 nor more than 25 percent between 300-µm (No. 50) and the 150-µm (No. 100) sieve.

4.3. If the fineness modulus varies by more than 0.20 from the value assumed in selecting proportions for the mortar, the aggregate shall be rejected unless suitable adjustments are made in proportions to compensate for the change in grading.

Note 1—For heavy construction employing joints thicker than 12.5 mm ($^1/_2$ in.), a coarser aggregate may be desirable. For such work a fine aggregate conforming to M 6 is satisfactory.

4.4. When an aggregate fails the gradation limits specified in Sections 4.1 and 4.2, it may be used provided the mortar can be prepared to comply with the aggregate ratio, water retention, air content, and compressive strength requirements of the property specifications of ASTM C 270.

5. COMPOSITION

5.1. *Deleterious Substances*—The amount of deleterious substances in aggregate for masonry mortar, each determined on independent samples complying with the grading requirements of Section 4 shall not exceed the following:

Item	Max Permissible Mass, percent
Clay lumps and friable particles	1.0
Lightweight particles, floating on liquid having a specific gravity of 2.0	0.5[a]

[a] This requirement does not apply to blast-furnace slag aggregate.

5.2. *Organic Impurities*:

5.2.1. The aggregate shall be free of injurious amounts of organic impurities. Except as herein provided, aggregates subjected to the test for organic impurities and producing a color darker than the standard shall be rejected.

5.2.2. Aggregate failing in the test may be used provided that the discoloration is due principally to the presence of small quantities of coal, lignite, or similar discrete particles.

5.2.3. Aggregate failing in the test may be used provided that, when tested for the effect of organic impurities on strength of mortar by T 71, the relative strength at seven days is not less than 95 percent.

6. SOUNDNESS

6.1. Except as herein provided, aggregate subjected to five cycles of the soundness test shall show a loss, weighted in accordance with the grading of a sample complying with the limitations set forth in Section 4, not greater than 10 percent when sodium sulfate is used or 15 percent when magnesium sulfate is used.

6.2. Aggregate failing to meet the requirements of Section 6.1 may be accepted, provided that mortar of comparable properties made from similar aggregates from the same source has been exposed to weathering, similar to that to be encountered, for a period of more than 5 years without appreciable disintegration.

7. METHODS OF SAMPLING AND TESTING

7.1. Sample and test the aggregate in accordance with the following procedures:

7.1.1. *Sampling*—T 2,

7.1.2. *Sieve Analysis and Fineness Modulus*—T 27,

7.1.3. *Amount of Material Finer Than 75-µm (No. 200) Sieve*—T 11,

7.1.4. *Organic Impurities*—T 21,

7.1.5. *Effect of Organic Impurities on Strength*—T 71,

7.1.6. *Clay Lumps and Friable Particles*—T 112,

7.1.7. *Lightweight Constituents*—T 113, and

7.1.8. *Soundness*—T 104.

7.1.9. *Density*—Determine the bulk specific gravity (oven dry basis) of the fine aggregate in accordance with T 84. The specific gravity equals the density expressed in units of g/cm^3. The density of the fine aggregate in g/cm^3 is used in the calculation of the air content of the mortars, as required by ASTM C 270.

---

[1] Except for Sections 5.1 and 7.1.6, this specification is identical to ASTM C 144-04.

Standard Specification for

Coarse Aggregate for Hydraulic Cement Concrete

AASHTO Designation: M 80-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Coarse Aggregate for Hydraulic Cement Concrete

AASHTO Designation: M 80-08

1. SCOPE

1.1. This specification covers coarse aggregate, other than lightweight aggregate, for use in concrete. Several classes and gradings of coarse aggregate are described (Notes 1 and 2).

Note 1—This specification is regarded as adequate to ensure satisfactory materials for most concrete. It is recognized that, for certain work or in certain regions, it may be either more or less restrictive than needed.

Note 2—Definitions of terms used in this specification may be found in ASTM C 125.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 43, Sizes of Aggregate for Road and Bridge Construction
- M 92, Wire-Cloth Sieves for Testing Purposes
- T 2, Sampling of Aggregates
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 19M/T 19, Bulk Density (“Unit Weight”) and Voids in Aggregate
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 96, Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine
- T 104, Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate
- T 112, Clay Lumps and Friable Particles in Aggregate
- T 113, Lightweight Pieces in Aggregate
- T 303, Accelerated Detection of Potentially Deleterious Expansion of Mortar Bars Due to Alkali-Silica Reaction

2.2. *ASTM Standards*:

- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates
- C 227, Standard Test Method for Potential Alkali Reactivity of Cement-Aggregate Combinations (Mortar-Bar Method)
- C 289, Standard Test Method for Potential Alkali-Silica Reactivity of Aggregates (Chemical Method)
- C 295, Standard Guide for Petrographic Examination of Aggregates for Concrete

- C 586, Standard Test Method for Potential Alkali Reactivity of Carbonate Rocks as Concrete Aggregates (Rock Cylinder Method)
- C 1260, Standard Test Method for Potential Alkali Reactivity of Aggregates (Mortar-Bar Method)
- C 1293, Standard Test Method for Determination of Length Change of Concrete Due to Alkali-Silica Reaction
- STP 169D, Significance of Tests and Properties of Concrete and Concrete-Making Materials

3. ORDERING INFORMATION

3.1. The purchaser or specifier shall include the following information in the purchase order or contract documents:

3.1.1. Reference to this specification, M 80, and year of issue;

3.1.2. Grading to be furnished (Size No.) (Section 5.1);

3.1.3. Class designation of aggregate (Section 6.1 and Table 2);

3.1.4. In the case of the sulfate soundness test (Table 2), which salt is to be used. If none is stated, either salt may be used;

3.1.5. Whether the restriction on reactive materials applies (Section 6.2); and

3.1.6. Any exceptions or additions to this specification.

4. GENERAL CHARACTERISTICS

4.1. Coarse aggregate shall consist of gravel, crushed gravel, crushed stone, crushed air-cooled blast-furnace slag, or crushed concrete, or a combination thereof, conforming to the requirements of this specification.

5. GRADING

5.1. Coarse aggregates shall conform to the requirements prescribed in M 43 for the size number specified.

Note 3—The ranges shown in M 43 are by necessity very wide in order to accommodate nationwide conditions. For quality control of any specific operation, a producer should develop an average gradation for the particular source and production facilities, and control the gradation within reasonable tolerances from this average. Where coarse aggregate sizes numbers 357 or 467 are used, the aggregate should be furnished in at least two separate sizes.

6. DELETERIOUS SUBSTANCES AND PHYSICAL PROPERTIES

6.1. Coarse aggregates shall conform to the limits given in Table 2 for the class specified, except as provided in Section 6.3 (Notes 4 and 5).

Note 4—Aggregate conforming to the requirements for the various classes should generally be suitable for the following uses as shown in Table 1.

Note 5—The purchaser or specifier, due to his knowledge of the requirements for concrete aggregates for specific uses in specific areas, may wish to supplement the requirements of Table 2 by placing limits on the amount of local deleterious substances permitted.

Table 1—Typical Uses for Aggregate Conforming to the Requirements for the Various Classes

Typical Uses (Suggested)	Weathering Exposure	Class of Aggregate
Architectural concrete, bridge decks, other uses where surface disfigurement due to popouts, etc., is objectionable	Severe	A
	Moderate	B
	Negligible	C
Concrete pavements, base courses, sidewalks where a moderate number of popouts can be tolerated	Severe	B
	Moderate	C
	Negligible	D
Concealed concrete not exposed to the weather: footings, structural members to be covered by a facing material, interior floors, etc.	—	E

Table 2—Limits for Deleterious Substances and Physical Property Requirements of Coarse Aggregate for Concrete

	Maximum Allowable Percent						
Class Designation	Clay Lumps and Friable Particles	Chert (Less Than 2.40 sp gr SSD)[a]	Sum of Clay Lumps, Friable Particles, and Chert (Less Than 2.40 sp gr SSD)[a]	Material Finer Than 75-µm (No. 200) Sieve	Coal and Lignite	Abrasion[b]	Sodium Sulfate Soundness (5 Cycles)[c]
A	2.0	3.0	3.0	1.0[d]	0.5	50	12
B	3.0	3.0	5.0	1.0[d]	0.5	50	12
C	5.0	5.0	7.0	1.0[d]	0.5	50	12
D	5.0	8.0	10.0	1.0[d]	0.5	50	12
E	10.0	—	—	1.0[d]	1.0	50	—

[a] These limitations apply only to aggregate in which chert appears as an impurity. They are not applicable to gravels that are predominantly chert. Limitations on soundness of such aggregate must be based on service records in the environment in which they are used.

[b] Crushed air-cooled, blast-furnace slag is excluded from the abrasion requirements. The unit mass (by rodding or jigging) of crushed air-cooled blast-furnace slag shall be not less than 1120 kg/m^3 (70 lb/ft^3). The grading of slag used in the unit mass test shall conform to the grading to be used in the concrete. Abrasion loss of gravel, crushed gravel, or crushed stone shall be determined on the test size or sizes most nearly corresponding to the grading or gradings to be used in the concrete. When more than one grading is to be used, the limit on abrasion loss shall apply to each.

[c] The allowable limits for soundness shall be 18 percent if magnesium sulfate is used. If the salt to be used is not designated, the aggregate will be acceptable if it meets the indicated limit for either sodium sulfate or magnesium sulfate.

[d] In the case of crushed aggregates, if the material finer than the 75-µm (No. 200) sieve consists of the dust fraction, essentially free of clay or shale, this percentage may be increased to 1.5.

6.2. Coarse aggregate for use in concrete that will be subject to wetting, extended exposure to humid atmosphere, or contact with moist ground shall not contain any materials that are deleteriously reactive with the alkalies in the cement in an amount sufficient to cause excessive expansion of mortar or concrete, except that if such materials are present in injurious amounts, the coarse aggregate may be used with the addition of a material that has been shown to prevent harmful expansion due to the alkali-aggregate reaction. (See Supplementary Requirement S1 and Appendix X1.)

6.3. Coarse aggregate having test results exceeding the limits specified in Table 2 may be accepted provided that concrete made with similar aggregate from the same source has given satisfactory service when exposed in a similar manner to that to be encountered, or, in the absence of a demonstrable service record—provided that the aggregate produces concrete having satisfactory relevant properties when tested in the laboratory.

Note 6—Relevant properties are those properties of the concrete that are important to the particular application being considered. ASTM Special Technical Publication 169D provides a discussion of important concrete properties.

7. METHODS OF SAMPLING AND TESTING

7.1. Sample and test the aggregates in accordance with the following methods of the American Association of State Highway and Transportation Officials, except as otherwise provided in this specification. Make the required tests on test samples that comply with requirements of the designated test methods. The same test sample may be used for sieve analysis and for determination of material finer than the 75-µm (No. 200) sieve. Separated sizes from the sieve analysis may be used in preparation of samples for soundness or abrasion tests. For determination of all other tests and for evaluation of potential alkali reactivity where required, use independent test samples.

7.1.1. *Sampling*—T 2;

7.1.2. *Grading*—T 27;

7.1.3. *Amount of Material Finer than 75-µm (No. 200) Sieve*—T 11;

7.1.4. *Soundness*—T 104;

7.1.5. *Clay Lumps and Friable Particles*—T 112;

7.1.6. *Coal and Lignite*—T 113, using a liquid of 2.0 specific gravity to remove the particles of coal and lignite; only material that is brownish-black, or black, shall be considered coal or lignite; coke shall not be classed as coal or lignite;

7.1.7. *Unit Mass of Slag*—T 19M/T 19 using the procedure for unit mass by rodding or jigging; and

7.1.8. *Abrasion*—T 96.

SUPPLEMENTARY REQUIREMENT

The following supplementary requirement applies only when specifically stated in the order or contract.

S1. REACTIVE AGGREGATE

S1.1. *Potential Reactivity of Siliceous Aggregates*—Alkali-silica reactions shall be mitigated either by a performance specification as given in S1.1.1 or a prescriptive specification as given in S1.1.2:

S1.1.1. *Performance Type*—One of the following options shall be used:

S1.1.1.1. Obtain a service record of the aggregate in a service condition at least as severe as that in which it is intended to be used, with similar cementitious materials having similar alkali content. If satisfactory, no mitigation is necessary.

S1.1.1.2. Test the aggregate in accordance with T 303, ASTM C 1260, or ASTM C 1293. If the expansion is less than 0.10 percent at 14 days after initial reading when tested in accordance with T 303 or ASTM C 1260, or less than 0.04 percent at 1 year with ASTM C 1293, no mitigation is necessary.

S1.1.1.3. If reactive aggregates are used, testing shall be performed using the proposed materials (aggregates, cementitious, and supplementary materials) in proportions to be used on the project according to the selected test method(s). Selection of appropriate test methods to evaluate mitigation effectiveness shall be based on the procedure’s ability to identify behavior of materials that correlate well with field performance. An example of a test that has been used to evaluate deleterious expansion and effectiveness of mitigation is T 303.

S1.1.1.4. If specified, T 303 test shall be used with the pozzolan or slag or blended cements to detect the potential for deleterious expansion. The test shall be performed by using 440 grams of the proposed blended cementitious materials, in the proportion to be used on the project, and 990 grams of the combined aggregates, in the proportions to be used on the project. For acceptance using T 303, the expansion shall not exceed 0.10 percent at 14 days.

S1.1.2. *Prescriptive Type*—Use of prescriptive methods may not be adequate to prevent alkali-silica reactions for every combination of materials in all service environments. Limits and properties established in prescriptive methods utilized by an agency should be based on proven field performance of locally available materials. One of the following options shall be used:

S1.1.2.1. Select aggregates with proven field performance when similar cementitious materials having similar alkali content are used.

S1.1.2.2. Use varying percentage of pozzolan or slag for different levels of alkali content of cement.

S1.1.2.3. Use lithium salts at a dosage rate of 1:1 $LiOH.H_2O$: equivalent Na_2O in the portland cement.

APPENDIX

(Nonmandatory Information)

X1. METHODS FOR EVALUATING POTENTIAL REACTIVITY OF AN AGGREGATE

X1.1. A number of methods for detecting potential reactivity have been proposed. However, they do not provide quantitative information on the degree of reactivity to be expected or tolerated in service. Therefore, evaluation of potential reactivity of an aggregate should be based upon judgment and on the interpretation of test data and examination of concrete structures containing a combination of fine and coarse aggregates and cements for use in the new work. Results of the following tests will assist in making the evaluation:

X1.1.1. *ASTM C 295*—Certain materials are known to be reactive with the alkalies in cements. These include the following forms of silica: opal, chalcedony, tridymite, and cristobalite; intermediate to acid (silica-rich) volcanic glass such as is likely to occur in rhyolite, andesite, or dacite; and certain constituents of some phyllites. Determination of the presence and quantities of these materials by petrographic examination is helpful in evaluating potential alkali reactivity. Some of these materials render an aggregate deleteriously reactive when present in quantities as little as 1.0 percent or even less.

X1.1.2. *ASTM C 289*—In this test, aggregates represented by points lying to the right of the solid line of Figure 2 of ASTM C 289 usually should be considered potentially reactive.

X1.1.2.1. If R_c exceeds 70, the aggregate is considered potentially reactive if S_c is greater than R_c.

X1.1.2.2. If R_c is less than 70, the aggregate is considered potentially reactive if S_c is greater than $35 + (R_c/2)$.

X1.1.2.3. These criteria conform to the solid line curve given in Figure 2 of ASTM C 289. The test can be made quickly and, while not completely reliable in all cases, can provide helpful information, especially where results of the more time-consuming tests are not available.

X1.1.3. *ASTM C 227*—The results of this test, when made with a high-alkali cement, furnish information on the likelihood of harmful reactions occurring. The alkali content of the cement should be substantially above 0.6 percent (preferably above 0.8 percent) expressed as sodium oxide. Combinations of aggregate and cement, which have produced excessive expansions in this test, usually should be considered potentially reactive. While the line of demarcation between nonreactive and reactive combinations is not clearly defined, expansion is generally considered to be excessive if it exceeds 0.05 percent at 3 months or 0.10 percent in 6 months. Expansions greater than 0.05 percent at 3 months should not be considered excessive where the 6-month expansion remains below 0.10 percent. Data for the 3-month tests should be considered only when 3-month results are not available.

X1.1.3.1. In addition to its usefulness in research, this test method has been found useful in the selection of aggregates of the so-called "sand-gravel" type found mainly in some parts of Kansas, Nebraska, and Iowa, which contain very little coarse material, generally 5 to 15 percent retained on the 4.75-mm (No. 4) sieve. Much work has been done on the problems of using these aggregates successfully in concrete and is reported in summary in the "Final Report of Cooperative Tests of Proposed Tentative Method of Test for Potential Volume Change of Cement-Aggregate Combinations," Appendix to *Committee C-9 Report*, Proceedings, ASTM, Volume 54, 1954, p. 356. It indicates that cement-aggregate combinations tested by this procedure in which expansion equals or exceeds 0.200 percent at an age of 1 year may be considered unsatisfactory for use in concrete exposed to wide variations of temperature and degree of saturation with water. In that geographical region, the problem has been reduced through the use of partial replacement of the "sand-gravel" with limestone coarse aggregate.

X1.2. *Potential Reactivity of Carbonate Aggregates*—The reaction of the dolomite in certain carbonate rocks with alkalies in portland cement paste has been found to be associated with deleterious expansion of concrete containing such rocks as coarse aggregate. Carbonate rocks capable of such reaction possesses a characteristic texture and composition. The characteristic texture is that in which large crystals of dolomite are scattered in a finer-grained matrix of calcite and clay. The characteristic composition is that in which the carbonate portion consists of substantial amounts of both dolomite and calcite, and the acid-insoluble residue contains a significant amount of clay. Except in certain areas, such rocks are of relatively infrequent occurrence and seldom make up a significant proportion of the material present in a deposit of rock being considered for use in making aggregate for concrete. ASTM C 586 has been successfully used in (1) research and (2) preliminary screening of aggregate sources to indicate the presence of material with a potential for deleterious expansions when used in concrete.

Standard Specification for

Lightweight Aggregates for Structural Concrete

AASHTO Designation: M 195-06
ASTM Designation: C 330-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Lightweight Aggregates for Structural Concrete

AASHTO Designation: M 195-06
ASTM Designation: C 330-04

1. SCOPE

1.1. This specification covers lightweight aggregates intended for use in structural concrete in which the prime considerations are reducing the density while maintaining compressive strength of the concrete. Procedures covered in this specification are not intended for job control of concrete.

1.2. The values stated in SI units are to be regarded as the standard. The values shown in parentheses are for information purposes only.

1.2.1. With regard to other units of measure, the values stated in inch-pound units are to be regarded as standard.

1.3. The text of this standard references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

Note 1—This specification is regarded as adequate to ensure satisfactory lightweight aggregates for most concrete. It is recognized that it may be either more or less restrictive than needed for some conditions and for special purposes, such as fire resistance, fill, and concrete constructions, the use of which is based on load tests rather than conventional design procedures.

- C 641, Standard Test Method for Iron Staining Materials in Lightweight Concrete Aggregates

2.3. *ACI Standard*:

- ACI 211.2, Standard Practice for Selecting Proportions for Structural Lightweight Concrete

3. GENERAL CHARACTERISTICS

3.1. Two general types of lightweight aggregates are covered by this specification, as follows:

3.1.1. Aggregates prepared by expanding, pelletizing or sintering products such as blast-furnace slag, clay, diatomite, fly ash, shale, or slate; and

3.1.2. Aggregates prepared by processing natural materials, such as pumice, scoria, or tuff.

3.2. The aggregates shall be composed predominately of lightweight-cellular and granular inorganic material.

4. CHEMICAL COMPOSITION

4.1. Lightweight aggregates shall not contain excessive amounts of deleterious substances, as determined by the following limits:

4.1.1. *Organic Impurities—T 21*. Lightweight aggregates that, upon being subjected to test for organic impurities, produce a color darker than the standard shall be rejected, unless it is demonstrated that the discoloration is due to small quantities of materials not harmful to the concrete.

4.1.2. *Staining—ASTM C 641*. An aggregate producing a heavy stain index 60 or higher shall be rejected when the deposited stain is found upon chemical analysis to contain an iron content, expressed as Fe_2O_3, equal to or greater than 1.5 mg/200 g of sample.

4.1.3. *Loss on Ignition—T 105*. The loss on ignition of lightweight aggregates shall not exceed 5 percent.

Note 2—Some aggregates may contain carbonates or water of hydration that contribute to loss on ignition, but may not affect the quality of the product. Therefore, when evaluating an aggregate, consideration should be given to the material characteristics that cause the ignition loss.

5. PHYSICAL PROPERTIES

5.1. Lightweight aggregate under test shall meet the following requirements:

5.1.1. *Clay Lumps and Friable Particles*—The total amount of clay lumps and friable particles shall not exceed 2 percent by dry mass.

5.1.2. *Grading*—The grading shall conform to the requirements shown in Table 1.

Table 1—Grading Requirements for Lightweight Aggregates for Structural Concrete

	Percentages (Mass) Passing Sieves Having Square Openings								
Nominal Size Designation	25.0 mm (1 in.)	19.0 mm ($^{3}/_{4}$ in.)	12.5 mm ($^{1}/_{2}$ in.)	9.5 mm ($^{3}/_{8}$ in.)	4.75 mm (No. 4)	2.36 mm (No. 8)	1.18 mm (No. 16)	300 µm (No. 50)	150 µm (No. 100)
Fine aggregate:									
4.75 mm to 0	—	—	—	100	85–100	—	40–80	10–35	5–25
Coarse aggregate:									
25.0 to 4.75 mm	95–100	—	25–60	—	0–10	—	—	—	—
19.0 to 4.75 mm	100	90–100	—	10–50	0–15	—	—	—	—
12.5 to 4.75 mm	—	100	90–100	40–80	0–20	0–10	—	—	—
9.5 to 2.36 mm	—	—	100	80–100	5–40	0–20	0–10	—	—
Combined fine and coarse aggregate:									
12.5 mm to 0	—	100	95–100	—	50–80	—	—	5–20	2–15
9.5 mm to 0	—	—	100	90–100	65–90	35–65	—	10–25	5–15

Note 3—The surfaces of pyro-processed lightweight aggregate particles finer than 75-µm (No. 200) sieves are not deleterious and may be moderately pozzolanic.

5.1.3. *Uniformity of Grading*—To ensure reasonable uniformity in the grading of successive shipments of lightweight aggregate, fineness modulus shall be determined on samples taken from shipments at intervals stipulated by the purchaser. If the fineness modulus of the aggregate in any shipment differs by more than 7 percent from that of the sample submitted for acceptance tests, the aggregate in the shipment shall be rejected, unless the supplier demonstrates that it will produce concrete of the required characteristics.

5.1.4. *Bulk Density (Dry Loose)*—The dry loose bulk density of the lightweight aggregates shall conform to the requirements shown in Table 2.

Table 2—Maximum Dry Loose Bulk Density Requirements of Lightweight Aggregates for Structural Concrete

Size Designation	Maximum Dry Loose Bulk Density, kg/m^3 (lb/ft^3)
Fine aggregate	1120 (70)
Coarse aggregate	880 (55)
Combined fine and coarse aggregate	1040 (65)

5.1.5. *Uniformity of Bulk Density (Dry Loose)*—The dry loose bulk density of lightweight aggregate shipments, sampled and tested, shall not differ by more than 10 percent from that of the sample submitted for acceptance tests, but the dry loose bulk density shall not exceed the limits in Table 2.

5.1.6. *Density Factor*—When specified, the density factor shall be determined in accordance with Section 8.9.

5.2. Concrete specimens containing lightweight aggregate under test shall meet the following requirements:

5.2.1. *Compressive Strength—T 22, Density—ASTM C 567, and Splitting Tensile Strength—T 198*. Compressive strength and density shall be an average of three specimens and the splitting tensile strength shall be the average of eight specimens. It shall be possible to produce structural concrete using the lightweight aggregates under test, so that from the same batch of concrete one or more of the compressive strength requirements and splitting tensile strength requirements in the Table 3 will be satisfied without exceeding the corresponding maximum bulk density values.

Table 3—Compressive and Tensile Strength Requirements

Calculated Equilibrium Density, max kg/m^3 (lb/ft^3)	Average 28-day Splitting Tensile Strength, min MPa (psi)	Average 28-day Compressive Strength, min MPa (psi)
	All Lightweight Aggregate	
1760 (110)	2.2 (320)	28 (4000)
1680 (105)	2.1 (300)	21 (3000)
1600 (100)	2.0 (290)	17 (2500)
	Sand/Lightweight Aggregate	
1840 (115)	2.3 (330)	28 (4000)
1760 (110)	2.1 (310)	21 (3000)
1680 (105)	2.1 (300)	17 (2500)

Note 4—Intermediate values for strength and corresponding density values shall be established by interpolation. Materials that do not meet the minimum average splitting tensile strength requirement may be used provided the design is modified to compensate for the lower value.

5.2.2. *Natural Aggregates*—Natural aggregates, when used to replace part or all of the lightweight-aggregate fines, shall comply with the applicable requirements of M 6. The test report shall record the proportion of all ingredients and the characteristics of the natural aggregates to ensure compliance with these minimum requirements.

5.2.3. *Drying Shrinkage*—The drying shrinkage of concrete specimens prepared, cured, and tested in accordance with Section 8.4 shall not exceed 0.07 percent.

5.2.4. *Popouts*—Concrete specimens prepared as described in the method for preparation of sample for shrinkage of concrete and tested in accordance with T 107 shall show no surface popouts.

5.2.5. *Resistance to Freezing and Thawing*—When required, the aggregate supplier shall demonstrate by test or proven field performance that the lightweight aggregate when used in concrete, had the necessary resistance to freezing and thawing to perform satisfactorily in its intended use.

6. SAMPLING

6.1. Sample lightweight aggregates in accordance with T 2.

6.2. Reduce sample to test size in accordance with T 248.

7. NUMBER OF TESTS

7.1. *Tests on Aggregate*—One representative sample is required for each test for organic impurities, staining, loss on ignition, grading, bulk density, and clay lumps.

7.2. *Tests on Concrete*—At least three specimens are required for each of the following tests of concrete: compressive strength, shrinkage, density, resistance to freezing and thawing, and presence of popout materials. At least eight concrete specimens are required for splitting tensile strength tests.

8. TEST METHODS

8.1. *Compressive Strength—T 22*. Make test specimens in accordance with R 39. Unless otherwise specified, cure specimens in accordance with R 39 until the time of test. When specified, an alternative curing method is allowed. The alternative method shall be in accordance with R 39 for the first seven days, after which the specimens shall be removed from the moist curing and stored at 23 ± 2ºC (73.5 ± 3.5ºF) with a relative humidity of 50 ± 5 percent until the time of test.

8.2. *Splitting Tensile Strength*—Make 152 by 305 mm (6 by 12 in.) cylindrical test specimens in accordance with R 39, cure, and test in accordance with T 198.

8.3. *Density of Concrete—ASTM C 567*. Follow the procedures in ASTM C 567.

8.4. *Shrinkage of Concrete—T 160*. Follow the procedures of T 160 with the following exceptions:

8.4.1. Prepare the concrete mixture using 335 kilograms of cement per cubic meter (564 pounds of cement per cubic yard), admixture (if any), and with an air content of 6 ± 1 percent. Adjust the water content so as to produce a slump of 50 to 100 mm (2 to 4 in.). Thoroughly consolidate the concrete in steel molds not smaller than 50 by 50 mm (2 by 2 in.) nor larger than 100 by 100 mm (4 by 4 in.) in cross section, and long enough to provide a 250-mm (10-in.) gauge length. The surface of the concrete shall be steel troweled.

8.4.2. *Curing*—To prevent evaporation of water from the unhardened concrete, cover the specimen with a nonabsorptive, nonreactive plate or sheet of tough, durable, impervious plastic or wet burlap. When wet burlap is used for covering, the burlap must be kept wet until the specimens are removed from the molds. (See Note 5.) Remove specimens from the molds not less than 20 nor more than 48 hours after casting and store in a moist room maintained at 23 ± 2ºC (73.5 ± 3.5ºF) with a relative humidity of not less than 95 percent. At the age of seven days, remove the specimens from the moist room, measure for length, and store in a curing cabinet maintained at 37.8 ± 1.1ºC (100 ± 2ºF) with a relative humidity of 32 ± 2 percent.

Note 5—Placing a sheet of plastic over the burlap will facilitate keeping it wet.

Note 6—The air immediately above a saturated solution of magnesium chloride ($MgCl_2$) at 37.8ºC (100ºF) is approximately 32 percent relative humidity.

8.4.3. *Report*—After storage in the cabinet for 28 days, determine the change in length of each specimen to the nearest 0.01 percent of the effective gauge length. Report the change in length as the drying shrinkage of the specimen; report the average drying shrinkage of the specimens as the drying shrinkage of the concrete.

8.5. *Test for Popout Materials*—Prepare concrete specimens for the test for popout materials as described in method for preparation of samples for shrinkage of concrete. Cure and autoclave the specimens in accordance with T 107. Visually inspect the autoclaved specimens for the number of popouts that have developed on the surface. Report the average number of popouts per specimen.

8.6. *Test for Freezing and Thawing*—Make freezing and thawing tests of concrete, when required, in accordance with T 161, with the following modification to the section on Test Specimens and on Procedure. Unless otherwise specified, remove the lightweight aggregate concrete specimens from moist curing at an age of 14 days and allow to air dry for another 14 days exposed to a relative humidity of 50 ± 5 percent and a temperature of 23 ± 2ºC (73.5 ± 3.5ºF). Then submerge the specimens in water for 24 hours, prior to the freezing and thawing test.

Table 4—Mass of Sieve Test Sample for Fine Lightweight Aggregates

Nominal Bulk Density (Loose) of Aggregate		Mass of Test Sample, g
kg/m^3	lb/ft^3	
80–240	5–15	50
240–400	15–25	100
400–560	25–35	150
560–720	35–45	200
720–880	45–55	250
880–1040	55–65	300
1040–1120	65–70	350

8.7. *Bulk Density (Loose)—T 19M/T 19.* The aggregate shall be tested in an oven dry condition utilizing the shoveling procedure.

8.8. *Clay Lumps and Friable Particles in Aggregates*—Shall be in accordance with T 112.

8.9. *Density Factor*—Determine the Density (“Specific Gravity”) Factor in accordance with ACI 211.2.

9. REJECTION

9.1. Material that fails to conform to the requirements of this specification shall be subject to rejection. Rejection shall be reported to the producer or supplier promptly and in writing.

10. CERTIFICATION

10.1. When specified in the purchase order or contract, a producer’s or supplier’s certification shall be furnished to the purchaser that the material was manufactured, sampled, and tested in accordance with this specification and has been found to meet the requirements. When specified in the purchase order or contract, a report of the test results shall be furnished.

Standard Specification for

Processing Additions for Use in the Manufacture of Hydraulic Cements

AASHTO Designation: M 327-09
ASTM Designation: C 465-99 (2005)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Processing Additions for Use in the Manufacture of Hydraulic Cements

AASHTO Designation: M 327-09
ASTM Designation: C 465-99 (2005)

1. SCOPE

1.1. This specification pertains to the criteria and tests to be used for determining whether an organic or inorganic processing addition, when used in the recommended amount at the option of the cement producer in the manufacture of hydraulic cements, meets the requirements as prescribed by definition in M 85 and M 240 as well as ASTM C 1157 and C 845. The materials listed in the following former AASHTO and ASTM specifications shall be considered as meeting the organic processing additions requirements of this specification:

- M 85-57 I, for Portland Cement
- ASTM C 205-58 T, for Portland Blast-Furnace Slag Cement
- ASTM C 340-58 T, for Portland-Pozzolan Cement
- ASTM C 358-58, for Slag Cement

1.2. *The following safety hazards caveat pertains only to the test methods described in this specification. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. MATERIALS

3.1. *Cements:*

3.1.1. In cases where it is desired that the proposed organic processing addition be accepted for general use in portland cement, tests shall be made on cements prepared from at least five different clinkers. As a minimum, these clinkers shall represent two Type I cements containing not less than 9.0 percent C_3A, one Type II cement, and two Type III cements, all conforming to M 85.

3.1.2. In cases where it is also desired that the proposed organic processing addition be used in blended cements, the test and test procedures shall be as specified with a control and an addition for cement conforming to the appropriate M 240 or ASTM C 1157.

3.1.3. Organic processing additions that have been shown to meet the requirements of this specification may also be used in cements conforming to ASTM C 845. Testing of the addition with these special cements, where desired, shall be done using the tests and test procedures as specified with a control cement and a cement containing the addition, both conforming to ASTM C 845.

3.1.4. In cases where it is desired that the proposed organic processing addition be limited in use to specific types of cement less in number than required in 3.1.1, the tests and test procedures shall be as specified, and at least two pairs of cements shall be prepared from two clinkers from different plants for each type under specific consideration.

3.1.5. For inorganic processing additions, or in cases where it is desired that the proposed organic processing addition be limited in use to a single plant, the tests and test procedures shall be as specified and at least two pairs of cements shall be prepared from clinkers representing each type under specific consideration.

3.1.6. The two companion cements to be made from any one clinker shall be ground to the same fineness within 7 m^2/kg when tested in accordance with T 98 or within 13 m^2/kg when tested in accordance with T 153, and the SO_3 content, expressed as a percentage of the cement mass and reported to the nearest 0.01 percent, shall differ by not more than 0.3, so as to afford comparable samples for indicating the effect of the addition on the cement. Each control cement shall comply with all requirements in the specification applicable to that type of cement, and shall not contain the proposed addition when tested by the method furnished by the producer or seller of the addition.

3.1.7. The percentage of each of the following shall be determined for each lot of cement tested: silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), ferric oxide (Fe_2O_3), calcium oxide (CaO), magnesium oxide (MgO), sulfur trioxide (SO_3), ignition loss, insoluble residue, sodium oxide (Na_2O), and potassium oxide (K_2O). There shall also be calculated the potential percentages of the following compounds: tricalcium silicate, dicalcium silicate, tricalcium aluminate, and tetracalcium aluminoferrite. Determinations for the percentage of the addition shall be made, both on the control cements and on those with which the addition was interground, using the method proposed therefore by the sponsor.

3.2. *Aggregates*—The fine and coarse aggregates shall comply with M 6 and M 80; the coarse aggregate shall comply with the grading requirements for Size No. 57 or Size No. 67. A sufficient quantity from a single lot of coarse aggregate and from a single lot of fine aggregate shall be provided to complete all tests. To prevent the segregation of particle sizes in the fine aggregate, a single lot of sand sufficient for all tests shall either (1) be separated on the 4.75-mm (No. 4), 1.18-mm (No. 16), 300-µm (No. 50), and 150-µm (No. 100) sieves and then be recombined in the required quantity for each batch; or (2) be blended while in a damp condition, and maintained in that condition for the duration of the tests. Under option (2), lots of appropriate size for single mortar and concrete batches shall be carefully split or quartered from the entire batch.

4. GENERAL REQUIREMENTS

4.1. Processing additions shall conform to the respective requirements in this specification.

4.2. The trade name, source, character of the material, and means for the quantitative determination of the addition in the finished cement shall be furnished by the sponsor, manufacturer, or supplier of the addition, and the information shall form a part of the record of tests of the addition. If the processing addition is a liquid, the specific gravity and percent water content shall also be part of the record. If the processing addition is an inorganic solid, the allowable ranges of chemical analysis and specific gravity of the addition shall also be part of the record.

4.2.1. The specific gravity, run in accordance with Section 7.1.1 shall be within ±0.05 units of the value reported in Section 4.2.

4.2.2. The chemical analysis in Section 7.2.1 and specific gravity in Section 7.2.2 shall be within the ranges given in Section 4.2.

4.3. Processing additions shall be evaluated by comparing cements containing the addition to otherwise identical cements from the same source without the addition, or containing one processing addition that has been shown to comply with this specification using control cements without any additions, hereinafter designated the “control” cement.

4.4. The amount of the processing addition to be interground with the cement for evaluation purposes shall be determined by the sponsor of the addition.

4.4.1. The amount of the addition in the cement containing the addition and showing compliance with the requirements of this specification shall be determined quantitatively by means of the quantitative determination required by Section 4.2.

4.4.2. The amount of addition, so determined, shall be used to state the amount of addition that shows compliance with this specification.

4.4.3. When tests on cements containing the addition show compliance with the requirements of this specification, the addition in cement may be used in any amount up to the maximum amount showing compliance.

4.5. The cement produced for evaluation purposes with the processing addition shall comply with the appropriate specifications M 85 or M 240 and ASTM C 845 or C 1157, except that it contains the addition under test. The effect of the addition on the properties of the cement shall also be within the following limits:

4.5.1. The percentage of water by mass of cement required for normal consistency of cement containing the addition shall not exceed that required by the corresponding control cement by more than 1.0 percent. For those cements not limited to a fixed water requirement, the percentage of water by mass of cement required for standard consistency of the mortar used for strength determinations as described in Section 4.5.4 shall not be increased by more than 2.0 percent by the addition over that required for the control cement.

4.5.2. The time of setting of cement containing the addition shall not vary from the time of setting of the corresponding control cement by more than 1 h or 50 percent, whichever is the lesser.

4.5.3. The autoclave expansion of cement containing the addition, expressed as a percentage change in length, shall not be more than 0.10 percent greater than that of the corresponding control cement.

4.5.4. The compressive strength of mortar cubes made with cement containing the addition, in accordance with T 106M/T 106, and tested at 1, 3, 7, and 28 days for all types, shall be compared with strengths obtained with the control cement at similar ages. The grand average of these individual strength percentages shall not be less than 95 percent of the control cement values. It is required that cubes for companion cements be made and tested on the same days, with storage of specimens side by side in the same section of the moist cabinet during the 24-h curing period. Retesting of companion cements on the same, or a following, day is required in order to provide six, rather than three, test specimens for each cement and age of test.

4.5.5. The ultimate drying shrinkage of mortar made with cement containing the addition shall not be more than 0.025 percent greater than that of similar mortar made with the corresponding control cement when tested in accordance with ASTM C 596.

4.5.6. The compressive strength of the concrete made with cement containing the addition shall be compared with strengths obtained with the control cement at similar ages. The grand average of these individual strength percentages shall not be less than 90 percent of the values for the control cement.

4.5.7. The flexural strength of concrete made with cement containing the addition shall be compared with strengths obtained with the control cement at similar ages. The grand average of these individual strength percentages shall not be less than 90 percent of the values for the control cement.

4.5.8. The amount of air-entraining addition required to produce 19 ± 3 percent air in the mortar test made in accordance with T 137, with the cement containing the addition under test, shall not be greater than 120 percent of the amount required to produce, within ±1 percent, the air content obtained with the control cement. The air-entraining addition used shall meet the requirements of ASTM C 226.

4.6. Processing additions that provide maximum effects as grinding aids or pack set inhibitors may increase cement flowability to a point where mill retention time is reduced sufficiently to affect significantly the particle size distribution of the resulting cement and its physical-chemical properties. Mill retention times are controllable by mechanical means in full-scale grinding mills. Hence, the true physical-chemical effects of the test additive may be determined for acceptance purposes by making supplementary laboratory or pilot-mill grinds in instances where full-scale tests have shown mill retention time reductions to have significant effects on the properties of the resulting cement.

4.7. In the event that the effect of the addition on the properties of cement are determined on the basis of laboratory or pilot mill grinds, this fact shall be entered in the report specified in Section 13, and the specific tests shall be indicated.

5. SAMPLING CEMENT

5.1. Samples of the plant-ground cement shall be taken from the product stream during grinding. Prior to the start of sampling a given lot of cement, the mill shall have run for 4 h or long enough to have reached equilibrium under the general conditions that are to govern during the sampling period.

Note 1—Records should be kept as to the rate and continuity of feed of the addition, the form in which the addition is used, strength of solution (if applicable), magnitude of circulating loads, mill discharge temperature, and feed rate of clinker and gypsum. Product fineness should be determined during the grinding immediately subsequent to sampling.

5.2. As the cement samples are taken, they shall be placed in sealable containers that shall be sealed immediately at the end of the sampling period. Prior to use, the samples of a given lot of cement shall be thoroughly blended to form a uniform, representative composite.

6. TEST METHODS

6.1. Determine the properties enumerated in this specification in accordance with the test methods prescribed in Sections 7–12.

7. TESTS ON PROCESSING ADDITIONS

7.1. Test the liquid, organic processing addition, in the form normally marketed, in accordance with the following test methods:

7.1.1. *Specific Gravity*—Use ASTM D 891, Test Method A or B.

7.1.2. *Water Content*—Use ASTM E 203.

7.2. Conduct the following tests on solid, inorganic processing addition in accordance with the following test methods:

7.2.1. *Chemical Analysis*—Use T 105 to determine silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), ferric oxide (Fe_2O_3), calcium oxide (CaO), magnesium oxide (MgO), sulfur trioxide (SO_3), ignition loss, insoluble residue, sodium oxide (Na_2O), and potassium oxide (K_2O).

7.2.2. *Specific Gravity*—Use T 133 except use the inorganic processing addition instead of hydraulic cement.

8. TESTS ON CEMENT

8.1. Test cement in accordance with the following standards:

8.1.1. *Chemical Analysis of Cement*—T 105.

8.1.2. *Compound Composition*—M 85.

8.1.3. *Fineness of Cement*—T 98 or T 153.

8.1.4. *Normal Consistency*—T 129.

8.1.5. *Time of Setting (Vicat)*—T 131.

8.1.6. *Autoclave Expansion*—T 107.

8.1.7. *Air Content of Mortar*—T 137.

8.1.8. *Compressive Strength of Mortar*—T 106M/T 106.

8.1.9. *Drying Shrinkage of Mortar*—ASTM C 596.

9. CONCRETE MIXTURES

9.1. *Preparation and Weighing*—Prepare all materials used in making the concrete mixtures and make all weighings as prescribed in R 39. Report the amount of mixing water used in each batch on the basis of saturated, surface-dry aggregates.

9.2. *Proportions*—Design one basic concrete mixture having an actual cement content of 307 ± 3 kg/m^3 (517 ± 5 lb/yd^3), and use in all concrete tests herein specified. Adjust the water content of mixtures to provide concrete having a consistency equal to a 64 ± 13-mm ($2^1/_2 \pm {}^1/_2$-in.) slump in each case. Adjust the ratio of fine to coarse aggregate to the optimum for concrete to be consolidated by hand rodding. Recommended trial values for the percentage of fine aggregate in the total aggregate, by absolute volume, are as follows:

Coarse Aggregate, Max 25.0 mm (1 in.)	Concrete Without Entrained Air
Angular	45
Rounded	40

9.3. *Mixing of Concrete*—Mix the concrete in accordance with R 39 except as follows:

9.3.1. Hand mixing will not be permitted.

9.3.2. The rated capacity of the machine mixer shall not be more than twice the size of the batch used.

10. TESTS ON FRESHLY MIXED CONCRETE

10.1. Test samples of the freshly mixed concrete for slump in accordance with T 119; unit weight in accordance with T 121M/T 121; and air content in accordance with T 121M/T 121, T 152, or T 196M/T 196.

11. TEST SPECIMENS OF HARDENED CONCRETE

11.1. *Number of Specimens*—At least three specimens shall be made for each test condition. For each cement containing an addition and its companion control cement, make three rounds of concrete mixed on different days. One round of mixes on a given day shall include both the cement containing the addition and its companion control cement. From each round, make at least one test specimen for each test condition. To obtain enough concrete for all test specimens to be made in any one round, it may be necessary to make more than one concrete batch for each round.

11.2. *Types of Specimens:*

11.2.1. *Compressive Strength*—Compressive strength test specimens shall be cylinders made and cured as prescribed in R 39. Cylinders shall be capped as prescribed in T 231.

11.2.2. *Flexural Strength*—Flexural strength test specimens shall be beams made and cured as prescribed in R 39.

12. TESTS ON HARDENED CONCRETE

12.1. Test the specimens on hardened concrete, as specified in Section 11, in accordance with the following methods and at the specified ages:

12.1.1. *Compressive Strength*—Test specimens in accordance with T 22 at ages 3, 7, and 28 days, except also test Type III cement at 24 h.

12.1.2. Flexural Strength—Test specimens in accordance with T 177 or T 97, ages at 3, 7, and 28 days, except also test Type III cement at 24 h. By either method of test, turn the specimen on its side with respect to its position as molded and center it on the bearing blocks.

13. REPORT

13.1. The report covering the results of the evaluation of a material proposed for use as a processing addition in the manufacture of portland cement under this specification shall include the following information:

13.1.1. Trade name, source and character of the material, and the amount recommended for use, together with the means used for determining the amount of the proposed addition in the finished cement, all as furnished by the sponsor, manufacturer, or seller of the addition;

13.1.2. If the proposed processing addition is an organic liquid, the specific gravity and percent water content by mass;

13.1.3. If the proposed processing addition is an inorganic solid, report chemical analysis and specific gravity;

13.1.4. Detailed results of all analyses and tests prescribed by this specification, and the amount of the addition used, as well as other pertinent information required;

13.1.5. Comparison of test results to determine compliance with the requirements prescribed in Section 4.4;

13.1.6. Name and location of the laboratory or laboratories that made the tests covered by the report;

13.1.7. Include, as an appendix to the report, letters of certification from the various cement manufacturers stating the name of the addition, the amount used, and the type of cement in which it is used; and

13.1.8. The highest amount of addition that has demonstrated compliance with the specification in a particular type of cement (see Section 4.4.3).

14. MANUFACTURER’S CERTIFICATION PROCESSING ADDITIONS

14.1. *Organic Processing Additions*—Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at the time of shipment stating the water content and specific gravity of the samples of the material taken during production or transfer and certifying that the specific gravity value is within the specified limits of the originally qualified product and that the product meets the requirements of this specification.

14.2. *Inorganic Processing Additions*—Upon request of the purchaser in the contract or order, a manufacturer’s report shall be furnished at time of shipment stating the chemical analysis and specific gravity of the samples of the material taken during production or transfer and certifying that they are within the specified limits of the originally qualified product and that the product meets the requirements of this specification.

15. KEYWORDS

15.1. Additions; hydraulic cements; processing.

Standard Specification for

Cutback Asphalt (Rapid-Curing Type)

AASHTO Designation: M 81-92 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Cutback Asphalt (Rapid-Curing Type)

AASHTO Designation: M 81-92 (2008)

1. SCOPE

1.1 This specification covers liquid petroleum products, produced by fluxing an asphalt base with suitable petroleum distillates, to be used in the treatment of road surfaces.

1.2 The values stated in SI units are to be regarded as the standard.

2. GENERAL REQUIREMENTS

2.1 The cutback asphalt shall show no separation or curdling prior to use and shall not foam when heated to the application temperature.

3. PROPERTIES

3.1 Cutback asphalt of the grade designated shall conform to the requirements shown in Table 1.

4. METHODS OF SAMPLING AND TESTING

4.1 Sampling and testing cutback asphalt (rapid-curing type) shall be in accordance with the following AASHTO standards:

- T 40, Sampling Bituminous Materials
- T 44, Solubility of Bituminous Materials
- T 49, Penetration of Bituminous Materials
- T 51, Ductility of Asphalt Materials
- T 55, Water in Petroleum Products and Bituminous Materials by Distillation
- T 72, Saybolt Viscosity
- T 78, Distillation of Cutback Asphaltic (Bituminous) Products
- T 79, Flash Point with Tag Open-Cup Apparatus for Use with Material Having a Flash Point Less Than 93.3ºC (200ºF)
- T 102, Spot Test of Asphaltic Materials
- T 201, Kinematic Viscosity of Asphalts (Bitumens)
- T 202, Viscosity of Asphalts by Vacuum Capillary Viscometer

Table 1—Minimum and Maximum Cutback Asphalt Grade Requirements

	RC-70		RC-250		RC-800		RC-3000	
	Min	Max	Min	Max	Min	Max	Min	Max
Kinematic viscosity at 60˚C (140˚F),								
mm^2/s[a]	70	140	250	500	800	1600	3000	6000
Flash point (tag open-cup), degrees °C (°F)	—	—	27 (80)	—	27 (80)	—	27(80)	—
Water, percent	—	0.2	—	0.2	—	0.2	—	0.2
Distillation test:								
Distillation, percentage by volume of total								
distillate to 360˚C (680˚F)								
to 190˚C (374˚F)	10	—	—	—	—	—	—	—
to 225˚C (437˚F)	50	—	35	—	15	—	—	—
to 260˚C (500˚F)	70	—	60	—	45	—	25	—
to 315˚C (600˚F)	85	—	80	—	75	—	70	—
Residue from distillation to 360˚C (680˚F),				—				
volume percentage of sample by difference	55	—	65	—	75	—	80	—
Tests on residue from distillation:								
Absolute viscosity at 60˚C (140˚F),	60	240	60	240	60	240	60	240
Pa·s (P)[b]	(600)	(2400)	(600)	(2400)	(600)	(2400)	(600)	(2400)
Ductility, 5 cm/min at 25˚C (77˚F), cm	100	—	100	—	100	—	100	—
Solubility in Trichloroethylene, percent	99.0	—	99.0	—	99.0	—	99.0	—
Spot test[c] with:								
Standard naphtha	Negative for all grades							
Naphtha-xylene solvent, percent xylene	Negative for all grades							
Heptane-xylene solvent, percent xylene	Negative for all grades							

[a] As an alternate, Saybolt-Furol viscosities may be specified as follows:
Grade RC-70–Furol viscosity at 50˚C (122˚F)—60 to 120 s.
Grade RC-250–Furol viscosity at 60˚C (140˚F)—125 to 250 s.
Grade RC-800–Furol viscosity at 82.2˚C (180˚F)—100 to 200 s.
Grade RC-3000–Furol viscosity at 82.2˚C (180˚F)—300 to 600 s.

[b] In lieu of viscosity of the residue, the specifying agency, at its option, can specify penetration at 100 g, 5 s at 25˚C (77˚F) of 80 to 120 for Grades RC-70, RC-250, RC-800, and RC-3000. However, in no case will both viscosity and penetration be required.

[c] The use of the spot test is optional. When specified, indicate whether the standard naphtha solvent, naphtha-xylene solvent, or heptane-xylene solvent will be used in determining compliance with the requirement, and also, in the case of the xylene solvents, the percentage of xylene to be used.

Standard Specification for

Cutback Asphalt (Medium-Curing Type)

AASHTO Designation: M 82-75 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Cutback Asphalt (Medium-Curing Type)

AASHTO Designation: M 82-75 (2008)

1. SCOPE

1.1 This specification covers liquid petroleum products, produced by fluxing an asphaltic base with suitable petroleum distillates, to be used in the treatment of road surfaces.

1.2 The values stated in SI units are to be regarded as the standard.

2. GENERAL REQUIREMENTS

2.1 The cutback asphalt shall show no separation or curdling prior to use and shall not foam when heated to the application temperature.

3. PROPERTIES

3.1 Cutback asphalt of the grade designated shall conform to the requirements shown in Table 1.

4. METHODS OF SAMPLING AND TESTING

4.1 Sampling and testing cutback asphalt (medium-curing type) shall be in accordance with the following standard methods of the AASHTO standards:

- T 40, Sampling Bituminous Materials
- T 44, Solubility of Bituminous Materials
- T 49, Penetration of Bituminous Materials
- T 51, Ductility of Asphalt Materials
- T 55, Water in Petroleum Products and Bituminous Materials by Distillation
- T 72, Saybolt Viscosity
- T 78, Distillation of Cutback Asphaltic (Bituminous) Products
- T 79, Flash Point with Tag Open-Cup Apparatus for Use with Material Having a Flash Point Less Than 93.3°C (200°F)
- T 102, Spot Test of Asphaltic Materials
- T 201, Kinematic Viscosity of Asphalts (Bitumens)
- T 202, Viscosity of Asphalts by Vacuum Capillary Viscometer

Table 1—Minimum and Maximum Cutback Asphalt Grade Requirements

	MC-30		MC-70		MC-250		MC-800		MC-3000	
	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max
Kinematic viscosity at 60˚C (140˚F)										
mm^2/s^a	30	60	70	140	250	500	800	1600	3000	6000
Flash point (tag open-cup),	38	—	38	—	66	—	66	—	66	—
°C (°F)	(100)		(100)		(150)		(150)		(150)	
Water, percent	—	0.2	—	0.2	—	0.2	—	0.2	—	0.2
Distillation test:										
Distillation, percentage by volume of total distillate to 360˚C (680˚F)										
to 225˚C (437˚F)	—	25	0	20	0	10	—	—	—	—
to 260˚C (500˚F)	40	70	20	60	15	55	0	35	0	15
to 315˚C (600˚F)	75	93	65	90	60	87	45	80	15	75
Residue from distillation to 360˚C (680˚F),										
volume percentage of sample by difference	50	—	55	—	67	—	75	—	80	—
Tests on residue from distillation:										
Absolute viscosity at 60˚C (140˚F) Pa·s (P)[b]	30	120	30	120	30	120	30	120	30	120
	(300)	(1200)	(300)	(1200)	(300)	(1200)	(300)	(1200)	(300)	(1200)
Ductility, 5 cm/min, cm[c]	100	—	100	—	100	—	100	—	100	—
Solubility in trichloroethylene, percent	99.0	—	99.0	—	99.0	—	99.0	—	99.0	—
Spot test[d] with:										
Standard naphtha	Negative for all grades									
Naphtha-xylene solvent, percent xylene	Negative for all grades									
Heptane-xylene solvent, percent xylene	Negative for all grades									

[a] As an alternate, Saybolt-Furol viscosities may be specified as follows:
Grade MC-30–Furol viscosity at 25°C (77°F)—75 to 150 s.
Grade MC-70–Furol viscosity at 50˚C (122˚F)—60 to 120 s.
Grade MC-250–Furol viscosity at 60˚C (140˚F)—125 to 250 s.
Grade MC-800–Furol viscosity at 82.2˚C (180˚F)—100 to 200 s.
Grade MC-3000–Furol viscosity at 82.2˚C (180˚F)—300 to 600 s.

[b] In lieu of viscosity of the residue, the specifying agency, at its option, can specify penetration at 100 g, 5 s at 25˚C (77˚F) of 120 to 250 for Grades MC-30, MC-70, MC-250, MC-800, and MC-3000. However, in no case will both viscosity and penetration be required.

[c] If the ductility at 25˚C (77˚F) is less than 100, the material will be acceptable if its ductility at 15.5˚C (60˚F) is more than 100.

[d] The use of the spot test is optional. When specified, indicate whether the standard naphtha solvent, naphtha-xylene solvent, or heptane-xylene solvent will be used in determining compliance with the requirement, and also, in the case of the xylene solvents, the percentage of xylene to be used.

Standard Specification for

Emulsified Asphalt

AASHTO Designation: M 140-08
ASTM Designation: D 977-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Emulsified Asphalt

AASHTO Designation: M 140-08
ASTM Designation: D 977-05

AASHTO M 140-08 is identical to ASTM D 977-05 except for the following provisions:

1. All references to the ASTM standards listed in the following table shall be replaced with the corresponding AASHTO standard.

Referenced Standards

ASTM	AASHTO
D 140	T 40
D 244	T 59

2. Add the following to Section 2:

   2.2 *AASHTO Standard*:

   R 5, Selection and Use of Emulsified Asphalts

3. Replace Section 3.1 with the following:

   3.1 Within 30 days after delivery and provided separation has not been caused by freezing, the emulsified asphalt shall be homogeneous after thorough mixing.

4. Add the following footnotes at the bottom of Table 1:

   [b] *Demulsibility*—The demulsibility test shall be performed within 30 days from the date of shipment.

   [c] *Sieve Test*—A maximum percentage of 0.30 is acceptable for samples taken at the point of use.

   [d] Refer to R 5 for typical applications.

Standard Specification for

Requirements for Mixing Plants for Hot-Mixed, Hot-Laid Bituminous Paving Mixtures

AASHTO Designation: M 156-97 (2009)
ASTM Designation: D 995-95b (2002)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Requirements for Mixing Plants for Hot-Mixed, Hot-Laid Bituminous Paving Mixtures

AASHTO Designation: M 156-97 (2009)
ASTM Designation: D 995-95b (2002)

AASHTO M 156-97 (2009) is identical to ASTM D 995-95b (2002) except for the following provisions:

1. All references to the ASTM standards listed in the following table shall be replaced with the corresponding AASHTO standard.

Referenced Standards

ASTM	AASHTO
C 136	T 27
D 140	T 40

2. Replace Section 4.2.4 with the following:

   A sampling tap and valve shall be provided in the asphalt binder storage tank or in the feedline between the pump and the return line discharge. The sampling valve shall be readily accessible and free from obstructions. An acceptable sample valve detail is shown in T 40.

3. Add the following sentence to Section 4.3:

   Baghouse fines recirculated into the mix shall be considered as a mineral filler.

4. Add the following sentence to Section 4.5:

   Leave no visible unburned oil or carbon residue on the aggregate when discharged from the dryer.

5. Change the first sentence of Section 4.8.1 to read as follows:

   Plants located in areas regulated by emission standards shall have a dust collection system.

6. Change Section 4.9 to the following:

   4.9 Surge and Storage Bins or Silos

   4.9.1 Bins or silos may be provided for surge or storage capacity of mixtures.

   4.9.2 Bins or silos used for surge capacity during mixing and delivery periods shall be such that the mixture discharged into delivery units meets the requirements of the applicable specifications. The surge bin or silo shall be emptied at the cessation of each mixing and delivery period.

7. Add the following sentence to Section 9.1.3:

   Baghouse fines recirculated into the mix shall be considered as a mineral filler.

8. Add the following sentence to Section 10.2.4:

   Baghouse fines recirculated into the mix shall be considered as a mineral filler.

9. Add the following to Section 10.4:

   10.4.1 The plant shall be equipped with approved recording thermometers, pyrometers, or other approved recording thermometric instruments at the discharge chute of the drum mixer.

10.4.2 The plant shall have means of diverting mixes at startup and shutdowns or when mixing is not complete or uniform.

10. Add the following requirements:

12. STORAGE OF MIXTURES

12.1 *Conditions of Use*:

12.1.1 A plant may be permitted to store hot mix asphalt in a silo after prior evaluation and approval by the engineer. Use will be in conformance with all limitations on retention time, type of mixture, heater operation, silo atmosphere, mix level, or other characteristics set forth in the applicable specifications. Affixed to each silo and visible to the loading operator shall be an indicating device, which will be activated when the material drops below the top of the sloped portion of the silo.

12.2 *Approval Procedure*:

12.2.1 An evaluation of a unit will determine the degree of mix composition uniformity, temperature characteristics, and degree of asphalt binder hardening of mixture processed through the unit. Approval will be granted for operation that consistently results in mixtures having gradation and temperature properties of no less quality than specified mixtures discharged directly from the plant's mixing operation. Storage times beyond those listed in Table 1 require demonstration that the properties of the asphalt binder are not changed and the asphalt binder does not undergo additional hardening compared to samples stored under Table 1 conditions. Mixtures which the engineer determines visually to be segregated will be rejected.

12.3 *Limits for Storage of Asphalt Mix*:

12.3.1 Dense-graded asphalt mix will not exceed 18 hours in storage.

Open-graded asphalt mix will not exceed 2 hours in storage.

The indicated storage times may be reduced by the engineer if it is determined that asphalt absorption is a concern. Storage of open-graded mixtures will not be allowed if it is determined that migration of asphalt during the storage period is excessive.

12.3.2 Samples for asphalt binder tests shall be taken from trucks loaded from the storage unit or mixing operation, chilled immediately, and maintained at a temperature below 0ºC (32ºF) until tested.

12.4 *Changes in System*:

12.4.1 In the event that an approved storage unit is changed or altered, the engineer shall be notified of the modifications. Any departure from the approved unit will necessitate reevaluation.

12.5 *Temporary Use of Unapproved Silos*:

12.5.1 In the event that a unit is permitted to be used prior to evaluation and approval, the maximum storage times to be used are shown in the following table:

Table 1—Maximum Storage Times (h)

	Fine-Graded Mix, Nominal-Maximum Aggregate Size of 12.5 mm ($^1/_2$ in.)	Coarse-Graded Mix, Nominal-Maximum Aggregate Size of 38 mm (1$^1/_2$ in.)
Untreated asphalt binder, air in silo	8	4
Treated asphalt binder (Note 1), air in silo	12	6
Untreated asphalt binder, inert gas in silo	12	6
Treated asphalt binder (Note 1), inert gas in silo	12	12

Note 1—Treated with Dow Corning Fluid DC-200 at a rate of approximately 30 mL (1 oz) per 18.9 kL (5000 gal) of asphalt binder.

Standard Specification for

Cationic Emulsified Asphalt

AASHTO Designation: M 208-01 (2009)
ASTM Designation: D 2397-02

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Cationic Emulsified Asphalt

AASHTO Designation: M 208-01 (2009)
ASTM Designation: D 2397-02

1. SCOPE

1.1 This specification covers seven grades of cationic emulsified asphalt for use in pavement construction in the manner designated.

Note 1—See M 140 for emulsions other than cationic.

1.2 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:
- M 140, Emulsified Asphalt
- R 5, Selection and Use of Emulsified Asphalts
- T 40, Sampling Bituminous Materials
- T 59, Emulsified Asphalts

3. REQUIREMENTS

3.1 Within 14 days after delivery, and provided separation has not been caused by freezing, the emulsified asphalt shall be homogeneous after thorough mixing.

3.2 Emulsified asphalt shall conform to the requirements in Table 1.

Table 1—Requirements and Typical Applications for Cationic Emulsified Asphalt[a]

Type	Rapid-Setting				Medium-Setting				Slow-Setting				Quick-Setting	
Grade	CRS -1		CRS-2		CMS-2		CMS-2 h		CSS-1		CSS-1 h		CQS-1 h	
	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max
Test on emulsions:														
Viscosity, Saybolt Furol at 25°C (77°F), s									20	100	20	100	20	100
Viscosity, Saybolt Furol at 50°C (122°F), s	20	100	100	400	50	450	50	450						
Storage stability test, 24 h, percent[b]		1		1		1		1		1		1		
Demulsibility, 35 mL, 0.8 percent														
Sodium dioctyl sulfosucinate, percent	40		40

Solubility in trichloroethylene, percent	97.5		97.5		97.5		97.5		97.5		97.5		97.5	

[a] Refer to R 5 for typical applications.

[b] This test requirement on representative samples may be waived if successful application of the material has been achieved in the field.

4. SAMPLING

4.1 Samples of emulsified asphalt shall be taken in accordance with T 40.

4.2 Samples shall be stored in clean, airtight sealed containers at a temperature of not less than 4ºC (39ºF) until tested.

5. METHODS OF TEST

5.1 The properties of the emulsified asphalts given in Table 1 shall be determined in accordance with T 59, with the following exception:

5.1.1 *Sieve Test*—Use distilled water in all wetting and washing operations in place of sodium oleate solution (2 percent).

Standard Specification for

Viscosity-Graded Asphalt Cement

AASHTO Designation: M 226-80 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Viscosity-Graded Asphalt Cement

AASHTO Designation: M 226-80 (2008)

1. SCOPE

1.1. This specification covers asphalt binders graded by viscosity at 60°C (140°F) for use in pavement construction. Three sets of limits are offered in this specification. The purchaser shall specify the applicable table of limits. In the event the purchaser does not specify limits, Table 1 shall apply.

1.2. The values stated in SI units are to be regarded as the standard.

2. MANUFACTURE

2.1. The asphalt binder shall be prepared for crude petroleum by suitable methods.

3. REQUIREMENTS

3.1. The asphalt binder shall be homogeneous, free from water, and shall not foam when heated to 175ºC (347ºF).

3.2. The asphalt binders shall conform to the requirements given in Tables 1, 2, or 3, as specified by the purchaser.

Table 1—Requirements for Asphalt Binder Graded by Viscosity at 60ºC (140ºF) (Grading Based on Original Asphalt)

Test	Viscosity Grade				
	AC-2.5	AC-5	AC-10	AC-20	AC-40
Viscosity, 60°C (140°F), Pa·s (Poises)	25 ± 5 (250 ± 50)	50 ± 10 (500 ± 100)	100 ± 20 (1000 ± 200)	200 ± 40 (2000 ± 400)	400 ± 80 (4000 ± 800)
Viscosity, 135°C (275°F), mm^2/s—min	80	100	150	210	300
Penetration, 25°C (77°F), 100 g, 5 s—min	200	120	70	40	20
Flash point, COC, °C (°F)—min	163 (325)	177 (350)	219 (425)	232 (450)	232 (450)
Solubility in trichloroethylene, percent—min	99.0	99.0	99.0	99.0	99.0
Tests on residue from thin-film oven test:					
Viscosity, 60°C (140°F), Pa·s (Poises), max	100 (1000)	200 (2000)	400 (4000)	800 (8000)	1600 (16000)
Ductility, 25°C (77°F), 5 cm/min, cm—min	100[a]	100	50	20	10
Spot test (when and as specified)[b] with:					
Standard naphtha solvent	Negative for all grades				
Naphtha-xylene solvent, percent xylene	Negative for all grades				
Heptane-xylene solvent, percent xylene	Negative for all grades				

[a] If ductility is less than 100 cm, material will be accepted if ductility at 15.6°C (60°F) is 100 cm minimum.

[b] The use of the spot test is optional. When it is specified, the engineer shall indicate whether the standard naphtha solvent, the naphtha-xylene solvent, or the heptane-xylene solvent will be used in determining compliance with the requirement, and also, in the case of xylene solvents, the percentage of xylene to be used.

Table 2—Requirements for Asphalt Binder Graded by Viscosity at 60ºC (140ºF) (Grading Based on Original Asphalt)

Test	Viscosity Grade					
	AC-2.5	AC-5	AC-10	AC-20	AC-30	AC-40
Viscosity, 60°C (140°F), Pa·s (Poises)	25 ± 5 (250 ± 50)	50 ± 10 (500 ± 100)	100 ± 20 (1000 ± 200)	200 ± 40 (2000 ± 400)	300 ± 60 (3000 ± 600)	400 ± 80 (4000 ± 800)
Viscosity, 135°C (275°F), mm^2/s—min	125	175	250	300	350	400
Penetration, 25°C (77°F), 100 g, 5 s—min	220	140	80	60	50	40
Flash point, COC, °C (°F)—min	163 (325)	177 (350)	219 (425)	232 (450)	232 (450)	232 (450)
Solubility in trichloroethylene, percent—min	99.0	99.0	99.0	99.0	99.0	99.0
Tests on residue from thin-film oven test:						
Loss on heating percent—max[a]	—	1.0	0.5	0.5	0.5	0.5
Viscosity, 60°C (140°F), Pa·s (Poises)—max	100 (1000)	200 (2000)	400 (4000)	800 (8000)	1200 (12000)	1600 (16000)
Ductility, 25°C (77°F), 5 cm/min, cm—min	100[b]	100	75	50	40	25
Spot test (when and as specified)[c] with:						
Standard naphtha solvent	Negative for all grades					
Naphtha-xylene solvent, percent xylene	Negative for all grades					
Heptane-xylene solvent, percent xylene	Negative for all grades					

[a] The use of loss on heating requirement is optional.

[b] If ductility is less than 100 cm, material will be accepted if ductility at 15.6°C (60°F) is 100 cm minimum.

[c] The use of the spot test is optional. When it is specified, the engineer shall indicate whether the standard naphtha solvent, the naphtha-xylene solvent, or the heptane-xylene solvent will be used in determining compliance with the requirement, and also, in the case of xylene solvents, the percentage of xylene to be used.

Table 3—Requirements for Asphalt Binder Graded by Viscosity at 60ºC (140ºF) (Grading Based on Residue from Rolling Thin-Film Oven Test)

Tests on Residue from AASHTO Test Method T 240[a]	Viscosity Grade				
	AR-10	AR-20	AR-40	AR-80	AR-160
Viscosity, 60°C (140°F), Pa·s (Poises)	100 ± 25 (1000 ± 250)	200 ± 50 (2000 ± 500)	400 ± 100 (4000 ± 1000)	800 ± 200 (8000 ± 2000)	1600 ± 400 (16000 ± 4000)
Viscosity, 135°C (275°F), mm^2/s—min	140	200	275	400	550
Penetration, 25°C (77°F), 100 g, 5 s—min	65	40	25	20	20
Percent of original penetration, 25°C (77°F)—min	—	40	45	50	52
Ductility, 25°C (77°F), 5 cm/min, cm—min	100[b]	100[b]	75	75	75
Tests on original asphalt:					
Flash point, COC, °C (°F)—min	205 (400)	219 (425)	227 (440)	232 (450)	238 (460)
Solubility in trichloroethylene, percent—min	99.0	99.0	99.0	99.0	99.0

[a] AASHTO T 179 (Rolling Thin-Film Oven Test) may be used, but AASHTO T 240 shall be the referee method.

[b] If ductility is less than 100 cm, material will be accepted if ductility at 15.6°C (60°F) is 100 cm minimum.

4. METHODS OF SAMPLING AND TESTING

4.1. Sampling and testing of asphalt binders shall be in accordance with the following standard methods of the American Association of State Highway and Transportation Officials:

- T 40, Sampling
- T 44, Solubility in Bituminous Materials
- T 48, Flash Point (COC)
- T 49, Penetration
- T 51, Ductility
- T 55, Water
- T 102, Spot Test
- T 179, Thin-Film Oven Test
- T 201, Viscosity at 135°C (275°F)
- T 202, Viscosity at 60°C (140°F)
- T 240, Rolling Thin-Film Oven Test

Standard Specification for

Lime for Asphalt Mixtures

AASHTO Designation: M 303-89 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Lime for Asphalt Mixtures

AASHTO Designation: M 303-89 (2006)

1. SCOPE

1.1. This specification covers two types of lime to be used for reducing water susceptibility in asphalt mixtures.

1.1.1. *Type I*—High calcium-hydrated lime containing maximum magnesium content, calculated as magnesium oxide, of 4 percent by mass. Compliance with chemical composition requirements shall be determined by use of T 219. (Note 1)

1.1.2. *Type II*—Magnesium or dolomitic lime containing magnesium, calculated as magnesium oxide, greater than 4 but no more than 36 percent by mass. Compliance with chemical composition requirements shall be determined by use of ASTM C 25. (Note 2)

1.2. The values stated in SI units are to be regarded as the standard.

Note 1—Magnesium oxide content may be determined by ASTM C 25.

Note 2—Except that Section 2, "Samples for Analysis," is excluded.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 165, Effect of Water on Cohesion of Compacted Bituminous Mixtures (Discontinued)
- T 218, Sampling Hydrated Lime
- T 219, Testing Lime for Chemical Constituents and Particle Sizes
- T 283, Resistance of Compacted Hot Mix Asphalt (HMA) to Moisture-Induced Damage

2.2. *ASTM Standard*:

- C 25, Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

3. CHEMICAL LIMITS

3.1. Types I and II lime, when sampled and tested by procedures prescribed herein, shall conform to the following requirements. (See Tables 1 and 2.)

3.2. Type II lime, when tested in accordance with ASTM C 25, shall conform to the requirements listed in Table 2.

Table 1—Types I and II Requirements

Min total active lime content, percent by mass (Percent by mass $Ca(OH)_2$ + percent by mass Ca(O)[a])	90
Max unhydrated lime content, percent by mass CaO	7
Max "Free Water" content, percent by mass H_2O	3

[a] No more than 7 percent by mass calcium oxide (unhydrated lime) will be allowed in determining total active lime content.

Table 2—Type II Requirements (when tested by ASTM C 25)

Calcium and magnesium oxide content of ignition residue, min, percent[a]	96
Carbon dioxide (as received basis), max, percent	4
Unhydrated calcium oxide (as received basis), max, percent	7

[a] Ignition to constant mass shall be performed utilizing an electric muffle furnace operating at 1000–1100°C [1800–2000°F].

4. PHYSICAL REQUIREMENTS

4.1. Types I and II lime shall conform to the following particle size requirements when tested according to T 219:

Maximum residue retained on a 600-µm (No. 30) sieve, percent by mass	3
Maximum residue retained on a 75-µm (No. 200) sieve, percent by mass	20

5. PACKAGING AND MARKING

5.1. When the lime is delivered in bags, the name and brand of the manufacturer and type shall be plainly identified thereon. A bag shall contain a nominal mass of 25 kg (50 lb) and all bags shall be in good condition at the time of inspection. When lime is delivered in bulk, information regarding type and manufacturer shall be contained in the invoice accompanying the shipment.

6. INSPECTION

6.1. Every facility shall be provided the purchaser for careful sampling and inspection of the lime at either the plant or at the site of the work as may be specified by the purchaser.

7. REJECTION

7.1. The lime shall be rejected if it fails to meet any of the requirements of this specification.

7.2. In the case of bag lime, bags varying more than 5 percent from the specified mass may be rejected. If the average mass of bags in any shipment as shown by weighing 50 bags taken at random is less than that specified, the entire shipment may be rejected.

8. METHODS OF SAMPLING AND TESTING

8.1. The sampling and testing of lime shall be in accordance with the following standard methods of AASHTO or ASTM:

- *Sampling*—T 218
- *Chemical Analysis for Type I*—T 219
- *Chemical Analysis for Type II Lime*—ASTM C 25
- *Physical Requirements*—Quantity of lime required to correct water susceptibility can be determined from test results obtained in accordance with T 165 or T 283.

Standard Specification for

Polymer-Modified Cationic Emulsified Asphalt

AASHTO Designation: M 316-99 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Polymer-Modified Cationic Emulsified Asphalt

AASHTO Designation: M 316-99 (2007)

1. SCOPE

1.1. This specification covers grades of polymer-modified cationic emulsified asphalt for use in pavement construction. The modifier may be either a solid or latex polymer. The modifier may be added either to the asphalt binder or during the emulsification process.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 40, Sampling Bituminous Materials
- T 59, Emulsified Asphalts

3. DEFINITIONS

3.1. *CRS-2P*—A cationic emulsion made with base asphalt binder typically modified with styrene-butadiene or styrene-butadiene styrene block copolymers.

3.2. *CRS-2L*—A cationic emulsion made with base asphalt binder typically modified with styrene-butadiene rubber latex or polychloroprene latex.

4. REQUIREMENTS

4.1. Within 30 days after delivery and provided separation has not been caused by freezing, the emulsified asphalt shall be homogeneous after thorough mixing.

4.2. The emulsified asphalt shall conform to the requirements in Table 1.

Table 1—Requirements for Polymer-Modified Cationic Emulsified Asphalt

Type, Grade		Rapid-Setting			
		CRS-2P		CRS-2L	
		Min	Max	Min	Max
Test on emulsions:					
Viscosity, Saybolt Furol at 50˚C (122˚F)	s	100	400	100	400
Storage stability test, 24-h	%		1		1
Demulsibility, 35 mL of 0.8 % dioctyl sodium sulfosucinate	%	40		40	
Particle charge test		positive		positive	
Sieve test	%		0.10		0.10
Evaporation residue	%	65		65	
Test on residue from evaporation test:					
Penetration, 25˚C (77˚F), 100 g, 5 s	0.1 mm	100	175	100	175
Ductility, 4˚C (39˚F), 5 cm/min	cm	30		30	
Ductility, 25˚C (77˚F), 5 cm/min	cm	125		125	
Force ratio	(f_2/f_1)	0.3		NA	
Elastic recovery	%	50		NA	
Polymer solids content	%	2.5		2.5	
Solubility in trichloroethylene	%	97.5[a]		97.5[a]	

[a] If the solubility of the residue is less than 97.5 percent, the base asphalt binder for the emulsion shall be tested. The solubility of the base asphalt binder shall be greater than 99 percent.

5. SAMPLING

5.1. Samples of emulsified asphalt shall be taken in accordance with T 40.

5.2. Samples shall be stored in clean, airtight, plastic containers at a temperature of not less than 4.5ºC (40ºF) until tested.

6. METHOD OF TEST

6.1. The properties of the emulsified asphalt given in Table 1 shall be determined in accordance with T 59, with the following exception:

6.1.1. *Sieve Test*—Use distilled water in all wetting and washing operations rather than a sodium oleate solution (2 percent).

Standard Specification for

Performance-Graded Asphalt Binder

AASHTO Designation: M 320-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Performance-Graded Asphalt Binder

AASHTO Designation: M 320-10

1. SCOPE

1.1. This specification covers asphalt binders graded by performance. Grading designations are related to the average seven-day maximum pavement design and minimum pavement design temperatures. This specification contains Table 1 and Table 2. If no table is specified, the default is Table 1.

1.2. Table 2 incorporates R 49 for determining the critical low cracking temperature using a combination of T 313 and T 314 test procedures.

Note 1—For asphalt cements graded by viscosity at 60°C, see M 226.

Note 2—R 29 provides information for determining the performance grade of an asphalt binder.

Note 3—For specifying performance-graded asphalt binder using Multiple Stress Creep Recovery (MSCR), see MP 19.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 226, Viscosity-Graded Asphalt Cement
- M 323, Superpave Volumetric Mix Design
- MP 19, Performance-Graded Asphalt Binder Using Multiple Stress Creep Recovery (MSCR) Test
- R 28, Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)
- R 29, Grading or Verifying the Performance Grade (PG) of an Asphalt Binder
- R 35, Superpave Volumetric Design for Hot Mix Asphalt (HMA)
- R 49, Determination of Low-Temperature Performance Grade (PG) of Asphalt Binders
- T 40, Sampling Bituminous Materials
- T 44, Solubility of Bituminous Materials
- T 48, Flash and Fire Points by Cleveland Open Cup
- T 55, Water in Petroleum Products and Bituminous Materials by Distillation
- T 240, Effect of Heat and Air on a Moving Film of Asphalt Binder (Rolling Thin-Film Oven Test)
- T 313, Determining the Flexural Creep Stiffness of Asphalt Binder Using the Bending Beam Rheometer (BBR)
- T 314, Determining the Fracture Properties of Asphalt Binder in Direct Tension (DT)
- T 315, Determining the Rheological Properties of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)
- T 316, Viscosity Determination of Asphalt Binder Using Rotational Viscometer

2.2. *ASTM Standards*:

- D 8, Standard Terminology Relating to Materials for Roads and Pavements
- D 5546, Standard Test Method for Solubility of Asphalt Binders in Toluene by Centrifuge

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. Definitions for many terms common to asphalt binder are found in ASTM D 8.

3.1.2. *asphalt binder*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of non-particulate organic modifiers.

4. ORDERING INFORMATION

4.1. When ordering under this specification, include in the purchase order the performance grade (PG) of asphalt binder required and the table used (e.g., (1) M 320, PG 52-16, Table 1, or (2) M 320, PG 64-34, Table 2). If no table is specified, the default is Table 1.

4.2. Asphalt binder grades may be selected by following the procedures described in M 323 and R 35.

5. MATERIALS AND MANUFACTURE

5.1. Asphalt binder shall be prepared by the refining of crude petroleum by suitable methods, with or without the addition of modifiers.

5.2. Modifiers may be any organic material of suitable manufacture that is used in virgin or recycled condition and that is dissolved, dispersed, or reacted in asphalt binder to enhance its performance.

5.3. The asphalt binder shall be homogeneous, free from water and deleterious materials, and shall not foam when heated to 175°C.

5.4. The asphalt binder shall be at least 99.0 percent soluble as determined by T 44 or ASTM D 5546.

5.5. This specification is not applicable for asphalt binders in which fibers or other discrete particles are larger than 250 μm in size.

5.6. The grades of asphalt binder shall conform to the requirements given in Table 1 or Table 2.

6. SAMPLING

6.1. The material shall be sampled in accordance with T 40.

7. TEST METHODS

7.1. The properties outlined in Sections 5.3, 5.4, and 5.6 shall be determined in accordance with R 28, T 44 or ASTM D 5546, T 48, T 55, T 240, T 313, T 314, T 315, and T 316.

8. INSPECTION AND CERTIFICATION

8.1. Inspection and certification of the material shall be agreed upon between the purchaser and the seller. Specific requirements shall be made part of the purchase contract. The seller shall provide material handling and storage procedures to the purchaser for each asphalt binder grade certified.

9. REJECTION AND RETESTING

9.1. If the results of any test do not conform to the requirements of this specification, retesting to determine conformity is performed as indicated in the purchase order or as otherwise agreed upon between the purchaser and the seller.

10. KEYWORDS

10.1. Asphalt binder; asphalt cement; direct tension; flash point; modifier; performance specifications; pressure aging; rheology.

Table 1—Performance-Graded Asphalt Binder Specification

Performance Grade	PG 46			PG 52							PG 58					PG 64

[a] Pavement temperatures are estimated from air temperatures using an algorithm contained in the LTPP Bind program, may be provided by the specifying agency, or by following the procedures as outlined in M 323 and R 35.

[b] This requirement may be waived at the discretion of the specifying agency if the supplier warrants that the asphalt binder can be adequately pumped and mixed at temperatures that meet all applicable safety standards.

[c] For quality control of unmodified asphalt binder production, measurement of the viscosity of the original asphalt binder may be used to supplement dynamic shear measurements of G*/sinδ at test temperatures where the asphalt is a Newtonian fluid.

[d] G*/sinδ = high temperature stiffness and G* sinδ = intermediate temperature stiffness.

[e] The mass change shall be less than 1.00 percent for either a positive (mass gain) or a negative (mass loss) change.

[f] The PAV aging temperature is based on simulated climatic conditions and is one of three temperatures, 90°C, 100°C, or 110°C. Normally the PAV aging temperature is 100°C for PG 58-xx and above. However, in desert climates, the PAV aging temperature for PG 70-xx and above may be specified as 110°C.

[g] If the creep stiffness is below 300 MPa, the direct tension test is not required. If the creep stiffness is between 300 and 600 MPa, the direct tension failure strain requirement can be used in lieu of the creep stiffness requirement. The m-value requirement must be satisfied in both cases.

Critical low cracking temp, R 49:[g] Critical cracking temp determined by R 49, test temp, °C	–24	–30	–36	0	–6	–12	–18	–24	–30	–36	–6	–12	–18	–24	–30	0	–6	–12	–18	–24	–30

[a] Pavement temperatures are estimated from air temperatures using an algorithm contained in the LTPP Bind program, may be provided by the specifying agency, or by following the procedures as outlined in M 323 and R 35.

[b] This requirement may be waived at the discretion of the specifying agency if the supplier warrants that the asphalt binder can be adequately pumped and mixed at temperatures that meet all applicable safety standards.

[c] For quality control of unmodified asphalt binder production, measurement of the viscosity of the original asphalt binder may be used to supplement dynamic shear measurements of G*/sinδ at test temperatures where the asphalt is a Newtonian fluid.

[d] G*/sinδ = high temperature stiffness and G* sinδ = intermediate temperature stiffness.

[e] The mass change shall be less than 1.00 percent for either a positive (mass gain) or a negative (mass loss) change.

[f] The PAV aging temperature is based on simulated climatic conditions and is one of three temperatures, 90°C, 100°C, or 110°C. Normally the PAV aging temperature is 100°C for PG 58-xx and above. However, in desert climates, the PAV aging temperature for PG 70-xx and above may be specified as 110°C.

[g] For verification of grade, at a minimum perform T 313 at the test temperature and at the test temperature minus 6°C and T 314 at the test temperature. Testing at additional temperatures for T 313 may be necessary if 300 MPa is not bracketed at the initial two test temperatures. Compare the failure stress from T 314 to the calculated induced thermal stress as per R 49. If the failure stress exceeds the induced thermal stress, the asphalt binder is deemed a "PASS" at the specification temperature.

[a] Pavement temperatures are estimated from air temperatures using an algorithm contained in the LTPP Bind program, may be provided by the specifying agency, or by following the procedures as outlined in M 323 and R 35.

[b] This requirement may be waived at the discretion of the specifying agency if the supplier warrants that the asphalt binder can be adequately pumped and mixed at temperatures that meet all applicable safety standards.

[c] For quality control of unmodified asphalt binder production, measurement of the viscosity of the original asphalt binder may be used to supplement dynamic shear measurements of G*/sinδ at test temperatures where the asphalt is a Newtonian fluid.

[d] G*/sinδ = high temperature stiffness and G* sinδ = intermediate temperature stiffness.

[e] The mass change shall be less than 1.00 percent for either a positive (mass gain) or a negative (mass loss) change.

[f] The PAV aging temperature is based on simulated climatic conditions and is one of three temperatures 90°C, 100°C, or 110°C. Normally the PAV aging temperature is 100°C for PG 58-xx and above. However, in desert climates, the PAV aging temperature for PG 70-xx and above may be specified as 110°C.

[g] For verification of grade, at a minimum perform T 313 at the test temperature and at the test temperature minus 6°C and T 314 at the test temperature. Testing at additional temperatures for T 313 may be necessary if 300 MPa is not bracketed at the initial two test temperatures. Compare the failure stress from T 314 to the calculated induced thermal stress as per R 49. If the failure stress exceeds the induced thermal stress, the asphalt binder is deemed a "PASS" at the specification temperature.

Standard Specification for

Superpave Volumetric Mix Design

AASHTO Designation: M 323-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Superpave Volumetric Mix Design

AASHTO Designation: M 323-07

1. SCOPE

1.1. This specification for Superpave volumetric mix design uses aggregate and mixture properties to produce a hot mix asphalt (HMA) job-mix formula.

1.2. This standard specifies minimum quality requirements for binder, aggregate, and HMA for Superpave volumetric mix designs.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

---

3. TERMINOLOGY

3.1. *HMA*—hot mix asphalt.

3.2. *design ESALs*—design equivalent (80 kN) single-axle loads.

3.2.1. *Discussion*—Design ESALs are the anticipated project traffic level expected on the design lane over a 20-year period. For pavements designed for more or less than 20 years, determine the design ESALs for 20 years when using this standard.

3.3. *air voids* (V_a)—the total volume of the small pockets of air between the coated aggregate particles throughout a compacted paving mixture, expressed as a percent of the bulk volume of the compacted paving mixture (Note 1).

Note 1—Term defined in Asphalt Institute Manual MS-2, *Mix Design Methods for Asphalt Concrete and Other Hot-Mix Types*.

3.4. *voids in the mineral aggregate (VMA)*—the volume of the intergranular void space between the aggregate particles of a compacted paving mixture that includes the air voids and the effective binder content, expressed as a percent of the total volume of the specimen (Note 1).

3.5. *voids filled with asphalt (VFA)*—the percentage of the VMA filled with binder (the effective binder volume divided by the VMA).

3.6. *dust-to-binder ratio* ($P_{0.075}/P_{be}$)—by mass, the ratio between the percent of aggregate passing the 75-µm (No. 200) sieve ($P_{0.075}$) and the effective binder content (P_{be}).

3.7. *nominal maximum aggregate size*—one size larger than the first sieve that retains more than 10 percent aggregate (Note 2).

3.8. *maximum aggregate size*—one size larger than the nominal maximum aggregate size (Note 2).

Note 2—The definitions given in Sections 3.7 and 3.8 apply to Superpave mixes only and differ from the definitions published in other AASHTO standards.

3.9. *reclaimed asphalt pavement (RAP)*—removed and/or processed pavement materials containing asphalt binder and aggregate.

3.10. *primary control sieve (PCS)*—the sieve defining the break point between fine- and coarse-graded mixtures for each nominal maximum aggregate size.

4. SIGNIFICANCE AND USE

4.1. This standard may be used to select and evaluate materials for Superpave volumetric mix designs.

5. BINDER REQUIREMENTS

5.1. The binder shall be a performance-graded (PG) binder, meeting the requirements of M 320, which is appropriate for the climate and traffic-loading conditions at the site of the paving project or as specified by the contract documents.

5.1.1. Determine the mean and the standard deviation of the yearly, 7-day-average, maximum pavement temperature, measured 20 mm below the pavement surface, and the mean and the standard deviation of the yearly, 1-day-minimum pavement temperature, measured at the pavement surface, at the site of the paving project. These temperatures can be determined by use of the LTPPBind 3.1 software or can be supplied by the specifying agency. If the LTPPBind software is used, the LTPP high- and low-temperature models should be selected in the software when determining the binder grade. Often, actual site data are not available, and representative data from the nearest weather station will have to be used.

5.1.2. Select the design reliability for the high- and low-temperature performance desired. The design reliability required is established by agency policy.

Note 3—The selection of design reliability may be influenced by the initial cost of the materials and the subsequent maintenance costs.

5.1.3. Using the pavement temperature data determined, select the minimum required PG binder that satisfies the required design reliability.

5.2. If traffic speed or the design ESALs warrant, increase the high-temperature grade by the number of grade equivalents indicated in Table 1 to account for the anticipated traffic conditions at the project site.

Table 1—Binder Selection on the Basis of Traffic Speed and Traffic Level

	Adjustment to the High-Temperature Grade of the Binder[a]		
	Traffic Load Rate		
Design ESALs[b] (Million)	Standing[c]	Slow[d]	Standard[e]
<0.3	—[f]	—	—
0.3 to <3	2	1	—
3 to <10	2	1	—
10 to <30	2	1	—[f]
≥30	2	1	1

[a] Increase the high-temperature grade by the number of grade equivalents indicated (one grade is equivalent to 6˚C). Use the low-temperature grade as determined in Section 5.

[b] The anticipated project traffic level expected on the design lane over a 20-year period. Regardless of the actual design life of the roadway, determine the design ESALs for 20 years.

[c] *Standing Traffic*—where the average traffic speed is less than 20 km/h.

[d] *Slow Traffic*—where the average traffic speed ranges from 20 to 70 km/h.

[e] *Standard Traffic*—where the average traffic speed is greater than 70 km/h.

[f] Consideration should be given to increasing the high-temperature grade by one grade equivalent.

Note 4—Practically, PG binders stiffer than PG 82-xx should be avoided. In cases where the required adjustment to the high-temperature binder grade would result in a grade higher than a PG 82, consideration should be given to specifying a PG 82-xx and increasing the design ESALs by one level (e.g., 10 to <30 million increased to ≥30 million).

5.3. If RAP is to be used in the mixture, adjust the binder grade selected in Sections 5.1.3 and 5.2 according to Table 2 to account for the amount and stiffness of the RAP binder. Procedures for developing a blending chart are included in the appendix.

Note 5—Research conducted as part of NCHRP Project 9-12 indicated that the high stiffness RAP (PG 88-4 after recovery) used in the study had a greater effect on the low-temperature properties of the blended asphalt binder than the medium and low stiffness RAP (PG 82-16 and PG 82-22, respectively). These data suggests that the limiting RAP values in Table 2 may be modified depending on the low-temperature stiffness of the recovered RAP binder. Refer to NCHRP Report 452 for more details.

Table 2—Binder Selection Guidelines for Reclaimed Asphalt Pavement (RAP) Mixtures

Recommended Virgin Asphalt Binder Grade	RAP Percentage
No change in binder selection	<15
Select virgin binder one grade softer than normal (e.g., select a PG 58-28 if a PG 64-22 would normally be used)	15 to 25
Follow recommendations from blending charts	>25

6. COMBINED AGGREGATE REQUIREMENTS

6.1. *Size Requirements:*

6.1.1. *Nominal Maximum Size*—The combined aggregate shall have a nominal maximum aggregate size of 4.75 to 19.0 mm for HMA surface courses and no larger than 37.5 mm for HMA subsurface courses.

Note 6—Additional guidance on selection of the appropriate nominal maximum size mixture can be found in the National Asphalt Pavement Association's IS 128.

6.1.2. *Gradation Control Points*—The combined aggregate shall conform to the gradation requirements specified in Table 3 when tested according to T 11 and T 27.

Table 3—Aggregate Gradation Control Points

Sieve Size	Nominal Maximum Aggregate Size—Control Points (Percent Passing)											
	37.5 mm		25.0 mm		19.0 mm		12.5 mm		9.5 mm		4.75 mm	
	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max
50.0 mm	100	—	—	—	—	—	—	—	—	—	—	—
37.5 mm	90	100	100	—	—	—	—	—	—	—	—	—
25.0 mm	—	90	90	100	100	—	—	—	—	—	—	—
19.0 mm	—	—	—	90	90	100	100	—	—	—	—	—
12.5 mm	—	—	—	—	—	90	90	100	100	—	100	—
9.5 mm	—	—	—	—	—	—	—	90	90	100	95	100
4.75 mm	—	—	—	—	—	—	—	—	—	90	90	100
2.36 mm	15	41	19	45	23	49	28	58	32	67	—	—
1.18 mm	—	—	—	—	—	—	—	—	—	—	30	60
0.075 mm	0	6	1	7	2	8	2	10	2	10	6	12

6.1.3. *Gradation Classification*—The combined aggregate gradation shall be classified as coarse-graded when it passes below the Primary Control Sieve (PCS) control point as defined in Table 4. All other gradations shall be classified as fine-graded.

Table 4—Gradation Classification

PCS Control Point for Mixture Nominal Maximum Aggregate Size (% Passing)					
Nominal Maximum Aggregate Size	37.5 mm	25.0 mm	19.0 mm	12.5 mm	9.5 mm
Primary Control Sieve	9.5 mm	4.75 mm	4.75 mm	2.36 mm	2.36 mm
PCS Control Point (% Passing)	47	40	47	39	47

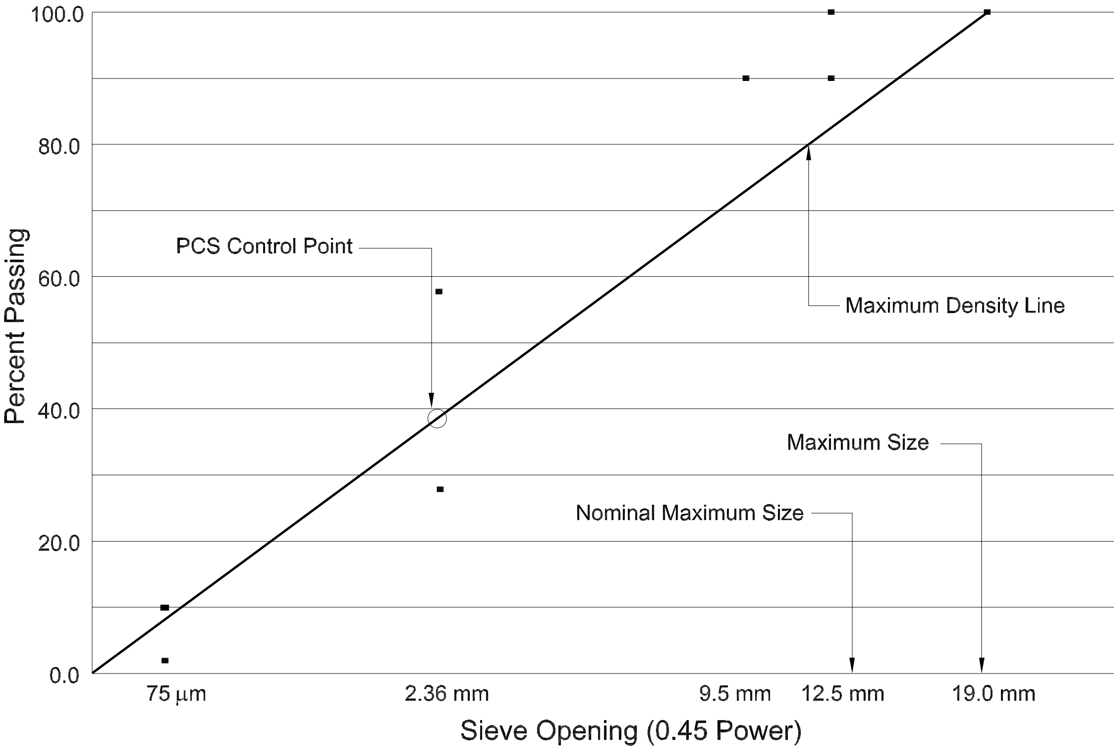

Figure 1—Superpave Gradation Control Points for a 12.5-mm Nominal Maximum Size Aggregate Gradation

6.2. *Coarse Aggregate Angularity Requirements*—The aggregate shall meet the percentage of fractured faces requirements, specified in Table 5, measured according to D 5821.

6.3. *Fine Aggregate Angularity Requirements*—The aggregate shall meet the uncompacted void content of fine aggregate requirements, specified in Table 5, measured according to T 304, Method A.

6.4. *Sand Equivalent Requirements*—The aggregate shall meet the sand equivalent (clay content) requirements, specified in Table 5, measured according to T 176.

6.5. *Flat-and-Elongated Requirements*—The aggregate shall meet the flat-and-elongated requirements, specified in Table 5, measured according to D 4791, with the exception that the material passing the 9.5-mm sieve and retained on the 4.75-mm sieve shall be included. The aggregate shall be measured using the ratio of 5:1, comparing the length (longest dimension) to the thickness (smallest dimension) of the aggregate particles.

6.6. When RAP is used in the mixture, the RAP aggregate shall be extracted from the RAP using a solvent extraction (T 164) or ignition oven (T 308) as specified by the agency. The RAP aggregate shall be included in determinations of gradation, coarse aggregate angularity, fine aggregate angularity, and flat-and-elongated requirements. The sand equivalent requirements shall be waived for the RAP aggregate but shall apply to the remainder of the aggregate blend.

Table 5—Superpave Aggregate Consensus Property Requirements

Design ESALs[a] (Million)	≤100 mm	>100 mm	≤100 mm	>100 mm		
<0.3	55/—	—/—	—	—	40	—
0.3 to <3	75/—	50/—	40	40	40	10
3 to <10	85/80[b]	60/—	45	40	45	10
10 to <30	95/90	80/75	45	40	45	10
≥30	100/100	100/100	45	45	50	10

[a] The anticipated project traffic level expected on the design lane over a 20-year period. Regardless of the actual design life of the roadway, determine the design ESALs for 20 years.

[b] 85/80 denotes that 85 percent of the coarse aggregate has one fractured face and 80 percent has two or more fractured faces.

[c] This criterion does not apply to 4.75-mm nominal maximum size mixtures.

Note 7—If less than 25 percent of a construction lift is within 100 mm of the surface, the lift may be considered to be below 100 mm for mixture design purposes.

7. HMA DESIGN REQUIREMENTS

7.1. The binder and aggregate in the HMA shall conform to the requirements of Sections 5 and 6.

7.2. The HMA design, when compacted in accordance with T 312, shall meet the relative density, VMA, VFA, and dust-to-binder ratio requirements specified in Table 6. The initial, design, and maximum number of gyrations are specified in R 35.

Table 6—Superpave HMA Design Requirements

	Required Relative Density, Percent of Theoretical Maximum Specific Gravity			Voids in the Mineral Aggregate (VMA), Percent Minimum						Voids Filled with Asphalt (VFA) Range,[b] Percent	Dust-to-Binder Ratio Range[c]
				Nominal Maximum Aggregate Size, mm							
Design ESALs[a] (Million)	N_{initial}	N_{design}	N_{max}	37.5	25.0	19.0	12.5	9.5	4.75		
<0.3	≤91.5	96.0	≤98.0	11.0	12.0	13.0	14.0	15.0	16.0	70–80[d]	0.6–1.2
0.3 to <3	≤90.5	96.0	≤98.0	11.0	12.0	13.0	14.0	15.0	16.0	65–78	0.6–1.2
3 to <10	≤89.0	96.0	≤98.0	11.0	12.0	13.0	14.0	15.0	16.0	65–75[e]	0.6–1.2
10 to <30	≤89.0	96.0	≤98.0	11.0	12.0	13.0	14.0	15.0	16.0	65–75[e]	0.6–1.2
≥30	≤89.0	96.0	≤98.0	11.0	12.0	13.0	14.0	15.0	16.0	65–75[e]	0.6–1.2

[a] Design ESALs are the anticipated project traffic level expected on the design lane over a 20-year period. Regardless of the actual design life of the roadway, determine the design ESALs for 20 years.

[b] For 37.5-mm nominal maximum size mixtures, the specified lower limit of the VFA range shall be 64 percent for all design traffic levels.

[c] For 4.75-mm nominal maximum size mixtures, the dust-to-binder ratio shall be 0.9 to 2.0.

[d] For 25.0-mm nominal maximum size mixtures, the specified lower limit of the VFA range shall be 67 percent for design traffic levels <0.3 million ESALs.

[e] For design traffic levels >3 million ESALs, 9.5-mm nominal maximum size mixtures, the specified VFA range shall be 73 to 76 percent and for 4.75-mm nominal maximum size mixtures shall be 75 to 78 percent.

Note 8—If the aggregate gradation passes beneath the PCS Control Point specified in Table 4, the dust-to-binder ratio range may be increased from 0.6–1.2 to 0.8–1.6 at the agency's discretion.

Note 9—Mixtures with VMA exceeding the minimum value by more than 2 percent may be prone to flushing and rutting. Unless satisfactory experience with high VMA mixtures is available, mixtures with VMA greater than 2 percent above the minimum should be avoided.

7.3. The HMA design, when compacted according to T 312 at 7.0 ± 0.5 percent air voids and tested in accordance with T 283, shall have a minimum tensile strength ratio of 0.80.

APPENDIX

(Nonmandatory Information)

X1. PROCEDURES FOR DEVELOPING A BLENDING CHART

X1.1. Blending of RAP binders can be accomplished by knowing the desired final grade (critical temperature) of the blended binder, the physical properties (and critical temperatures) of the recovered RAP binder, and either the physical properties (and critical temperatures) of the virgin asphalt binder or the desired percentage of RAP in the mixture.

X1.2. *Determine the physical properties and critical temperatures of the RAP binder.*

X1.2.1. Recover the RAP binder using T 319 (Note 10) with an appropriate solvent. At least 50 g of recovered RAP binder are needed for testing. Perform binder classification testing using the tests in M 320. Rotational viscosity, flash point, and mass loss tests are not required.

Note X1—While T 319 is the preferred method, at the discretion of the agency, T 170 may be used. Research conducted under NCHRP 9-12 indicated that T 170 might affect recovered binder properties.

X1.2.2. Perform original dynamic shear rheometer (DSR) testing on the recovered RAP binder to determine the critical high temperature, $T_c(High)$, based on original DSR values where $G^*/\sin\delta = 1.00$ kPa. Calculate the critical high temperature as follows:

X1.2.2.1. Determine the slope of the Stiffness-Temperature curve as follows:

$$a = \Delta\log(G^*/\sin\delta)/\Delta T \qquad (X1.1)$$

X1.2.2.2. Determine T_c (*High*) to the nearest 0.1°C using the following equation:

$$T_c\ (High) = \left(\frac{Log(1.00) - Log(G_1)}{a}\right) + T_1 \qquad (X1.2)$$

where:

G_1 = the $G^*/\sin\delta$ value at a specific temperature T_1, and

a = the slope as described in Equation X1.1.

Note X2—Although any temperature (T_1) and the corresponding stiffness (G_1) can be selected, it is advisable to use the $G^*/\sin\delta$ value closest to the criterion (1.00 kPa) to minimize extrapolation errors.

X1.2.3. Perform rolling thin-film oven (RTFO) aging on the remaining binder.

X1.2.4. Perform RTFO DSR testing on the RTFO-aged recovered binder to determine the critical high temperature (based on RTFO DSR). Calculate the critical high temperature (RTFO DSR).

X1.2.4.1. Determine the slope of the Stiffness-Temperature curve as follows:

$$a = \Delta \log(G^*/\sin \delta)/\Delta T \qquad (X1.3)$$

X1.2.4.2. Determine $T_c(High)$ based on RTFO DSR, to the nearest 0.1°C using the following equation:

$$T_c(High) = \left(\frac{Log(2.20) - Log(G_1)}{a} \right) + T_1 \qquad (X1.4)$$

where:

G_1 = the G*/sin δ value at a specific temperature T_1, and

a = the slope as described in Equation X1.3.

Note X3—Although any temperature (T_1) and the corresponding stiffness (G_1) can be selected, it is advisable to use the G*/sin δ value closest to the criterion (2.20 kPa) to minimize extrapolation errors.

X1.2.5. Determine the critical high temperature of the recovered RAP binder as the lowest of the original DSR and RTFO DSR critical temperatures. Determine the high temperature performance grade (PG) of the recovered RAP binder based on this single critical high temperature.

X1.2.6. Perform intermediate temperature DSR testing on the RTFO-aged recovered RAP binder to determine the critical intermediate temperature $T_c\,(Int)$, as if the RAP binder were pressure aging vessel (PAV) aged.

X1.2.6.1. Determine the slope of the Stiffness-Temperature curve as follows:

$$a = \Delta \log(G^*/\sin \delta)/\Delta T \qquad (X1.5)$$

X1.2.6.2. Determine $T_c\,(Int)$ to the nearest 0.1°C using the following equation:

$$T_c(Int) = \left(\frac{Log(5000) - Log(G_1)}{a} \right) + T_1 \qquad (X1.6)$$

where:

G_1 = the G*/sin δ value at a specific temperature T_1, and

a = the slope as described in Equation X1.5.

Note X4—Although any temperature (T_1) and the corresponding stiffness (G_1) can be selected, it is advisable to use the G*/sin δ value closest to the criterion (5000 kPa) to minimize extrapolation errors.

X1.2.7. Perform BBR testing on the RTFO-aged recovered RAP binder to determine the critical low temperature, $T_c\,(S)$ or $T_c\,(m)$, based on bending beam rheometer (BBR) Stiffness or *m*-value.

X1.2.7.1. Determine the slope of the Stiffness-Temperature curve as follows:

$$a = \Delta \log(S)/\Delta T \qquad (X1.7)$$

X1.2.7.2. Determine $T_c(S)$ to the nearest 0.1°C using the following equation:

$$T_c(S) = \left(\frac{Log(300) - Log(S_1)}{a} \right) + T_1 \qquad (X1.8)$$

where:

S_1 = the *S*-value at a specific temperature T_1, and

a = the slope as described in Equation X1.7.

Note X5—Although any temperature (T_1) and the corresponding stiffness (S_1) can be selected, it is advisable to use the *S*-value closest to the criterion (300 MPa) to minimize extrapolation errors.

X1.2.7.3. Determine the slope of the *m*-value-Temperature curve as follows:

$$a = \Delta m\text{-value}/\Delta T \qquad (X1.9)$$

X1.2.7.4. Determine $T_c(m)$ to the nearest 0.1°C using the following equation:

$$T_c(m) = \left(\frac{0.300 - m_1}{a} \right) + T_1 \qquad (X1.10)$$

where:

m_1 = the *m*-value at a specific temperature T_1, and

a = the slope as described in Equation X1.9.

Note X6—Although any temperature (T_1) and the corresponding *m*-value (m_1) can be selected, it is advisable to use the *m*-value closest to the criterion (0.300) to minimize extrapolation errors.

X1.2.7.5. Select the higher of the two low critical temperatures, $T_c(S)$ or $T_c(m)$, to represent the low critical temperature for the recovered asphalt binder, $T_c(Low)$. Determine the low temperature PG of the recovered RAP binder based on this single critical low temperature.

X1.2.8. Once the physical properties and critical temperatures of the recovered RAP binder are known, proceed with blending at a known RAP percentage or with a known virgin binder grade.

X1.3. *Blending at a known RAP percentage.*

X1.3.1. If the desired final blended binder grade, the desired percentage of RAP, and the recovered RAP binder properties are known, then the required properties of an appropriate virgin binder grade can be determined.

X1.3.1.1. Determine the critical temperatures of the virgin asphalt binder at high, intermediate, and low properties using the following equation:

$$T_{Virgin} = \frac{T_{Blend} - (\%\text{RAP} \times T_{RAP})}{(1 - \%\text{RAP})} \qquad (X1.11)$$

where:

T_{Virgin} = critical temperature of virgin asphalt binder (high, intermediate, or low);

T_{Blend} = critical temperature of blended asphalt binder (final desired) (high, intermediate, or low);

%RAP = percentage of RAP expressed as a decimal; and

T_{RAP} = critical temperature of recovered RAP binder (high, intermediate, or low).

X1.3.1.2. Using Equation X1.11 for the high, intermediate, and low critical temperatures respectively, the properties of the virgin asphalt binder needed can be determined.

X1.4. *Blending with a known virgin binder*.

X1.4.1. If the final blended binder grade, virgin asphalt binder grade, and recovered RAP properties are known, then the allowable RAP percentage can be determined.

X1.4.1.1. Determine the allowable RAP percentage using the following equation:

$$\%RAP = \frac{T_{Blend} - T_{Virgin}}{T_{RAP} - T_{Virgin}} \tag{X1.12}$$

where:

T_{Virgin} = critical temperature of virgin asphalt binder (high, intermediate, or low);

T_{Blend} = critical temperature of blended asphalt binder (high, intermediate, or low); and

T_{RAP} = critical temperature of recovered RAP binder (high, intermediate, or low).

X1.4.1.2. Using Equation X1.12 for the high, intermediate, and low critical temperatures, respectively, the allowable RAP percentage that will satisfy all temperatures can be determined.

Standard Specification for

Stone Matrix Asphalt (SMA)

AASHTO Designation: M 325-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Stone Matrix Asphalt (SMA)

AASHTO Designation: M 325-08

1. SCOPE

1.1. This specification covers the design of Stone Matrix Asphalt (SMA) using the Superpave Gyratory Compactor (SGC). The SMA design is based on the volumetric properties of the SMA in terms of air voids (V_a), the voids in mineral aggregate (VMA), and the presence of stone-on-stone contact.

1.2. This standard specifies minimum quality requirements for asphalt binder, aggregate, mineral filler, and stabilizing additives for SMA mixture designs.

1.3. The values stated in SI units are to be regarded as the standard. The U.S. Customary units in parentheses are for information only.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

---

3. TERMINOLOGY

3.1. *stone matrix asphalt* (SMA)—a hot mix asphalt (HMA) consisting of two parts, a coarse aggregate skeleton and a rich asphalt binder mortar. The mixture must have an aggregate skeleton with coarse aggregate-on-coarse aggregate contact (generally referred to as stone-on-stone contact). The coarse aggregate is generally considered to be that fraction of the aggregate retained on the 4.75-mm (No. 4) sieve but may be designated as other sizes.

3.2. *air voids* (V_a)—the total volume of the small pockets of air between the coated aggregate particles throughout a compacted paving mixture, expressed as a percent of the bulk volume of the compacted paving mixture (Note 1).

Note 1—Term defined in the Asphalt Institute Publication MS-2.

3.3. *voids in the mineral aggregate (VMA)*—the volume of the intergranular void space between the aggregate particles of a compacted paving mixture that includes the air voids and the effective binder content, expressed as a percent of the total volume of the specimen (Note 1).

3.4. *voids in the coarse aggregate (VCA)*—the volume between the coarse aggregate particles. This volume includes filler, fine aggregate, air voids, asphalt binder, and stabilizing additive (if used).

3.5. *SMA mortar*—a mixture of asphalt binder, filler [material passing the 0.075-mm (No. 200) sieve], and stabilizing additive.

3.6. *stabilizing additive*—either cellulose or mineral fiber.

---

4. SIGNIFICANCE AND USE

4.1. This standard may be used for designing and evaluating material and mixture properties for SMA.

---

5. ASPHALT BINDER REQUIREMENTS

5.1. The asphalt binder shall be a performance grade meeting the requirements of M 320, which is appropriate for the climate and traffic-loading conditions at the site of the paving project. Guidance for the selection of the appropriate asphalt binder is provided in M 323.

6. AGGREGATE REQUIREMENTS

6.1. Aggregates used in SMA shall conform to the requirements listed below.

6.1.1. *Coarse Aggregate*—Coarse aggregates shall be 100 percent crushed and conform to the quality requirements of Table 1.

6.1.2. *Fine Aggregate*—Fine aggregates shall be 100 percent crushed and conform to the quality requirements of Table 2.

Table 1—Coarse Aggregate Quality Requirements

Test		Method	Minimum	Maximum
Los Angeles (L.A.) Abrasion, percent loss		T 96	—	30[a]
Flat and Elongated, percent[b]	3 to 1	D 4791	—	20
	5 to 1	D 4791	—	5
Absorption, percent		T 85	—	2.0
Soundness (5 Cycles), percent[c]		T 104		
Sodium sulfate or			—	15
Magnesium sulfate			—	20
Crushed Content, percent		D 5821		
One Face			100	—
Two Face			90	—

[a] Aggregates with higher L.A. Abrasion values have been used successfully to produce SMA mixes. However, when the L. A. Abrasion exceeds 30, excessive breakdown may occur in the laboratory compaction process or during in-place compaction.

[b] Flat and Elongated criteria apply to the design aggregate blend.

[c] Sodium sulfate or magnesium sulfate may be used. It is not a requirement to perform both methods.

Table 2—Fine Aggregate Quality Requirements

Test	Method	Minimum	Maximum
Soundness (5 Cycles), percent[a]	T 104		
Sodium sulfate or		—	15
Magnesium sulfate		—	20
Liquid Limit, percent	T 89	—	25
Plasticity Index, percent	T 90	Non-plastic	

[a] Sodium sulfate or magnesium sulfate may be used. It is not a requirement to perform both methods.

7. MINERAL FILLER

7.1. Mineral filler shall consist of finely divided mineral matter such as crusher fines and fly ash. At the time of use, it should be sufficiently dry to flow freely and essentially free from agglomerations. Filler shall be free from organic impurities and have a plasticity index not greater than four.

Note 2—It is recommended that mineral fillers with modified Rigden voids (IS 127) higher than 50 percent not be used in SMA. Experience has shown that fillers exceeding 50 percent excessively stiffen the SMA mortar.

8. STABILIZING ADDITIVE

8.1. A stabilizer such as cellulose or mineral fiber will be added to the mixture. The dosage rate for cellulose shall be approximately 0.3 percent or more by total mixture mass and sufficient to prevent draindown. For mineral fibers, the dosage rate shall be approximately 0.4 percent by total mixture mass and sufficient to prevent draindown. The maximum draindown will be 0.3 percent by weight of the mix when held at the plant temperature for 1 hour.

Note 3—If the draindown from the plant-produced samples exceeds the draindown from laboratory-prepared samples, the quantity of the stabilizer should be increased. To maximize durability (through binder volume), fibers also can be added regardless of draindown.

9. SMA DESIGN REQUIREMENTS

9.1. The combined aggregates shall conform to the gradation requirements of Table 3. When the bulk specific gravities of the different stockpiles to be used in the mixture vary by more than 0.2, the trial blend gradations shall be based on the volumetric percentage.

Table 3—SMA Gradation Specification Bands

Sieve, mm (in.)	Nominal-Maximum Aggregate Size					
	19 mm ($^3/_4$ in.)		12.5 mm ($^1/_2$ in.)		9.5 mm ($^3/_8$ in.)	
	Lower	Upper	Lower	Upper	Lower	Upper
25.0 mm (1 in.)	100					
19.0 mm ($^3/_4$ in.)	90	100	100			
12.5 mm ($^1/_2$ in.)	50	88	90	100	100	
9.5 mm ($^3/_8$ in.)	25	60	50	80	70	95
4.75 mm (No. 4)	20	28	20	35	30	50
2.36 mm (No. 8)	16	24	16	24	20	30
1.18 mm (No. 16)	—	—	—	—	—	21
0.60 mm (No. 30)	—	—	—	—	—	18
0.30 mm (No. 50)	—	—	—	—	—	15
0.075 mm (No. 200)	8.0	11.0	8.0	11.0	8.0	12.0

9.2. The designed SMA mixture shall meet the requirements of Table 4.

Table 4—SMA Mixture Specifications for Superpave Gyratory Compactor[a]

Property	Requirement
Air Voids, %	4.0 (Note 4)
VMA, %	17.0 min
VCA_{MIX}, %	Less than VCA_{DRC} (Note 6)
TSR	0.80 min
Draindown at Production Temperature, %	0.3 max
Asphalt Binder Content, %	6.0 min (Note 7)

[a] SMA Mixture Specifications refer to specimens compacted in accordance with T 312 at 100 gyrations (Note 5).

Note 4—For low-traffic-volume roadways or colder climates, target air void contents less than 4.0 percent can be used, but should not be less than 3.0 percent.

Note 5—When aggregates have a Los Angeles Abrasion loss value greater than 30 percent, the desirable number of SGC design gyrations is 75.

Note 6—See R 46 for instructions on calculating VCA_{MIX} and VCA_{DRC}.

Note 7—Experience has shown that binder contents should be from 6.0 to 7.0 percent. Lowering the binder content below 6.0 percent can detrimentally affect the durability of the SMA. When an SMA mix cannot be designed within the minimum binder content requirements of Table 4 using the available aggregates, refer to the guidance given on this issue in R 46.

9.3. The tensile strength ratio (TSR) of the SMA shall be at least 0.80, at 6.0 ± 1.0 percent air voids, when tested in accordance with T 283.

9.4. Draindown sensitivity shall be determined on the SMA mixture in accordance with T 305 at the anticipated plant-production temperature and shall not exceed 0.3 percent.

Standard Practice for

Selection and Use of Emulsified Asphalts

AASHTO Designation: R 5-08
ASTM Designation: D 3628-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249

D 140	T 40	D 2872	T 240
D 1298	T 227	D 3381	M 226
D 1754	T 179		

2. Replace Table 1 with the following table:

Table 1—Physical Properties of Hot Mix Recycling Agents

Test	Test Method	RA 1		RA 5		RA 25		RA 75		RA 250		RA 500	
		Min	Max	Min	Max	Min	Max	Min	Max	Min	Max	Min	Max
Viscosity at 140°F, cSt[a]	T 201 or T 202	50	150	200	800	1000	4000	5000	10000	15000	35000	40000	60000
Flash point, COC, °F	T 48	425	—	425	—	425	—	425	—	425	—	425	—
Saturates, weight, %[b]	D 2007	—	25	—	25	—	25	—	25	—	25	—	25
Tests on residue from RTF or TF oven, 325°F	T 240 or T 179												
Viscosity ratio[c]		—	3	—	3	—	3	—	3	—	3	—	3
Weight change, ±, %		—	4	—	4	—	3	—	3	—	3	—	3
Specific gravity	T 228 or T 227	Report		Report		Report		Report		Report		Report	

[a] A recycling agent having a viscosity value outside the specified range is acceptable providing it meets all the above criteria, except viscosity, and has a minimum-to-maximum viscosity range comparable to the nearest RA grade.

[b] A recycling agent having a "Saturates weight percent" above 25 and below 30 is acceptable providing it meets all the above criteria except "Saturates weight percent."

[c]
$$\text{Viscosity Ratio} = \frac{\text{Viscosity of Residue from RTF or TF Oven Test at 140°F, cSt}}{\text{Original Viscosity at 140°F, cSt}}$$

Note: Compliance requires the asphalt be extracted from the pavement to be recycled and combined with the recycling agent being tested. This combination should be in accordance with the ratio of recycling agent to recovered asphalt used in the mix. The resulting mixture must meet all specifications for the appropriate grade from M 20 or M 226.

Standard Practice for

Asphalt Additives and Modifiers

AASHTO Designation: R 15-00 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Asphalt Additives and Modifiers

AASHTO Designation: R 15-00 (2008)

1. SCOPE

1.1. This standard practice covers the laboratory testing required to evaluate asphalt additives and modifiers in both neat asphalt and in asphalt-aggregate hot mixtures. The terms “additive” and “modifier” are used interchangeably and are broadly interpreted to include any materials added to asphalt binder in minor amounts, other than mineral fillers, sand, and aggregates, whose purported effect is to improve the performance and service life of pavements or maintenance materials by improving the properties of the asphalt binder or hot mix asphalt, or both.

1.2. Following is a list of the common purposes for which an additive/modifier may be added:

1.2.1. *Anti-Rutting* (permanent deformation).

1.2.2. *Anti-Cracking*.

1.2.2.1. Thermal Cracking (low-temperature cracking, thermal-fatigue cracking).

1.2.2.2. Load-Associated Fatigue Cracking.

1.2.3. *Anti-Stripping*—Moisture susceptibility of the asphalt-aggregate bond.

1.2.4. *Antioxidants*.

1.2.5. *Recycling* (not included).

Recycling is omitted from this standard practice. It is felt that consideration of the various characteristics of the material from the pavement to be recycled and formulation of the recycle mix are so involved as to make inclusion of recycling in this standard practice cumbersome and impractical.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

- NCHRP Report 268, Influence of Asphalt Temperature Susceptibility on Pavement Construction and Performance, Transportation Research Board, Washington, DC, December 1983

3. SUMMARY OF METHOD

3.1. The testing is divided into two phases. Phase I tests the modified binder (with tests of appropriate unmodified controls), while Phase II tests the modified hot mix asphalt. The purpose of dividing the testing into two phases is to use the faster and easier tests of Phase I as a screening method. If an asphalt additive or modifier shows no promise in Phase I, there may be no need to continue to Phase II. This, of course, would not apply if the additive/modifier interacts specifically with the aggregate, e.g., in the case of anti-stripping agents.

4. SIGNIFICANCE AND USE

4.1. This standard practice details the tests and procedure for evaluating asphalt modifiers to be used for paving. The modified asphalt binder is compared, as is appropriate, either with the same asphalt binder unmodified or with asphalt binder from the same base crude refined to a specification grade mimicking the specification-defining properties of the modified asphalt binder as closely as possible.

In most respects the evaluation procedures are those desirable for an unmodified asphalt binder. Both modified asphalt binder and hot mix asphalt using modified asphalt binders are evaluated. Performance-based testing is emphasized.

The procedures go beyond those that would be desirable for unmodified asphalt binder in that unmodified control asphalt binders are used and tested specifically for those properties to be enhanced by the modifier.

If testing (at appropriate additive levels) indicates that the functional purpose of the additive is not fulfilled, testing of the additive may be terminated.

If any of the other important performance properties of the modified asphalt binder are either unsatisfactory or significantly degraded, and cannot be remedied by, e.g., further modification, evaluation of the modifier may likewise be terminated.

If the results of evaluation according to this standard practice are positive, small-scale field trials and economic cost-benefit analysis may be warranted.

If the additive/modifier is being promoted by a supplier to a customer or evaluating laboratory, e.g., a governmental agency, a suggested list of information to be provided by the supplier to such a customer/evaluator is provided in Appendix X1.

5. CHOICE OF CONTROL SAMPLES

5.1. Control samples may be chosen for three purposes. Type A control samples are used for the most general evaluation of additive/modifiers. Type B is used when the supplier believes that his additive/modifier is useful under rather specific circumstances. Type C is used in evaluating an additive/modifier for a specific paving project. A minimum of three samples, i.e., three hot mix asphalt and their corresponding neat asphalt binders, which are commonly used as paving materials, must be chosen.

A. Hot mix asphalt and their corresponding neat asphalt binders spanning the range of those typically used throughout the United States may be chosen. It is recommended that the additive manufacturer obtain representative hot mix asphalt designs and constituent materials currently being produced for and approved by three State highway administrations. Depending upon the purpose of the additive, the manufacturer should obtain the hot mix asphalt and materials from states having experienced that type of asphalt pavement problem.

B. Hot mix asphalt and the corresponding neat asphalt binders recommended by the additive/modifier supplier as particularly appropriate to demonstrate the additive’s enhancement properties may be chosen, or

C. Specific hot mix asphalt and their corresponding neat asphalt binders considered for use in a particular modified asphalt project or in particular States or regions may be chosen.

6. EVALUATION TESTING

Note 1—It is suggested that the testing be done by a laboratory inspected for the appropriate tests by the AASHTO Materials Reference Laboratory (AMRL) and enrolled in the appropriate reference sample program by the AMRL.

6.1. *Relationship of Modified Asphalt Testing to Tests in Standard AASHTO Asphalt Specification*:

6.1.1. A modified asphalt binder, in the first instance, is compared to, and, in general, has to meet the applicable specifications for unmodified asphalt binders. These tests are found in M 320.

6.2. *Order of Performing Tests*:

6.2.1. The testing order should be based on what the asphalt additive is designed to accomplish. The most crucial tests (“go” or “no-go” tests) should be performed first. For example, if the proposed additive is purported to alleviate stripping as its only benefit, it is most appropriate to run Section 6.4.5, Moisture Damage Test, first. Should this test show that the additive provides no anti-stripping properties, there would likely be no reason to run any further tests. If the neat asphalt binder/asphalt binder-aggregate mixture responds favorably to this initial test (or tests), the remaining tests should be performed in order to make sure that the modifier does not have an unfavorable impact on any of the properties of the material.

6.3. *Phase I Testing—Asphalt Binders*:

6.3.1. Pressurized Aging Vessel (PAV) Aging—R 28;

6.3.2. Grading or Verifying the Performance Grade of an Asphalt Binder—R 29;

6.3.3. Bending Beam Rheometer (BBR) Test—T 313;

6.3.4. Direct Tension Test (DTT)—T 314;

6.3.5. Dynamic Shear Rheometer (DSR) Test—T 315;

6.3.6. Viscosity Using Rotational Viscometer—T 316;

6.3.7. Sampling—T 40;

6.3.8. Solubility—T 44;

6.3.9. Flash Point by Cleveland Open Cup—T 48;

6.3.10. Water in Petroleum Products and Bituminous Materials—T 55;

6.3.11. Specific Gravity of Semi-Solid Bituminous Materials—T 228;

6.3.12. Rolling Thin-Film Oven Test—T 240;

Note 2—The following tests need at least verification and often basic development. Hence, the references given are often indicative rather than definitive.

6.3.13. Limiting Stiffness Method for Predicting Cracking Temperature—FHWA/RD-87/001;

6.3.14. Critical Stress Method for Predicting Temperature—FHWA/RD-87/001;

6.3.15. Force-Ductility—FHWA/TX85/347/1;

6.3.16. Dynamic Mechanical Analysis (DMA)—Including Aging Index—FHWA/RD-87/001;

6.3.17. Time-Temperature Degradation Profile of Additive/Modifier—FHWA/RD-87/001;

6.3.18. Aging as Measured by Infrared Spectroscopy (IR)—FHWA/RD-87/001; and

6.3.19. Homogeneity Test (Compatibility Between Modifier and Asphalt)—FHWA/RD-87/001.

6.4. *Phase II Hot Mix Asphalt*:

6.4.1. Short- and Long-Term Aging of Hot Mix Asphalt (HMA)—R 30;

6.4.2. Superpave Volumetric Design for Hot Mix Asphalt (HMA)—R 35 and M 323;

6.4.3. Hot Mix Asphalt (HMA) Specimens by Means of the SHRP Gyratory Compactor—T 312;

6.4.4. Volumetric Analysis (Air Voids and VMA);

6.4.4.1. Theoretical Maximum Specific Gravity—T 209;

6.4.4.2. Bulk Specific Gravity—T 166 or T 275;

6.4.4.3. Percent Air Voids Calculation—T 269;

6.4.4.4. Specific Gravities and Absorption of Aggregate—T 84, T 85, and T 133;

Note 3—The bulk specific gravity of the aggregate is needed to calculate VMA.

6.4.5. Moisture Damage Test—T 283 or NCHRP-274;

Note 4—When testing anti-stripping additives, it is recommended that the retained ratio from these tests for the untreated mixture be less than 70 percent.

6.4.6. Permanent Deformation and Fatigue Cracking Characteristics of Hot Mix Asphalt (HMA) Using the Simple Shear Test (SST) Device—T 320; and

6.4.7. Resilient Modulus by Indirect Tension (IDT)—TP 31.[1]

7. REPORT

7.1. Description of asphalt binders;

7.2. Description of Aggregates;

7.3. Mix Design Properties; and

7.4. Results of Tests Performed.

APPENDIX

(Nonmandatory Information)

X1. INFORMATION FROM ADDITIVE/MODIFIER SUPPLIER:

X1.1. What is the material (trade name, generic name, and specific chemical identity)?

X1.2. Who is the manufacturer (company name, street address, mailing address, zip code, telephone number, fax number, contact person)? Who supplied it for testing (company name, street address, mailing address, zip code, telephone number, fax number, contact person)?

X1.3. Physical properties?

X1.4. Material Safety Data Sheet (MSDS).

Is the material a Resource Conservation and Recovery Act of 1976 (RCRA) hazardous waste?

X1.5. What properties does the Additive/Modifier improve?

X1.5.1. In asphalt binder.

X1.5.1.1. What tests demonstrate this? Give details or references.

X1.5.2. In hot mix asphalt.

X1.5.2.1. What tests demonstrate this? Give details or references.

X1.6. Instructions for Use.

X1.6.1. Percent.

X1.6.2. Method of addition.

X1.6.3. Restrictions on use.

X1.7. Qualitative and Quantitative Analysis of Additive/Modifier.

X1.7.1. Neat.

X1.7.2. In asphalt binder.

X1.7.3. In hot mix asphalt.

X1.8. What asphalt binder, aggregate, and mix design should be used with the additive/modifier? Answer with reference to Section X1.5.

X1.9. Marketing Data.

X1.9.1. Availability.

X1.9.2. Approximate cost.

X1.9.3. Sample availability (optional).

X1.9.4. Which public agencies have used this material?

---

Standard Practice for

Certifying Suppliers of Performance-Graded Asphalt Binders

AASHTO Designation: R 26-01 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Certifying Suppliers of Performance-Graded Asphalt Binders

AASHTO Designation: R 26-01 (2009)

1. SCOPE

1.1. This standard specifies requirements and procedures for a certification system that shall be applicable to all suppliers of performance-graded asphalt binder (PGAB). The requirements and procedures shall apply to materials that meet the requirements of M 320, Section 5, Materials and Manufacture, and which are manufactured at refineries, mixed at terminals, in-line blended, or modified at the hot mix asphalt (HMA) plant.

1.2. *This standard may involve hazardous materials, operations, and equipment. It does not purport to address all of the safety problems associated with this use. The user of this standard shall be responsible for appropriate safety and health practices.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 320, Performance-Graded Asphalt Binder
- R 29, Grading or Verifying the Performance Grade (PG) of an Asphalt Binder
- T 40, Sampling Bituminous Materials

2.2. *ASTM Standards*:

- D 8, Standard Terminology Relating to Materials for Roads and Pavements
- D 3665, Standard Practice for Random Sampling of Construction Materials

3. TERMINOLOGY

3.1. *AAP*—AASHTO accreditation program.

3.2. *agency*—agency shall be defined as a state highway agency or other agency responsible for the final acceptance of the PGAB.

3.3. *AS*—approved supplier.

3.4. *ASC*—approved supplier certification.

3.5. *asphalt binder*—an asphalt based cement that is produced from petroleum residue either with or without the addition of nonparticulate organic modifiers.

3.6. *PGAB*—performance-graded asphalt binder.

3.7. *quality control testing*—the quality control testing shall be described in the supplier's quality control plan. The supplier's quality control plan shall be approved by the agency.

3.8. *specification compliance testing*—complete testing in accordance with the M 320 specification requirements. The procedure for verification of PGAB as described in R 29 shall be followed.

3.9. *supplier*—a *supplier* shall be defined as one who produces the final product or who makes the blend or modification that alters the properties of the PGAB specified in M 320. A supplier shall be a refinery, a terminal, or an HMA producer. If no modification is made to the PGAB after its initial production at the refinery, the refinery shall be the supplier and must provide the certification. If any modifications are made to the PGAB at the terminal, the terminal shall be the supplier and must provide certification. If any modification, blending, or blending of PGAB from different sources is made at the HMA plant, the HMA producer shall be the supplier and must provide the certification.

Note 1—Various refining techniques can produce equivalent PGAB; however, these asphalts may be incompatible with each other. Users shall consider compatibility before combining asphalts from different sources.

Note 2—Definitions for many terms common to asphalt binder are found in ASTM D 8.

4. SIGNIFICANCE AND USE

4.1. This standard specifies procedures for minimizing disruption of PGAB shipments. This is accomplished by a certification system which evaluates quality control and specification compliance tests performed by the supplier on samples obtained prior to shipment.

4.2. The number of PGAB available under M 320 may require construction of additional storage facilities if the procedure of "sample and hold while testing" is followed exclusively. The addition of new storage capacity at a facility may be infeasible at some locations. Standardization of procedures that allow shipment under an approved supplier certification provides the flexibility needed to use existing facilities and to limit the shipment disruptions.

4.3. This standard provides information on the following activities:

4.3.1. General requirements that the supplier shall satisfy to be given approved-supplier status;

4.3.2. Minimum requirements that shall be included in a supplier's quality control plan;

4.3.3. General requirements that the agency shall satisfy before certification;

4.3.4. Procedure for shipping PGAB under an ASC system;

4.3.5. Procedure for agency monitoring of an ASC system at the shipping facility; and

4.3.6. Procedure for field sampling and testing of PGAB shipped under an ASC system.

5. HAZARDS

5.1. The safety requirements of the field and/or laboratory organization and/or OSHA shall be observed.

6. SAMPLING

6.1. All test samples required by this standard shall be obtained in accordance with T 40 and ASTM D 3665. The use of a random sampling procedure is mandatory to the establishment of a valid certification program.

7. TESTING REQUIREMENTS

7.1. Testing required for this standard shall be performed by a laboratory currently accredited by the AAP. Any satellite laboratory of a supplier that performs required testing under this standard shall be identified in the AS quality control plan (Section 9) and shall be approved by the agency.

Note 3—Cost of this inspection shall be borne by the source of data. Satellite laboratories may be inspected by the source's primary AMRL inspected laboratory staff. A copy of the report of the satellite laboratory inspection shall be provided with the test report, if requested.

8. SUPPLIER REQUIREMENTS

8.1. The supplier shall submit a written request to the agency for authorization to ship PGAB under the ASC system and shall list the PGAB to which the request applies.

8.2. The supplier shall allow the agency to visit the production and/or shipping site to observe the supplier's quality control activities, to inspect the facilities, and to obtain samples for test.

8.3. The supplier shall submit to the agency for approval a complete quality control plan, which complies with the requirements of Section 9.

8.4. The supplier shall follow the procedures described in the approved quality control plan.

8.5. The supplier shall establish a continuing test record for each test required on each PGAB included in the written request prepared to satisfy the requirements of Section 8.1.

8.6. The supplier shall forward to the agency the initial series of test data for each performance grade included in the written request prepared to satisfy the requirements of Section 8.1. The supplier shall also obtain and provide a split sample for the agency if requested.

8.7. The supplier shall submit to the agency all reports required by this standard in a form approved by the agency. A sample of an acceptable worksheet and standard report form is shown in Figures 1 and 2.

8.8. The supplier shall have a satisfactory record of compliance with governing specifications. Judgments by the agency concerning this requirement shall be based on the test results furnished by the supplier and satisfactory results when the monitoring and field tests are compared with supplier tests.

9. SUPPLIER QUALITY CONTROL PLAN—MINIMUM REQUIREMENTS

9.1. The supplier's quality control plan shall identify the following:

9.1.1. Facility type (refinery, terminal, in-line blending or HMA plant);

9.1.2. Facility location;

9.1.3. Name and telephone number of the person responsible for quality control at the facility;

9.1.4. The quality control tests to be performed on each PGAB; and

9.1.5. Name and location of the laboratory performing quality control tests on the PGAB that is shipped.

9.2. The supplier's quality control plan shall include a declaration stating that if a test result indicates that a shipment of PGAB is not in compliance with the purchase specifications, the supplier shall (1) immediately notify the agency of the shipment in question; (2) identify the material; (3) cease shipment until material complies with the specification; (4) notify the agency prior to resuming shipment; and (5) implement any mutually agreed upon procedures for the disposition of the material. In the event a mutual agreement is not obtained, the specifying agency shall have final authority in the decision on specification compliance.

9.3. The supplier's quality control plan shall describe method and frequency for initial testing, quality control testing, and specification compliance testing.

9.3.1. *Initial Testing*—For each grade of PGAB to be supplied, specification compliance testing (complete M 320 testing) shall be performed for at least three consecutive lots. A lot may be a fixed batch of material or a specified quantity in a continuous operation (see Note 4). The supplier and the agency shall agree on a lot size. The agency must approve any change to a lot size.

Note 4—If a batch operation is used to manufacture the PGAB, a tank may be defined as a lot. Lot size would be the amount of material batched into the tank. If a continuous process (in-line blending or a shipment from "live" tanks) is used to manufacture the PGAB, lot size may be obtained at random during the production for continuous operations. Lot size shall depend on the production method used and the quantity of the PGAB produced.

9.3.2. *Reduced Frequency of Testing for Specification Compliance*—If approved by the agency, the frequency of testing for specification compliance may be decreased if the individual M 320 test result for every sample of the initial testing is within specification by at least the tolerance of the test method for each of the required test methods. With the approval of the agency, the frequency of testing may be further reduced as long as the individual test results continue to meet the tolerance criterion. If the tolerance criterion is not met, every lot will continue to be tested for the individual M 320 property until three consecutive lots comply with the tolerance criterion.

9.3.3. *Minimum Frequency*—Specification compliance testing shall be run at the minimum frequency required by the agency for each PGAB that is supplied.

9.3.4. *Quality Control Testing for Guiding Manufacturer*—At least two M 320 tests shall be used for monitoring high and low temperature properties of the PGAB. Non-M 320 tests may be used for guiding manufacturer, if approved by the agency. The use of non-M 320 tests does not preclude the need to meet M 320 specifications or to run complete M 320 tests according to the guidelines in Section 9.3.

9.4. The supplier's quality control plan shall include a statement that the supplier will prepare monthly summary reports for all quality control and specification compliance tests performed during that period and will submit them to the agency on request.

9.5. The supplier quality control plan shall provide an outline of the procedure to be followed for checking transport vehicles before loading to prevent contamination of shipments. The outline shall include a statement that the transport vehicle inspection report, signed by the responsible inspector, shall be maintained in the supplier's records, and will be made available to the agency on request.

9.6. The supplier shall submit a written request to the agency for authorization to use in-line blending of additives that meet Section 5 of M 320 at the HMA plant to produce PGAB. With the request, the supplier shall submit (1) a sample of the additives; (2) a sample of the base binder materials; (3) a notice of the proportions that will be used; and (4) the M 320 test results for the base binder material and for the blended binder material determined under the requirements of Section 8.

9.6.1. The supplier, if an HMA producer, shall submit a detailed plan for QC at the HMA plant. The QC plan shall conform to the procedure established in Section 9.3 with the following modifications: (1) the initial testing shall be conducted on the modified binder that is sampled beyond the in-line blending point, and (2) the supplier shall keep a record of the proportions, based on mass or other indicators. The supplier and agency shall agree on the frequency for recording the proportions. (See Section 3.6.)

Note 5—For additives that do **not** meet the requirements of Section 5, M 320, the supplier may submit a written request to the agency for authorization to use solid additives that are to be added directly to the mix at the asphalt batch plant or the drum mix plant. With the request, the supplier shall submit (1) a sample of the additives; (2) a sample of the base binder materials; (3) a notice of the proportions that will be used; and (4) the M 320 test results for the base binder material and for the blended binder material, as applicable under M 320, determined under the requirements of Section 8.

M 320 and the test procedures may not be applicable for some of the solid additives because of their size range after blending with the base binder or other characteristics of the modifier. If the binder fails to meet any of the criteria under Section 5 of M 320, acceptance of the binder shall be at the discretion of the agency. Supplier and agency shall therefore agree on the test methods to be used. The agency may allow the use of M 320 tests or may require testing of the resultant HMA using selected test procedures to assure the level of performance expected.

The supplier shall submit a detailed plan for QC at the HMA plant. The QC plan shall conform to the procedure established in Section 9.3 with the following modifications: (1) initial testing shall be conducted on a laboratory blend of the solid additive and the binder to be added at the HMA plant; (2) the supplier shall keep a record of the proportions, based on mass or other indicators; and (3) the supplier and agency shall agree on the frequency for recording the proportions.

Note 6—*Reclaimed Asphalt Pavement* (RAP)—The HMA producer may submit a written request to the agency for authorization to add RAP to the mix at the HMA plant to meet the PGAB specified. With the request, the HMA producer shall submit (1) a sample of the RAP; (2) a sample of the base binder materials; (3) a notice of the proportions that will be used; and (4) the M 320 test results for the base binder material and for the blended binder material determined under the requirements of Section 8.

The HMA producer shall submit a detailed plan for QC at the HMA plant. The QC plan shall conform to the procedure established in Section 9.3 with the following modifications: (1) initial testing shall be conducted on a laboratory blend of the asphalt cement extracted from the RAP sample, any addition of additive, and the binder material that is to be added at the HMA plant; (2) the HMA producer shall keep a record of the proportions, based on mass or other indicators; and (3) the HMA producer and agency shall agree on the frequency for recording the proportions.

The agency may waive the requirement for testing the laboratory-blended binder and may use other guidelines for selecting the performance grade of the new binder relative to the amount of RAP used.

10. AGENCY REQUIREMENTS

10.1. The agency shall verify that the supplier's quality control plan is adequate. The agency may visit the shipping site when required.

10.2. The agency shall notify the supplier that the supplier's application for AS status has been granted. The notification shall include a list of the PGAB covered.

10.3. The agency shall verify that the supplier's primary testing laboratory is currently AASHTO accredited.

10.4. The agency may perform split sample testing in accordance with Section 12.

10.5. The agency may perform quality assurance sampling and testing in accordance with Section 13.

10.6. The agency shall authorize shipment of each listed PGAB under the ASC system only after all ASC system requirements have been satisfied.

10.7. The agency shall inspect the operations of the supplier's facility related to the PGAB shipments when required.

10.8. The agency shall notify the supplier when split sample data versus supplier sample data do not compare within the limits established in Sections 12 and 13.

Note 7—The supplier and/or the HMA producer may take a split sample for comparison purposes. If a split sample is taken, a third sample shall be taken as a referee. The referee sample shall be retained either by the agency or by the HMA producer until the test results are available. If the test results are disputed, the agency and supplier shall agree upon a test procedure for the referee sample.

11. REQUIREMENTS FOR SHIPPING PGAB BY AN APPROVED SUPPLIER

11.1. The supplier's quality control plan as approved by the agency shall be implemented. (See Section 9.)

11.2. The supplier shall make PGAB shipments covered by the certification as dictated by shipping schedules.

11.3. Each shipment shall be accompanied by two copies of the bill of lading, which shall include (1) the name and location of the supplier; (2) the performance grade of material; (3) the quantity of material shipped; (4) the date of shipment; (5) a statement certifying the material meets specification requirements; and (6) a statement certifying that the transport vehicle was inspected before loading and was found acceptable for the material shipped.

Note 8—On any invoice or Bill of Lading, it is recommended that metric tons be used as the primary unit of measurement.

11.4. If the specification compliance test results do not conform to PGAB specifications, the supplier shall remove the noncompliant material from the shipping queue as outlined in Section 9.2.

11.5. Based on the agency's split sample testing on the referee sample (see Note 7), price adjustment may be made for material that does not comply with the specified PGAB requirements. The price adjustment shall be determined by the agency. If problems with the PGAB recur at the HMA plant, the agency may suspend use of the PGAB until the cause for noncompliance with specifications can be identified and corrected.

12. SPLIT SAMPLE TESTING

12.1. The agency may test split samples that are obtained at random from the supplier's facility.

Note 9—Split samples will be obtained from the same general points in the supplier's shipping process from which the supplier's samples are taken, for example, from a storage tank at the refinery, from a holding tank at a terminal, or from a loading line downstream from the blending operation of an in-line blending process.

12.2. The agency shall determine the frequency of split sample testing.

12.3. If the split sample data and the supplier test data are not within the test tolerance specified (see Section 15), an immediate investigation shall be conducted to determine the reason for the difference between the data. Unless available facts indicate otherwise, the investigation shall include a review of sampling and testing procedures of both supplier and agency.

13. FIELD SAMPLING

13.1. The agency or HMA producer may design the field-sampling plan to accomplish the intended purpose.

Note 10—Field samples may be taken for several different purposes: to determine the type and magnitude of any changes in the properties of the PGAB during transportation and storage; to determine that the material received in the field is the material ordered; or to verify that the quality control/quality assurance system is performing as intended.

13.2. The agency may obtain samples from the field facility on a random basis for the purpose of quality assurance.

13.3. The agency shall determine a minimum frequency of field sampling that shall be adequate to satisfy the purpose for which the field samples are taken.

13.4. If the field test data are not within tolerance, the agency shall immediately notify the approved supplier and HMA producer. Unless available facts indicate otherwise, an investigation shall be conducted that shall include a review of quality control and sampling and testing procedures for field sampling and split sampling. When the differences are not readily resolved, all facts available to identify the problem shall be used to decide on an appropriate course of corrective action.

13.5. If the PGAB fails to comply with the specification, the supplier or HMA producer shall immediately investigate the possibility of contamination in transport vehicles, field storage tanks, pumps, lines, and at handling facilities. If the cause is determined, correction shall be made promptly. If field test data show a serious departure from the specifications, the supplier or HMA producer shall delay the project work pending corrective action.

14. REPORT AND DATA SHEETS

14.1. *Supplier Reports*—The supplier shall prepare the reports described in Sections 8.1, 8.3, 8.6, 8.7, 9.2, 9.4, 9.5, 11.2, and 11.3.

14.2. *Agency Reports*—The supplier may request copies of the split sample test results and field test data.

Standard Practice for

Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)

AASHTO Designation: R 28-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)

AASHTO Designation: R 28-09

1. SCOPE

1.1. This standard practice covers the accelerated aging (oxidation) of asphalt binders by means of pressurized air and elevated temperature. The practice is intended to simulate in-service oxidative aging of asphalt binders and is intended for use with residue from T 240 (RTFOT).

1.2. The aging of asphalt binders during service is affected by mixture-associated variables such as the volumetric proportions of the mix, permeability of the mix, properties of the aggregates, and possibly other factors. This practice is intended to provide an evaluation of the relative resistance of different asphalt binders to oxidative aging at selected temperatures and cannot account for mixture variables.

1.3. *This standard practice may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- M 320, Performance-Graded Asphalt Binder
- T 240, Effect of Heat and Air on a Moving Film of Asphalt Binder (Rolling Thin-Film Oven Test)

2.2. *ASTM Standard*:

- E 220, Standard Test Method for Calibration of Thermocouples by Comparison Techniques

2.3. *Deutche Industrie Norm (DIN) Standard*:

- 43760, Standard for Calibrating Thermocouples

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *asphalt binder*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of non-particulate organic modifiers.

3.1.2. *in-service*—refers to aging of the asphalt binder that occurs in the pavement as a result of the combined effects of time, traffic, and the environment.

4. SUMMARY OF PRACTICE

4.1. Asphalt binder is first aged using T 240 (RTFOT). A specified thickness of residue, from the RTFOT, is then placed in stainless steel pans and aged at the specified aging temperature for 20 hours in a vessel pressurized with air to 2.10 MPa. The aging temperature is selected according to the grade of the asphalt binder. At the completion of the PAV process, the asphalt binder residue is then vacuum degassed.

5. SIGNIFICANCE AND USE

5.1. This practice is designed to simulate the in-service oxidative aging that occurs in asphalt binders during pavement service. Residue from this practice may be used to estimate the physical or chemical properties of asphalt binders after 5 to 10 years of in-service aging in the field.

5.2. Asphalt binders aged using R 28 are used to determine specification properties in accordance with M 320. The asphalt binder is aged with the RTFO test prior to this conditioning step. Tank asphalt binders, as well as RTFOT and residue from this practice, are used to determine specification properties in accordance with M 320.

5.3. For asphalt binders of different grades or from different sources, there is no unique correlation between the aging time and temperature in this practice and in-service pavement age and temperature. Therefore, for a given set of in-service climatic conditions, it is not possible to select a single PAV aging time and temperature that will predict the properties of all asphalt binders after a specific set of in-service exposure conditions.

5.4. The relative degree of hardening of different asphalt binders varies at different aging temperatures in the PAV. Therefore, two asphalt binders may age similarly at one temperature, but age differently at another temperature.

6. APPARATUS

6.1. A test system consists of a pressure vessel, pressure controlling devices, temperature controlling devices, pressure and temperature measuring devices, and a temperature-recording device (Figure 1).

6.1.1. *Pressure Vessel*—A stainless steel pressure vessel designed to operate at 2.1 ± 0.1 MPa between 90 and 110°C with interior dimensions adequate to hold ten stainless steel pans and a pan holder. The pressure vessel shall contain a pan holder capable of holding ten stainless steel pans in a horizontal (level) position such that the asphalt binder film thickness in the bottom of the pans does not vary by more than 0.5 mm across any diameter of the pan. The holder shall be designed for easy insertion and removal from the vessel when the holder, pans, and asphalt binder are at the test temperature. A schematic showing the vessel, pan holder and pans, and specifying the dimensional requirements is shown in Figure 2.

Note 1—The vessel may be a separate unit to be placed in a forced draft oven for conditioning the asphalt binders or an integral part of the temperature control system (for example, by direct heating of the vessel or by surrounding the vessel with a permanently affixed heating unit, forced air oven, or liquid bath).

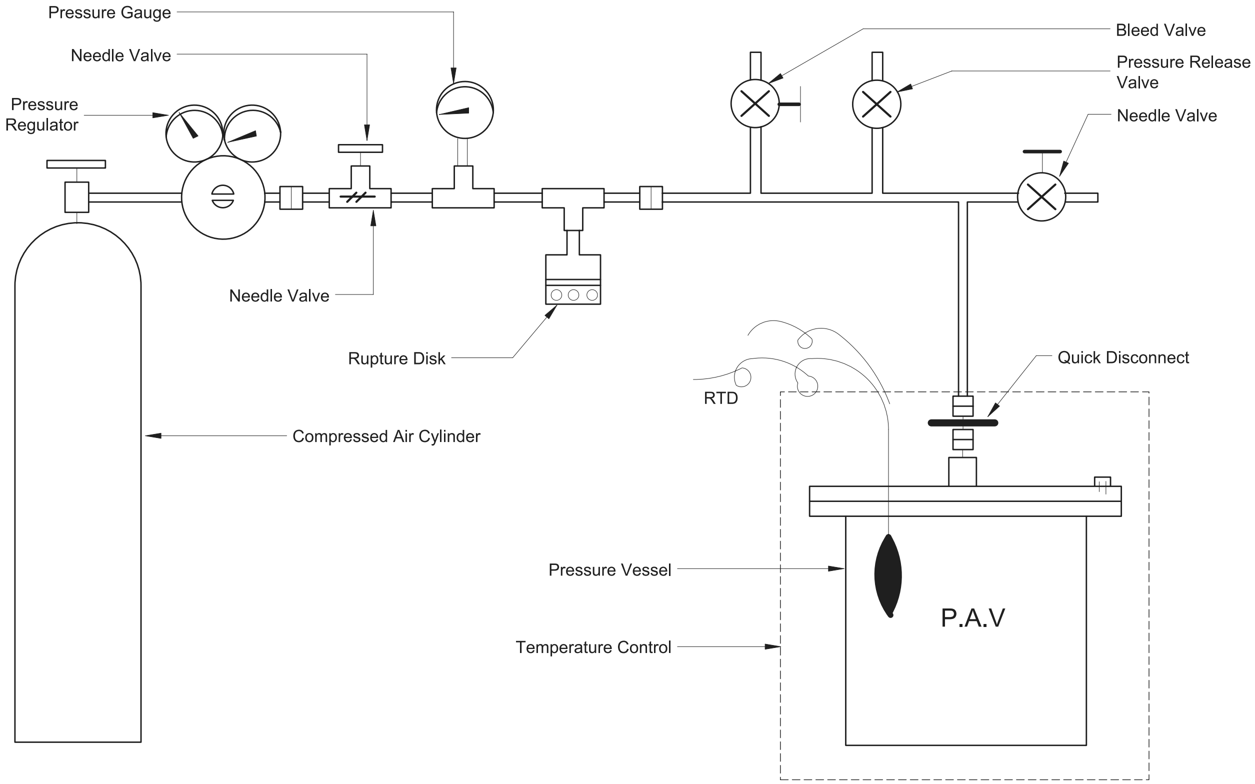

Figure 1—Schematic of Typical PAV Test System

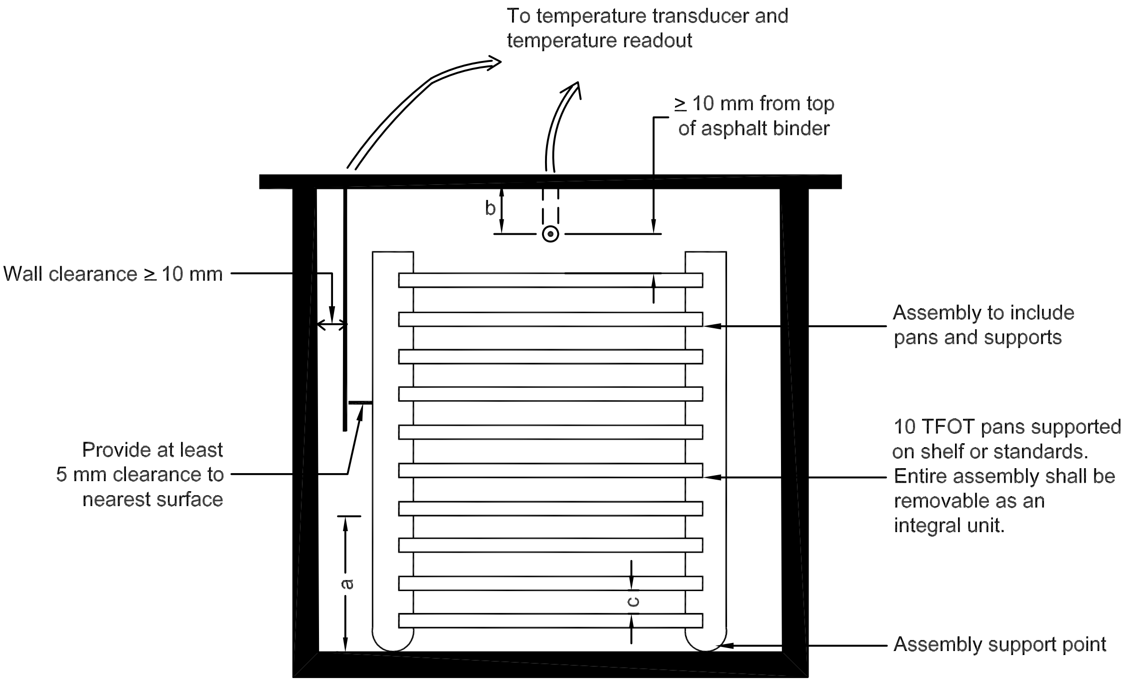

Notes:
1. Distance "a" controls the levelness of the pans. The assembly shall be supported at three or more support points. The distance "a", measured from each assembly support point to the bottom of the pan (top of shelf or pan support point), shall be controlled to ±0.05 mm. Provisions shall be made to ensure that the bottom of the vessel is leveled so that the thickness of the binder in the pan varies by no more than ±0.05 mm across the diameter of any pan.
2. Distance "b" shall be such that any active portion of the temperature transducer is ≥10 mm from the top surface of the vessel.
3. Distance "c" shall be ≥12 mm.

Figure 2—Schematic Showing Location of Pans and RTD within Representative PAV

6.1.2. *Pressure Controlling Devices*:

6.1.2.1. A pressure release valve that prevents pressure in the vessel from exceeding 2.2 MPa during the aging procedure.

6.1.2.2. A pressure regulator capable of controlling the pressure within the vessel to ±1 percent, and with a capacity adequate to reduce the pressure from the source of compressed air so that the pressure within the loaded pressure vessel is maintained at 2.1 ± 0.1 MPa during the practice.

6.1.2.3. A slow release bleed valve that allows the pressure in the vessel at the completion of the conditioning procedure to be reduced at an approximately linear rate from 2.1 MPa to local atmospheric pressure within 9 ± 1 minutes.

6.1.3. *Temperature Controlling Devices*—A temperature control device as described in Section 6.1.3.1 or Section 6.1.3.2 for maintaining the temperature during the aging procedure at all points within the pressure vessel at the aging temperature ±0.5°C and a digital proportional controller for maintaining the specified temperature control.

6.1.3.1. A forced-draft oven or fluid bath capable of (1) bringing the loaded unpressurized vessel to the desired conditioning temperature ±0.5°C, as recorded by the Resistance Thermal Detector (RTD) inside the vessel within 2 hours, and (2) maintaining the temperature at all points within the pressure vessel at the aging temperature ±0.5°C. The oven shall have sufficiently large interior dimensions to allow forced air to freely circulate within the oven and around the pressure vessel when the vessel is placed in the oven. The oven shall contain a stand or shelf which supports the loaded pressure vessel in a level position above the lower surface of the oven (i.e., maintains the film thickness in the aging pans within the specified tolerance).

6.1.3.2. A pressure vessel with integral temperature control system that is capable of (1) bringing the loaded pressure vessel to the desired conditioning temperature ±0.5°C within 2 hours, as recorded by the RTD inside the loaded pressure vessel, and (2) maintaining the temperature at all points within the pressure vessel at the aging temperature ±0.5°C.

6.1.4. *Temperature and Pressure Measuring Devices*:

6.1.4.1. A platinum RTD accurate to the nearest 0.1°C and meeting DIN Standard 43760 (Class A), or equal, for measuring temperature inside the pressure vessel. The RTD shall be calibrated as an integral unit with its respective meter or electronic circuitry.

Note 2—The RTD or thermistor and its meter may be calibrated by the manufacturer or a commercial vendor. Verification can be obtained by comparing the output from the RTD with an NIST traceable ASTM 94C mercury in glass thermometer in accordance with ASTM E 220. A stirred fluid bath is suitable for calibrating the thermal detector. Select a partial immersion mercury-in-glass thermometer with an appropriate range and place the thermal detector and the thermometer in the stirred water bath. Fasten the detector to the glass thermometer with a rubber band or rubber O-ring. Allow the bath, detector, and thermometer to come to thermal equilibrium and record the temperature of the glass thermometer and the readout from the thermal detector. The temperature in the bath shall not change by more than 0.1°C per minute during the calibration process.

6.1.4.2. *Temperature-Recording Device*—A strip chart recorder or other data acquisition system capable of recording temperature throughout the test to 0.1°C. As an alternative, an electronic device capable of reporting maximum and minimum temperatures (accurate to ±0.1°C) may be used.

6.1.4.3. A pressure gauge capable of measuring the pressure in the pressure vessel to within ±1 percent during the test.

6.2. *Stainless Steel Pans*—Ten standard stainless steel pans with an inside diameter of 140 mm ($5^1/_2$ in.) and 9.5 mm ($^3/_8$ in.) deep with a flat bottom. Pans shall be made of stainless steel and should have a metal thickness of approximately 0.635 mm ($^1/_4$ in.).

6.3. *Balance*—A balance conforming to the requirements of M 231, Class G 2.

6.4. *Vacuum Oven*—A vacuum oven capable of maintaining a temperature up to 180°C with an accuracy of ±5.0°C and a vacuum of 1.0 kPa absolute.

6.5. *Vacuum System*—A vacuum system capable of generating and maintaining pressures below 15 kPa absolute. Suitable vacuum systems include a vacuum pump, air aspirator, or house vacuum system.

7. MATERIALS

7.1. Commercial bottled air or equivalent.

8. HAZARDS

8.1. Use standard laboratory safety procedures in handling the hot asphalt binder when preparing test specimens and removing the residue from the pressure vessel. Use special precaution when lifting the pressure vessel.

9. CALIBRATION AND STANDARDIZATION

9.1. *Temperature Detector*—Verify the calibration of the RTD to 0.1°C at least every 6 months using a calibrated thermometer.

9.2. *Pressure Gauge*—Standardize the pressure gauge to an accuracy of 1 percent at least every 6 months.

Note 3—The pressure gauge is usually calibrated by the manufacturer or a commercial calibration service. Verification of the continued stability of the pressure gauge within the specified requirements should be done periodically by checking against another certified pressure measurement device.

9.3. To determine the optimum temperature at which to apply pressure to the pressure vessel, several tests should be made. With the vessel loaded with pan rack and empty pans, increase the temperature to aging temperature. When the temperature inside the pressure vessel is within 10°C of the aging temperature, apply an air pressure of 2.1 ± 0.1 MPa. Record the temperature increase when the pressure is applied. Perform the procedure at least three times and use the average temperature increase to establish the temperature at which to apply pressure to the vessel for performing the aging procedure.

10. PROCEDURE

10.1. Condition the asphalt binder and determine the mass change during conditioning in accordance with T 240 (RTFOT).

10.2. Combine the hot residue from the RTFOT into a single container and stir it to blend. Transfer the residue into (or leave it in) stainless steel pans for PAV conditioning or allow the hot residue in the container to cool to room temperature and cover and store at room temperature for PAV conditioning at a later date. If conditioned asphalt binder is allowed to cool to room temperature, heat it until it is sufficiently fluid to pour and stir it before pouring it into the stainless steel pans.

10.3. Place the pan holder inside the pressure vessel. If an oven is used, place the pressure vessel inside the oven. If an integrated temperature control pressure vessel is used, turn on the heater. Select an aging temperature and preheat the pressure vessel to the aging temperature selected.

Note 4—If conditioning asphalt binders for conformance to M 320, select the appropriate aging temperature from Table 1 of M 320.

Note 5—Preheating the vessel 10 to 15°C above the conditioning temperature can be used to reduce the drop in PAV temperature during the loading process and minimize the time required to stabilize the system, after loading, to attain the required temperature.

Note 6—Aging temperature in the PAV is selected to account for different climatic regions. Temperatures in excess of approximately 115°C can change the chemistry of asphalt binders aged in accelerated tests and should be avoided.

10.4. Place the stainless steel pan on a balance and add 50 ± 0.5 g of asphalt binder to the pan. This amount will yield approximately a 3.2-mm-thick film of asphalt binder.

Note 7—The mass change is not measured as part of this procedure. Mass change is not meaningful because the asphalt binder absorbs air as a result of pressurization. Any gain in mass as a result of oxidation is masked by air absorbed by the asphalt binder as a result of the pressurization.

10.5. If the vessel is preheated to other than the desired aging temperature, reset the temperature control on the heating device to the aging temperature.

10.6. Place the filled pans in the pan holder. (Pans containing asphalt binders from different sources and grades may be placed in the pressure vessel during a single test.) Place the pan holder with filled pans inside the pressure vessel, and close the pressure vessel.

10.7. If an oven is used, place the loaded and closed pressure vessel in the oven.

10.8. Connect the temperature transducer line and the air pressure supply line to the loaded pressure vessel's external connections.

10.9. Perform the operations described in Sections 10.5 to 10.8 as quickly as possible to avoid cooling of the vessel and pan holder.

10.10. Wait until the temperature inside the pressure vessel is within 20°C of the aging temperature, apply an air pressure of 2.1 ± 0.1 MPa, and then start timing the test. If the temperature inside the vessel has not reached the desired temperature for applying pressure within 2 hours of loading the pan holders and pans, discontinue the procedure and discard the asphalt samples.

Note 8—Pressures in excess of 2.1 MPa do not substantially increase the rate of aging. Therefore, higher pressures are not warranted.

Note 9—Once pressurized, the temperature inside the pressure vessel will equilibrate rapidly. The time under pressure, not to include any preheating time at ambient pressure, is the aging time. Relatively little aging occurs at ambient pressure during the time that the vessel is being reheated to the test temperature, given that asphalt binder residue under test has been exposed to 163°C in the RTFOT.

10.11. Maintain the temperature and air pressure inside the pressure vessel for 20 h ± 10 min.

10.12. At the end of the 20-hour test period, slowly begin reducing the internal pressure of the PAV, using the air pressure bleed valve. Adjust the bleed valve to an opening that requires 9 ± 1 min to equalize the internal and external pressures on the PAV, thus avoiding excessive bubbling and foaming of the asphalt binder. During this process it may be necessary to adjust the setting of the needle valve as the pressure drops in order to maintain an approximate linear rate of pressure decrease. Do not include the pressure release and equalization time as part of the 20-hour aging period.

10.13. If the temperature indicated by the temperature-recording device falls above or below the target aging temperature ±0.5°C for more than 60 minutes during the 20-hour aging period, declare the test invalid and discard the material.

10.14. Remove the pan holder and pans from the PAV, and place the stainless steel pans in an oven set at a minimum temperature for a minimum time until sufficiently fluid to pour. Stir it gently to assist in the removal of air bubbles.

Note 10—A temperature of 163°C has been found to be suitable for many binder grades.

10.15. Preheat the vacuum oven until it stabilizes at 170 ± 5°C. Select a container of dimensions such that the depth of the residue in the container is between 15 and 40 mm. If tests to determine the properties of the PAV residue are not performed immediately, it is permissible to divide the contents of the container into individual tins and to cover and store them at room temperature for future testing.

10.16. Remove the pans from the oven, and pour the hot residue from the pans into a single container. After the last pan is scraped, transfer the container to the vacuum oven within one minute and maintain the temperature in the vacuum oven at 170 ± 5°C for 10 ± 1 min, without a vacuum applied. After the 10 minutes of equilibration, open the vacuum valve as rapidly as possible to reduce the pressure in the oven to 15 ± 2.5 kPa absolute. Maintain the absolute pressure in the oven at 15 ± 2.5 kPa for 30 ± 1 min. At the end of the 30 minutes, release the vacuum, and remove the container. If any bubbles are visible on the surface of the residue, remove them by flashing the surface of the residue with a torch or hot knife.

Note 11—A pressure of 15 ± 2.5 kPa absolute is equal to a standard vacuum gauge reading of 25 to $26^1/_2$ in. Hg. Consult the manufacturer for adjusting the pressure for local barometric pressure conditions.

Note 12—If the material foams over the lip of the container during the de-gassing, slowly and temporarily reduce the vacuum until the foaming ceases.

11. REPORT

11.1. *Report the following information*:

11.1.1. Sample identification;

11.1.2. Aging test temperature, nearest 0.5°C;

11.1.3. Maximum and minimum aging temperature recorded, nearest 0.1°C;

11.1.4. Total time during aging that temperature was outside the specified range, nearest minute;

11.1.5. Total aging time, hours and minutes; and

11.1.6. Report the heating temperature and heating time if temperatures greater than 163°C are required at any time during the handling of the material.

12. PRECISION AND BIAS

12.1. *Precision*—The research required to develop precision estimates for tests performed on PAV residue has not been conducted.

12.2. *Bias*—The research required to establish the bias of tests performed on PAV residue has not been conducted.

13. KEYWORDS

13.1. Accelerated aging; elevated temperature; in-service aging; PAV; pressure aging; pressure aging vessel.

Standard Practice for

Grading or Verifying the Performance Grade (PG) of an Asphalt Binder

AASHTO Designation: R 29-08

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Practice for

Grading or Verifying the Performance Grade (PG) of an Asphalt Binder

AASHTO Designation: R 29-08

1. SCOPE

1.1. This standard practice describes the testing required to determine the performance grade (PG) of an asphalt binder according to M 320, Table 1. It presents two approaches. In the first, the PG of an unknown asphalt binder is determined. In the second, the nominal PG of an asphalt binder is verified. It also provides an estimate of the time required to complete a single test sequence.

1.2. *This standard practice may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 320, Performance-Graded Asphalt Binder
- R 28, Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)
- T 48, Flash and Fire Points by Cleveland Open Cup
- T 240, Effect of Heat and Air on a Moving Film of Asphalt Binder (Rolling Thin-Film Oven Test)
- T 313, Determining the Flexural Creep Stiffness of Asphalt Binder Using the Bending Beam Rheometer (BBR)
- T 314, Determining the Fracture Properties of Asphalt Binder in Direct Tension (DT)
- T 315, Determining the Rheological Properties of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)
- T 316, Viscosity Determination of Asphalt Binder Using Rotational Viscometer

3. SUMMARY OF THE PRACTICE

3.1. The tank (as-received) sample of asphalt binder is tested to determine the flash point (T 48), viscosity at 135°C (T 316), and shear modulus (G^*) and phase angle (δ) (T 315).

3.2. The asphalt binder is aged in the rolling thin-film oven (T 240), and the residue is tested to determine the mass change (T 240) and the shear modulus (G^*) and phase angle (δ) (T 315).

3.3. The residue from the rolling thin-film oven (RTFO) is aged in the pressurized aging vessel (R 28), and this residue is tested to determine the shear modulus (G^*) and phase angle (δ) (T 315), creep stiffness (S) and slope, *m*, of the log creep stiffness versus log time relationship at 60 seconds (T 313), and the failure strain in direct tension (T 314), as necessary.

3.4. Based on these test results, the asphalt binder is graded according to M 320, Table 1.

4. SIGNIFICANCE AND USE

4.1. This practice describes the testing required for grading or verifying the PG of an asphalt binder according to M 320, Table 1.

5. ESTIMATED TIME NECESSARY FOR TESTING

5.1. For both grading and verification, if the analysis is started at the beginning of a morning work shift, all testing and analysis should be completed during the afternoon of the next day. This schedule provides the 20 hours needed for PAV conditioning. Of course, samples can be aged and analyzed in parallel, and the productivity of the laboratory thus increased. However, for the purpose of this document, analysis of a single asphalt binder will be discussed.

6. TEST PROCEDURE FOR GRADING AN UNKNOWN ASPHALT BINDER

6.1. Prepare samples and test specimens using the procedures specified in the applicable test methods. In the case where the grade of the asphalt binder is unknown, approximately 400 g of unaged asphalt binder is required to complete the tests with the necessary replicates.

6.2. Begin conditioning asphalt binder in the RTFO. Condition a sufficient amount of asphalt binder depending on the type and number of tests to be performed.

Note 1—Two BBR beams requiring PAV aged material are needed at each test temperature. In addition, at least six direct tension (DT) specimens requiring PAV aged material may also be needed at each test temperature. A minimum of two test temperatures will be required. This testing will utilize approximately 200 g of RTFO residue.

6.3. Perform the DSR test (T 315) on the original asphalt binder beginning at 58°C, and increase or decrease the test temperature at 6.0°C increments until a value for $G^*/\sin\delta \leq 1.00$ kPa is obtained. The highest test temperature where the value for $G^*/\sin\delta \geq 1.00$ kPa determines the starting PG grade.

Note 2—For example, if $G^*/\sin\delta$ is 0.60 kPa at 64°C and 1.20 kPa at 58°C, the starting asphalt binder grade is PG 58-xx.

6.4. Determine the flash point on a sample of original binder using T 48. The flash point must be greater than 230°C to meet the requirements of M 320.

6.5. Determine the viscosity of the original asphalt binder at 135°C using T 316. The viscosity must not exceed 3 Pa·s to meet the requirements of M 320.

6.6. After the RTFO conditioning (T 240) is complete, determine the mass change of the original asphalt binder. The mass change must be ≤1.00 percent to meet the requirements of M 320.

6.7. If the original asphalt binder does not meet M 320 requirements for the tests in Sections 6.4, 6.5, or 6.6, the asphalt binder will not satisfy the specification for any PG, and no further testing is required.

6.8. Perform the DSR test (T 315) on the RTFO residue at the test temperature used to determine the starting PG grade (Section 6.3) to confirm the high temperature grade of the asphalt binder (e.g. PG 46-xx, 52-xx, 58-xx, etc.). The value for $G^*/\sin\delta$ of the RTFO residue must be ≥2.20 kPa. Choose the lower performance grade in cases where the test values in Sections 6.3 and 6.8 give conflicting grades.

6.9. Age a sufficient quantity of RTFO residue in the PAV (R 28) (Note 1). Use an aging temperature of 90°C for starting grades PG 46-xx or 52-xx and 100°C for starting grades PG 58-xx and higher. A PAV temperature of 110°C is used in simulating desert environments.

Note 3—Complete Sections 6.1 through 6.9 during the first day of testing. This schedule will allow further testing to begin on the second day after PAV aging is complete.

6.10. At the conclusion of the PAV aging procedure (R 28), including aging, combining, and degassing the binder, prepare two BBR specimens for each test temperature according to T 313. Retain sufficient residue to prepare at least six DT specimens for each test temperature, if required.

6.11. Perform the DSR test (T 315) on the PAV residue beginning at a test temperature of 16 and 19°C, respectively, for starting grades PG 52-xx and 58-xx, 22°C for starting grade PG 64-xx, and 28°C for starting grade PG 70-xx, unless there is other information to suggest the temperature at which $G^*\sin\delta \leq 5000$ kPa. Decrease or increase the test temperature at 3.0°C increments until the value for $G^*\sin\delta > 5000$ kPa.

6.12. Determine the beginning test temperature for the BBR test (T 313) on the PAV residue from Table 1 of M 320 using the starting PG grade determined in Section 6.3 and the lowest temperature from Section 6.11 where the value for $G^*\sin\delta \leq 5000$ kPa, unless there is other information to suggest the temperature at which the creep stiffness (S) ≤300 MPa and the slope (m) ≥0.300.

6.13. Test pairs of BBR specimens according to T 313 beginning at the test temperature selected in Section 6.12 and increasing at 6.0°C increments, until a creep stiffness (S) and slope (m) meeting the requirements of M 320, Table 1 are obtained. Test fresh BBR specimens at each temperature.

6.14. Certain asphalt binders may satisfy the M 320, Table 1 slope requirement at substantially lower temperatures than they satisfy the creep stiffness (S) requirement. If the creep stiffness is between 300 and 600 MPa at a test temperature at which the slope, m, ≥0.300, it may be possible to satisfy the DT (T 314) failure strain requirement in lieu of the creep stiffness requirement. Test DT specimens according to T 314 at the test temperature at which $m \geq 0.300$, and determine if the failure strain ≥1.0 percent. Test a sufficient number of specimens so that a minimum of six valid test results are obtained.

6.15. If the failure strain <1.0 percent, test additional sets of DT specimens, increasing the test temperature in 6.0°C increments, until a failure strain ≥1.0 percent is obtained.

6.16. Using the results of Sections 6.11 through 6.15, determine the final grade of the asphalt binder.

7. TEST PROCEDURE FOR VERIFYING THE NOMINAL GRADE OF AN ASPHALT BINDER

7.1. Prepare samples and test specimens using the procedures specified in the applicable test methods. In the case where the grade of the asphalt binder is being verified, approximately 250 g of unaged asphalt binder are required to complete the tests with the necessary replicates.

7.2. Begin conditioning asphalt binder in the RTFO. Condition a sufficient amount of asphalt binder depending on the type and number of tests to be performed.

Note 4—Two BBR beams requiring PAV aged material are needed. In addition, at least six DT specimens requiring PAV aged material may also be required. Only one test temperature will be required. This testing will utilize approximately 100 g of RTFO residue.

7.3. Perform the DSR test (T 315) on the original asphalt binder at the test temperature indicated by the high temperature grading designation. For example, test a PG 70-16 asphalt binder at 70°C. The value for $G^*/\sin\delta$ must be ≥ 1.0 kPa to meet the requirements of M 320.

Note 5—This step verifies the starting PG grade. For example, if a PG 58-22 is tested at 58°C and $G^*/\sin\delta \geq 1.00$ kPa, the high temperature grading designation for the asphalt binder is verified to be PG 58-xx.

Note 6—If the asphalt binder fails to meet the requirements of M 320, Table 1 for the grade designated, it may be treated as a binder of unknown grade and tested according to Section 6, or the testing may be stopped because the grade was not verified.

7.4. Determine the flash point on a sample of original binder using T 48. The flash point must be greater than 230°C to meet the requirements of M 320.

7.5. Determine the viscosity of the original asphalt binder at 135°C using T 316. The viscosity must not exceed 3 Pa·s to meet the requirements of M 320.

7.6. After the RTFO conditioning (T 240) is complete, determine the mass change of the original asphalt binder. The mass change must be ≤ 1.00 percent to meet the requirements of M 320.

7.7. If the original asphalt binder does not meet M 320, Table 1 requirements for any of the tests performed in Sections 7.4, 7.5, or 7.6, the asphalt binder will not satisfy the specification for any PG, and no further testing is required.

7.8. To verify the high temperature properties of the binder, perform the DSR test (T 315) on the RTFO residue at the test temperature indicated by the high temperature grading designation. For example, test a PG 70-16 asphalt binder at 70°C. The value for $G^*/\sin\delta$ of the RTFO residue must be ≥ 2.20 kPa to meet the requirements of M 320, Table 1 (Note 6).

7.9. Age a sufficient quantity of RTFO residue in the PAV (R 28). Use an aging temperature of 90°C for binders having a high temperature grading designation of PG 46-xx or PG 52-xx and 100°C for binders having high temperature grading designations of PG 58-xx and higher. A PAV temperature of 110°C is used in simulating desert environments.

Note 7—Two BBR beams (requiring PAV-aged material) are required. In addition, six DT samples may also be needed requiring about 60 g of PAV-aged asphalt binder.

Note 8—Complete Sections 7.1 through 7.9 during the first day of testing. This schedule will allow further testing to begin on the second day after PAV aging is complete.

7.10. At the conclusion of the PAV aging procedure (R 28), including aging, combining, and degassing the binder, prepare two BBR specimens according to T 313. Retain sufficient residue to prepare at least six DT specimens if required.

7.11. Perform the DSR test (T 315) on the PAV residue at the test temperature specified in Table 1 of M 320 for the high temperature and low temperature grading designation of the binder being verified. For example, test a PG 64-40 asphalt binder at 16°C. The value for G*sin δ must not exceed 5000 kPa to meet the requirements of M 320 (Note 6).

7.12. Test two BBR specimens according to T 313 at the test temperature specified in Table 1 of M 320 for the high temperature and low temperature grading designation of the binder being verified. For example, test a PG 58-28 asphalt binder at –18°C. The value of the slope, *m*, must be ≥0.300 to meet the requirements of M 320, Table 1. The value of the creep stiffness (S) must be ≤300 MPa to meet the requirements of M 320, Table 1. Certain asphalt binders may satisfy the BBR slope requirement at substantially lower temperatures than they satisfy the BBR stiffness requirement (Note 6).

7.13. If the creep stiffness (S) is between 300 and 600 MPa and the slope (*m*) ≥0.300 at the test temperature, it may be possible to satisfy the DT (T 314) failure strain requirement in lieu of the creep stiffness (S) requirement. Test DT samples according to T 314 at the same test temperature used to test the BBR specimens. Test a sufficient number of specimens so that a minimum of six valid test results are obtained. The failure strain must be ≥1.0 percent to meet the requirements of M 320, Table 1 (Note 6).

8. REPORT

8.1. If the grade of the asphalt binder tested is determined, report the results of all tests performed and the high temperature grading designation determined followed by the low temperature designation (e.g., PG 52-34).

8.2. If the grade of an asphalt binder is verified, report the results of all tests performed and if the binder meets the requirements of M 320, Table 1.

9. KEYWORDS

9.1. Asphalt binder; performance grading.

Standard Practice for

Mixture Conditioning of Hot Mix Asphalt (HMA)

AASHTO Designation: R 30-02 (2006)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Mixture Conditioning of Hot Mix Asphalt (HMA)

AASHTO Designation: R 30-02 (2006)[1]

1. SCOPE

1.1. This standard practice describes procedures for mixture conditioning of compacted and uncompacted hot mix asphalt (HMA). Three types of conditioning are described: (1) mixture conditioning for volumetric mixture design; (2) short-term conditioning for mixture mechanical property testing (both of which simulate the precompaction phase of the construction process); and (3) long-term conditioning for mixture mechanical property testing to simulate the aging that occurs over the service life of a pavement. The procedures for long-term conditioning for mixture mechanical property testing are preceded by the procedure for short-term conditioning for mixture mechanical property testing.

1.2. *This standard practice may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- PP 3, Preparing Hot Mix Asphalt (HMA) Specimens by Means of the Rolling Wheel Compactor[2]
- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor
- T 316, Viscosity Determination of Asphalt Binder Using Rotational Viscometer

3. SUMMARY OF PRACTICE

For mixture conditioning for volumetric mixture design, a mixture of aggregate and binder is conditioned in a forced-draft oven for 2 hours at the mixture's specified compaction temperature. For short-term mixture conditioning for mechanical property testing, a mixture of aggregate and binder is conditioned in a forced-draft oven for 4 hours at 135°C. For long-term mixture conditioning for mechanical property testing, a compacted mixture of aggregate and binder is conditioned in a forced-draft oven for 5 days at 85°C.

4. SIGNIFICANCE AND USE

The properties and performance of HMA can be more accurately predicted by using conditioned test samples. The mixture conditioning for the volumetric mixture design procedure is designed to allow for binder absorption during the mixture design. The short-term mixture conditioning for the mechanical property testing procedure is designed to simulate the plant-mixing and construction effects on the mixture. The long-term mixture conditioning for the mechanical property testing procedure is designed to simulate the aging the compacted mixture will undergo during 7 to 10 years of service.

5. APPARATUS

5.1. *Oven*—A forced-draft oven, thermostatically controlled, capable of maintaining any desired temperature setting from room temperature to 176°C within ±3°C.

5.2. *Thermometers*—Thermometers having a range from 50 to 260°C and readable to 1°C.

5.3. *Miscellaneous*—A metal pan for heating aggregates, a shallow metal pan for heating uncompacted HMA, a metal spatula or spoon, timer, and gloves for handling hot equipment.

6. HAZARDS

6.1. This standard involves the handling of hot binder, aggregate, and HMA, which can cause severe burns if allowed to contact skin. Follow standard safety precautions to avoid burns.

7. MIXTURE CONDITIONING PROCEDURES

7.1. *Mixture Conditioning for Volumetric Mixture Design*:

7.1.1. The mixture conditioning for the volumetric mixture design procedure applies to laboratory-prepared, loose mixture only. No mixture conditioning is required when conducting quality control or quality assurance testing on plant-produced mixture.

Note 1—The Agency may identify the need to condition plant-produced mixture to be more representative of field conditions, particularly where absorptive aggregates are used.

7.1.2. Place the mixture in a pan, and spread it to an even thickness ranging between 25 and 50 mm. Place the mixture and pan in a forced-draft oven for 2 h ± 5 min at a temperature equal to the mixture's compaction temperature ±3°C. The compaction temperature range of a HMA mixture is defined as the range of temperatures where the unaged binder has a kinematic viscosity of 280 ± 30 mm^2/s (approximately 0.28 ± 0.03 Pa·s) measured in accordance with T 316 (Note 2). The target compaction temperature is generally the midpoint of this range.

Note 2—Modified binders may not adhere to the equi-viscosity requirements noted. The agency should consider the manufacturer's recommendations when establishing the mixing and compaction temperatures for modified binders. Practically, the mixing temperature should not exceed 165°C and the compaction temperature should not be lower than 115°C.

7.1.3. Stir the mixture after 60 ± 5 min to maintain uniform conditioning.

7.1.4. After 2 h ± 5 min, remove the mixture from the forced-draft oven. The conditioned mixture is now ready for compaction or testing.

7.2. *Short-Term Conditioning for Mixture Mechanical Property Testing*:

7.2.1. The short-term conditioning for the mixture mechanical property testing procedure applies to laboratory-prepared, loose mix only.

7.2.2. Place the mixture in a pan, and spread it to an even thickness ranging between 25 and 50 mm. Place the mixture and pan in the conditioning oven for 4 h ± 5 min at a temperature of 135 ± 3°C.

7.2.3. Stir the mixture every 60 ± 5 min to maintain uniform conditioning.

7.2.4. After 4 h ± 5 min, remove the mixture from the forced-draft oven. The conditioned mixture is now ready for further conditioning or testing as required.

7.3. *Long-Term Conditioning for Mixture Mechanical Property Testing*:

7.3.1. The long-term conditioning for the mixture mechanical property testing procedure applies to laboratory-prepared mixtures that have been subjected to the short-term conditioning for the mixture mechanical property testing procedure described in Section 7.2, plant-mixed HMA, and compacted roadway specimens.

7.3.2. *Preparing Specimens from Loose HMA*:

7.3.2.1. Specimens Compacted Using the Superpave Gyratory Compactor:

7.3.2.1.1. Compact the specimens in accordance with T 312. Cool the test specimen at room temperature for 16 ± 1 h.

Note 3—Extrude the specimen from the compaction mold after cooling for 2 to 3 h.

Note 4—Specimen cooling is usually scheduled as an overnight step. Cooling may be accelerated by placing the specimen in front of a fan.

7.3.2.2. Specimens Compacted Using the Rolling Wheel Compactor:

7.3.2.2.1. Compact the specimens in accordance with PP 3.

7.3.2.2.2. Cool the test specimen at room temperature for 16 ± 1 h.

7.3.2.2.3. Remove the slab from the mold, and saw or core the required specimens from the slab.

7.3.3. *Preparing Compacted Roadway Specimens*:

7.3.3.1. Cool test specimens at room temperature for 16 ± 1 h.

7.3.4. *Long-Term Conditioning of Prepared Test Specimens*—Place the compacted test specimens in the conditioning oven for 120 ± 0.5 h at a temperature of 85 ± 3°C.

7.3.5. After 120 ± 0.5 h, turn the oven off; open the doors, and allow the test specimen to cool to room temperature. Do not touch or remove the specimen until it has cooled to room temperature.

Note 5—Cooling to room temperature will take approximately 16 h.

7.3.6. After cooling to room temperature, remove the test specimen from the oven. The long-term-conditioned specimen is now ready for testing as required.

---

8. REPORT

8.1. Report the binder grade, binder content (nearest 0.1 percent), and the aggregate type and gradation, if applicable.

8.2. Report the following mixture conditioning information for the volumetric mixture design conditions, if applicable:

8.2.1. Mixture conditioning temperature in laboratory (compaction temperature, nearest 1°C);

8.2.2. Mixture conditioning duration in laboratory (nearest minute); and

8.2.3. Laboratory compaction temperature (nearest 1°C).

8.3. Report the following short-term conditioning information for the mixture mechanical property testing conditions, if applicable:

8.3.1. Short-term mixture conditioning temperature in laboratory (nearest 1°C);

8.3.2. Short-term mixture conditioning duration in laboratory (nearest minute); and

8.3.3. Laboratory compaction temperature (nearest 1°C).

8.4. Report the following long-term conditioning information for the mixture mechanical property testing conditions, if applicable:

8.4.1. Laboratory compaction temperature (nearest 1°C);

8.4.2. Long-term mixture conditioning temperature in laboratory (nearest 1°C); and

8.4.3. Long-term mixture conditioning duration in laboratory (nearest 5 minutes).

Standard Practice for

Superpave Volumetric Design for Hot Mix Asphalt (HMA)

AASHTO Designation: R 35-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Superpave Volumetric Design for Hot Mix Asphalt (HMA)

AASHTO Designation: R 35-09

1. SCOPE

1.1. This standard practice for mix design evaluation uses aggregate and mixture properties to produce a hot mix asphalt (HMA) job-mix formula. The mix design is based on the volumetric properties of the HMA in terms of the air voids, voids in the mineral aggregate (VMA), and voids filled with asphalt (VFA).

1.2. This standard practice may also be used to provide a preliminary selection of mix parameters as a starting point for mix analysis and performance prediction analyses that primarily use T 320 and T 322.

1.3. *This standard practice may involve hazardous materials, operations, and equipment. This standard practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *HMA*—hot mix asphalt.

3.2. *design ESALs*—design equivalent (80 kN) single-axle loads.

3.2.1. *Discussion*—Design ESALs are the anticipated project traffic level expected on the design lane over a 20-year period. For pavements designed for more or less than 20 years, determine the design ESALs for 20 years when using this standard practice.

3.3. *air voids* (V_a)—the total volume of the small pockets of air between the coated aggregate particles throughout a compacted paving mixture, expressed as a percent of the bulk volume of the compacted paving mixture (Note 1).

Note 1—Term defined in Asphalt Institute Manual SP-2, Superpave Mix Design.

3.4. *voids in the mineral aggregate (VMA)*—the volume of the intergranular void space between the aggregate particles of a compacted paving mixture that includes the air voids and the effective binder content, expressed as a percent of the total volume of the specimen (Note 1).

3.5. *absorbed binder volume* (V_{ba})—the volume of binder absorbed into the aggregate (equal to the difference in aggregate volume when calculated with the bulk specific gravity and effective specific gravity).

3.6. *binder content* (P_b)—the percent by mass of binder in the total mixture including binder and aggregate.

3.7. *effective binder volume* (V_{be})—the volume of binder which is not absorbed into the aggregate.

3.8. *voids filled with asphalt (VFA)*—the percentage of the VMA filled with binder (the effective binder volume divided by the VMA).

3.9. *dust-to-binder ratio* ($P_{0.075}/P_{be}$)—by mass, the ratio between the percent passing the 75-µm (No. 200) sieve ($P_{0.075}$) and the effective binder content (P_{be}).

3.10. *nominal maximum aggregate size*—one size larger than the first sieve that retains more than 10 percent aggregate (Note 2).

3.11. *maximum aggregate size*—one size larger than the nominal maximum aggregate size (Note 2).

Note 2—The definitions given in Sections 3.10 and 3.11 apply to Superpave mixes only and differ from the definitions published in other AASHTO standards.

3.12. *reclaimed asphalt pavement (RAP)*—removed and/or processed pavement materials containing asphalt binder and aggregate.

3.13. *primary control sieve (PCS)*—the sieve defining the break point between fine and coarse-graded mixtures for each nominal maximum aggregate size.

4. SUMMARY OF THE PRACTICE

4.1. *Materials Selection*—Binder, aggregate and RAP stockpiles are selected that meet the environmental and traffic requirements applicable to the paving project. The bulk specific gravity of all aggregates proposed for blending and the specific gravity of the binder are determined.

Note 3—If RAP is used, the bulk specific gravity of the RAP aggregate may be estimated by determining the theoretical maximum specific gravity (G_{mm}) of the RAP mixture and using an assumed asphalt absorption for the RAP aggregate to back-calculate the RAP aggregate bulk specific gravity, if the absorption can be estimated with confidence. The RAP aggregate effective specific gravity may be used in lieu of the bulk specific gravity at the discretion of the Agency. The use of the effective specific gravity may introduce an error into the combined aggregate bulk specific gravity and subsequent VMA calculations. The Agency may choose to specify adjustments to the VMA requirements to account for this error based on experience with local aggregates.

4.2. *Design Aggregate Structure*—It is recommended at least three trial aggregate blend gradations from selected aggregate stockpiles are blended. For each trial gradation, an initial trial binder content is determined, and at least two specimens are compacted in accordance with T 312. A design aggregate structure and an estimated design binder content are selected on the basis of satisfactory conformance of a trial gradation meeting the requirements given in M 323 for V_a, VMA, VFA, dust-to-binder ratio at N_{design}, and relative density at N_{initial}.

Note 4—Previous Superpave mix design experience with specific aggregate blends may eliminate the need for three trial blends.

4.3. *Design Binder Content Selection*—Replicate specimens are compacted in accordance with T 312 at the estimated design binder content and at the estimated design binder content ±0.5 percent and +1.0 percent. The design binder content is selected on the basis of satisfactory conformance with the requirements of M 323 for V_a, VMA, VFA, and dust-to-binder ratio at N_{design}, and the relative density at N_{initial} and N_{max}.

4.4. *Evaluating Moisture Susceptibility*—The moisture susceptibility of the design aggregate structure is evaluated at the design binder content: the mixture is conditioned according to the mixture conditioning for the volumetric mixture design procedure in R 30, compacted to 7.0 ± 0.5 percent air voids in accordance with T 312, and evaluated according to T 283. The design shall meet the tensile strength ratio requirement of M 323.

5. SIGNIFICANCE AND USE

5.1. The procedure described in this standard practice is used to produce HMA which satisfies Superpave HMA volumetric mix design requirements.

6. PREPARING AGGREGATE TRIAL BLEND GRADATIONS

6.1. Select a binder in accordance with the requirements of M 323.

6.2. Determine the specific gravity of the binder according to T 228.

6.3. Obtain samples of aggregates proposed to be used for the project from the aggregate stockpiles in accordance with T 2.

Note 5—Each stockpile usually contains a given size of an aggregate fraction. Most projects employ three to five stockpiles to generate a combined gradation conforming to the job-mix formula and M 323.

6.4. Reduce the samples of aggregate fractions according to T 248 to samples of the size specified in T 27.

6.5. Wash and grade each aggregate sample according to T 11 and T 27.

6.6. Determine the bulk and apparent specific gravity for each coarse and fine aggregate fraction in accordance with T 85 and T 84, respectively, and determine the specific gravity of the mineral filler in accordance with T 100.

6.7. Blend the aggregate fractions using Equation 1:

$$P = Aa + Bb + Cc, \text{ etc.} \qquad (1)$$

where:

P = Percentage of material passing a given sieve for the combined aggregates A, B, C, etc.;

A, B, C, etc. = Percentage of material passing a given sieve for aggregates A, B, C, etc.; and

a, b, c, etc. = Proportions of aggregates A, B, C, etc., used in the combination, and where the total = 1.00.

6.8. Prepare a minimum of three trial aggregate blend gradations; plot the gradation of each trial blend on a 0.45-power gradation analysis chart, and confirm that each trial blend meets M 323 gradation controls (see Table 3 of M 323). Gradation control is based on four control sieve sizes: the sieve for the maximum aggregate size, the sieve for the nominal maximum aggregate size, the 4.75- or 2.36-mm sieve, and the 0.075-mm sieve. An example of three acceptable trial blends in the form of a gradation plot is given in Figure 1.

6.9. Obtain a test specimen from each of the trial blends according to T 248, and conduct the quality tests specified in Section 6 of M 323 to confirm that the aggregate in the trial blends meets the minimum quality requirements specified in M 323.

Note 6—The designer has an option of performing the quality tests on each stockpile instead of the trial aggregate blend. The test results from each stockpile can be used to estimate the results for a given combination of materials.

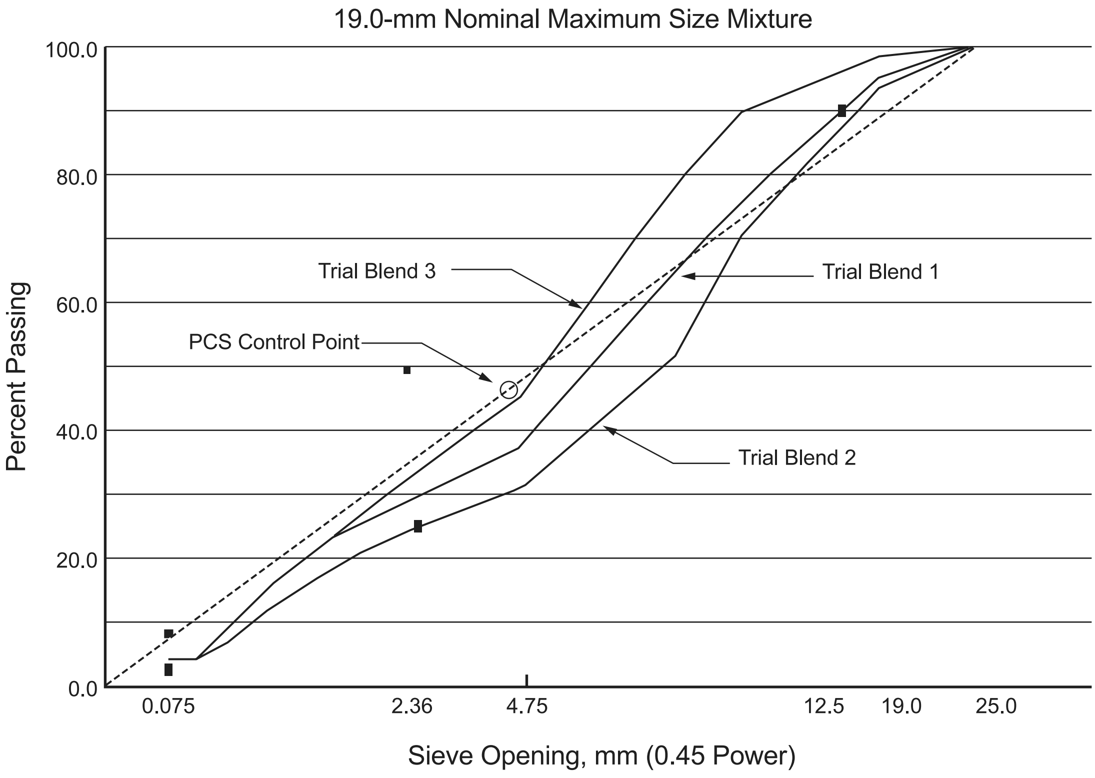

Figure 1—Evaluation of the Gradations of Three Trial Blends (Example)

7. DETERMINING AN INITIAL TRIAL BINDER CONTENT FOR EACH TRIAL AGGREGATE GRADATION

7.1. Designers can either use their experience with the materials or the procedure given in Appendix A1 to determine an initial trial binder content for each trial aggregate blend gradation.

Note 7—When using RAP, the initial trial asphalt content should be reduced by an amount equal to that provided by the RAP.

8. COMPACTING SPECIMENS OF EACH TRIAL GRADATION

8.1. Prepare replicate mixtures (Note 8) at the initial trial binder content for each of the chosen trial aggregate trial blend gradations. From Table 1, determine the number of gyrations based on the design ESALs for the project.

Note 8—At least two replicate specimens are required, but three or more may be prepared if desired. Generally, 4500 to 4700 g of aggregate is sufficient for each compacted specimen with a height of 110 to 120 mm for aggregates with combined bulk specific gravities of 2.55 to 2.70, respectively.

8.2. Condition the mixtures according to R 30, and compact the specimens to N_{design} gyrations in accordance with T 312. Record the specimen height to the nearest 0.1 mm after each revolution.

8.3. Determine the bulk specific gravity (G_{mb}) of each of the compacted specimens in accordance with T 166 or T 275 as appropriate.

Table 1—Superpave Gyratory Compaction Effort

Design ESALs[a] (million)	Compaction Parameters			Typical Roadway Application[b]
	N_{initial}	N_{design}	$N_{\max}$	
<0.3	6	50	75	Applications include roadways with very light traffic volumes such as local roads, county roads, and city streets where truck traffic is prohibited or at a very minimal level. Traffic on these roadways would be considered local in nature, not regional, intrastate, or interstate. Special purpose roadways serving recreational sites or areas may also be applicable to this level.
0.3 to <3	7	75	115	Applications include many collector roads or access streets. Medium-trafficked city streets and the majority of county roadways may be applicable to this level.
3 to <30	8	100	160	Applications include many two-lane, multilane, divided, and partially or completely controlled access roadways. Among these are medium to highly trafficked city streets, many state routes, U.S. highways, and some rural Interstates.
≥30	9	125	205	Applications include the vast majority of the U.S. Interstate system, both rural and urban in nature. Special applications such as truck-weighing stations or truck-climbing lanes on two-lane roadways may also be applicable to this level.

[a] The anticipated project traffic level expected on the design lane over a 20-year period. Regardless of the actual design life of the roadway, determine the design ESALs for 20 years.

[b] As defined by *A Policy on Geometric Design of Highways and Streets*, 2004, AASHTO.

Note 9—When specified by the Agency and the top of the design layer is ≥100 mm from the pavement surface and the estimated design traffic level is ≥0.3 million ESALs, decrease the estimated design traffic level by one, unless the mixture will be exposed to significant mainline construction traffic prior to being overlaid. If less than 25 percent of a construction lift is within 100 mm of the surface, the lift may be considered to be below 100 mm for mixture design purposes.

Note 10—When the estimated design traffic level is between 3 and <10 million ESALs, the Agency may, at its discretion, specify N_{initial} at 7, N_{design} at 75, and $N_{\max}$ at 115.

8.4. Determine the theoretical maximum specific gravity (G_{mm}) according to T 209 of separate samples representing each of these combinations that have been mixed and conditioned to the same extent as the compacted specimens.

Note 11—The maximum specific gravity for each trial mixture shall be based on the average of at least two tests.

9. EVALUATING COMPACTED TRIAL MIXTURES

9.1. Determine the volumetric requirements for the trial mixtures in accordance with M 323.

9.2. Calculate V_a and VMA at N_{design} for each trial mixture using Equations 2 and 3:

$$V_a = 100 \times \left(1 - \left(\frac{G_{mb}}{G_{mm}}\right)\right) \qquad (2)$$

$$\text{VMA} = 100 \times \left(1 - \frac{G_{mb}P_s}{G_{sb}}\right) \qquad (3)$$

where:

G_{mb} = bulk specific gravity of the extruded specimen;
G_{mm} = theoretical maximum specific gravity of the mixture;
P_s = percent of aggregate in the mix; and
G_{sb} = bulk specific gravity of the combined aggregate.

Note 12—Although the initial trial binder content was estimated for a design air void content of 4.0 percent, the actual air void content of the compacted specimen is unlikely to be exactly 4.0 percent. Therefore, the change in binder content needed to obtain a 4.0 percent air void content, and the change in VMA caused by this change in binder content, is estimated. These calculations permit the evaluation of VMA and VFA of each trial aggregate gradation at the same design air void content, 4.0 percent.

9.3. Estimate the volumetric properties at 4.0 percent air voids for each compacted specimen.

9.3.1. Determine the difference in average air void content at N_{design} (ΔV_a) of each aggregate trial blend from the design level of 4.0 percent using Equation 4:

$$\Delta V_a = 4.0 - V_a \qquad (4)$$

where:

V_a = air void content of the aggregate trial blend at N_{design} gyrations.

9.3.2. Estimate the change in binder content (ΔP_b) needed to change the air void content to 4.0 percent using Equation 5:

$$\Delta P_b = -0.4(\Delta V_a) \qquad (5)$$

9.3.3. Estimate the change in VMA (ΔVMA) caused by the change in the air void content (ΔV_a) determined in Section 9.3.1 for each trial aggregate blend gradation, using Equation 6 or 7.

$$\Delta VMA = 0.2(\Delta V_a) \text{ if } V_a > 4.0 \qquad (6)$$

$$\Delta VMA = -0.1(\Delta V_a) \text{ if } V_a < 4.0 \qquad (7)$$

Note 13—A change in binder content affects the VMA through a change in the bulk specific gravity of the compacted specimen (G_{mb}).

9.3.4. Calculate the VMA for each aggregate trial blend at N_{design} gyrations and 4.0 percent air voids using Equation 8:

$$VMA_{\text{design}} = VMA_{\text{trial}} + \Delta VMA \qquad (8)$$

where:

$\text{VMA}_{\text{design}}$ = VMA estimated at a design air void content of 4.0 percent; and
$\text{VMA}_{\text{trial}}$ = VMA determined at the initial trial binder content.

9.3.5. Using the values of ΔV_a determined in Section 9.3.1 and Equation 9, estimate the relative density of each specimen at N_{initial} when the design air void content is adjusted to 4.0 percent at N_{design}:

$$\%G_{mm_{\text{initial}}} = 100 \times \left(\frac{G_{mb} h_d}{G_{mm} h_i}\right) - \Delta V_a \qquad (9)$$

where:

$\%G_{mm_{\text{initial}}}$ = relative density at N_{initial} gyrations at the adjusted design binder content;

h_d = height of the specimen after N_{design} gyrations, from the Superpave gyratory compactor, mm; and

h_i = height of the specimen after N_{initial} gyrations, from the Superpave gyratory compactor, mm.

9.3.6. Calculate the effective specific gravity of the aggregate (G_{se}), the estimated percent of effective binder ($P_{be_{est}}$), and the estimated dust-to-binder ratio ($P_{0.075}/P_{be}$) for each trial blend using Equations 10, 11, and 12:

$$G_{se} = \frac{100 - P_b}{\dfrac{100}{G_{mm}} - \dfrac{P_b}{G_b}} \qquad (10)$$

$$P_{be_{est}} = -\left(P_s \times G_b\right)\frac{\left(G_{se} - G_{sb}\right)}{\left(G_{se} \times G_{sb}\right)} + P_{b_{est}} \qquad (11)$$

where:

$P_{be_{est}}$ = estimated effective binder content;

P_s = aggregate content;

G_b = specific gravity of the binder;

G_{se} = effective specific gravity of the aggregate;

G_{sb} = bulk specific gravity of the combined aggregate; and

$P_{b_{est}}$ = estimated binder content.

$$P_{0.075} \Big/ P_{be} = \frac{P_{0.075}}{P_{be_{est}}} \qquad (12)$$

where:

$P_{0.075}$ = percent passing the 0.075-mm sieve.

9.3.7. Compare the estimated volumetric properties from each trial aggregate blend gradation at the adjusted design binder content with the criteria specified in M 323. Choose the trial aggregate blend gradation that best satisfies the volumetric criteria.

Note 14—Table 2 presents an example of the selection of a design aggregate structure from three trial aggregate blend gradations.

Note 15—Many trial aggregate blend gradations will fail the VMA criterion. Generally, the $\%\,G_{mm_{\text{initial}}}$ criterion will be met if the VMA criterion is satisfied. Section 12.1 gives a procedure for the adjustment of VMA.

Note 16—If the trial aggregate gradations have been chosen to cover the entire range of the gradation controls, then the only remaining solution is to make adjustments to the aggregate production or to introduce aggregates from a new source. The aggregates that fail to meet the required criteria will not produce a quality mix and should not be used. One or more of the aggregate stockpiles should be replaced with another material which produces a stronger structure. For example, a quarry stone can replace a crushed gravel, or crushed fines can replace natural fines.

Table 2—Selection of a Design Aggregate Structure (Example)

Volumetric Property	Trial Mixture (19.0-mm Nominal Maximum Aggregate) 20-Year Project Design ESALs = 5 million			Criteria
	1	2	3	
	At the Initial Trial Binder Content			
P_b (trial)	4.4	4.4	4.4	
% $G_{mm_{\text{initial}}}$ (trial)	88.3	88.0	87.3	
% $G_{mm_{\text{design}}}$ (trial)	95.6	94.9	94.5	
V_a at N_{design}	4.4	5.1	5.5	4.0
$\text{VMA}_{\text{trial}}$	13.0	13.6	14.1	
	Adjustments to Reach Design Binder Content (V_a = 4.0% at N_{design})			
ΔV_a	–0.4	–1.1	–1.5	
ΔP_b	0.2	0.4	0.6	
ΔVMA	–0.1	–0.2	–0.3	
	At the Estimated Design Binder Content (V_a = 4.0 % at N_{design})			
Estimated P_b (design)	4.6	4.8	5.0	
VMA (design)	12.9	13.4	13.8	≥13.0
% $G_{mm_{\text{initial}}}$ (design)	88.7	89.1	88.5	≤89.0

Notes:

1. The top portion of this table presents measured densities and volumetric properties for specimens prepared for each aggregate trial blend at the initial trial binder content.
2. None of the specimens had an air void content of exactly 4.0 percent. Therefore, the procedures described in Section 9 must be applied to: (1) estimate the design binder content at which V_a = 4.0 percent, and (2) obtain adjusted VMA and relative density values at this estimated binder content.
3. The middle portion of this table presents the change in binder content (ΔP_b) and VMA (ΔVMA) that occurs when the air void content (V_a) is adjusted to 4.0 percent for each trial aggregate blend gradation.
4. A comparison of the VMA and densities at the estimated design binder content to the criteria in the last column shows that trial aggregate blend gradation No. 1 does not have sufficient VMA (12.9 percent versus a requirement of ≥13.0 percent). Trial blend No. 2 exceeds the criterion for relative density at N_{initial} gyrations (89.1 percent versus a requirement of ≤89.0 percent). Trial blend No. 3 meets the requirement for relative density and VMA and, in this example, is selected as the design aggregate structure.

10. SELECTING THE DESIGN BINDER CONTENT

10.1. Prepare replicate mixtures (Note 8) containing the selected design aggregate structure at each of the following four binder contents: (1) the estimated design binder content, P_b (design); (2) 0.5 percent below P_b (design); (3) 0.5 percent above P_b (design); and (4) 1.0 percent above P_b (design).

10.1.1. Use the number of gyrations previously determined in Section 8.1.

10.2. Condition the mixtures according to R 30, and compact the specimens to N_{design} gyrations according to T 312. Record the specimen height to the nearest 0.1 mm after each revolution.

10.3. Determine the bulk specific gravity of each of the compacted specimens in accordance with T 166 or T 275 as appropriate.

10.4. Determine the theoretical maximum specific gravity (G_{mm}) according to T 209 of each of the four mixtures using companion samples which have been conditioned to the same extent as the compacted specimens (Note 11).

10.5. Determine the design binder content which produces a target air void content (V_a) of 4.0 percent at N_{design} gyrations using the following steps:

10.5.1. Calculate V_a, VMA, and VFA at N_{design} using Equations 2, 3, and 13:

$$VFA = 100 \times \left[\frac{VMA - V_a}{VMA} \right] \quad (13)$$

10.5.2. Calculate the dust-to-binder ratio using Equation 14.

$$P_{0.075} \Big/ P_{be} = \frac{P_{0.075}}{P_{be}} \quad (14)$$

where:

P_{be} = effective binder content.

10.5.3. For each of the four mixtures, determine the average corrected specimen relative densities at N_{initial} ($\%G_{mm_{\text{initial}}}$), using Equation 15.

$$\%G_{mm_{\text{initial}}} = 100 \times \left(\frac{G_{mb} h_d}{G_{mm} h_i} \right) \quad (15)$$

10.5.4. Plot the average V_a, VMA, VFA, and relative density at N_{design} for replicate specimens versus binder content.

Note 17—All plots are generated automatically by the Superpave software. Figure 2 presents a sample data set and the associated plots.

10.5.5. By graphical or mathematical interpolation (Figure 2), determine the binder content to the nearest 0.1 percent at which the target V_a is equal to 4.0 percent. This is the design binder content (P_b) at N_{design}.

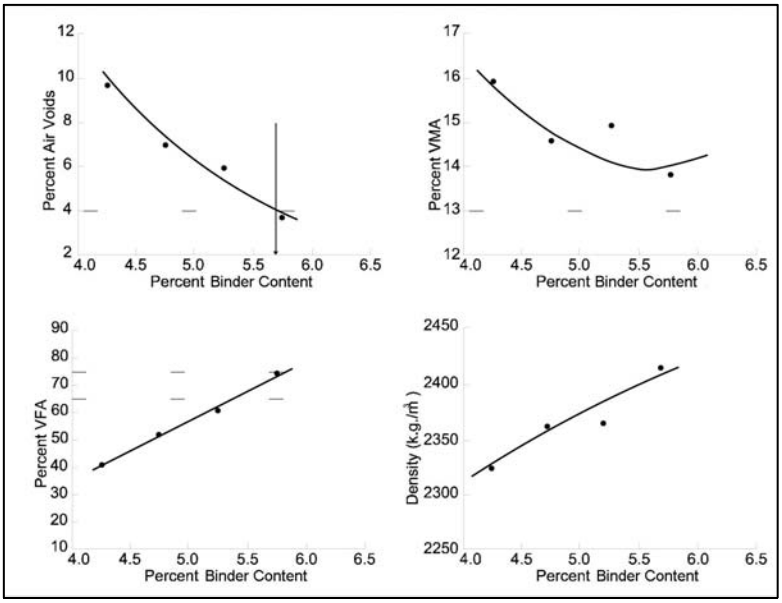
10.5.6. By interpolation (Figure 2), verify that the volumetric requirements specified in M 323 are met at the design binder content.

10.6. Compare the calculated percent of maximum relative density with the design criteria at N_{initial} by interpolation, if necessary. This interpolation can be accomplished by the following procedure.

10.6.1. Prepare a densification curve for each mixture by plotting the measured relative density at X gyrations, $\%G_{mm_x}$, versus the logarithm of the number of gyrations (see Figure 3).

10.6.2. Examine a plot of air void content versus binder content. Determine the difference in air voids between 4.0 percent and the air void content at the nearest, lower binder content. Determine the air void content at the nearest, lower binder content at its data point, not on the line of best fit. Designate the difference in air void content as ΔV_a.

10.6.3. Using Equation 15, determine the average corrected specimen relative densities at N_{initial} ($\%G_{mm_{\text{initial}}}$). Confirm that $\%G_{mm_{\text{initial}}}$ satisfies the design requirements in M 323 at the design binder content.



Average V_a, VMA, VFA, and Relative Density at N_{design}

P_b (%)	V_a (%)	VMA (%)	VFA (%)	Density at N_{design} (kg/m^3)
4.3	9.5	15.9	40.3	2320
4.8	7.0	14.7	52.4	2366
5.3	6.0	14.9	59.5	2372
5.8	3.7	13.9	73.5	2412

Notes:

1. In this example, the estimated design binder content is 4.8 percent; the minimum VMA requirement for the design aggregate structure (19.0-mm nominal maximum size) is 13.0 percent, and the VFA requirement is 65 to 75 percent.
2. Entering the plot of percent air voids versus percent binder content at 4.0 percent air voids, the design binder content is determined as 5.7 percent.
3. Entering the plots of percent VMA versus percent binder content and percent VFA versus percent binder content at 5.7 percent binder content, the mix meets the VMA and VFA requirements.

Figure 2—Sample Volumetric Design Data at N_{design}

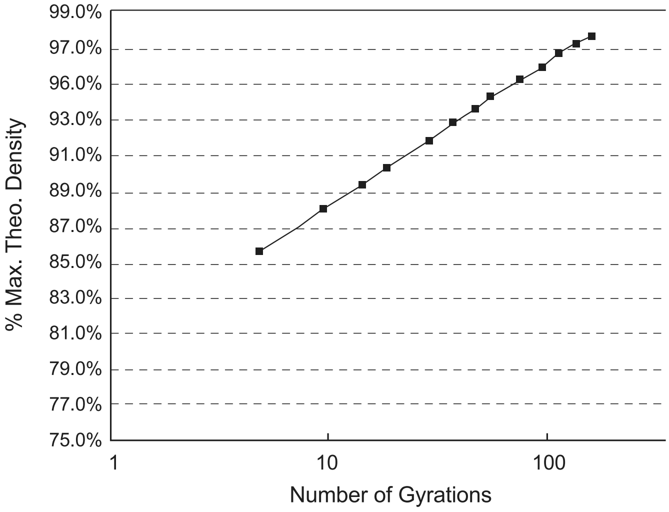


Figure 3—Sample Densification Curve

10.7. Prepare replicate (Note 8) specimens composed of the design aggregate structure at the design binder content to confirm that $\%G_{mm_{\max}}$ satisfies the design requirements in M 323.

10.7.1. Condition the mixtures according to R 30, and compact the specimens according to T 312 to the maximum number of gyrations, $N_{\max}$, from Table 1.

10.7.2. Determine the average specimen relative density at $N_{\max}$, $\%G_{mm_{\max}}$, by using Equation 16, and confirm that $\%G_{mm_{\max}}$ satisfies the volumetric requirement in M 323.

$$\%G_{mm_{\max}} = 100\frac{G_{mb}}{G_{mm}} \qquad (16)$$

where:

$\%G_{mm_{\max}}$ = relative density at $N_{\max}$ gyrations at the design binder content.

11. EVALUATING MOISTURE SUSCEPTIBILITY

11.1. Prepare six mixture specimens (nine are needed if freeze-thaw testing is required) composed of the design aggregate structure at the design binder content. Condition the mixtures in accordance with R 30, and compact the specimens to 7.0 ± 0.5 percent air voids in accordance with T 312.

11.2. Test the specimens and calculate the tensile strength ratio in accordance with T 283.

11.3. If the tensile strength ratio is less than 0.80, as required in M 323, remedial action such as the use of anti-strip agents is required to improve the moisture susceptibility of the mix. When remedial agents are used to modify the binder, retest the mix to assure compliance with the 0.80 minimum requirement.

12. ADJUSTING THE MIXTURE TO MEET PROPERTIES

12.1. *Adjusting VMA*—If a change in the design aggregate skeleton is required to meet the specified VMA, there are three likely options: (1) change the gradation (Note 18); (2) reduce the minus 0.075-mm fraction (Note 19); or (3) change the surface texture and/or shape of one or more of the aggregate fractions (Note 20).

Note 18—Changing gradation may not be an option if the trial aggregate blend gradation analysis includes the full spectrum of the gradation control area.

Note 19—Reducing the percent passing the 0.075-mm sieve of the mix will typically increase the VMA. If the percent passing the 0.075-mm sieve is already low, this is not a viable option.

Note 20—This option will require further processing of existing materials or a change in aggregate sources.

12.2. *Adjusting VFA*—The lower limit of the VFA range should always be met at 4.0 percent air voids if the VMA meets the requirements. If the upper limit of the VFA is exceeded, then the VMA is substantially above the minimum required. If so, redesign the mixture to reduce the VMA. Actions to consider for redesign include: (1) changing to a gradation that is closer to the maximum density line; (2) increasing the minus 0.075-mm fraction, if room is available within the specification control points; or (3) changing the surface texture and shape of the aggregates by incorporating material with better packing characteristics, e.g., less thin, elongated aggregate particles.

12.3. *Adjusting the Tensile Strength Ratio*—The tensile strength ratio can be increased by: (1) adding chemical anti-strip agents to the binder to promote adhesion in the presence of water; or (2) adding hydrated lime to the mix.

13. REPORT

13.1. The report shall include the identification of the project number, traffic level, and mix design number.

13.2. The report shall include information on the design aggregate structure including the source of aggregate, kind of aggregate, required quality characteristics, and gradation.

13.3. The report shall contain information about the design binder including the source of binder and the performance grade.

13.4. The report shall contain information about the HMA including the percent of binder in the mix; the relative density; the number of initial, design, and maximum gyrations; and the VMA, VFA, V_{be}, V_{ba}, V_a, and dust-to-binder ratio.

14. KEYWORDS

14.1. HMA mix design; Superpave; volumetric mix design.

APPENDIX

(Nonmandatory Information)

X1. CALCULATING AN INITIAL TRIAL BINDER CONTENT FOR EACH AGGREGATE TRIAL BLEND

X1.1. Calculate the bulk and apparent specific gravities of the combined aggregate in each trial blend using the specific gravity data for the aggregate fractions obtained in Section 6.6 and Equations X1.1 and X1.2:

$$G_{sb} = \frac{P_1 + P_2 + \cdots + P_n}{\frac{P_1}{G_1} + \frac{P_2}{G_2} + \cdots + \frac{P_n}{G_n}} \qquad (X1.1)$$

$$G_{sa} = \frac{P_1 + P_2 + \cdots + P_n}{\frac{P_1}{G_1} + \frac{P_2}{G_2} + \cdots + \frac{P_n}{G_n}} \qquad (X1.2)$$

where:

G_{sb} = bulk specific gravity for the combined aggregate;
G_{sa} = apparent specific gravity for the combined aggregate;
$P_1, P_2, \ldots P_n$ = percentages by mass of aggregates 1, 2, …*n*; and

$G_1, G_2, \ldots G_n$ = bulk specific gravities (Equation X1.1) or apparent specific gravities (Equation X1.2) of aggregates 1, 2, *n*.

X1.2. Estimate the effective specific gravity of the combined aggregate in the aggregate trial blend using Equation X1.3:

$$G_{se} = G_{sb} + 0.8\left(G_{sa} - G_{sb}\right) \qquad (X1.3)$$

where:

G_{se} = effective specific gravity of the combined aggregate;
G_{sb} = bulk specific gravity of the combined aggregate; and
G_{sa} = apparent specific gravity of the combined aggregate.

Note X1—The multiplier, 0.8, can be changed at the discretion of the designer. Absorptive aggregates may require values closer to 0.6 or 0.5.

Note X2—The Superpave mix design system includes a mixture conditioning step before the compaction of all specimens; this conditioning generally permits binder absorption to proceed to completion. Therefore, the effective specific gravity of Superpave mixtures will tend to be close to the apparent specific gravity in contrast to other design methods where the effective specific gravity generally will lie near the midpoint between the bulk and apparent specific gravities.

X1.3. Estimate the volume of binder absorbed into the aggregate, V_{ba}, using Equations X1.4 and X1.5:

$$V_{ba} = W_s\left(\frac{1}{G_{sb}} - \frac{1}{G_{se}}\right) \qquad (X1.4)$$

where:

W_s, the mass of aggregate in 1 cm^3 of mix, g, is calculated as:

$$W_s = \frac{P_s(1 - V_a)}{\frac{P_b}{G_b} + \frac{P_s}{G_{se}}} \qquad (X1.5)$$

and where:

P_b = mass percent of binder, in decimal equivalent, assumed to be 0.05;
P_s = mass percent of aggregate, in decimal equivalent, assumed to be 0.95;
G_b = specific gravity of the binder; and
V_a = volume of air voids, assumed to be 0.04 cm^3 in 1 cm^3 of mix.

Note X3—This estimate calculates the volume of binder absorbed into the aggregate, V_{ba}, and subsequently, the initial, trial binder content at a target air void content of 4.0 percent.

X1.4. Estimate the volume of effective binder using Equation X1.6:

$$V_{be} = 0.176 - \left[\, 0.0675 \log(S_n)\right] \qquad (X1.6)$$

where:

V_{be} = volume of effective binder, cm^3; and
S_n = nominal maximum sieve size of the largest aggregate in the aggregate trial blend, mm.

Note X4—This regression Equation is derived from an empirical relationship between: (1) VMA and V_{be} when the air void content, V_a, is equal to 4.0 percent: V_{be} = VMA – V_a = VMA – 4.0; and (2) the relationship between VMA and the nominal maximum sieve size of the aggregate in M 323.

X1.5. Calculate the estimated initial trial binder (P_{bi}) content for the aggregate trial blend gradation using Equation X1.7:

$$P_{bi} = 100 \times \left(\frac{G_b(V_{be} + V_{ba})}{(G_b(V_{be} + V_{ba})) + W_s}\right) \qquad (X1.7)$$

where:

P_{bi} = estimated initial trial binder content, percent by weight of total mix.

Standard Practice for

Designing Stone Matrix Asphalt (SMA)

AASHTO Designation: R 46-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Designing Stone Matrix Asphalt (SMA)

AASHTO Designation: R 46-08

1. SCOPE

1.1. This standard practice covers the design of Stone Matrix Asphalt (SMA) using the Superpave Gyratory Compactor™ (SGC). The SMA design is based on the volumetric properties of the SMA in terms of air voids (V_a), voids in the mineral aggregate (VMA), and the presence of stone-on-stone contact.

1.2. The values stated in SI units are to be regarded as the standard. The U.S. Customary units in parentheses are for information only.

1.3. *This standard practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard practice to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2. *Asphalt Institute Publication*:

- MS-2, *Mix Design Methods for Asphalt Concrete and Other Hot-Mix Types*

3. TERMINOLOGY

3.1. *Definitions*:

3.2. *stone matrix asphalt (SMA)*—a hot mix asphalt (HMA) consisting of two parts, a coarse aggregate skeleton and a rich asphalt binder mortar. The mixture must have an aggregate skeleton with coarse aggregate-on-coarse aggregate contact (generally referred to as stone-on-stone contact). The coarse aggregate is generally considered to be that fraction of the aggregate retained on the 4.75-mm (No. 4) sieve but may be designated as other sizes.

3.3. *air voids* (V_a)—the total volume of the small pockets of air between the coated aggregate particles throughout a compacted paving mixture, expressed as a percent of the bulk volume of the compacted paving mixture (Note 1).

Note 1—Term defined in the Asphalt Institute Publication MS-2.

3.4. *voids in the mineral aggregate (VMA)*—the volume of the intergranular void space between the aggregate particles of a compacted paving mixture that includes the air voids and the effective binder content, expressed as a percent of the total volume of the specimen (Note 1).

3.5. *voids in the coarse aggregate (VCA)*—the volume between the coarse aggregate particles. This volume includes filler, fine aggregate, air voids, asphalt binder, and stabilizing additive (if used).

3.6. *SMA mortar*—a mixture of asphalt binder, filler [material passing the 0.075-mm (No. 200) sieve], and stabilizing additive.

3.7. *stabilizing additive*—either cellulose or mineral fiber.

4. SUMMARY OF THE PRACTICE

4.1. *Materials Selection*—Asphalt binder, aggregate, mineral fillers, and stabilizing additives that meet the applicable specification are selected.

4.2. *Selecting Optimum Gradation*—Three recommended trial aggregate gradations from the selected aggregates are blended. The dry-rodded unit weight for the coarse aggregate for each trial gradation is determined in accordance with T 19/T 19M. For each trial gradation, an initial trial asphalt binder content is selected, and at least two specimens are compacted in accordance with T 312. Where no previous history is available, an initial trial asphalt binder content between 6.0 and 6.5 percent is recommended. Gradations of the three blends are selected to ensure that minimum VMA requirements and stone-on-stone contact are achieved.

4.3. *Selecting Design Binder Content* —Replicate specimens are compacted in accordance with T 312 at three binder contents. The design binder content is selected on the basis of satisfactory conformance with the requirements of Section 10 (Note 2).

Note 2—When an SMA mix cannot be designed within the minimum binder content requirements, the guidelines given in Table X2.1 can be used to establish minimum binder content requirements based on the combined-aggregate bulk specific gravity.

4.4. *Evaluating Moisture Susceptibility*—The moisture susceptibility of the mixture, designed and compacted in accordance with T 312 to a V_a content of 6.0 ± 1.0 percent, is evaluated in accordance with T 283.

4.5. *Evaluating Draindown*—The mixture is evaluated for sensitivity to asphalt binder draindown in accordance with T 305. If the mixture fails the moisture susceptibility or draindown tests, it must be modified so that the specification requirements are met.

5. TEST SPECIMENS

5.1. *Number of Samples*—A total of nine samples are initially required; at least three samples at each of the three trial gradations are produced. Each sample is mixed with the trial asphalt binder content, and two of the three samples for each trial gradation are compacted. The remaining sample of each trial gradation is used to determine the theoretical maximum density in accordance with T 209.

5.2. *Preparation of Aggregates*—Dry aggregates to a constant mass at 105°C to 110°C (221°F to 230°F), and separate the aggregates by dry-sieving into the desired size fractions. The following size fractions are recommended:

- 37.5 mm ($1^1/_2$ in.) to 25.0 mm (1 in.);
- 25.0 mm (1 in.) to 19.0 mm ($^3/_4$ in.);
- 19.0 mm ($^3/_4$ in.) to 12.5 mm ($^1/_2$ in.);
- 12.5 mm ($^1/_2$ in.) to 9.5 mm ($^3/_8$ in.);
- 9.5 mm ($^3/_8$ in.) to 4.75 mm (No. 4);
- 4.75 mm (No. 4) to 2.36 mm (No. 8);
- 2.36 mm (No. 8) to 0.075 mm (No. 200); and
- Passing 0.075 mm (No. 200).

5.3. *Determination of Mixing and Compaction Temperatures*:

5.3.1. The temperature to which the asphalt binder must be heated to produce a viscosity of 170 ± 20 cSt shall be the mixing temperature.

5.3.2. The temperature to which the asphalt binder must be heated to produce a viscosity of 280 ± 30 cSt shall be the compaction temperature.

Note 3—While the temperatures given in Sections 5.3.1 and 5.3.2 are appropriate for neat asphalt binders, the selected temperatures may not be applicable to modified asphalt binders. In those cases, it is recommended that the manufacturer’s guidelines for mixing and compaction temperatures be used.

5.4. *Preparation of Mixtures*:

5.4.1. A mechanical mixing apparatus shall be used.

5.4.2. An initial batch shall be mixed for the purpose of “buttering” the mixing bowl and stirrers. This batch shall be emptied after mixing, and the sides of the bowl and stirrers shall be cleaned of mixture residue by scraping with a small limber spatula but shall not be wiped with a cloth or washed clean with solvent, except when a change is to be made in the asphalt binder or at the end of a design.

5.4.3. Into separate pans for each test specimen, weigh sufficient material to produce compacted samples of the desired volume, approximately 4700 g. Mix the aggregate in each pan. Place the aggregate in an oven and heat to a temperature not exceeding the mixing temperature established in Section 5.3 by more than approximately 28°C (50°F). Heat the asphalt binder to the established mixing temperature. The stabilizing additive is added to the heated aggregate prior to the introduction of the asphalt binder.

Note 4—It is recommended that the stabilizing additive be manually mixed with the heated aggregate. This procedure is needed to ensure an even distribution of the stabilizing additive during the laboratory mixing process. The use of stabilizing additives generally requires slightly longer mixing times.

5.4.4. Form a crater in the dry blended aggregate and stabilizing additive, and weigh the preheated required amount of asphalt binder into the crater. Care must be exercised to prevent loss of the mix during mixing and subsequent handling. At this point, the temperature of the aggregate and asphalt binder shall be within the limits of the mixing temperature established in Section 5.3. Mix the aggregate and asphalt binder rapidly until the aggregate is thoroughly coated.

5.5. *Compaction of Specimens*—The compaction temperature is determined in accordance with Section 5.3. Laboratory samples of SMA are short-term conditioned in accordance with R 30 and then compacted for 100 gyrations.

Note 5—When aggregates have a Los Angeles Abrasion loss value greater than 30 percent, the desirable number of SGC design gyrations is 75.

6. SELECTION OF TRIAL GRADATIONS

6.1. The trial gradations must be selected to be within the desired specification range as defined in M 325. To design an SMA mixture, it is recommended that at least three trial gradations be initially evaluated. It is suggested that one of the trial blends fall along the coarse limits, one along the fine limits, and one in the middle of the gradation bands as defined in M 325. When the bulk specific gravities of the different aggregates to be used in the mixture vary by more than 0.2, the trial blend gradations should be based upon volumetric percentage. An example problem illustrating how to blend aggregates based on volume is given in Appendix X1.1.

7. SELECTION OF TRIAL BINDER CONTENT

7.1. As a starting point, for aggregates with bulk specific gravities approximately equal to 2.75, a binder content of approximately 6.0 percent or greater, by mass, needs to be selected. If the bulk specific gravity of the coarse aggregate exceeds 2.75, the trial binder content can be reduced by approximately 0.1 percent for each specific-gravity increment of 0.05 above 2.75. If the bulk specific gravity of the coarse aggregate is below 2.75, the trial binder content can be increased approximately 0.1 percent for each specific gravity increment of 0.05 below 2.75 (see Table X2.1).

8. DETERMINATION OF VCA IN COARSE-AGGREGATE FRACTION OF MIXTURE

8.1. For best performance, the SMA must have a coarse-aggregate skeleton with stone-on-stone contact. The course-aggregate fraction is that portion of the total aggregate blend retained on the 4.75-mm (No. 4) sieve for 12.5-mm ($^1/_2$-in.) and 19-mm ($^3/_4$-in.) SMA. For the 9.5-mm ($^3/_8$-in.) nominal-maximum aggregate size SMA, the coarse aggregate is that portion of the total aggregate blend retained on the 2.36-mm (No. 8) sieve. The condition of stone-on-stone contact within an SMA is defined as the point at which the VCA of the compacted mixture is less than the VCA of the coarse aggregate in the dry-rodded test.

8.2. The dry-rodded VCA of the coarse-aggregate fraction (VCA_{DRC}) is determined by compacting the stone with the dry-rodded technique in accordance with T 19M/T 19. When the dry-rodded density of the stone fraction has been determined, the VCA_{DRC} can be calculated using Equation 1:

$$VCA_{DRC} = \frac{G_{CA}\gamma_w - \gamma_s}{G_{CA}\gamma_w} \times 100 \qquad (1)$$

where:

G_{CA} = the bulk specific gravity of the coarse aggregate (T 85);

γ_s = the unit weight of the coarse-aggregate fraction in the dry-rodded condition [kg/m^3 (lb/ft^3)] (T 19/T 19M); and

γ_w = the unit weight of water [1000 kg/m^3 (62.4 lb/ft^3)].

9. SELECTION OF DESIRED GRADATION

9.1. After the trial samples have been compacted and allowed to cool, they are removed from the molds and tested to determine their bulk specific gravity in accordance with T 166. The uncompacted samples are used to determine the theoretical maximum density in accordance with T 209. Using the bulk specific gravity and theoretical maximum density, the V_a, VMA, and VCA of the compacted mixture (VCA_{mix}) can be calculated using Equations 2, 3, and 4:

$$\text{VMA} = 100 - \left(G_{mb}/G_{sb}\right)P_s \qquad (2)$$

$$\text{VCA}_{\text{mix}} = 100 - \left(G_{mb}/G_{CA}\right)P_{CA} \qquad (3)$$

$$V_a = 100 \times (1 - (G_{mb}/G_{mm})) \qquad (4)$$

where:

G_{mb} = the bulk specific gravity of the compacted mixture (T 166);

G_{sb} = the bulk specific gravity of the total aggregate;

P_s = the percent of aggregate in the mixture;

G_{CA} = the bulk specific gravity of the coarse-aggregate fraction (T 85);

P_{CA} = the percent of coarse aggregate in the total mixture; and

G_{mm} = the theoretical maximum density of the mixture (T 209).

9.2. Of the three trial gradations evaluated, the one with the lowest percent of coarse aggregate that meets or exceeds the minimum VMA requirement, and has a VCA_{mix} less than VCA_{DRC}, is selected as the desired gradation. The trial gradation selected, based on the above conditions, is referred to as the optimum gradation.

Note 6—If possible, the selected gradation should have a VMA somewhat higher than the minimum criteria to allow for some reduction in VMA during plant production.

10. SELECTION OF OPTIMUM BINDER CONTENT

10.1. Once the optimum gradation of the mixture has been chosen, it may be necessary to raise or lower the binder content to obtain the proper amount of V_a in the mixture. In this case, additional samples are prepared using the selected gradation and varying the binder content. The optimum binder content is chosen to produce the V_a in the mixture specified in M 325.

10.2. Twelve samples are needed for this portion of the procedure. This number provides for three compacted samples and one uncompacted sample (used to determine the theoretical maximum density) at each of the three binder contents. The mixture properties are determined and the optimum binder content is selected to provide the desired V_a level. The SMA selected should have properties meeting the criteria as specified in M 325. If these criteria are not satisfied, the mixture should be modified so that the requirements are satisfied.

11. MOISTURE SUSCEPTIBILITY

11.1. Moisture susceptibility of the selected mixture is determined in accordance with T 283 using samples compacted in accordance with T 312 to a V_a content of 6.0 ± 1.0 percent. The retained tensile strength level of the SMA shall be as specified in MP 8 at 6.0 ± 1.0 percent V_a.

12. DRAINDOWN SENSITIVITY

12.1. Draindown sensitivity of the selected mixture is determined using T 305. Draindown sensitivity is determined at the anticipated plant-production temperature and shall satisfy the requirements of M 325.

13. ADJUSTING MIXTURE TO MEET PROPERTIES

13.1. *V_a Content*—The amount of V_a in the mixture can be controlled by the binder content. However, a problem occurs when low V_a contents exist at binder contents below the minimum values specified. Lowering the binder content below these values to achieve a proper amount of V_a violates the minimum binder-content specification. Instead, the mixture gradation must be modified to increase the VMA.

13.2. *VMA*—The VMA may be raised by increasing the percentage of coarse aggregate. Changing the aggregate source may also be required to increase VMA.

13.3. *VCA_{mix}*—If the $\mathrm{VCA}_{\mathrm{mix}}$ is higher than the $\mathrm{VCA}_{\mathrm{DRC}}$, then the mixture gradation must be modified. This modification is typically accomplished by increasing the percentage of coarse aggregate.

13.4. *Moisture Susceptibility*—If the mixture fails to meet the moisture-susceptibility requirements, anti-strip agents can be used. If these measures prove ineffective, the aggregate source and/or binder source can be changed to obtain better aggregate/binder compatibility.

13.5. *Draindown Sensitivity*—Problems with draindown sensitivity can be remedied by increasing the amount of, or by selecting a different, stabilizing additive.

14. REPORT

14.1. *Report the following information*:

14.1.1. Identification of the project name and project number;

14.1.2. Information on the materials used, including aggregate source, binder source and performance grade, type and amount of stabilizing additive, and material quality characteristics;

14.1.3. Results of the gradation optimization (results of all trial gradations);

14.1.4. Optimum gradation and binder content;

14.1.5. Volumetric properties for each trial blend and at the optimum binder content;

14.1.6. Moisture susceptibility results; and

14.1.7. Draindown sensitivity results.

APPENDIX

(Nonmandatory Information)

X1. EXAMPLE OF BLENDING AGGREGATE COMPONENTS TO SATISFY SMA GRADATION BANDS

X1.1. In HMA designs, specified aggregate gradations should be based on aggregate volume and not aggregate mass. However, for most conventional HMA mixtures (dense-graded), the specific gravities of the different aggregate stockpiles are assumed to be sufficiently comparable to make the gradations based on mass percentages similar to those based on volumetric percentages. This assumption is often not true in the aggregate components and, particularly in the mineral fillers used in SMA, where specific gravities vary widely. Therefore, in SMA, the specified gradation bands presented in the mixture design procedure are based on the percent passing by volume. This appendix gives an illustrative example with the objective of providing guidance on blending aggregate components based on volumes to meet the SMA gradation bands. However, if the G_{sb} of the different aggregates to be used within the mixture varies by 0.2 or less, gradations based on mass percentages may be used.

X1.2. The first step is to perform gradation tests based on mass in accordance with T 27 for the various aggregates to be used in SMA. For the example covered in this appendix, a 19.0-mm ($^3/_4$-in.) nominal-maximum aggregate size SMA is to be blended. Table X1.1 provides the results of the gradation tests performed on four aggregates that are to be blended. Also needed to determine aggregate gradations based on volume are the G_{sb} of the different aggregates. Table X1.1 also provides the G_{sb} values for each aggregate. Notice that the G_{sb} values differ by more than 0.2.

X1.3. The second step is to determine the percent, by mass, retained on each sieve for the different aggregates. For a given sieve, this calculation is performed by subtracting the percent passing the given sieve from the percent passing the next larger sieve. For example, using Aggregate C, the percent, by mass, retained on the 4.75-mm (No. 4) sieve would be calculated as follows:

Percent retained on 4.75-mm (No. 4) Sieve = 84.6 – 48.9 = 35.7 percent

where:

84.6 = the percent by mass passing the 9.5-mm ($^3/_8$-in.) sieve (Table X1.1);

48.9 = the percent by mass passing the 4.75-mm (No. 4) sieve (Table X1.1); and

35.7 = the percent by mass retained on the 4.75-mm (No. 4) sieve.

Table X1.1—Results of Gradation and Specific Gravity Tests for Aggregates to Be Used

	Stockpile Designation and Percent Passing Based on Mass			
Sieve	Aggregate A	Aggregate B	Aggregate C	Mineral Filler
19.0 mm ($^3/_4$ in.)	100.0	100.0	100.0	100.0
12.5 mm ($^1/_2$ in.)	66.0	71.0	97.4	100.0
9.5 mm ($^3/_8$ in.)	43.0	46.0	84.6	100.0
4.75 mm (No. 4)	9.0	6.0	48.9	100.0
2.36 mm (No. 8)	5.0	4.0	27.8	100.0
1.18 mm (No. 16)	2.0	4.0	16.6	100.0
0.60 mm (No. 30)	2.0	3.0	10.7	100.0
0.30 mm (No. 50)	2.0	3.0	7.6	100.0
0.075 mm (No. 200)	1.0	1.5	4.6	72.5
G_{sb}	2.616	2.734	2.736	2.401

X1.4. In the third step, assume the mass of each aggregate stockpile is 100 g. Using this assumption allows for the mass that would be retained on each sieve for each aggregate to be determined and shown to be equal to the numbers displayed in Table X1.2.

X1.5. Table X1.2 presents the values for the percent, by mass, retained for all sieves and aggregates. Note that a row has been added to reflect the material finer than the 0.075-mm (No. 200) sieve.

Table X1.2—Percent, by Mass, Retained on Each Sieve

	Stockpile Designation and Percent, by Mass, Retained on Each Sieve			
Sieve	Aggregate A	Aggregate B	Aggregate C	Mineral Filler
19.0 mm ($^3/_4$ in.)	0.0	0.0	0.0	0.0
12.5 mm ($^1/_2$ in.)	34.0	29.0	2.6	0.0
9.5 mm ($^3/_8$ in.)	23.0	25.0	12.8	0.0
4.75 mm (No. 4)	34.0	40.0	35.7	0.0
2.36 mm (No. 8)	4.0	2.0	21.1	0.0
1.18 mm (No. 16)	3.0	0.0	11.2	0.0
0.60 mm (No. 30)	0.0	1.0	5.9	0.0
0.30 mm (No. 50)	0.0	0.0	3.1	0.0
0.075 mm (No. 200)	1.0	1.5	3.0	27.5
–0.075 mm (No. 200)	1.0	1.5	4.6	72.5
Total, Σ	100	100	100	100

X1.6. The fourth step converts the masses determined in Step 3 to volumes per sieve. To make this conversion, the G_{sb} of the individual aggregates is needed. The volume of aggregate retained on each sieve for each aggregate can be determined from Equation X1.1:

$$\text{Volume of aggregate for a given sieve (cm}^3\text{)} = \frac{\text{Mass of aggregate retained, } g}{\text{Specific gravity } x\, \gamma_w} \qquad (X1.1)$$

where:

γ_w = the unit weight of water (1.0 g/cm^3).

X1.7. The following calculation applies for the volume of the aggregate retained on the 4.75-mm (No. 4) sieve of Aggregate C.

$$\text{Volume} = \frac{35.7\text{ g}}{2.736 \times 1\text{ g/cm}^3} = 13.05\text{ cm}^3$$

where:

35.7 g = the mass of Aggregate C retained on the 4.75-mm (No. 4) sieve (Table X1.2);
2.736 = the bulk specific gravity of Aggregate C (Table X1.1);
1.0 g/cm^3 = the unit weight of water; and
13.05 cm^3 = the volume of Aggregate C retained on the 4.75-mm (No. 4) sieve.

X1.8. The volumes retained on all sieves for each of the four aggregates are provided in Table X1.3.

Table X1.3—Volumes of Aggregate Retained on Each Sieve

	Stockpile Designation and Volume of Aggregate Retained on Each Sieve, cm^3			
Sieve	Aggregate A	Aggregate B	Aggregate C	Mineral Filler
19.0 mm ($^3/_4$ in.)	0.00	0.00	0.00	0.00
12.5 mm ($^1/_2$ in.)	13.00	10.61	0.95	0.00
9.5 mm ($^3/_8$ in.)	8.79	9.14	4.68	0.00
4.75 mm (No. 4)	13.00	14.63	13.05	0.00
2.36 mm (No. 8)	1.53	0.73	7.71	0.00
1.18 mm (No. 16)	1.15	0.00	4.09	0.00
0.60 mm (No. 30)	0.00	0.37	2.16	0.00
0.30 mm (No. 50)	0.00	0.00	1.13	0.00
0.075 mm (No. 200)	0.38	0.55	1.10	11.45
–0.075 mm (No. 200)	0.38	0.55	1.68	30.20

X1.9. The values provided in Table X1.3 are used to blend the different aggregates to meet the desired gradation based on volumes. In this procedure, the aggregate is blended by mass; then the final gradation is determined based on volume. As with gradations based on mass, this is a trial-and-error process. To perform the blending, select the estimated percentages, by mass, of the different aggregates to be used. For this example, the percentages in Table X1.4 will be tried first.

Table X1.4—Percentages of the Four Aggregates Used for the First Trial

Stockpile	% of Blend by Mass
Aggregate A	30
Aggregate B	30
Aggregate C	30
Mineral Filler	10

X1.10. Notice that the percentages in Table X1.4 are based on mass. This format indicates that the volume represented by 30 percent of Aggregate A, by mass, will be used in the blending of the aggregates based on volumes.

X1.11. The percent of each aggregate in the blend is multiplied by the volume retained on a given sieve for each aggregate to determine the total volume retained on that sieve. Using the 4.75-mm (No. 4) sieve, the total volume retained on the 4.75-mm (No. 4) sieve is calculated as follows:

$$\text{Total volume retained on the 4.75-mm (No. 4) sieve} = (0.30 \times 13.00) + (0.30 \times 14.63) + (0.30 \times 13.05) + (0.10 \times 0.00) = 12.20\ \text{cm}^3$$

where:

0.30, 0.30, 0.30, and 0.10 = the percentage, by mass, of each aggregate in the blend expressed as a decimal; and

13.00, 14.63, 13.05, and 0.00 = the volume retained on the 4.75-mm (No. 4) sieve for each aggregate (Table X1.3).

X1.12. The calculation in Section X1.11 is performed for each of the sieves in the gradation. Table X1.5 presents the total volume retained for each of the sieves in the gradation.

Table X1.5—Total Volumes Retained for Each Sieve for the First Trial

Sieve	Volume Retained for Each Sieve, cm^3
19.0 mm ($^3/_4$ in.)	0.00
12.5 mm ($^1/_2$ in.)	7.37
9.5 mm ($^3/_8$ in.)	6.78
4.75 mm (No. 4)	12.20
2.36 mm (No. 8)	2.99
1.18 mm (No. 16)	1.57
0.60 mm (No. 30)	0.76
0.30 mm (No. 50)	0.34
0.075 mm (No. 200)	1.75
–0.075 mm (No. 200)	3.80
Total Volume, Σ	37.56

X1.13. Now, based on the total volume retained per sieve and the total volume of the blended aggregates, the percent retained for each sieve, by volume, can be determined for the blend. This calculation is accomplished for a given sieve by dividing the volume retained on that sieve by the total volume of the blend. The following illustrates this calculation for the 4.75-mm (No. 4) sieve.

$$\text{Percent volume retained on the 4.75-mm (No. 4) sieve} = \frac{12.20\ \text{cm}^3}{37.56\ \text{cm}^3} \times 100 = 32.48\ \text{percent}$$

where:

12.20 cm^3 = the volume retained on the 4.75-mm (No. 4) sieve (Table X1.5);

37.56 cm^3 = the total volume of the blend (Table X1.5); and

32.48 = the percent volume of the blend retained on the 4.75-mm (No. 4) sieve.

X1.14. Using the percent retained per sieve based on volume, the percent passing, by volume, for the gradation can be determined similarly to the method used for gradations based on mass. Determine the cumulative percent retained for each sieve, and then subtract that value from 100.

X1.15. Table X1.6 provides the percents retained, based on volumes, for each of the sieves and converts these values to percent passing.

Table X1.6—Percents Passing Based on Volumes for the First Trial

Sieve	Percent Retained on Each Sieve	Cumulative Percent Retained	Percent Passing by Volume
19.0 mm ($^3/_4$ in.)	0.0	0.0	100.0
12.5 mm ($^1/_2$ in.)	19.6	19.6	80.4
9.5 mm ($^3/_8$ in.)	18.0	37.6	62.4
4.75 mm (No. 4)	32.5	70.1	29.9
2.36 mm (No. 8)	8.0	78.1	21.9
1.18 mm (No. 16)	4.2	82.3	17.7
0.60 mm (No. 30)	2.0	84.3	15.7
0.30 mm (No. 50)	0.9	85.2	14.8
0.075 mm (No. 200)	4.7	89.9	10.1
–0.075 mm (No. 200)	10.1	100.0	0.0

X1.16. Now, the blended gradation is compared to the required gradation band (also based on volume). Table X1.7 compares the gradation band for a 19.0-mm ($^3/_4$-in.) nominal-maximum aggregate size SMA from MP 8 to the gradation shown in Table X1.6.

Table X1.7—Comparison of Gradation Blend Based on Volume for the First Trial to Specified Gradation Band

Sieve	Gradation Band	Percent Passing for Blend
19.0 mm ($^3/_4$ in.)	90 to 100	100.0
12.5 mm ($^1/_2$ in.)	50 to 88	80.4
9.5 mm ($^3/_8$ in.)	25 to 60	62.4[a]
4.75 mm (No. 4)	20 to 28	29.9[a]
2.36 mm (No. 8)	16 to 24	21.9
1.18 mm (No. 16)	—	17.7
0.60 mm (No. 30)	—	15.7
0.30 mm (No. 50)	—	14.8
0.075 mm (No. 200)	8.0 to 11.0	10.1

[a] Does not meet the applicable requirements.

X1.17. Based on Table X1.7, the blended gradation did not meet the specified gradation band for a 19.0-mm ($^3/_4$-in.) nominal-maximum aggregate size SMA. Therefore, different blending percentages for the various aggregates are needed. Table X1.8 shows the percentages of the four aggregates used for the second trial.

Table X1.8—Percentages of the Four Aggregates Used for the Second Trial

Stockpile	% of Blend by Mass
Aggregate A	40
Aggregate B	41
Aggregate C	10
Mineral Filler	9

X1.18. Table X1.9 presents the blending of the four aggregates for the second trial. The second trial blend percentages were used along with the values from Table X1.3 to determine the percent passing, by volume, for the blend.

Table X1.9—Percents Passing Based on Volumes for the Second Trial

Sieve	Percent Retained on Each Sieve by Volume	Cumulative Percent Retained by Volume	Percent Passing by Volume	Percent Passing by Mass (for Comparison)	Gradation Band by Volume
19.0 mm ($^3/_4$ in.)	0.0	0.0	100.0	100.0	90 to 100
12.5 mm ($^1/_2$ in.)	25.6	25.6	74.4	74.3	50 to 88
9.5 mm ($^3/_8$ in.)	20.5	46.1	53.9	53.5	25 to 60
4.75 mm (No. 4)	33.2	79.3	20.7	20.0	20 to 28
2.36 mm (No. 8)	4.5	83.8	16.2	15.4	16 to 24
1.18 mm (No. 16)	2.3	86.1	13.9	13.1	—
0.60 mm (No. 30)	1.0	87.1	12.9	12.1	—
0.30 mm (No. 50)	0.3	87.4	12.6	11.8	—
0.075 mm (No. 200)	4.0	91.4	8.6	8.0	8.0 to 11.0
–0.075 mm (No. 200)	8.6	100.0	—	—	—

X1.19. Based on Table X1.9, the following percentages in Table X1.10 produce a gradation, based on volume, which satisfies the 19.0-mm ($^3/_4$-in.) nominal-maximum-aggregate size gradation band for SMA.

Table X1.10—Acceptable Blend of the Four Aggregates

Stockpile	% of Blend by Mass
Aggregate A	40
Aggregate B	41
Aggregate C	10
Mineral Filler	9

Standard Practice for

Reducing Samples of Hot Mix Asphalt (HMA) to Testing Size

AASHTO Designation: R 47-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Reducing Samples of Hot Mix Asphalt (HMA) to Testing Size

AASHTO Designation: R 47-08

1. SCOPE

1.1 This standard practice outlines methods for the reduction of large samples of hot mix asphalt (HMA) to the appropriate size for testing, employing techniques that are intended to minimize variations in the measured characteristics between the test samples so selected and the large sample.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard practice may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- T 168, Sampling Bituminous Paving Mixtures

3. TERMINOLOGY

3.1 *mastic*—a mixture of asphalt binder and fine mineral material.

4. SIGNIFICANCE AND USE

4.1 Specifications for HMA mixtures require sampling portions of the material for testing. Other factors being equal, larger samples will tend to be more representative of the total supply. This method provides procedures for reducing the large sample obtained in the field or produced in the laboratory to a convenient size for conducting a number of tests to describe the material and measure its quality in a manner that the smaller test sample portion is most likely to be a representation of the larger sample, and thus of the total supply. The individual test methods provide the minimum quantity of material necessary.

5. SELECTION OF METHOD

5.1 The selection of a particular method to reduce the large sample to test size depends on the amount of material comprising the large sample. It is recommended that for a large amount of material a mechanical splitter be employed whenever possible, thus lessening the time needed for reduction and minimizing the loss of temperature. To further reduce the sample size, a quartering method can be utilized.

6. SAMPLING

6.1 Obtain samples of HMA according to T 168 or as required by individual test methods. When additional tests are to be conducted, ensure that the initial size of the field sample is adequate to accomplish all intended tests. Use similar procedures for HMA produced in the laboratory.

MECHANICAL SPLITTER METHOD

7. APPARATUS

7.1 *Mechanical Splitter Type A*—The splitter shall have four equal-width chutes that discharge the material into four appropriate size containers. The splitter shall be designed with a receiving hopper that will hold the HMA field sample until a handle releases the material to fall through a divider and distribute it into four equal portions. The splitter shall be designed so that the HMA field sample will flow smoothly and freely through the divider without restriction or the loss of material (see Figures 1 to 3).

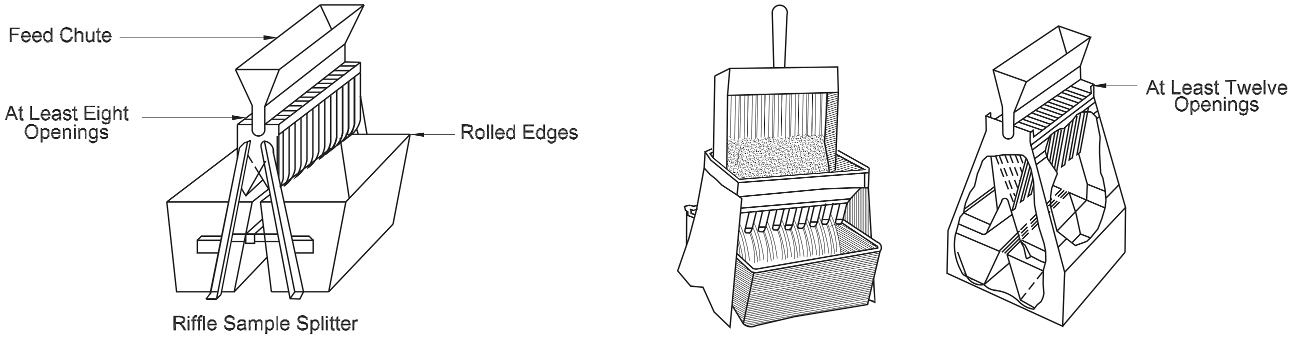
Figure 3—Elevation and Plan View of Bottom Portion of Splitter

7.2 *Mechanical Splitter Type B*—This splitter shall have an even number of equal-width chutes (no fewer than a total of eight for a Large Splitter and no fewer than 12 for a Small Splitter) which discharge alternately to each side of the splitter. The minimum width of the individual chutes shall be approximately 50 percent larger than the largest particle to be split. The splitter shall be equipped with two receptacles to catch the two halves of the sample following splitting. It shall also be equipped with a hopper or straightedged pan that has a width equal to or slightly less than the overall width of the assembly of chutes, by which the sample may be fed at a controlled rate to the chutes. The splitter and accessory equipment shall be so designed that the sample will flow smoothly and freely without restriction or the loss of material.



a. Large Splitter for large samples

b. Small Splitters for small samples

Figure 4—Mechanical Splitter Type B

Note 1—Type B Mechanical splitters are commonly available in sizes adequate for HMA having a nominal maximum aggregate size not over 25.4 mm (1 in.). Use closed versions for larger sizes.

7.3 *Non-Contact Temperature Device*

7.4 *Asphalt Release Agent*—Shall not contain any solvents or petroleum-based products that could affect asphalt binder properties.

8. PROCEDURE FOR MECHANICAL SPLITTER METHOD

8.1 Place the splitter on a level surface. The splitter and accessory equipment may be heated, not to exceed 110°C (230°F), as determined by a non-contact temperature device. Surfaces of the mechanical splitter that will come in contact with the HMA may be lightly coated with an approved asphalt release agent to prevent a buildup and loss of asphalt binder and fines. The release agent shall not contain any solvents or petroleum-based products that could affect asphalt binder properties.

8.2 *Mechanical Splitter Type A*—Place the field or laboratory-prepared HMA into the mechanical splitter hopper, and position four sample receptacles to receive the reduced portions of the original sample. Fill the hopper in such a manner as to avoid segregation of the HMA, typically using a continuous or segmented pour from multiple directions around the hopper. Release the handle to drop the HMA through the dividers into the sample receptacles. Reintroduce selected receptacles from opposite corners into the splitter hopper as many times as necessary to further reduce the HMA sample to the size specified for the intended test.

8.3 *Mechanical Splitter Type B*—Place the field or laboratory-prepared HMA into the sample splitter pan or hopper, and uniformly distribute it from edge to edge so that when it is introduced into the chutes, approximately equal amounts will flow through each chute. The rate at which the sample is introduced shall be such as to allow free flow through the chutes into the receptacles below. The entire sample may be mixed by repeated use of the mechanical splitter. Reintroduce the portion of the sample from one of the receptacles into the splitter as many times as necessary to reduce the sample to the size necessary for the intended test. The portion of the material collected in the other receptacle may be reserved for reduction in size for other tests.

QUARTERING METHOD

9. APPARATUS

9.1 *Quartering Template*—A quartering template manufactured from a suitable metal that withstands heat and use without deforming is recommended. The template should be configured in the form of a cross with sides of equal length sufficient to be 1.1 times the diameter of a flattened cone of HMA sample to be quartered. The height of the sides should be sufficient to extend above the thickness of the flattened cone of the HMA sample to be quartered. The sides shall form a 90 degree angle at their juncture (see Figure 5).

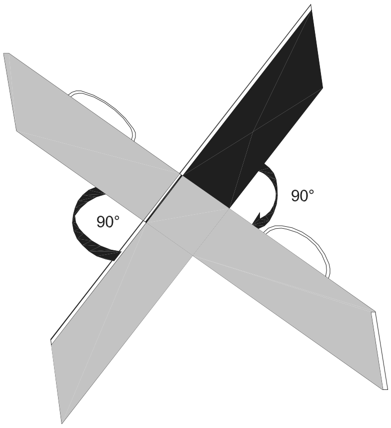


Figure 5—Quartering Device

9.2 *Flat-Bottom Scoop*—A large, straightedged, flat-bottom scoop should be used to sample HMA. A square shovel or trowel will meet this requirement.

9.3 *Straightedge*—Large spatula, trowel, or metal straightedge.

9.4 *Non-stick paper or heat resistant plastic*.

9.5 *Asphalt Release Agent*—Shall not contain any solvents or petroleum-based products that could affect asphalt binder properties.

10. PROCEDURE FOR QUARTERING METHOD

10.1 Place the original sample on a hard, “non-stick”, clean, level surface where there will be neither a loss of material nor the accidental addition of foreign material. The surface can be made non-stick by the application of an approved asphalt release agent, non-stick paper or heat resistant plastic.

10.2 Mix the material thoroughly by turning the entire sample over a minimum of four times with a flat-bottom scoop or by alternately lifting each corner of the paper and pulling it over the sample diagonally toward the opposite corner causing the material to be rolled. Create a conical pile by either depositing each scoop or shovelful of the last turning on top of the preceding one, or lifting both opposite corners. Carefully flatten the conical pile to a uniform thickness and diameter by pressing down the apex with a shovel or large, flat-bottomed, square scoop. The diameter should be approximately four to eight times the thickness. Make a visual observation to ensure that the material is homogeneous.

10.3 Divide the flattened mass into four quarters by inserting the quartering template and pressing down until the template is in complete contact with the surface on which the sample is placed. Straightedges may be used in lieu of the quartering device to completely separate the material into approximately equal quarters.

10.4 Reduce the sample using one of the following procedures:

10.5 Remove two diagonally opposite quarters, including all fine mastic material. Remove the quartering template. Successively mix and quarter the remaining material until the sample is reduced to the desired size.

10.6 Using a straightedge, slice through a quarter of the HMA from the center point to the outer edge of the quarter. Pull or drag the material from the quarter holding one edge of the straightedge in contact with the quartering device. Two straightedges may be used in lieu of the quartering device. Remove an equal portion from the opposite quarter.

INCREMENTAL METHOD

11. APPARATUS

11.1 *Flat-Bottom Scoop*—A large, straightedged, flat-bottom scoop should be used to sample HMA. A square shovel or trowel will meet this requirement.

11.2 *Non-stick heavy paper or heat-resistant plastic*.

11.3 *Large spatulas, trowels, metal straightedge, or 305 mm (12 in.) drywall taping knife*.

11.4 *Miscellaneous Equipment*—Including hot plate, non-asbestos heat-resistant gloves or mittens, pans, buckets, and cans.

12. PROCEDURE FOR INCREMENTAL METHOD

12.1 Place the original sample on a hard, non-stick, clean, level surface where there will be neither loss of material nor the accidental addition of foreign material. The surface shall be covered with a non-stick heavy paper, heat resistant plastic, or other suitable material.

12.2 Mix the material thoroughly by turning the entire sample over a minimum of four times with a flat-bottom scoop or by alternately lifting each corner of the paper and pulling it over the sample diagonally toward the opposite corner causing the material to be rolled. Create a conical pile by either depositing each scoop or shovelful of the last turning on top of the preceding one, or lifting both opposite corners. Make a visual observation to ensure that the material is homogeneous.

12.3 Grasp the paper; roll the material into a cylindrical roll (loaf), and flatten the top.

12.4 Pull the paper so at least $^1/_4$ of the length of the loaf is off the edge of the counter. Allow this material to drop into a container. Alternately, use a straightedge to slice off approximately $^1/_4$ of the length of the loaf and place the material in a sample pan or container. Set the material obtained aside.

12.5 Pull additional material off the edge of the counter and drop the appropriate-size sample into a sample pan or container. Alternately, use a straightedge to slice off an appropriate-size sample from the length of the loaf and place in a sample pan or container.

12.6 Repeat Section 12.5 as necessary until the proper-size sample has been obtained (Note 2). Repeat Sections 12.4 and 12.5 until all the samples for testing have been obtained. At any time while obtaining test samples, it may be necessary to re-roll the material as described in Sections 12.2 and 12.3.

Note 2—When reducing the sample to test size, it is advisable to take several small increments, determining the mass each time until the proper minimum size is achieved. Unless the sample size is grossly in excess of the minimum or exceeds the maximum test size, use the sample as reduced for the test.

Standard Practice for

Determination of Low-Temperature Performance Grade (PG) of Asphalt Binders

AASHTO Designation: R 49-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Determination of Low-Temperature Performance Grade (PG) of Asphalt Binders

AASHTO Designation: R 49-09[1]

1. SCOPE

1.1. This standard practice covers the determination of low-temperature properties of asphalt binders using data from the bending beam rheometer (T 313) and the direct tension tester (T 314). This standard practice can be used on data from unaged material or from material aged using T 240 (RTFOT), R 28 (PAV), or T 240 (RTFOT) and R 28 (PAV). This standard practice can be used on data generated within the temperature range from +6 to –36°C.

1.2. This standard practice is only valid for data on materials that fall within the scope of suitability for both test methods T 313 and T 314.

1.3. This standard practice can be used to determine the following:

1.3.1. *PG Grade Determination of an Asphalt Binder*—The determination of a low-temperature grade or grades that are satisfied by an asphalt binder. The determination of the temperature corresponds to the specification parameter, T_{cr}, the critical cracking temperature.

1.3.2. *Prequalification of an Asphalt Binder*—The procedure required to qualify an asphalt binder for supply.

1.3.3. *Verification of an Asphalt Binder Grade*—The testing required to certify that a binder complies with an existing prequalified binder.

1.4. While this standard practice determines the critical cracking temperature for typical hot mix asphalt (HMA), the intent of this standard practice is grading of asphalt binder according to M 320, not performance prediction for asphalt pavement. This standard practice should not be used in lieu of T 322.

1.5. *This standard practice may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

Note 1—The algorithms contained in this standard require implementation by a person trained in the subject of numerical methods and visco-elasticity. However, due to the complexity of the calculations they must, of necessity, be performed on a computer. Software to perform the calculations may be written or purchased as a spreadsheet or as a stand-alone program.[2]

3. TERMINOLOGY

3.1. *Definitions of Terms Specific to This Standard*:

3.1.1. *Arrhenius parameter* (a_1)—this is the constant coefficient in the Arrhenius model for shift factors, $\ln(a_T) = a_1(1/T - 1/T_{\mathrm{ref}})$.

3.1.2. *asphalt binder*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of non-particulate organic modifiers.

3.1.3. *coefficient of linear thermal expansion* (α)—the fractional change in size in one dimension associated with a temperature increase of 1°C.

3.1.4. *conventional unmodified asphalt binders*—asphalt binders for which the following two conditions are satisfied: (1) The difference between the temperature at which $S(60) = 300$ MPa and m-value $(60) = 0.300$ is less than or equal to ±2.0°C. The $S(60)$ and the m-value are determined using the T 313 BBR test; (2) The failure strength determined using T 314 must be within 3.77 ± 0.77 MPa.

3.1.5. *creep compliance* [$D(T,t)$]—the reciprocal of the stiffness of a material, $1/S(T,t)$, at temperature, T, and time, t. Creep compliance may also be expressed using reduced time, ξ, as $D(T_{\mathrm{ref}}, \xi)$.

3.1.6. *critical cracking temperature* (T_{cr})—the temperature, estimated using this standard practice, at which the induced thermal stress in a material exceeds its fracture stress. The critical cracking temperature is a "single event cracking" limit prediction that does not include the effect of low-temperature thermal fatigue.

3.1.7. *failure stress* (σ_f)—the tensile stress value at the point of failure obtained from T 314.

3.1.8. *glassy modulus*—the modulus at which the binder exhibits glass-like behavior, assumed to be 3×10^9 Pa for this procedure.

3.1.9. *induced thermal stress* (σ_{th})—the stress induced in a material by cooling it while it is restrained so that it cannot contract.

3.1.10. *master curve*—a composite curve at a single reference temperature, T_{ref}, which can be constructed by shifting, along the log time or log frequency axis, a series of overlapping modulus data curves at various test temperatures. The modulus data curve at the reference temperature is not shifted. The shifted smooth curve is called the master curve at the reference temperature.

3.1.11. *pavement constant* (*C*)—an empirical, constant factor that serves as a damage transfer function to convert the thermal stresses calculated from laboratory data to the thermal stresses generated in the pavement. The damage transfer function is needed to account for the differences in the strain rates experienced by the distribution of binder films in the pavement and the bulk strain rate used in the T 314 direct tension test (DDT). Critical cracking temperatures of conventional unmodified asphalt binders were used to determine the pavement constant, *C*. The value of the pavement constant, *C*, is the value that minimizes the difference between the critical cracking temperature, T_{cr}, determined using the procedure described in this standard practice and the T 313 bending beam rheometer (BBR) test. The T_{cr} from the BBR test is determined as the higher value between the temperature where *S*(60) is 300 MPa and the temperature where the *m*-value at 60 seconds is 0.3. Using the above procedure, the value of the pavement constant was determined to be 18. The pavement constant of 18 is based on the most current pavement performance data available. Federal Highway Administration (FHWA) and the Transportation Research Board (TRB) Binder Expert Task Group (ETG) continue to collect and analyze field-performance data.

3.1.12. *reduced time* (ξ)—the computed loading time at the reference temperature, T_{ref}, equivalent to actual loading at temperature *T*. The reduced time is determined by dividing actual loading time, *t*, at temperature *T*, by the shift factor, *aT*, $\xi = t/a_T$.

3.1.13. *reference temperature* (T_{ref})—the temperature at which the master curve is constructed in degrees Kelvin.

3.1.14. *relaxation modulus* [$E(T,t)$]—the modulus of a material determined using a strain-controlled (relaxation) experiment at temperature, *T*, and time, *t*. Relaxation modulus may also be expressed using reduced time as $E(T_{\mathrm{ref}}, \xi)$.

3.1.15. *shift factor* (a_T)—the shift in the time or frequency domain associated with a shift from temperature, *T*, to the reference, T_{ref}.

3.1.16. *specification temperature* (T_{spec})—the specified low-temperature grade of the binder being prequalified.

3.1.17. *stiffness modulus* [$S(T,t)$]—the modulus (stress/strain) of a material at temperature, *T*, and time, *t*. Stiffness modulus may also be expressed using reduced time as $S(T_{\mathrm{ref}}, \xi)$.

4. SUMMARY OF THE PRACTICE

4.1. This standard practice describes the procedure used to calculate the relaxation modulus master curve and subsequently the thermally induced stress curve for an asphalt binder from data generated from the bending beam rheometer test.

4.2. The stiffness master curve is calculated from the stiffness versus time data measured in the BBR at two temperatures. The fitting procedure follows the Christensen-Anderson-Marasteanu (CAM) rheological model for asphalt binder. The stiffness master curve is then converted to the creep compliance curve by taking its inverse.

4.3. The creep compliance is converted to relaxation modulus using the Hopkins and Hamming method, which is fitted to the CAM model. The Hopkins and Hamming method is a numerical solution of the convolution integral.

4.4. The thermally induced stress is calculated by numerically solving the convolution integral. The thermal stress calculations are based on Boltzmann's superposition principle for linear viscoelastic materials. The calculated thermally induced stress is then multiplied by the pavement constant to predict the thermal stress produced in the hot mix asphalt pavement. A value of 18 is used for the pavement constant.

4.5. The calculated thermal stress is then compared to the failure stress from the direct tension test to determine the critical cracking temperature of the pavement.

5. SIGNIFICANCE AND USE

5.1. Estimated cracking temperature, as determined by this standard practice, is a criterion for specifying the low-temperature properties of asphalt binder in accordance with M 320.

5.2. This standard practice is designed to identify the temperature region where the induced thermal stress in a typical hot mix asphalt subjected to rapid cooling (1°C/h) exceeds the fracture stress of the HMA.

5.3. For evaluating an asphalt binder for conformance to M 320, the test temperature for the bending beam rheometer (BBR) and direct tension test (DTT) data is selected from Table 2 of M 320 according to the grade of asphalt binder.

Note 2—Other cooling rates and test temperatures may be used to test asphalt binders for experimental purposes.

6. METHODOLOGY AND REQUIRED DATA

6.1. This standard practice uses data from both bending beam rheometer and direct tension measurements on an asphalt binder.

6.1.1. The DTT data required is the stress at failure obtained by testing at a strain rate of 3 percent per minute. For continuous grade and PG determination, DTT results are required at a minimum of two test temperatures. The DT tests shall be conducted at the test temperatures from M 320 at 6°C increments corresponding to the low-temperature binder grade. For prequalification and verification, DTT results are required at a single temperature that is equal to the low-temperature grade plus 10°C.

6.1.2. Two BBR data sets at two different temperatures are required with deflection measurements at 8, 15, 30, 60, 120, and 240 seconds. The BBR test temperatures, T and $T - 6$°C, are selected such that $S(T,60) \leq 300$ MPa and $S(T - 6,60) > 300$ MPa. T shall be the appropriate test temperatures from M 320 at 6°C increments corresponding to the low-temperature binder grade.

Note 3—It is helpful to begin testing at a temperature that is 6°C lower than the critical low cracking temperature for a given grade in Table 2 of M 320. Depending upon the result, perform the next test either at the critical low cracking temperature for a given grade in Table 2 of M 320 or 12°C lower than that temperature. Additional tests may be necessary to bracket 300 MPa.

Using a PG xx-22 as an example, test the first set of BBR beams at a test temperature of –18°C. If *S*(–18°C,60) > 300 MPa, test the next set of BBR beams at a test temperature of –12°C. If *S*(–8°C,60) ≤ 300 MPa, test the next set of BBR beams at a test temperature of –24°C.

7. CALCULATIONS

7.1. *Calculation of the Stiffness Master Curve*:

7.1.1. Calculate the BBR compliance data in accordance with T 313 to obtain the following data:

$D(T,t)$ = compliance at temperature, T, and time, t.

$D(T,8)$, $D(T,15)$, $D(T,30)$, $D(T,60)$, $D(T,120)$,
$D(T,240)$, $D(T-6,8)$, $D(T-6,15)$, $D(T-6,30)$, $D(T-6,60)$,
$D(T-6,120)$, $D(T-6,240)$

7.1.2. Calculate the BBR stiffness data in accordance with T 313 as:

$S(T,t) = 1/D(T,t)$

7.1.3. Determine a_{T-6}, the shift factor for the data at temperature T – 6°C, numerically using the Gordon and Shaw method (Gordon and Shaw, 1994) to produce a master curve. The reference temperature shall be the higher of the two test temperatures. The linear coefficient of thermal expansion, above and below the glass transition temperature, shall be 0.00017 m/m/°C. The glass transition temperature is taken as –20°C.

Note 4—This procedure is described in Gordon and Shaw, *Computer Programs for Rheologists*, Hanser Gardner (1994). The SHIFTT routine, which can be found in Chapter 5 of *Computer Programs for Rheologists*, is to be used. The value of –20°C is used for glass transition but has no effect on the calculation since the linear expansion coefficient is assumed to be the same either side of this temperature. Experimental data have indicated that some binders may have a variation in their glass transition temperature and α value. For research purposes, these values may be determined and the measured values used in the calculations.

7.1.4. From a_{T-6}, calculate the Arrhenius parameter as:

$$\ln\left(a_{T-6}\right) = a_1\left(\frac{1}{T_{\mathrm{ref}}-6} - \frac{1}{T_{\mathrm{ref}}}\right) \qquad (1)$$

where:

$$a_1 = \frac{\ln(a_{T-6})}{\left[\frac{1}{T_{\mathrm{ref}}-6} - \frac{1}{T_{\mathrm{ref}}}\right]} \qquad (2)$$

Note 5—The Gordon/Shaw method uses a shift factor (a_T) in the form of a base 10 log (log10). However, this specification is based on the natural log (ln or loge).

7.1.5. Reduced time, ξ, for data at temperature, T, is determined by integrating the reciprocal of the shift factor with respect to time as:

$$\xi(t) = \int_0^t \frac{dt'}{a_T} \qquad (3)$$

When T is constant with time, this reduces to the equation, as follows:

$$\xi(t) = \frac{t}{a_T} \tag{4}$$

7.1.6. All 12 values for $S(T,t)$ obtained, as described in Section 7.1.1, are converted to $S(T_{\text{ref}},\xi)$ with time being replaced by reduced time.

7.1.7. The values are fitted to the Christensen-Anderson-Marasteanu (CAM) model for asphalt master curves solving three parameters (λ, κ, and β):

$$S(T_{\text{ref}},\xi) = S_{\text{glassy}}[1+(\xi/\lambda)^{\beta}]^{-\kappa/\beta} \tag{5}$$

where:

S_{glassy} is the assumed glassy modulus of the binder: $S_{\text{glassy}} = 3 \times 10^9$ Pa.

7.1.8. Fit the resulting stiffness master curve data to this equation using a non-linear least squares fitting method to achieve a root mean square error, rms(percent), of less than or equal to 1.25 percent. Appendix X1 contains an example calculation of this error criterion. Appendix X2 contains a routine for curve fitting which may be used.

7.2. *Convert Stiffness Master Curve to Relaxation Modulus Master Curve*:

7.2.1. Use the Hopkins and Hamming method to convert creep compliance obtained from the master curve values $D(T_{\text{ref}}, \xi) = 1/S(T_{\text{ref}}, \xi)$ to relaxation modulus $E(T_{\text{ref}}, \xi)$.

Note 6—This procedure is described in Hopkins L. L., and Hamming R. W., “On Creep and Relaxation,” *Journal of Applied Physics*, Vol. 28, No. 8, August 1957, pp. 906-909.

7.2.2. The glassy modulus value of 3×10^9 Pa shall be adopted in the analysis for $S(T_{\text{ref}}, 1 \times 10^8 \text{ s}) = E(T_{\text{ref}}, 1 \times 10^8 \text{ s})$. Calculate relaxation modulus data points using the following iterative formula from $t = 1 \times 10^8$ to $t = 1 \times 10^7$ seconds with intervals of 4 points per decade—1.000, 1.778, 3.162, and 5.623 ($10^{0.0}$, $10^{0.25}$, $10^{0.5}$, $10^{0.75}$ seconds).

$$E(t_{n+\frac{1}{2}}) = \frac{t_{n+1} - \sum_{i=0}^{n-1} E(t_{i+\frac{1}{2}})\left[f(t_{n+1}-t_i) - f(t_{n+1}-t_{i+1})\right]}{f(t_{n+1}-t_n)} \tag{6}$$

where:

$$f(t_{n+1}) = f(t_n) + \frac{1}{2}\left[D(t_{n+1}) + D(t_n)\right]\left[t_{n+1} - t_n\right] \tag{7}$$

Use the same time intervals as above and use $f(t_0) = 0$. A cubic spline has been found to be suitable for interpolation.

7.2.3. Fit the relaxation modulus values to the CAM as described in Sections 7.1.7 and 7.1.8.

7.3. *Calculation of Thermal Stress*:

Note 7—The calculation of thermal stress is performed using three procedures: stress generation, stress relaxation, and stress summation. Stress calculations are based on Boltzmann's superposition principle for linear visco-elastic materials.

7.3.1. *Stress Generation*:

7.3.1.1. Use the following 7 constants:

- Start temperature, 0°C;
- End temperature, –45°C;
- Temperature increment, $\Delta T^N = 0.2°C$;
- Coefficient of linear thermal expansion, $\alpha = 1.7 \times 10^{-4}$ m/m/°C;
- Time per increment, $\Delta t = 720$ s;
- Strain per increment, $\in\ = \Delta T_i \alpha = 3.4 \times 10^{-5}$ m/m; and
- Strain rate = 4.72×10^{-8} m/m/s.

7.3.1.2. For the *N*th increment, the initial temperature shall be $T^N = -0.2(N - 1)$.

7.3.1.3. Divide each increment *N* into sub-steps.

7.3.1.3.1. Use *n* sub-steps where $n = 20 - 0.048(N - 1)$ truncated to an integer. "*n*" varies from 20 sub-steps at 0°C to 9 sub-steps at –45°C.

7.3.1.3.2. Divide the increment logarithmically so that each sub-step is approximately twice the size of the previous one. This defines $n + 1$ points in the increment.

Note 8—For example, with nine sub-steps, the 10 points are t_0, $t_0 + \Delta t/255$, $t_0 + 2\Delta t/255$, $t_0 + 4\Delta t/255$, $t_0 + 8\Delta t/255$, $t_0 + 16\Delta t/255$, $t_0 + 32\Delta t/255$, $t_0 + 64\Delta t/255$, $t_0 + 128\Delta t/255$ and $t_0 + \Delta t$.

7.3.1.3.3. Define the midpoint of each sub-step as the arithmetic midpoint. This defines additional *n* points.

7.3.1.3.4. The endpoints and midpoints of the sub-steps now define $2n + 1$ points in the increment. Define T_i^N and t_i^N for $i = 0$ to $2n$ as the temperature and time, respectively, at each of these points in order.

7.3.1.4. For each increment, calculate the shift factor, a_{Ti}, as follows:

7.3.1.4.1. Calculate the second-order gauss-points as follows:

$$t_{p1} = \Delta t \left(1 - 1/\sqrt{3}\right)/2 \quad (8)$$

$$t_{p2} = \Delta t \left(1 + 1/\sqrt{3}\right)/2 \quad (9)$$

7.3.1.4.2. Denote the temperatures at these points as T_{p1} and T_{p2} where:

$$T_{p1} = T^N + \Delta T\left(1 - 1/\sqrt{3}\right)/2 \qquad (10)$$

$$T_{p2} = T^N + \Delta T\left(1 + 1/\sqrt{3}\right)/2 \qquad (11)$$

7.3.1.4.3. The shift factors at these points are then:

$$a_{Tp1} = e^{\left(a_1\left(\frac{1}{T_{p1}} - \frac{1}{T_{\mathrm{ref}}}\right)\right)} \qquad (12)$$

$$a_{Tp2} = e^{\left(a_1\left(\frac{1}{T_{p2}} - \frac{1}{T_{\mathrm{ref}}}\right)\right)} \qquad (13)$$

7.3.1.4.4. The shift factor for the increment is then approximated by:

$$a_T = b_0 + b_1 t \qquad (14)$$

where:

$$b_1 = \left(a_{Tp2} - a_{Tp1}\right)/\left(t_{p2} - t_{p1}\right) \qquad (15)$$

and

$$b_0 = a_{Tp1} - t_{p1} b_1 \qquad (16)$$

7.3.1.5. The reduced time at time t from the start of the increment is then given by:

$$\xi(t) = \left(\frac{1}{b_1^N}\right)\ln\left(\frac{b_0^N + b_1^N t}{b_0^N}\right) \qquad (17)$$

7.3.1.6. Calculate the average modulus for the increment.

7.3.1.6.1. Calculate t_i^N for $i = 0$ to $2n$ as $t_0^N = 0$; $t_{2i}^N = 2^{(i/N-1)}\Delta t$ and $t_{2i-1}^N = (t_{2i} + t_{2i-2})/2$ for $i = 1$ to n.

7.3.1.6.2. The reduced time at each point is then:

$$\xi\left(t_i^N\right) = \left(\frac{1}{b_1^N}\right)\ln\left(\frac{b_0^N + b_1^N t_i^N}{b_0^N}\right) \qquad (18)$$

7.3.1.6.3. The relaxation modulus at each point is then given by the CAM fitted master curve:

$$E\left(\xi_i^N\right) = E_{\mathrm{glassy}}\left[1 + \left(\xi_i^N/\lambda\right)^{\beta}\right]^{-\kappa/\beta} \qquad (19)$$

7.3.1.6.4. Finally, the average relaxation modulus for the increment is given by the numerical quadrature as follows:

$$\bar{E} = \left(\sum_{i=1}^{n}\left[\left(E_{2i-2} + 4E_{2i-1} + E_{2i}\right)\left(t_{2i} - t_{2i-2}\right)\right]\right)/\left(6\Delta t\right) \qquad (20)$$

7.3.1.7. The generated stress at increment N, σ_{str}^N, is determined as follows:

$$\sigma_{str}^N = \overline{E}^N \times \in = \overline{E}^N \times \Delta T \times \alpha \qquad (21)$$

7.3.1.8. This cycle is repeated for all increments.

7.3.2. *Stress Relaxation*:

7.3.2.1. The stress relaxation of the stress generated in each individual strain increment *N* is modeled.

7.3.2.2. The stress relaxation is approximated by evaluating the equation, as follows:

$$\sigma\left(t\right) = \in E\left[\xi(t) - \tau\right] \quad (22)$$

7.3.2.3. The first operation in the stress relaxation calculation is to obtain the correction term τ in Equation 22.

7.3.2.4. This correction term τ is the difference between $\xi(\Delta t)$, the reduced time at the cessation of increment strain, and ξ_m, the reduced time at which the increment strain multiplied by relaxation modulus, equals the stress generated in the initial time step of the strain increment *N*. This is shown by the following equation:

$$\tau = \xi(\Delta t) - \xi_m \quad (23)$$

7.3.2.5. The value of τ is calculated immediately after the numerical quadrature defined by Equation 20 has been carried out, by storing temporarily the *E* and ξ values needed to estimate the integral. Interpolating in these values for the reduced time ξ_m at which $E\left[\xi_m\right]$ equals the value of the integral yields the amount of reduced time to be carried forward to the relaxation time steps, and accounts for the term τ.

7.3.2.6. The increase in reduced time during each relaxation time step is found using the same linearization of a_T versus *t* as described previously for the stress-generating time step of the strain increment.

Note 9—In order to use Equation 17, the linearization is calculated afresh for each time step, as specified by Equations 8 through 16.

7.3.2.7. The increase of reduced time during a time step is calculated with Equation 17 and added to the reduced time brought forward from the previous time step. The resulting reduced time is substituted in the CAM equation and the modulus obtained is multiplied by the increment strain to obtain the relaxed stress at the end of the time step.

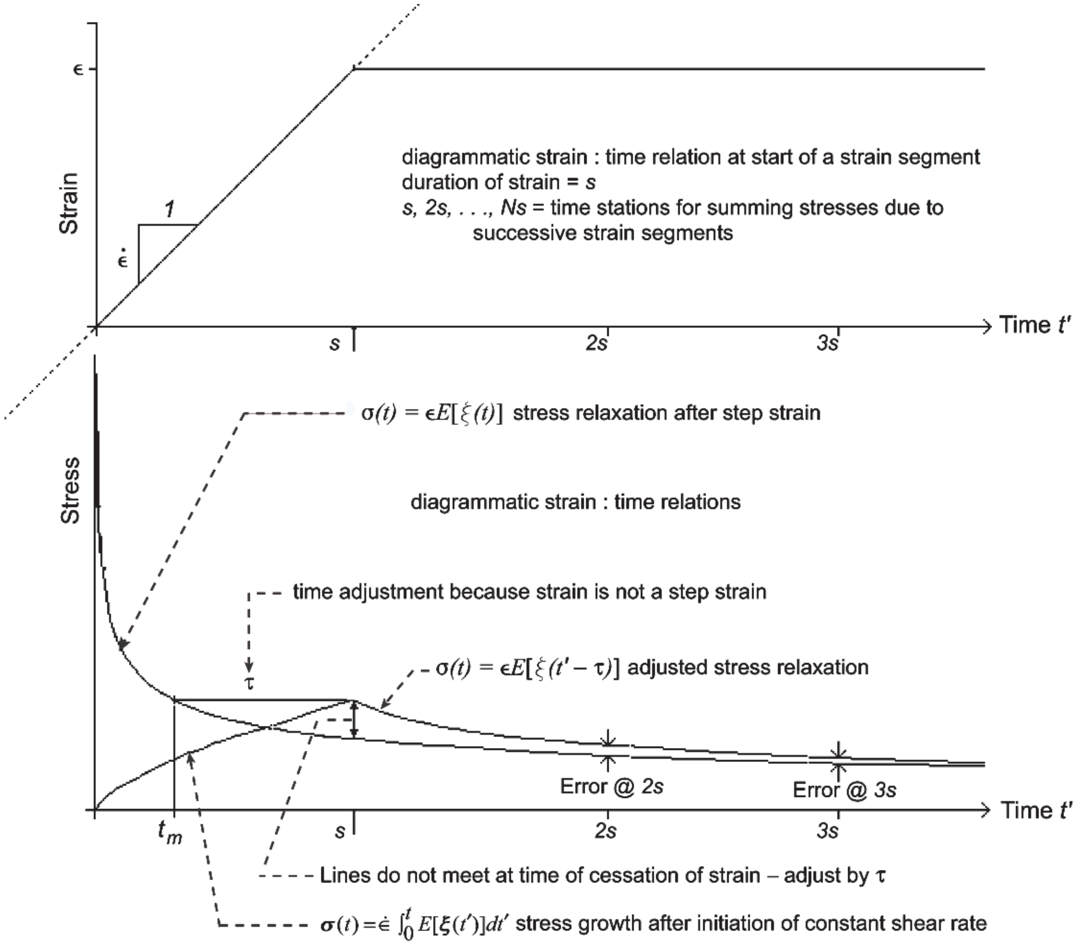

Figure 1—Strain versus Time and Stress versus Time Diagrams

7.3.3. *Stress Summation*:

7.3.3.1. The generated stress for interval *N* is summed with the stress relaxation from all the preceding intervals.

$$\sigma^N = \sigma_{str}^N + \sum_{i=1}^{N-1} \sigma_{rel}^{i,N} \qquad (24)$$

7.3.3.2. These calculations yield the calculated binder thermal stress at temperatures from 0 to –45°C, at 0.2°C increments.

7.3.3.3. The stress resulting from the calculation is multiplied by the pavement constant of 18 to yield the thermally induced stress in the pavement to which all comparisons shall be made in subsequent sections of this procedure. The generated stress in the pavement for interval *N* is summed with the stress relaxation from all the preceding intervals as described in Section 7.3.3.1.

$$(\sigma^n)_{\text{pavement}} = \left(\sigma_{str}^n + \sum_{i=1}^{n-1} \sigma_{rel}^{i,n}\right) \times C \qquad (25)$$

8. PERFORMANCE GRADE LOW-TEMPERATURE GRADE DETERMINATION OF AN ASPHALT BINDER

8.1. Grading of an asphalt binder requires bending beam rheometer data at two test temperatures and direct tension test data at a minimum of two test temperatures.

Note 10—The temperatures to be selected for the DTT may not be consistent with the BBR test temperatures as defined in Section 6.1.2, and additional tests may be required. The example given in Appendix X2 required that one of the DTT temperatures be lower than that used for the BBR tests.

8.2. Using a linear relationship between the DTT results, determine the intercept with the thermally induced stress curve using linear interpolation. The intercept, rounded to the nearest 0.1 degree, shall be reported as the estimated critical cracking temperature, T_{cr}.

8.3. In the case of no intercept being determined, additional direct tension tests shall be performed until an intercept is determined as described in Section 8.2.

Note 11—It may be necessary to conduct direct tension tests at additional test temperatures.

8.4. The grades that the low-temperature grade meets are evaluated by comparing the T_{cr} value to the 6°C temperature grade intervals given in M 320. The grades met are those which have a higher temperature than T_{cr}.

Note 12—For example, if a binder has a T_{cr} value of –24.5°C, it meets the specification at –22, –16, and –10.

9. VERIFICATION OF A PERFORMANCE GRADE OF AN ASPHALT BINDER

9.1. This section describes the testing and analysis required for verification of an already known Performance Grade of an asphalt binder at a specified low-temperature grade, T_{spec}.

9.2. Verification of an asphalt binder grade requires bending beam rheometer data at two test temperatures and direct tension test data at one test temperature.

9.3. To pass verification, the failure stress shall be equal to or greater than the thermal stress at the specification temperature of the binder. The thermal stress at the specification temperature shall be determined as follows.

9.3.1. Execute the procedure given in Section 7 using BBR data at both test temperatures.

9.3.2. Determine the failure stress using the DTT at a test temperature that is 10°C higher than the specification temperature, $T_{\mathrm{spec+10°C}}$.

9.3.3. Compare the failure stress from the DTT to the calculated thermally induced stress at the specification temperature, T_{spec}. If the failure stress exceeds the thermally induced stress, the asphalt binder shall be deemed a “Pass” at the specification temperature. If the failure stress does not exceed the thermally induced stress, the asphalt binder shall be deemed a “Fail” at the specification temperature.

10. REPORT

10.1. *Report the following information*:

10.1.1. Sample identification;

10.1.2. Identifying information for the BBR and DTT data sets used;

10.1.3. Date and time of calculations;

10.1.4. rms(percent) error as defined in Appendix X1;

10.1.5. Low-temperature grade being verified;

10.1.6. Estimated thermal stress at this temperature;

10.1.7. DTT failure stress to the nearest 0.01 MPa;

10.1.8. Whether the comparison of these two values results in a "Pass" or a "Fail" (This reporting item only applies to low-temperature binder grade verification, not to determination.); and

10.1.9. If determined, the estimated critical cracking temperature to the nearest 0.1°C.

11. PRECISION AND BIAS

11.1. *Precision and Bias*—The precision or bias associated with this standard practice is being determined.

12. KEYWORDS

12.1. Asphalt binder; bending beam rheometer; critical cracking temperature; direct tension; failure; failure stress; fracture; thermal cracking; thermally induced stress.

APPENDIXES

(Nonmandatory Information)

X1. EXAMPLE OF RMS CALCULATION

X1.1. In this example, a binder is being evaluated for a PG xx-34 grade. Two BBR data sets are collected according to the prescribed method. The data stiffness data collected in MPa are as follows:

t, s	*T* = –24°C	*T* = –30°C
8	456	760
15	390	670
30	321	581
60	262	493
120	211	412
240	168	338

X1.2. At *t* = 60 seconds, the stiffness conforms to the 300 MPa criteria specified in Section 6.1.2. The data are shifted to obtain a master curve in accordance with Section 7. The results are as follows:

S(*t*) Master Curve Points Determined by Non-Linear Fit		
t, s	*S*(*t*), MPa	CAM fit *S*(*t*)
0.746762829	777.956079	780.1128634
1.400180304	685.8297012	686.7969332
2.800360608	594.7269499	590.3342984
5.600721215	504.6478249	501.4979943
11.20144243	421.7340849	420.9415568
22.40288486	345.9857299	349.0372177
8	456	458.9964638
15	390	389.5836724
30	321	321.3666772
60	262	261.8456021
120	211	210.7390985
240	168	167.5525635

X1.3. In the above example, the fit was obtained using computer software. The CAM fit parameters, for this example, are as follows:

CAM fit to S(ξ) master curve	
λ	35.04887058
β	0.176793727
κ	0.581197694

X1.4. The relative error for each reduced time ξ is determined by the following:

$$Error = \frac{\left(S(\xi) - S(\xi)_{fitted}\right)}{S(\xi)}$$

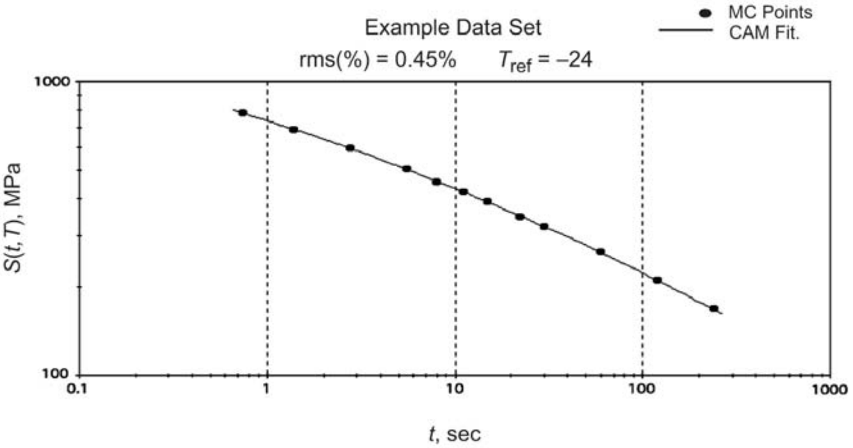
X1.5. The square of the relative error is determined. These values for this data set are given below.

Relative Error of S(ξ)	Square of Relative Error
–0.002772373	7.68605E-06
–0.001410309	1.98897E-06
0.007385997	5.4553E-05
0.006241641	3.89581E-05
0.001879213	3.53144E-06
–0.008819693	7.7787E-05
–0.006571192	4.31806E-05
0.001067507	1.13957E-06
–0.001142296	1.30484E-06
0.000589305	3.4728E-07
0.0012365	1.52893E-06
0.002663312	7.09323E-06

X1.6. The sum of the square of the relative error (SSRE) is computed and from this, the rms(percent) is determined as follows:

$$\mathrm{rms}(\%) = 100\sqrt{\frac{\mathrm{SSRE}}{12}}$$

X1.7. For the data in this example, the computed rms(percent) is 0.45 percent. This fit of the master curve is illustrated below.



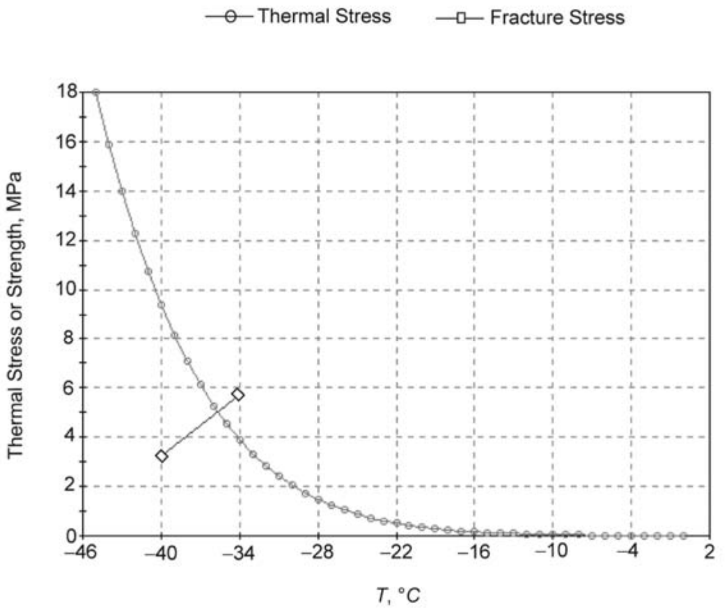
X1.8. The rms(percent) shall be less than or equal to 1.25 percent for the data set to be deemed acceptable.

X2. EXAMPLE OF RESULTS FOR THE EXAMPLE DATA NBS SET

X2.1. In addition to BBR data sets, the DTT testing was performed at two temperatures. These data are as follows:

Temperature, °C	DTT Failure Stress, Mpa
–24	5.713
–30	3.238

X2.2. The graph obtained from the stress calculation is plotted below with the DTT test points. Using linear interpolation, the intersection is determined to be –35.7°C.



Fracture Strength and Thermal Stress, MPa
Critical Temperature –35.7°C

X2.3. At –34°C (the grade for which this binder would be evaluated), report:

1. The sample ID;
2. The BBR and DTT data sets as given above;
3. The date and time of the calculations;
4. The rms(%) error as 0.45 percent;
5. The grade being verified as PG xx-34;
6. The estimated stress at –34°C as 3.88 MPa;
7. The DTT failure stress at –34°C as 5.71 MPa;
8. The result is a PASS;
9. The critical cracking temperature is –35.7°C.

X3. FORTRAN 77 SOURCE CODE USED FOR CAM FIT ROUTINE COMPILED USING COMPAQ VISUAL FORTRAN PROFESSIONAL

Note X1—This code is provided as a suggested procedure. It has not been thoroughly tested. However, preliminary use of this code has resulted in satisfactory and stable results.

[1] This standard is based on NCHRP Project Study 9-10. Approved for publication in 2001 as PP 42.

[2] The software TSAR™ obtainable from Abatech Inc. (http://www.abatech.com) has been found suitable for performing the calculations.

Standard Specification for

Corrugated Steel Pipe, Metallic-Coated, for Sewers and Drains

AASHTO Designation: M 36-03 (2007)[1]
ASTM Designation: A 760/A 760M-01a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Corrugated Steel Pipe, Metallic-Coated, for Sewers and Drains

AASHTO Designation: M 36-03 (2007)[1]
ASTM Designation: A 760/A 760M-01a

1. SCOPE

1.1. This specification covers corrugated steel pipe (CSP) intended for use for storm water drainage, underdrains, the construction of culverts, and similar uses. Pipe covered by this specification is not normally used for the conveyance of sanitary or industrial wastes. The steel sheet used in fabrication of the pipe has a protective metallic coating of zinc (galvanizing), aluminum Type 2, 55 percent aluminum-zinc alloy, zinc-5 percent aluminum-mischmetal alloy, or aluminum Type 1.

1.1.1. Steel sheet with zinc and aramid fiber composite coating may be specified for fabrication of pipe. Pipe made from sheet with this composite coating is always furnished with an asphalt coating. Therefore, the requirements in this specification should be considered as applying to a semi-finished pipe; the finished pipe must include provisions of M 190.

Note 1—Pipe fabricated with zinc and aramid fiber composite coated sheet and asphalt post-coating may be used for sanitary sewers and industrial applications. Petroleum products or similar materials in the sewer effluent may affect the performance of the asphalt coating.

1.2. The several different metallic coatings may not provide equal protection of the base metal against corrosion or abrasion, or both, in all environments. Some environments may be so severe that none of the metallic coatings included in this specification will provide adequate protection. Additional protection for CSP can be provided by use of coatings applied after fabrication of the pipe as described in M 190, or by use of polymer-precoated CSP as described in M 245.

1.3. This specification does not include requirements for bedding, backfill, or the relationship between earth cover load and sheet thickness of the pipe. Experience has shown that the successful performance of this product depends upon the proper selection of sheet thickness, type of bedding and backfill, controlled manufacture in the plant, and care in the installation. The installation procedure is described in *AASHTO LRFD Bridge Construction Specifications*, Section 26.

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *fabricator*—the producer of the pipe.

3.1.2. *manufacturer*—the producer of the sheet.

3.1.3. *minimized coating structure*—a coating characterized by a finer metallurgical coating structure obtained by a treatment designed to restrict the formation of the normal coarse-grain structure formed during solidification of the Zn-5 Al-MM alloy coating.

3.1.4. *purchaser*—the purchaser of the finished product.

3.1.5. *regular coating structure*—the normal coating structure resulting from unrestricted grain growth during normal solidification of the Zn-5 A1-MM alloy coating.

3.2. *Abbreviations*:

3.2.1. *55 Al-Zn*—55 percent aluminum-zinc,

3.2.2. *MM*—mischmetal,

3.2.3. *Zn-5 Al-MM*—zinc-5 percent aluminum-mischmetal,

3.2.4. *AlT2*—aluminum-coated Type 2, and

3.2.5. *AlT1*—aluminum-coated Type 1.

4. PIPE CLASSIFICATION

4.1. The CSP covered by this specification is classified as follows:

4.1.1. *Type I*—This pipe shall have a full circular cross section, with a single thickness of corrugated sheet, fabricated with annular (circumferential) or helical corrugations.

4.1.2. *Type IA*—This pipe shall have a full circular cross section, with an outer shell of corrugated sheet and an inner liner of smooth (uncorrugated) sheet, fabricated with helical corrugations and lock seams.

4.1.3. *Type IR*—This pipe shall have a full circular cross section with a single thickness of smooth sheet, fabricated with helical ribs projecting outwardly.

4.1.4. *Type II*—This pipe shall be a Type I pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.5. *Type IIA*—This pipe shall be a Type IA pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.6. *Type IIR*—This pipe shall be a Type IR pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.7. *Type III*—This pipe, intended for use as underdrains or for underground disposal of water, shall be a Type I pipe that has been perforated to permit the inflow or outflow of water.

4.1.8. *Type IIIA*—This pipe, intended for use as underdrains, shall consist of a semicircular cross section having a smooth (uncorrugated) bottom with a corrugated top shield.

4.2. Perforations in Type III pipe are included in three classes as described in Section 8.3.2.

4.3. Zn-5 Al-MM alloy-coated material is available in two coating classes, or structures, as follow:

4.3.1. *Class A*—Minimized coating structure.

4.3.2. *Class B*—Regular coating structure.

5. ORDERING INFORMATION

5.1. Orders for material to this specification shall include the following information, as necessary, to adequately describe the desired product:

5.1.1. Name of material (corrugated steel pipe);

5.1.2. Type of metallic coating (zinc, aluminum-coated Type 2, aluminum-coated Type 1, 55 Al-Zn alloy, Zn-5 Al-MM alloy, or zinc and aramid fiber composite coating) (Section 6.1);

5.1.2.1. For Zn-5 Al-MM alloy, class of coating structure (Class A, minimized, etc.) (Section 4.3);

5.1.3. AASHTO designation and date of issue (M 36-____);

5.1.4. Type of pipe (Section 4.1);

5.1.5. Diameter of circular pipe (Table 6), or span and rise of pipe-arch section (Tables 8, 9, 10, or 11);

5.1.6. Length, either total length or length of each piece and number of pieces;

5.1.7. Description of corrugations (Section 7.2);

5.1.8. Sheet thickness (Section 8.1.2);

5.1.9. For Type I and Type II pipe, the pipe fabrication method, whether with annular corrugations or helical corrugations (Section 7.1.1) (Note 2);

Note 2—Pipe with annular corrugations with spot welded or riveted seams is designed by different criteria than pipe with helical corrugations. Pipe with annular corrugations must consider seam strength. Therefore, consideration of the method of fabrication is important when pipe is installed under certain conditions of loading.

5.1.10. When zinc and aramid fiber composite coated sheet is used for fabrication of pipe, the type of asphalt coating (Sections 1.1.1 and 8.5);

Note 3—See M 190 for additional information appropriate to bituminous post-coatings on pipe.

5.1.11. Joining systems, including the type of joint from Section 9.1 and gasket, if required (If no joining system is specified, the fabricator shall select the system.);

5.1.12. For Type III pipe, class of perforations, if other than Class 1 (Section 8.3.2);

5.1.13. Certification, if required (Section 14.1); and

5.1.14. Special requirements.

6. MATERIALS

6.1. *Steel Sheet for Pipe*—All pipe fabricated under this specification shall be formed from zinc-coated sheet conforming to M 218, or aluminum-coated Type 2 sheet conforming to M 274M, 55 percent aluminum-zinc alloy-coated sheet conforming to M 289, or zinc-5 percent aluminum-mischmetal alloy-coated sheet conforming to ASTM A 929/A 929M, or aluminum-coated Type 1 conforming to ASTM A 929/A 929M. If the type of metallic coating is not stated in the order, zinc-coated sheet conforming to M 218 shall be used. All pipe furnished on the order shall have the same metallic coating, unless otherwise specified.

6.2. *Steel Sheet for Coupling Bands*—The sheet used in fabricating coupling bands shall have the same coating and shall conform to the same specification listed in Section 6.1 as that used for fabrication of the pipe furnished under the order.

6.3. *Rivets*—The rivets used in riveted pipe shall be of the same material as the base metal specified for the corrugated sheets. They shall be thoroughly galvanized or sherardized. If bolts and nuts are substituted for rivets (Section 7.3.1), they shall meet the following requirements:

Bolts	Nuts
F 568	M 291M
Class 8.8	Class 12

6.4. The bolts and nuts shall be hot-dip galvanized in conformance with M 232M/M 232 mechanically galvanized in conformance with M 298, Class 40.

6.5. *Hardware for Joining Systems*—Bolts and nuts for coupling bands shall conform to the following requirements:

Bolts	Nuts
F 568	M 291M
Class 4.6	Class 5

6.6. Bolts, nuts, and other threaded items used with joining systems shall be zinc coated by one of the following processes: hot-dip process as provided in M 232M/M 232; electroplating process as provided in ASTM B 633, Class Fe/Zn 8; or mechanical process as provided in M 298, Class 8. Other hardware items used with coupling bands shall be zinc coated by one of the following processes: hot-dip process as provided in M 232M/M 232; electroplating process as provided in ASTM B 633, Class Fe/Zn 25; or mechanical process as provided in M 298, Class 25.

6.7. *Gaskets*—If gaskets are used in joining systems, they shall be a band of expanded rubber meeting the requirements of ASTM D 1056 for the “RE’’ closed cell grades, or O-rings meeting the requirements of M 315M.

7. FABRICATION

7.1. *General Requirements*—Pipe shall be fabricated in full circular cross section except for Type IIIA, which is described in Section 8.4.

7.1.1. Type I pipe shall have annular corrugations with lap joints fastened with rivets or resistance spot welds, or shall have helical corrugations with a continuous lock seam or welded seam extending from end to end of each length of pipe. The type of fabrication used shall be the option of the fabricator unless otherwise specified, except that the pipe fabricated from zinc and aramid fiber composite coated sheet shall be fabricated by riveted or lock seam fabrication only.

7.1.2. Type IA pipe shall be fabricated with a smooth liner and helically corrugated shell integrally attached at helical lock seams extending from end to end of each length of pipe. The shell shall have corrugations of nominal 68- or 75-mm pitch. Zinc and aramid fiber composite coated sheet shall not be used for fabrication of Type IA pipe.

7.1.3. Type IR pipe shall be fabricated with helical ribs projecting outward with a continuous lock seam extending from end to end of each length of pipe.

7.2. *Corrugations*—The corrugations shall be either annular or helical as provided in Section 7.1. The direction of the crests and valleys of helical corrugations shall not be less than 60 degrees from the axis of the pipe for pipe diameters larger than 525 mm, and not less than 45 degrees from the axis for pipe diameters of 525 mm and smaller.

7.2.1. For Type I and IA pipe, corrugations shall form smooth continuous curves and tangents. The dimensions of the corrugations shall be in accordance with Table 1 for the size indicated in the order, except if the depth measurement of one or more corrugations is less than the minimum depth in Table 1, the depth of all corrugations between adjacent seams shall be measured and the values of Table 2 for minimum average depth and minimum corrugation depth shall apply.

Table 1—Corrugation Requirements for Type I, IA, II, IIA, and III Pipe

			Inside Radius[c]	
Nominal Size, mm	Maximum Pitch,[a] mm	Minimum Depth,[b] mm	Nominal, mm	Minimum, mm
38 by 6.5[d]	48	6.0	7	6.5
68 by 13	73	12	17	12
75 by 25	83	24	14	12
125 by 25	135	24	40	36

[a] Pitch is measured from crest to crest of corrugation, at 90 degrees to the direction of corrugation.

[b] Depth is measured as the vertical distance from a straightedge resting on the corrugation crests parallel to the axis of the pipe to the bottom of the intervening valley. If the depth measurement of one or more corrugations is less than the value indicated herein, the depth of all corrugations between seams shall be measured, and the requirements of Table 2 shall be applied. (See Section 7.2.1.)

[c] Minimum inside radius requirement does not apply to a corrugation containing a helical lock seam.

[d] The corrugation size of 38 by 6.5 mm is available only in helically corrugated pipe.

Table 2—Referee Requirements for Corrugation Depth[a]

Nominal Size, mm	Diameter, mm	Minimum Average Depth, mm	Minimum Corrugation Depth, mm
38 by 6.5	All	6.1	5
68 by 13	300 through 525	12.1	10
68 by 13	Greater than 525	12.4	11
75 by 25	All	24.9	23
125 by 25	All	24.9	23

[a] See Section 7.2.1 for application of Table 2.

Note 4—Inspection frequently consists of measurement of the depth of one or a few corrugations. If such measurement indicates insufficient depth, application of the requirements in Table 2 provides for acceptance in cases in which greater depth of some corrugations compensates for lack of depth of others. These measurements would normally be made at one location between seams on a length of pipe.

7.2.2. For Type IR pipe, the corrugations shall be essentially rectangular ribs projecting outward from the pipe wall. The dimensions and spacing of the ribs shall be in accordance with Table 3 for the size indicated on the order. For the 292-mm rib spacing, if the sheet between the ribs does not include a lock seam, a stiffener shall be included midway between the ribs. This stiffener shall have a nominal radius of 6.4 mm and a minimum height of 5.1 mm toward the outside of the pipe.

Table 3—Rib Requirements for Types IR and IIR Pipe

Nominal Size, mm	Rib Width,[a] Min, mm	 Depth,[b] Min, mm	 Spacing,[c] Min, mm	Bottom Outside Radius, Min, mm	Bottom Outside Radius,[d] Max Avg, mm	Top Outside Radius, Min, mm	Top Outside Radius,[d] Max Avg, mm
19 by 19 by 190	17	19	197	2.5	6.0	2.5 + *t*	6.0 + *t*
19 by 25 by 216	17	24	222	2.5	6.0	2.5 + *t*	6.0 + *t*
19 by 25 by 292	17	24	298	2.5	6.0	2.5 + *t*	6.0 + *t*

[a] Width is a dimension of the inside of the rib, but is measured on the outside of the pipe (outside of the rib) and shall meet or exceed the stated minimum width plus two times the wall thicknesses, that is, 2*t* + 17 mm.

[b] Depth is an average of three ribs within one sheet width.

[c] Spacing is an average of three adjacent rib spacings for 19 by 19 by 190 pipe and two adjacent rib spacings for 19 by 25 by 292 pipe measured center-to-center of the ribs, at 90 degrees to the direction of the ribs.

[d] The average of the two top rib radii and of the two bottom rib radii shall be within the minimum and maximum tolerances. The term "outside" refers to the outside surface of the pipe.

Note 5—The nominal dimensions and properties for smooth corrugations and for ribs are given in *AASHTO LRFD Bridge Design Specifications*, Section 12, and in ASTM A 796.

7.3. *Riveted Seams*—The longitudinal seams shall be staggered to the extent that no more than three thicknesses of sheet are fastened by any rivet. Pipe to be reformed into pipe-arch shape shall have seams meeting the longitudinal seam requirement of Section 8.2.2. (See also Note 6.)

Note 6—Fabrication of pipe without longitudinal seams in 120 degrees of arc, so that the pipe may be installed without longitudinal seams in the invert, is subject to negotiation between the purchaser and fabricator.

7.3.1. The size of rivets, number per corrugation, and width of lap at the longitudinal seam shall be as stated in Table 4, depending on sheet thickness, corrugation size, and diameter of pipe. For pipe with 25-mm deep corrugations, M12-diameter bolts and nuts may be used in lieu of rivets on a one-for-one replacement ratio. Circumferential seams shall be riveted using rivets of the same size as for longitudinal seams and shall have a maximum rivet spacing of 150 mm, measured on centers, except that six rivets will be sufficient in 300-mm diameter pipe.

Table 4—Riveted and Spot Welded Longitudinal Seams

Specified Sheet Thickness, mm	68 by 13 mm[a,b]	75 by 25 mm[c,d]	125 by 25 mm[d,e]
	Rivet or Spot Weld Diameters, Min, mm		
1.32	8.0	—	—
1.63	8.0	9.5	9.5
2.01	8.0	9.5	9.5
2.77	9.5	11.0	11.0
3.51	9.5	11.0	11.0
4.27	9.5	11.0	11.0

[a] One rivet or spot weld each valley for pipe diameters 900 mm and smaller. Two rivets or spot welds each valley for pipe diameters 1050 mm and larger.

[b] Minimum width of lap: 38 mm for pipe diameters 900 mm and smaller, and 75 mm for pipe diameters 1050 mm and larger.

[c] Two rivets or spot welds each valley for all pipe diameters.

[d] Minimum width of lap: 75 mm for pipe of all diameters.

[e] Two rivets or spot welds each crest and valley for all pipe diameters.

7.3.2. All rivets shall be driven cold in such a manner that the sheets shall be drawn tightly together throughout the entire lap. The center of a rivet shall be no closer than twice its diameter from the edge of the sheet. All rivets shall have neat, workmanlike, and full hemispherical heads or heads of a form acceptable to the purchaser, shall be driven without bending, and shall completely fill the hole.

7.4. *Resistance Spot Welded Seams*—The longitudinal seams shall be staggered to the extent that no more than three thicknesses of sheet are fastened by any spot weld. Pipe to be reformed into pipe-arch shape shall also meet the longitudinal seam requirement of Section 8.2.2 (Note 6).

7.4.1. The size of spot welds, number per corrugation, and width of lap at the longitudinal seam shall be as stated in Table 4, depending on sheet thickness, corrugation size, and diameter of pipe. Circumferential seams shall be welded using spot welds of the same size as for longitudinal seams and shall have a maximum weld spacing of 150 mm, except that six welds will be sufficient in 300-mm diameter pipe.

7.4.2. All spot welds shall be made in such a manner that the sheets will be drawn tightly together throughout the lap. The outside edge of each spot weld shall be at least 6.5 mm from the edge of the sheet. The welding shall be performed in such a manner that the exterior surfaces of 90 percent or more of the spot welds on a length of pipe shall show no evidence of melting or burning of the base metal, and the base metal shall not be exposed when the area adjacent to the electrode contact surface area is wire brushed. Discoloration of the spot weld surfaces will not be cause for rejection.

7.4.3. Welding equipment shall be qualified before use, and the qualification shall be verified before each work shift and when changing sheet thickness, all as described in Appendix A1. If use of the equipment at the approved machine settings fails to produce satisfactory welds, fabrication shall be stopped until adjustments are made and the equipment is requalified.

7.5. *Helical Lock Seams*—The lock seam for Type I pipe shall be formed in the tangent element of the corrugation profile with its center near the neutral axis of the corrugation profile. The lock seam for Type IA pipe shall be in the valley of the corrugation, shall be spaced not more than 760 mm apart, and shall be formed from both the liner and the shell in the same general manner as Type I helical lock seam pipe. The lock seam for Type IR pipe shall be formed in the flat zone of the pipe wall, midway between two ribs.

7.5.1. The edges of the sheets within the cross section of the lock seam shall lap at least 4.0 mm for pipe 250 mm or less in diameter and at least 7.9 mm for pipe greater than 250 mm in diameter, with an occasional tolerance of –10 percent of lap width allowable. The lapped surfaces shall be in tight contact. The profile of the sheet shall include a retaining offset adjacent to the 180-degree fold (as described in T 249M) of one sheet thickness on one side of the lock seam, or one-half sheet thickness on both sides of the lock seam, at the fabricator's option. There shall be no visible cracks in the metal, loss of metal-to-metal contact, or excessive angularity on the interior of the 180-degree fold of metal at the completion of forming the lock seam.

7.5.2. Specimens cut from production pipe normal to and across the lock seam shall develop the tensile strength as provided in Table 5, when tested according to T 249. For Type IA pipe, the lock seam strength shall be as tabulated based on the thickness of the corrugated shell.

Table 5—Lock Seam Tensile Strength

Specified Sheet Thickness,[a] mm	Lock Seam Tensile Strength, per Unit Width, Min, kN/m
1.02	30
1.32	42
1.63	60
2.01	91
2.77	122
3.50	154
4.27	210

[a] For Type IA pipe, the thickness shall be that of the corrugated shell.

7.5.3. When the ends of helically corrugated lock seam pipe have been rerolled to form annular corrugations, either with or without a flanged end finish, the lock seam in the rerolled end shall not contain any visible cracks in the base metal and the tensile strength of the lock seam shall be not less than 60 percent of that required in Section 7.5.2.

7.6. *Helical Continuous Welded Seams*—The seam shall be parallel to the corrugations and shall have a continuous weld extending from end to end of each length of pipe. Welding shall be done utilizing ultra-high frequency resistance equipment. Seams shall be welded in such a manner that they will develop the full strength of the pipe and not affect shape or nominal diameter of the pipe. Welded seams shall be controlled such that the combined width of weld and adjacent coating burned by welding does not exceed three times the metal thickness. Damage outside this width shall be repaired as required in Section 11. The fabricator shall certify that the welds have been tested and found satisfactory.

7.6.1. Continuous welded seams shall be tested in accordance with the cup test procedure (Section 3) of T 241. The welded seam shall be acceptable if the sum of the length of cracks or other defects on either side of the cup does not exceed 6.5 mm, basing the result on the second test if the first shows greater defects. The provisions of the referee test method of Section 4 of T 241 shall be applicable in the event of disagreement between the purchaser and the fabricator.

7.6.1.1. Tests of continuous welded seams shall be made as follows:

7.6.1.2. Pipe lengths of 7.3 m or less shall be tested on one end of each length, normally the trailing end.

7.6.1.3. If a length of pipe having a diameter greater than 1200 mm and length of 7.3 m or less is rejected, the following length of pipe produced shall be tested on both ends. If the test on either end fails, this entire length shall also be rejected.

7.6.1.4. Pipe lengths greater than 7.3 m shall be tested on each end of each length of pipe. If either end fails, the entire length shall be rejected.

7.6.2. The requirement for conducting quality control tests in accordance with Section 7.6.1 shall not apply for pipe in which the ends have been rerolled to form annular corrugations. The manufacturer shall maintain visual evaluation of the quality of the weld after rerolling and any indication of weld or base metal failure will be cause for rejection of the pipe.

7.6.3. Any indication of cracks, skips, or deficient welds found through visual inspection will be cause for rejection unless repaired. It is the option of the fabricator to remove the defective portion of the length of pipe or to manually repair defects in the automatically welded seam. Altered or repaired pipe shall meet the applicable requirements of Section 7.6. Where a manual repair occurs within 400 mm of the end of the length of pipe, a test shall be conducted on both the manually repaired section and on the immediately adjacent automatically welded section. If either test results in failure under the criterion of Section 7.6.1, the length of pipe shall be rejected.

7.7. *End Finish*:

7.7.1. To facilitate field jointing, the ends of the individual pipe sections with helical corrugations or ribs may be rerolled to form annular corrugations extending at least two corrugations from the pipe end, or to form an upturned flange meeting the requirements in Section 7.7.2, or both. The diameter of ends shall not exceed that of the pipe barrel by more than the depth of the corrugation. All types of pipe ends, whether rerolled or not, shall be matched in a joint such that the maximum difference in the diameter of abutting pipe ends is 13 mm.

7.7.1.1. When pipe with any size helical corrugation or rib is rerolled to form annular corrugations in the ends, the usual size of the annular corrugation is 68 by 13 mm.

7.7.2. If a flanged finish is used on the ends of individual pipe sections to facilitate field jointing, the flange shall be uniform in width, not less than 13 mm wide, and square to the longitudinal axis of the pipe.

7.7.3. The ends of all pipe that will form the inlet and outlet of culverts, fabricated of sheets having nominal thicknesses of 2.01 mm and less, shall be reinforced in a manner approved by the purchaser, when specified.

8. PIPE REQUIREMENTS

8.1. *Type I, Type IA, and Type IR Pipe*:

8.1.1. *Pipe Dimensions*—The nominal diameter of the pipe shall be as stated in the order, selected from the size listed in Table 6. The sizes of corrugations that are standard for each size of pipe are also shown in Table 6. The average inside diameter of circular pipe and pipe to be reformed into pipe-arches shall not vary more than 1 percent or 13 mm, whichever is greater, from the nominal diameter when measured on the inside crest of the corrugations for Type I pipe, or the inside liner or surface for Type IA or Type IR pipe, respectively. Alternately, for pipe having annular corrugations, conformance with the inside diameter requirement may be determined by measuring the outside circumference, for which minimum values are given in Table 6.

Note 7—The outside circumference of helically corrugated pipe is influenced by the corrugation size and the angle of the corrugation, affecting the number of corrugations crossed; therefore, no minimum measurement can be specified.

8.1.2. *Sheet Thickness*—Sheet thickness shall be specified by the purchaser from the specified sheet thicknesses listed in Table 7 (Notes 8 and 9). For Type IA pipe, the thickness of both the shell and the liner shall be given; the thickness of the corrugated shell shall not be less than 60 percent of the thickness of the equivalent Type I pipe; the liner shall have a nominal thickness of at least 1.02 mm; and the sum of the specified thicknesses of shell and liner shall equal or exceed the specified thickness of an equivalent pipe of identical corrugations as the shell according to the design criteria in *AASHTO LFRD Bridge Design Specifications*.

Table 6—Pipe Sizes

Nominal Inside Diameter, mm	Corrugation Sizes[a]				Ribbed Pipe			Minimum Outside Circumference,[c] mm
	38 by 6.5 mm	68 by 13 mm	75 by 25 mm	125 by 25 mm	19 by 19 by 190 mm[b]	19 by 25 by 292 mm	19 by 25 by 216 mm	
100	X							264
150	X							441

2550			X	X	X	X	X	7941
2700			X	X	X	X	X	8408
2850			X	X	X		X	8874
3000			X	X	X		X	9341
3150			X	X			X	9807
3300			X	X			X	10274
3450			X	X			X	10740
3600			X	X			X	11207

[a] An “X” indicates standard corrugation sizes for each nominal diameter of pipe.

[b] Rib sizes 19 by 19 by 190 mm and 19 by 25 by 292 mm.

[c] Measured in valley of annular corrugations. Not applicable to helically corrugated pipe.

Table 7—Thicknesses of Metallic-Coated Steel Sheet[a]

	Specification Designation					
Specified Thickness, mm	M 218, Zinc Coated	M 274 AlT2, Aluminum Coated	M 289, 55 Percent Aluminum-Zinc Alloy Coated	A 885, Zinc and Aramid Fiber Coated	A 929M Zn-5 Al-MM, Alloy Coated	A 929M AlT1, Aluminum Coated
1.02	X		X		X	
1.32	X	X	X		X	X
1.63	X	X	X	X	X	X
2.01	X	X	X	X	X	X
2.77	X	X	X	X	X	X
3.51	X	X	X	X	X	X
4.27	X			X	X	

[a] An “X” indicates sheet thickness included in the applicable specification for coating types listed.

Note 8—The sheet thicknesses indicated in Table 7 are the thicknesses listed as available in M 218, M 274, M 289, ASTM A 885, and ASTM A 929M for zinc and aramid fiber composite coated sheet.

Note 9—The purchaser should determine the required thickness for each of the types of pipe described in Section 4.1.1 through Section 4.1.6 according to the design criteria in *AASHTO LRFD Bridge Design*, Section 12, or other appropriate guidelines.

8.1.3. When specified by the purchaser, the finished pipe shall be factory elongated to the extent specified. The elongation shall be accomplished by the use of a mechanical apparatus that will produce a uniform deformation throughout the length of the section.

8.2. *Type II, IIA, and IIR Pipe*:

8.2.1. *Pipe-Arch Dimensions*—Pipe furnished as Type II, IIA, or IIR shall be made from Type I, IA, or IR pipe respectively, and shall be reformed to provide a pipe-arch shape. All applicable requirements for Types I, IA, and IR pipe shall be met by finished Types II, IIA, and IIR pipe, respectively. Pipe-arches shall conform to the dimensional requirements of Tables 8, 9, 10, or 11. All dimensions shall be measured from the inside crests of corrugations for Type II pipe or from the inside liner or surface for Types IIA or IIR, respectively.

8.2.2. *Longitudinal Seams*—Longitudinal seams of riveted or spot welded pipe-arches shall not be placed in the corner radius.

8.2.3. Reforming Type IR into Type IIR pipe shall be done in a manner that avoids damage to the external ribs.

8.3. *Type III Pipe*:

8.3.1. Type III pipe shall have a full circular cross-section and shall conform to the requirements for Type I pipe and, in addition, shall contain perforations conforming to one of the classes described in Section 8.3.2.

Table 8—(M 36) Pipe-Arch Requirements 68 by 13 mm Corrugations

Pipe Arch Size, mm	Equivalent Dia, mm	Span,[a] mm	Rise,[a] mm	Minimum Corner Radius, mm	Maximum B,[b] mm

1800 by 1200	1500	1800	1200	180	420
1950 by 1320	1650	1950	1320	205	460
2100 by 1450	1800	2100	1450	230	510

[a] A tolerance of 25 mm or 2 percent of equivalent diameter, whichever is greater, will be permissible in span and rise.

[b] B is defined as the vertical dimension from a horizontal line across the widest portion of the arch to the lowest portion of the base.

Table 9—(M 36) Pipe-Arch Requirements 75 by 25 mm or 125 by 25 mm Corrugations

Pipe Arch Size, mm	Equivalent Dia, mm	Span,[a] mm	Rise,[a] mm	Minimum Corner Radius, mm
1010 by 790	900	1010 – 45	790 + 45	130
1160 by 920	1050	1160 – 55	920 + 55	155
1340 by 1050	1200	1340 – 60	1050 + 60	180
1520 by 1350	1350	1520 – 70	1170 + 70	205
1670 by 1300	1500	1670 – 75	1300 + 75	230
1850 by 1400	1650	1850 – 85	1400 + 85	305
2050 by 1500	1800	2050 – 95	1500 + 95	355
2200 by 1620	1950	2200 – 110	1620 + 110	355
2400 by 1720	2100	2400 – 120	1720 + 120	410
2600 by 1820	2250	2600 – 130	1820 + 130	410
2840 by 1920	2400	2840 – 145	1920 + 145	460
2970 by 2020	2550	2970 – 150	2020 + 150	480
3240 by 2120	2700	3240 – 165	2120 + 165	480
3470 by 2220	2850	3470 – 175	2220 + 175	480
3600 by 2320	3000	3600 – 180	2320 + 180	480

[a] Negative and positive numbers listed with span and rise dimensions are negative and positive tolerances; no tolerance in opposite direction.

Table 10—Pipe-Arch Requirements, 19 by 19 by 190 mm Rib Corrugations

Pipe Arch Size, mm	Equivalent Diameter, mm	Span,[a] mm	Rise,[a] mm	Minimum Corner Radius, mm
500 by 410	450	500 – 25	410 + 25	130
580 by 490	525	550 – 25	490 + 25	130
680 by 540	600	680 – 40	540 + 40	130
750 by 620	675	750 – 40	620 + 40	130
830 by 670	750	830 – 40	670 + 40	130
900 by 750	825	900 – 45	750 + 45	130
1010 by 790	900	1010 – 45	790 + 45	130
1160 by 920	1050	1160 – 55	920 + 55	155
1340 by 1050	1200	1340 – 60	1050 + 60	180
1520 by 1170	1350	1520 – 70	1170 + 70	205
1670 by 1300	1500	1670 – 75	1300 + 75	230
1850 by 1400	1650	1850 – 85	1400 + 85	305
2050 by 1500	1800	2050 – 95	1500 + 95	355
2200 by 1620	1950	2200 – 100	1620 + 100	355
2400 by 1720	2100	2400 – 105	1720 + 105	410
2600 by 1820	2250	2600 – 115	1820 + 115	410
2840 by 1920	2400	2840 – 120	1850 + 120	450
2920 by 1980	2550	2920 – 130	1980 + 130	450

[a] Negative and positive numbers listed with span and rise dimensions are negative and positive tolerances; no tolerance in opposite direction.

Table 11—Pipe Arch Requirements, 19 by 25 by 292 mm Rib Corrugation

Pipe Arch Size, mm	Equivalent Diameter, mm	Span,[a] mm	Rise,[a] mm	Minimum Corner Radius, mm
500 by 410	450	500 – 25	410 + 25	130
580 by 490	525	550 – 25	490 + 25	130
680 by 540	600	680 – 40	540 + 40	130
750 by 620	675	750 – 40	620 + 40	130
830 by 670	750	830 – 40	670 + 40	130
900 by 750	825	900 – 45	750 + 45	130
1010 by 790	900	1010 – 45	790 + 45	130
1160 by 920	1050	1160 – 55	920 + 55	155
1340 by 1050	1200	1340 – 60	1050 + 60	180
1520 by 1170	1350	1520 – 70	1170 + 70	205
1670 by 1300	1500	1670 – 75	1300 + 75	230
1850 by 1400	1650	1850 – 85	1400 + 85	305
2050 by 1500	1800	2050 – 95	1500 + 95	355

[a] Negative and positive numbers listed with span and rise dimensions are negative and positive tolerances; no tolerance in opposite direction.

8.3.2. *Perforations*—The perforations shall conform to the requirements for Class 1, unless otherwise specified in the order. Class 1 perforations are for pipe intended to be used for subsurface drainage. Class 2 and 3 perforations are for pipe intended to be used for subsurface disposal of water, but pipe containing Class 2 and 3 perforations may also be used for subsurface drainage.

8.3.2.1. *Class 1 Perforations*—The perforations shall be approximately circular and cleanly cut; shall have nominal diameters of not less than 4.8 mm nor greater than 9.5 mm; and shall be arranged in rows parallel to the axis of the pipe. The perforations shall be located on the inside crests or along the neutral axis of the corrugations, with one perforation in each row for each corrugation. Pipe connected by couplings or bands may be unperforated within 100 mm of each end of each length of pipe. The rows of perforations shall be arranged in two equal groups placed symmetrically on either side of a lower unperforated segment corresponding to the flow line of the pipe. The spacing of the rows shall be uniform. The distance between the centerlines of rows shall be not less than 25 mm. The minimum number of longitudinal rows of perforations, the maximum heights of the centerlines of the uppermost rows above the bottom of the invert, and the inside chord lengths of the unperforated segments illustrated in Figure 1 shall be as specified in Table 12.

Note 10—Pipe with Class 1 perforations is generally available in diameters from 100 to 525 mm inclusive, although perforated pipe in larger sizes may be obtained.

8.3.2.2. *Class 2 Perforations*—The perforations shall be circular holes with nominal diameters of 8.0 to 9.5 mm, or slots with nominal widths of 4.8 to 8.0 mm and not to exceed 13 mm in length. The perforations shall be uniformly spaced around the full periphery of the pipe. The perforations shall provide an opening area of not less than 230 square centimeters per square meter of pipe surface based on nominal diameter and length of pipe.

Note 11—323 perforations, 9.5-mm diameter, per square meter satisfies this requirement.

8.3.2.3. *Class 3 Perforations*—The perforations shall be slots with a width of 2.5 ± 1.0 mm and length of 25 ± 6.5 mm, spaced 45 to 65 mm on centers around the circumference and staggered on the outside crests of the corrugations of the pipe. No metal shall be removed in making the slot. Slots shall be made from the inside of the pipe.

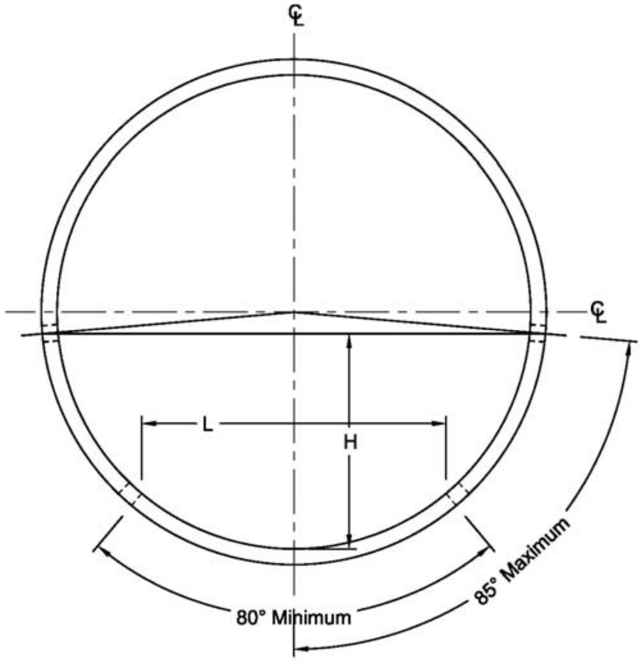

Figure 1—Requirements for Perforations

Table 12—Rows of Perforations, Height *H* of the Centerline of the Uppermost Rows Above the Invert, and Chord Length *L* of Unperforated Segment, for Class 1 Perforations

Internal Diameter of Pipe, mm	Rows of Perforations[a]	*H*, Max,[b] mm	*L*, Min,[b] mm
100	2	46	64
150	4	69	96
200	4	92	128
250	4	115	160
300	6[c]	138	192
375	6[c]	172	240
450	6[c]	207	288
525	6	241	336
600 and larger	8	[d]	[d]

[a] Minimum numbers of rows. A greater number of rows for increased inlet area shall be subject to agreement between purchaser and fabricator. Note that the number of perforations per unit length in each row (and inlet area) is dependent on the corrugation pitch.

[b] See Figure 1 for location of dimensions *H* and *L*.

[c] Minimum of four rows permitted in pipe with 38 by 6.5 mm corrugations.

[d] $H(\max) = 0.46D$; $L(\min) = 0.64D$, where D = internal diameter of pipe, mm or in. as appropriate.

8.4. *Type IIIA Pipe*:

8.4.1. Type IIIA pipe shall be fabricated of an unperforated semicircular bottom section with a top shield of corrugated steel, both of nominal 1.32-mm thickness or greater. The smooth semicircular bottom section shall be approximately 120 mm in diameter and shall have a continuous lip extending outward along each side; the corrugated top shield shall be approximately 160 mm wide including a 19-mm sloping overhang on each side and shall be secured to the lip of the bottom section by integral tabs spaced at about 90 mm center-to-center. The top shield shall have corrugations approximately 22 mm center-to-center and approximately 8.0-mm depth.

8.5. *Pipe Fabricated from Zinc and Aramid Fiber Composite Coated Sheet*—Pipe that has been fabricated from zinc and aramid fiber composite coated sheet shall be coated with asphalt as described in M 190, Type A, Fully Bituminous Coated. If full or partial smooth lining is desired, it shall be specified by the purchaser. (See Section 1.1.1 and M 190.)

9. JOINING SYSTEMS

9.1. *Types of Joining Systems*—Joining systems shall be of the following types, depending upon the configuration of the steel band joining the pipe together. If required, the joining system shall incorporate a flat, O-ring, or profile gasket. The corrugations at the ends of pipe sections being joined shall conform to one of the corrugations detailed in ASTM A 796/A 796M.

Note 12—Bands are classified according to their ability to resist shear, moment, and tensile forces as described in AASHTO *LRFD Bridge Construction Specifications, Section 26* and identified as “standard joints” and “special joints.” The first five types of bands listed in Section 9.1 and meeting the requirements of Section 9.2 are expected to meet the requirements for “standard joints.” Some may also be able to meet the requirements for “special joints,” but such capability should be determined by analysis or test.

9.1.1. *Corrugated Bands*—Bands with either annular or helical corrugations. The band corrugation shall match that of the pipe sections being joined or the annular rerolled ends of those pipe sections.

9.1.2. *Partially Corrugated Bands*—Flat bands with a minimum of one corrugation formed along each circumferential edge of the band. These bands are intended for use with helically corrugated pipe with its ends rerolled to a 68 mm by 13 mm corrugation.

9.1.3. *Bands with Projections*—Flat bands with projections, such as dimples, are used to join pipe with either helical or annular corrugations. The bands shall be formed with the projections in annular rows with one projection for each corrugation of helical pipe engaged by the band. Bands 265 or 300 mm wide shall have two annular rows of projections, and bands 415 or 560 mm wide shall have four annular rows of projections.

9.1.4. *Channel Bands*—Channel bands that incorporate a connector formed into a channel (hat) shape shall be used only with pipe having upturned flanges on the pipe ends. Channel bands shall conform with the requirements of Section 9.3.3.

9.1.5. *Flat Bands*—When specified by the purchaser, flat bands shall be used on pipe with helically corrugated ends, annular corrugated pipe, or helical pipe on which the ends have been rerolled to form annular corrugations.

9.1.6. *Sleeve Couplers*—When specified by the purchaser, the joining system shall incorporate a push-on type coupler designed to properly interface with the pipes being joined. Sleeve couplers generally do not have any external device for tightening around the pipe. Sleeve couplers shall provide a centering device so the coupler laps equally on both pipes being joined. Sleeve couplers for pipe diameters less than 300 mm shall have a minimum stab depth of 75 mm. The minimum stab depth for 300-mm through 1050-mm diameters shall be 150 mm. When sleeve couplers are used with pipes other than Type III or Type IIIA, pipe with annular corrugations or rerolled ends shall be used. Sleeve couplers are not intended for pipe diameters larger than 1050 mm.

9.1.7. *Bell and Spigot*—Bell and spigot configurations incorporate an integral bell that is permanently installed at the factory to one end of the pipe, while the other end of the pipe serves as a spigot. The bell shall be affixed to the pipe by welding or with mechanical fasteners. The steel in the bell shall meet the thickness requirements of Section 9.3.1. The bell and spigot configuration shall be classified in accordance with Section 9.2. The spigot end of the pipe shall be re-rolled or provide annular corrugations to allow placement of a gasket if required. The bell shall provide a minimum stab depth of 150 mm, or 8 percent of the pipe diameter, whichever is greater.

9.1.8. *Special Design*—Other joining systems that meet the requirements of Sections 9.3, 9.4 (if required), and 9.5 (if required), and are specified by the purchaser, shall be used on the project for which they are specified.

9.2. *Joining Systems, Significance and Use*—Joining systems are classified as standard or gasketed, based on the ability of the system to control infiltration and/or exfiltration. These classifications of standard and gasketed systems are covered in Sections 9.2.1 and 9.2.2. When site conditions near the pipe are such that movement or differential settlement is possible at the joint, the joining system shall have structural requirements that conform with Section 9.4.

9.2.1. *Standard Systems*:

9.2.1.1. Standard joining systems for CSP are intended to control the infiltration of soil into the pipe. Standard joining systems are used in the majority of CSP installations. The gradation and plasticity of the backfill materials around the pipe are important factors in the selection of a joining system. The greater the concentration of very fine particles, such as silts which pass the 75-µm sieve, the greater the possibility of soil infiltration. Additionally, when the water table is above the pipe or where the backfill is otherwise saturated and the flow level in the pipe varies rapidly, soil infiltration is more likely to occur.

9.2.1.2. External bands conforming with Sections 9.1.1 through 9.1.3, or 9.1.5, when used with annular pipe or with helical pipe with rerolled ends, generally provide adequate control of infiltration of soil particles. Properly installed, these bands provide continuous metal-to-metal contact with the periphery of the annular portion of the pipe. Where these bands do not provide adequate soil infiltration control, a geotextile wrap around the exterior of the joining system and the adjacent pipe will inhibit the movement of silt and larger soil particles into the pipe.

9.2.2. *Gasketed Systems*:

9.2.2.1. Gasketed joining systems are used to limit the flow of water from the pipe interior to the backfill, to limit the flow of groundwater into the pipe, and, where necessary, to provide further control of soil particle infiltration. Joining systems such as those described in Sections 9.1.4, 9.1.6, and 9.1.7 require gaskets to adequately control soil particle infiltration, except where the pipe is used in underdrain applications. Gaskets used in all joining systems shall conform to the requirements of Sections 6.7 and 9.5.

9.2.2.2. Sites where excessive water infiltration is expected or where the pipe will carry hazardous pollutants require a gasketed joining system. In these cases, the joining system shall be tested to establish a leakage rate not to exceed 18.5 L per millimeter of diameter per kilometer per day with no pressure applied to the pipe or joining system. The joining system shall be tested at the pipe fabricator’s plant or a laboratory, with the pipe in straight alignment. The test shall be witnessed and certified by an approved laboratory.

9.3. *Requirements*—Joining systems shall be fabricated in a manner that ensures that the band or coupler extends over each pipe section an equal length. The joining system shall be fabricated in such a way that proper installation will result in performance conforming with Sections 9.2.1 or 9.2.2 as required for the project.

9.3.1. *Band, Sleeve, or Bell Thickness and Width*—The band, sleeve coupler, or bell portion of the joining system shall be sufficiently strong to resist the forces to which it is subjected. Table 13 provides minimum steel thickness requirements for bands, sleeves, or bells based on the steel thickness of the pipes being connected. Table 13 does not apply to channel (hat) bands, which are covered under Section 9.3.3. The width of coupling bands (Sections 9.1.1–9.1.3 and 9.1.5) shall be equal to or greater than the minimum widths shown in Tables 14 and 15.

9.3.2. *Band Connectors*—The bands shall be connected in a manner approved by the purchaser with hardware that has been suitably galvanized to provide durability. This hardware includes angles and integrally or separately formed and attached flanges that will be connected together with galvanized or cadmium-plated bolts, bars and straps, wedge locks, and straps or lugs. Bands shall be connected with the bolts in accordance with Table 16.

9.3.3. *Channel Bands*—Pipe sections provided with flanges on the ends will be connected by interlocking the flanges of two pipes with a channel (hat) band or other band incorporating an interlocking channel, not less than 19 mm in width. The depth of the channel shall be not less than 13 mm. The channel band shall have a minimum thickness of 1.62 mm.

9.3.4. *Sleeve Couplers*—Sleeve couplers for pipes smaller than 300 mm in diameter shall be made from steel with a minimum thickness of 1.02 mm. The steel thickness for larger sizes shall conform to Table 13. Alternatively the coupler shall be a plastic sleeve with adequate strength to maintain the in-service pipe alignment and meet the requirements of Section 9.2.1.

9.4. *Structural Properties*—Joining systems that are subject to forces created by differential soil movement or settlement require certain structural properties to withstand the applied forces. Minimum values for these structural properties are shown in Table 17. These values for a joining system are determined by either a rational analysis or a suitable physical test.

9.4.1. *Shear Strength*—The shear strength required of the joining system is expressed as a percentage of the calculated shear strength of the pipe at a typical cross section at a location other than a rerolled end.

9.4.2. *Moment Strength*—The moment strength required of a joining system is expressed as a percent of the calculated moment strength of the pipe at a typical cross section at a location other than a rerolled end.

9.4.3. *Tensile Strength*—Where pull-apart (tensile) strength is required to control disjointing in slope drains and similar applications, corrugated, partially corrugated, or channel bands shall be specified. When special requirements exist, joining systems shall provide tensile strength levels of 22 kN for 1050 mm and smaller sizes and 46 kN for larger sizes.

9.5. *Gaskets*—Where infiltration or exfiltration is a concern, as defined in Section 9.2.2, the joining system shall incorporate gaskets. Rubber gaskets shall meet the requirements of Section 6.7 and shall be flat, O-ring, or have a profile shape. Flat gaskets shall be continuous or have a lap joint and be approximately 18 mm wide and approximately 9.5 mm thick. O-ring gaskets shall be 20 mm or 22 mm in diameter for pipe diameters of 900 mm and smaller, or 22-mm diameter for larger diameters of pipe fabricated with a 13-mm deep corrugation. O-ring gaskets shall be 35 mm in diameter when used on pipes having a 25-mm or deeper corrugation. Other types of gaskets may be used, including profile gaskets that meet the specific requirements of the joining system.

Table 13—Band, Sleeve, or Bell Thickness[a,b]

Nominal Pipe Thickness, mm	Nominal Coupling Band Thickness, Min, mm
2.77 and thinner	1.32
3.51	1.63
4.27	2.01

[a] For annular corrugated pipe or helically corrugated pipe with 68 by 13 mm annular rerolled ends.

[b] Applies to joining systems covered by Sections 9.1.1 through 9.1.3, 9.1.5, 9.1.7, and 9.1.6, when the coupler is 300 mm or larger and made from steel.

Note 13—Riveted and spot welded pipe is not watertight, having small openings at the intersection of longitudinal and circumferential seams. Therefore, these types of fabrication should not be used where watertightness is a concern unless the pipe is bituminous coated or lined prior to installation.

Table 14—Band Width Requirements for Pipe with Annular Corrugated Ends[a,b]

Nominal Pipe Diameter, mm	Minimum Band Width, mm
300 to 900	175
1050 to 3600	265

[a] For annular pipe or helical pipe with 68 by 13 mm rerolled ends.

[b] Applies to joining systems covered by Sections 9.1.1 through 9.1.3 and 9.1.5.

Table 15—Band Width Requirements for Helically Corrugated Pipe

Nominal Corrugation, mm	Nominal Pipe Diameter, mm	Minimum Band Width, mm
38 by 6.5	100 to 450	175
68 by 13	300 to 2100	300
75 by 25	900 to 3600	350
125 by 25	900 to 3600	550

Note 1—Corrugation of band shall match that pipe.

Note 2—Band shall be centered on pipes being joined.

Note 3—Applies to joining systems covered by Sections 9.1.1 through 9.1.3 and 9.1.5.

Table 16—Band Connector Bolt Size

Pipe Diameter, mm	Bolt Diameter, mm
450	M10
525	M12
Type III and IIIA	M8

Table 17—Structural Properties of Joining System

	Minimum Value
Shear strength (% of barrel strength)	2
Moment strength (% of barrel strength)	5
Tensile (pull-apart) strength	none

9.6. Other types of coupling bands or fastening devices that are equally effective as those described, and which comply with the joint performance criteria of *AASHTO LRFD Bridge Construction Specifications*, Section 26 may be used when approved by purchaser.

10. WORKMANSHIP

10.1. The complete pipe shall show careful, finished workmanship in all particulars. Pipe that has been damaged, either during fabrication or in shipping, may be rejected unless repairs are made that are satisfactory to the purchaser. Among others, the following defects shall be considered as constituting poor workmanship:

- Variation from a straight centerline;
- Elliptical shape in pipe intended to be round;
- Dents or bends in the metal;
- Metallic coating that has been bruised, broken, or otherwise damaged;
- Lack of rigidity;
- Illegible markings on the steel sheet;
- Ragged or diagonal sheared edges;
- Uneven laps in riveted or spot welded pipe;
- Loose, unevenly lined, or unevenly spaced rivets;
- Defective spot welds or continuous welds; and
- Loosely formed lock seams.

11. REPAIR OF DAMAGED COATINGS

11.1. Pipe on which the metallic coating has been burned by welding beyond the limits provided in Sections 7.4.2 and 7.6, or has been otherwise damaged in fabricating or handling, shall be repaired. The repair shall be done so that the completed pipe shall show careful finished workmanship in all particulars. Pipe which, in the opinion of the purchaser, has not been cleaned or coated satisfactorily may be rejected. If the purchaser so elects, the repair shall be done in his presence.

11.2. The damaged area shall be repaired in conformance with ASTM A 780 (Note 14), except as described herein. The damaged area shall be cleaned to bright metal by blast cleaning, power disk sanding, or wire brushing. The cleaned area shall extend at least 13 mm into the undamaged section of the coating. The cleaned area shall be coated within 24 hours and before any rusting or soiling.

Note 14—While ASTM A 780 specifically refers to repair of damaged zinc coatings, the same procedures are applicable to repair of other metallic coatings except as described in this section.

11.3. *Zinc-Rich Paint Coating*—Zinc-rich paint, as described in the Materials section of ASTM A 780, shall be applied to a dry film thickness of at least 0.13 mm over the damaged section and surrounding cleaned area. Zinc-rich paint shall be used for repair of damage to all types of metallic coating—zinc, aluminum, and aluminum-zinc alloy.

11.4. *Metallizing Coating*—The damaged area shall be cleaned as described in Section 11.2, except it shall be cleaned to the near-white condition. The repair coating applied to the cleaned section shall have a thickness of not less than 0.13 mm over the damaged section and shall taper off to zero thickness at the edges of the cleaned undamaged section.

11.4.1. Where zinc coating is to be metallized, it shall be done with zinc wire containing not less than 99.98 percent zinc.

11.4.2. Where aluminum coating is to be metallized, it shall be done with aluminum wire containing not less than 99 percent aluminum.

11.4.3. Where 55 percent aluminum-zinc alloy coating is to be metallized, it shall be done by using the materials described in Section 11.4.1 or Section 11.4.2, or by using an alloy wire of 55 percent aluminum and 45 percent zinc by mass.

11.4.4. When Zn-5 Al-MM alloy coating is to be metallized, it shall be done using the materials described in Section 11.4.1 or by using an alloy wire of 85 percent zinc and 15 percent aluminum by weight.

11.5. Pipe on which zinc and aramid fiber composite coating is damaged by welding during fabrication of fittings, or otherwise damaged during handling or shipping, shall be repaired as described in Sections 11.2 through 11.4.

12. INSPECTION

12.1. The purchaser or his representative shall have free access to the fabricating plant for inspection, and every facility shall be extended to him for this purpose. This inspection shall include an examination of the pipe for the items in Section 10.1 and the specific requirements of this specification applicable to the type of pipe and method of fabrication.

12.2. On a random basis, samples may be taken for chemical analysis and metallic coating measurements for check purposes. These samples will be secured from fabricated pipe or from sheets or coils of the material used in fabrication of the pipe. The mass of metallic coating shall be determined in accordance with T 65M/T 65 for zinc, 55 Al-Zn alloy, and Zn-5 Al-MM alloy, and T 213M/T 213 for aluminum.

13. REJECTION

13.1. Pipe that fails to conform to the specific requirements of this specification, or that shows poor workmanship, may be rejected. This requirement applies not only to the individual pipe, but to any shipment as a whole in which a substantial number of pipe are defective. If the average deficiency in length of any shipment of pipe is greater than 1 percent, the shipment may be rejected.

14. CERTIFICATION

14.1. When specified in the purchase order or contract, a manufacturer's or fabricator's certification, or both, shall be furnished to the purchaser stating that samples representing each lot have been tested and inspected in accordance with this specification and have been found to meet the requirements for the material described in the order. When specified in the order, a report of the test results shall be furnished.

ANNEX

(Mandatory Information)

A1. QUALIFICATION OF RESISTANCE SPOT WELDING EQUIPMENT

A1.1. *General*—Welding equipment shall be of sufficient capacity, of such design, and in such condition as to make possible the production of first-class welds. Before being permitted to perform welding on CSP, resistance spot welding machines and operations shall be qualified by means of the test prescribed in Section A1.2. Tests shall be performed by the fabricator's shop or by a recognized independent laboratory at no expense to the purchaser. Qualification tests performed by the fabricator's shop shall be made in the presence of the representative of the purchaser.

A1.2. *Qualification*—Perform three tension shear tests representing each thickness of sheet to be used in the fabrication of the pipe. Prepare specimens by lapping two strips of corrugated steel sheet 38 mm minimum width by 125 mm minimum length and joining them together by a single spot weld duplicating the size to be used in production. The length of lap shall be 38 mm. The longer axis of specimen shall be parallel to the direction of rolling. Test the specimens in tension to destruction in a standard calibrated testing machine. The minimum shear strength in kilonewtons as determined by this test shall be not less than that shown in Table A1.1 for nominal thickness of sheet used in the test.

Table A1.1—Shear Strength of Spot Welds

Specified Sheet Thickness, mm	Minimum Shear Strength, kN
1.63	18.2
2.01	23.1
2.77	31.1
3.51	37.8
4.27	44.5

A1.3. *Verification*—After a machine and operator have been qualified by the foregoing procedure, to ensure that qualification is maintained, make three tension shear tests at the start of each work shift, and make three tension shear tests for each change in sheet thickness.

A1.4. *Machine Setting*—One copy of the approved machine setting shall be posted on the machine for use by the machine operator. No settings shall be varied, except weld phase shift and pressure, which may be varied by ±10 percent.

---

[1] This specification is technically identical to ASTM A 760/A 760M-01a.

Standard Specification for

Nonreinforced Concrete Sewer, Storm Drain, and Culvert Pipe

AASHTO Designation: M 86M/M 86-09[1]
ASTM Designation: C 14M-07 and C 14-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Nonreinforced Concrete Sewer, Storm Drain, and Culvert Pipe

AASHTO Designation: M 86M/M 86-09[1]
ASTM Designation: C 14M-07 and C 14-07

1. SCOPE

1.1 This specification covers nonreinforced concrete pipe intended to be used for the conveyance of sewage, industrial wastes, storm water, and for the construction of culverts.

1.2 This specification is applicable for orders in either SI units (M 86M) or in inch-pound units (M 86). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 86.

Note 1—This specification is a manufacturing and purchasing specification only and does not include requirements for bedding, backfill, or the relationship between field load conditions and the strength classification of pipe. However, experience has shown that the successful performance of this product depends upon the proper selection of the class of pipe, type of bedding and backfill, and care that the installation conforms to the construction specifications. The owner is cautioned that he must correlate the field requirements with the class of pipe specified and provide for or require inspection at the construction site.

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. CLASSIFICATION

4.1 Pipe manufactured according to this specification shall be of three classes identified as “Class 1 Nonreinforced Concrete Pipe,” “Class 2 Nonreinforced Concrete Pipe,” and “Class 3 Nonreinforced Concrete Pipe.” The corresponding strength requirements are prescribed in Table 1.

Table 1— Physical and Dimensional Requirements for Nonreinforced Concrete Pipe[a]

		Class 1				Class 2				Class 3			
Internal Designated Diameter		Minimum Thickness of Wall		Minimum Strength, Three-Edge Bearing		Minimum Thickness of Wall		Minimum Strength, Three-Edge Bearing		Minimum Thickness of Wall		Minimum Strength, Three-Edge Bearing

[a] Subject to tolerance in Section 11.

5. BASIS OF ACCEPTANCE

5.1 The acceptability of the pipe shall be determined by the results of the test prescribed in this section, when required, and by inspection to determine whether the pipe conforms to this specification as to design and freedom from defects.

5.2 *Acceptance as to Strength Properties*—Pipe shall be acceptable under the strength tests when they have met the requirements as prescribed in Section 10.3.

5.3 *Acceptance as to Absorption Properties*—Pipe shall be acceptable under the absorption test when they have met the requirements as prescribed in Section 10.4.

5.4 *Acceptance as to Permeability Properties*—Pipe shall be acceptable under the permeability test when they have met the requirements as prescribed in Section 10.5.

Note 2—Prior to purchase the owner has the option to specify the hydrostatic test prescribed in Section 10.6 instead of the permeability test.

5.5 *Acceptance as to Hydrostatic Properties*—Pipe shall be acceptable under the hydrostatic test when they have met the requirements as prescribed in Section 10.6.

6. MATERIALS

6.1 *Concrete*—The concrete shall consist of cementitious materials, mineral aggregates, and water.

6.2 *Cementitious Materials*:

6.2.1 *Cement*—Cement shall conform to the requirements for portland cement of M 85 or shall be portland blast-furnace slag cement or slag modified portland cement, or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash.

6.2.2 *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.3 *Ground Granulated Blast-Furnace Slag (GGBFS)*—GGBFS shall conform to the requirements of Grade 100 or 120 of Specification C 989.

6.2.4 *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

6.2.4.1 Portland cement only,

6.2.4.2 Portland blast-furnace slag cement only,

6.2.4.3 Slag modified portland cement only,

6.2.4.4 Portland-pozzolan cement only, or

6.2.4.5 A combination of portland cement and fly ash.

6.2.4.6 A combination of portland cement and ground granulated blast-furnace slag, or

6.2.4.7 A combination of portland cement, fly ash (not to exceed 25 percent of the total cementitious weight) and ground granulated blast-furnace slag (not to exceed 25 percent of the total cementitious weight).

6.3 *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirement for gradation shall not apply.

6.4 *Admixtures and Blends*—Admixtures and blends shall only be used with the approval of the owner.

6.5 *Synthetic Fibers*—Polypropylene fibers are permitted, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM Specification C 1116 shall be accepted.

7. DESIGN

7.1 *Design Tables*—Design requirements shall be in accordance with Table 1. Wall thickness used shall be not less than the value shown, except as affected by the tolerance herein specified and by the provision for modified design.

7.2 *Modified or Special Design*—Manufacturers shall submit to the owner for approval, prior to manufacture, wall thicknesses other than those shown in Table 1. Such pipe shall meet all of the physical requirements listed in Section 10 that are specified by the owner.

8. JOINTS

8.1 The joints shall be of such design and the ends of the concrete pipe sections so formed that the pipe can be laid together to make a continuous line of pipe compatible with the permissible variations given in Section 11.

9. MANUFACTURE

9.1 *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious materials ratio not exceeding 0.53 by mass. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 280 kg/m^3 [470 lb/yd^3] unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this specification.

9.2 *Curing*—Pipe shall be subjected to any one of the methods of curing described in Sections 9.2.1 through 9.2.4 or to any other method or combination of methods approved by the owner that will give satisfactory results. The pipe shall be adequately cured to obtain the strength properties as described in Section 5.2.

9.2.1 *Steam Curing*—Pipe shall be placed in a curing chamber, free from outside drafts, and cured in a moist atmosphere maintained by the injection of steam for such time and such temperature as needed to enable the pipe to meet the strength requirements. The curing chamber shall be so constructed as to allow full circulation of steam around the entire pipe.

9.2.2 *Water Curing*—Concrete pipe shall be water cured by covering with water-saturated material or by a system of perforated pipes, mechanical sprinklers, porous hose, or by any other approved method that will keep the pipe moist during the specified curing period.

9.2.3 The manufacturer is not prohibited from combining the methods described in Sections 9.2.1 and 9.2.2 provided the specified strength is attained.

9.2.4 *Membrane Curing*—A sealing membrane conforming to the requirements of M 148 is not prohibited from being applied and left intact until the specified strength requirements are met. The concrete at the time of application shall be within 6ºC [10ºF] of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

9.3 *Specials*:

9.3.1 *General Requirements*—Special shapes or fittings such as wyes, tees, bends, and adapters for use with concrete pipe conforming to this specification shall conform to the applicable requirements for concrete pipe of corresponding class and internal diameter. Joints shall be compatible with those used in adjoining concrete pipes.

9.3.2 *Fabricated Branches*—Fabricated branches for wyes and tees shall be securely attached to the wall of the pipe in such a manner as not to restrict or otherwise interfere with the flow characteristics of the pipe.

10. PHYSICAL REQUIREMENTS

10.1 *Test Specimen*—The specified number of pipe required for the tests shall be furnished by the manufacturer and shall be selected at random by the owner, and shall be pipe that would not otherwise be rejected under this specification. The selection shall be made at the point or points designated by the owner when placing the order. The test pipe shall first be freed from all visible moisture. When dry, each pipe shall be measured and inspected. The results of these observations shall be recorded.

10.2 *Number and Type of Test Specimens Required*—The manufacturer shall furnish pipe for crushing and absorption tests, up to 0.5 percent of the number of pipe of each size included in the order except that in no case shall fewer than two pipes be furnished. For the permeability test, 2 percent of the number of pipe of each size included in the order, but in no case fewer than two pipes shall be furnished. For the hydrostatic test, 0.5 percent of the number of pipe of each size included in the order, but in no case fewer than two pipes shall be furnished.

10.3 *External Load Crushing Requirement*—The crushing strength of nonreinforced concrete pipe shall conform to the requirements prescribed in Table 1. The individual results of the various tests for each size of pipe and for each shipment and plant shall be tabulated separately. The crushing strength shall ordinarily be applied to not less than 75 percent of the pipe received for purpose of test. All tests shall be made in accordance with T 280. Pipe shall be acceptable when all test pipe conform to the specified requirement. Should any of the test pipe provided in Section 10.2 fail to meet the strength requirement, the manufacturer will be allowed to test two pipes for each pipe that failed, and the pipe shall be acceptable only when all of these additional test pipe meet the strength requirement.

10.4 *Absorption Requirement*—When required by the owner, absorption shall be determined by the boiling absorption test and shall not exceed 9 percent. The individual results of the various tests for each size of pipe for each shipment and plant shall be tabulated separately. All tests shall be made in accordance with T 280. The number of absorption test specimens shall be equal to the number of pipe provided for crushing strength testing. These specimens shall be obtained from pipe that are acceptable as to strength, and shall be taken from pipe used in making the strength test after the test is made. These specimens shall be marked with the number or identification mark of the pipe from which they were taken. Each specimen shall have an area of 77 [12] to 129 cm^2 [20 $in.^2$], as measured on one surface of the pipe, and a thickness equal to the pipe wall, and shall be free of visible cracks. Pipe shall be acceptable when all test pipe conform to the specified absorption requirement.

10.5 *Permeability Requirement*—When subjected to the permeability test as specified in T 280, the outer pipe surface of not less than 80 percent of the pipe tested shall show no moist or damp spots at the end of the test period due to water passing through the walls of the pipe.

10.6 *Hydrostatic Requirement*—When subjected to the hydrostatic test as described in T 280, the pipe shall show no leakage during 10 minutes at 70 kPa [10 psi]. Moisture appearing on the surface of the pipe in the form of patches or beads adhering to the surface shall not be considered leakage. The test pipe shall be filled with water and held under 70 kPa [10 psi] pressure for 24 hours prior to the test, except that the manufacturer is not prohibited from reducing, this presoak time or pressure, or both. The manufacturer is not prohibited from continuing this test up to 24 hours, and the pipe will be considered to have passed when, during any 10-minute period, no leakage is observed. When the hydrostatic requirement is used for acceptance of the pipe joint as specified in Section 10 of M 198, it is not prohibited to use the same joint test runs as the basis of acceptance for pipe hydrostatic requirements in accordance with Sections 5.5 and 10.6 of this specification.

10.7 *Retest*—Should more than 20 percent of the samples fail to meet the specified requirements for the permeability or not more than 20 percent of the samples fail to meet the specified requirement for absorption or hydrostatic requirements of this section, it is not prohibited for the manufacturer to cull his stock and eliminate any quantity of pipe and must so mark those pipe that will not be shipped. The required tests shall be made on the balance of the order and they are acceptable if they conform to the specified requirements. If the second sample fails to meet the specified requirements, the whole lot is subject to rejection.

11. DIMENSIONS AND PERMISSIBLE VARIATIONS

11.1 *Sizes and Dimensions*—Pipe shall be furnished of the sizes, internal diameters, and dimensions prescribed in Table 1.

11.2 *Permissible Variations in Dimensions*—Permissible variations in dimensions shall be limited to the following:

11.2.1 *Internal Diameter*—Permissible variations are as prescribed in Table 2.

Table 2—Permissible Variation in Internal Diameter

Designated Diameter of Pipe		Permissible Variation Internal Diameter of Pipe			
		Minimum		Maximum	
mm	[in.]	mm	[in.]	mm	[in.]
100	4	95	$3^{13}/_{16}$	105	$4^{3}/_{16}$
150	6	145	$5^{13}/_{16}$	155	$6^{3}/_{16}$
200	8	195	$7^{13}/_{16}$	205	$8^{3}/_{16}$
250	10	245	$9^{13}/_{16}$	255	$10^{3}/_{16}$
300	12	295	$11^{13}/_{16}$	305	$12^{3}/_{16}$
375	15	368	$14^{3}/_{4}$	382	$15^{1}/_{4}$
450	18	443	$17^{3}/_{4}$	457	$18^{1}/_{4}$
525	21	517	$20^{11}/_{16}$	533	$21^{5}/_{16}$
600	24	590	$23^{5}/_{8}$	610	$24^{3}/_{8}$
675	27	665	$26^{5}/_{8}$	685	$27^{3}/_{8}$
750	30	740	$29^{5}/_{8}$	760	$30^{3}/_{8}$
825	33	815	$32^{5}/_{8}$	835	$33^{3}/_{8}$
900	36	890	$35^{5}/_{8}$	910	$36^{3}/_{8}$

11.2.2 *Thickness of Wall*—The wall thickness shall be not less than the values shown in Table 1 or the manufacturer's designated thickness if greater than shown in Table 1 by more than 2 mm [$^1/_{16}$ in.] for pipe 250 mm [10 in.] or less in diameter; by more than 3 mm [$^1/_8$ in.] for pipe 300 [12 in.] to 600 mm [24 in.] in diameter; and by more than 5 mm [$^3/_{16}$ in.] for pipe more than 600 mm [24 in.] in diameter; or by more than 5 percent of the tabulated or designated wall thickness, whichever is greater. Localized variations in wall thickness exceeding those specified above shall be accepted if the physical test requirements specified herein are met.

11.2.3 *Length*—The length of any section of pipe shall vary not more than minus 13 mm [$^1/_2$ in.] from a specified or designated design length.

11.2.4 *Length of Two Opposite Sides*—The length of two opposite sides of any section of pipe shall vary not more than 6 mm [$^1/_4$ in.] or 2 percent of the designated diameter, whichever is larger.

11.2.5 *Straightness*—Pipe intended to be straight shall not vary in alignment more than 10 mm/m [$^1/_8$ in./ft] of length.

12. REPAIRS

12.1 Pipe repaired because of imperfections in manufacturing or damage during handling are acceptable if, in the opinion of the owner, the repaired pipe conforms to the requirements of this specification.

13. INSPECTION

13.1 The quality of all materials and the finished pipe shall be subject to inspection and approval by the owner. Such inspection shall be performed either at the point of manufacture or delivery, or both. The method of marking as to acceptance or rejection of pipe shall be agreed upon, prior to inspection, between the owner and the manufacturer. Rejected pipe shall be replaced by the manufacturer with pipe that meets the requirements of this specification.

14. REJECTION

14.1 Pipe shall be subject to rejection if it fails to conform to any of the specification requirements. This specification is a manufacturing and purchasing specification only. Therefore, damage to pipe during installation or caused by field loading in the installed condition shall not be cause for rejection on the basis of not meeting this specification. Individual sections of pipe are subject to rejection because of any of the following:

14.1.1 Fractures or cracks passing through the wall or joints, except that a single crack not exceeding 50 mm [2 in.] in length at either end of a pipe or a single fracture or spall in the joints not exceeding 75 mm [3 in.] around the circumference of the pipe nor 50 mm [2 in.] in length into joint shall not be considered cause for rejection unless these defects exist in more than 5 percent of the entire shipment or delivery.

14.1.2 The planes of the ends of the pipe are not perpendicular to the longitudinal axis, subject to the limits of variation as shown in Section 11.2.4.

14.1.3 Defects that indicates mixing and molding not in accordance with Section 9.1.

14.1.4 Cracks sufficient to impair the strength, durability, or serviceability of the pipe.

15. PRODUCT MARKING

15.1 The following information shall be legibly marked on each pipe:

15.1.1 The pipe class and specification designation,

15.1.2 The date of manufacture,

15.1.3 The name or trademark of the manufacturer, and

15.1.4 Identification of the plant.

15.2 Marking shall be indented on the pipe section or painted thereon with waterproof paint.

16. KEYWORDS

16.1 Concrete sewer; culvert; nonreinforced; pipe; storm drain.

---

[1] Agrees with ASTM C 14M-07 and C 14-07 except for limiting absorption testing to the 5-hour boil method, the use of fibers in Section 6.5 is at the owners option, and the manufacturer is not afforded the option to supply inch-pound sized pipe when the order is placed in SI units.

Standard Specification for

Corrugated Steel Structural Plate, Zinc-Coated, for Field-Bolted Pipe, Pipe-Arches, and Arches

AASHTO Designation: M 167M/M 167-09
ASTM Designation: A 761/A 761M-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Corrugated Steel Structural Plate, Zinc-Coated, for Field-Bolted Pipe, Pipe-Arches, and Arches

AASHTO Designation: M 167M/M 167-09
ASTM Designation: A 761/A 761M-04

1. SCOPE

1.1. This specification covers corrugated steel structural plate, zinc-coated, used in the construction of pipe, pipe-arches, arches, underpasses, and special shapes for field assembly. Appropriate fasteners and accessory materials are also described. The pipe, arches, and other shapes are generally used for drainage purposes, pedestrian and vehicular underpasses, and utility tunnels.

1.2. This specification does not include requirements for bedding, backfill, or the relationship between earth cover load and plate thickness of the pipe. Experience has shown that the successful performance of this product depends upon the proper selection of plate thickness, type of bedding and backfill, manufacture in the plant, and care in the installation. The purchaser must correlate the above factors and also the corrosion and abrasion requirements of the field installation with the plate thickness. The structural design of corrugated steel structural plate pipe and the proper installation procedures are described in *AASHTO LRFD Bridge Design Specifications*, Section 12 and *AASHTO LRFD Bridge Construction Specifications*, Section 26, respectively.

1.3. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

3. DESCRIPTIONS OF TERMS SPECIFIC TO THIS STANDARD

3.1. *arch*—a partial circle shape spanning an open invert between the footings on which it rests.

3.2. *box culvert*—a rectangular box with a long-radius crown and either short-radius corners or welded corners. It can be with full invert or with footings.

3.3. *fabricator*—the producer of the components for the finished product.

3.4. *flat plate*—sheet or plate used to fabricate structural plate.

3.5. *manufacturer*—the producer of the flat plate and accessories.

3.6. *pipe*—a conduit having full circular shape; also, in a general context, all structural shapes covered by this specification.

3.7. *pipe-arch*—an arch shape with an approximate semicircular crown, small-radius corners, and large-radius invert.

3.8. *pipe, horizontal ellipse*—an elliptically shaped pipe with the horizontal diameter approximately 25 percent greater than the nominal diameter.

3.9. *pipe, vertically elongated*—an elliptically shaped pipe with the vertical diameter up to 10 percent greater than the nominal diameter.

3.10. *purchaser*—the purchaser of the finished product.

3.11. *special shape*—a shape, other than described elsewhere in this section, suitable for fabrication with structural plate.

3.12. *structural plate*—a corrugated and curved plate that is field assembled with other structural plates to form the required structure.

3.13. *vehicular underpass*—a high arch shape with an approximate semicircular crown, large-radius sides, small-radius corners between sides and invert, and large-radius invert.

---

4. ORDERING INFORMATION

4.1. Orders for material under this specification shall include the following information, as necessary, to adequately describe the desired product:

4.1.1. Name of material (corrugated steel structural plate and accessories);

4.1.2. Description of structure (Section 3);

4.1.3. Number of structures;

4.1.4. AASHTO designation and year of issue;

4.1.5. Dimensions of structure (diameter or span and rise, and length, etc.) (Section 8.2 and Note 7);

4.1.6. Thickness of plate (Section 8.1), and for the 150 × 50 mm [6 × 2 in.] corrugation, the type of steel in accordance with 5.1.3. and Table 2;

4.1.7. Description of corrugations (Section 6.2);

4.1.8. End treatment (bevel, skew, grade or slope corrections, or other special provision if required by the project plans or specifications);

4.1.9. Seam bolt size and number per corrugation, if different from the minimums indicated by Tables 3 and 5 (Section 6.3);

4.1.10. Special requirements (including reinforcement locations, shapes, and thicknesses), if required; and

4.1.11. Certification, if required (Section 12.1).

Note 1—A typical ordering description is as follows: (1) Structural plates and fasteners for two corrugated steel plate pipe-arch, per M 167-____, 180-in. diameter, 0.168-in. plate thickness, 6 × 2-in. corrugations, 140-ft. nominal centerline length with square ends, longitudinal seams with four M20 bolts per corrugation. (2) Structural plates and fasteners for two corrugated steel plate pipe-arch, per M 167M-____, 3860-mm span by 2460-mm rise, 5.54-mm plate thickness, 150 × 50-mm corrugations, 27.0-m nominal centerline length with square ends, longitudinal seams with four M20 bolts per corrugation.

5. MATERIALS

5.1. *Flat Plate*:

5.1.1. *Manufacture*—The base steel shall be made by any of the following processes: open-hearth, basic-oxygen, or electric-furnace.

5.1.2. *Chemical Composition*—The base metal cast or heat (formerly ladle) analysis shall conform to the chemical requirements of Table 1. The requirements of this specification shall be met in continuous mass production during which the manufacturer has made analysis of individual heats to ensure that material is controlled within the specified limits.

5.1.3. *Mechanical Requirements*—The mechanical properties of the flat plate material prior to corrugating shall conform to the requirements in Table 2. For the 150 × 50 mm [6 × 2 in.] corrugation, either Type 33 or Type 38 must be specified.

Note 2—The properties enumerated in Table 2 for the flat plate normally provide the minimum yield strength of 230 MPa [33 ksi] for Type 33 material and 265 MPa [38 ksi] for Type 38 material (used in structural design for pipe with 150 × 50 mm [6 × 2 in.] corrugations), or 300 MPa [44 ksi] (used in structural design for pipes with 380 × 140 mm [15 × 5$^1/_2$ in.] and 400 × 150 mm [16 × 6 in.] corrugations) after the plate is corrugated.

Table 1—Chemical Composition by Cast Analysis

Corrugations, mm [in.]		Composition, percent	Tolerance Over the Maximum Limit by Product Analysis, percent
150 × 50 [6 × 2]	Sulfur, max	0.05	+0.01
	Sum of carbon, manganese, phosphorus, silicon, and sulfur, max	0.70	+0.04
380 × 140 [15 × 5 $^1/_2$] and 400 × 150 [16 × 6]	Sulfur, max	0.04	+0.01
	Sum of carbon, manganese, phosphorus, silicon, and sulfur, max	1.86	+0.13

Table 2—Mechanical Requirements for Flat Plate[a]

	Yield Point,[b] Min, MPa [ksi]	Tensile Strength,[b] Min, MPa, [ksi]	Elongation in 50 mm [2 in.],[c] Min, percent
150 × 50 [6 × 2]			
Type 33	190 [28.0]	290 [42.0]	25
Type 38	225 [33.0]	310 [45.0]	25
380 × 140 [15 × 5 $^1/_2$] and 400 × 150 [16 × 6]	275 [40.0]	380 [55.0]	25

[a] To determine conformance with this specification, each value for tensile strength and for yield point shall be rounded to the nearest 1 MPa [0.1 ksi] and each value for elongation to the nearest 1 percent, both in accordance with the rounding-off method of ASTM E 29.

[b] Yield point and tensile strength are based on thickness of the base metal. If tests are made after coating, determine the base metal thickness after stripping the coating from the ends of the specimen contacting the grips of the tension testing machine.

[c] Elongation requirement does not apply to material tested after corrugating.

5.2. *Bearings for Arches*—When specified, metal bearings for arches may be cold-formed channels made from flat plate material conforming to Section 5.1, and not less than 4.78 mm [0.188 in.] in specified thickness.

5.3. *Members for Structural Reinforcement*—Steel members for circumferential or longitudinal stiffeners, or secondary structural components, shall be fabricated from rolled shapes conforming to A 36/A 36M, or from flat plate material conforming to Section 5.1.

Note 3—Steel transverse structural reinforcing members, when used, are part of long span or box corrugated steel structural plate structures. The structural reinforcement for either of these types of structures can be designed using *AASHTO LRFD Bridge Design Specifications*. The structural design of long span structures is given in *AASHTO LRFD Bridge Design Specification,* Section 12.

5.4. *Assembly Fasteners*—Except as provided elsewhere in this section, bolts and nuts shall conform to the requirements specified in Table 3. The bearing surface of both bolts and nuts for use with 150 × 50 mm [6 × 2 in.] and 400 × 150 mm [16 × 6 in.] corrugations shall be shaped to a 25-mm [1-in.] radius spherical surface. In lieu of bolts and nuts with the special bearing surface, standard type bolts and nuts with special washers providing comparable bearing surface may be used. Bolts and nuts with standard bearing surfaces shall be used with 380 × 140 mm [15 × 5 $^1/_2$ in.] corrugations. The number of bolts and nuts of each size and length furnished shall be 2 percent in excess of the theoretical number required to field erect the structure or structures. Bolt lengths shall be such as to result in at least “full nut” engagement when tightened in place.

5.5. *Head Wall and Bearing Anchorage*—Bolts and nuts for head wall anchorage and for anchoring arch bearings to foundations shall be fabricated as shown on the plans and shall conform to the requirements specified in Table 3.

Table 3—Bolt and Nut Requirements

	Bolts[a]	Nuts
General Dimensions[b]	ANSI B18.2.3.6M Heavy Hex	ANSI B18.2.4.6M Heavy Hex
Seam bolts and nuts[c]	F 568 Class 8.8	M 291 Class 12
Anchorage bolts and nuts	F 568 Class 4.6	M 291 Class 5
Zinc coating	M 232M/M 232	M 232M/M 232
Nominal diameter, min, metric size[d]	M 20	M 20

[a] Bolts with special hemispherical base under the head are only available in inch sizes. They are also intended for use with metric plate.

[b] See Section 5.4 for permissible modifications to bearing surface.

[c] Bolts and nuts also used for connecting arch plates to bearing and structural reinforcement to structural plates.

[d] Bolt size of M 22, M 24, or M 27 may be required with thicker plates, especially with 380 × 140 mm corrugation, and shall be furnished when specified in the order.

6. FABRICATION

6.1. *Structural Plates*—Structural plates shall be fabricated from flat sheets or plates, corrugated in accordance with Section 6.2, punched for bolted lap seams in accordance with Section 6.3, and curved to the required radius.

6.2. *Corrugations*—Corrugations shall form smooth continuous curves and tangents. Corrugations shall form annular rings (complete or partial) about the axis of the structure. The dimensions of the corrugations shall be in accordance with Table 4 for the size specified in the order.

Table 4—Corrugation Requirements

Nominal Size	Maximum Pitch[a]	Minimum Depth[b]	Minimum Inside Radius
		M 167M (mm)	
150 × 50	158	48	25
380 × 140	394	133	68
400 × 150	413	144	74
		M 167 (in.)	
6 × 2	6.25	—	1.0
15 × 5$^1/_2$	15.5	5.23	2.7
16 × 6	16.3	5.67	2.9

[a] Pitch is measured from crest to crest of corrugation, at 90 degrees to the direction of the corrugations.

[b] Depth is measured as the vertical distance from a straightedge resting on the corrugation crests parallel to the axis of the pipe to the bottom of the intervening valley.

6.3. *Bolt Holes*—The bolt holes shall be punched so that all plates having like dimensions, curvature, and same size and number of bolts per meter [foot] of seam shall be interchangeable. Except as otherwise specified, the location and number of seam bolt holes shall conform to the requirements of Table 5 for the size of bolts indicated in Table 3 (Note 4). For 150 × 50 mm [6 × 2 in.] corrugations, the diameter of bolt holes in the longitudinal seams shall not exceed the bolt diameter by more than 3 mm [$^1/_8$ in.] except those in plate corners. Bolt holes in circumferential seams, including plate corners, shall not exceed the bolt diameter by more than 6 mm [$^1/_4$ in.] or may be slotted with a width equal to the bolt diameter plus 3 mm [$^1/_8$ in.] and a length equal to the bolt diameter plus 10 mm [$^3/_8$ in.]. For 380 × 140 mm [15 × 5 $^1/_2$ in.] corrugations, the diameter of bolt holes in the longitudinal and circumferential seams shall not exceed the bolt diameter by more than 6 mm [$^1/_4$ in.]. Bolt holes for the attachment of circumferential reinforcing, where required, shall be slotted with a width not greater than the bolt diameter plus 6 mm [$^1/_4$ in.] and a length not greater than the bolt diameter plus 12 mm [$^1/_2$ in.]. For 400 × 150 mm [16 × 6 in.] corrugations, the diameter of bolt holes in the longitudinal seams shall not exceed the bolt diameter by more than 6 mm [$^1/_4$ in.] except those in the plate corners and two other locations (aligned with the center hole of the group of three corner holes, and in adjacent corrugations), which will be the same as the circumferential holes. The bolt holes in circumferential seams shall be slotted holes with a width not greater than the bolt diameter plus 5 mm [$^3/_{16}$ in.] and a length not greater than the bolt diameter plus 10 mm [$^3/_8$ in.].

6.4. Holes shall be provided as required for connecting headwall anchors, structural reinforcement, and miscellaneous attachments.

Note 4—Determine the appropriate bolt size and number of bolts per corrugation for longitudinal seams according to the design criteria in *AASHTO LRFD Bridge Design Specifications*, Section 12, or other appropriate guidelines.

Table 5—Bolt Hole Patterns in Structural Plate[a]

	Corrugation Size, mm [in.]		
	150 × 50 [6 × 2]	380 × 140 [15 × 5$^1/_2$]	400 × 150 [16 × 6]
Longitudinal Seams:			
Number of rows	2	3	3
Holes per corrugation, each row, min:			
For plates thinner than 7.87 mm [0.310 in.]	1[b]	2[c]	2
For 7.87 mm [0.310 in.] and thicker plates	2	2[c]	2
Spacing between rows, min, mm [in.]	50 [2]	75 [3]	100 [4]
Circumferential Seams:			
Number of rows	1	1	1
Spacing in rows, max, mm [in.]	250 [10]	400 [16]	425 [16.75]
Arch Anchorage Seams:			
Number of rows	1	1	1
Spacing in rows, nominal max, mm [in.]	600 [24]	380 [15]	400 [16]

[a] All bolt holes shall be located 1.75 × bolt diameter minimum, center of the hole to edge of sheet.

[b] For minimum of one hole per corrugation, holes shall be staggered with holes in one row in valleys and holes in the other row in crests of corrugation.

[c] One hole each crest and valley of all corrugations for each row.

6.4.1. *Bolt Holes in Bearings for Arches*—Bolt holes for anchoring bearings to foundation shall be punched as shown on the plans, with spacing at not more than 600 mm [24 in.] on centers. Bolt holes shall be punched in the vertical leg of bearings to match corresponding bolt holes in the bottom arch plate.

6.5. *Special Plates*—Plates for forming skewed ends, beveled ends, or curved alignment shall be accurately cut to fit the order plans. Cut edges of plates shall be free of notches, gouges, or burrs, and shall present a workmanlike finish. Legible identification shall be placed on each special plate to designate its proper position in the finished structure and referenced to the approved erection drawings.

6.6. *Structural Reinforcement*—Members for longitudinal or circumferential reinforcing, if required, shall be as sized and located on the order plans and fabricated from materials described in Section 5.3.

7. ZINC COATING

7.1. All structural plates, including fittings and cut ends, shall be zinc coated after cutting, corrugating, punching of holes, and welding (when required), but they may be curved to the required radius either before or after zinc coating when it has been demonstrated that this fabrication can be done on specific tooling and equipment without damage to the zinc coating. All arch bearings and structural reinforcement shall be zinc coated after all fabrication is completed. The zinc used for the coating shall conform to M 120 and shall be at least equal to the grade designated as "Prime Western."

7.2. *Coating Mass (Plates)*—Plates shall be zinc coated to provide an average coating mass of 910 g/m^2 [3.0 oz/ft^2] of sheet (total both surfaces), and a minimum coating mass for any single specimen of 820 g/m^2 [2.7 oz/ft^2] of sheet.

7.2.1. To determine conformance with this specification, each single value for coating mass and the average of all values shall be rounded to the nearest 10 g/m^2 [0.1 oz/ft^2] in accordance with the rounding-off method of ASTM E 29.

7.3. *Coating Mass (Structural Reinforcement and Arch Bearings)*—Members fabricated from rolled shapes shall be zinc coated to conform to M 111M/M 111. Members fabricated from plate material shall be zinc coated as specified in Section 7.2.

7.4. *Repair of Damaged Zinc Coating*—Plate or accessory material on which the metallic coating has been burned by welding, or has been otherwise damaged in fabricating or handling, shall be repaired. The repair shall be done so the completed material shall show careful finished workmanship in all particulars. Material which, in the opinion of the purchaser, has not been cleaned or coated satisfactorily may be rejected. If the purchaser so elects, the repair shall be done in his presence.

7.4.1. The damaged area shall be cleaned to bright metal by blast cleaning, power disk sanding, or wire brushing. The cleaned area shall extend at least 13 mm [$^1/_2$ in.] into the undamaged section of the coating. The cleaned area shall be coated within 24 hours and before any rusting or soiling, using either the procedure in Section 7.4.2 or Section 7.4.3, unless specified otherwise.

7.4.2. *Zinc-Rich Paint Coating*—Zinc-rich paint shall be applied to a dry film thickness of at least 0.13 mm [0.005 in.] over the damaged section and surrounding cleaned area.

7.4.3. *Metallizing Coating*—The damaged area shall be cleaned as described in Section 7.4.1 except it shall be cleaned to the near-white condition. The repair coating applied to the cleaned section shall have a thickness of not less than 0.13 mm [0.005 in.] over the damaged section and shall taper off to zero thickness at the edges of the cleaned undamaged section. Metallizing shall be performed using zinc wire containing not less than 99.98 percent zinc.

Note 5—ASTM A 780 contains additional information on repair of damaged zinc coatings.

7.5. *Coating Adherence*—The coating shall adhere to the base metal so that no peeling or flaking occurs during normal handling.

8. DIMENSIONS AND TOLERANCES

8.1. *Plate Thickness*—Plate thickness shall conform to the requirements of Table 6 as specified by the purchaser from the specified plate thicknesses listed in that table (Note 6). For corrugated plate, the thickness shall be measured on the tangents of the corrugations. The thickness shall include both the base metal and the coating.

Note 6—Determine the required thickness according to the design criteria in *AASHTO LRFD Bridge Design Specifications*, Section 12 or other appropriate guidelines.

Table 6—Thickness for Zinc-Coated Plates[a]

Corrugated Size mm [in.]	Specified Thickness, mm [in.]	Minimum Thickness, mm [in.]
150 × 50 [6 × 2] and 380 × 140 [15 × 5$^1/_2$]	2.82 [0.111]	2.51 [0.099]
	3.56 [0.140]	3.25 [0.128]
	4.32 [0.170]	4.01 [0.158]
	4.78 [0.188]	4.47 [0.176]
	5.54 [0.218]	5.23 [0.206]
	6.32 [0.249]	6.02 [0.237]
	7.11 [0.280]	6.81 [0.268]
	7.87 [0.310]	7.49 [0.295]
	9.65 [0.380]	9.09 [0.358]
400 × 150 [16 × 6]	3.0 [0.118]	2.70 [0.106]
	4.0 [0.157]	3.70 [0.146]
	5.0 [0.197]	4.70 [0.185]
	6.0 [0.236]	5.70 [0.224]
	7.0 [0.276]	6.70 [0.264]

[a] Thickness is measured at any point on the plate not less than 10 mm [$^3/_8$ in.] from an edge and, if corrugated, on the tangents of corrugations. There is no limit on overthickness.

8.2. *Cross-Section Dimensions*—Cross-section dimensions, such as diameter, span and rise, and radius of curvature, shall be measured to the inside crest of corrugations. Tolerances herein specified apply to the as-erected shape before backfill placement. The diameter of circular pipe, based on two measurements at 90 degrees to each other, shall not vary more than ±2 percent from the calculated inside diameter shown in Tables 7 and 8. The span and rise of pipe-arch, arch, underpass, and other noncircular structures shall be as specified within ±2 percent.

Note 7—The purchaser should consult the fabricator to determine the standard dimensions for the various types of structures, other than circular structures.

Table 7—Diameter of Circular Pipe
150 × 50 mm [6 × 2 in.] Corrugation

15965 [629]	15815 [622.6]

9. WORKMANSHIP

9.1. Plates, fasteners, and accessories shall be of uniform quality consistent with good manufacturing and inspection practices.

10. SAMPLING AND TESTING

10.1. Sampling and testing of plate for chemical composition shall be according to ASTM A 751, and for mechanical requirements shall be according to the procedure for sheet type specimens in T 244. The manufacturer or steel supplier shall make adequate tests and measurements to ensure that the material produced complies with this specification. If tests are provided by the steel supplier and not the manufacturer, the steel supplier shall also submit documentation supporting that they are ISO 9001 certified or equivalent.

10.2. *Coating Mass Determination*—Except as provided herein, coating mass shall be determined according to T 65M/T 65, using a specimen with an area of 3000 mm^2 [5 $in.^2$] or greater. The average coating mass shall be the average of three or more single-spot tests, each taken from different plates in the order. Instead of using the stripping procedure in T 65M/T 65, the mass may be converted from the sum of the readings on both surfaces of the plate by a magnetic coating thickness gauge suitably checked and demonstrated for accuracy (Note 8), 1 mil (0.001 in.) = 0.59 oz/ft^2 [1 μm = 7.1 g/m^2]. Alternately, the coating mass may be determined by the x-ray fluorescence procedure according to ASTM A 754/A 754M. In case of dispute, results of testing according to T 65M/T 65 shall govern.

Note 8—Several magnetic and electromagnetic types of coating thickness gauges are commercially available and are a satisfactory basis for acceptance when properly calibrated just prior to inspection use. (See ASTM E 376.)

10.3. Mechanical properties shall be determined on plate prior to corrugating or other fabricating, except tests may be made after fabrication by the purchaser for tensile and yield strengths.

10.4. Test results, including chemical composition and mechanical properties, shall be maintained by the steel manufacturer or supplier for 7 years. Test results for coating mass or other tests, and a copy of the steel manufacturer's or supplier's certified test results for chemical composition and mechanical properties shall be maintained by the fabricator for 7 years. Such results shall be made available to the purchaser upon request.

---

11. REJECTION AND REHEARING

11.1. Material that fails to conform to the requirements of this specification may be rejected. Rejection should be reported to the manufacturer, supplier, or fabricator promptly and in writing. In case of dissatisfaction with the results of the test, the manufacturer, supplier, or fabricator may make claim for a rehearing.

---

12. CERTIFICATION

12.1. When specified in the purchase order or contract, a steel manufacturer's or supplier's certification or fabricator's certification, or both, shall be furnished to the purchaser stating that samples representing each lot have been tested and inspected in accordance with this specification and have been found to meet the requirements for the material described in the order. When specified in the purchase order or contract, a report of the test results shall be furnished.

---

13. PRODUCT MARKING

13.1. Each plate shall be identified by showing the following:

13.1.1. Name of fabricator;

13.1.2. Specified zinc-coated plate thickness;

13.1.3. Specified coating mass;

13.1.4. Identification showing heat number and coating lot number; the heat number may be omitted if the fabricator's records tie the coating lot number to a specific heat number and manufacturer; and

13.1.5. AASHTO Designation.

13.2. The marking shall be so placed that when the structure is erected, the identification will appear on the inside.

Standard Specification for

Reinforced Concrete Culvert, Storm Drain, and Sewer Pipe

AASHTO Designation: M 170-10[1]
ASTM Designation: C 76-08a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Reinforced Concrete Culvert, Storm Drain, and Sewer Pipe

AASHTO Designation: M 170-10[1]
ASTM Designation: C 76-08a

1. SCOPE

1.1 This specification covers reinforced concrete pipe intended to be used for the conveyance of sewage, industrial wastes, and storm water, and for the construction of culverts.

1.2 A complete metric companion to M 170 has been developed—M 170M; therefore, no metric equivalents are presented in this specification.

Note 1—This specification is a manufacturing and purchase specification only, and does not include requirements for bedding, backfill, or the relationship between field load condition and the strength classification of pipe. However, experience has shown that the successful performance of this product depends upon the proper selection of the class of pipe, type of bedding and backfill, and care that installation conforms to the construction specifications. The owner of the reinforced concrete pipe specified herein is cautioned that he must correlate the field requirements with the class of pipe specified and provide inspection at the construction site.

Note 2—Attention is called to the specification for reinforced concrete D-load culvert, storm drain, and sewer pipe (M 242M/M 242).

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 31M/M 31, Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement
- M 32M/M 32, Steel Wire, Plain, for Concrete Reinforcement
- M 55M/M 55, Steel Welded Wire Reinforcement, Plain, for Concrete
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 85, Portland Cement
- M 86M/M 86, Nonreinforced Concrete Sewer, Storm Drain, and Culvert Pipe
- M 148, Liquid Membrane-Forming Compounds for Curing Concrete (Discontinued)
- M 154, Air-Entraining Admixtures for Concrete
- M 170M, Reinforced Concrete Culvert, Storm Drain, and Sewer Pipe [Metric]
- M 194M/M194, Chemical Admixtures for Concrete
- M 221M/M 221, Steel Welded Wire Reinforcement, Deformed, for Concrete
- M 225M/M 225, Steel Wire, Deformed, for Concrete Reinforcement
- M 240, Blended Hydraulic Cement
- M 242M/M 242, Reinforced Concrete D-Load Culvert, Storm Drain, and Sewer Pipe

- M 262, Concrete Pipe and Related Products
- M 295, Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete
- M 302, Ground Granulated Blast-Furnace Slag for Use in Concrete and Mortars
- T 280, Concrete Pipe, Manhole Sections, or Tile

2.2 *ASTM Standards*:

- A 36/A 36M Standard Specification for Carbon Structural Steel
- A 706/A706M Standard Specification for Low-Alloy Steel Deformed and Plain Bars for Concrete Reinforcement
- C 1017/C 1017M, Standard Specification for Chemical Admixtures for Use in Producing Flowing Concrete
- C 1116, Standard Specification for Fiber-Reinforced Concrete

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. CLASSIFICATION

4.1 Pipe manufactured in accordance with this specification shall be of five classes identified as Class I, Class II, Class III, Class IV, and Class V. The corresponding strength requirements are prescribed in Tables 1 to 5.

Table 1—Design Requirements for Class I Reinforced Concrete Pipe[a]

	Reinforcement, in.^{2}/Linear ft of Pipe Wall									
	Wall A					Wall B				
	Concrete Strength, 4000 psi					Concrete Strength, 4000 psi				
Internal Designated Diameter, in.	Wall Thickness, in.	Circular Reinforcement[b]		Elliptical Reinforcement[c]		Wall Thickness, in.	Circular Reinforcement[b]		Elliptical Reinforcement[c]	
		Inner Cage	Outer Cage				Inner Cage	Outer Cage		
60	5	0.25	0.15	0.28		6	0.21	0.13	0.23

144	[a]	—	—	—	—	[a]	—	—	—	—

[a] For modified or special designs, see Section 7.2 or, with the permission of the owner, utilize the provision of M 242M/M 242. Steel areas may be interpolated between those shown for variations in diameter, loading or wall thickness. Pipe over 96 in. in diameter shall have two circular cages or an inner circular cage plus one elliptical cage.

[b] As an alternative to design requiring both inner and outer circular cages, the reinforcement may be positioned and proportioned in either of the following manners: (1) An inner circular cage plus an elliptical cage such that area of the elliptical cage shall not be less than that specified for the outer cage in the table and the total area of the inner circular cage plus the elliptical gauge shall not be less than that specified for the inner cage in the table; (2) An inner and outer cage plus quadrant mats in accordance with Figure 1; or (3) An inner and outer cage plus an elliptical cage in accordance with Figure 2.

[c] Elliptical and quadrant steel must be held in place by means of holding rods, chairs, or other positive means throughout the entire casting operation.

Notes: See Section 5 for basis of acceptance specified by the owner. The strength test requirements in pounds-force per linear foot of pipe under the three-edge-bearing method shall be either the D-load (test load expressed in pounds-force per linear foot per foot of diameter) to produce a 0.01-in. crack or the D-loads to produce the 0.01-in. crack, and the ultimate load as specified below, multiplied by the internal diameter of the pipe in feet.

D-load to produce a 0.01-in. crack	800
D-load to produce the ultimate load	1200

132	[a]	—	—	—	—	[a]	—	—	—	—	[a]	—	—	—	—
138	[a]	—	—	—	—	[a]	—	—	—	—	[a]	—	—	—	—
144	[a]	—	—	—	—	[a]	—	—	—	—	[a]	—	—	—	—

[a] For modified or special designs, see Section 7.2 or, with the permission of the owner, utilize the provision of M 242M/M 242. Steel areas may be interpolated between those shown for variations in diameter, loading, or wall thickness. Pipe more than 96 in. in diameter shall have two circular cages or an inner circular cage plus one elliptical cage.

[b] As an alternative to designs requiring both inner and outer circular cages, the reinforcement may be positioned and proportioned in either of the following manners: (1) An inner circular cage plus an elliptical cage such that the area of elliptical cage shall not be less than that specified for the outer cage in the table and the total area of the inner circular cage plus the elliptical cage shall not be less than that specified for the inner cage in the table; (2) An inner and outer cage plus quadrant mats in accordance with Figure 1; or (3) An inner and outer cage plus an elliptical cage in accordance with Figure 2.

[c] Elliptical and quadrant steel must be held in place by means of holding rods, chairs, or other positive means throughout the entire casting operation.

[d] For these classes and sizes, the minimum practical steel reinforcement is specified. The specified ultimate strength of non-reinforced pipe is greater than the minimum specified strength for the equivalent diameters.

[e] As an alternative, single cage reinforcement may be used. The reinforcement area in square in. per linear foot shall be 0.20 for Wall B and 0.16 for Wall C.

Notes: See Section 5 for basis of acceptance specified by the owner. The strength test requirement in pound-force per linear foot of pipe under the three-edge-bearing method shall be either the D-load (test load expressed in pound-force per linear foot per foot of diameter) to produce the 0.01-in. crack, or the D-loads to produce the 0.01-in. crack and the ultimate load as specified below, multiplied by the internal diameter of the pipe in feet.

D-load to produce a 0.01-in. crack	1000
D-load to produce the ultimate load	1500

144	[a]	—	—	—	—	[a]	—	—	—	—	[a]	—	—	—	—

[a] For modified or special designs, see Section 7.2 or, with the permission of the owner, utilize the provision of M 242M/M 242. Steel areas may be interpolated between those shown for variations in diameter, loading, or wall thickness. Pipe more than 96 in. in diameter shall have two circular cages or an inner circular cage plus one elliptical cage.

[b] As an alternative to designs requiring both inner and outer circular cages, the reinforcement may be positioned and proportioned in one of the following manners: (1) an inner circular cage plus an elliptical cage such that the area of elliptical cage shall not be less than that specified for the outer cage in the table and the total area of the inner circular cage plus the elliptical cage shall not be less than that specified for the inner cage in the table; (2) an inner and outer cage plus quadrant mats in accordance with Figure 1; or (3) an inner and outer cage plus an elliptical cage in accordance with Figure 2.

[c] Elliptical and quadrant steel must be held in place by means of holding rods, chairs, or other positive means throughout the entire casting operation.

[d] For these classes and sizes, the minimum practical steel reinforcement is specified. The specified ultimate strength of non-reinforced pipe is greater than the minimum specified strength for the equivalent diameters.

[e] As alternative, single cage reinforcement may be used. The reinforcement area in square in. per linear foot shall be 0.30 for Wall B and 0.20 for Wall C.

Notes: See Section 5 for basis of acceptance specified by the owner. The strength test requirements in pounds-force per linear foot of pipe under the three-edge-bearing method shall be either the D-load (test load expressed in pounds-force per linear foot per foot of diameter) to produce the 0.01-in. crack or the D-loads to produce the 0.01-in. crack, and the ultimate load as specified below, multiplied by the internal diameter of the pipe in feet.

D-load to produce a 0.01-in. crack	1350
D-load to produce the ultimate load	2000

[a] For modified or special designs, see Section 7.2 or, with the permission of the owner, utilize the provision of M 242M/M 242. Steel areas may be interpolated between those shown for variations in diameter, loading, or wall thickness. Pipe more than 96 in. in diameter shall have two circular cages or an inner circular cage plus one elliptical cage.

[b] As an alternative to designs requiring both inner and outer circular cages, the reinforcement may be positioned and proportioned in one of the following manners: (1) an inner circular cage plus an elliptical cage such that the area of the elliptical cage shall not be less than that specified for the outer cage in the table and the total area of the inner circular cage plus the elliptical cage shall not be less than that specified for the inner cage in the table; (2) an inner and outer cage plus quadrant mats in accordance with Figure 1; or (3) an inner and outer cage plus an elliptical cage in accordance with Figure 2.

[c] Elliptical and quadrant steel must be held in place by means of holding rods, chairs, or other positive means throughout the entire casting operation.

Continued on next page.

Table 5—Design Requirements for Class V Reinforced Concrete Pipe[a] *(Continued)*

[d] For these classes and sizes, the minimum practical steel reinforcement is specified.

Notes: See Section 5 for basis of acceptance specified by the owner. The strength test requirements in pounds-force per linear foot of pipe under the three-edge-bearing method shall be either the D-load (test load expressed in pounds-force per linear foot per foot of diameter) to produce the 0.01-in. crack or the D-loads to produce the 0.01-in. crack, and the ultimate load as specified below, multiplied by the internal diameter of the pipe in feet.

D-load to produce a 0.01-in. crack	3000
D-load to produce the ultimate load	3750

---

5. BASIS OF ACCEPTANCE

5.1 Unless otherwise designated by the owner at the time of, or before placing an order, there are two separate and alternative bases of acceptance. Independent of the method of acceptance, the pipe shall be designed to meet both the 0.01 in. crack and ultimate strength requirements specified in Tables 1 to 5.

5.1.1 *Acceptance on the Basis of Plant Load-Bearing Tests, Material Tests, and Inspection of Manufactured Pipe for Visual Defects and Imperfections*—Acceptability of the pipe in all diameters and classes produced in accordance with Section 7.1 or Section 7.2 shall be determined by the results of the three-edge-bearing tests as defined in Section 11.3.1; by such material tests as are required in Sections 6.2, 6.3, 6.5, and 6.6; by an absorption test of the concrete from the wall of the pipe for each mix design that is used for an order; and by visual inspection of the finished pipe to determine its conformance with the accepted design and its freedom from defects.

5.1.2 *Acceptance on the Basis of Material Tests and Inspection of Manufactured Pipe for Defects and Imperfections*—Acceptability of the pipe in all diameters and classes produced in accordance with Section 7.1 or Section 7.2 shall be determined by the results of such material tests as are required in Sections 6.2, 6.3, 6.5, and 6.6; by crushing tests on concrete cores or cured concrete cylinders; by an absorption test of the concrete from the wall of the pipe for each mix design that is used for an order; and by inspection of the finished pipe including amount and placement of reinforcement to determine its conformance with the accepted design and its freedom from defects.

5.1.3 When agreed upon by the owner and the manufacturer, any portion or any combination of the tests itemized in Section 5.1.1 or Section 5.1.2 may form the basis of acceptance.

5.2 *Age for Acceptance*—Pipe shall be considered ready for acceptance when it conforms to the requirements as indicated by the specified tests.

---

6. MATERIALS

6.1 The aggregate shall be sized, graded, proportioned, and mixed with such proportions of portland cement, blended hydraulic cement, or portland cement and supplementary cementing materials, or admixtures, or a combination thereof, and water to produce a homogenous concrete mixture of such quality that the pipe will conform to the test and design requirements of the specification. In no case, however, shall the proportion of portland cement, blended hydraulic cement, or a combination of portland cement and supplementary cementing materials be less than 470 lb/yd^3.

6.2 *Cementitious Materials*:

6.2.1 *Cement*—Cement shall conform to the requirements for portland cement of M 85, or shall be portland blast-furnace slag cement, or slag modified portland cement or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash.

6.2.2 *Ground Granulated Blast-Furnace Slag (GGBFS)*—GGBFS shall conform to the requirements of grade 100 or 120 of M 302.

6.2.3 *Fly Ash*—Fly ash shall conform to the requirements of Class F or Class C of M 295.

6.2.4 *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

6.2.4.1 Portland cement only,

6.2.4.2 Portland-blast furnace slag cement only,

6.2.4.3 Slag modified portland cement only,

6.2.4.4 Portland-pozzolan cement only,

6.2.4.5 A combination of portland cement and ground granulated blast-furnace slag,

6.2.4.6 A combination of portland cement and fly ash, or

6.2.4.7 A combination of portland cement, ground granulated blast-furnace slag (not to exceed 25 percent of the total cementitious weight) and fly ash (not to exceed 25 percent of the total cementitious weight).

6.3 *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirement for gradation shall not apply.

6.4 *Admixtures and Blends*—The following admixtures and blends are allowed with the approval of the owner:

6.4.1 Air-entraining admixture conforming to M 154;

6.4.2 Chemical admixtures conforming to M 194;

6.4.3 Chemical admixtures for use in producing flowing concrete conforming to ASTM C 1017/C 1017M; and

6.4.4 Chemical admixture or blend approved by the owner.

6.5 *Steel Reinforcement*—Reinforcement shall consist of wire conforming to M 32M/M 32 or M 225M/M 225; or of wire fabric conforming to M 55M/M55 or M 221M/M 221; or of bars conforming to M 31M/M 31 Grade 40 or 60, ASTM A36/A 36M, or ASTM A 706/A 706M Grade 60.

6.6 *Synthetic Fibers*—Collated fibrillated virgin polypropylene fibers are not prohibited from being used, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be used.

7. DESIGN

7.1 *Design Tables*—The diameter, wall thickness, compressive strength of the concrete, and the area of the circumferential reinforcement shall be as prescribed for Class I to V in Tables 1 to 5, except as provided in Section 7.2.

7.1.1 The reinforcement as presented in the tables herein allows single circular cage reinforcement, or separate inner and outer circular cage reinforcement or a combination thereof. Footnotes to the tables are intended to clarify tabulated requirements, or provide acceptable alternative reinforcement designs, either of which are to be considered applicable and binding as if they were contained in the body of the specification.

7.2 *Modified and Special Designs*:

7.2.1 If permitted by the owner, the manufacturer may request approval by the owner of modified designs that differ from the designs in Section 7.1; or special designs for sizes and loads beyond those shown in Tables 1 to 5, Section 7.1, or special designs for pipe sizes that do not have steel reinforcement areas shown in Tables 1 to 5 of Section 7.1.

7.2.2 Such modified or special designs shall be based on rational or empirical evaluations of the ultimate strength and cracking behavior of the pipe and shall fully describe to the owner any deviations from the requirements of Section 7.1. The descriptions of modified or special designs shall include the wall thickness, the concrete strength, and the area, type, placement, number of layers, and strength of the steel reinforcement.

7.2.3 The manufacturer shall submit to the owner proof of the adequacy of the proposed modified or special design. Such proof may comprise the submission of certified three-edge-bearing tests already made, which are acceptable to the owner or, if such three-edge-bearing tests are not available or acceptable, the manufacturer may be required to perform proof tests on sizes and classes selected by the owner to demonstrate the adequacy of the proposed design.

7.2.4 Such pipe must meet all of the test and performance requirements specified by the owner in accordance with Section 5.

7.3 *Area*—In this specification, when the word “area” is not described by adjectives, such as cross-section or single wire, it shall be understood to be the cross-sectional area of reinforcement per unit lengths of pipe.

8. REINFORCEMENT

8.1 *Circumferential Reinforcement*—A line of circumferential reinforcement for any given total area may be composed of two layers for pipe with wall thicknesses of less than 7 in. or three layers for pipe with wall thicknesses of 7 in. or greater. The layers shall not be separated by more than the thickness of one longitudinal plus $^1/_4$ in. The multiple layers shall be fastened together to form a single cage. All other specification requirements such as laps, welds, and tolerances of placement in the wall of the pipe, etc., shall apply to this method of fabricating a line of reinforcement.

8.1.1 Where one line of circular reinforcement is used, it shall be placed from 35 to 50 percent of the wall thickness from the inner surface of the pipe, except that for wall thicknesses less than $2^1/_2$ in., the protective cover of the concrete over the circumferential reinforcement in the wall of the pipe shall be $^3/_4$ in.

8.1.2 In pipe having two lines of circular reinforcement, each line shall be so placed that the protective covering of concrete over the circumferential reinforcement in the wall of the pipe shall be 1 in.

8.1.3 In pipe having elliptical reinforcement with wall thicknesses $2^1/_2$ in. or greater, the reinforcement in the wall of the pipe shall be so placed that the protective covering of concrete over the circumferential reinforcement shall be 1 in. from the inner surface of the pipe at the vertical diameter and 1 in. from the outer surface of the pipe at the horizontal diameter. In pipe having elliptical reinforcement with wall thicknesses less than $2^1/_2$ in., the protective covering of the concrete shall be $^3/_4$ in. at the vertical and horizontal diameters.

8.1.4 The location of the reinforcement shall be subject to the permissible variations in dimensions given in Section 12.5.

8.1.5 The spacing center-to-center of circumferential reinforcement in a cage shall not exceed 4 in. for pipe up to and including pipe having a 4-in. wall thickness nor exceed the wall thickness for larger pipe, and shall in no case exceed 6 in.

8.1.6 Where the wall reinforcement does not extend into the joint, the maximum longitudinal distance to the last circumferential from the inside shoulder of the bell or the shoulder of the spigot shall be 3 in., except that if this distance exceeds one-half the wall thickness, the pipe wall shall contain at least a total reinforcement area of the minimum specified area per linear foot times the laying length of the pipe section. The minimum cover on the last circumferential near the spigot shoulder shall be $^1/_2$ in.

8.1.6.1 Where reinforcement is in the bell or spigot the minimum end cover on the last circumferential shall be $^1/_2$ in. in the bell or $^1/_4$ in. in the spigot.

8.1.7 The continuity of the circumferential reinforcing steel shall not be destroyed during the manufacture of the pipe, except that when agreed upon by the owner, lift eyes or holes may be provided in each pipe for the purpose of handling.

8.1.8 If splices are not welded, the reinforcement shall be lapped not less than 20 diameters for deformed bars and deformed cold-worked wire, and 40 diameters for plain bars and cold-drawn wire. In addition, where lapped cages of welded-wire fabric are used without welding, the lap shall contain a longitudinal wire.

8.1.8.1 When splices are welded and are not lapped to the minimum requirements above, pull tests of representative specimens shall develop at least 50 percent of the minimum specified strength of the steel, and there shall be a minimum lap of 2 in. For butt-welded splices in bars or wire, permitted only with helically wound cages, pull tests of representative specimens shall develop at least 75 percent of the minimum specified strength of the steel.

8.2 *Longitudinal Reinforcement*—Each line of circumferential reinforcement shall be assembled into a cage that shall contain sufficient longitudinal bars or members, to maintain the reinforcement in shape and in position within the form to comply with permissible variations in Section 8.1. The exposure of the ends of longitudinals, stirrups, or spacers that have been used to position the cages during the placement of the concrete shall not be a cause for rejection.

8.3 *Joint Reinforcement*—The length of the joint as used herein means the inside length of the bell or the outside length of the spigot from the shoulder to the end of the pipe section. The end distances or cover on the end circumferential shall apply to any point on the circumference of the pipe or joint. When convoluted reinforcement is used, these distances and reinforcement areas shall be taken from the points on the convolutions closest to the end of the pipe section. Unless otherwise permitted by the owner, the following requirements for joint reinforcement shall apply.

8.3.1 *Joint Reinforcement for Non-Rubber Gasket Joints*:

8.3.1.1 For pipe 36 in. and larger in diameter, either the bell or spigot shall contain circumferential reinforcement. This reinforcement shall be an extension of a wall cage, or may be a separate cage of at least the area per foot of that specified for the outer cage or one-half of that specified for single cage wall reinforcement, whichever is less.

8.3.1.2 Where bells or spigots require reinforcement, the maximum end cover on the last circumferential shall be one-half the length of the joint or 3 in., whichever is less.

8.3.2 *Joint Reinforcement for Rubber Gasket Joints*:

8.3.2.1 For pipe 12 in. and larger in diameter, the bell ends shall contain circumferential reinforcement. This reinforcement shall be an extension of the outer cage or a single wall cage, whichever is less, or may be a separate cage of at least the same area per foot with longitudinals as required in Section 8.2. If a separate cage is used, the cage shall extend into the pipe with the last circumferential wire at least one in past the inside shoulder where the pipe barrel meets the bell of the joint.

8.3.2.2 Where bells require reinforcement, the maximum end cover on the last circumferential shall be 2 in.

9. JOINTS

9.1 The joints shall be of such design and the ends of the concrete pipe sections so formed that the pipe can be laid together to make a continuous line of pipe compatible with the permissible variations given in Section 12.

10. MANUFACTURE

10.1 *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water–cementitious materials ratio not exceeding 0.53 by weight. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 470 lb/yd^3 unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this specification.

10.2 *Curing*—Pipe shall be subjected to any one of the methods of curing described in Sections 10.2.1 to 10.2.4 or to any other method or combination of methods approved by the owner, that will give satisfactory results. The pipe shall be cured for a sufficient length of time so that the specified D-load is obtained when acceptance is based on Section 5.1.1 or so that the concrete will develop the specified compressive strength at 28 days or less when acceptance is based on Section 5.1.2.

10.2.1 *Steam Curing*—Pipe may be placed in a curing chamber, free of outside drafts, and cured in a moist atmosphere maintained by the injection of steam for such time and such temperature as may be needed to enable the pipe to meet the strength requirements. The curing chamber shall be so constructed as to allow full circulation of steam around the entire pipe.

10.2.2 *Water Curing*—Concrete pipe may be water cured by covering with water-saturated material or by a system of perforated pipes, mechanical sprinklers, porous hose, or by any other approved method that will keep the pipe moist during the specified curing period.

10.2.3 The manufacturer may, at the manufacturer's option, combine the methods described in Sections 10.2.1 to 10.2.4, provided the required concrete compressive strength is attained.

10.2.4 A sealing membrane conforming to the requirements of M 148 may be applied and should be left intact until the required strength requirements are met. The concrete at the time of application shall be within 10ºF of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

11. PHYSICAL REQUIREMENTS

11.1 *Test Specimens*—The specified number of pipe required for the tests shall be furnished without charge by the manufacturer and shall be selected at random by the owner, and shall be pipe that would not otherwise be rejected under this specification. The selection shall be made at the point or points designated by the owner when placing the order. Unless designated otherwise by the owner in the order, the manufacturer shall select the type of test (external load crushing strength test, compression test of cylinders or compression test of cores) to be used to determine the acceptability of the pipe strength. Pipe that fails to meet the strength requirements as determined by the selected test type may not be retested using one of the other test types without approval of the owner.

11.2 *Number and Type of Tests Required for Various Delivery Schedules*:

11.2.1 *Preliminary Tests for Extended Delivery Schedules*—An owner of pipe, whose needs require shipments at intervals over extended periods of time, shall be entitled to such tests, preliminary to delivery of pipe, as are required by the type of basis of acceptance specified by the owner in Section 5, of not more than three sections of pipe covering each size in which the owner is interested.

11.2.2 *Additional Tests*—After the preliminary tests described in Section 11.2.1, an owner shall be entitled to additional tests at such times as the owner may deem necessary, provided that the total number of pipe tested (including preliminary tests) shall not exceed one pipe or one percent, whichever is the greater, of each size of pipe delivered.

11.3 *External Load Crushing Strength*:

11.3.1 The load to produce a 0.01-in. crack or the ultimate load, as determined by the three-edge-bearing method as described in T 280, shall be not less than that prescribed in Tables 1 to 5 for each respective class of pipe. Pipe that support the prescribed load to produce the 0.01-in. crack and do not show a wider crack shall be considered to have met the test requirement. It is not a requirement of this specification that the pipe be cracked or loaded to failure during these tests. Pipe that have been tested only to the formation of a 0.01-in. crack and that meet the 0.01-in. crack or lesser crack load requirements shall be accepted for use. Three-edge-bearing test to ultimate load is not required for any class of pipe 60 in. or less in diameter listed in Tables 1 to 5 provided all other requirements of this specification are met.

Note 3—As used in this specification, the 0.01-in. crack is a test criterion for pipe tested in the three-edge-bearing test and is not intended as an indication of overstressed or failed pipe under installed conditions.

11.3.2 *Retests of Pipe Not Meeting the External Load Crushing Strength Requirements*—Pipe shall be considered as meeting the strength requirements when all test specimens conform to the strength requirements. Should any of the test specimens fail to meet the strength requirements, the manufacturer shall be allowed a retest on two additional specimens for each specimen that failed, and the pipe shall be acceptable only when all of the retest specimens meet the strength requirements.

11.4 *Type of Specimen*—Compression tests determining concrete compressive strength may be made on either standard rodded concrete cylinders or concrete cylinders compacted and cured in like manner as the pipe, or on cores drilled from the pipe.

11.5 *Compression Testing of Cylinders*:

11.5.1 *Cylinder Production*—Cylinders shall be prepared, cured, and tested in accordance with Section 11 of T 280.

11.5.2 *Number of Cylinders*—Prepare no fewer than five test cylinders from a group (one day's production of each concrete strength) of pipe sections.

11.5.3 *Acceptability on the Basis of Cylinder Test Results*:

11.5.3.1 When the compressive strengths of all cylinders tested for a group are equal to or greater than the required concrete strength, the compressive strength of concrete in the group of pipe sections shall be accepted.

11.5.3.2 When the average compressive strength of all cylinders tested is equal to or greater than the required concrete strength, and not more than 10 percent of the cylinders tested have a compressive strength less than the required concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the required concrete strength, then the group shall be accepted.

11.5.3.3 The pipe shall be acceptable only when the compressive strength of the cylinders tested conforms to the acceptance criteria stated in Section 11.5.3.1 or Section 11.5.3.2.

11.6 *Compression Testing of Cores*:

11.6.1 *Obtaining Cores*—Cores shall be obtained and prepared in accordance with Section 6 of T 280.

11.6.2 *Number of Cores*—One core shall be taken from a pipe section selected at random from each day's production run of a single concrete strength.

11.7 *Acceptability on the Basis of Core Test Results*:

11.7.1 When the compressive strength of a core tested for a group of pipe sections is equal to or greater than the required concrete strength, the compressive strength of the concrete for the group is acceptable.

11.7.2 If the compressive strength of the core tested is less than the required concrete strength, two additional cores shall be taken from that pipe section and tested. Concrete represented by these three core tests shall be considered acceptable if: (1) the average of three core strengths is equal to at least 85 percent of the required strength, and (2) no single core is less than 75 percent of the required strength.

11.7.3 If the compressive strength of the three cores does not meet the requirements of Section 11.7.2, the pipe section from which the core was taken shall be rejected. Two pipe sections from the remainder of the group shall be selected at random and cored and tested for conformance with either Section 11.7.1 or Section 11.7.2. If both pipe sections meet the core strength requirements of either Section 11.7.1 or Section 11.7.2, the remainder of the group shall be acceptable. If both pipe sections do not meet the test strength requirement, the remainder of the group shall be either rejected or, at the option of the manufacturer, each pipe section of the remaining group shall be cored and accepted individually and any of the pipe sections that have core strengths less than the requirements of Section 11.7.1 or Section 11.7.2 shall be rejected.

11.8 *Plugging Core Holes*—Core holes shall be plugged and sealed by the manufacturer in a manner such that the pipe section will meet all of the requirements of this specification. Pipe sections so plugged and sealed shall be considered satisfactory for use.

11.9 *Absorption*—The absorption of a sample from the wall of the pipe, as determined in accordance with T 280, shall not exceed nine percent of the dry mass. Each sample shall have a minimum mass of 1.0 kg, shall be free of visible cracks, and shall represent the full wall thickness of the pipe. When the initial absorption sample from a pipe fails to conform to this specification, the absorption test shall be made on another sample from the same pipe and the results of the retest shall be substituted for the original test results.

11.10 *Retests of Pipe*—When not more than 20 percent of the concrete specimens fail to pass the requirements of this specification, the manufacturer may cull the project stock and may eliminate whatever quantity of pipe desired and shall mark those pipe so that they will not be shipped. The required tests shall be made on the balance of the order and the pipes shall be accepted if they conform to the requirements of this specification.

11.11 *Test Equipment*—Every manufacturer furnishing pipe under this specification shall furnish all facilities and personnel necessary to carry out the tests described in T 280.

12. PERMISSIBLE VARIATIONS

12.1 *Internal Diameter*—The internal diameter of 12 through 24-in. pipe shall vary not more than ±2 percent of the design diameter for 12-in. pipe and ±1.5 percent for 24 in. pipe with intermediate sizes variation being a linear scale between 2 percent and 1.5 percent. The internal diameter of sizes 27 in. and larger shall not vary by more than ±1 percent of the design diameter or $\pm{}^{3}/_{8}$ in., whichever is greater. These diameter requirements are based on the average of four diameter measurements at a distance of 12 in. from the end of the bell or spigot end of the pipe. Diameter verification shall be made on the number of pipe selected for test per section 11.

12.2 *Wall Thickness*—The wall thickness shall not vary more than shown in the design or specified wall by more than ±5 percent or ${}^{3}/_{16}$ in., whichever is greater. A specified wall thickness greater than required in the design is not cause for rejection. Pipe having localized variations in wall thickness exceeding those specified above shall be accepted if the three-edge-bearing strength and minimum steel cover requirements are met.

12.3 *Length of Two Opposite Sides*—Variations in the laying length of two opposite sides of the pipe shall not be more than ${}^{1}/_{4}$ in. for all sizes through 24-in. internal diameter, and not more than ${}^{1}/_{8}$ in./ft for all sizes larger with a maximum of ${}^{5}/_{8}$ in. in any length of pipe through 84-in. internal diameter, and a maximum of ${}^{3}/_{4}$ in. for 90-in. internal diameter or larger, except where beveled end pipe for laying on curves is specified by the owner.

12.4 *Length of Pipe*—The underrun in length of a section of pipe shall not be more than $^1/_8$ in./ft with a maximum of $^1/_2$ in. in any length of pipe. Regardless of the underrun or overrun in any section of the pipe, the end cover requirements of Sections 8 and 12 shall apply.

12.5 *Position or Area of Reinforcement*:

12.5.1 *Position*—The maximum variation in the position of a line of circumferential reinforcement shall be ±10 percent of the wall thickness or $\pm^1/_2$ in., whichever is greater. Pipe having variations in the position of a line of circumferential reinforcement exceeding those specified above shall be accepted if the three-edge-bearing strength requirements obtained on a representative specimen are met. In no case, however, shall the cover over the circumferential reinforcement be less than $^1/_4$ in. as measured to the end of the spigot or $^1/_2$ in. as measured to any other surface. The preceding minimum cover limitations do not apply to mating surfaces of non-rubber gasket joints or gasket grooves in rubber gasket joints. If convoluted reinforcement is used, the convoluted circumferential end wire may be at the end surface of the joint providing the alternate convolutions have at least 1-in. cover from the end surface of the joint.

12.5.2 *Area of Reinforcement*—Reinforcement will be considered as meeting the design requirements if the area, computed on the basis of nominal area of the wire or bars used, equals or exceeds the requirements of Sections 7.1 or 7.2. Actual area of the reinforcing used may vary from the nominal area according to permissible variations of the standard specifications for the reinforcing. When inner cage and outer cage reinforcing is used, the inner cage nominal area may vary to the lower limit of 85 percent of the elliptical nominal area and the outer cage nominal area may vary to the lower limit of 51 percent of the elliptical nominal area provided that the total nominal area of the inner cage plus the outer cage shall not vary beyond the lower limit of 140 percent of the elliptical nominal area.

13. REPAIRS

13.1 Pipe may be repaired, if necessary, because of imperfections in manufacture or damage during handling and will be acceptable if, in the opinion of the owner, the repaired pipe conforms to the requirements of this specification.

14. INSPECTION

14.1 The quality of materials, the process of manufacture, and the finished pipe shall be subject to inspection and approval by the owner.

15. REJECTION

15.1 Pipe shall be subject to rejection if it fails to conform to any of the specification requirements. Individual sections of pipe may be rejected because of any of the following:

15.1.1 Fractures or cracks passing through the wall, except for a single end crack that does not exceed the depth of the joint.

15.1.2 Defects that indicate proportioning, mixing, and molding not in compliance with Section 10.1 or surface defects indicating honey-combed or open texture that would adversely affect the function of the pipe.

15.1.3 The ends of the pipe are not normal to the walls and centerline of the pipe, within the limits of variations given in Sections 12.3 and 12.4.

15.1.4 Damaged or cracked ends where such damage would prevent making a satisfactory joint.

15.1.5 Any continuous crack having a surface width of 0.01 in. or more and extending for a length of 12 in. or more, regardless of position in the wall of the pipe.

16. PRODUCT MARKING

16.1 The following information shall be legibly marked on each section of pipe:

16.1.1 The pipe class and specification designation,

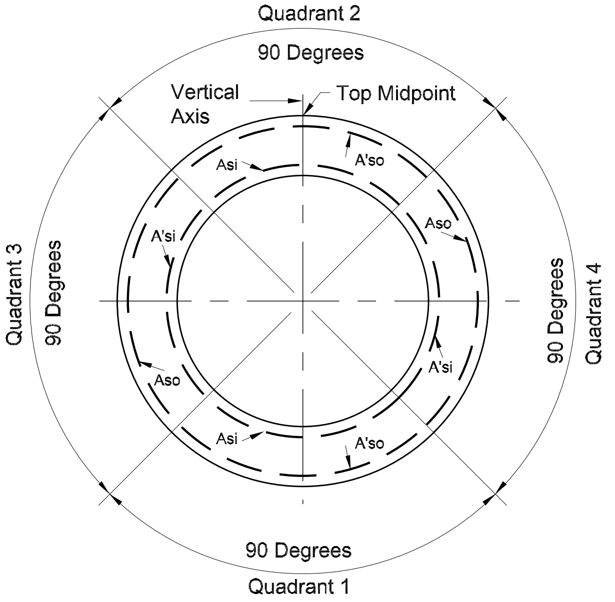
16.1.2 The date of manufacture,

16.1.3 The name or trademark of the manufacturer, and

16.1.4 Identification of plant.

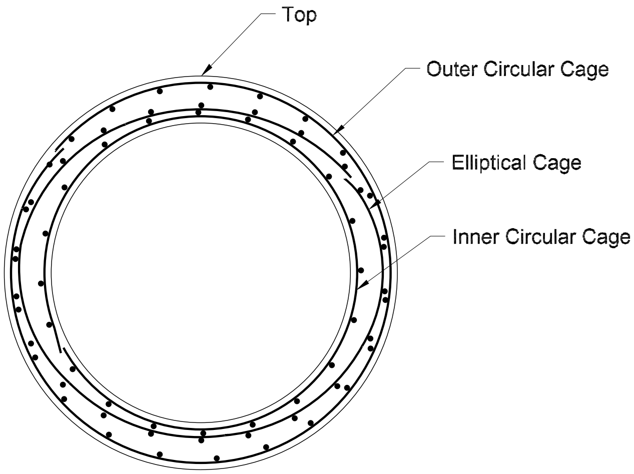
16.2 One end of each section of pipe with elliptical or quadrant reinforcement shall be clearly marked during the process of manufacturing or immediately thereafter, on the inside and the outside of opposite walls along the minor axis of the elliptical reinforcing or along the vertical axis for quadrant reinforcing.

16.3 Markings shall be indented on the pipe section or painted thereon with waterproof paint.



Notes:
1. The total reinforcement area (Asi) of the inner cage plus the quadrant mat in Quadrants 1 and 2 shall not be less than that specified for the inner cage in Tables 1 to 5.
2. The total reinforcement area (Aso) of the outer cage plus the quadrant mat in Quadrants 3 and 4 shall not be less than that specified for the outer cage in Tables 1 to 5.
3. The total reinforcement area (A′si) of the inner cage in Quadrants 3 and 4 shall not be less than 25 percent of that specified for the inner cage in Tables 1 to 5.
4. The total reinforcement area (A′so) of the outer cage in Quadrants 1 and 2 shall not be less than 25 percent of that specified for the outer cage in Tables 1 to 5.
5. If the reinforcement area (A′so) of the outer cage in Quadrants 1 and 2 is less than 50 percent of that specified for the outer cage in Tables 1 to 5, the quadrant mats used for the outer cage in Quadrants 3 and 4 shall extend into Quadrants 1 and 2 not less than a distance equal to the wall thickness as specified in Tables 1 to 5.

Figure 1—Quadrant Reinforcement



Notes:
1. The total reinforcement area of the inner circular cage and the elliptical cage shall not be less than that specified for the inner cage in Tables 1 to 5.
2. The total reinforcement area of the outer circular cage and the elliptical cage shall not be less than that specified for the outer cage in Tables 1 to 5.

Figure 2—Triple Cage Reinforcement

17. KEYWORDS

17.1 Circular pipe; culvert; D-load; pipe; reinforced concrete; sewer pipe; storm drain.

---

[1] Agrees with ASTM C 76-08a except for limiting the absorption testing to the five-hour boil method, the manufacturer is not afforded the option to supply SI sized pipe when the order is placed in inch-pound units, the use of synthetic fibers are at the option of the owner, and the method of acceptance is changed as per Sections 11.1, 11.5.3.3, and 11.7.3.

Standard Specification for

Reinforced Concrete Culvert, Storm Drain, and Sewer Pipe [Metric]

AASHTO Designation: M 170M-10[1]
ASTM Designation: C 76M-08a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Reinforced Concrete Culvert, Storm Drain, and Sewer Pipe [Metric]

AASHTO Designation: M 170M-10[1]
ASTM Designation: C 76M-08a

1. SCOPE

1.1 This specification covers reinforced concrete pipe intended to be used for the conveyance of sewage, industrial wastes, and storm water, and for the construction of culverts.

1.2 This specification is the metric counterpart of M 170.

Note 1—This specification is a manufacturing and purchase specification only, and does not include requirements for bedding, backfill, or the relationship between field load condition and the strength classification of pipe. However, experience has shown that the successful performance of this product depends upon the proper selection of the class of pipe, type of bedding and backfill, controlled manufacture in the plant, and care that installation conforms to the construction specifications. The owner of the reinforced concrete pipe specified herein is cautioned that he must correlate the field requirements with the class of pipe specified and provide inspection at the construction site.

Note 2—Attention is called to the specification for reinforced concrete D-load culvert, storm drain, and sewer pipe (M 242M/M 242).

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. CLASSIFICATION

4.1 Pipe manufactured in accordance with this specification shall be of five classes identified as Class I, Class II, Class III, Class IV, and Class V. The corresponding strength requirements are prescribed in Tables 1 to 5.

Table 1—Design Requirements for Class I Reinforced Concrete Pipe[a]

	Reinforcement, cm^2/Linear m of Pipe Wall

3150	[a]	—	—	—	—	[a]	—	—	—	—
3300	[a]	—	—	—	—	[a]	—	—	—	—
3450	[a]	—	—	—	—	[a]	—	—	—	—
3600	[a]	—	—	—	—	[a]	—	—	—	—

[a] For modified or special designs, see Section 7.2 or, with the permission of the owner, utilize the provision of M 242M/M 242. Steel areas may be interpolated between those shown for variations in diameter, loading or wall thickness. Pipe more than 2400 mm in diameter shall have two circular cages or an inner circular cage plus one elliptical cage.

[b] As an alternative to design requiring both inner and outer circular cages, the reinforcement may be positioned and proportioned in one of the following manners: (1) An inner circular cage plus an elliptical cage such that area of the elliptical cage shall not be less than that specified for the outer cage in the table and the total area of the inner circular cage plus the elliptical cage shall not be less than that specified for the inner cage in the table; (2) An inner and outer cage plus quadrant mats in accordance with Figure 1; or (3) An inner and outer cage plus an elliptical cage in accordance with Figure 2.

[c] Elliptical and quadrant steel must be held in place by means of holding rods, chairs, or other positive means throughout the entire casting operation.

Note: See Section 5 for basis of acceptance specified by the owner. The strength test requirements in newtons per linear meter of pipe under the three-edge-bearing method shall be either the D-load (test load expressed in newtons per linear meter per millimeter of diameter) to produce the 0.3-mm crack, or the D-loads to produce the 0.3mm crack and the ultimate load as specified below, multiplied by the internal diameter of the pipe in millimeters.

D-load to produce a 0.3-mm crack	40.0
D-load to produce the ultimate load	60.0

Continued on next page.

Table 2—Design Requirements for Class II Reinforced Concrete Pipe[a] *(Continued)*

[a] For modified or special designs, see Section 7.2 or, with the permission of the owner, utilize the provision of M 242M/M 242. Steel areas may be interpolated between those shown for variations in diameter, loading, or wall thickness. Pipe more than 2400 mm in diameter shall have two circular cages or an inner circular cage plus one elliptical cage.

[b] As an alternative to designs requiring both inner and outer circular cages, the reinforcement may be positioned and proportioned in one of the following manners: (1) An inner circular cage plus an elliptical cage such that the area of elliptical cage shall not be less than that specified for the outer cage in the table and the total area of the inner circular cage plus the elliptical cage shall not be less than that specified for the inner cage in the table; (2) An inner and outer cage plus quadrant mats in accordance with Figure 1; or (3) An inner and outer cage plus an elliptical cage in accordance with Figure 2.

[c] Elliptical and quadrant steel must be held in place by means of holding rods, chairs, or other positive means through the entire casting operation.

[d] For these classes and size, the minimum practical steel reinforcement is specified. The specified ultimate strength of nonreinforced pipe is greater than the minimum specified strength for the equivalent diameters.

[e] As an alternative, single cage reinforcement may be used. The reinforcement area in square centimeters per linear meter shall be 4.2 for Wall B and 3.4 for Wall C.

Note: See Section 5 for basis of acceptance specified by the owner. The strength test requirement in newtons per linear meter of pipe under the three-edge-bearing method shall be either the D-load (test load expressed in newtons per linear meter per millimeter of diameter) to produce the 0.3-mm crack, or the D-loads to produce the 0.3-mm crack, and the ultimate load as specified below, multiplied by the internal diameter of the pipe in millimeter.

D-load to produce a 0.3-mm crack	50.0
D-load to produce the ultimate load	75.0

[a] For modified or special designs, see Section 7.2 or with the permission of the owner utilize the provision of M 242M/M 242. Steel areas may be interpolated between those shown for variations in diameter, loading, or wall thickness. Pipe more than 2400 mm in diameter shall have two circular cages or an inner circular cage plus one elliptical cage.

[b] As an alternative to designs requiring both inner and outer circular cages the reinforcement may be positioned and proportioned in one of the following manners: (1) An inner circular cage plus an elliptical cage such that the area of elliptical cage shall not be less than that specified for the outer cage in the table and the total area of the inner circular cage plus the elliptical cage shall not be less than that specified for the inner cage in the table; (2) An inner and outer cage plus quadrant mats in accordance with Figure 1; or (3) An inner and outer cage plus an elliptical cage in accordance with Figure 2.

[c] Elliptical and quadrant steel must be held in place by means of holding rods, chairs, or other positive means throughout the entire casting operation.

[d] For these classes and sizes, the minimum practical steel reinforcement is specified. The specified ultimate strength of non-reinforced pipe is greater than the minimum specified strength for the equivalent diameters.

[e] As an alternative, single cage reinforcement may be used. The reinforcement area in square centimeters per linear meter shall be 6.4 for Wall B and 4.2 for Wall C.

Note: See Section 5 for basis of acceptance specified by the owner. The strength test requirements in newtons per linear meter of pipe under the three-edge-bearing method shall be either the D-load (test load expressed in newtons per linear meter per millimeter of diameter) to produce the 0.3-mm crack, or the D-loads to produce the 0.3-mm crack, and the ultimate load as specified below, multiplied by the internal diameter of the pipe in millimeters.

D-load to produce a 0.3-mm crack	65.0
D-load to produce the ultimate load	100.0

[a] For modified or special designs, see Section 7.2 or, with the permission of the owner, utilize the provision of M 242M/M 242. Steel areas may be interpolated between those shown for variations in diameter, loading, or wall thickness. Pipe more than 2400 mm in diameter shall have two circular cages or an inner circular cage plus one elliptical cage.

[b] As an alternative to designs requiring both inner and outer circular cages the reinforcement may be positioned and proportioned in one of the following manners: (1) an inner circular cage plus an elliptical cage such that the area of elliptical cage shall not be less than that specified for the outer cage in the table and the total area of the inner circular cage plus the elliptical cage shall not be less than that specified for the inner cage in the table; (2) an inner and outer cage plus quadrant mats in accordance with Figure 1; or (3) an inner and outer cage plus an elliptical cage in accordance with Figure 2.

Continued on next page.

Table 5—Design Requirements for Class V Reinforced Concrete Pipe[a] *(Continued)*

[c] Elliptical and quadrant steel must be held in place by means of holding rods, chairs, or other positive means throughout the entire casting operation.

[d] For these classes and sizes, the minimum practical steel reinforcement is specified.

Notes: See Section 5 for basis of acceptance specified by the owner. The strength test requirements in newtons per linear meter of pipe under the three-edge-bearing method shall be either the D-load (test load expressed in newtons per linear meter per millimeter of diameter) to produce the 0.3-mm crack, or the D-loads to produce the 0.3-mm crack, and the ultimate load as specified below, multiplied by the internal diameter of the pipe in millimeters.

D-load to produce a 0.3-mm crack	140.0
D-load to produce the ultimate load	175.0

5. BASIS OF ACCEPTANCE

5.1 Unless otherwise designated by the owner at the time of, or before placing an order, there are two separate and alternative bases of acceptance. Independent of the method of acceptance, the pipe shall be designed to meet both the 0.3-mm crack and ultimate strength requirements specified in Tables 1 to 5.

5.1.1 *Acceptance on the Basis of Plant Load-Bearing Tests, Material Tests, and Inspection of Manufactured Pipe for Visual Defects and Imperfections*—Acceptability of the pipe in all diameters and classes produced in accordance with Section 7.1 or Section 7.2 shall be determined by the results of the three-edge-bearing tests as defined in Section 11.3.1; by such material tests as are required in Sections 6.2, 6.3, 6.5, and 6.6; by an absorption test of the concrete from the wall of the pipe for each mix design that is used on an order; and by visual inspection of the finished pipe to determine its conformance with the accepted design and its freedom from defects.

5.1.2 *Acceptance on the Basis of Material Tests and Inspection of Manufactured Pipe for Defects and Imperfections*—Acceptability of the pipe in all diameters and classes produced in accordance with Section 7.1 or Section 7.2 shall be determined by the results of such material tests as are required in Sections 6.2, 6.3, 6.5, and 6.6; by crushing tests on concrete cores or cured concrete cylinders; by an absorption test of the concrete from the wall of the pipe for each mix design that is used on an order; and by inspection of the finished pipe including amount and placement of reinforcement to determine its conformance with the accepted design and its freedom from defects.

5.1.3 When agreed upon by the owner and the manufacturer, any portion or any combination of the tests itemized in Section 5.1.1 or Section 5.1.2 may form the basis of acceptance.

5.2 *Age for Acceptance*—Pipe shall be considered ready for acceptance when it conforms to the requirements as indicated by the specified tests.

6. MATERIALS

6.1 *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water, in which steel has been embedded in such a manner that the steel and concrete act together.

6.2 *Cementitious Materials*:

6.2.1 *Cement*—Cement shall conform to the requirements for portland cement of M 85, or shall be portland blast-furnace slag cement, or slag modified portland cement, or portland-pozzolan cement conforming to the requirements of M 240 except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash.

6.2.2 *Ground Granulated Blast-Furnace Slag (GGBFS)*—GGBFS shall conform to the requirements of grade 100 or 120 of M 302.

6.2.3 *Fly Ash*—Fly ash shall conform to the requirements of Class F or Class C of M 295.

6.2.4 *Admixtures and Blends*—The following admixtures and blends are allowable with the approval of the owner:

6.2.4.1 Portland cement only,

6.2.4.2 Portland blast-furnace slag cement only,

6.2.4.3 Slag modified portland cement only,

6.2.4.4 Portland-pozzolan cement only,

6.2.4.5 A combination of portland cement and ground granulated blast-furnace slag,

6.2.4.6 A combination of portland cement and fly ash, or

6.2.4.7 A combination of portland cement, ground granulated blast-furnace slag (not to exceed 25 percent of the total cementitious weight) and fly ash (not to exceed 25 percent of the total cementitious weight.)

6.3 *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirement for gradation shall not apply.

6.4 *Admixtures and Blends*—Admixtures and blends may be used with the approval of the owner.

6.5 *Steel Reinforcement*—Reinforcement shall consist of wire conforming to M 32M/M 32 or M 225M/M 225; or of wire fabric conforming to M 55M/M 55 or M 221M/M 221; or of bars conforming to M 31M/M 31 Grade 280 or 420, ASTM A36/A 36M, or ASTM A 706/A 706M Grade 420.

6.6 *Synthetic Fibers*—Collated fibrillated virgin polypropylene fibers are not prohibited from being used, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM Specification C 1116 shall be used.

7. DESIGN

7.1 *Design Tables*—The diameter, wall thickness, compressive strength of the concrete, and the area of the circumferential reinforcement shall be as prescribed for Class I to V in Tables 1 to 5, except as provided in Section 7.2.

7.1.1 The reinforcement as presented in the tables herein allows single circular cage reinforcement, or separate inner and outer circular cage reinforcement or a combination thereof. Footnotes to the tables are intended to clarify tabulated requirements, or provide acceptable alternative reinforcement designs, either of which are to be considered applicable and binding as if they were contained in the body of the specification.

7.2 *Modified and Special Designs*:

7.2.1 If permitted by the owner the manufacturer may request approval by the owner of modified designs that differ from the designs in Section 7.1; or special designs for sizes and loads beyond those shown in Tables 1 to 5, Section 7.1, or special designs for pipe sizes that do not have steel reinforcement areas shown in Tables 1 to 5 of Section 7.1.

7.2.2 Such modified or special designs shall be based on rational or empirical evaluations of the ultimate strength and cracking behavior of the pipe and shall fully describe to the owner any deviations from the requirements of Section 7.1. The descriptions of modified or special designs shall include the wall thickness, the concrete strength, and the area, type, placement, number of layers, and strength of the steel reinforcement.

7.2.3 The manufacturer shall submit to the owner proof of the adequacy of the proposed modified or special design. Such proof may comprise the submission of certified three-edge-bearing tests already made, which are acceptable to the owner or, if such three-edge-bearing tests are not available or acceptable, the manufacturer may be required to perform proof tests on sizes and classes selected by the owner to demonstrate the adequacy of the proposed design.

7.2.4 Such pipe must meet all of the test and performance requirements specified by the owner in accordance with Section 5.

7.3 *Area*—In this specification, when the word "area" is not described by adjectives, such as cross-section or single wire, it shall be understood to be the cross-sectional area of reinforcement per unit lengths of pipe.

8. REINFORCEMENT

8.1 *Circumferential Reinforcement*—A line of circumferential reinforcement for any given total area may be composed of two layers for pipe with wall thicknesses of less than 180 mm or three layers for pipe with wall thicknesses of 180 mm or greater. The layers shall not be separated by more than the thickness of one longitudinal plus 6 mm. The multiple layers shall be fastened together to form a single cage. All other specification requirements such as laps, welds, and tolerances of placement in the wall of the pipe, etc. shall apply to this method of fabricating a line of reinforcement.

8.1.1 Where one line of circular reinforcement is used, it shall be placed from 35 to 50 percent of the wall thickness from the inner surface of the pipe, except that for wall thicknesses less than 63 mm, the protective cover of the concrete over the circumferential reinforcement in the wall of the pipe shall be 19 mm.

8.1.2 In pipe having two lines of circular reinforcement, each line shall be so placed that the protective covering of concrete over the circumferential reinforcement in the wall of the pipe shall be 25 mm.

8.1.3 In pipe having elliptical reinforcement with wall thicknesses 63 mm or greater, the reinforcement in the wall of the pipe shall be so placed that the protective covering of concrete over the circumferential reinforcement shall be 25 mm from the inner surface of the pipe at the vertical diameter and 25 mm from the outer surface of the pipe at the horizontal diameter. In pipe having elliptical reinforcement with wall thicknesses less than 63 mm, the protective covering of the concrete shall be 19 mm at the vertical and horizontal diameters.

8.1.4 The location of the reinforcement shall be subject to the permissible variations in dimensions given in Section 12.5.

8.1.5 The spacing center-to-center of circumferential reinforcement in a cage shall not exceed 100 mm for pipe up to and including pipe having a 100-mm wall thickness nor exceed the wall thickness for larger pipe, and shall in no case exceed 150 mm.

8.1.6 Where the wall reinforcement does not extend into the joint, the maximum longitudinal distance to the last circumferential from the inside shoulder of the bell or the shoulder of the spigot shall be 75 mm, except that if this distance exceeds one-half the wall thickness, the pipe wall shall contain at least a total reinforcement area of the minimum specified area per linear meter times the laying length of the pipe section. The minimum cover on the last circumferential near the spigot shoulder shall be 13 mm.

8.1.6.1 Where reinforcement is in the bell or spigot the minimum end cover on the last circumferential shall be 13 mm in the bell or 6 mm in the spigot.

8.1.7 The continuity of the circumferential reinforcing steel shall not be destroyed during the manufacture of the pipe, except that when agreed upon by the owner, lift eyes or holes may be provided in each pipe for the purpose of handling.

8.1.8 If splices are not welded, the reinforcement shall be lapped not less than 20 diameters for deformed bars and deformed cold-worked wire, and 40 diameters for plain bars and cold-drawn wire. In addition, where lapped cages of welded-wire fabric are used without welding, the lap shall contain a longitudinal wire.

8.1.8.1 When splices are welded and are not lapped to the minimum requirements above, pull tests of representative specimens shall develop at least 50 percent of the minimum specified strength of the steel, and there shall be a minimum lap of 50 mm. For butt-welded splices in bars or wire, permitted only with helically wound cages, pull tests of representative specimens shall develop at least 75 percent of the minimum specified strength of the steel.

8.2 *Longitudinal Reinforcement*—Each line of circumferential reinforcement shall be assembled into a cage that shall contain sufficient longitudinal bars or members, to maintain the reinforcement in shape and in position within the form to comply with permissible variations in Section 8.1. The exposure of the ends of longitudinals, stirrups, or spacers that have been used to position the cages during the placement of the concrete shall not be a cause for rejection.

8.3 *Joint Reinforcement*—The length of the joint as used herein means the inside length of the bell or the outside length of the spigot from the shoulder to the end of the pipe section. The end distances or cover on the end circumferential shall apply to any point on the circumference of the pipe or joint. When convoluted reinforcement is used, these distances and reinforcement areas shall be taken from the points on the convolutions closest to the end of the pipe section. Unless otherwise permitted by the owner, the following requirements for joint reinforcement shall apply.

8.3.1 *Joint Reinforcement for Non-Rubber Gasket Joints*:

8.3.1.1 For pipe 900 mm and larger in diameter, either the bell or spigot shall contain circumferential reinforcement. This reinforcement shall be an extension of a wall cage, or may be a separate cage of at least the area per meter of that specified for the outer cage or one-half of that specified for single cage wall reinforcement, whichever is less.

8.3.1.2 Where bells or spigots require reinforcement, the maximum end cover on the last circumferential shall be one-half the length of the joint or 75 mm, whichever is less.

8.3.2 *Joint Reinforcement for Rubber Gasket Joints*:

8.3.2.1 For pipe 300 mm and larger in diameter, the bell ends shall contain circumferential reinforcement. This reinforcement shall be an extension of the outer cage or a single wall cage, whichever is less, or may be a separate cage of at least the same area per meter with longitudinals as required in Section 8.2. If a separate cage is used, the cage shall extend into the pipe with the last circumferential wire at least 25 mm past the inside shoulder where the pipe barrel meets the bell of the joint.

8.3.2.2 Where bells require reinforcement, the maximum end cover on the last circumferential shall be 38 mm.

9. JOINTS

9.1 The joints shall be of such design and the ends of the concrete pipe sections so formed that when the sections are laid together they will make a continuous line of pipe with a smooth interior free from appreciable irregularities in the flow line, all compatible with the permissible variations given in Section 12.

10. MANUFACTURE

10.1 *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water–cementitious materials ratio not exceeding 0.53 by mass. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 280 kg/m^3 unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this specification.

10.2 *Curing*—Pipe shall be subjected to any one of the methods of curing described in Sections 10.2.1 to 10.2.4 or to any other method or combination of methods approved by the owner, that will give satisfactory results. The pipe shall be cured for a sufficient length of time so that the specified D-load is obtained when acceptance is based on Section 5.1.1 or so that the concrete will develop the specified compressive strength at 28 days or less when acceptance is based on Section 5.1.2.

10.2.1 *Steam Curing*—Pipe may be placed in a curing chamber, free of outside drafts, and cured in a moist atmosphere maintained by the injection of steam for such time and such temperature as may be needed to enable the pipe to meet the strength requirements. The curing chamber shall be so constructed as to allow full circulation of steam around the entire pipe.

10.2.2 *Water Curing*—Concrete pipe may be water cured by covering with water-saturated material or by a system of perforated pipes, mechanical sprinklers, porous hose, or by any other approved method that will keep the pipe moist during the specified curing period.

10.2.3 The manufacturer has the option of combining the methods described in Sections 10.2.1 to 10.2.4, provided the required concrete compressive strength is attained.

10.2.4 A sealing membrane conforming to the requirements of M 148 may be applied and should be left intact until the required strength requirements are met. The concrete at the time of application shall be within 6ºC of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

11. PHYSICAL REQUIREMENTS

11.1 *Test Specimens*—The specified number of pipe required for the tests shall be furnished without charge by the manufacturer and shall be selected at random by the owner, and shall be pipe that would not otherwise be rejected under this specification. The selection shall be made at the point or points designated by the owner when placing the order. Unless designated otherwise by the owner in the order, the manufacturer shall select the type of test (external load crushing strength test, compression test of cylinders or compression test of cores) to be used to determine the acceptability of the pipe strength. Pipe that fails to meet the strength requirements as determined by the selected test type may not be retested using one of the other test types without approval of the owner.

11.2 *Number and Type of Tests Required for Various Delivery Schedules*:

11.2.1 *Preliminary Tests for Extended Delivery Schedules*—An owner of pipe, whose needs require shipments at intervals over extended periods of time, shall be entitled to such tests, preliminary to delivery of pipe, as are required by the type of basis of acceptance specified by the owner in Section 5, of not more than three sections of pipe covering each size in which the owner is interested.

11.2.2 *Additional Tests*—After the preliminary tests described in Section 11.2.1, an owner shall be entitled to additional tests at such times as the owner may deem necessary, provided that the total number of pipe tested (including preliminary tests) shall not exceed 1 pipe or 1 percent, whichever is the greater, of each size of pipe delivered.

11.3 *External Load-Crushing Strength*:

11.3.1 The load to produce a 0.3-mm crack or the ultimate load, as determined by the three-edge-bearing method as described in T 280, shall be not less than that prescribed in Tables 1 to 5 for each respective class of pipe. Pipe that support the prescribed load to produce the 0.3-mm crack and do not show a wider crack shall be considered to have met the test requirement. It is not a requirement of this specification that the pipe be cracked or loaded to failure during these tests. Pipe that have been tested only to the formation of a 0.3-mm crack or lesser crack and that meet the 0.3-mm crack load requirements shall be accepted for use. Three-edge-bearing test to ultimate load is not required for any class of pipe 1500 mm or less in diameter listed in Tables 1–5 provided all other requirements of this specification are met.

Note 3—As used in this specification, the 0.3-mm crack is a test criterion for pipe tested in the three-edge-bearing test and is not intended as an indication of overstressed or failed pipe under installed conditions.

11.3.2 *Retests of Pipe Not Meeting the External Load-Crushing Strength Requirements*—Pipe shall be considered as meeting the strength requirements when all test specimens conform to the strength requirements. Should any of the test specimens fail to meet the strength requirements, the manufacturer shall be allowed a retest on two additional specimens for each specimen that failed, and the pipe shall be acceptable only when all of the retest specimens meet the strength requirements.

11.4 *Type of Specimen*—Compression tests determining concrete compressive strength may be made on either standard rodded concrete cylinders or concrete cylinders compacted and cured in like manner as the pipe, or on cores drilled from the pipe.

11.5 *Compression Testing of Cylinders*:

11.5.1 *Cylinder Production*—Cylinders shall be prepared, cured, and tested in accordance with Section 11 of T 280.

11.5.2 *Number of Cylinders*—Prepare no fewer than five test cylinders from a group (one day's production of each concrete strength) of pipe sections.

11.5.3 *Acceptability on the Basis of Cylinder Test Results*:

11.5.3.1 When the compressive strengths of all cylinders tested for a group are equal to or greater than the required concrete strength, the compressive strength of concrete in the group of pipe sections shall be accepted.

11.5.3.2 When the average compressive strength of all cylinders tested is equal to or greater than the required concrete strength, and not more than 10 percent of the cylinders tested have a compressive strength less than the required concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the required concrete strength, then the group shall be accepted.

11.5.3.3 The pipe shall be acceptable only when the compressive strength of the cylinders tested conform to the acceptance criteria stated in Section 11.5.3.1 or Section 11.5.3.2.

11.6 *Compression Testing of Cores*:

11.6.1 *Obtaining Cores*—Cores shall be obtained and prepared in accordance with Section 6 of T 280.

11.6.2 *Number of Cores*—One core shall be taken from a pipe section selected at random from each day's production run of a single concrete strength.

11.7 *Acceptability on the Basis of Core Test Results*:

11.7.1 When the compressive strength of a core tested for a group of pipe sections is equal to or greater than the required concrete strength, the compressive strength of the concrete for the group is acceptable.

11.7.2 If the compressive strength of the core tested is less than the required concrete strength, two additional cores shall be taken from that pipe section and tested. Concrete represented by these core tests shall be considered acceptable if: (1) the average of three cores is equal to at least 85 percent of the required strength, and (2) no single core is less than 75 percent of the required strength.

11.7.3 If the compressive strength of the three cores does not meet the requirements of Section 11.7.2, the pipe section from which the core was taken shall be rejected. Two pipe sections from the remainder of the group shall be selected at random and cored and tested for conformance with either Section 11.7.1 or Section 11.7.2. If both pipe sections meet the core strength requirements of Section 11.7.1 or Section 11.7.2, the remainder of the group shall be acceptable. If both pipe sections do not meet the test strength requirement, the remainder of the group shall be either rejected or, at the option of the manufacturer, each pipe section of the remaining group shall be cored and accepted individually and any of the pipe sections that have core strengths less than the requirements of Section 11.7.1 or Section 11.7.2 shall be rejected.

11.8 *Plugging Core Holes*—Core holes shall be plugged and sealed by the manufacturer in a manner such that the pipe section will meet all of the requirements of this specification. Pipe sections so plugged and sealed shall be considered satisfactory for use.

11.9 *Absorption*—The absorption of a sample from the wall of the pipe, as determined in accordance with T 280, shall not exceed 9 percent of the dry mass. Each sample shall have a minimum mass of 1.0 kg, shall be free of visible cracks, and shall represent the full wall thickness of the pipe. When the initial absorption sample from a pipe fails to conform to this specification, the absorption test shall be made on another sample from the same pipe and the results of the retest shall be substituted for the original test results.

11.10 *Retests of Pipe*—When not more than 20 percent of the concrete specimens fail to pass the requirements of this specification, the manufacturer may cull the project stock and may eliminate whatever quantity of pipe desired and shall mark those pipes so that they will not be shipped. The required tests shall be made on the balance of the order and the pipes shall be accepted if they conform to the requirements of this specification.

11.11 *Test Equipment*—Every manufacturer furnishing pipe under this specification shall furnish all facilities and personnel necessary to carry out the tests described in T 280.

12. PERMISSIBLE VARIATIONS

12.1 *Internal Diameter*—See Table 6. The internal diameter shall be one of two alternatives, the Designated Diameter or, contingent upon the owner's approval, the Converted English Diameter. Pipe sections that are intended to be jointed to each other shall be furnished with the same internal diameter alternative. The internal diameter of pipe manufactured to the Designated Diameters shall vary not more than ±1.5 percent from the Designated Diameters for 300 to 600 mm and ±1 percent or ±10 mm, whichever is greater, for larger pipe. The internal diameter of pipe manufactured to the Converted English Diameters shall vary not more than ±1.5 percent from the Converted English Diameters for 305 to 610 mm and ±1 percent or ±10 mm, whichever is greater, for larger pipe. For pipe manufactured to Converted English Diameters, the corresponding Designated Diameter shown in Table 6 shall apply for all other requirements of this specification.

Table 6—Design Internal Diameter

Designated Diameter of Pipe, mm	Equivalent English Dia, in.	Converted English Dia, mm
300	12	305
375	15	381
450	18	457
525	21	533
600	24	610
675	27	686
750	30	762
825	33	838
900	36	914
1050	42	1067
1200	48	1219
1350	54	1372
1500	60	1524
1650	66	1676
1800	72	1829
1950	78	1981
2100	84	2134
2250	90	2286
2400	96	2438
2550	102	2591
2700	108	2743
2850	114	2896
3000	120	3048
3150	126	3200
3300	132	3353
3450	138	3505
3600	144	3658

12.2 *Wall Thickness*—The wall thickness shall not vary more than shown in the design or specified wall by more than ±5 percent or 5 mm, whichever is greater. A specified wall thickness more than required in the design is not cause for rejection. Pipe having localized variations in wall thickness exceeding those specified above shall be accepted if the three-edge-bearing strength and minimum steel cover requirements are met.

12.3 *Length of Two Opposite Sides*—Variations in the laying length of two opposite sides of the pipe shall not be more than 6 mm for all sizes through 600-mm internal diameter, and not more than 10 mm/m of internal diameter for all sizes larger with a maximum of 16 mm in any length of pipe through 2100-mm internal diameter, and a maximum of 19 mm for 2250-mm internal diameter or larger, except where beveled end pipe for laying on curves is specified by the owner.

12.4 *Length of Pipe*—The underrun in length of a section of pipe shall not be more than 10 mm/m with a maximum of 13 mm in any length of pipe. Regardless of the underrun or overrun in any section of pipe, the end cover requirements of Sections 8 and 12 shall apply.

12.5 *Position or Area of Reinforcement*:

12.5.1 *Position*—The maximum variation in the position of a line of circumferential reinforcement shall be ±10 percent of the wall thickness or ±13 mm, whichever is greater. Pipe having variations in the position of a line of circumferential reinforcement exceeding those specified above shall be accepted if the three-edge-bearing strength requirements obtained on a representative specimen are met. In no case, however, shall the cover over the circumferential reinforcement be less than 6 mm as measured to the end of the spigot or 13 mm as measured to any other surface. The preceding minimum cover limitations do not apply to mating surfaces of non-rubber gasket joints or gasket grooves in rubber gasket joints. If convoluted reinforcement is used, the convoluted circumferential end wire may be at the end surface of the joint providing the alternate convolutions have at least 25 mm cover from the end surface of the joint.

12.5.2 *Area of Reinforcement*—Reinforcement will be considered as meeting the design requirements if the area, computed on the basis of nominal area of the wire or bars used, equals or exceeds the requirements of Section 7.1 or Section 7.2. Actual area of the reinforcing used may vary from the nominal area according to permissible variations of the standard specifications for the reinforcing. When inner cage and outer cage reinforcing is used, the inner cage nominal area may vary to the lower limit of 85 percent of the elliptical nominal area and the outer cage nominal area may vary to the lower limit of 51 percent of the elliptical nominal area provided that the total nominal area of the inner cage plus the outer cage shall not vary beyond the lower limit of 140 percent of the elliptical nominal area.

13. REPAIRS

13.1 Pipe may be repaired, if necessary, because of imperfections in manufacturing or damage during handling and will be acceptable if, in the opinion of the owner, the repaired pipe conforms to the requirements of this specification.

14. INSPECTION

14.1 The quality of materials, the process of manufacture, and the finished pipe shall be subject to inspection and approval by the owner.

15. REJECTION

15.1 Pipe shall be subject to rejection if it fails to conform to any of the specification requirements. Individual sections of pipe may be rejected because of any of the following:

15.1.1 Fractures or cracks passing through the wall, except for a single end crack that does not exceed the depth of the joint.

15.1.2 Defects that indicate proportioning, mixing, and molding not in compliance with Section 10.1 or surface defects indicating honey-combed or open texture that would adversely affect the function of the pipe.

15.1.3 The ends of the pipe are not normal to the walls and centerline of the pipe, within the limits of variations given in Sections 12.3 and 12.4.

15.1.4 Damaged or cracked ends where such damage would prevent making a satisfactory joint.

15.1.5 Any continuous crack having a surface width of 0.3 mm or more and extending for a length of 300 mm or more, regardless of position in the wall of the pipe.

16. PRODUCT MARKING

16.1 The following information shall be clearly marked on each section of pipe:

16.1.1 The pipe class and specification designation,

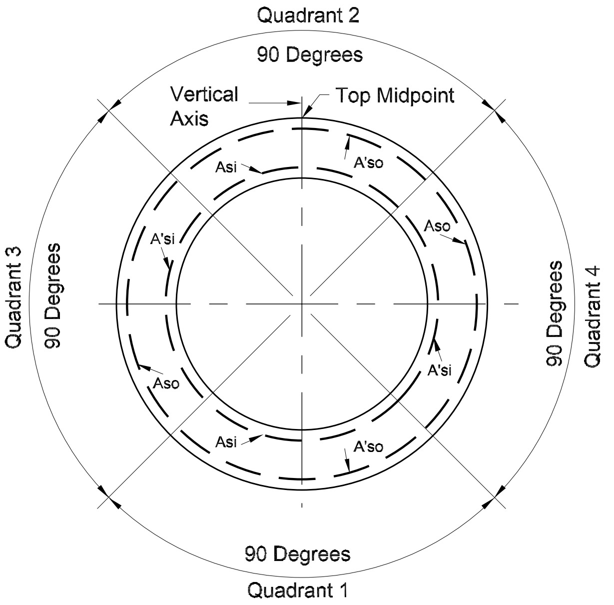
16.1.2 The date of manufacture,

16.1.3 The name or trademark of the manufacturer, and

16.1.4 Identification of plant.

16.2 One end of each section of pipe with elliptical or quadrant reinforcement shall be clearly marked during the process of manufacturing or immediately thereafter, on the inside and the outside of opposite walls along the minor axis of the elliptical reinforcing or along the vertical axis for quadrant reinforcing.

16.3 Markings shall be indented on the pipe section or painted thereon with waterproof paint.



Notes: 1. The total reinforcement area (Asi) of the inner cage plus the quadrant mat in Quadrants 1 and 2 shall not be less than that specified for the inner cage in Tables 1 to 5.

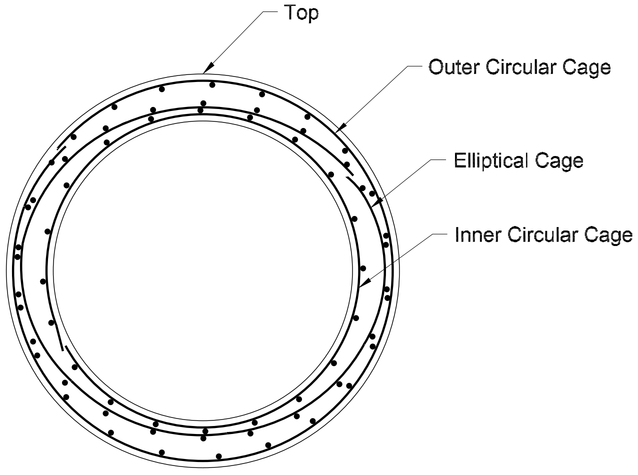
2. The total reinforcement area (Aso) of the outer cage plus the quadrant mat in Quadrants 3 and 4 shall not be less than that specified for the outer cage in Tables 1 to 5.

3. The total reinforcement area (A′si) of the inner cage in Quadrants 3 and 4 shall not be less than 25 percent of that specified for the inner cage in Tables 1 to 5.

4. The total reinforcement area (A′so) of the outer cage in Quadrants 1 and 2 shall not be less than 25 percent of that specified for the outer cage in Tables 1 to 5.

5. If the reinforcement area (A′so) of the outer cage in Quadrants 1 and 2 is less than 50 percent of that specified for the outer cage in Tables 1 to 5, the quadrant mats used for the outer cage in Quadrants 3 and 4 shall extend into Quadrants 1 and 2 not less than a distance equal to the wall thickness as specified in Tables 1 to 5.

Figure 1—Quadrant Reinforcement



Notes: 1. The total reinforcement area of the inner circular cage and the elliptical cage shall not be less than that specified for the inner cage in Tables 1 to 5.

2. The total reinforcement area of the outer circular cage and the elliptical cage shall not be less than that specified for the outer cage in Tables 1 to 5.

Figure 2—Triple Cage Reinforcement

17. KEYWORDS

17.1 Circular pipe; culvert; D-load; pipe; reinforced concrete; sewer pipe; storm drain.

---

[1] Agrees with ASTM C 76M-08a except for limiting the absorption testing to the 5-hour boil method, the use of synthetic fibers are at the option of the owner, supplying inch-pound sized pipe when the order is placed in SI units is contingent upon owner approval, and the method of acceptance is changed as per Sections 11.1, 11.5.3.3, and 11.7.3.

Standard Specification for

Perforated Concrete Pipe

AASHTO Designation: M 175M/M 175-05 (2009)
ASTM Designation: C 444M-03 and C 444-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Perforated Concrete Pipe

AASHTO Designation: M 175M/M 175-05 (2009)
ASTM Designation: C 444M-03 and C 444-03

1. SCOPE

1.1 This specification covers perforated concrete pipe intended to be used for underdrainage.

1.2 This specification is applicable for orders in either SI units (M 175M) or in inch-pound units (M 175). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 175.

2. REFERENCED DOCUMENT

2.1 *AASHTO Standards*:

- M 86M/M 86, Nonreinforced Concrete Sewer, Storm Drain, and Culvert Pipe
- M 262, Concrete Pipe and Related Products

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. CLASSIFICATION

4.1 Pipe manufactured according to this specification shall be of two classes known as Type 1 and Type 2, which cover two arrangements of perforations to be used with pipe manufactured according to any of the standard specifications for plain or reinforced concrete pipe, and any of the classifications within those standard specifications.

4.1.1 Type 1 perforated pipe shall have circular perforations conforming to Section 6.1 and Table 1.

4.1.2 Type 2 perforated pipe shall have slotted perforations conforming to Section 6.2 and Table 2.

4.1.3 It is intended that perforated pipe shall be specified by reference to this specification and the specification for the type and class of pipe desired.

Note 1—Example—“Perforated concrete pipe shall conform to the requirements of M 175M/M 175, Type 2, and all applicable requirements of M 86, Class 2.”

5. BASIS OF ACCEPTANCE

5.1 The acceptability of the pipe shall be determined by the results of all applicable tests (Note 2) prescribed for the type and class of pipe specified, and by inspection to determine whether the pipe conforms to this specification as to design and freedom from defects.

Note 2—It is intended that all tests will be applicable except those having to do with permeability and the hydrostatic test.

6. PERFORATIONS

6.1 *Type 1*—Perforations shall be circular, not more than 8 mm [$^5/_{16}$ in.] or less than 5 mm [$^3/_{16}$ in.] in diameter, and arranged in rows parallel to the axis of the pipe. Perforations shall be 75 mm [3 in.] center-to-center, along rows. The spigot or tongue end shall not be perforated for a length equal to the depth of the socket, or depth of the groove plus 19 mm [$^3/_4$ in.] and perforations shall continue at uniform spacing along the entire length of the barrel. The total number of rows shall be as shown in Table 1. The rows shall be spaced over not more than 165 degrees of circumference. Rows shall be symmetrically arranged with respect to the intended top or bottom of the pipe.

Table 1—Number of Rows of Perforations Required

Internal Designation Diameter		Rows of Perforations
mm	in.	
100	4	4
150	6	4
200	8	4
250	10	6
300	12	6
350	14	6
375	15	6
400	16	6
450	18	8
500	20	8
525	21	8
600	24	8
675 and larger	27 and larger	space rows approximately 150 mm [6 in].

6.2 *Type 2*—Slots shall be circumferential in direction, not more than 5 mm [$^3/_{16}$ in.] or less than 3 mm [$^1/_8$ in.] in width, and of the lengths shown in Table 2. There shall be two rows of slots, spaced 165 degrees apart, and centered, in the case of elliptically reinforced pipe, about the minor axis of the reinforcing. Slots shall be spaced as shown in Table 2, except as modified herein for plain-end pipe. The distance from the spigot end, or from the shoulder of the tongue end, to the first pair of slots shall be not more than 25 mm [1 in.] greater than the specified slot spacing, nor less than 25 mm [1 in.] less than the specified slot spacing. Slots shall continue at uniform spacing along the entire length of the barrel.

Table 2—Requirements for Length and Spacing of Slots

Internal Designation Diameter		Slot Length		Slot Spacing[a]	
mm	in.	mm	in.	mm	in.
100	4	25	1	75	3
150	6	38	1½	75	3
200	8	50	2	100	4
250	10	50	2	100	4
300	12	75	3	150	6
350	14	75	3	150	6
375	15	75	3	150	6
400	16	75	3	150	6
450	18	75	3	150	6
500	20	75	3	150	6
525	21	75	3	150	6
600	24	75	3	150	6
675 and larger	27 and larger	100	4	150	6

[a] See Section 6.2 for exceptions for plain-end pipe.

6.2.1 Slots in plain-end pipe shall be spaced as shown in Table 2 except that smaller spacing shall be used where necessary to provide not less than three equally spaced slots in each row. Slots shall be centered with respect to the ends of the pipe and there shall be not more than the specified slot spacing from the pipe end to the first pair of slots, or less than one-half of the slot spacing employed.

6.3 The manufacturer shall submit to the owner for approval, prior to manufacture, sizes and arrangements of perforations other than specified herein.

7. JOINTS

7.1 The joints shall be of such design and the ends of the concrete pipe sections so formed that the pipe can be laid together to make a continuous line of pipe compatible with the permissible variations given in Section 8.

8. PERMISSIBLE VARIATION IN DIMENSIONS

8.1 The permissible variation in circular perforation size or slot width shall be as specified in Section 6. Slot length tolerance is +6 mm [$+^{1}/_{4}$ in.] or –3 mm [$-^{1}/_{8}$ in.] Variation in row spacing, or in the spacing of holes or slots in any row, shall be ±13 mm [$\pm^{1}/_{2}$ in.] except as required to provide specified cover for reinforcing steel.

9. REPAIRS

9.1 Pipe repaired because of imperfections in manufacture or damage during handling will be acceptable, if in the opinion of the owner, the repairs are sound and properly finished and cured and the pipe conforms to the requirements of this specification.

10. MARKING OF REJECTED SPECIMENS

10.1 All rejected pipe shall be marked clearly by the owner and shall be replaced by the manufacturer with pipe that will meet the requirements of this specification, without additional cost to the owner.

11. INSPECTION

11.1 The quality of all materials and the finished pipe shall be subject to inspection and approval by the owner. Such inspection shall be performed at the point of manufacture or delivery. The method of marking as to acceptance or rejection of the pipe shall be agreed upon, prior to inspection, between the owner and manufacturer. Rejected pipe shall be replaced by the manufacturer with pipe that meets the requirements of this specification.

12. REJECTION

12.1 Pipe shall be subject to rejection on account of any of the applicable causes for rejection listed for the type and class of pipe specified, or on account of any of the following:

12.1.1 Variations in dimensions exceeding those specified in Sections 6 and 8, or

12.1.2 Any spall more than 19 mm [$^3/_4$ in.] in diameter or 5 mm [$^3/_{16}$ in.] in depth caused by making perforations or slots.

13. KEYWORDS

13.1 Concrete pipe; perforated; subsurface drainage; underdrainage.

Standard Specification for

Porous Concrete Pipe

AASHTO Designation: M 176M/M 176-07[1]
ASTM Designation: C 654M-05a and C 654-05a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Porous Concrete Pipe

AASHTO Designation: M 176M/M 176-07[1]

ASTM Designation: C 654M-05a and C 654-05a

1. SCOPE

1.1 This specification covers porous nonreinforced concrete pipe for use in underdrains.

1.2 This specification is applicable for orders in either SI units (M 176M) or in inch-pound units (M 176). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 176.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 85, Portland Cement
- M 154, Air-Entraining Admixtures for Concrete
- M 240, Blended Hydraulic Cement
- M 262, Concrete Pipe and Related Products
- M 295, Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete
- M 302, Ground Granulated Blast-Furnace Slag for Use in Concrete and Mortars
- T 280, Concrete Pipe, Manhole Sections, or Tile

2.2 *ASTM Standard*:

- C 1116, Standard Specification for Fiber-Reinforced Concrete

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. CLASSIFICATION

4.1 Pipe manufactured according to this specification shall be of two classes identified as "Standard-Strength Porous Nonreinforced Concrete Pipe" and "Extra-Strength Porous Nonreinforced Concrete Pipe."

5. BASIS OF ACCEPTANCE

5.1 The acceptability of the pipe shall be determined by the results of the strength and porosity or rate of infiltration tests, and by inspection to determine whether the pipe conforms to this specification as to design and freedom from defects.

5.2 The pipe shall be acceptable under the strength tests when they have met the requirements as prescribed in Section 10.

5.3 *Acceptance as to Infiltration Properties*—Pipe shall be acceptable under the infiltration test when all test pipe conform to the test requirements as prescribed in Section 10.

6. MATERIALS

6.1 *Concrete*—The concrete shall consist of cementitious materials, aggregates, and water.

6.2 *Cementitious Materials*:

6.2.1 *Cement*—Cement shall conform to the requirements of M 85 or shall be portland blast-furnace slag cement or slag modified portland cement, or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash and shall not exceed 25 percent by weight.

6.2.2 *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.3 *Ground Granulated Blast-Furnace Slag (GGBFS)*—GGBFS shall conform to the requirements of grade 100 or 120 of Specification C 989.

6.2.4 *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

6.2.4.1 Portland cement only,

6.2.4.2 Portland blast-furnace slag cement only,

6.2.4.3 Slag modified portland cement only,

6.2.4.4 Portland-pozzolan cement only, or

6.2.4.5 A combination of portland cement and fly ash.

6.2.4.6 A combination of portland cement and ground granulated blast-furnace slag, or

6.2.4.7 A combination of portland cement, fly ash (not to exceed 25 percent of the total cementitious weight) and ground granulated blast-furnace slag (not to exceed 25 percent of the total cementitious weight).

Note 1—The user of this specification is advised that porous pipe may experience leaching detrimental to durability when subjected to drainage of soft or acid waters (less than 50 ppm hardness or less than 6.0 pH). Type V portland cement should be specified where high sulfate resistance is required, and Type II or IIA portland cement should be specified where the pipe will be exposed to moderate sulfate conditions. More than 3,000 mg/L [ppm] of chiefly sodium or magnesium sulfates, or both, may be considered high sulfate content.

6.3 *Aggregates*—Aggregates shall conform to M 6 and M 80 except that the requirement for gradation shall not apply.

6.4 *Admixtures and Blends*—Admixtures and blends shall only be used with the approval of the owner.

6.5 *Synthetic Fibers*—Polypropylene fibers are permitted, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be accepted.

7. DESIGN

7.1 *Design Table*—Design requirements shall be in accordance with Tables 1 and 2 and Figure 1. Wall thickness used shall be not less than the value shown, except as affected by the tolerance herein specified.

Table 1—Physical and Dimensional Requirements of Porous Concrete Pipe

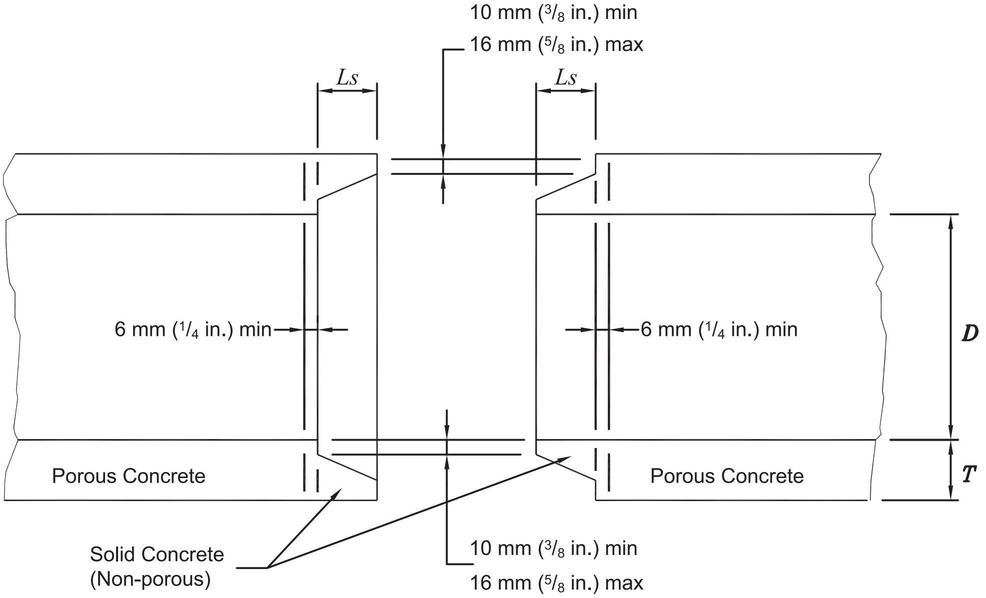
Internal Designated Diameter, *D*		Minimum Wall Thickness, *T*		Minimum Laying Length[a]		Minimum Socket Depth, *Ls*		Minimum Strength Three-Edge-Bearing		Minimum Infiltration	
mm	in.	mm	in.	mm	in.	mm	in.	kN/m	lbf/ft	(*L*/s)/m	(gal/min)/ft
100	4	25	1	600	24	25	1	14.5	1000	0.8	4
150	6	25	1	600	24	25	1	16.0	1100	1.0	6
200	8	32	$1^{1}/_{4}$	600	24	32	$1^{1}/_{4}$	19.0	1300	1.5	8
250	10	35	$1^{1}/_{8}$	600	24	35	$1^{1}/_{8}$	20.5	1400	2.0	10
300	12	38	$1^{1}/_{2}$	600	24	38	$1^{1}/_{2}$	22.0	1500	2.5	12
375	15	44	$1^{3}/_{4}$	600	24	44	$1^{3}/_{4}$	25.5	1750	3.0	15
450	18	50	2	600	24	50	2	29.0	2000	3.5	18
525	21	57	$2^{1}/_{4}$	600	24	57	$2^{1}/_{4}$	32.0	2200	4.0	21
600	24	63	$2^{1}/_{2}$	600	24	63	$2^{1}/_{2}$	35.0	2400	4.5	24

[a] Normally, the minimum laying length is 600 mm [24 in.] in length, but if the owner has no objections, then 450 mm [18-in.] length pipe up to 300 mm [12 in.] in diameter shall be acceptable.

Table 2—Physical and Dimensional Requirements of Extra-Strength Porous Concrete Pipe

Internal Designated Diameter, *D*		Minimum Wall Thickness, *T*		Minimum Laying Length[a]		Minimum Socket Depth, *Ls*		Minimum Strength Three-Edge-Bearing		Minimum Infiltration	
mm	in.	mm	in	mm	in.	mm	in	kN/m	lbf/ft	(L/s)/m	(gal/min)/ft
150	6	32	$1^{1}/_{4}$	600	24	32	$1^{1}/_{4}$	32.0	2200	1.0	6
200	8	38	$1^{1}/_{2}$	600	24	38	$1^{1}/_{2}$	38.0	2600	1.5	8
250	10	41	$1^{5}/_{8}$	600	24	41	$1^{5}/_{8}$	41.0	2800	2.0	10
300	12	50	2	600	24	50	2	44.0	3000	2.5	12
375	15	57	$2^{1}/_{4}$	600	24	57	$2^{1}/_{4}$	46.5	3200	3.0	15
450	18	63	$2^{1}/_{2}$	600	24	63	$2^{1}/_{2}$	46.5	3200	3.5	18

[a] Normally, the minimum laying length is 600 mm [24 in.] length, but if the owner has no objections, then 450 mm [18-in.] length pipe up to 300 mm [12 in.] in diameter shall be acceptable.



Note: See Tables 1 and 2 for values of *D*, *T*, and *Ls*.

Figure 1—Joint Dimensions

8. JOINTS

8.1 The joints shall be of such design and the ends of the concrete pipe sections so formed that the pipe can be laid together to make a continuous line of pipe compatible with the permissible variations given in Section 7.

9. MANUFACTURE

9.1 *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed in a batch mixer with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification.

9.2 *Curing*—Pipe shall be subjected to any one of the methods of curing described in Sections 9.2.1 through 9.2.3, or to any other method or combination of methods approved by the owner that will give satisfactory results. The pipe shall be cured for a sufficient length of time so that the concrete will develop the specified strength requirement at 28 days or less.

9.2.1 *Steam Curing*—Pipe shall be placed in a curing chamber, free from outside drafts, and cured in a moist atmosphere maintained by the injection of steam for such time and at such temperature as needed to enable the pipe to meet the strength requirements. The curing chamber shall be constructed as to allow full circulation of steam around the entire pipe.

9.2.2 *Water Curing*—Concrete pipe shall be water cured by covering with water-saturated material or by a system of perforated pipes, mechanical sprinklers, porous hose, or by any other approved method that will keep the pipe moist during the specified curing period.

9.2.3 The manufacturer has the option to combine the methods described in Sections 9.2.1 and 9.2.2 provided the specified strength is attained.

9.3 *Specials*:

9.3.1 *General Requirements*—Special shapes or fittings such as wyes, tees, bends, and adapters for use with concrete pipe conforming to this specification shall be made of porous or nonporous concrete in such manner as will provide strength at least equal to the class of the adjacent pipe to which they are joined, and shall conform to all other requirements specified for pipe of corresponding class and internal diameter, except minimum infiltration. Joints shall be the same types as used in the adjoining pipe.

9.3.2 *Wyes and Tees*—Fabricated branches for wyes and tees shall be securely attached to the wall of the pipe and shall be flush with the inside surface of the pipe.

10. PHYSICAL REQUIREMENTS

10.1 *Test Specimen*—The specified number of pipe required for the tests shall be furnished by the manufacturer and shall be selected at random by the owner, and shall be pipe that would not otherwise be rejected under this specification. The selection shall be made at the point or points designated by the owner when placing the order. The test pipe shall first be freed from all visible moisture. When dry, each pipe shall be measured and inspected. The results of these observations shall be recorded.

10.2 *Number and Types of Test Specimens*—The manufacturer shall furnish pipe for crushing tests, up to 0.5 percent of the number of pipe of each size included in the order, except that in no case shall fewer than two pipes be furnished.

10.3 *External Load Crushing Requirements*—The crushing strength of porous nonreinforced concrete pipe shall conform to the requirements prescribed in Tables 1 and 2. The individual results of the various tests for each size of pipe and for each shipment and plant shall be tabulated separately. The crushing strength shall ordinarily be applied to not less than 75 percent of the pipe received for purpose of test. All tests shall be made in accordance with T 280. Pipe shall be acceptable when all test pipe conform to the specified strength requirement. Should any of the preliminary test pipe provided in Section 10.2 fail to meet the strength requirement, the manufacturer will be allowed to test two pipes for each pipe that failed, and the pipe shall be acceptable only when all of these additional test pipe meet the strength requirement.

10.4 *Infiltration Requirement*—Infiltration (or porosity) shall conform to the requirements in Tables 1 or 2.

10.4.1 The test pipe shall be placed with a spigot end down on a soft rubber nonpermeable mat, or its equivalent, and weighted or clamped down if necessary to prevent the escape of water through the spigot end of the pipe.

10.4.2 Water shall be introduced into the pipe, and the distance above the bottom of the porous section at which the water level becomes constant shall be determined. The rate of flow shall be at least equal to the required minimum infiltration for 1 m [ft] of pipe as given in Tables 1 or 2.

10.4.3 When using metric units, the rate of infiltration per meter of pipe shall be determined as follows:

$$\mathit{LITERS/S} = L/h$$

where:

$\mathit{LITERS/S}$ = infiltration rate in liters per second per meter of pipe,

L = liters per second of flow introduced into the test pipe, and

h = height in meters from the bottom of the porous section of the pipe at which the level of water becomes constant.

When using inch pound units the rate of infiltration per foot of pipe shall be determined as follows:

$$\mathit{GPM} = g/h$$

where:

GPM = infiltration rate in gallons per minute per foot of pipe,

g = gallons per minute of flow introduced into the test pipe, and

h = height in feet from the bottom of the porous section of the pipe at which the level of water becomes constant.

10.5 *Test Equipment*—The manufacturer shall furnish all equipment, facilities, and personnel necessary to perform at his plant the tests specified in Section 10. In the event that the owner elects to have tests performed at any other location, the manufacturer will not be required to furnish equipment, facilities, or personnel.

11. PERMISSIBLE VARIATIONS

11.1 *Size and Dimensions*—Pipe shall be furnished in the sizes, internal diameters, and dimensions prescribed in Tables 1, 2, and 3 and Figure 1.

Table 3—Permissible Variations in Dimensions of Porous Concrete Pipe

Internal Designated Diameter		Internal Diameter[a]		Length, Two Opposite Sides		Wall Thickness[a]		Length[a]		Depth of Socket[a]	
mm	in.	mm	in.	mm	in.	mm	in.	mm/m	in./ft	mm	in.
100	4	± 3	± $^{1}/_{8}$	– 2	– $^{1}/_{16}$	6	$^{1}/_{4}$	– 20	– $^{1}/_{4}$	– 3	– $^{1}/_{8}$
150	6	± 3	± $^{1}/_{8}$	– 2	– $^{1}/_{16}$	6	$^{1}/_{4}$	– 20	– $^{1}/_{4}$	– 3	– $^{1}/_{8}$
200	8	± 6	± $^{1}/_{4}$	– 2	– $^{1}/_{16}$	8	$^{5}/_{16}$	– 20	– $^{1}/_{4}$	– 6	– $^{1}/_{4}$
250	10	± 6	± $^{1}/_{4}$	– 2	– $^{1}/_{16}$	10	$^{3}/_{8}$	– 20	– $^{1}/_{4}$	– 6	– $^{1}/_{4}$
300	12	± 6	± $^{1}/_{4}$	– 2	– $^{1}/_{16}$	10	$^{3}/_{8}$	– 20	– $^{1}/_{4}$	– 6	– $^{1}/_{4}$
375	15	± 6	± $^{1}/_{4}$	– 2	– $^{3}/_{32}$	11	$^{7}/_{16}$	– 20	– $^{1}/_{4}$	– 6	– $^{1}/_{4}$
450	18	± 6	± $^{1}/_{4}$	– 2	– $^{3}/_{32}$	13	$^{1}/_{2}$	– 20	– $^{1}/_{4}$	– 6	– $^{1}/_{4}$
525	21	± 6	± $^{1}/_{4}$	– 3	– $^{1}/_{8}$	14	$^{9}/_{16}$	– 20	– $^{1}/_{4}$	– 6	– $^{1}/_{4}$
600	24	± 6	± $^{1}/_{4}$	– 3	– $^{1}/_{8}$	14	$^{9}/_{16}$	– 31	– $^{3}/_{8}$	– 6	– $^{1}/_{4}$

[a] The minus sign (–) indicates that the plus variation is not limited; the plus and minus sign (±) indicates variation in both excess and deficiency in dimension.

11.2 Permissible variations from the dimensions described in Tables 1 and 2 shall not exceed those stated in Table 3. This is not to be construed, however, that heavier wall thickness pipe cannot be furnished at the option of the manufacturer. Pipe intended to be straight shall not have variation in alignment of more than 10 mm/m [$^{1}/_{8}$ in./ft] of length.

12. REPAIRS

12.1 Pipe repaired because of imperfections in manufacturing or damage during handling is acceptable if, in the opinion of the owner, the repaired pipe conforms to the requirements of this specification.

13. INSPECTION

13.1 The quality of all materials, the process of manufacture, and the finished pipe shall be subject to the inspection and approval by the owner. Such inspection shall be performed either at the point of manufacture or delivery.

14. REJECTION

14.1 Pipe shall be subject to rejection if it fails to conform to any of the specification requirements. It is not prohibited for individual sections of pipe to be rejected because of any of the following:

14.1.1 Fractures or cracks passing through the wall or joints, except a single crack not exceeding 50 mm [2 in.] in length at either end of a pipe or a single fracture in the joints not exceeding 75 mm [3 in.] in width and not more than 50 mm [2 in.] in length, shall not be considered cause for rejection unless these defects exist in more than 5 percent of the entire shipment or delivery.

14.1.2 The planes of the ends of the pipe are not perpendicular to the longitudinal axis, subject to the limits of variation as shown in Table 3.

14.1.3 Defects that indicate mixing and molding not in accordance with Section 9.1.

14.1.4 Cracks sufficient to impair the strength, durability, or serviceability of the pipe.

15. MARKING

15.1 The letters “ES” shall be legibly stamped with waterproof ink, or other permanent matter, on all extra-strength porous concrete pipe.

16. KEYWORDS

16.1 Concrete pipe; nonreinforced; porous; underdrains.

---

[1] Agrees with ASTM C 654M-05a and C 654-05a except for limiting absorption testing to the 5-hour boil method, the manufacturer is not afforded the option to supply inch-pound sized pipe when the order is placed in SI units and the use of fibers in Section 6.5 is at the owner’s option.

Standard Specification for

Concrete Drain Tile

AASHTO Designation: M 178M/M 178-07[1]
ASTM Designation: C 412M-05a and C 412-05a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Concrete Drain Tile

AASHTO Designation: M 178M/M 178-07[1]
ASTM Designation: C 412M-05a and C 412-05a

1. SCOPE

1.1 This specification covers concrete drain tile with internal diameters from 100 mm (4 in.) to 900 mm (36 in.) that is intended to be used for surface and subsurface drainage.

1.2 This specification is applicable for orders in either SI units (M 178M) or in inch-pound units (M 178). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 178.

Note 1—This specification is a manufacturing and purchase specification only and does not include requirements for bedding, backfill, or the relationship between field load condition and the strength classification of drain tile. However, experience has shown that the successful performance of the product depends upon the proper selection of the class of drain tile, type of bedding and backfill, and care that the installation conforms to the construction specifications. The owner of the reinforced concrete pipe specified herein is cautioned that the field requirements must be correlated with the class of pipe specified and provide inspection at the construction site.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 85, Portland Cement
- M 240, Blended Hydraulic Cement
- M 262, Concrete Pipe and Related Products
- M 295, Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete
- M 302, Ground Granulated Blast-Furnace Slag for Use in Concrete and Mortars
- T 280, Concrete Pipe, Manhole Sections, or Tile

2.2 *ASTM Standard:*

- C 1116, Standard Specification for Fiber-Reinforced Concrete

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. CLASSIFICATION

4.1 Drain tile manufactured according to this specification shall be of the following four classes:

4.1.1 *Standard-Quality Concrete Drain Tile*—intended for land drainage of ordinary soils where the tile are laid in trenches of moderate depths and widths. Standard-Quality concrete drain tile are not recommended for use where internal diameters in excess of 300 mm [12 in.] are required.

4.1.2 *Extra-Quality Concrete Drain Tile*—intended for land drainage of ordinary soils where the tile are laid in trenches of considerable depths or widths, or both.

4.1.3 *Heavy-Duty Extra-Quality Concrete Drain Tile*—intended for land drainage of ordinary soils where the tile are laid in trenches of large depths or widths, or both.

4.1.4 *Special-Quality Concrete Drain Tile*—intended for land drainage where special precautions are necessary for concrete tile laid in soils that are markedly acid or contain unusual quantities of sulfates (Section 7), and where the tile are laid in trenches of considerable depths or widths, or both.

4.1.4.1 Where the calculated loads are in excess of the crushing strengths prescribed in the physical requirements for extra-quality and special-quality concrete drain tile, tile strengths must be specified in advance by the owner.

5. BASIS OF ACCEPTANCE

5.1 The acceptability of drain tile shall be determined by (1) the results of the physical tests as specified in Section 8, and in T 280, (2) measurements and inspection to ascertain whether the tile conform to the requirements regarding dimensions, shape, and freedom from visible defects, and (3) the manufacturer's certification in writing that the tile have been made in accordance with any special provisions, such as strength, absorption, permeability, type of cement, admixture, curing conditions, etc.

5.2 The owner shall specify in writing the class or classes of concrete tile to be supplied, whether Standard-Quality, Extra-Quality, Heavy-Duty Extra-Quality, or Special-Quality. Unless Extra-Quality, Heavy-Duty Extra-Quality, or Special-Quality concrete drain tile have been specified, Standard-Quality drain tile shall be accepted.

6. MATERIALS

6.1 *Concrete*—The concrete shall consist of cementitious materials, mineral aggregates, and water.

6.2 *Cementitious Materials*:

6.2.1 *Cement*—Cement shall conform to the requirements for portland cement of M 85 or shall be portland blast-furnace slag cement or slag modified portland cement or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash.

6.2.2 *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.3 *Ground Granulated Blast-Furnace Slag (GGBFS)*—GGBFS shall conform to the requirements of Grade 100 or 120 of Specification C 989.

6.2.4 *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

6.2.4.1 Portland cement only,

6.2.4.2 Portland blast-furnace slag cement only,

6.2.4.3 Slag modified portland cement only,

6.2.4.4 Portland-pozzolan cement only,

6.2.4.5 A combination of portland cement and fly ash,

6.2.4.6 A combination of portland cement and ground granulated blast-furnace slag, or

6.2.4.7 A combination of portland cement, fly ash (not to exceed 25 percent of the total cementitious weight) and ground granulated blast-furnace slag (not to exceed 25 percent of the total cementitious weight).

6.3 *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirement for gradation shall not apply.

6.4 *Admixtures and Blends*—Admixtures and blends shall only be used with the approval of the owner.

6.5 *Synthetic Fibers*—At the owner's option, collated fibrillated virgin polypropylene fibers are not prohibited from being used as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be used.

7. CHEMICAL REQUIREMENTS

7.1 *Acid and Sulfate Resistance*:

7.1.1 The owner is not prohibited from specifying special requirements in order to increase the durability of the drain tile in cases where the soils, soil waters, or drainage waters are markedly acid (Section 7.1.1.1) or contain moderate or severe quantities of soil sulfates (Section 7.1.1.2). Without a specific agreement in advance, no drain tile shall be rejected by reason of its composition as determined later by chemical analyses.

7.1.1.1 Soils or drainage water with a pH of 6.0 or lower shall be considered to be markedly acid.

7.1.1.2 Where the sulfates are chiefly sodium or magnesium, singly or in combination, from 400 to 2000 ppm in the soil or drainage water samples shall be considered to constitute moderate sulfate quantities, while in excess of 2000 ppm shall be considered to be severe sulfate quantities.

7.1.2 Concrete drain tile that will be installed in markedly acid soils shall meet the physical requirements given in the table for Special-Quality concrete drain tile.

7.1.3 Tile that will be exposed to moderate or severe sulfate quantities (Note 2) if required by the owner, shall be specified to meet the physical requirements for Special-Quality concrete drain tile (Section 8.3.4). Tile that will be exposed to moderate sulfate quantities (Note 2) if required by the owner, shall be specified to be made with portland cement (M 85) containing not more than 8 percent tricalcium aluminate (C_3A). Tile that will be exposed to severe sulfate quantities (Note 2) if required by the owner, shall be specified to be made with portland cement (M 85) containing not more than 5 percent C_3A. If mutually agreed by the manufacturer and owner, other cements, as described in Section 6, that have been proven to be adequately sulfate resistant shall be used.

8. PHYSICAL REQUIREMENTS

8.1 *Test Specimens*—The drain tile to be tested shall be selected at random by the owner or his representative at the point or points specified in the order. If agreeable to the owner, the tile shall be inspected and tested in advance of shipment. Any additional expense for making tests and inspection in advance of shipment shall be paid by the manufacturer.

8.2 *Standard Sample*—Each standard physical test shall be made on five individual tiles of each size ranging from 100 mm [4-in.] through 300 mm [12-in.] diameters; two individual tiles of each size ranging from 350 mm [14-in.] through 600 mm [24-in.] diameters; or on one tile of each size exceeding 600 mm [24 in.] in diameter. The manufacturer shall furnish tile without separate charge up to 0.5 percent of each size. The owner shall pay for all the tile in excess of 0.5 percent at the same price as paid for other tile of the same size and quality.

8.3 *External Load Crushing Strength Test Requirements*:

8.3.1 For Standard-Quality concrete drain tile, the three-edge-bearing crushing strength shall meet the requirements given in Table 1, Column A, where no absorption test is required, or the three-edge-bearing crushing strength shall meet the requirements given in Table 1, Column B, where an absorption test is required of the limits noted in Table 1.

Table 1—Physical Test Requirements for Standard-Quality Concrete Drain Tile

		Standard Quality Concrete Drain Tile									
				Three-Edge-Bearing Crushing Strength[a]						Absorption	
Internal Designated Diameter,		Maximum Wall Thickness for Indicated Strength,[c]		Minimum Average, A		Minimum Average, B		Minimum for Individual Tile,		Minimum Average, percent	Minimum for Individual Tile, percent
mm	in.	mm	in.	kN/linear m	lbf/linear ft	kN/linear m	lbf/linear ft	kN/linear m	lbf/linear ft		
100	4	—	—	—	—	12	800	10	700	10	11

[a] Drain tile meeting the above strength requirements are not necessarily safe against cracking in deep and wide trenches.

[b] Tile with diameters greater than 12 in. shall meet the requirements specified in Table 2 for Extra-Quality, Table 3 for Heavy-Duty Extra-Quality, or Table 4 for Special-Quality concrete drain tile.

[c] Maximum wall thickness for the indicated minimum average crushing strength, Column A, when no absorption test is required.

8.3.2 For Extra-Quality concrete drain tile, the three-edge-bearing crushing strength shall meet the requirements given in Table 2, Column A, where no absorption test is required, or the three-edge-bearing crushing strength shall meet the requirements given in Table 2, Column B, where an absorption test is required of the limits noted in Table 2.

[a] For crushing strengths greater than or equal to those shown in the above table, it is not prohibited to supply tile designed with increased wall thickness, higher strength concrete, or reinforcing.

[b] Maximum wall thickness for the indicated minimum average crushing strength, Column A, when no absorption test is required.

8.3.3 For Heavy-Duty Extra-Quality concrete drain tile, the three-edge-bearing crushing strength shall meet the requirements given in Table 3.

Table 3—Physical Test Requirements for Heavy-Duty Extra-Quality Concrete Drain Tile

		Heavy-Duty Extra-Quality Concrete Drain Tile							
				Three-Edge-Bearing Crushing Strength[a]				Absorption	
Internal Designated Diameter,		Wall Thickness,		Minimum Average,[b]		Minimum for Individual Tile,

900	36	75	3	65.5	4500	59.0	4050	9	10

[a] For crushing strengths greater than or equal to those shown in the above table, it is not prohibited to supply tile designed with increased wall thickness, higher strength concrete, or reinforcing.

[b] Calculated average crushing strength for tile size above 10-in. diameter is based on a minimum ultimate three-edge-bearing load of 1500 *D*, where *D* is the internal diameter of tile in feet.

8.3.4 For Special-Quality concrete drain tile, the three-edge-bearing crushing strength shall meet the requirements given in Table 4, or the higher specified load.

Table 4—Physical Test Requirements for Special-Quality Concrete Drain Tile

		Special-Quality Concrete Drain Tile (for Tile Exposed to Corrosive Waters)						
Internal Designated Diameter,		Minimum Wall Thickness,		Minimum Individual Three-Edge-Bearing Crushing Strength,[a]		Absorption		
mm	in.	mm	in.	kN/ linear m	lbf/ linear ft	Maximum Average, percent	Maximum for Individual Tile, percent	Sulfate Exposures
100	4	13	$^{1}/_{2}$	16.0	1100	8	9	For sulfate exposures, sulfate-resistant cement should be specified. (See Section 7.)
125	5	14	$^{9}/_{16}$	16.0	1100	8	9	
150	6	16	$^{5}/_{8}$	16.0	1100	8	9	
200	8	19	$^{3}/_{4}$	16.0	1100	8	9	
250	10	22	$^{7}/_{8}$	16.0	1100	8	9	
300	12	25	1	16.0	1100	8	9	
350	14	29	1$^{1}/_{8}$	16.0	1100	8	9	
375	15	32	1$^{1}/_{4}$	16.0	1100	8	9	
400	16	35	1$^{3}/_{8}$	16.0	1100	8	9	
450	18	38	1$^{1}/_{2}$	17.5	1200	8	9	
500	20	41	1$^{5}/_{8}$	19.5	1330	8	9	
550	22	44	1$^{3}/_{4}$	21.5	1460	8	9	
600	24	50	2	23.5	1600	8	9	
650	26	54	2$^{1}/_{8}$	25.0	1730	8	9	
700	28	60	2$^{3}/_{8}$	27.5	1870	8	9	
750	30	63	2$^{1}/_{2}$	29.0	2000	8	9	
800	32	66	2$^{5}/_{8}$	31.0	2130	8	9	
850	34	72	2$^{7}/_{8}$	33.0	2270	8	9	
900	36	75	3	35.0	2400	8	9	

[a] For crushing strengths greater than or equal to those shown in the above table, tile may be supplied using designs with increased wall thickness, higher strength concrete, or reinforcing.

Note 2—To meet the crushing strength requirements shown in the tables, it is not prohibited to supply tile designed with increased wall thickness, high-compressive strength concrete, or reinforcing, or a combination.

8.4 *Absorption Tests*:

8.4.1 For Standard-Quality concrete drain tile, the boiling absorption test shall meet the requirements given in Table 1. No absorption tests are required if the strength requirements of Table 1, Column A, are met.

8.4.2 For Extra-Quality concrete drain tile, the boiling absorption test shall meet the requirements given in Table 2. No absorption tests are required if the strength requirements of Table 2, Column A, are met.

8.4.3 For Heavy-Duty Extra-Quality concrete drain tile, the boiling absorption test shall meet the requirements given in Table 3.

8.4.4 For Special-Quality concrete drain tile, the boiling absorption test shall meet the requirements given in Table 4.

8.4.5 Specimens for the boiling absorption tests shall be selected in accordance with the following provisions:

8.4.5.1 For the tile with inside diameters of 300 mm [12 in.] or less, and lengths of 300 mm [12 in.], the absorption test shall be made on one full-length quarter segment taken from each of the five tile broken in the strength test, constituting a standard sample as defined in Section 8.2. By quarter segment is meant one of the four pieces into which a tile usually breaks in the strength test. If a tile breaks in such a manner that a satisfactory quarter segment cannot be obtained, then the absorption test shall be made of two or more pieces that approximate the area of a quarter tile of that size selected so that both ends and the center portion of the tile are represented. The average absorption of the pieces so selected shall be considered the absorption for that tile.

8.4.5.2 For nonreinforced tile with inside diameters or lengths in excess of 300 mm [12 in.], the absorption test shall be made on three specimens; one of the specimens shall be taken from one end of the tile, another specimen from the opposite end, and the third specimen from near the center. The average absorption of the three specimens shall be considered the absorption for that tile.

8.4.5.3 For reinforced tile the absorption test shall be made on one specimen taken from each test tile.

8.4.5.4 The specimens shall be the full thickness of the tile, as broken or cut from segments that result from the strength test. Each specimen shall have a minimum area of not less than 0.016 m^2 [25 $in.^2$] as measured on one wall surface.

8.4.5.5 The average absorption for Standard-Quality, Extra-Quality, and Heavy-Duty Extra-Quality tile shall be the average of the absorption tests for the standard sample as defined in Section 8.2 or the average of the absorption tests for the strongest and the weakest tile as measured by the crushing strength of the standard sample. When drain tile fail to meet the absorption test requirement as computed by averaging the absorptions from the weakest and the strongest tile of a standard sample, then the average absorption test shall be computed by averaging the absorption tests from all the tile from the standard sample. The average absorption for the Special-Quality tile shall be the average of the absorption tests for the tile constituting the standard sample.

8.5 *Retests*:

8.5.1 Should the tile first selected fail to conform to the test requirements, the manufacturer, at his expense, is not prohibited from culling the tile and selecting other tile for retest from the remaining stock. For such retests, the number of tile shall be twice the number of tile used in the previous failed test for each standard physical test. In the event of failure of the tile after retest, reject the tile without further test. The manufacturer shall pay all cost for any retest demanded and made.

8.6 *Apparatus*—All apparatus used shall be in accordance with that described in T 280.

8.7 *Test Methods*—The test methods shall be as described in T 280.

9. PERMISSIBLE VARIATIONS

9.1 *Internal Diameter*—Permissible variations are as prescribed in Table 5.

Table 5—Permissible Variation in Internal Diameter

Designated Diameter of tile		Permissible Variation in Internal Diameter of Tile			
		Minimum		Maximum	
mm	in.	mm	in.	mm	in.
100	4	93	$3^{3}/_{4}$	107	$4^{1}/_{4}$
125	5	118	$4^{3}/_{4}$	132	$5^{1}/_{4}$
150	6	140	$5^{5}/_{8}$	160	$6^{3}/_{8}$
200	8	190	$7^{5}/_{8}$	210	$8^{3}/_{8}$
250	10	237	$9^{1}/_{2}$	263	$10^{1}/_{2}$
300	12	287	$11^{1}/_{2}$	313	$12^{1}/_{2}$
350	14	337	$13^{1}/_{2}$	363	$14^{1}/_{2}$
375	15	359	$14^{3}/_{8}$	391	$15^{5}/_{8}$
400	16	384	$15^{3}/_{8}$	416	$16^{5}/_{8}$
450	18	434	$17^{3}/_{8}$	466	$18^{5}/_{8}$
500	20	481	$19^{1}/_{4}$	519	$20^{3}/_{4}$
550	22	531	$21^{1}/_{4}$	569	$22^{3}/_{4}$
600	24	581	$23^{1}/_{4}$	619	$24^{3}/_{4}$
650	26	625	25	675	27
700	28	675	27	725	29
750	30	725	29	775	31
800	32	775	31	825	33
850	34	825	33	875	35
900	36	875	35	925	37

9.2 *Wall Thickness*:

9.2.1 No wall thickness is specified for Standard-Quality concrete drain tile where the crushing strength and the absorption tests are used to determine the tile quality. When only the crushing strength is used to determine Standard Quality tile then the wall thickness for Standard-Quality tile shall be as indicated in Table 1. The wall thickness of Extra-Quality and Heavy-Duty Extra-Quality concrete drain tile at any point shall not be less than the full thickness specified in Tables 2 or 3 by more than 2 mm [$^{1}/_{16}$ in.] for the tile having inside diameters of 100 mm [4 in.], 125 mm [5 in.], and 150 mm [6 in.]; 2 mm [$^{3}/_{32}$ in.] for tile having inside diameters of 200 mm [8 in.] to 250 mm [10 in.]; 3 mm [$^{1}/_{8}$ in.] for tile having inside diameters of 200 mm [12 in.] to 250 mm [24 in.]; and 3 mm [$^{5}/_{32}$ in.] for tile having inside diameters of 650 mm [26 in.] to 900 mm [36 in.] The minimum thickness of Special-Quality drain tile walls at any point shall be not less than shown in Table 4.

9.2.2 The tile wall thickness shall be recorded as the average of 12 wall thickness measurements as made at the top, center, and bottom locations on each of the four quarter tile segments that usually result when a tile is tested for crushing strength. If a tile breaks in such a manner that a satisfactory quarter segment is not obtained, then the 12 wall thickness measurements shall be made on the broken pieces that best represent the top, center, and bottom on the four circumferential location of the tile.

9.3 *Length of Tile*—The length of drain tile smaller than 300 mm [12 in.] in diameter shall be not less than 300 mm [12 in.] Tile of 300 mm [12 in.] to 900 mm [36 in.] in diameter, inclusive, shall have lengths not less than the diameters. The underrun of individual tile shall not exceed 3 percent of the length.

9.4 *Shape*—All drain tile shall be circular in cross section, except when otherwise specified in advance. They shall be approximately straight, except in the case of special connections. The ends of tile shall be so regular and smooth as to readily permit the making of satisfactory close joints and shall be so formed that when the tile are laid together the effective space at the joints will be satisfactory for good drainage.

10. INSPECTION

10.1 All drain tile shall be given a thorough inspection at the agreed delivery point by an inspector approved by the owner, unless a satisfactory inspection has been made in advance of delivery as specified in Section 8.1. The purpose of the inspection shall be to determine whether the tile, independently of meeting the physical test requirements, conform to the specifications as regards shapes and sizes as prescribed in Section 9 and to eliminate defective tile as defined in Section 11. The manufacturer of the drain tile shall afford the inspector all reasonable facilities for his work—both as to the selection of tile for tests and as to inspection of the tile. Inspection shall be completed and reported promptly and full reports of all tests and inspection shall be furnished the manufacturer upon his request.

11. REJECTION

11.1 The owner shall plainly designate all drain tile that he rejects, and such rejected tile shall be removed promptly by the manufacturer, from any job to which the tile have been delivered.

11.2 Drain tile that, when placed in a vertical position, do not give a metallic ring when struck with a light metal hammer, or that are observed to have cracks that extend through the tile wall and are of a length in excess of 13 mm [$^1/_2$ in.], or other defects in the form or dimensions in excess of the limits permitted in this specification, shall be discarded. Outside surface irregularities that do not affect the tile strength shall not be considered reason for rejection of the tile.

12. KEYWORDS

12.1 Concrete drain tile; subsurface drainage; surface drainage; tile.

---

[1] Agrees with ASTM C 412M-05a and C 412-05a except for limiting absorption testing to the 5-hour boil method and the manufacturer is not afforded the option to supply inch-pound sized pipe when the order is placed in SI units.

Standard Specification for

Bituminous-Coated Corrugated Metal Culvert Pipe and Pipe Arches

AASHTO Designation: M 190-04 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Bituminous-Coated Corrugated Metal Culvert Pipe and Pipe Arches

AASHTO Designation: M 190-04 (2008)

1. SCOPE

1.1 This specification covers bituminous-coated corrugated metal pipe and pipe-arches intended to be used for the construction of metal culverts of the following types.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 36, Corrugated Steel Pipe, Metallic-Coated, for Sewers and Drains
- M 196, Corrugated Aluminum Pipe for Sewers and Drains
- T 44, Solubility of Bituminous Materials
- T 49, Penetration of Bituminous Materials

2.2 *ASTM Standards*:

- A 849, Standard Specification for Post-Applied Coatings, Pavings, and Linings for Corrugated Steel Sewer and Drainage Pipe
- A 862/A 862M, Standard Practice for Application of Asphalt Coatings to Corrugated Steel Sewer and Drainage Pipe
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- D 6, Standard Test Method for Loss on Heating of Oil and Asphaltic Compounds
- D 1005, Standard Test Method for Measurement of Dry-Film Thickness of Organic Coatings Using Micrometers

3. DESCRIPTION

3.1 This specification covers four types of pipe as follows:

Type A—Fully Bituminous-Coated

Type B—Half Bituminous-Coated with Paved-Invert

Type C—Fully Bituminous-Coated and Paved-Invert

Type D—Fully Bituminous-Coated and 100 Percent Paved or Lined

3.2 Bituminous-coated corrugated metal culvert pipe and pipe-arches shall conform to the requirements of M 36 or M 196 and, in addition, shall be coated with bituminous material as hereinafter described for the particular type specified.

3.2.1 *Type A*—The pipe shall be uniformly coated, inside and outside, to a minimum thickness of 1.3 mm measured on the crest of the corrugations or, in the case of Type 1A pipe, over the inner surface of the pipe. This coating is also used for Type 1A pipe.

3.2.2 *Type B*—The pipe shall be uniformly coated for approximately one-half the circumference of the pipe (bottom of the pipe installed), inside and outside to a minimum thickness of 1.3 mm and, in addition, the bituminous material shall be applied in such a manner that one or more smooth pavements will be formed in the invert (inside bottom of the pipe when installed), filling the corrugations for at least 25 percent of the circumference of a pipe and 40 percent of the circumference of a pipe-arch. The pavement shall have a minimum thickness of 3.2 mm above the crest of the corrugations, except where the upper edges intersect the corrugations.

3.2.3 *Type C*—The pipe shall be fully coated as required for Type A and, in addition, a smooth pavement shall be provided as required for Type B.

3.2.4 *Type D*—The pipe shall be fully coated as required for Type A and, in addition, a smooth lining of asphalt shall be centrifugally spun inside the pipe. The lining shall have a minimum thickness of 3.2 mm above the crest of the corrugations.

4. BITUMINOUS MATERIAL

4.1 The bituminous material for coating shall be an asphalt having the following properties:

	Limit, percent
Solubility in trichloroethylene, not less than	99.0
Loss on heating to 163°C, not more than	1
Penetration of residue after heating compared with penetration of same sample before testing for loss on heating, not less than	85

4.2 *Shock Test*—The bitumen shall be considered acceptable if not more than one of four test specimens shows a crack. If it is difficult to determine visually whether a specimen has cracked, the specimen should be removed from the test apparatus and subjected to a slight bending.

4.3 *Flow Tests*—The bitumen shall be considered acceptable if the flow does not exceed 6.4 mm on either of the two test specimens.

5. TANK CONTROL AND MAINTENANCE

5.1 *Tank Temperature*—The asphalt temperature in the tank shall be maintained between 200 and 210°C during the coating operation.

5.2 *Tank Cleanliness*:

5.2.1 The asphalt in the tank shall be kept free of contaminants such as dirt, drum paper, and asphalt drippings from the shop floor.

5.2.2 The asphalt tank shall be cleaned as necessary with a minimum frequency of once per year.

5.2.3 The foam that results from the inadvertent introduction of moisture to the tank shall be skimmed off or moved to the side of the tank before inserting or extracting the product.

6. PROCEDURE

6.1 *Coating Application*—Apply the asphalt coating by inserting the product into the bath twice; the first application results in a thin coating to achieve good adherence, and the second achieves the coating thickness required in Section 3.2.

6.1.1 Steel surfaces shall be free of dirt, grease, dust, and moisture before placement in the asphalt bath. The product shall be prepared immediately prior to the coating operation.

6.1.2 Rotate any large structures in the tank to ensure that all surfaces are coated.

6.1.3 The product must remain in the tank until it achieves a minimum temperature of 190°C. The specific time requirements will depend on factors unique to each operation and the product being coated. The time to reach the required temperature is dependent on the initial temperature of the product, the steel thickness, the size of the product, and the volume of the tank.

6.1.4 The following table contains minimum immersion times:

Steel Thickness, mm	Time, min
1.32	2 to 2.5
1.63	2.5 to 3
2.01	3.5 to 5
2.77	5 to 6
3.50	6.5 to 8
4.27	8 to 14

6.1.5 Cool the product to ambient temperature before application of the second coat.

6.1.6 Insert the product a second time to provide the minimum thickness of each surface.

6.2 *Paving*:

6.2.1 Pave the interior of the coated pipe by applying the hot asphalt from the tank to the interior surface of the pipe to provide a thickness over the crest of the corrugation as required by Section 3.2. Pump the hot asphalt to the pipe by appropriate mechanical means, not by transfer with buckets. The asphalt used for paving shall be at least 200°C to ensure good adhesion to the coated pipe. Pave the pipe as soon as possible after coating to avoid poor adhesion associated with the accumulation of dirt and other residue on the coating surface.

6.2.2 Place end dams of wood or heavy paper at the ends of the pipe to retain the asphalt in the pipe. Three or more applications are usually required for most operations.

6.3 *Smooth Lining*:

6.3.1 Line the interior of the pipe that has been coated by covering the corrugations with hot asphalt. Provide a thickness over the crest of the corrugations as required by Section 3.2.

6.3.2 Spray the hot asphalt, taken from the tank, while rotating the pipe on a powered rotary device to provide a uniform smooth lining.

6.4 *Storage and Handling*:

6.4.1 Store and handle the coated product properly to avoid bruising, scaling, or scuffing of the asphalt coating.

6.5 *Repair*—Repair damaged coatings with a cold-applied asphalt mastic material described in ASTM A 849. Repair coatings shall be of equal thickness to the previous coating as a minimum and shall have equal adherence.

7. POST TESTING OF APPLIED ASPHALT

7.1 All asphalt used by pipe fabricators/coaters shall be purchased to meet the requirements of Section 4.1. Post testing of applied asphalt coatings shall be in accordance with state Department Of Transportation requirements and follow the procedures described in this specification. Samples of the bituminous coating shall be obtained by gathering strippings, sufficient to make a 0.283-kg sample, from the inside top of one or more lengths of pipe on or about to be delivered to the project. Care shall be taken in sampling to avoid contamination from sand or soapstone that may have been applied after dipping.

7.2 Testing of the asphalts shall be in accordance with the following standard methods of the American Association of State Highway and Transportation Officials:

Solubility in trichloroethylene	T 44
Loss on heating	D 6
Penetration of residue	T 49

7.3 Physical requirements of the coating.

7.3.1 *Shock Test*—The apparatus for making the test consists of a rigid metal anvil or base plate not less than 12.7 mm thick resting on a solid foundation; a 2000-gr hammer arranged to fall freely in suitable guides against a 1000-gr plunger sliding freely in a vertical sleeve; the lower end of the plunger being spherical in shape with a radius of 12.7 mm; means for raising the hammer and dropping it through a distance of 130 mm upon the head of the plunger.

7.3.1.1 Four test specimens shall be prepared in the form of disks 44.5 mm in diameter and 9.5 mm thick. Approximately 110 g of the bituminous sample shall be heated over a low flame until it becomes fluid and then poured into a brass mold or molds. Care must be exercised to melt the sample at the lowest possible temperature and to stir thoroughly until it is homogeneous and free from air bubbles. The test specimens may be molded separately or the material may be poured in one cylinder 44.5 mm in diameter and of such length that the four specimens may be cut from it with a wire cutter.

Split brass molds, coated with a suitable release agent (Note 1) having an inside diameter of 44.5 mm, slightly tapered outside surfaces, and held together by slip rings will be found suitable for molding the test specimens.

7.3.1.2 If disk molds are used to prepare the specimens, they shall be removed after the asphalt has cooled to room temperature. The four specimens shall be cooled for a period of at least 1 hour in a bath of ice and salt brine at a temperature of –1°C. The specimens shall then be removed from the bath one at a time and quickly placed on the anvil of the test apparatus and centered under the plunger, the hammer tripped to fall through a height of 130 mm upon the head of the plunger. Not more than 8 seconds shall elapse from the time each specimen is removed from the bath until the hammer strikes the plunger.

7.3.1.3 *Precision*—The shock test described in this method is defined as a determination that at least three of four separate specimens comprising a single test sample will exhibit no cracking to yield an acceptable result. Analysis of an interlaboratory study (a blind study carried out by nine laboratories on four different materials with three replicates of each material) reveals a pass/fail ratio for tests on the same material ranging from 0.22 to 1.45, with an overall pass/fail ratio for all 108 samples (27 samples of each of 4 materials) of 0.54. Further, in each of 11, out of the total of 36 cases, where three replicate samples of the same material were tested in the same laboratory, the same laboratory obtained passing results on one of the three replicate samples and failing results on the other two replicate samples or vice versa.

7.3.1.4 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in the test method for measuring shock, no statement on bias is being made.

7.3.2 *Flow Tests*—The apparatus for making the test shall consist of corrugated brass plate approximately 0.8 mm thick, 203.2 mm long, and 101.6 mm wide, with corrugations running lengthwise of the plate, and a metal support to hold the plate on a 45-degree angle with the horizontal. The corrugations shall have a crest-to-crest dimension of 15.9 mm and a depth of 4.8 mm. A line shall be scribed 150 mm from the lower edge.

7.3.2.1 Test specimens shall be in the form of cylinders 9.5 mm in diameter and 19.0 mm in length. Two specimens shall be used for each test. These shall be made by pouring the excess bituminous material from the specimens for the shock test into split brass molds coated with a suitable release agent (Note 1).

Note 1—Mixtures of glycerine and dextrin or talc, Dow-Corning Stop Cock Grease, and castor oil—Versamid 900 (100:1 mixture by mass heated to 204 to 232ºC and stirred until homogeneous), have proven suitable. Other release agents may be used provided results obtained are comparable to those obtained when using one of the above.

7.3.2.2 With the corrugated plate held at an angle of 45 degrees with the horizontal, lay each test specimen in a corrugation so that its lower end will rest exactly along the line scribed 150 mm from the bottom edge of the plate and place the test apparatus in an oven maintained at a temperature of 65 ± 1ºC. After 4 hours in the oven, remove the apparatus and specimens and allow to cool to room temperature. Measure the distance from the bottom of the corrugated plate to the lower edge of the test specimens. This distance subtracted from 150 mm determines the amount of flow.

7.3.2.3 *Precision*:

Single Operator Precision-Flow Test—The single operator coefficient of variation for a single test result (a test result in this method has been defined as the measurements on two separate specimens) has been found to be 65 percent (Note 2). Therefore, two properly conducted tests by the same operator (each consisting of measurements on two specimens from the same sample) should not differ by more than 184 percent (Note 2) of their average. The range (difference between the highest and lowest) of the two individual measurements comprising a test result should not exceed 260 percent (Note 3) of the average of the two.

Multilaboratory Precision-Flow Test—The multilaboratory coefficient of variation of a single test result (a test result in this method has been defined as the measurements on two separate specimens) has been found to be 97 percent (Note 2). Therefore, results of two properly conducted tests in different laboratories on the same bituminous coating should not differ by more than 275 percent (Note 2) of their average.

Note 2—These numbers represent respectively the (1s percent) and (d2s percent) limits described in ASTM C 670.

Note 3—Calculated as described in the paragraph on precision of individual measurements averaged to obtain a test result in ASTM C 670.

Note 4—These precision statements are based on results of an interlaboratory test program using three replicates of each of four materials. Nine laboratories participated in the tests.

7.3.2.4 *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in the test method for measuring flow, no statement on bias is being made.

7.3.3 *Imperviousness Test*—A 25 percent solution of sulfuric acid, a 25 percent solution of sodium hydroxide, and a saturated solution of sodium chloride shall be held in separate valleys of the coated corrugations for a period of 48 hours, during which time no loosening or separation of the bituminous material from the galvanizing shall have taken place. This test may be made on an uncut section of pipe provided provision is made to prevent excessive evaporation of the three test solutions.

7.3.3.1 *Precision and Bias*—No statement is made about either the precision or the bias of the imperviousness test since the result only states whether there is conformance to the criteria for success specified in the procedure.

8. INSPECTION

8.1 The purchaser or his representative shall have free access to the fabricating plant for inspection, and every facility shall be extended to him for this purpose. This inspection shall include an examination of the pipe for defects in the coating. Defects include bruising, cracking, disbanding, or other damage.

8.2 On a random basis, samples may be taken for analysis and asphalt coating measurements for check purposes. These samples may be taken from post-coated pipe or from the dip tank during the dipping process. The thickness of the asphalt coating shall be measured in accordance with test ASTM D 1005.

9. REJECTION

9.1 Asphalt coatings failing to conform to the specific requirements of this specification, or that show poor workmanship in general or poor workmanship in limited areas that have not been repaired in accordance with Section 6.5 are subject to rejection. This requirement applies not only to the individual pipe, but to any shipment as a whole in which a substantial number of pipes have defective coatings.

10. CERTIFICATION

10.1 Pipe fabricator/coater shall furnish certifications from the asphalt suppliers that the asphalt meets the requirements of Section 4 and that the asphalt for the supplied pipe has been applied in accordance with this specification and the appropriate tank control and maintenance have been performed in accordance with this specification.

Standard Specification for

Corrugated Aluminum Pipe for Sewers and Drains

AASHTO Designation: M 196-92 (2008)
ASTM Designation: B 745/B 745M-95

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Corrugated Aluminum Pipe for Sewers and Drains

AASHTO Designation: M 196-92 (2008)
ASTM Designation: B 745/B 745M-95

1. SCOPE

1.1. This specification covers corrugated aluminum pipe intended for use for storm water drainage, underdrains, the construction of culverts, and similar uses. Pipe covered by this specification is not normally used for the conveyance of sanitary or industrial wastes.

1.2. This specification does not include requirements for bedding, backfill, or the relationship between earth cover load and sheet thickness of the pipe. Experience has shown that the successful performance of this product depends upon the proper selection of sheet thickness, type of bedding and backfill, controlled manufacture in the plant, and care in the installation. The purchaser must correlate the above factors and also the corrosion and abrasion requirements of the field installation with the sheet thickness. The structural design of corrugated aluminum pipe and the proper installation procedures are given in *AASHTO LRFD Bridge Design Specifications* and *AASHTO LRFD Bridge Construction Specifications*.

2. REFERENCED DOCUMENTS

- F 836M, Standard Specification for Style 1 Stainless Steel Metric Nuts

3. DESCRIPTIONS OF TERMS SPECIFIC TO THIS STANDARD

3.1. *fabricator*—the producer of the pipe.

3.2. *manufacturer*—the producer of the sheet.

3.3. *purchaser*—the purchaser of the finished product.

4. CLASSIFICATION

4.1. The corrugated aluminum pipe covered by this specification is classified as follows:

4.1.1. *Type I*—This pipe shall have a full circular cross section, with a single thickness of corrugated sheet, fabricated with annular (circumferential) or helical corrugations.

4.1.2. *Type IA*—This pipe shall have a full circular cross section, with an outer shell of corrugated sheet and an inner liner of smooth (uncorrugated) sheet, fabricated with helical corrugations and lock seams.

4.1.3. *Type IR*—This pipe shall have a full circular cross section with a single thickness of smooth sheet, fabricated with helical ribs projecting outwardly.

4.1.4. *Type II*—This pipe shall be a Type I pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.5. *Type IIA*—This pipe shall be a Type IA pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.6. *Type IIR*—This pipe shall be a Type IR pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.7. *Type III*—This pipe, intended for use as underdrains or for underground disposal of water, shall be a Type I pipe which has been perforated to permit the inflow or outflow of water.

4.1.8. *Type IIIR*—This pipe, intended for the underground disposal of water or for subsurface drainage, shall be a Type IR pipe that has been perforated to permit the outflow or inflow of water.

4.2. Perforations in Type III pipe are classified as Class 1 or Class 2 and perforations in Type IIIR pipe are classified as Class 4, as described in Section 8.3.2.

5. ORDERING INFORMATION

5.1. Orders for material to this specification shall include the following information, as necessary, to adequately describe the desired product:

5.1.1. Name of material (corrugated aluminum pipe);

5.1.2. AASHTO designation and year of issue;

5.1.3. Type of pipe (Section 4.1);

5.1.4. Method of fabrication for Type I and Type II pipe (Section 7.1);

5.1.5. Diameter of circular pipe (Section 8.1.1), or span and rise of pipe-arch section (Section 8.2.1);

5.1.6. Length, either total length or length of each piece and number of pieces;

5.1.7. Description of corrugations (Section 7.2);

5.1.8. Sheet thickness (Section 8.1.2);

5.1.9. Coupling bands, number, and type (Section 9.1) if special type is required;

5.1.10. Gaskets for coupling bands, if required (Section 9.3);

5.1.11. For perforated pipe, the class of perforations. If no class is specified for Type III pipe, Class 1 perforations will be furnished. Type IIIR pipe is furnished with Class 4 perforations only (Section 8.3.2);

5.1.12. Certification, if required (Section 13.1); and

5.1.13. Special requirements.

6. MATERIALS

6.1. *Aluminum Sheet for Pipe*—All pipe fabricated under this specification shall be formed from aluminum alloy sheet conforming to M 197.

6.2. *Aluminum Sheet for Coupling Bands*—The sheet used in fabricating coupling bands shall conform to M 197.

6.3. *Rivets*—The material used for rivets in riveted pipe shall conform to the requirements of ASTM B 316/B 316M for alloy 6053-T4, with the following mechanical properties:

Tensile strength, min, MPa	170
Yield strength, min, MPa	95
Shear strength, min, MPa	105
Elongation in 50 mm, or 4 × diameter, min, percent	16

If bolts and nuts are substituted for rivets (see Section 7.3.1), they shall meet the following requirements for either steel bolts and nuts, stainless steel bolts and nuts, or aluminum alloy bolts and nuts:

	Bolts	Nuts
For M 196 pipe:		
(Steel)	F 568, Cl 4.6	M 291M, Cl 5
(Stainless steel)	F 738, Alloy Grp A1, A2, or A4	F 836, Alloy Grp A1, A2, or A4
(Aluminum alloy)	F 468M, Alloy 6061-T6	F 467M, Alloy 6061-T6

The steel bolts and nuts shall be hot-dip galvanized in conformance with M 232M/M 232, or be mechanically galvanized in conformance with M 298, Class 40.

6.4. *Hardware for Coupling Bands*—Bolts and nuts for coupling bands shall conform to the requirements shown in Section 6.3 except for the coating on steel bolts and nuts. Steel bolts, nuts, and other threaded steel items used with coupling bands shall be zinc coated by one of the following processes: hot-dip process as provided in M 232M/M 232; electroplating process as provided in ASTM B 633, Class Fe/Zn 8; or mechanical process as provided in M 298, Class 8. Other steel hardware items used with coupling bands shall be zinc coated by one of the following processes: hot-dip process as provided in M 232M/M 232; electroplating process as provided in ASTM B 633 Class Fe/Zn 25; or mechanical process as provided in M 298, Class 25. Aluminum angles and lugs shall conform to the requirements of ASTM B 221M for alloy 6063-T6.

6.5. *Gaskets*—If gaskets are used in couplings, they shall be a band of expanded rubber meeting the requirements of ASTM D 1056 for the “RE” closed cell grades, or O-rings meeting the requirements of M 198.

7. FABRICATION

7.1. *General Requirements*—Pipe shall be fabricated in full circular cross section.

7.1.1. Type I pipe shall have annular corrugations with lap joints fastened with rivets or shall have helical corrugations with a continuous lock seam extending from end to end of each length of pipe. As there are important differences in the structural characteristics of annular riveted pipe versus helical pipe, it is important for the purchaser to stipulate, for Type I and Type II pipe, the method of fabrication desired. If the method of fabrication is not stated in the ordering information, the fabrication method shall be at the option of the fabricator.

7.1.2. Type IA pipe shall be fabricated with a smooth liner and helically corrugated shell integrally attached at helical lock seams extending from end to end of each length of pipe. The shell shall have corrugations of nominal 68- or 75-mm pitch.

7.1.3. Type IR pipe shall be fabricated with helical ribs projecting outward with a continuous lock seam extending from end to end of each length of pipe.

7.2. *Corrugations*—The corrugations shall be either annular or helical as provided in Section 7.1. The direction of the crests and valleys of helical corrugations shall not be less than 60 degrees from the axis of the pipe for pipe diameters larger than 525 mm, and not less than 45 degrees from the axis for pipe diameters of 525 mm and smaller.

7.2.1. For Type I and IA pipe, corrugations shall form smooth continuous curves and tangents. The dimensions of the corrugations shall be in accordance with Table 1 for the size indicated in the order.

Table 1—Corrugated Requirements for Types I, IA, II, and III Pipe

Nominal Size, mm	Max Pitch,[a] mm	Min Depth,[b] mm	Inside Radius[c]	
			Nominal, mm	Min, mm
38 × 6.5[d]	48	6.0	7	6.5
68 × 13	73	12[e]	17	12
75 × 25	83	24	14	12
150 × 25	160	24	56	51

[a] Pitch is measured from crest to crest of corrugations, at 90 degrees to the direction of the corrugations.

[b] Depth is measured as the vertical distance from a straightedge resting on the corrugation crests parallel to the axis of the pipe, to the bottom of the intervening valley.

[c] Minimum inside radius requirement does not apply to a corrugation containing a helical lock seam.

[d] The corrugation size of 38 × 6.5 mm is available only in helically corrugated pipe.

[e] For pipe 300 to 525 mm diameter inclusive, the minimum corrugation depth shall be 11 mm.

7.2.2. For Type IR pipe, the corrugations shall be essentially rectangular ribs projecting outward from the pipe wall. The dimensions and spacings of the ribs shall be in accordance with Table 2 for the size indicated in the order. For the 292-mm rib spacing, a stiffener shall be included midway between the ribs if the sheet between the ribs does not include a lock seam. This stiffener shall have a nominal radius of 6.4 mm and a minimum height of 5.1 mm toward the outside of the pipe.

Table 2—Rib Requirements for Type IR Pipe

Nominal Size, mm	Rib			Bottom Outside Radius, Min, mm	Bottom Outside Radius,[d] Max Avg, mm	Top Outside Radius, Min, mm	Top Outside Radius,[d] Max Avg, mm
	Width,[a] Min, mm	Depth,[b] Min, mm	Spacing,[c] Max, mm				
19 × 19 × 190	17	19	197	2.5	6.0	2.5 + ^{t}	6.0 + ^{t}
19 × 25 × 292	17	24	298	2.5	6.0	2.5 + ^{t}	6.0 + ^{t}

[a] Width is a dimension of the inside of the rib, but is measured on the outside of the pipe (outside of the rib) and shall meet or exceed the stated minimum width plus two times the wall thickness; that is, 2t + 17 mm.

[b] Depth is an average of three ribs (one sheet width) measured from the inside by placing a straightedge across the open rib and measuring to the bottom of the ribs.

[c] Spacing is an average of three ribs (one sheet width) measured center-to-center of the ribs at 90 degrees to the direction of the ribs.

[d] The average of the four rib radii (Top and Bottom) shall be within the minimum and maximum tolerances. The outside radius refers to the surface outside of the pipe.

Note 1—The nominal dimensions and properties for smooth corrugations and for ribs are given in *AASHTO LRFD Design Specifications*, Section 12.

7.3. *Riveted Seams*—The longitudinal seams shall be staggered to the extent that no more than three thicknesses of sheet are fastened by any rivet. Pipe to be reformed into pipe-arch shape shall have seams meeting the longitudinal seam requirement of Section 8.2.2.

Note 2—Fabrication of pipe without longitudinal seams in 120 degrees of arc, so that the pipe may be installed without longitudinal seams in the invert, is subject to negotiation between the purchaser and fabricator.

7.3.1. The size of rivets, number per corrugation, and width of lap at the longitudinal seam shall be as stated in Table 3, depending on sheet thickness, corrugation size, and diameter of pipe. For pipe with 25-mm deep corrugations, M12 diameter bolts and nuts may be used in lieu of rivets on a one-for-one replacement ratio. Circumferential seams shall be riveted using rivets of the same size as for longitudinal seams and shall have a maximum rivet spacing of 150 mm measured on centers, except that six rivets will be sufficient in 300-mm diameter pipe.

Table 3—Riveted Longitudinal Seams

Specified Sheet Thickness, mm	Nominal Corrugation Size		
	68×13 mm[a,b]	75×25 mm[c,d]	150×25 mm[d,e]
	Rivet Diameters, Min, mm		
1.52	8.0	9.5	12.7
1.91	8.0	9.5	12.7
2.67	9.5	12.7	12.7
3.43	9.5	12.7	12.7
4.17	9.5	12.7	12.7

[a] One rivet each valley for pipe diameters 900 mm and smaller. Two rivets each valley for pipe diameters 1050 mm and larger.

[b] Minimum width of lap 38 mm for pipe diameters 900 mm and smaller, and 75 mm for pipe diameters 1050 mm and larger.

[c] Two rivets each valley for all pipe diameters.

[d] Minimum width of lap 75 mm for pipe of all diameters.

[e] Two rivets each crest and valley for all pipe diameters.

7.3.2. All rivets shall be driven cold in such a manner that the sheets shall be drawn tightly together throughout the entire lap. The center of a rivet shall be no closer than twice its diameter from the edge of the sheet. The distance between the centerlines of the two rows of rivets, where two rows are required, shall not be less than 38 mm. All rivets shall have neat, workmanlike, and full hemispherical heads or heads of a form acceptable to the purchaser, shall be driven without bending, and shall completely fill the hole.

7.4. *Helical Lock Seams*—The lock seam for Type I pipe shall be formed in the tangent element of the corrugation profile with its center near the neutral axis of the corrugation profile. The lock seam for Type IA pipe shall be in the valley of the corrugation, shall be spaced not more than 760 mm apart, and shall be formed from both the liner and the shell in the same general manner as Type I helical lock seam pipe. The lock seam for Type IR pipe shall be formed in the flat zone of the pipe wall, midway between two ribs.

7.4.1. The edges of the sheets within the cross section of the lock seam shall lap at least 4.0 mm for pipe 250 mm or less in diameter and at least 7.9 mm for pipe greater than 250 mm in diameter, with an occasional tolerance of –10 percent of lap width allowable. The lapped surfaces shall be in tight contact. The profile of the sheet shall include a retaining offset adjacent to the 180-degree fold (as described in T 249) of one sheet thickness on one side of the lock seam, or one-half sheet thickness on both sides of the lock seam, at the fabricator's option. There shall be no visual cracks in the metal, loss of metal-to-metal contact, or excessive angularity on the interior of the 180-degree fold of metal at the completion of forming the lock seam. The lock seam shall be mechanically staked (indented) at periodic intervals, or otherwise specially constructed to prevent slippage.

7.4.2. Specimens cut from production pipe normal to and across the lock seam shall develop the tensile strength as provided in Table 4, when tested according to T 249. For Type IA pipe, the lock seam strength shall be as tabulated based on the thickness of the corrugated shell.

7.4.3. When the ends of helically corrugated lock seam pipe have been rerolled to form annular corrugations, either with or without a flanged end finish, the lock seam in the rerolled end shall not contain any visible cracks in the base metal and the tensile strength of the lock seam shall be not less than 60 percent of that required in Section 7.4.2.

Table 4—Specified Aluminum Alloy Sheet Thickness and Lock Seam Tensile Strength

Specified Sheet Thickness,[a, b] mm	Lock Seam Tensile Strength, Min, kN/mm
0.91	17
1.22	25
1.52	30
1.91	43
2.67	74
3.43	96
4.17	122

[a] Thicknesses listed are those included in M 197.

[b] For Type IA pipe, the lock seam tensile strength requirements shall be based on the thickness of the corrugated shell.

7.5. *End Finish*:

7.5.1. To facilitate field jointing, the ends of individual pipe sections with helical corrugations or ribs may be rerolled to form annular corrugations extending at least two corrugations from the pipe end, or to form an upturned flange meeting the requirements in Section 7.5.3, or both. The diameter of ends shall not exceed that of the pipe barrel by more than the depth of the corrugation. All types of pipe ends, whether rerolled or not, shall be matched in a joint such that the maximum difference in the diameter of abutting pipe ends is 13 mm.

7.5.2. When pipe with helical corrugations or ribs is rerolled to form annular corrugations in the ends, the usual size of annular corrugations is 68 × 13 mm.

7.5.3. If a flanged finish is used on the ends of individual pipe sections to facilitate field jointing, the flange shall be uniform in width, not less than 13 mm wide, and square to the longitudinal axis of the pipe.

7.5.4. The ends of all pipe that will form the inlet and outlet of culverts, fabricated of sheets having nominal thicknesses of 1.91 mm and less, shall be reinforced in a manner approved by the purchaser, when specified.

8. PIPE REQUIREMENTS

8.1. *Type I, Type IA, and Type IR Pipe*:

8.1.1. *Pipe Dimensions*—The nominal diameter of the pipe shall be as stated in the order, selected from the sizes listed in Table 5. The size of corrugations that are standard for each size of pipe are also shown in Table 5. The average inside diameter of circular pipe and pipe to be reformed into pipe-arches shall not vary more than 1 percent or 13 mm, whichever is greater, from the nominal diameter when measured on the inside crest of the corrugations. Alternately, for pipe having annular corrugations, conformance with the inside diameter requirement may be determined by measuring the outside circumference, for which minimum values are given in Table 5.

Note 3—The outside circumference of helically corrugated pipe is influenced by the corrugation size and the angle of the corrugations, affecting the number of corrugations crossed; therefore, no minimum circumferential measurement can be specified.

Table 5—Pipe Sizes

Nominal Inside Diameter, mm	Corrugation Sizes[a]					Min Outside Circumference,[c] mm
	38 × 6.5 mm	68 × 13 mm	75 × 25 mm	150 × 25 mm	Ribbed Pipe[b]	
100	X					284
150	X					441

[a] An “X” indicates standard corrugation sizes for each nominal diameter of pipe.

[b] Rib size 19 × 19 × 190 mm and 19 × 25 × 292 mm.

[c] Measured in valley of annular corrugations. Not applicable to helically corrugated pipe.

8.1.2. *Sheet Thickness*—Sheet thickness shall be specified by the purchaser from the specified sheet thicknesses listed in Table 4 (Notes 4 and 5). For Type IA pipe, the thickness of both the shell and the liner shall be given; the thickness of the corrugated shell shall be at least 60 percent of the thickness of the equivalent Type I pipe; the liner shall have a nominal thickness of at least 0.91 mm; and the sum of the specified thicknesses of shell and liner shall equal or exceed the specified thickness of an equivalent pipe of identical corrugations as the shell according to the design criteria in the *AASHTO LRFD Bridge Design Specifications*.

Note 4—The sheet thicknesses indicated in Table 4 are the thicknesses listed as available in M 197.

Note 5—The purchaser should determine the required thickness for Type I, IA, or IR pipe, or Type I, IA, or IR pipe to be reformed into Type II, IIA, or IIR pipe according to the design criteria in *AASHTO LRFD Bridge Design Specifications*, or other appropriate guidelines. Specified thickness of 0.91 mm is generally used only for Type IA pipe.

8.1.3. When specified by the purchaser, the finished pipe shall be factory elongated to the extent specified. The elongation shall be accomplished by the use of a mechanical apparatus that will produce a uniform deformation throughout the length of the section.

Note 6—When corrugated aluminum pipe is designed and installed according to *AASHTO LRFD Bridge Construction Specifications*, vertical elongation (factory or field) is not required for structural purposes.

8.2. *Type II, IIA, and IIR Pipe*:

8.2.1. *Pipe-Arch Dimensions*—Pipe furnished as Type II, IIA, or IIR shall be made from Type I, IA, or IR pipe respectively, and shall be reformed to provide a pipe-arch shape. All applicable requirements for Types I, IA, or IR pipe shall be met by finished Types II, IIA, and IIR respectively. Pipe-arches shall conform to the dimensional requirements of Tables 6, 7, or 8. All dimensions shall be measured from the inside crest of corrugations for Type II pipe or from the inside liner or surface for Types IIA or IIR pipe, respectively.

Table 6—Pipe-Arch Requirements—68 × 13 mm Corrugations

Pipe Arch Size, mm	Equiv Dia, mm	Span,[a] mm	Rise,[a] mm	Min Corner Radius, mm	Max B,[b] mm
430 × 330	375	430	330	75	135
530 × 380	450	530	380	75	155
610 × 460	525	610	460	75	185
710 × 510	600	710	510	75	205
780 × 560	675	780	560	75	225
885 × 610	750	870	610	75	240
970 × 690	825	970	690	75	255
1060 × 740	900	1060	740	90	265
1240 × 840	1050	1240	840	100	290
1440 × 970	1200	1440	970	130	345
1620 × 1100	1350	1620	1100	155	380
1800 × 1200	1500	1800	1200	180	420
1950 × 1320	1650	1950	1320	205	460
2100 × 1450	1800	2100	1450	230	510

[a] A tolerance of ±25 mm or 2 percent of equivalent diameter, whichever is greater, is permissible in span and rise.

[b] B is defined as the vertical dimension from a horizontal line across the widest portion of the arch to the lowest portion of the base.

Table 7—Pipe-Arch Requirements—75 × 25 mm Corrugations

Pipe Arch Size, mm	Equiv Dia, mm	Span,[a] mm	Rise,[a] mm	Min Corner Radius, mm
1340 × 1050	1200	1340 – 60	1050 + 60	180
1520 × 1170	1350	1520 – 70	1170 + 70	205
1670 × 1300	1500	1670 – 75	1300 + 75	230
1850 × 1400	1650	1150 – 85	1400 + 85	305
2050 × 1500	1800	2050 – 90	1500 + 95	355
2200 × 1620	1950	2200 – 110	1620 + 110	355
2400 × 1720	2100	2400 – 120	1720 + 120	410
2600 × 1820	2250	2600 – 130	1820 + 130	410
2840 × 1920	2400	2840 – 145	1920 + 145	460
2970 × 2020	2550	2970 – 150	2020 + 150	460
3240 × 2120	2700	3240 – 165	2120 + 165	460
3470 × 2220	2850	3470 – 175	2220 + 175	460
3600 × 2320	3000	3600 – 180	2320 + 180	460

[a] Negative and positive number listed with span and rise dimensions are negative and positive tolerances, zero tolerance in opposite direction.

Table 8—Pipe-Arch Requirements—19 × 19 mm and 19 × 25 × 292 mm Rib Corrugations

Pipe Arch Size, mm	Equiv Dia, mm	Span,[a] mm	Rise,[a] mm	Min Corner Radius, mm
500 × 410	450	500 – 25	410 + 25	130
580 × 490	525	580 – 25	490 + 25	130
680 × 540	600	680 – 40	540 + 40	130
750 × 620	675	750 – 40	620 + 40	130
830 × 670	750	830 – 40	670 + 40	130
900 × 750	825	900 – 45	750 + 45	130
1010 × 790	900	1010 – 45	790 + 45	130
1160 × 920	1050	1160 – 55	920 + 55	155
1340 × 1050	1200	1340 – 60	1050 + 60	180
1520 × 1170	1350	1520 – 70	1170 + 70	205
1670 × 1300	1500	1670 – 75	1300 + 75	230
1850 × 1400	1650	1850 – 85	1400 + 85	305
2050 × 1500	1800	2050 – 95	1500 + 95	355

[a] Negative and positive number listed with span and rise dimensions are negative and positive tolerances, zero tolerance in opposite direction.

8.2.2. *Longitudinal Seams*—Longitudinal seams of riveted pipe-arches shall not be placed in the corner radius.

8.2.3. Reforming Type IR pipe into Type IIR pipe shall be done in a manner that avoids damage to the external ribs.

8.3. *Type III and IIIR Pipe*:

8.3.1. Type III and IIIR pipe shall have a full circular cross section and shall conform to the requirements for Type I or Type IR pipe and, in addition, shall contain perforations conforming to one of the classes described in Section 8.3.2.

8.3.2. *Perforations*—The perforations in Type III pipe shall conform to the requirements for Class 1 or Class 2 as specified in the order and described in Section 8.3.2.1 and Section 8.3.2.2, respectively. The perforations in Type IIIR pipe shall conform to the requirements for Class 4 as described in Section 8.3.2.3. Class 1 perforations are for pipe intended to be used for subsurface drainage. Class 2 and Class 4 perforations are for pipe intended to be used for subsurface disposal of water, but pipe containing these classes of perforations may also be used for subsurface drainage.

8.3.2.1. *Class 1 Perforations*—The perforations shall be approximately circular and cleanly cut; shall have nominal diameters of not less than 4.8 mm nor greater than 9.5 mm; and shall be arranged in rows parallel to the axis of the pipe. The perforations shall be located on the inside crests or along the neutral axis of the corrugations, with one perforation in each row for each corrugation. Pipe connected by couplings or bands may be unperforated within 100 mm of each end of each length of pipe. The rows of perforations shall be arranged in two equal groups placed symmetrically on either side of a lower unperforated segment corresponding to the flow line of the pipe. The spacing of the rows shall be uniform. The distance between the centerlines of rows shall be not less than 25 mm. The minimum number of longitudinal rows of perforations, the maximum heights of the centerlines of the uppermost rows above the bottom of the invert, and the inside chord lengths of the unperforated segments illustrated in Figure 1 shall be as specified in Table 9.

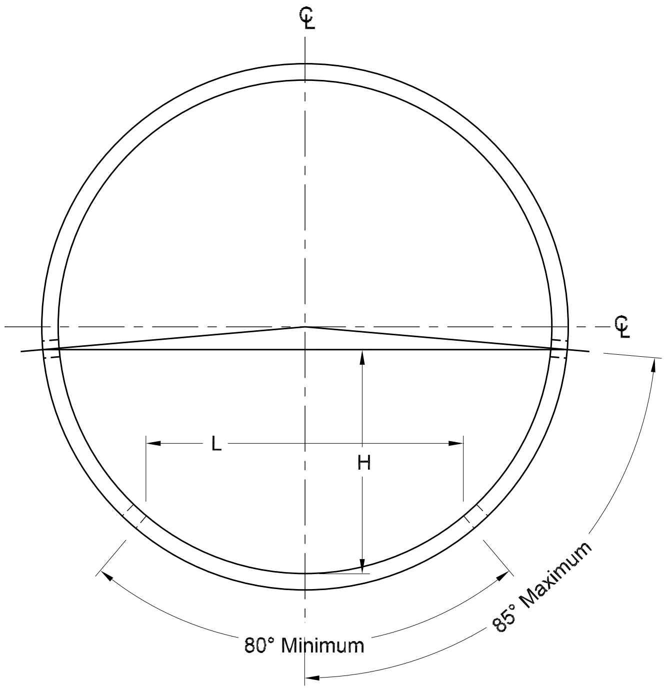

Figure 1—Circumferential Location of Class 1 Perforations

Table 9—Rows of Perforations, Height *H* of the Centerline of the Uppermost Rows Above the Invert, and Chord Length *L* of Unperforated Segment, for Class 1 Perforations

Internal Diameter, mm	Rows of Perforation[a]	*H*, Max,[b] mm	*L*, Min,[b] mm
100	2	46	64
150	4	69	96
200	4	92	128
250	4	115	160
300	6	138	192
375	6	172	240
450	6	207	288
525	6	241	338
600 and larger	8	[c]	[c]

[a] Minimum number of rows. A greater number of rows for increased inlet area shall be subject to agreement between purchaser and fabricator. Note that the number of perforations per unit length in each row (and inlet area) is dependent on the corrugation pitch.

[b] See Figure 1 for location of dimensions H and L.

[c] H(max) = 0.46D; L(min) = 0.64D, where D = internal diameter of pipe, mm.

Note 7—Pipe with Class 1 perforations is generally available in diameters from 100 to 500 mm inclusive, although perforated pipe in larger sizes may be obtained.

8.3.2.2. *Class 2 Perforations*—The perforations shall be circular holes with nominal diameters of 8.0 to 9.5 mm, or slots with nominal width of 4.8 to 8.0 mm and maximum length of 13 mm. The perforations shall be uniformly spaced around the full periphery of the pipe. The perforations shall provide an opening area of not less than 230 square centimeters per square meter of pipe surface based on nominal diameter and length of pipe.

Note 8—323 perforations, 9.5-mm diameter per square meter satisfies the inlet area requirement for Class 2 perforations.

8.3.2.3. *Class 4 Perforations*—The perforations shall be circular holes with nominal diameters of 8.0 to 9.5 mm, or slots with nominal width of 4.8 to 8.0 mm and maximum length of 12.7 mm. All perforations shall occur in the flat sheet between spiral ribs or lock seam with the center of any hole no closer than 19.0 mm from the outside edge of a rib. The perforations shall be uniformly spaced around the full periphery of the pipe. The perforations shall provide an opening area of not less than 140 square centimeters per square meter of pipe surface based on nominal diameter and length of pipe.

Note 9—There is no provision for Class 3 perforations in this specification.

9. COUPLING BANDS

9.1. *Types of Coupling Bands*—Field joints for each type of corrugated aluminum pipe shall maintain pipe alignment during construction and prevent infiltration of fill material during the life of the installation.

9.1.1. *Coupling bands may be of the following types*:

9.1.1.1. Bands with annular corrugations;

9.1.1.2. Bands with helical corrugations;

9.1.1.3. Bands with projections (dimples);

9.1.1.4. Channel bands for upturned flanges, with or without annular corrugations;

9.1.1.5. Flat bands; and

9.1.1.6. Smooth sleeve-type couplers.

9.1.2. Except as provided in Sections 9.1.3 through 9.1.7, the type of coupling furnished shall be at the option of the fabricator unless the type is specified in the order.

Note 10—Bands are classified according to their ability to resist shear, moment, and tensile forces as described in *AASHTO LRFD Bridge Construction Specifications*, and identified as “standard joints” and “special joints.” The four types of bands listed in Sections 9.1.1.1 through 9.1.1.4, and meeting the requirements of Section 9.2, are expected to meet the requirements for “standard joints.” Some may also be able to meet the requirements for “special joints,” but such capability should be determined by analysis or test.

9.1.3. Coupling bands with annular corrugations shall be used only with pipe with annular corrugations, or helical pipe in which the ends have been rerolled to form annular corrugations. The corrugations in the band shall have the same dimensions as the corrugations in the pipe end, or may be of a special design to engage either the first or second corrugation from the end of each pipe. The band may also include a U-shaped channel to accommodate upturned flanges on the pipe.

9.1.4. Coupling bands with helical corrugations shall be used only with pipe with helically corrugated ends. The corrugations in the bands shall be designed to properly mesh with the corrugations in the pipe.

9.1.5. Coupling bands with projections (dimples) may be used with pipe with either annular or helical corrugations. The bands shall be formed with the projections in annular rows with one projection for each corrugation of helical pipe. Bands 265 mm wide shall have two annular rows of projections, and bands 415 and 660 mm wide shall have four annular rows of projections.

9.1.6. Channel bands may be used only with pipe having upturned flanges on the pipe ends.

9.1.7. Smooth sleeve-type couplers and flat bands may be used with Type III pipe of 300-mm diameter or smaller.

9.2. *Requirements*—Coupling bands shall be fabricated to lap on an equal portion of each of the pipe sections to be connected. The ends of the bands shall lap or be fabricated to form a tightly closed joint upon installation. Coupling band thickness shall conform to the requirements in Table 10, based on the sheet thickness of the pipe to be connected, except as provided in Sections 9.2.1 and 9.2.2. The band width shall be not less than as shown in Table 11. The bands shall be connected in a manner approved by the purchaser with suitable aluminum or galvanized steel devices, such as angles, or integrally or separately formed and attached flanges, bolted with bolts as described in Section 6.4; bars and straps; wedge lock and straps; or lugs. Coupling bands shall be fastened with the following size of bolts: pipe diameters 450 mm and less—M10 diameter; pipe diameters 525 mm and greater—M12 diameter.

Table 10—Coupling Band Thickness

Nominal Pipe Thickness, mm	Nominal Coupling Band Thickness, Min, mm
2.67 and thinner	1.22
3.43	1.52
4.17	1.91

Table 11—Coupling Band Width Requirements

Nominal Corrugation Size,[a] mm	Nominal Pipe Inside Dia,[b] mm	Coupling Band Width, Min Annular Corrugated Bands, mm	Coupling Band Width, Min Helically Corrugated Bands, mm	Coupling Band Width, Min Bands with Projections, mm
38 × 65	100 to 250	265	180	265
68 × 13	300 to 900	180	300	265
	1000 to 1800	265	300	265
	2000 to 3000[c]	265	300	415
75 × 25	800 to 1800	300	350	265
	2000 to 3000	300	350	415
150 × 25	1200 to 2700	600	600	660

[a] For helically corrugated pipe with rerolled ends, the nominal corrugation size refers to the dimension of the end corrugations in the pipe.

[b] Equivalent diameter of Type II, Type IIA, and Type IIR pipe.

[c] Diameters through 3000 mm for annular corrugated bands used on rerolled ends of helically corrugated pipe.

9.2.1. If flanges are provided on the pipe ends, the coupling may also be made by interlocking the flanges with a preformed channel band or other band incorporating a locking channel not less than 19 mm in width. The depth of the channel shall be not less than 13 mm. The channel band shall have a minimum nominal thickness of 1.91 mm.

9.2.2. Smooth sleeve-type couplings and flat bands shall be aluminum sheet having a nominal thickness of not less than 0.91 mm or, as an option, may be a plastic sleeve to provide equivalent strength. The coupling shall be close-fitting to hold the pipe firmly in alignment without the use of sealing compounds or gaskets. The coupling or flat band shall contain a device so that the band or coupling will lap equally on the two pipes being joined. The overall length of the coupling shall be equal to or greater than the nominal diameter of the pipe.

9.3. *Gaskets*—Where infiltration or exfiltration is a concern, the couplings may be required to have gaskets. The closed-cell expanded rubber gaskets shall be a continuous band, approximately 180 mm wide and approximately 9.5 mm thick. Rubber O-ring gaskets shall be 20-mm diameter for pipe diameters of 900 mm or smaller, and 22-mm diameter for larger pipe diameters, having 13 mm deep end corrugations. Rubber O-ring gaskets shall be 35-mm diameter for pipe having 25 mm deep end corrugations.

Note 11—Riveted pipe is not watertight, having small openings at the intersection of longitudinal and circumferential seams. Therefore, this type of fabrication should not be used where watertightness is a concern unless the pipe is bituminous coated or lined prior to installation.

9.4. Other types of coupling bands or fastening devices that are equally effective as those described, and which comply with the joint performance criteria of *AASHTO LRFD Bridge Construction Specifications*, may be used when approved by the purchaser.

10. WORKMANSHIP

10.1. The completed pipe shall show careful, finished workmanship in all particulars. Pipe that has been damaged, either during fabrication or in shipping, may be rejected unless repairs are made that are satisfactory to the purchaser. Among others, the following defects shall be considered as constituting poor workmanship:

10.1.1. Variation from a straight centerline;

10.1.2. Elliptical shape in pipe intended to be round;

10.1.3. Dents or bends in the metal;

10.1.4. Lack of rigidity;

10.1.5. Illegible markings on the aluminum sheet;

10.1.6. Ragged or diagonal sheared edges;

10.1.7. Uneven laps in riveted pipe;

10.1.8. Loose, unevenly lined, or unevenly spaced rivets; and

10.1.9. Loosely formed lock seams.

11. INSPECTION

11.1. When agreed as part of the purchase contract, the purchaser or representative shall have free access to the fabricating plant for inspection, and every facility shall be extended for this purpose. This inspection shall include an examination of the pipe for the items in Section 10.1 and the specific requirements of this specification applicable to the type of pipe and method of fabrication.

11.2. On a random basis, samples may be taken for chemical analysis and mechanical property determination for check purposes. These samples will be secured from fabricated pipe or from sheets or coils of the material used in fabrication of the pipe. Testing shall be as described in M 197.

12. REJECTION

12.1. Pipe failing to conform to the requirements of this specification may be rejected. This requirement applies not only to the individual pipe, but to any shipment as a whole in which a substantial number of pipes are defective. If the average deficiency in length of any shipment of pipe is greater than 1 percent, the shipment may be rejected.

13. CERTIFICATION

13.1. When specified in the purchase order or contract, a manufacturer's or fabricator's certification, or both, shall be furnished to the purchaser stating that samples representing each lot have been tested and inspected in accordance with this specification and have been found to meet the requirements for the material described in the order. When specified in the order, a report of the mechanical test results and chemical composition limits shall be furnished.

Note 12—As the identity of the sheet is not maintained from the original ingot production, if numerical results are required by the purchaser, tests should be performed on the finished sheet.

14. PRODUCT MARKING

14.1. If the aluminum alloy sheet was not marked by the manufacturer as indicated in M 197, it shall be marked by the fabricator as described in Section 14.2, during the course of corrugating the sheet and fabricating the pipe.

14.2. Each corrugated sheet used in annular corrugated pipe, and each 0.6 to 1.5 m of coiled sheet used in helically corrugated pipe, shall be identified by the fabricator, showing the following:

14.2.1. Name of sheet manufacturer;

14.2.2. Identification of the pipe fabricator, if different than the sheet manufacturer;

14.2.3. Alloy and temper;

14.2.4. Specified thickness;

14.2.5. Fabricator's date of corrugating or forming into pipe by a six-digit number indicating, in order, the year, month, and day of the month; and

14.2.6. AASHTO designation number.

14.3. The marking shall be applied to the sheet by a permanent method, such as coining, in accordance with ASTM B 666/B 666M. This identification shall appear on the outside of the pipe.

Standard Specification for

Aluminum Alloy Sheet for Corrugated Aluminum Pipe

AASHTO Designation: M 197-06[1]
ASTM Designation: B 744/B 744M-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Aluminum Alloy Sheet for Corrugated Aluminum Pipe

AASHTO Designation: M 197-06[1]
ASTM Designation: B 744/B 744M-05

1. SCOPE

1.1. This specification covers aluminum alloy sheets used in the fabrication of corrugated aluminum pipe intended for use for storm water drainage, underdrains, culverts, and similar uses. The material is furnished corrugated in cut lengths, and uncorrugated in coils and cut lengths.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:
- B 209M, Standard Specification for Aluminum-Alloy Sheet and Plate [Metric]
- B 666/B 666M, Standard Practice for Identification Marking of Aluminum and Magnesium Products

2.2. *ANSI*:
- H35.2M, Dimensional Tolerances for Aluminum Mill Products [Metric]

3. DESCRIPTIONS OF TERMS SPECIFIC TO THIS STANDARD

3.1. *fabricator*—the producer of the pipe.

3.2. *manufacturer*—the producer of the sheet.

3.3. *purchaser*—the purchaser of the finished pipe.

4. ORDERING INFORMATION

4.1. Sheet covered by this specification shall be ordered only to the specified thicknesses listed in Table 1.

Table 1—Sheet Thickness[a]

Specified Thickness, mm	Minimum Thickness, mm
1.22	1.14
1.52	1.44
1.91	1.82
2.67	2.55
3.43	3.29
4.17	3.99

[a] Thickness is measured at any point on the sheet not less than 10 mm from an edge and, if corrugated, on the tangents of corrugations.

4.2. Orders for material to this specification shall include the following information, as necessary, to adequately describe the desired product.

4.2.1. Name of material (aluminum alloy sheet for corrugated aluminum pipe),

4.2.2. AASHTO designation number and year of issue,

4.2.3. Corrugation size, if corrugated (Section 8.4),

4.2.4. Dimensions (thickness; width, either flat or overall corrugated; and length, if cut length),

4.2.5. Coil size requirements (specify maximum outside diameter (OD), acceptable inside diameter (ID), and maximum mass)),

4.2.6. Certification, if required (Section 11.1), and

4.2.7. Special requirements.

Note 1—Typical ordering descriptions are as follows: Aluminum alloy sheet for corrugated aluminum pipe conforming to M 197-____, 2.67 by 760 mm by coil, 1200 mm OD max, 600 mm ID min, 5000 kg max, certified with test report.

5. GENERAL REQUIREMENTS

5.1. Aluminum alloy sheets or coils supplied under this specification shall conform to the applicable requirements of ASTM B 209M for alclad alloy 3004-H34 for annular pipe and alclad alloy 3004-H32 for helical pipe.

6. CHEMICAL COMPOSITION

6.1. The sheet material shall conform to the chemical composition limits in ASTM B 209M, as shown in Table 2.

Table 2—Chemical Composition[a]

	Sheet Core, percent	Sheet Cladding,[b] percent
Alloy	3004	7072
Silicon	0.30	(Si + Fe) = 0.7
Iron	0.7	
Copper	0.25	0.10
Manganese	1.0–1.5	0.10
Magnesium	0.8–1.3	0.10
Zinc	0.25	0.8–1.3
Other each	0.05	0.05
Total	0.15	0.15
Aluminum	Remainder	Remainder

[a] Composition in mass percent maximum unless shown as range.

[b] Composition of cladding alloy as applied during the course of manufacture. Samples from finished sheet or plate shall not be required to conform to these limits.

7. MECHANICAL REQUIREMENTS

7.1. The sheet material shall conform to the requirements for mechanical properties specified in ASTM B 209M, as shown in Table 3 when tested prior to corrugating or other fabrication.

Note 2—Sheet material tested after corrugating and other fabricating should conform to the specified tensile and yield strength requirements, but due to cold working, conformance to the elongation requirements may not be obtained.

Table 3—Mechanical Requirements, Alclad Alloy 3004-H34

Specified Thickness, mm	Tensile Strength		Yield Strength (0.2 Percent Offset), Min, MPa	Elongation in 50 mm, Min, Percent
	Min, MPa	Max, MPa		
Alclad 3004-H32 alloy				
0.91, 1.20	185	235	140	3
1.2 through 4.17	185	235	140	5
Alclad 3004-H34 alloy				
0.91, 1.20	215	260	165	3
1.20 through 4.17	215	260	165	4

8. DIMENSIONS AND TOLERANCES

8.1. Sheet thickness shall conform to dimensions prescribed in Table 1.

8.2. The nominal cladding thickness on each side shall be 5 percent of the total composite thickness. The average cladding thickness, determined according to Section 9.4, shall not be less than 4 percent of the total composite thickness.

8.3. Permissible variations in flat width, length, and squareness shall be in accordance with ANSI H35.2M.

8.4. Corrugations shall form smooth continuous curves and tangents. The dimensions of the corrugations shall be in accordance with Table 4.

8.5. Covering width of corrugated sheet shall be in accordance with Table 5. Covering width is the distance between the crests of the extreme corrugations. There is no established tolerance for overall width since the covering width and lip dimensions are the governing factors for the formed product. The lip dimension of corrugated sheet shall be in accordance with Table 6. This dimension is measured along the radial curvature from the crest of the corrugation to the edge of the sheet.

Table 4—Corrugation Requirements

Nominal Size, mm	Max Pitch[a], mm	Min Depth[b], mm	Inside Radius	
			Nominal, mm	Min, mm
68 × 13	73	12	17	12
75 × 25	83	24	14	12

[a] Pitch is measured from crest to crest of corrugations, at 90 degrees to the direction of the corrugations.

[b] Depth is measured as the vertical distance from a straightedge resting on the corrugation crests to the bottom of the intervening valley.

Table 5—Covering Width Tolerance for Corrugated Sheet

Covering Width, mm	Tolerance Over and Under, mm
To 610, inclusive	6.5
Over 610 to 915, inclusive	9.5
Over 915 to 1220, inclusive	13

Table 6—Corrugated Sheet Lip Dimensions

Nominal Corrugation Size, mm	Lip Dimension	
	Min, mm	Max, mm
68 × 13	19	24
75 × 25	22	28
150 × 25	22	38

9. SAMPLING AND TESTING

9.1. Sampling and testing shall be according to ASTM B 209M. The manufacturer shall make adequate tests and measurements to ensure that the material produced complies with this specification.

9.1.1. Test results, including chemical composition, mechanical properties, and cladding thickness, shall be maintained by the sheet manufacturer for 7 years and shall be made available to the fabricator and purchaser upon request, for examination at the manufacturer's facility unless otherwise agreed upon.

9.2. The fabricator or the purchaser may make such tests as are necessary to determine the acceptability of the material or to verify the correctness of a certification.

9.3. Mechanical properties shall be determined on sheet prior to corrugating or other fabricating, except tests may be made after fabrication by the purchaser for tensile and yield strengths.

9.4. When the thickness of the cladding is to be determined on finished material, no fewer than three transverse samples approximately 19 mm in length shall be mounted to expose a transverse cross section and polished for examination with a metallurgical microscope. Using a 100X magnification, the maximum and minimum cladding thickness shall be measured in each of five fields approximately 2.5 mm apart along both sides of the cross section. The average of ten thickness measurements on each side is the average cladding thickness.

Note 3—If necessary to better define the interface between core and cladding, the polished surface may be etched with Keller's etch or equivalent. Keller's etch contains: 1 part HF conc., 1.5 parts HCl conc., 2.5 parts HNO_3 conc., and 95 parts water.

10. REJECTION

10.1. Material tested by the purchaser and found not conforming to this specification may be rejected.

11. CERTIFICATION

11.1. When specified in the purchase order or contract, a manufacturer's certification shall be furnished to the purchaser of the sheet (fabricator) or to the purchaser of the finished pipe stating that samples representing each lot have been tested and inspected in accordance with this specification and the requirements have been met. When specified in the purchase order or contract, a report of the mechanical test results and the chemical composition limits shall be furnished.

Note 4—As the identity of the sheet is not maintained from the original ingot production, if numerical results are required by the purchaser, tests should be performed on the finished sheet.

12. PRODUCT MARKING

12.1. Each corrugated sheet furnished for use in annular corrugated pipe shall be identified by the sheet manufacturer showing the following:

12.1.1. Name or trademark of sheet manufacturer,

12.1.2. Alloy and temper,

12.1.3. Specified thickness,

12.1.4. Date of corrugating by a six-digit number indicating, in order, the year, month, and day of the month, and

12.1.5. AASHTO designation number.

12.2. Coils and cut-length flat sheets shall be similarly marked by the manufacturer (except Section 12.1.4) at 0.6 to 1.5 m intervals, or the information shall be included on a tag so that the fabricator can mark the sheet at the time of fabrication.

12.3. The marking shall be applied to the sheet by a permanent method such as coining in accordance with ASTM B 666/B 666M.

---

[1] This specification is equivalent to ASTM B 744/B 744M-05 except for including requirements from ASTM B 209M on cladding thickness, chemical composition, and mechanical requirements.

ASTM Designation: C 478M-09 and C 478-09

PART I—GENERAL

1. SCOPE

1.1 This specification covers the manufacture and purchase requirements of products used for the assembly and construction of circular vertical precast reinforced concrete manholes and structures used in sewer, drainage, and water works.

1.2 Part I, Sections 1 through 11, of this specification presents general requirements and requirements that are common to each precast concrete product covered by this specification.

1.3 Part II of this specification presents specific requirements for each manhole product in the following sections:

Product	Section
Grade rings	12
Flat slab tops	13
Risers and conical tops	14
Base sections	15
Steps and ladders	16

Note 1—Future products will be included in Part II in a future revision of this specification.

1.4 This specification is applicable for orders in either SI units (M 199M) or in inch-pound units (M 199). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 199.

Note 2—This specification is a manufacturing and purchase specification only, and does not include requirements for backfill, or the relationship between field load conditions and the strength requirements of the manhole products and appurtenances. Experience has shown, however, that the successful performance of this product depends upon the proper selection of the product strength, type of foundation and backfill, and care in the field installation of the manhole products and connecting pipes. The owner of the project for which these products are specified herein is cautioned to require inspection at the construction site.

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete manholes, see M 262.

4. MATERIALS AND MANUFACTURE

4.1 General material requirements for precast reinforced concrete manhole products are presented in Sections 4.1.1 through 4.1.8. Other materials or additional requirements for a product, if any, are covered in the Part II section for that specific product.

4.1.1 *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water, in which steel reinforcement has been embedded in such a manner so that the steel reinforcement and concrete act together.

4.1.2 *Cementitious Materials*:

4.1.2.1 *Cement*—Cement shall conform to the requirements for portland cement of M 85, or shall be portland blast-furnace slag cement or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash.

4.1.2.2 *Fly Ash*—Fly ash shall conform to the requirements of Class F or Class C of M 295.

4.1.2.3 *Ground Granulated Blast-Furnace Slag (GGBFS)*—GGBFS shall conform to the requirements of Grade 100 or 120 of M 302.

4.1.3 *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

4.1.3.1 Portland cement only,

4.1.3.2 Portland blast-furnace slag cement only,

4.1.3.3 Slag modified portland cement only,

4.1.3.4 Portland-pozzolan cement only, or

4.1.3.5 A combination of portland cement and ground granulated blast furnace slag,

4.1.3.6 A combination of portland cement and fly ash, or

4.1.3.7 A combination of portland cement, ground granulated blast-furnace slag (not to exceed 25 percent of the total cementitious weight).

4.1.4 *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirement for gradation shall not apply.

4.1.5 *Admixtures and Blends*—Admixtures and blends shall only be used with the approval of the owner.

4.1.5.1 Air-Entraining Admixture conforming to M 154;

4.1.5.2 Chemical Admixture conforming to M 194M/M 194;

4.1.5.3 Chemical Admixture for use in producing flowing concrete conforming to ASTM C 1017/C 1017M;

4.1.5.4 Chemical Admixture or Blend approved by the owner.

4.1.6 *Steel Reinforcement*—Reinforcement shall consist of wire conforming to M 32M/M 32 or M 225M/M 225, of wire fabric conforming to M 55M/M 55 or M 221M/M 221, or of bars of Grade 300 [40] steel conforming to M 31M/M 31 or bars confirming to Specification A706/A 706M.

4.1.7 *Secondary Synthetic Fiber*—Collated fibrillated polypropylene virgin fibers shall not be prohibited when used in steel reinforced concrete manholes as a non-structural manufacturing enhancement. Only fibers designed and manufactured specifically for use in concrete and so certified by the manufacturer shall be accepted.

4.1.8 *Other Materials*—Other materials required for a product and not covered in Section 4 will be covered in the Part II section for that specific product.

5. DESIGN

5.1 Design requirements for a product are prescribed in the specific Part II section for that product.

5.1.1 The minimum compressive strength of concrete manhole products covered by this specification shall be 27.6 MPa [4000 psi] unless specified otherwise in Part II of this specification.

5.2 *Modified or Special Design*:

5.2.1 Manufacturers are not prohibited from submitting to the owner, for approval prior to manufacture, designs other than those prescribed in the specific section for a product. If such approval is obtained, then the product shall meet all the tests and performance requirements specified by the owner in accordance with the appropriate sections on manufacture and physical requirements.

5.2.2 If permitted by the owner, the manufacturer is not prohibited from requesting approval of designs of special sections, such as reducers, tees, and bases.

6. REINFORCEMENT

6.1 This section presents requirements for reinforcement cover, continuity, laps, welds, and splices. Other reinforcement requirements are presented in Section 4 and any additional requirements are given in the Part II section for a specific product.

6.2 *Cover*—The exposure of the ends of reinforcement, stirrups or spacers used to position the reinforcement during placement of the concrete shall not be cause for rejection.

6.3 *Continuity*—The continuity of the circumferential reinforcement shall not be destroyed during the manufacture of the product, except when lift holes or pipe openings are provided in the product.

6.4 *Welded Steel Cage Laps, Welds, and Splices*:

6.4.1 If splices are not welded, the reinforcement shall be lapped not less than 20 diameters for deformed bars, and 40 diameters for plain bars and cold-drawn wire. In addition, where lapped cages of welded wire fabric are used without welding, the lap shall contain a longitudinal wire.

6.4.2 When splices are welded and are not lapped to the minimum requirements in Section 6.4.1, pull tests of representative specimens shall develop at least 50 percent of the minimum specified strength of the steel, and there shall be a minimum lap of 50 mm [2 in.] For butt welded splices in bars or wire, permitted only with helically wound cages, pull tests of representative specimens shall develop at least 75 percent of the minimum specified strength of the steel.

6.5 *Steel Hoop Splices*—A representative sample steel hoop with welded splices shall develop at least 50 percent of the minimum specified strength of the steel, and there shall be a minimum lap of

50 mm [2 in.] For butt-welded splices, the representative steel hoop sample shall develop at least 75 percent of the minimum specified strength of the steel.

7. PRECAST CONCRETE MANUFACTURE

7.1 *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the products will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious ratio not exceeding 0.53 by weight. Cementitious materials shall be as specified in Section 4.1.2 and shall be added to the mix in a proportion not less than 280 kg/m^3 [470 lb/yd^3], unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the product meet the requirements of this specification.

7.2 *Curing*—Concrete products shall be subjected to any one of the methods of curing prescribed in Sections 7.2.1 through 7.2.4 or to any other method or combination of methods approved by the owner that will give satisfactory results.

7.2.1 *Steam Curing*—Concrete products are placed in a curing chamber, free of outside drafts, and cured in a moist atmosphere maintained by the injection of steam for such time and such temperatures as needed to enable the products to meet the strength requirements. The curing chamber shall be so constructed as to allow full circulation of the steam around the entire product.

7.2.2 *Water Curing*—Concrete products are water cured by covering with water-saturated material, or by a system of perforated pipes, mechanical sprinklers, porous hose, or by any other approved method that will keep the products moist during the curing period.

7.2.3 *Sealing Membrane*—A sealing membrane conforming to the requirements of M 148 is applied and shall be left intact until the required concrete strength requirements are met. The concrete at the time of application of the membrane shall be within 6ºC [10ºF] of the atmospheric temperature. All concrete surfaces shall be kept moist prior to the application of the membrane and shall be damp when the membrane is applied.

7.2.4 The manufacturer is not prohibited from combining the methods prescribed in Sections 7.2.1 through 7.2.3 provided the required concrete compressive strength is attained.

8. ACCEPTANCE

8.1 *Acceptance Procedures*:

8.1.1 Unless otherwise designated by the owner at the time of, or before, placing an order, acceptance procedures for precast reinforced concrete manhole products shall be as specified in the Part II section for a particular product, and shall not be prohibited from consisting of one or more of the following:

8.1.1.1 Acceptance of a product on the basis of tests of materials, including concrete compressive strength and absorption;

8.1.1.2 Acceptance of a product on the basis of inspection of the finished product, including amount and placement of reinforcement to determine conformance with the design prescribed under this specification, and freedom from defects.

8.2 *Test Methods*:

8.2.1 *Concrete Compressive Strength Test*:

8.2.1.1 *Type of Specimen*—Compression tests for satisfying the minimum specified concrete strength requirement shall be made on either concrete cylinders or, at the option of the manufacturer, on cores cut from the concrete manhole product.

8.2.1.2 *Compression Testing of Cylinders*—Cylinders shall be made in accordance with T 280, and shall be tested in accordance with T 22. For manhole products, an owner shall not be prohibited from requiring concrete compressive tests on cylinder specimens numbering in the amount of 5 percent of the total order of a manhole product, but not to exceed two cylinders for each day's production. The average compressive strength of all cylinders tested shall be equal to or greater than the specified strength of the concrete. Not more than 10 percent of the cylinders tested shall fall below the specified strength of the concrete. In no case shall any cylinder tested fall below 80 percent of the specified strength of the concrete.

8.2.1.3 *Compression Testing of Cores*—Cores shall be cut from the concrete manhole product and tested in accordance with Test Methods T 280 except that the requirements for moisture conditioning shall not apply. One core shall be taken from a manhole product selected at random from each day's production run of a single concrete strength. When the concrete compressive strength of the core is equal to or greater than 80 percent of the specified strength of the concrete, the concrete strength of the production run is acceptable. If the core does not meet the preceding concrete strength requirement, another core from the same manhole product shall be taken and tested.

8.2.1.4 If the concrete compressive strength of the recore is equal to or greater than 80 percent of the specified strength of the concrete, the concrete strength of the production run is acceptable. If the recore does not meet the preceding concrete strength requirement, that manhole product shall be rejected. Two manhole products from the remainder of the day's production run shall be selected at random and one core taken from each manhole product and tested. When the average concrete strength of the two cores is equal to or greater than 80 percent of the specified strength of the concrete with no core below 75 percent of the specified strength of the concrete, the concrete strength of the day's production run shall be acceptable.

8.2.1.5 If the concrete strength of the two cores does not meet the preceding concrete strength requirement, then the remainder of the day's production run shall be either rejected, or, at the option of the manufacturer, each manhole product of the remainder of the day's production run is not prohibited from being cored and accepted individually.

8.2.1.6 *Plugging Core Holes*—Core holes on accepted concrete manhole products shall be plugged and sealed by the manufacturer in a manner such that the manhole products will meet all of the requirements of this specification. Manhole sections so sealed shall be considered as satisfactory for use.

8.2.2 *Absorption Test*:

8.2.2.1 The absorption of a specimen from a concrete product, as determined in T 280, shall not exceed 9 percent of the dry mass. All specimens shall be free of visible cracks and shall represent the full thickness of the product.

8.2.2.2 Each specimen tested shall have a minimum mass of 1.0 kg [2.2 lb].

8.2.2.3 When the initial absorption specimen from a concrete product fails to conform to this specification, the absorption test shall be made on another specimen from the same product and the results of the retest shall be substituted for the original test results.

8.2.3 *Retests*—When not more than 20 percent of the concrete test specimens tested under either Section 8.2.2.1 or Section 8.2.2.2 fail to pass the requirements of this specification, the manufacturer is not prohibited from culling his stock and eliminating whatever quantity of product he desires, and shall so mark the culled product that they will not be shipped for the order. The required tests shall be made on the balance of the order and the products shall be accepted if in conformance with the requirements of this specification.

8.3 *Test Equipment*—Every manufacturer furnishing manhole products under this specification shall furnish all facilities and personnel necessary to carry out the tests required for acceptance.

9. REPAIRS

9.1 Repair of manhole products shall not be prohibited, if necessary, because of imperfections in manufacture or damage during handling, and will be acceptable if, in the opinion of the owner, the repaired products conform to the requirements of this specification.

10. INSPECTION

10.1 The quality of materials, the process of manufacture, and the finished manhole products shall be subject to inspection and approval by the owner.

11. PRODUCT MARKING

11.1 The following information shall be legibly marked on each precast concrete product:

11.1.1 Specification and product designation: MH for manhole base, riser, conical tops, and grade rings;

11.1.2 Date of manufacture; and

11.1.3 Name or trademark of the manufacturer.

11.2 Marking shall be indented into the concrete or shall be painted thereon with waterproof paint.

PART II—PRODUCTS

12. GRADE RINGS

12.1 *Scope*—This section covers precast reinforced concrete grade rings used for final adjustment of manholes to grade.

12.2 *Acceptance*—Acceptability of grade rings covered by this specification shall be determined by the results of such tests of materials as are required by Section 4; by compressive strength tests on concrete cores or concrete cylinders required by Section 8; and by inspection of the finished product, including amount and placement of reinforcement as prescribed by Sections 12.4, 12.5, and 12.6, to determine its conformance with the design prescribed under this specification and its freedom from defects.

12.3 *Design*—The minimum wall thickness shall be one-twelfth of the internal diameter of the grade ring or 100 mm [4 in.], whichever is greater.

12.3.1 *Joints*—Grade rings are not required to have the joint formed with male and female ends.

12.4 *Circumferential Reinforcement*:

12.4.1 The circumferential reinforcement shall have an equivalent area of not less than 150 mm^2/vertical m [0.07 in.^2/vertical ft], but not less than 15 mm^2 [0.024 in.^2] in any one grade ring.

12.4.2 The circumferential reinforcement shall be one line in the center third of the wall of the grade ring.

12.5 *Permissible Variations*:

12.5.1 *Internal Diameter*—The internal diameter of grade rings shall not vary more than ±1 percent.

12.5.2 *Wall Thickness*—The wall thickness of grade rings shall be not less than that prescribed in the design by more than 5 percent or ±5 mm [$\pm{}^3/_{16}$ in.], whichever is greater. A wall thickness greater than that prescribed in the design shall not be cause for rejection.

12.5.3 Height of Two Opposite Sides—Variations in laying height of two opposite sides of grade rings shall be not more than 6 mm [${}^1/_4$ in.].

12.5.4 *Height of Grade Ring*—The underrun in height of a grade ring shall be not more than 20 mm/m [${}^1/_8$ in./ft] of height.

12.5.5 *Position of Reinforcement*—For grade rings with a 100 mm [4-in.] wall thickness, the maximum variation in the design position of circumferential reinforcement from that described in Section 12.4.1 shall be ±10 percent of the wall thickness or ±6 mm [$\pm{}^1/_4$ in.], whichever is greater. For grade rings with a wall thickness greater than 100 mm [4 in.], the maximum variation from the design position of reinforcement shall be ±10 percent of the wall thickness or ±16 mm [$\pm{}^5/_8$ in.], whichever is the lesser. In no case, however, shall the cover over the reinforcement be less than 19 mm [${}^3/_4$ in.] The preceding minimum cover limitation does not apply to the mating surfaces of the joint.

12.5.6 *Area of Reinforcement*—Steel reinforcement areas that are 10 mm^2/linear m [0.005 in.^2/linear ft] less than called for by design shall be considered as meeting the required steel reinforcement area.

12.6 *Rejection*:

12.6.1 Grade rings shall be subject to rejection for failure to conform to any of the specification requirements. In addition, an individual grade ring shall be subject to rejection because of any of the following:

12.6.1.1 Fractures or cracks passing through the wall, except for a single end crack that does not exceed the depth of the joint;

12.6.1.2 Defects that indicate mixing and molding not in compliance with Section 7.1 or surface defects indicating honey-combed or open texture that would adversely affect the function of the grade ring;

12.6.1.3 The planes of the ends are not perpendicular to the longitudinal axis of the grade ring, within the limits of permissible variations prescribed in Section 12.5;

12.6.1.4 Damaged or cracked ends, where such damage would prevent making a satisfactory joint; and

12.6.1.5 Any continuous crack having a surface width of 0.3 mm [0.01 in.] or more, and extending for a length of 300 mm [12 in.] or more, regardless of position in the wall.

13. FLAT SLAB TOPS

13.1 *Scope*—This section covers precast reinforced concrete flat slab tops used in the construction of manholes for use in sewer, drainage, and water works.

13.2 *Acceptance*:

13.2.1 Acceptability of flat slab tops shall be determined by the results of such tests of materials as are required by Section 4; by compressive strength tests on concrete cores or concrete cylinders required by Section 8; and by inspection of the finished product, including amount and placement of reinforcement as prescribed by Sections 13.4 and 13.6, to determine its conformance with the design prescribed under this specification and its freedom from defects;

13.2.2 Unless otherwise designated by the owner at the time of, or before, placing an order, two separate and alternative methods of acceptance are permitted for flat slab top manufacturer designs, in addition to tests of materials and inspection required in Section 13.2.1;

13.2.2.1 *Acceptance on the Basis of Proof-of-Design Test*—Acceptance of flat slab tops on the basis of the results of a proof-of-design test performed in accordance with Section 13.5 in lieu of submission of design calculations and detailed drawings; and

13.2.2.2 *Acceptance on the Basis of Rational Design*—Acceptance of flat slab tops on the basis of design calculations by a rational method and detailed drawings.

13.3 *Design*:

13.3.1 The basis of flat slab top designs shall be the appropriate sections of the latest edition of ACI 318.

13.3.2 Flat slab tops shall have a minimum thickness of 150 mm [6 in.] for risers up to and including 1200 mm [48 in.] in diameter and 200 mm [8 in.] for larger diameters.

13.3.3 The flat slab top access opening shall be a minimum of 600 mm [24 in.] in diameter.

13.3.4 *Joint*—The reinforced concrete flat slab top shall be formed with or without a male or female end so that when the manhole base, riser and top section are assembled, they will make a continuous and uniform manhole compatible with the tolerances given in Section 13.6.

13.3.4.1 Joints are designed to perform in axial compression; therefore, shear or load testing of the joint is not required.

13.4 *Reinforcement*:

13.4.1 Flat slab tops manufactured with a joint or with other indication of the top or bottom of the slab shall be manufactured with one layer of reinforcement placed near the bottom surface so that the protective cover over the reinforcement shall be 25 mm [1 in.].

13.4.2 Flat slab tops manufactured without a joint or without other indication of the top or bottom of the slab shall be manufactured with two layers of steel reinforcement, one located near the bottom surface and one near the top surface so that the protective cover over each layer is 25 mm [1 in.].

13.4.3 A layer of reinforcement shall have a minimum area of 250 mm^2/liner m [0.12 in.^2/linear foot] in both directions.

13.4.4 Openings in flat slab tops shall be additionally reinforced with a minimum of the equivalent of 130 mm^2 [0.20 in.^2] of steel at 90 degrees. Straight rods used to reinforce openings shall have a minimum length equal to the diameter of the opening plus 50 mm [2 in.].

13.5 *Physical Requirements*: Physical requirements for tests shall conform to the requirements of Section 8.

13.5.1 *Proof-of-Design Test*:

13.5.1.1 If Section 13.2.2.2 has been designated as the basis of acceptance, one flat slab top for each design shall be tested unless the owner has indicated otherwise.

13.5.1.2 The flat slab top proof-of-design test procedures shall be in accordance with T 280.

13.5.1.3 The ultimate test load shall be the sum of at least 130 percent of the dead load on the slab plus at least 217 percent of the live-plus impact load on the slab. Dead load is the mass of the column of earth over the slab plus the mass of the riser supported by the slab. Live load is the maximum anticipated wheel load that may be transmitted through the riser to the slab.

13.5.1.4 The flat slab top shall be acceptable if it supports the required ultimate test load without failure. Ultimate strength failure is defined as the inability of the slab to resist an increase in the applied load.

13.5.1.5 When agreed upon by the owner and manufacturer, the flat slab top shall be acceptable based on certified copies of the results of tests performed on identical flat slab tops instead of requiring new proof-of-design acceptance tests.

13.6 *Permissible Variations*:

13.6.1 *Internal Diameter*—The internal diameter of the flat slab tops entrance hole shall not vary more than ±1 percent.

13.6.2 *Thickness*—The thickness of flat slab tops shall be not less than that prescribed in the design by more than 5 percent or ±5 mm [$\pm ^3/_{16}$ in.], whichever is greater. A thickness greater than that prescribed in the design shall not be cause for rejection.

13.6.3 *Length of Two Opposite Sides*—Variations in lengths of two opposite sides of flat slab tops shall be not more than 6 mm [$^1/_4$ in.]

13.6.4 *Length*—The underrun in length of a flat slab top shall be not more than 20 mm/m [$^1/_8$ in./ft] of length.

13.6.5 *Position of Reinforcement*—For flat slab tops with less than a 150 mm [6 in.] thickness, the maximum variation in the position of reinforcement from that prescribed in Section 13.4 shall be ±10 percent of the thickness or ±6 mm [±$^1/_4$ in.], whichever is greater. For flat slab tops with a thickness greater than 150 mm [6 in.], the maximum variation shall be ±10 percent of the thickness or ±16 mm [±$^5/_8$ in.], whichever is the lesser. In no case, however, shall the cover over the reinforcement be less than 19 mm [$^3/_4$ in.].

13.6.6 *Area of Reinforcement*—Steel reinforcement areas that are 10 mm^2/linear m [0.005 in.^{2}/linear ft] less than called for by design shall be considered as meeting the required steel reinforcement area.

13.7 *Rejection*:

13.7.1 Flat slab tops shall be subject to rejection for failure to conform to any of the specification requirements. In addition, an individual flat slab top shall be subject to rejection because of any of the following:

13.7.1.1 Fractures or cracks passing through the wall, except for a single end crack that does not exceed the depth of the joint;

13.7.1.2 Defects that indicate mixing and molding not in compliance with Section 7.1 or surface defects indicating honey-combed or open texture that would adversely affect the function of the flat slab top;

13.7.1.3 The planes of the ends are not perpendicular to the longitudinal axis of the flat slab top, within the limits of permissible variations prescribed in Section 13.6;

13.7.1.4 Damaged or cracked ends, where such damage would prevent making a satisfactory joint; and

13.7.1.5 Any continuous crack having a surface width of 3 mm [0.01 in.] or more and extending for a length of 300 mm [12 in.] or more, regardless of position in the slab.

14. RISERS AND CONICAL TOPS

14.1 *Scope*—This section covers precast reinforced concrete risers and conical tops used in construction of manholes for use in sewer, drainage, and water works.

14.2 *Acceptance*—Acceptability of risers and conical tops covered by this specification shall be determined by the results of such tests of materials as required by Section 4; by compressive strength tests on concrete cores or concrete cylinders required by Section 8; and by inspection of the finished product, including the amount of reinforcement as prescribed by Sections 14.4 or 14.5, and meeting permissible variations as prescribed by Section 14.7, to determine its conformance with the design prescribed under this specification and its freedom from defects.

14.3 *Design*—The minimum wall thickness shall be one-twelfth of the largest internal diameter of the riser or conical top.

14.4 *Welded Steel Cage Reinforcement*:

14.4.1 *Circumferential Reinforcement for Risers and Conical Tops*:

14.4.1.1 Circumferential reinforcement shall consist of either one or two lines of steel. The total area of reinforcement per vertical meter [foot] shall be not less than 0.0021 [0.0025] times the internal diameter in millimeters [inches].

14.4.1.2 A line of circumferential reinforcement for any given total area may be composed of two layers if the layers are not separated by more than the thickness of one cross member plus 6 mm [$^1/_4$ in.] The two layers shall be tied together to form a single cage. All other specification requirements such as laps, welds, and tolerances of placement in the wall of the riser or conical top shall apply to this method of fabricating a line of reinforcement.

14.4.1.3 Where one line of circumferential reinforcement is used, it shall be placed in the center third of the wall. The protective cover over the circumferential reinforcement in the wall shall be no less than 19 mm [$^3/_4$ in.] in accordance with Section 14.7.

14.4.1.4 Where two lines of circumferential reinforcement are used, each line shall be so placed that the protective covering over the circumferential reinforcement in the wall shall be 25 mm [1 in.].

14.4.1.5 The location of the reinforcement shall be subject to the permissible variations in dimensions prescribed in Section 14.7.

14.4.1.6 The spacing center-to-center of circumferential reinforcement in a cage shall not exceed 150 mm [6 in.].

14.4.2 *Longitudinal Members*—Each line of circumferential reinforcement shall be assembled into a cage that shall contain sufficient longitudinal bars or members to maintain the reinforcement in shape and position within the form to comply with permissible variations in Section 14.7.

14.4.3 *Joint Reinforcement*—The tongue or groove of the joint is not required to contain circumferential reinforcement.

14.5 *Steel Hoop Reinforcement*:

14.5.1 *Continuous Circumferential Reinforcement for Risers and Conical Tops Up to and Including 1200 mm [48-in.] Diameters*:

Note 3—Care shall be taken to ensure that none of the steel hoop reinforcement is cut prior to installation of the riser or conical top.

14.5.1.1 Circumferential reinforcement for manhole risers and conical tops up to and including 600 mm [24 in.] in height shall consist of no less than two hoops of steel wire or reinforcing bars. The steel hoop shall have a minimum cross-sectional diameter of 6 mm [0.250 in.] and shall be located in each end quarter of the riser or conical top, with a minimum distance of 25 mm [1 in.] from the shoulder of the riser or conical top.

14.5.1.2 Circumferential reinforcement for manhole risers and conical tops greater in height than 600 mm [24 in.] and up to and including 1200 mm [48 in.] in height shall consist of no less than three hoops of steel wire or reinforcing bars. The steel hoops shall have a minimum cross-sectional diameter of 6 mm [0.250 in.] and shall have a hoop located in each end quarter of the riser or conical top with a minimum distance of 25 mm [1 in.] from the shoulder of the riser or conical top. The third, or middle, hoop shall be located from the shoulder of the riser or conical top a distance equal to one-half the section height ±150 mm [±6 in.].

14.5.1.3 Circumferential reinforcement for manhole risers and conical tops greater in height than 1200 mm [48 in.] and up to and including 1800 mm [72 in.] in height shall consist of no less than four hoops of steel wire or reinforcing bars spaced equally ±75 mm [±3 in.] throughout the height of the riser or conical top. The steel hoops shall have a minimum cross-sectional diameter of 6 mm [0.250 in.] and shall have a hoop located in each end quarter of the riser or conical top with a minimum distance of 1 in. from the shoulder of the riser or conical top.

14.5.1.4 The hoop reinforcement shall be placed in the center third of the riser wall or conical top. The concrete cover over the hoop reinforcement in the wall of the section shall be no less than 19 mm [$^{3}/_{4}$ in.] in accordance with Section 14.7.

14.5.2 *Joint Reinforcement*—The tongue or groove of the joint is not required to contain circumferential reinforcement.

14.6 *Joints*—Precast reinforced concrete risers and conical tops shall be designed and manufactured with male and female ends, so that the assembled manhole base, riser, and conical top shall make a continuous and uniform manhole, compatible with the tolerances given in Section 14.7.

14.6.1 Joints are designed to perform in axial compression; therefore, shear or load testing of the joint is not required.

14.7 *Permissible Variations*:

14.7.1 *Internal Diameter*—The internal diameter of risers and conical tops shall not vary more than 1 percent.

14.7.2 *Wall Thickness*—The wall thickness of risers and conical tops shall be not less than that prescribed in the design by more than 5 percent or ±5 mm [±$^{3}/_{16}$ in.], whichever is greater. A wall thickness greater than that prescribed in the design shall not be cause for rejection.

14.7.3 *Height of Two Opposite Sides*—Variations in laying heights of two opposite sides of risers or conical tops shall be not more than 16 mm [$^{5}/_{8}$ in.].

14.7.4 *Height of Section*—The underrun in height of a riser or conical top shall be not more than 20 mm/m [$^{1}/_{4}$ in./ft] of height with a maximum of 13 mm [$^{1}/_{2}$ in.] in any one section.

14.7.5 *Position of Reinforcement*—For risers or conical tops with a 100 mm [4-in.] wall thickness or less, the maximum variation in the position of reinforcement from that prescribed in Sections 14.5 and 14.6 shall be ±10 percent of the wall thickness or ±6 mm [±$^{1}/_{4}$ in.], whichever is greater. For sections with a wall thickness greater than 100 mm [4 in.], the maximum variation in the position of reinforcement shall be ±10 percent of the wall thickness or ±16 mm [±$^{5}/_{8}$ in.], whichever is the lesser. In no case, however, shall the cover over the reinforcement be less than 19 mm [$^{3}/_{4}$ in.]. The preceding minimum cover limitation does not apply to the mating surfaces of the joint.

14.7.6 *Area of Reinforcement*—Steel reinforcement areas that are 0.1 mm^{2}/linear m [0.005 in.^{2}/linear ft] less than called for by design shall be considered as meeting the required steel reinforcement area.

14.8 *Rejection*:

14.8.1 Risers and conical tops shall be subject to rejection for failure to conform to any of the specification requirements. In addition, an individual riser or conical top shall be subject to rejected because of any of the following:

14.8.1.1 Fractures or cracks passing through the wall, except for a single end crack that does not exceed the depth of the joint;

14.8.1.2 Defects that indicate mixing and molding not in compliance with Section 7.1 or surface defects indicating honey-combed or open texture that would adversely affect the function of the riser or conical top;

14.8.1.3 The planes of the ends are not perpendicular to the longitudinal axis of the riser or conical top, within the limits of permissible variations prescribed in Section 14.7;

14.8.1.4 Damaged or cracked ends, where such damage would prevent making a satisfactory joint; and

14.8.1.5 Any continuous crack having a surface width of 0.3 mm [0.01 in.] or more and extending for a length of 300 mm [12 in.] or more, regardless of position in the wall.

15. BASE SECTIONS

15.1 *Scope*—This section covers three types of precast reinforced concrete base sections manufactured for use in the construction of manholes used in sewer and water works. The three types of base sections are (1) a base with riser wall and base slab cast monolithically as a single unit with or without benching, (2) a base consisting of a riser section with a secondary poured integral base slab with or without benching, and (3) a two-piece base consisting of a separate precast base slab and a riser section with a sealed joint between the two. The riser portions of a base section shall meet all the requirements of Section 14.

15.2 *Acceptance*—Acceptability of base sections covered by this specification shall be determined by the results of such tests of materials as are required by Section 4; by compressive strength tests on concrete cores or concrete cylinders required by Section 8; and by inspection of the finished product, including amount and placement of reinforcement as prescribed by Sections 15.4 and 15.6, to determine conformance with the design prescribed under this specification and its freedom from defects.

15.3 *Design*:

15.3.1 The basis of base slab designs shall be the appropriate sections of the latest edition of ACI 318.

15.3.2 Base slabs shall have a minimum thickness of 150 mm [6 in.] for manholes up to and including 1200 mm [48 in.] in diameter and 200 mm [8 in.] for larger diameter manholes.

15.3.2.1 When a base section is precast monolithically with a benched invert, the minimum concrete thickness from the invert to bottom of the base slab shall be 100 mm [4 in.].

15.3.3 Benched inverts cast either monolithically with the base section or as a secondary casting in a cured base section shall have the following minimum dimensions:

15.3.3.1 Minimum slope of 40 mm/m [$^1/_2$ in./ft] from the channel to the inside diameter (I.D.) of riser wall for the benching.

15.3.3.2 Minimum channel invert depth of one-half the pipe I.D.;

15.3.3.3 When a channel is cast in a cured base section, the minimum concrete thickness under the invert shall be 50 mm [2 in.];

15.3.3.4 Width of channel at top of benching shall be a minimum equal to the pipe I.D.;

15.3.3.5 Invert shall provide a positive flow between inlet to outlet pipes; and

15.3.3.6 The minimum channel centerline radius shall be equal to the pipe I.D.

15.4 *Reinforcement*:

15.4.1 *Base Section Circumferential Reinforcement*—Circumferential reinforcement shall meet all the requirements of Section 14 except that Section 14.5 is not permitted.

15.4.2 *Base Slab Reinforcement*:

15.4.2.1 A layer of reinforcement shall be placed above the midpoint, and shall have a minimum area of 250 mm^2/linear m [0.12 $in.^2$/linear ft] in both directions.

15.4.2.2 The minimum protective cover over the reinforcement shall be 25 mm [1 in.].

15.4.3 *Longitudinal Members*—Longitudinal bars or members used to maintain a cage of circumferential reinforcement in shape and position within the form shall meet all the requirements of Section 14.

15.4.4 *Joint Reinforcement*—The mating surface of the base section joint is not required to contain circumferential reinforcement.

Note 4—(Advisory) Base sections with multiple openings, large openings, or both may require special consideration of their handling reinforcement.

15.5 *Joints*—Precast reinforced base sections shall be designed and manufactured with a male or female end, so that the assembled manhole base, riser, and top will make a continuous and uniform manhole, compatible with the tolerances given in Section 15.6.

15.5.1 Joints are designed to perform in axial compression; therefore, shear or load testing of the joint is not required.

15.6 *Permissible Variations*:

15.6.1 *Internal Diameter*—The internal diameter of base sections shall not vary more than 1 percent.

15.6.2 *Thickness*—The thickness of base slabs with or without benching shall be not less than that prescribed in the design by more than 5 percent. A thickness greater than that prescribed in the design shall not be cause for rejection.

15.6.3 *Height of Two Opposite Sides*—Variations in laying heights of two opposite sides of base sections shall be not more than 16 mm [$^5/_8$ in.].

15.6.4 *Height of Sections*—The underrun in height of a base section shall be not more than $^1/_4$ in./ft of height with a maximum of 13 mm [$^1/_2$ in.] in any one base section.

15.6.5 *Position of Reinforcement*—For base slabs with monolithic benched inverts with a 100 mm [4-in.] thickness or less, the maximum variation in the position of reinforcement from that prescribed in Section 15.4 shall be ±10 percent of the thickness or ±6 mm [$\pm^1/_4$ in.], whichever is greater. For base slabs with a thickness greater than 100 mm [4 in.], the maximum variation shall be ±10 percent of the thickness or ±16 mm [$\pm^5/_8$ in.], whichever is the lesser. In no case, however, shall the cover over the reinforcement be less than 19 mm [$^3/_4$ in.]. The preceding minimum cover limitation does not apply to the mating surfaces of base section joints.

15.6.6 *Area of Reinforcement*—Steel reinforcement areas that are 10 mm^2/linear m [0.005 in.^{2}/linear ft] less than called for by design shall be considered as meeting the required steel reinforcement area.

15.7 *Rejection*:

15.7.1 Base sections shall be subject to rejection for failure to conform to any of the specification requirements. In addition, an individual base section with a flat slab floor, integral floor or integral floor with benching shall be subject to rejection because of any of the following:

15.7.1.1 Fractures or cracks passing through the riser wall, except for a single end crack that does not exceed the depth of the joint;

15.7.1.2 Defects that indicate mixing and molding not in compliance with Section 7.1 or surface defects indicating honey-combed or open texture that would adversely affect the function of the base section;

15.7.1.3 The planes of the ends are not perpendicular to the longitudinal axis of the base section, within the limits of permissible variations prescribed in Section 15.6;

15.7.1.4 Damaged or cracked ends, where such damage would prevent making a satisfactory joint; and

15.7.1.5 Any continuous crack having a surface width of 0.3mm [0.01 in.] or more and extending for a length of 300 mm [12 in.] or more, regardless of position in the base section.

16. STEPS AND LADDERS

16.1 *Scope*:

16.1.1 This section covers manhole steps and ladders used for providing access through manholes for use in sewer and water works.

16.1.2 The user of this specification is advised that access through manholes may be by steps that are cast, mortared, or attached by mechanical means into the walls of base, riser, or conical top sections or by ladder.

16.2 *Acceptance*—Unless otherwise designated by the owner at the time of, or before, placing an order, acceptance of steps and ladders installed in manholes will be on the basis of tests and inspection of the completed product.

16.3 *Materials*:

16.3.1 Except as required in this section, manhole steps and ladders shall conform to the requirements of the Occupational Safety and Health Standards, U.S. Department of Labor.

16.3.2 Manhole steps that are cast, mortared, or attached by mechanical means into the walls of base, riser, or conical top sections shall meet the requirements of Sections 16.4 and 16.5 in addition to the following:

16.3.2.1 When dissimilar types of materials are used in the steps, appurtenances, and fastenings, the materials shall be treated to prevent deleterious effects.

16.3.2.2 That portion of the step projecting into the base section, riser, or conical top opening shall be free of splinters, sharp edges, burrs, or projections which may be a hazard.

16.4 *Design*:

16.4.1 Steps in base section, riser, and conical top sections shall be aligned in each section so as to form a continuous ladder with rungs equally spaced vertically in the assembled manhole at a maximum design distance of 400 mm [16 in.] apart.

16.4.2 Steps shall be embedded in the base section, riser, or conical top section wall a minimum distance of 75 mm [3 in.].

16.5 *Dimensions*:

16.5.1 Ferrous metal steps not painted or treated to resist corrosion shall have a minimum cross-sectional dimension of 25 mm [1 in.].

16.5.2 The minimum width of rungs or cleats shall be 250 mm [10 in.].

16.5.3 The rung or cleat shall project a uniform clear distance of 100 mm (minimum) to 150 mm (maximum) ±6 mm [4 in. (minimum) to 6 in. (maximum) $\pm{}^{1}/_{4}$ in.] from the wall of the base, riser, or conical top section measured from the point of embedment to the embedment side of the rung.

Note 5—Embedment point is considered the junction of the centerline of the step leg and the wall of the base, riser or conical top section.

16.5.4 The minimum clear distance between the rung or cleat and the opposite wall of the base, riser, or conical top shall be 450 mm [18 in.] measured at the center face of the rung or cleat.

16.5.5 The vertical spacing and vertical alignment between adjacent manhole steps and horizontal distance from the inside wall to the centerline of a manhole step may vary 25 mm [1 in.] from the design dimension.

16.6 *Physical Requirements*:

16.6.1 *Testing*:

16.6.1.1 The manufacturer furnishing manhole sections with steps under this specification shall furnish all facilities and personnel necessary to carry out the tests required in the Manhole Step Test section of T 280.

16.6.1.2 One installed manhole step of the type to be used on a project shall be tested unless certified test results are available.

16.6.1.3 Vertical and horizontal load test procedures for manhole steps shall be in accordance with T 280.

16.6.1.4 The horizontal pull out load shall be 1800 N [400 lb.].

16.6.1.5 The vertical load shall be 3600 N [800 lb.].

16.6.2 *Acceptance*—The step shall be acceptable if the following requirements are met:

16.6.2.1 The step remains solidly embedded after application of the horizontal load test.

16.6.2.2 The step sustains a permanent set of 13 mm [$^1/_2$ in.] or less after application of the vertical load test.

16.6.2.3 No cracking or fracture of the step nor spalling of the concrete is evident.

16.6.2.4 If certified test results are not available and the step selected fails to conform to the test requirements, the manufacturer may select two other steps for retests. If either of these steps fail the retest, the steps shall be rejected.

17. KEYWORDS

17.1 Absorption; acceptance criteria; base sections; compressive strength; concrete; cone tops; design; flat slab tops; grade rings; ladders; manhole; manufacture; reinforced; riser sections; sewer; steps; tests; water.

---

[1] Agrees with ASTM C 478M-09 and C478-09 except for limiting absorption testing to the 5-hour boil method and the method of retest in case of failure of absorption specimens and compressive strength determination.

Standard Specification for

Reinforced Concrete Arch Culvert, Storm Drain, and Sewer Pipe

---

AASHTO Designation: M 206M/M 206-10[1]
ASTM Designation: C 506M-09 and C 506-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Reinforced Concrete Arch Culvert, Storm Drain, and Sewer Pipe

AASHTO Designation: M 206M/M 206-10[1]
ASTM Designation C 506M-09 and C 506-09

1. SCOPE

1.1 This specification covers reinforced arch-shaped concrete pipe to be used for the conveyance of sewage, industrial wastes, storm water, and for the construction of culverts.

1.2 This specification is applicable for orders in either SI units (M 206M) or in inch-pound units (M 206). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 206.

Note 1—This specification is a manufacturing and purchase specification only, and does not include requirements for bedding, backfill, or the relationship between field load condition and the strength classification of pipe. However, experience has shown that the successful performance of this product depends upon the proper selection of the class of pipe, type of bedding and backfill, and care that the installation conforms to the construction specifications. The owner of the reinforced concrete pipe specified herein is cautioned that he must correlate the field requirements with the class of pipe specified and provide inspection at the construction site.

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. CLASSIFICATION

4.1 Pipe manufactured according to this specification shall be of three classes identified as Class A-II, A-III, and A-IV. The strength requirements are prescribed in Table 1 for SI units or Table 2 for inch-pound units.

5. BASIS OF ACCEPTANCE

5.1 Unless otherwise designated by the owner at the time of or before placing an order, there are two separate and alternative bases of acceptance. Independent of the method of acceptance, the pipe shall be designed to meet both the 0.3-mm [0.01-in.] crack and ultimate strength requirements.

5.1.1 *Acceptance on Basis of Plant Load Bearing Tests, Material Tests, and Inspection of Manufactured Pipe for Visual Defects and Imperfections*—Acceptability of the pipe in all diameters and classes produced in accordance with Section 7.1 or Section 7.2 shall be determined by the results of the three-edge-bearing tests as defined in Section 11.3.1; by such material tests as are required in accordance with Sections 6.2, 6.3, 6.5, and 6.6, by an absorption test of the concrete from the wall of the pipe for each mix design that is used on an order; and by visual inspection of the finished pipe to determine its conformance with the accepted design and its freedom from defects.

5.1.2 *Acceptance on Basis of Material Tests and Inspection of the Complete Product*—Acceptability of the pipe in all diameters and classes produced in accordance with Section 7.1 or 7.2 shall be determined by the results of such material tests as are required in Sections 6.2, 6.3, 6.5, and 6.6; by crushing tests on concrete cores or cured concrete cylinders; by an absorption test of the concrete from the wall of the pipe for each mix design that is used on an order; and by inspection of the finished pipe, including amount and placement of reinforcement, to determine its conformance with the accepted design and its freedom from defects.

5.1.3 When agreed upon by the owner and the manufacturer, any portion or any combination of tests itemized in Section 5.1.1 or Section 5.1.2 may form the basis of acceptance.

5.2 *Age for Acceptance*—Pipe shall be considered ready for acceptance when they conform to the requirements as indicated by the specified tests.

[a] For modified or special designs, designs, see Section 7.3.

[b] f'_c MPa = minimum compressive strength of concrete in megapascals.

[c] As an alternative to designs requiring double line reinforcement, the reinforcement may be positioned and proportional so that the total reinforcement of the inner cage plus the middle cage shall not be less than that specified for the inner cage continuous basic reinforcement, and the additional reinforcement "U" and the total reinforcement of the outer cage plus the middle cage shall not be less than that specified for the outer cage continuous basic reinforcement and the additional reinforcement "V".

[d] A_s = circumferential steel area in square millimeters per longitudinal centimeter of pipe barrel in each continuous basic cage and additional cages in area denoted "U" and "V" Dimensions "U" and "V" are measured on the centerline of the culvert wall.

D-Loads for Three-Edge-Bearing Method

Class	0.3-mm Crack	Ultimate
A-II	50.0	75.0
A-III	65.0	100.0
A-IV	100.0	150.0

Note: Test load in newtons per linear meter equals D-load × inside span in millimeters.

6. MATERIALS

6.1 *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water, in which steel has been embedded in such a manner that the steel and concrete act together.

6.2 *Cementitious Materials*:

6.2.1 *Cement*—Cement shall conform to the requirements of M 85 or shall be portland blast-furnace slag cement, or slag modified portland cement, or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash.

6.2.2 *Ground Granulated Blast-Furnace Slag (GGBFS)*—GGBFS shall conform to the requirements of Grade 100 or 120 of M 302

6.2.3 *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.4 *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

6.2.4.1 Portland cement only,

6.2.4.2 Portland blast furnace slag cement only,

6.2.4.3 Slag modified portland cement only,

6.2.4.4 Portland-pozzolan cement only, or

6.2.4.5 A combination of portland cement and ground granulated blast-furnace slag,

6.2.4.6 A combination of portland cement and fly ash, or

6.2.4.7 A combination of portland cement, ground granulated blast-furnace slag (not to exceed 25 percent of the total cementitious weight) and fly ash (not to exceed 25 percent of the total cementitious weight).

6.3 *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirement for gradation shall not apply.

6.4 *Admixtures and Blends*—The following admixtures and blends are allowable:

6.4.1 Air-entraining admixture conforming to M 154;

6.4.2 Chemical admixture conforming to M 194;

6.4.3 Chemical admixture for use in producing flowing concrete conforming to C 1017/C 1017M; and

6.4.4 Chemical admixture or blend approved by the owner.

6.5 *Steel Reinforcement*—Reinforcement shall consist of wire conforming to M 32M/M 32 or M 225M/M 225; or of wire reinforcement conforming to M 55M/M 55 or M 221M/M 221; or of bars conforming to M 31M/M 31 Grade 280 [40] or 420 [60], ASTM A 36/A 36M, or ASTM A 706/A 706M Grade 420 [60].

6.6 *Synthetic Fibers*—Collated fibrillated virgin polypropylene fibers may be used at the owner's option in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be accepted.

---

7. DESIGN

7.1 *Size and Dimensions*—The standard sizes of arch pipe are listed in Table 3 for pipe specified in SI units or Table 4 for pipe specified in inch-pound units. The internal dimensions for each standard size shall be as defined in Table 3 or Table 4, subject to the permissible variations of Section 12.

7.2 *Design Tables*—The wall thickness, compressive strength of concrete, and the area of circumferential reinforcement shall be as prescribed in Table 1 or Table 2, subject to the provisions of Sections 7.3, 11, and 12.

7.2.1 Footnotes to the tables herein are intended to be amplifications of the tabulated requirements and are to be considered applicable and binding as if they were contained in the body of the specification.

7.3 *Modified and Special Designs*:

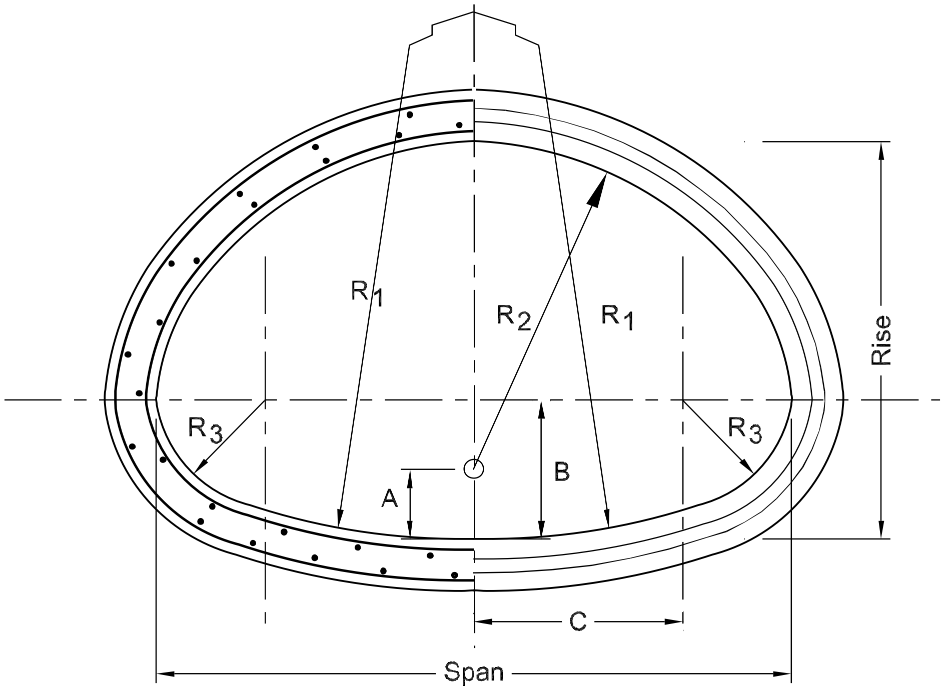
7.3.1 If permitted by the owner, the manufacturer may request approval by the owner of modified designs that differ from the designs in this Section 7 or special designs for sizes and loads beyond those shown in Table 1 or Table 2 as appropriate for the units being used: or special designs for pipe sizes that do not have steel reinforcement areas shown in Table 1 or Table 2.

7.3.2 Such modified or special designs shall be based on rational or empirical evaluations of the ultimate strength and cracking behavior of pipe and shall fully describe to the owner any deviations from the requirements of this Section 7. The descriptions of modified or special designs shall include the wall thickness; the concrete strength; the area, type, placement, number of layers; and strength of the steel reinforcement.

7.3.3 The manufacturer shall submit to the owner proof of the adequacy of the proposed modified or special design. Such proof may comprise the submission of certified three-edge-bearing tests already made, which are acceptable to the owner or, if such three-edge-bearing tests are not available or acceptable, the manufacturer may be required to perform proof tests on sizes and classes selected by the owner to demonstrate the adequacy of the proposed design.

7.3.4 Such pipe must meet all of the test and performance requirements specified by the owner in accordance with Section 5.

7.4 *Area*—In this specification, when the word "area" is not described by adjectives such as cross-sectional or single wire, it shall be understood to be the cross-sectional area of reinforcement per unit lengths of pipe.



$$A = \text{Rise} - R_2$$

$$B = A + \sqrt{(R_2 - R_3)^2 - C^2}$$

$$C = \frac{\text{Span}}{2} - R_3$$

8. REINFORCEMENT

8.1 *Circumferential Reinforcement*—A line of circumferential reinforcement for any given total area may be composed of two layers for pipe with wall thicknesses of less than 180 mm [7 in.] or three layers for pipe with wall thicknesses of 180 mm [7 in.] or greater. The layers shall not be separated by more than the thickness of one longitudinal plus 6 mm [$^1/_4$ in.] The multiple layers shall be fastened together to form a single cage. All other specification requirements such as laps, welds, tolerances of placement in the wall of the pipe, etc., shall apply to this method of fabricating a line of reinforcement.

8.1.1 Where one line of reinforcement is used, it shall be placed so that the cover of the concrete over the circumferential reinforcement at the vertical and horizontal diameters of the pipe is 25 mm [1 in.] from the inside and outside surfaces of the pipe, except for wall thicknesses less than 62 mm [$2^1/_2$ in.], the protective cover of the concrete over the circumferential reinforcement in the wall of the pipe shall be 18 mm [$^3/_4$ in.].

8.1.2 Where two lines of reinforcement of arch shape corresponding to the contour of the pipe are used, each line shall be so placed that the covering of concrete over the reinforcement is 25 mm [1 in.].

8.1.3 The location of the reinforcement shall be subject to the permissible variations in dimensions given in Section 12.5. Requirements for placement and protective covering of the concrete from the inner or outer surface of the pipe do not apply to that portion of a cage which is flared so as to extend into the bell or is reduced in diameter so as to extend into the spigot.

8.1.4 The spacing center-to-center of circumferential reinforcement in a cage shall not exceed 100 mm [4 in.] for pipe up to and including pipe having a 100-mm [4-in.] wall thickness nor exceed the wall thickness for larger pipe, and shall in no case exceed 150 mm [6 in.].

8.1.5 The continuity of the circumferential reinforcing steel shall not be destroyed during the manufacture of the pipe, except that when agreed upon by the owner, lift eyes or holes may be provided in each pipe for the purpose of handling.

8.1.6 If splices are not welded, the reinforcement shall be lapped not less than 20 diameters for deformed bars and deformed cold-worked wire and 40 diameters for plain bars and cold-drawn wire. In addition, where lapped cages of welded-wire fabric are used without welding, the lap shall contain a longitudinal wire.

8.1.6.1 When splices are welded and are not lapped to the minimum requirements in Section 8.1.6, pull tests of representative specimens shall develop at least 50 percent of the minimum specified strength of the steel and there shall be a minimum lap of 50 mm [2 in.]. For butt-welded splices in bars or wire, permitted only with helically wound cages, pull tests of representative specimens shall develop at least 75 percent of the minimum specified strength of the steel.

8.2 *Longitudinal Reinforcement*—Each line of circumferential reinforcement shall be assembled into a cage that shall contain sufficient longitudinal bars or members, to maintain the reinforcement in shape and in position within the form to comply with permissible variations in Section 8.1. The exposure of the ends of longitudinals, stirrups, or spacers that have been used to position the cages during the placement of the concrete shall not be a cause for rejection.

8.3 *Joint Reinforcement*—In all pipe 900 mm [36 in.] or larger in diameter, either the bell or the spigot of the joint shall contain circumferential reinforcement.

8.3.1 For single-cage pipe, joint reinforcement shall be at least equal in area to that required for an equivalent length of pipe wall.

8.3.2 For double-cage and triple-cage pipe, joint reinforcement shall be at least equal in area to that required for an equivalent length of the outer circular cage if placed in the bell, or at least equal in area to that required for an equivalent length of the inner circular cage if placed in the spigot.

9. JOINTS

9.1 The joints shall be of such design and the ends of the concrete pipe sections so formed that the pipe can be laid together to make a continuous line of pipe compatible with the permissible variations given in Section 12.

10. MANUFACTURE

10.1 *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious materials ratio not exceeding 0.53 by mass. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 280 kg/m^3 [470 lb/yd^3] unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this specification.

10.2 *Curing*—Pipe shall be subjected to any one of the methods of curing described in Sections 10.2.1 to 10.2.4, or to any other method or combination of methods approved by the owner, that will give satisfactory results. The pipe shall be cured for a sufficient length of time so that the specified

D-load is obtained when acceptance is based on Section 5.1.1 or so that the concrete will develop the specified compressive strength at 28 days or less when acceptance is based on Section 5.1.2.

10.2.1 *Steam Curing*—Pipe may be placed in a curing chamber free from outside drafts and cured in a moist atmosphere maintained by the injection of steam for such time and such temperature as may be needed to enable the pipe to meet the strength requirements. The curing chamber shall be so constructed as to allow full circulation of steam around the entire pipe.

10.2.2 *Water Curing*—Concrete pipe may be water cured by covering with water-saturated material or by a system of perforated pipes, mechanical sprinklers, porous hose, or by any other approved method that will keep the pipe moist during the specified curing period.

10.2.3 The manufacturer may, at his option, combine the methods described in Sections 10.2.1 to 10.2.4 as long as the required concrete compressive strength is attained.

10.2.4 A sealing membrane conforming to the requirements of M 148 may be applied and should be left intact until the required strength requirements are met. The concrete at the time of application shall be within 6ºC [10ºF] of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

11. PHYSICAL REQUIREMENTS

11.1 *Test Specimens*—The specified number of pipe required for the tests shall be furnished without charge by the manufacturer, shall be selected at random by the owner, and shall be pipe that would not otherwise be rejected under this specification. The selection shall be made at the point or points designated by the owner when placing the order. Unless designated otherwise by the owner in the order, the manufacturer shall select the type of test (external load crushing strength test, compression test of cylinders, or compression test of cores) to be used to determine the acceptability of the pipe strength. Pipe that fails to meet the strength requirements as determined by the selected test type may not be retested using one of the other test types without approval of the owner.

11.2 *Number and Type of Tests Required for Various Delivery Schedules*:

11.2.1 *Preliminary Tests for Extended Delivery Schedules*—An owner of pipe whose needs require shipments at intervals over extended periods of time shall be entitled to such tests as are required by the type of basis of acceptance specified by the owner in Section 5. The tests shall be preliminary to delivery of pipe and of not more than three sections of pipe covering each size in which the owner is interested.

11.2.2 *Additional Tests*—After the preliminary tests described in Section 11.2.1, an owner shall be entitled to additional tests at such times as the owner may deem necessary provided that the total number of pipe tested (including preliminary tests) shall not exceed one pipe or 1 percent, whichever is the greater, of each size of pipe delivered.

11.3 *External Load Crushing Strength*:

11.3.1 The load required to produce a 0.3-mm [0.01-in.] crack or the ultimate load, as determined by the three-edge-bearing method described in T 280, shall be not less than that prescribed in Table 1or Table 2, for each respective class of pipe. Pipe that have been tested only to the formation of a 0.3-mm [0.01-in.] crack and that meets the 0.3-mm [0.01-in.] crack load requirements shall be accepted for use.

Note 2—As used in this specification, the 0.3-mm [0.01-in.] crack is a test criterion for pipe under load in a three-edge-bearing test and is not intended as an indication of overstressed or failed pipe under installed conditions.

11.3.2 *Retests of Pipe Not Meeting the External Load Crushing Strength Requirements*—Pipe shall be considered as meeting the strength requirements when all test specimens conform to the requirements. Should any of the test specimens fail to meet the requirements, the manufacturer shall be allowed a retest on two additional specimens for each specimen that failed and the pipe shall be acceptable only when all of the retest specimens meet the strength requirements.

11.4 *Type of Specimen*—Compression tests determining concrete compressive strength may be made on either standard rodded concrete cylinders or concrete cylinders compacted and cured in like manner as the pipe, or on cores drilled from the pipe.

11.5 *Compression Testing of Cylinders*:

11.5.1 *Cylinder Production*—Cylinders shall be prepared in accordance with Section 11 of T 280.

11.5.2 *Number of Cylinders*—Prepare no fewer than five test cylinders from a group (one day's production of each concrete strength) of pipe sections.

11.5.3 *Acceptability on the Basis of Cylinder Test Results*:

11.5.3.1 When the compressive strengths of all cylinders tested for a group are equal to or greater than the required concrete strength, the compressive strength of concrete in the group of pipe sections shall be accepted.

11.5.3.2 When the average compressive strength of all cylinders tested is equal to or greater than the required concrete strength, not more than 10 percent of the cylinders tested have a compressive strength less than the required concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the required concrete strength, then the group shall be accepted.

11.5.3.3 The pipe shall be acceptable only when the compressive strength of the cylinders tested conforms to the acceptance criteria stated in Section 11.5.3.1 or Section 11.5.3.2.

11.6 *Compression Testing of Cores*:

11.6.1 *Obtaining Cores*—Cores shall be obtained and prepared in accordance with Section 6 of T 280.

11.6.2 *Number of Cores*—One core shall be taken from a pipe section selected at random from each day's production run of a single concrete strength.

11.7 *Acceptability on the Basis of Core Test Results*:

11.7.1 When the compressive strengths of cores tested for a group of pipe sections is equal to or greater than the required concrete strength, the compressive strength of the concrete for the group is acceptable.

11.7.2 If the compressive strength of the core tested is less than the required concrete strength, two additional cores shall be taken from that pipe section and tested. Concrete represented by these three core tests shall be considered acceptable if: (1) the average of the three core strengths is equal to at least 85 percent of the required strength and (2) no single core is less than 75 percent of the required strength.

11.7.3 If the compressive strength of the three cores does not meet the requirements of Section 11.7.2, the pipe from which the cores were taken shall be rejected. Two pipe sections from the remainder of the group shall be selected at random and cored and tested for conformance with either Section 11.7.1 or Section 11.7.2. If both pipe sections meet the core strength requirements of either Section 11.7.1 or Section 11.7.2, the remainder of the group shall be acceptable. If both pipe sections do not meet the test strength requirement, the remainder of the group shall be either rejected or, at the option of the manufacturer, each pipe section of the remaining group shall be cored and accepted individually and any of the pipe sections that have core strengths less than the requirements of Section 11.7.1 or Section 11.7.2 shall be rejected.

11.8 *Plugging Core Holes*—Core holes shall be plugged and sealed by the manufacturer in a manner such that the pipe section will meet all of the requirements of this specification. Pipe sections so plugged and sealed shall be considered satisfactory for use.

11.9 *Absorption*—The absorption of a sample from the wall of the pipe, as determined in accordance with T 280, shall not exceed 9 percent of the dry mass. Each sample shall have a minimum mass of 1.0 kg, shall be free of visible cracks, and shall represent the full wall thickness of the pipe. When the initial absorption sample from a pipe fails to conform to this specification, the absorption test shall be made on another sample from the same pipe and the results of the retest shall be substituted for the original test results.

11.10 *Retests of Pipe*—When not more than 20 percent of the concrete specimens fail to pass the requirements of the specification, the manufacturer may cull the project stock, may eliminate whatever quantity of pipe desired, and shall mark those pipes so that they will not be shipped. The required tests shall be made on the balance of the order and the pipe shall be accepted if they conform to the requirements of this specification.

11.11 *Test Equipment*—Every manufacturer furnishing pipe under this specification shall furnish all facilities and personnel necessary to carry out the tests described in T 280.

12. PERMISSIBLE VARIATIONS

12.1 *Internal Dimensions*—The internal dimensions of arch pipe shall not vary more than ±2 percent from the internal dimensions shown in Table 3 or Table 4. Variation shall normally be determined by measuring the span and rise. When measurement of other dimensions is necessary, templates constructed to maximum and minimum sizes shall be used.

12.2 *Wall Thickness*—The wall thickness shall not vary more than shown in the design or specified wall by more than ±5 percent or 5 mm [$^3/_{16}$ in.], whichever is greater. A specified wall thickness that is more than required in the design is not cause for rejection. Pipe having localized variations in wall thickness exceeding those specified above shall be accepted if the three-edge-bearing strength and minimum steel cover requirements are met.

12.3 *Length of Two Opposite Sides*—Variations in the laying length of two opposite sides of the pipe shall not be more than 6 mm [$^1/_4$ in.] for all sizes through 600-mm [24-in.] internal equivalent diameter, not more than 10 mm/m [$^1/_8$ in./ft] of internal equivalent diameter for all sizes larger with a maximum of 16 mm [$^5/_8$ in.] in any length of pipe through 2100-mm [84-in.] internal equivalent diameter, and a maximum of 19 mm [$^3/_4$ in.] for 2250-mm [90-in.] internal equivalent diameter or larger, except where beveled-end pipe for laying on curves is specified by the owner.

12.4 *Length of Pipe*—The underrun in length of a section of pipe shall be not more than 10 mm/m [$^1/_8$ in./ft] with a maximum of 13 mm [$^1/_2$ in.] in any length of pipe.

12.5 *Position or Area of Reinforcement*:

12.5.1 *Position*—The maximum variation in the position of the reinforcement shall be ±10 percent of the wall or ±13 mm [$\pm^1/_2$ in.], whichever is the greater. Pipe having variations in the position of the reinforcement exceeding those specified above shall be accepted if the three-edge-bearing strength requirements obtained on a representative specimen are met. In no case, however, shall the cover over the circumferential reinforcement be less than 13 mm [$^1/_2$ in.]. The preceding minimum cover limitation does not apply to the mating surfaces of the joint.

12.5.2 *Area of Reinforcement*—Reinforcement will be considered as meeting the design requirements if the area, computed on the basis of nominal area of the wire or bars used, equals or exceeds the requirements of Sections 7.2 or Section 7.3. Actual area of the reinforcing used may vary from the nominal area according to permissible variations of the standard specifications for the reinforcing.

13. REPAIRS

13.1 Pipe may be repaired, if necessary, because of imperfections in manufacture or damage during handling and will be acceptable if, in the opinion of the owner, the repaired pipe conforms to the requirements of this specification.

14. INSPECTION

14.1 The quality of materials, the process of manufacture, and the finished pipe shall be subject to inspection and approval by the owner.

15. REJECTION

15.1 Pipe shall be subject to rejection if it fails to conform to any of the specification requirements. Individual sections of pipe may be rejected because of any of the following:

15.1.1 Fractures or cracks passing through the wall, except for a single-end crack that does not exceed the depth of the joint;

15.1.2 Defects that indicate mixing and molding not in compliance with Section 10.1, or surface defects indicating honeycombed or open texture that would adversely affect the function of the pipe;

15.1.3 The ends of the pipe are not normal to the walls and center line of the pipe, within the limits of variations given in Sections 12.3 and 12.4;

15.1.4 Damaged or cracked ends, where such damage would prevent making a satisfactory joint; and

15.1.5 Any continuous crack having a surface width of 0.3 mm [0.01 in.] or more and extending for a length of 300 mm [12 in.] or more, regardless of position in the wall of the pipe. See Note 2 in Section 11.

16. PRODUCT MARKING

16.1 The following information shall be legibly marked on each section of pipe:

16.1.1 The pipe class and specification designation,

16.1.2 The date of manufacture,

16.1.3 The name or trademark of the manufacturer, and

16.1.4 Identification of the plant.

16.2 Markings shall be indented on the pipe section or painted thereon with waterproof paint.

17. KEYWORDS

17.1 Arch pipe; culvert; D-load; reinforced concrete; sewer pipe; storm drain.

---

[1] Agrees with ASTM C 506M-09 and C 506-09 except for limiting the absorption testing to the 5-hour boil method, the use of synthetic fibers are at the option of the owner, and the method of acceptance is changed as per Sections 11.1 and 11.5.3.3.

Standard Specification for

Reinforced Concrete Elliptical Culvert, Storm Drain, and Sewer Pipe

---

AASHTO Designation: M 207M/M 207-10[1]
ASTM Designation: C 507M-09 and C 507-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Reinforced Concrete Elliptical Culvert, Storm Drain, and Sewer Pipe

AASHTO Designation: M 207M/M 207-10[1]
ASTM Designation: C 507M-09 and C 507-09

1. SCOPE

1.1. This specification covers reinforced elliptically shaped concrete pipe to be used for the conveyance of sewage, industrial wastes, and storm water, and for the construction of culverts.

1.2. Pipe designed for placement with the major axis horizontal shall be designated as “Horizontal Elliptical Pipe.” Pipe designed for placement with the major axis vertical shall be designated as “Vertical Elliptical Pipe.”

1.3. This specification is applicable for orders in either SI units (M 207M) or in inch-pound units (M 207). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 207.

Note 1—This specification is a manufacturing and purchase specification only, and does not include requirements for bedding, backfill, or the relationship between field load condition and the strength classification of pipe. However, experience has shown that the successful performance of this product depends upon the proper selection of the class of pipe, type of bedding and backfill, and care that the installation conforms to the construction specifications. The owner of the reinforced concrete pipe specified herein is cautioned that he must correlate the field requirements with the class of pipe specified and provide inspection at the construction site.

3. TERMINOLOGY

3.1. *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. CLASSIFICATION

4.1. Pipe manufactured according to this specification shall be of five classes each for horizontal elliptical and vertical elliptical pipe with identification as follows:

Horizontal Elliptical Pipe	Vertical Elliptical Pipe
Class HE-A	Class VE-II
Class HE-I	Class VE-III
Class HE-II	Class VE-IV
Class HE-III	Class VE-V
Class HE-IV	Class VE-VI

4.2. The strength requirements for horizontal elliptical pipe are prescribed in Table 1 when using SI units and Table 2 when using inch-pound units; and for vertical elliptical pipe are prescribed in Table 3 when using SI units and Table 4 when using inch-pound units.

Table 1—Design Requirements for Horizontal Elliptical (HE) Pipe (SI units)[a]

[a] For size and loads beyond those shown in this table, pipe designs are available which make use of one or a combination of the following: shear steel, multiple cages, or thicker walls in accordance with the provision of Section 7.3.

[b] Concrete strength for designs with reinforcement tabulated. For modified or special designs, see Section 7.3.

Notes:
1. The test load in kilonewtons per linear meter equals D-load × inside span in millimeters.
2. Single cage reinforcement, providing tension steel at the top, bottom, and spring line, shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be 112 percent of the tabulated inner cage area.
3. An inner and outer cage plus quadrant mats shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be in accordance with Figure 1.
4. An inner and outer cage plus a middle cage shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be in accordance with Figure 2.

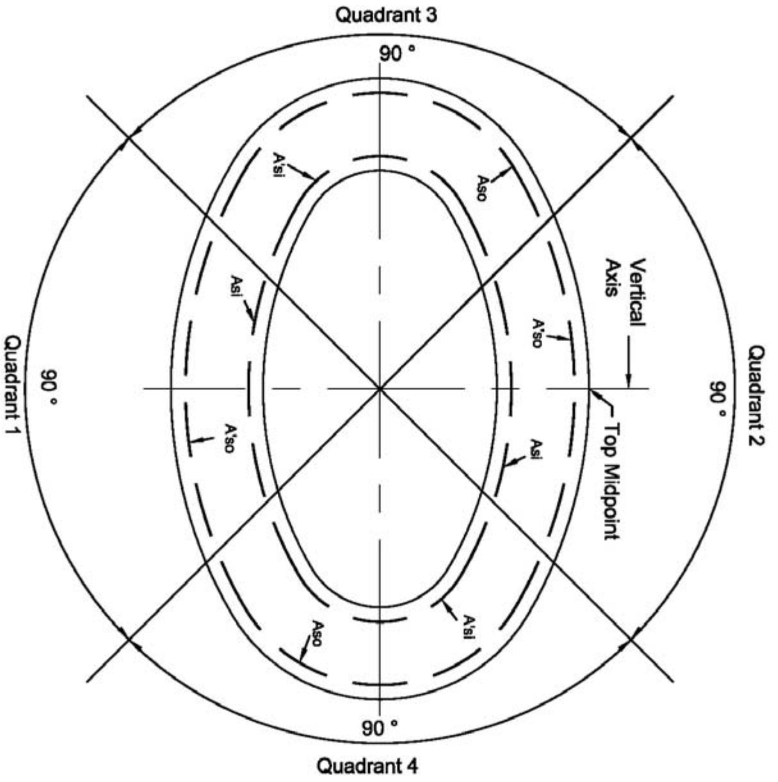
[a] For sizes and loads beyond those shown in this table, pipe designs are available which make use of one or a combination of the following: shear steel, multiple cages, or thicker walls in accordance with the provision of Section 7.3.

[b] Concrete strength for designs with reinforcement tabulated. For modified or special designs, see Section 7.3.

Notes:

1. The test load in pounds per linear foot equals D-load × inside span in feet.
2. Single cage reinforcement, providing tension steel at the top, bottom, and spring line, shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be 112 percent of the tabulated inner cage area.
3. An inner and outer cage plus quadrant mats shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be in accordance with Figure 1.
4. An inner and outer cage plus a middle cage shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be in accordance with Figure 2.



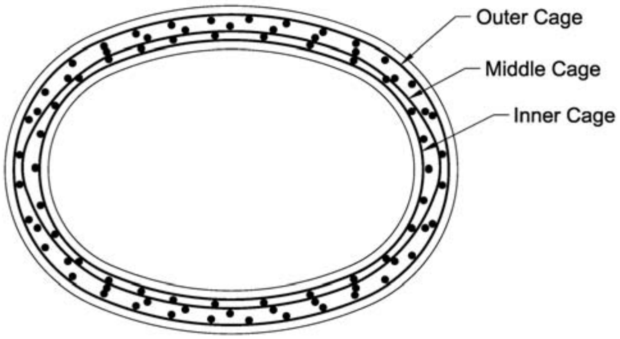
Notes: 1. The total reinforcement area (Asi) of the inner cage plus the quadrant mat in Quadrants 1 and 2 shall not be less than that specified for the inner cage in Table 1 or Table 2.

2. The total reinforcement area (Aso) of the outer cage plus the quadrant mat in Quadrants 3 and 4 shall not be less than that specified for the outer cage in Table 1 or Table 2.

3. The reinforcement area (A′si) of the inner cage in Quadrants 3 and 4 shall not be less than 25 percent of that specified for the inner cage in Table 1 or Table 2.

4. The reinforcement area (A′so) of the outer cage in Quadrants 1 and 2 shall not be less than 25 percent of that specified for the outer cage in Table 1 or Table 2.

Figure 1—Quadrant Reinforcement, Horizontal Elliptical Pipe



Notes: 1. The total reinforcement area of the inner cage plus the middle cage shall not be less than that specified for the inner cage in Table 1 or Table 2.

2. The total reinforcement area of the outer cage plus the middle cage shall not be less than that specified for the outer cage in Table 1 or Table 2.

Concrete strength,[b] MPa			27.6		27.6		27.6		34.5		41.4	

[a] For size and loads beyond those shown in this table, pipe designs are available which make use of one or a combination of the following: shear steel, multiple cages, or thicker walls in accordance with the provision of Section 7.3.

[b] Concrete strength for designs with reinforcement tabulated. For modified or special designs, see Section 7.3.

Notes:

1 Test load in kilonewtons per linear meter equals D-load × inside span in millimeters.

2. An inner and outer cage plus quadrant mats shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be in accordance with Figure 3.

3. Single cage reinforcement, providing tension steel at the top, bottom, and spring line, shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be 112 percent of the tabulated inner cage area.

4. An inner and outer cage plus a middle cage shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be in accordance with Figure 4.

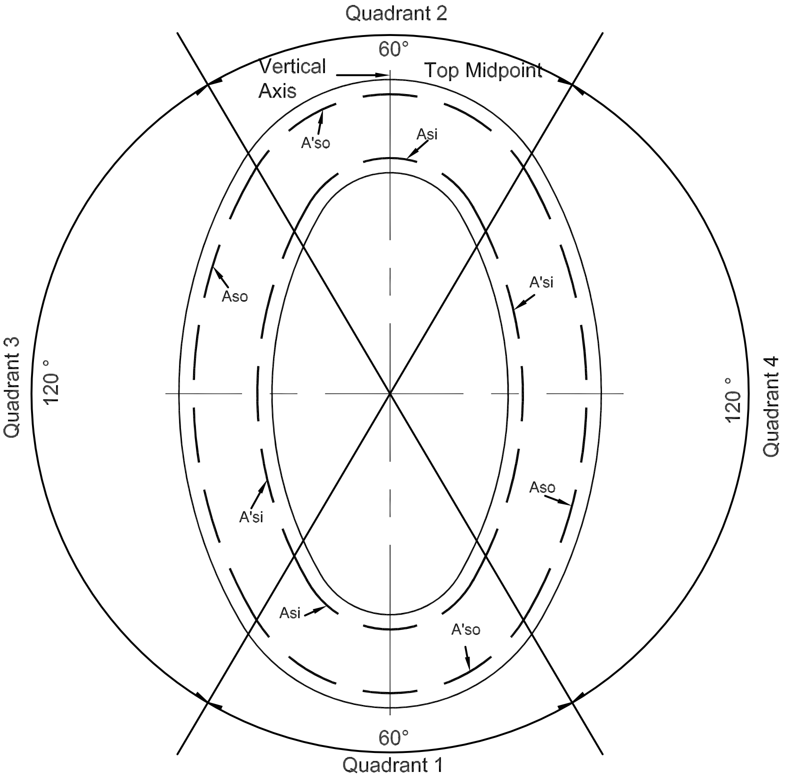
Concrete strength,[b] psi			4000		4000		4000		5000		6000	

[a] For size and loads beyond those shown in this table, pipe designs are available which make use of one or a combination of the following: shear steel, multiple cages, or thicker walls in accordance with the provision of Section 7.3.

[b] Concrete strength for designs with reinforcement tabulated. For modified or special designs, see Section 7.3.

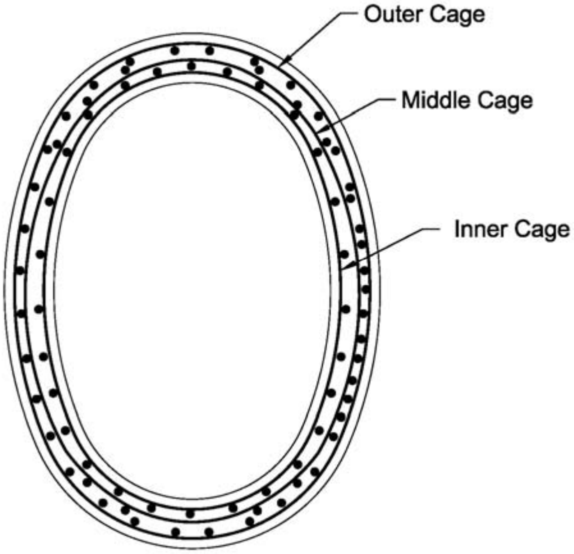
Notes:
1. Test load in pounds per linear foot equals D-load × inside span in feet.
2. An inner and outer cage plus quadrant mats shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be in accordance with Figure 3.
3. Single cage reinforcement, providing tension steel at the top, bottom, and spring line shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be 112 percent of the tabulated inner cage area.
4. An inner and outer cage plus a middle cage shall be permitted instead of double cage reinforcement. The area of such reinforcement shall be in accordance with Figure 4.



Notes:

1. The total reinforcement area (Asi) of the inner cage plus the quadrant mat in Quadrants 1 and 2 shall not be less than that specified for the inner cage in Table 3 or Table 4.
2. The total reinforcement area (Aso) of the outer cage plus the quadrant mat in Quadrants 3 and 4 shall not be less than that specified for the outer cage in Table 3 or Table 4.
3. The reinforcement area (A′si) of the inner cage in Quadrants 3 and 4 shall not be less than 25 percent of that specified for the inner cage in Table 3 or Table 4.
4. The reinforcement area (A′so) of the outer cage in Quadrants 1 and 2 shall not be less than 25 percent of that specified for the outer cage in Table 3 or Table 4.

Figure 3—Quadrant Reinforcement, Vertical Elliptical Pipe



Notes: 1. The total reinforcement area of the inner cage plus the middle cage shall not be less than that specified for the inner cage in Table 3 or Table 4.

2. The total reinforcement area of the outer cage plus the middle cage shall not be less than that specified for the outer cage in Table 3 or Table 4.

Figure 4—Vertical Elliptical Pipe

5. BASIS OF ACCEPTANCE

5.1. Unless otherwise designated by the owner at the time of or before placing an order, there are two separate and alternative bases of acceptance. Independent of the method of acceptance, the pipe shall be designated to meet both the 0.3 -mm [0.01 -in] crack and ultimate strength requirements specified in Table 1.

5.1.1. *Acceptance on Basis of Plant Load Bearing Tests, Material Tests, and Inspection of the Manufactured Pipe for Visual Defects and Imperfections*—Acceptability of the pipe in all diameters and classes produced in accordance with Section 7.1 or Section 7.2 shall be determined by the results of the three-edge-bearing tests as defined in 11.3.1; by such material tests as are required in Sections 6.2, 6.3, 6.5, and 6.6; by an absorption test of the concrete from the wall of the pipe for each mix design that is used on an order; and by inspection of the finished pipe to determine its conformance with the accepted design and its freedom from defects.

5.1.2. *Acceptance on the Basis of Material Tests and Inspection of Manufactured Pipe for Visual Defects and Imperfections* —Acceptability of the pipe in all diameters and classes produced in accordance with Section 7.1 or Section 7.2 shall be determined by the results of such material tests as are required in accordance with Sections 6.2, 6.3, 6.5, and 6.6; by crushing tests on concrete cores or cured concrete cylinders; by an absorption test on concrete from the wall of the pipe for each mix design that is used on an order; and by inspection of the finished pipe, including amount and placement of reinforcement, to determine its conformance with the accepted design and its freedom from defects.

5.1.3. When agreed upon by the owner and the manufacturer, any portion or any combination of the tests itemized in Section 5.1.1 or Section 5.1.2 may form the basis of acceptance.

5.2. *Age for Acceptance*—Pipe shall be considered ready for acceptance when they conform to the requirements as indicated by the specified tests.

6. MATERIALS

6.1. *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water, in which steel has been embedded in such a manner that the steel and concrete act together.

6.2. *Cementitious Materials*:

6.2.1. *Cement*—Cement shall conform to the requirements of M 85, or shall be portland blast-furnace slag cement, or slag modified portland cement, or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash.

6.2.2. *Ground Granulated Blast-Furnace Slag (GGBFS)*—GGBFS shall conform to the requirements of Grade 100 or 120 of M 302

6.2.3. *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.4. *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

6.2.4.1. Portland cement only,

6.2.4.2. Portland blast-furnace slag cement only,

6.2.4.3. Slag modified portland cement only,

6.2.4.4. Portland-pozzolan cement only, or

6.2.4.5. A combination of portland cement and ground granulated blast-furnace slag,

6.2.4.6. A combination of portland cement and fly ash, or

6.2.4.7. A combination of portland cement, ground granulated blast-furnace slag (not to exceed 25 percent of the total cementitious weight) and fly ash (not to exceed 25 percent of the total cementitious weight).

6.3. *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirement for gradation shall not apply.

6.4. *Admixtures and Blends*—The following admixtures and blends are allowable:

6.4.1. Air-entraining admixture conforming to M 154;

6.4.2. Chemical admixture conforming to M 194;

6.4.3. Chemical admixture for use in producing flowing concrete conforming to C 1017/C 1017M; and

6.4.4. Chemical admixture or blend approved by the owner.

6.5. *Steel Reinforcement*—Reinforcement shall consist of wire conforming to M 32M/M 32 or M 225M/M 225; or of wire reinforcement conforming to M 55M/M 55 or M 221M/M 221; or of bars conforming to M 31M/M 31 Grade 280 [40] or 420 [60], ASTM A 36/A 36M, or ASTM A 706/A 706M Grade 420 [60].

6.6. *Synthetic Fibers*—Collated fibrillated virgin polypropylene fibers may be used, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be accepted.

7. DESIGN

7.1. *Size and Shape*—The standard sizes of elliptical pipe shall be as listed in Tables 1 and 3 for SI units or Tables 2 and 4 for inch-pound units. The internal shape for each size pipe shall be defined by the internal dimensions shown in Table 5 for SI units or Table 6 for inch-pound units, subject to the permissible variations of Section 12.1.

7.2. *Design Tables*—The wall thickness, compressive strength of concrete, and the area of circumferential reinforcement shall be as prescribed in Tables 1 or 2 and 3 or 4, subject to the provisions of Sections 7.3, 11, and 12.

7.2.1. Footnotes to the tables herein are intended to be amplifications of the tabulated requirements and are to be considered applicable and binding as if they were contained in the body of the specification.

7.3. *Modified and Special Designs*:

7.3.1. If permitted by the owner, the manufacturer may request approval by the owner of modified designs which differ from the designs in this Section 7; or special designs for sizes and loads beyond those shown in Tables 1 or 2 and 3 or 4, or special designs for pipe sizes that do not have steel reinforcement areas shown in Tables 1 or 2 and 3 or 4.

7.3.2. Such modified and special designs shall be based on rational or empirical evaluations of the ultimate strength and cracking behavior of pipe and shall fully describe to the owner any deviations from the requirements of this Section 7. The descriptions of modified or special designs shall include the wall thickness; the concrete strength; and the area, type, placement, number of layers, and strength of the steel reinforcement.

Note: Rise, span, and radii are fixed; other dimensions and angles are calculated.

7.3.3. The manufacturer shall submit to the owner proof of the adequacy of the proposed modified and special design. Such proof may comprise the submission of certified three-edge-bearing tests already made which are acceptable to the owner or, if such three-edge-bearing tests are not available or acceptable, the manufacturer may be required to perform proof tests on sizes and classes selected by the owner to demonstrate the correctness and adequacy of the proposed design.

7.3.4. Such pipe shall meet all of the test and performance requirements specified by the owner in accordance with Section 5.

7.4. *Area*—In this specification, when the word "area" is not described by adjectives such as cross-sectional or single wire, it shall be understood to be the cross-sectional area of reinforcement per unit lengths of pipe.

8. REINFORCEMENT

8.1. *Circumferential Reinforcement*—A line of circumferential reinforcement for any given total area may be composed of two layers for pipe with wall thicknesses of less than 180 mm [7 in.] or three layers for pipe with wall thicknesses of 180 mm [7 in.] or greater. The layers shall not be separated by more than the thickness of one longitudinal plus 6 mm [$^{1}/_{4}$ in.] The multiple layers shall be fastened together to form a single cage. All other specification requirements such as laps, welds, and tolerances of placement in the wall of the pipe, etc., shall apply to this method of fabricating a line of reinforcement.

8.1.1. Where one line of reinforcement is used, it shall be placed so that the cover of the concrete over the circumferential reinforcement at the vertical and horizontal diameters of the pipe is 25 mm [1 in.] from the inside and outside surfaces of the pipe, except for wall thicknesses less than 62 mm [$2^1/_2$ in.], the protective cover of the concrete over the circumferential reinforcement in the wall of the pipe shall be 18 mm [$^3/_4$ in.].

8.1.2. Where two lines of reinforcement of elliptical shape corresponding to the contour of the pipe are used, each line shall be so placed that the covering of concrete over the reinforcement is 25 mm [1 in.].

8.1.3. The location of the reinforcement shall be subject to the permissible variations in dimensions given in Section 12.5. Requirements for placement and protective covering of the concrete from the inner or outer surface of the pipe do not apply to that portion of a cage which is flared so as to extend into the bell or reduced in diameter so as to extend into the spigot.

8.1.4. The spacing center-to-center of circumferential reinforcement in a cage shall not exceed 100 mm [4 in.] for pipe up to and including pipe having a 100 mm [4-in.] wall thickness nor exceed the wall thickness for larger pipe, and shall in no case exceed 150 mm [6 in.].

8.1.5. The continuity of the circumferential reinforcing steel shall not be destroyed during the manufacture of the pipe except that, when agreed upon by the owner, lift eyes or holes may be provided in each pipe for the purpose of handling.

8.1.6. If splices are not welded, the reinforcement shall be lapped not less than 20 diameters for deformed bars and deformed cold-worked wire and 40 diameters for plain bars and cold-drawn wire. In addition, where lapped cages of welded-wire fabric are used without welding, the lap shall contain a longitudinal wire.

8.1.6.1. When splices are welded and are not lapped to the minimum requirements in Section 8.1.6, pull tests of representative specimens shall develop at least 50 percent of the minimum specified strength of the steel and there shall be a minimum lap of 50 mm [2 in.]. For butt-welded splices in bars or wire, permitted only with helically wound cages, pull tests of representative specimens shall develop at least 75 percent of the minimum specified strength of the steel.

8.2. *Longitudinal Reinforcement*—Each line of circumferential reinforcement shall be assembled into a cage that shall contain sufficient longitudinal bars or members to maintain the reinforcement rigidly in shape and in position within the form to comply with permissible variations in Section 8.1. The exposure of the ends of longitudinals, stirrups, or spacers that have been used to position the cages during the placement of the concrete shall not be a cause for rejection.

8.3. *Joint Reinforcement*—In all pipe 900 mm [36 in.] or larger in diameter, either the bell or the spigot of the joint shall contain circumferential reinforcement.

8.3.1. For single-cage pipe, joint reinforcement shall be at least equal in area to that required for an equivalent length of pipe wall.

8.3.2. For double-cage and triple-cage pipe, joint reinforcement shall be at least equal in area to that required for an equivalent length of the outer circular cage if placed in the bell or at least equal in area to that required for an equivalent length of the inner circular cage if placed in the spigot.

9. JOINTS

9.1. The joints shall be of such design and the ends of the concrete pipe sections so formed that the pipe can be laid together to make a continuous line of pipe compatible with the permissible variations given in Section 12.

10. MANUFACTURE

10.1. *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious materials ratio not exceeding 0.53 by mass. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 280 kg/m^3 [470 lb/yd^3] unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this specification.

10.2. *Curing*—Pipe shall be subjected to any one of the methods of curing described in Sections 10.2.1 to 10.2.4 or to any other method or combination of methods approved by the owner that will give satisfactory results. The pipe shall be cured for a sufficient length of time so that the specified D-load is obtained when acceptance is based on Section 5.1.1 or so that the concrete will develop the specified compressive strength at 28 days or less when acceptance is based on Section 5.1.2.

10.2.1. *Steam Curing*—Pipe may be placed in a curing chamber, free from outside drafts and cured in a moist atmosphere maintained by the injection of steam, for such time and such temperature as may be needed to enable the pipe to meet the strength requirements. The curing chamber shall be so constructed as to allow full circulation of steam around the entire pipe.

10.2.2. *Water Curing*—Concrete pipe may be water cured by covering with water-saturated material or by a system of perforated pipes, mechanical sprinklers, porous hose, or by any other approved method that will keep the pipe moist during the specified curing period.

10.2.3. The manufacturer may, at his option, combine the methods described in Sections 10.2.1 to 10.2.4, provided the required strength is attained.

10.2.4. A sealing membrane conforming to the requirements of M 148 may be applied and should be left intact until the required strength requirements are met. The concrete at the time of application shall be within 6ºC [10ºF] of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

11. PHYSICAL REQUIREMENTS

11.1. *Test Specimens*—The specified number of pipe required for the tests shall be furnished without charge by the manufacturer, shall be selected at random by the owner, and shall be pipe that would not otherwise be rejected under this specification. The selection shall be made at the point or points designated by the owner when placing the order. Unless designated otherwise by the owner in the order, the manufacturer shall select the type of test (external load crushing strength test, compression test of cylinders, or compression test of cores) to be used to determine the acceptability of the pipe strength. Pipe that fails to meet the strength requirements as determined by the selected test type may not be retested using one of the other test types without approval of the owner.

11.2. *Number and Type of Tests Required for Various Delivery Schedules*:

11.2.1. *Preliminary Tests for Extended Delivery Schedules*—An owner of pipe whose needs require shipments at intervals over extended periods of time shall be entitled to such tests, preliminary to delivery of pipe, as are required by the type of basis of acceptance specified by the owner in Section 5, of not more than three sections of pipe covering each size in which the owner is interested.

11.2.2. *Additional Tests*—After the preliminary tests described in Section 11.2.1, an owner shall be entitled to additional tests at such times as the owner may deem necessary, provided that the total number of pipe tested (including preliminary tests) shall not exceed one pipe or one percent, whichever is the greater, of each size of pipe delivered.

11.2.3. A owner who places orders of 50 or fewer pipe sections for a particular size and class shall be entitled to one test for each size and class.

11.3. *External Load Crushing Strength*:

11.3.1. The load required to produce a 0.3 -mm [0.01-in.] crack or the ultimate load as determined by the three-edge-bearing method described in T 280 shall be not less than that prescribed in Tables 1or 2 and 3 or 4 for each respective class of pipe. Pipe that have been tested only to the formation of a 0.3 -mm [0.01-in.] crack and that meet the 0.3 -mm [0.01-in.] crack load requirements shall be accepted for use.

Note 2—As used in this specification, the 0.3-mm [0.01-in.] crack is a test criterion for pipe tested in a three-edge-bearing test and is not intended as an indication of overstressed or failed pipe under installed conditions.

11.3.2. *Retests of Pipe Not Meeting the External Load Crushing Strength Requirements*—Pipe shall be considered as meeting the strength requirements when all test specimens conform to the strength requirements. Should any of the test specimens fail to meet the strength requirements, the manufacturer shall be allowed a retest on two additional specimens for each specimen that failed and the pipe shall be acceptable only when all of the retest specimens meet the strength requirements.

CONCRETE TESTING

11.4. *Type of Specimen*—Compression tests determining concrete compressive strength may be made on either standard rodded concrete cylinders or concrete cylinders compacted and cured in like manner as the pipe or on cores drilled from the pipe.

11.5. *Compression Testing of Cylinders*:

11.5.1. *Cylinder Production*—Cylinders shall be prepared in accordance with Section 11 of T 280.

11.5.2. *Number of Cylinders*—Prepare no fewer than five test cylinders from a group (one day’s production of each concrete strength) of pipe sections.

11.5.3. *Acceptability on the Basis of Cylinder Test Results*:

11.5.3.1. When the compressive strengths of all cylinders tested for a group are equal to or greater than the required concrete strength, the compressive strength of concrete in the group of pipe sections shall be accepted.

11.5.3.2. When the average compressive strength of all cylinders tested is equal to or greater than the required concrete strength, not more than 10 percent of the cylinders tested have a compressive strength less than the required concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the required concrete strength, then the group shall be accepted.

11.5.3.3. The pipe shall be acceptable only when the compressive strength of the cylinders tested conforms to the acceptance criteria stated in Section 11.5.3.1 or Section 11.5.3.2.

11.6. *Compression Testing of Cores*:

11.6.1. *Obtaining Cores*—Cores shall be obtained and prepared in accordance with Section 6 of T 280.

11.6.2. *Number of Cores*—One core shall be taken from a pipe section selected at random from each day's production run of a single concrete strength.

11.7. *Acceptability on the Basis of Core Test Results*:

11.7.1. When the compressive strength of a core tested for a group of pipe sections is equal to or greater than the required concrete strength, the compressive strength of the concrete for the group is acceptable.

11.7.2. If the compressive strength of the core tested is less than the required concrete strength, two additional cores shall be taken from that pipe section and tested. Concrete represented by these three core tests shall be considered acceptable if: (1) the average of the three core strengths is equal to at least 85 percent of the required strength, and (2) no single core is less than 75 percent of the required strength.

11.7.3. If the compressive strength of the three cores does not meet the requirements of Section 11.7.2, the pipe from which the cores were taken shall be rejected. Two pipe sections from the remainder of the group shall be selected at random and cored and tested for conformance with either Section 11.7.1 or Section 11.7.2. If both pipe sections meet the core strength requirements of either Section 11.7.1 or Section 11.7.2, the remainder of the group shall be acceptable. If both pipe sections do not meet the test strength requirement, the remainder of the group shall be either rejected or, at the option of the manufacturer, each pipe section of the remaining group shall be cored and accepted individually and any of the pipe sections that have core strengths less than the requirements of Section 11.7.1 or Section 11.7.2 shall be rejected.

11.8. *Plugging Core Holes*—Core holes shall be plugged and sealed by the manufacturer in a manner such that the pipe section will meet all of the requirements of this specification. Pipe sections so plugged and sealed shall be considered satisfactory for use.

11.9. *Absorption*—The absorption of a sample from the wall of the pipe, as determined in accordance with T 280, shall not exceed nine percent of the dry mass. Each sample shall have a minimum mass of 1.0 kg, shall be free of visible cracks, and shall represent the full wall thickness of the pipe. When the initial absorption sample from a pipe fails to conform to this specification, the absorption test shall be made on another sample from the same pipe and the results of the retest shall be substituted for the original test results.

11.10. *Retests of Pipe*—When not more than 20 percent of the concrete specimens fail to pass the requirements of this specification, the manufacturer may cull the project stock, may eliminate whatever quantity of pipe desired, and shall mark those pipe so that they will not be shipped. The required tests shall be made on the balance of the order and the pipe shall be accepted if they conform to the requirements of this specification.

11.11. *Test Equipment*—Every manufacturer furnishing pipe under this specification shall furnish all facilities and personnel necessary to carry out the tests described in T 280.

---

12. PERMISSIBLE VARIATIONS

12.1. *Internal Dimensions*—The internal dimensions of the elliptical pipe shall not vary more than ±2 percent from the internal dimensions shown in Table 5 or Table 6. The variation shall normally be determined by measuring the major and minor axes of the pipe. Where measurements at other points are necessary, the lengths so measured shall not depart from those shown in Table 5 or Table 6 by more than ±2 percent.

12.2. *Wall Thickness*—The wall thickness shall not vary more than shown in the design or specified wall by more than ±5 percent or 5mm [$^3/_{16}$ in.], whichever is greater. A specified wall thickness that is more than required in the design is not cause for rejection. Pipe having localized variations in wall thickness exceeding those specified above shall be accepted if the three-edge-bearing strength and minimum steel cover requirements are met.

12.3. *Length of Two Opposite Sides*—Variations in the laying length of two opposite sides of the pipe shall not be more than 6 mm [$^1/_4$ in.] for all sizes through 600 mm [24-in.] internal equivalent diameter, not more than 10 mm/m [$^1/_8$ in./ft] of internal equivalent diameter for all sizes larger with a maximum of 16 mm [$^5/_8$ in.] in any length of pipe through 2100 mm [84 in.] internal equivalent diameter, and a maximum of 19 mm [$^3/_4$ in.] for 2250 mm [90-in.] internal equivalent diameter or larger, except where beveled-end pipe for laying on curves is specified by the owner.

12.4. *Length of Pipe*—The underrun in length of a section of pipe shall be not more than 10 mm/m [$^1/_8$ in./ft] with a maximum of 13 mm [$^1/_2$ in.] in any length of pipe.

12.5. *Position or Area of Reinforcement*:

12.5.1. *Position*—The maximum variation in the position of the reinforcement shall be ±10 percent of the wall or ±13 mm [$\pm^1/_2$ in.], whichever is the greater. Pipe having variations in the position of reinforcement exceeding those specified above shall be accepted if the three-edge-bearing strength requirements obtained on a representative specimen are met. In no case, however, shall the cover over the circumferential reinforcement be less than 13 mm [$^1/_2$ in.]. The preceding minimum cover limitation does not apply to the mating surfaces of the non-rubber gasket joints or gasket grooves in rubber gasket joints. If convoluted reinforcement is used, the convoluted circumferential end wire may be at the end surface of the joint, providing that alternative convolutions have at least 1 in. cover from the end surface of the joint.

12.5.2. *Area of Reinforcement*—Reinforcement will be considered as meeting the design requirements if the area, computed on the basis of nominal area of the wire or bars used, equals or exceeds the requirements of Section 7.2 or Section 7.3. Actual area of the reinforcing used may vary from the nominal area according to permissible variations of the standard specifications for the reinforcing.

13. REPAIRS

13.1. Pipe may be repaired, if necessary, because of imperfections in manufacture or damage during handling and will be acceptable if, in the opinion of the owner, the repaired pipe conforms to the requirements of this specification.

14. INSPECTION

14.1. The quality of materials, the process of manufacture, and the finished pipe shall be subject to inspection and approval by the owner.

15. REJECTION

15.1. Pipe shall be subject to rejection on account of failure to conform to any of the specification requirements. Individual sections of pipe may be rejected because of the following:

15.1.1. Fractures or cracks passing through the wall, except for a single end crack that does not exceed the depth of the joint;

15.1.2. Defects that indicate mixing and molding not in compliance with Section 10.1 or surface defects indicating honeycombed or open texture that would adversely affect the function of the pipe;

15.1.3. The ends of the pipe are not normal to the walls and centerline of the pipe within the limits of variations given in Sections 12.3 and 12.4;

15.1.4. Damaged or cracked ends where such damage would prevent making a satisfactory joint; and

15.1.5. Any continuous crack having a surface width of 0.3 mm [0.01 in.] or more and extending for a length of 300 mm [12 in.] or more, regardless of position in the wall of the pipe.

16. PRODUCT MARKING

16.1. The following information shall be legibly marked on each section of pipe:

16.1.1. Pipe class and specification designation,

16.1.2. Date of manufacture,

16.1.3. Name or trademark of the manufacturer, and

16.1.4. Identification of plant.

16.2. Pipe with quadrant reinforcement shall be marked with the letter “Q”.

16.3. Markings shall be indented on the pipe section or painted thereon with waterproof paint.

17. KEYWORDS

17.1. Culvert; D-load; elliptical pipe; reinforced concrete; sewer pipe; storm drain.

---

[1] Agrees with ASTM C 507M-09 and C 507-09 except for limiting the absorption testing to the five-hour boil method, the use of synthetic fibers are at the option of the owner and the method of acceptance is changed as per Sections 11.1 and 11.5.3.3.

Standard Specification for

Steel Sheet, Zinc-Coated (Galvanized), for Corrugated Steel Pipe

---

AASHTO Designation: M 218-03 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Sheet, Zinc-Coated (Galvanized), for Corrugated Steel Pipe

AASHTO Designation: M 218-03 (2007)

1. SCOPE

1.1. This specification covers steel sheet used in the manufacture of corrugated steel pipe (CSP) for storm sewers, culverts, drains, and similar uses. The sheet is zinc-coated (galvanized) by the hot-dip process, and is produced in two coating weights, 610 g/m^2 and 1220 g/m^2. Material for this use is furnished in coils, flat in cut lengths, and corrugated in cut lengths.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 120, Zinc
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

2.2. *ASTM Standards*:

- A 754, Standard Test Method for Coating Weight (Mass) of Metallic Coatings on Steel by X-Ray Fluorescence
- A 902, Standard Terminology Relating to Metallic Coated Steel Products
- A 924/A 924M, Standard Specification for General Requirements for Steel Sheet, Metallic-Coated by the Hot-Dip Process
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 376, Standard Practice for Measuring Coating Thickness by Magnetic-Field or Eddy-Current (Electromagnetic) Test Methods

3. TERMINOLOGY

3.1. *Definitions*—For definitions of terms used in this standard, refer to ASTM A 902. The following definitions are as stated in that standard.

3.1.1. *fabricator*—(1) the organization that produces the finished pipe, or (2) for structural plate pipe, the organization that processes flat sheets and other items needed for the field assembly of the finished products.

3.1.2. *manufacturer*—the organization that produces the metal sheet from which pipe is made.

3.1.3. *purchaser*—the person or agency that purchases the finished pipe.

Note 1—With regard to this specification for sheet for corrugated steel pipe, the fabricator may also be considered as the "purchaser" of the sheet, where that term is used in this specification. Such interpretation would not restrict the purchaser of the finished pipe from enforcing any provisions of this specification.

4. ORDERING INFORMATION

4.1. All sheet, both flat and formed, covered by this specification shall be ordered only to the specified thicknesses listed in Table 4.

4.2. Unless otherwise specified in the purchase order, all material furnished to this specification shall be chemically treated.

4.3. Orders for material to this specification shall include the following information, as necessary, to adequately describe the desired product:

4.3.1. Name of material (galvanized steel sheet for CSP);

4.3.2. AASHTO designation and year of issue as M 218-___;

4.3.3. Coating thickness (610 g/m^2 or 1220 g/m^2). A coating weight of 610 g/m^2 will be supplied as a default if no coating weight is specified;

4.3.4. *Quantity and dimensions*:

4.3.4.1. *Cut Lengths*—show number of sheets; thickness; width; either flat or overall corrugated; length; pitch and depth of corrugations, if corrugated;

4.3.4.2. *Coiled Sheet*—show total mass; thickness; width; coil requirements (maximum outside diameter, acceptable inside diameter, and maximum mass of individual coils);

4.3.5. Certification, if required (Section 11.1); and

4.3.6. Special requirements.

Note 2—A typical ordering description is as follows: Galvanized steel sheet for CSP in accordance with M 218-___, 610 g/m^2, 45000 kg, 2.77 by 700 mm by coil, 1500 mm max OD, 600 mm ID, 7000 kg max, certified.

5. CHEMICAL COMPOSITION

5.1. *Base Metal Analysis*—The base metal cast or product analyses shall conform to the chemical requirements of Table 1.

Table 1—Chemical Composition

	Cast Analysis	Product Analysis
Sulfur, max, percent	0.05	0.06
Sum of carbon, manganese, phosphorous, silicon, and sulfur, max, percent	0.70	0.74

5.2. *Coating Bath Composition (Zinc Coating)*—the coating bath metal shall contain not less than 99 percent zinc.

6. MECHANICAL PROPERTIES

6.1. The galvanized steel sheet shall conform to the mechanical requirements in Table 2.

Table 2—Mechanical Requirements
(Properties of Flat Sheet Prior to Fabrication)[a]

Tensile strength, min,[b] MPa	310
Yield point, min,[b] MPa	230
Elongation in 50 mm,[c] min, percent	20

[a] To determine conformance with this specification, round each value for tensile strength and for yield strength to the nearest 1 MPa and each value for elongation to the nearest 1 percent, both in accordance with the rounding method of ASTM E 29.

[b] Yield point and tensile strength are based on thickness of the base metal. If tests are made after coating, determine the base metal thickness after stripping the coating from the ends of the specimen contacting the grips of the tension-testing machine prior to tensile testing.

[c] Elongation requirement does not apply to material tested after corrugating.

6.2. Two tension tests shall be made on random samples of finished material from each cast or heat. When the finished material from said cast or heat is less than 45 Mg, one test is sufficient. When material rolled from one cast or heat differs 1.25 mm or more in thickness, one tension test shall be made from both the thickest and thinnest material rolled regardless of the mass represented. The samples shall be prepared and tested in accordance with the method specified in ASTM A 924M.

7. COATING REQUIREMENTS

7.1. The mass of zinc coating shall conform to the requirements in Table 3. The mass of coating is the total amount on both surfaces of the sheet expressed in g/m^2 of sheet.

Table 3—Coating Mass Requirements

Coating Mass, Total Both Sides		Equivalent Coating Thickness, Total Both Sides[a]	
Triple Spot Average, Min, g/m^2	Single Spot, Min, g/m^2	Triple Spot Average, Min, µm	Single Spot, Min, µm
610	550	86	78
1220	1100	172	156

[a] Coating thicknesses are approximate, for information only. (See Section 9.5.1.) Conversion is based on the following relationship: 1 g/m^2 = 0.1415 µm.

7.2. Adhesion of the coating shall be such that no peeling or flaking occurs while the coated sheet is being corrugated and formed into pipe.

8. DIMENSIONS AND TOLERANCES

8.1. *Thickness*—Sheet thickness shall conform to dimensions prescribed in Table 4. The thickness of the sheet includes both the base steel and the zinc coating.

Table 4—Coated Steel Sheet Thickness Requirements

Specified Thickness, mm	Minimum Thickness, mm
1.02	0.91
1.32	1.17
1.63	1.45
2.01	1.83
2.77	2.57
3.51	3.28
4.27	4.04

Note: Thickness is measured not less than 10 mm from an edge. On corrugated sheet, thickness is measured on the tangents of corrugations. For 1220 g/m^2 coating, the specified thickness and the minimum thickness shall be increased by 0.076 mm to account for the greater thickness as compared with the 610 g/m^2.

8.2. *Length*—Permissible variations in length of cut-length sheets, both flat and corrugated, shall be in accordance with ASTM A 924M.

8.3. *Flat Sheet*—Permissible variations in width and camber of flat materials shall be in accordance with ASTM A 924M. Flatness tolerances are shown in Table 5.

Table 5—Flatness Tolerances (Cut Lengths Only)

Specified Thickness, mm	Specified Width, mm	Flatness Tolerance (Maximum Deviation from a Horizontal Flat Surface), mm
1.63 and thicker	To 1500, incl	13
1.32 and thinner	To 900, incl	13
	Over 900 to 1500, incl	19

Note: This table also applies to sheets cut to length from coils by the fabricator when adequate flattening measures are performed.

8.4. *Corrugated Sheet*:

8.4.1. *Corrugations*—Corrugations shall form smooth continuous curves and tangents. The dimensions of the corrugations shall be in accordance with Table 6.

Table 6—Corrugation Size

			Radius of Curvature, mm	
Nominal Size, mm	Max Pitch,[a] mm	Min Depth,[b] mm	Nominal	Min
68 by 13	73	12	17	12
75 by 25	83	24	14	12
125 by 25	135	24	40	36

[a] Pitch is measured from crest to crest of corrugations, at 90 degrees to the direction of the corrugations.

[b] Depth is measured as the vertical distance from a straightedge resting on the corrugation crests to the bottom of the intervening valley.

8.4.2. *Covering Width and Lip Dimension*—Covering width of corrugated sheet shall be in accordance with Table 7. Covering width is the distance between the crests of the extreme corrugations. The lip dimension of corrugated sheet shall be in accordance with Table 8 and is measured along the radial curvature from the crest of the corrugation to the edge of the sheet. There is no established tolerance for overall width since the covering width and lip dimensions are the governing factors for the formed product.

Table 7—Covering Width Tolerance for Corrugated Sheet

Covering Width, mm	Tolerance Over and Under, mm
To 600, inclusive	6
Over 600 to 900, inclusive	10
Over 900 to 1200, inclusive	13

Table 8—Corrugated Sheet Lip Dimensions

Nominal Corrugation Size, mm	For Riveted Pipe Construction,[a] mm	For Spot-Welded Pipe Construction, Min, mm
68 by 13	19	11
75 by 25	22	13
125 by 25	22	13

[a] Tolerances, +5 mm, –0.

9. TESTING

9.1. The manufacturer shall make such tests and measurements as deemed necessary to ensure that the coated sheet produced complies with this specification.

9.2. The purchaser may make tests and measurements as determined to be necessary to confirm conformance with this specification.

9.3. *Chemical Analysis of Steel*—Cast analysis (by the manufacturer) and product analysis (by the purchaser) shall be in accordance with ASTM A 924M.

9.4. *Mechanical Testing*—Mechanical property tests shall be conducted on the sheet prior to corrugating or other fabrication, when possible, and shall be in accordance with ASTM A 924M. If tests are made after corrugating, specimens shall be taken on the tangents of corrugations and used for determination of tensile and yield strengths only.

9.5. *Coating Mass*:

9.5.1. Sampling for coating mass determinations shall be in accordance with ASTM A 924M. The mass of coating shall be determined according to T 65M/T 65.

9.5.2. The mass may be converted from the sum of readings on both surfaces of the sheet by a magnetic thickness gauge suitably checked and demonstrated for accuracy (Note 3) 1 μm = 7.1 g/m^2 each surface. When a magnetic thickness gauge is used and a dispute arises, the mass shall be determined by the stripping test in T 65M/T 65.

9.5.3. The mass of coating may be determined from the coating thickness measured by the x-ray fluorescence method, according to ASTM A 754. When this method is used and a dispute arises, the mass shall be determined by the stripping test in T 65M/T 65.

Note 3—Several magnetic and electromagnetic types of coating thickness gauges are commercially available and are a satisfactory basis for acceptance when properly calibrated just prior to inspection use. (See ASTM E 376.)

10. REJECTION AND REHEARING

10.1. Material tested by the purchaser and found not conforming to this specification may be rejected subject to the rejection and rehearing provisions of ASTM A 924M.

11. CERTIFICATION

11.1. When specified in the purchase order or contract, a manufacturer's certification shall be furnished to the purchaser. The certification shall be in accordance with the provisions of ASTM A 924M and shall include reference to this product specification designation.

11.2. Test results, including chemical composition, mechanical properties, and mass of coating for each heat and coating lot, shall be maintained by the sheet manufacturer for 7 years and shall be made available to the fabricator and purchaser upon request.

12. PRODUCT MARKING

12.1. Each 0.5 to 1.5 m of sheet in coils or cut lengths shall be identified by showing the following:

12.1.1. Name of manufacturer;

12.1.2. Brand name;

12.1.3. Specified thickness;

12.1.4. Specified coating mass;

12.1.5. Identification symbols relating to a specific heat number and coating lot number; and

12.1.6. AASHTO designation number.

12.2. The brand shall be removed, obliterated, or rebranded "Non-Specification" on each 0.5 to 1.5 m of sheet in a coating lot or heat in which control tests show, as prescribed herein, nonconformance to this specification.

Standard Specification for

Corrugated Aluminum Alloy Structural Plate for Field-Bolted Pipe, Pipe-Arches, and Arches

AASHTO Designation: M 219-92 (2008)
ASTM Designation: B 746/B 746M-92

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Corrugated Aluminum Alloy Structural Plate for Field-Bolted Pipe, Pipe-Arches, and Arches

AASHTO Designation: M 219-92 (2008)
ASTM Designation: B 746/B 746M-92

1. SCOPE

1.1. This specification covers corrugated aluminum alloy structural plate used in the construction of pipe, pipe-arches, arches, underpasses, and special shapes for field assembly. Appropriate fasteners are also described. The pipe, arches, and other shapes are generally used for drainage purposes, pedestrian and vehicular underpasses, and utility tunnels.

1.2. This specification does not include requirements for bedding, backfill, or the relationship between earth cover load and plate thickness of the pipe. Experience has shown that the successful performance of this product depends upon the proper selection of plate thickness, type of bedding and backfill, controlled manufacture in the plant, and care in the installation. The purchaser must correlate the above factors and also the corrosion and abrasion requirements of the field installation with the plate thickness. The structural design of corrugated aluminum structural plate pipe and the proper installation procedures are given in *AASHTO LRFD Bridge Design Specifications* and the *AASHTO LRFD Bridge Construction Specifications*. The *installation* is according to *AASHTO LRFD Bridge Construction Specifications*.

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *arch*—a partial circle shape spanning an open invert between the footings on which it rests.

3.1.2. *box culvert*—a rectangular box with short-radius in upper corners and a long-radius crown. It can be with full invert or with footings pads.

3.1.3. *fabricator*—the producer of the components for the finished product.

3.1.4. *flat plate*—sheet or plate used to fabricate structural plate.

3.1.5. *manufacturer*—the producer of the flat plate and accessories.

3.1.6. *pipe*—a conduit having full circular shape; also, in a general context, all structure shapes covered by this specification.

3.1.7. *pipe-arch*—an arch shape with an approximate semicircular crown, small-radius corners, and large-radius invert.

3.1.8. *pipe, horizontal ellipse*—an elliptically shaped pipe with the horizontal diameter approximately 20 percent greater than the nominal diameter.

3.1.9. *pipe, vertically elongated*—an elliptically shaped pipe with the vertical diameter up to 10 percent greater than the nominal diameter.

3.1.10. *purchaser*—the purchaser of the finished product.

3.1.11. *special shape*—a shape, other than described elsewhere in this section, suitable for fabrication with structural plate.

3.1.12. *structural plate*—a corrugated and curved plate, which is field assembled with other structural plates to form the required structure.

3.1.13. *vehicular underpass*—a high arch shape with an approximate semicircular crown, large-radius sides, small-radius corners between sides and invert, and large-radius invert.

4. ORDERING INFORMATION

4.1. Orders for material under this specification shall include the following information as necessary to adequately describe the desired product:

4.1.1. Name of material (aluminum alloy structural plate and accessories);

4.1.2. Description of structure (see Section 3);

4.1.3. Number of structures;

4.1.4. AASHTO designation and year of issue;

4.1.5. Dimensions of structure (diameter or span and rise, and length, etc.) (Section 7.2);

4.1.6. Thickness of plate (Section 7.1);

4.1.7. Type of bolts; whether aluminum, stainless steel, or steel bolts are required or permitted; if not specified, steel bolts and nuts shall be furnished (Section 5.3 and Note 2);

4.1.8. End treatment (bevel, skew, grade or slope corrections, or other special provision if required by the project plans or specifications);

4.1.9. Special requirements (including extrusion reinforcement locations and shapes), if required; and

4.1.10. Certification, if required.

Note 1—Typical ordering descriptions are as follows: Structural plates and fasteners for one aluminum alloy structural plate pipe arch, conforming to M 219-___, 3860-mm span by 2460-mm rise, 3.81-mm plate thickness, 27.0-m nominal centerline length with square ends.

5. MATERIALS

5.1. *Flat Plate*—Insofar as applicable, flat plate shall conform to the requirements of ASTM B 209M. The plates shall be fabricated from alloy 5052-H141. The mechanical properties for alloy 5052-H141 shall conform to the requirements of Table 1.

Table 1—Mechanical Properties of Aluminum Structural Plate, Alloy 5052-H141[a]

Specified Thickness, mm	Tensile Strength, Min, MPa	Yield Strength (0.2 Percent Offset), Min, MPa	Elongation Percent, Min in 50 mm
2.54–3.81	245	165	6
4.44–6.35	235	165	8

[a] To determine conformance with this specification, each value for tensile strength and for yield strength shall be rounded to the nearest 1 MPa and each value for elongation to the nearest 0.5 percent, both in accordance with the rounding method of ASTM E 29.

5.2. *Extrusions*—The extrusions for circumferential or longitudinal stiffeners, or secondary structural components, shall be fabricated from aluminum alloys 6061-T6 or 6063-T6 conforming to ASTM B 221M.

5.3. *Assembly Fasteners*—Except as provided elsewhere in this section, bolts and nuts shall conform to the requirements specified in Table 2. The bearing surface of both bolts and nuts shall be shaped to a 25-mm radius spherical surface, or to a uniform taper of approximately 22 degrees to form a conical surface. In lieu of bolts and nuts with the special bearing surface, standard type bolts and nuts with special washers may be used. The number of nuts and bolts of each size and length furnished shall be 2 percent in excess of the theoretical number required to field erect the structure or structures. Bolt lengths shall be such as to result in at least "full nut" engagement when tightened in place.

Table 2—(M 219) Bolt and Nut Requirements

	Bolts	Nuts
General dimensions	ANSI B18.2.3.6M Heavy Hex	ANSI B18.2.4.6M Heavy Hex
Steel bolts and nuts	F 568 Class 4.6[a]	M 291M Class 5
Zinc coating	M 232M/M 232 or M 298 Class 50	M 232M/M 232 or M 298 Class 50
Stainless steel bolts and nuts	F 738 Alloy Group A1, A2, or A4	F 836 Alloy Group A1, A2, or A4
Aluminum bolts and nuts	F 468M Alloy 6061-T6	F 467M Alloy 6061-T6
Nominal diameter, metric size	M 20	M 20

[a] Bolts through Class 8.8 with suitable nuts may be substituted.

Note 2—Aluminum bolts and nuts, due to lower strength properties than steel bolts, have lower allowable design seam strengths in pipe with all plate thicknesses, but especially so for plate thicknesses greater than 4.5 mm. The purchaser should indicate which bolts and nuts are acceptable or required based on his design calculations. Corrosion should be considered in selecting bolt types for use in corrosive environments.

6. FABRICATION

6.1. Structural plates shall be fabricated from flat sheets or plates, corrugated in accordance with Section 6.2, punched for bolted lap seams in accordance with Section 6.3, and curved to the required radius.

6.2. *Corrugations*—Corrugations shall form smooth continuous curves and tangents. Corrugations shall form annular rings (complete or partial) about the axis of the structure. The dimensions of the corrugations shall be in accordance with Table 3.

Table 3—Corrugation Requirements

			Inside Radius	
Nominal Size, mm	Max Pitch,[a] mm	Min Depth,[b] mm	Nominal, mm	Min, mm
230 × 64	238	60	57	51

[a] Pitch is measured from crest to crest of corrugations, at 90 degrees to the direction of the corrugations.

[b] Depth is measured as the vertical distance from a straightedge resting on corrugation crests parallel to the axis of the pipe, to the bottom of the intervening valley.

6.3. *Bolt Holes*—The bolt holes shall be punched so that all plates having like dimensions, curvature, and same number of bolts per foot of seam shall be interchangeable. Longitudinal seams shall have holes for four bolts per corrugation, with two holes in each valley and two holes in each crest, with the holes placed 45 mm apart. Circumferential seams in the finished product shall provide for a bolt spacing of not more than 250 mm. The diameter of the bolt holes in the longitudinal seams shall not exceed the bolt diameter by more than 3 mm except those in the plate corners. Bolt holes in circumferential seams, including plate corners, may be slotted with a width equal to the bolt diameter plus 10 mm. The minimum distance from the center of a hole to the edge of a plate shall be $1^3/_4$ times the diameter of the bolt. Holes shall be provided as required for connecting headwall anchors, bearings, and miscellaneous attachments.

6.4. *Special Plates*—Plates for forming skewed ends, beveled ends, or curved alignment shall be accurately cut to fit the order plans. Cut edges of plates shall be free of notches, gouges, or burrs and shall present a workmanlike finish. Legible identification shall be placed on each special plate to designate its proper position in the finished structure and referenced to the approved erection drawings.

6.5. *Extrusions*—Extrusions for longitudinal or circumferential structural reinforcing, if required, shall be as sized and located on the order plans, and fabricated from aluminum alloy 6061-T6. Extrusions for receiving angle on arches or other less critical structural members, if required, shall be as sized and located on the order plans, and shall be fabricated from aluminum alloy 6061-T6 or 6063-T6.

7. DIMENSIONS AND TOLERANCES

7.1. *Plate Thickness*—Plate thickness shall be as specified by the purchaser from the specified plate thickness listed in Table 4 (Note 3). For corrugated plate, the thickness shall be measured on the tangents of the corrugations.

Table 4—Plate Thickness[a]

Specified Thickness, mm	Min Thickness, mm
2.54	2.36
3.18	3.00
3.81	3.51
4.44	4.09
5.08	4.72
5.72	5.31
6.35	5.89

[a] Thickness is measured at any point on the plate not less than 10 mm from an edge and, if corrugated, on the tangents of corrugations.

Note 3—The purchaser should determine the required thickness according to the design criteria in *AASHTO LRFD Bridge Design Specifications* or other appropriate guidelines.

7.2. *Cross-Section Dimensions*—Cross-section dimensions, such as diameter, span and rise, and radius of curvature, shall be measured to the inside crest of corrugations. The average diameter of circular pipe, based on two measurements at 90 degrees to each other, shall not vary more than ±2 percent from the calculated inside diameter shown in Table 5. The span and rise of pipe arch, arch, underpass, and other noncircular structures shall be as specified within ±2 percent.

Note 4—The purchaser should consult the fabricator to determine the standard dimensions for the various types of structures other than circular structures.

Table 5—Diameter of Circular Pipe 230 by 65 mm Corrugation

Nominal Diameter Specified, mm	Calculated Inside Diameter, mm
1525	1490
1675	1645

7620	7715
7770	7870
7925	8025

8. WORKMANSHIP

8.1. Plates, fasteners, and accessories shall be of uniform quality consistent with good manufacturing and inspection practices.

9. SAMPLING AND TESTING

9.1. Sampling and testing of plate shall be according to ASTM B 209M. Sampling and testing of other materials shall be according to the specification referenced. The manufacturer shall make adequate tests and measurements to ensure that the material produced complies with this specification.

9.1.1. Test results including chemical composition and mechanical properties shall be maintained by the manufacturer for 7 years and shall be made available to the fabricator and purchaser upon request, for examination at the manufacturer's facility unless otherwise agreed upon.

9.2. The fabricator or the purchaser may make such tests as are necessary to determine the acceptability of the material or to verify the correctness of a certification.

9.3. Mechanical properties shall be determined on plate prior to corrugating or other fabricating, except tests may be made after fabrication by the purchaser for tensile and yield strengths.

10. REJECTION AND REHEARING

10.1. Material that fails to conform to the requirements of this specification may be rejected. Rejection should be reported to the manufacturer or fabricator promptly and in writing. In case of dissatisfaction with the results of the test, the manufacturer or fabricator may make claim for a rehearing.

11. CERTIFICATION

11.1. When specified in the purchase order or contract, a manufacturer's certification shall be furnished to the purchaser of the plate (fabricator), or manufacturer's and fabricator's certification shall be furnished to the purchaser of the finished pipe, stating that samples representing each lot have been tested and inspected in accordance with this specification and the requirements have been met. When specified in the purchase order or contract, a report of the mechanical test results and the chemical composition limits shall be furnished.

Note 5—As the identity of the plate is not maintained from the original ingot production, if numerical results are required by the purchaser, tests should be performed on the finished plate.

12. PRODUCT MARKING

12.1. Each plate shall be identified by showing the following:

12.1.1. Name or trademark of plate manufacturer;

12.1.2. Name of fabricator, if other than the manufacturer;

12.1.3. Alloy and temper;

12.1.4. Specified thickness;

12.1.5. Identification symbols showing date of fabricating by a six-digit number indicating in order the year, month, and day of the month; and

12.1.6. AASHTO designation number.

12.2. The marking shall be so placed that when the structure is erected, the identification will appear on the inside.

12.3. The marking shall be applied to the plate by a permanent method, such as coining, in accordance with ASTM B 666M.

Standard Specification for

Reinforced Concrete D-Load Culvert, Storm Drain, and Sewer Pipe

AASHTO Designation: M 242M/M 242-08[1]
ASTM Designation: C 655M-07[1] and C 655-07[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Reinforced Concrete D-Load Culvert, Storm Drain, and Sewer Pipe

AASHTO Designation: M 242M/M 242-08[1]
ASTM Designation: C 655M-07[1] and C 655-07[1]

1. SCOPE

1.1 This specification covers reinforced concrete pipe designed for specific D-loads and intended to be used for the conveyance of sewage, industrial wastes, and storm water, and for the construction of culverts.

1.2 This specification is applicable for orders in either SI units (M 242M) or in inch-pound units (M 242). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 242.

Note 1—Experience has shown that the successful performance of this product depends upon the proper selection of the pipe strength, the type of bedding and backfill, the care that the installation conforms to the construction specifications, and provision for adequate inspection at the construction site. This specification does not include requirements for bedding, backfill, the relationship between field load conditions and the strength designation of pipe, or durability under unusual environmental conditions. These requirements should be included in the project specification.

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. BASIS OF ACCEPTANCE

4.1 The acceptability of the pipe design shall be determined in accordance with Section 9. After the pipe design has been accepted, or if the pipe design has been accepted previously in accordance with Section 9, the owner may select and have applied the basis of acceptance described in either Section 4.1.1 or Section 4.1.2. Unless designated by the owner at the time of, or before placing an order, either basis of acceptance shall be permitted.

4.1.1 *Acceptance on the Basis of Pipe Load and Material Tests and Inspection of Manufactured Pipe for Defects*—Determine in accordance with Sections 5, 6, 8, and 10.

Note 2—It is necessary that samples be selected at random. For guidance, see ASTM E 105.

4.1.2 *Acceptance on the Basis of Concrete Compression and Materials Tests and Inspection of Manufactured Pipe for Defects*—Determine in accordance with Sections 5, 6, 8, and 11.

4.2 *Age for Acceptance*—Pipe shall be considered ready for acceptance when they conform to the requirements.

5. DESIGN AND MANUFACTURING DATA

5.1 The manufacturer shall provide the following information regarding the pipe unless waived by the owner:

5.1.1 Basis of acceptance, and

5.1.2 Pipe design strength.

5.1.3 *Physical Characteristics*:

5.1.3.1 Diameter, wall thickness, laying length, and joint details;

5.1.4 Design concrete strength, minimum f_c' equals 27.6 MPa [4000 psi]; and

5.1.5 Admixtures.

5.1.6 *Reinforcement*:

5.1.6.1 Type of reinforcement, applicable reinforcement specification, and grade; and

5.1.6.2 Placement, placement tolerances, diameter, spacing and cross-sectional area of circumferential, longitudinal, and special reinforcement.

5.1.7 Manufacturing and curing process.

---

6. MATERIALS AND MANUFACTURE

6.1 *Materials*:

6.1.1 *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water, in which steel has been embedded in such a manner that the steel and concrete act together.

6.1.2 *Cementitious Materials*:

6.1.2.1 *Cement*—Cement shall conform to the requirements for portland cement of M 85 or shall be portland blast-furnace slag cement or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash.

6.1.2.2 *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.1.2.3 *Ground Granulated Blast-Furnace Slag (GGBFS)—GGBFS shall conform to the requirements of Grade 100 or 120 of M 302.*

6.1.2.4 *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

(a) Portland cement only,
(b) Portland blast-furnace slag cement only,
(c) Slag modified portland cement only,
(d) Portland-pozzolan cement only,
(e) A combination of portland cement and fly ash,
(f) A combination of portland cement and ground granulated blast-furnace slag, or
(g) A combination of portland cement, ground granulated blast furnace slag (not to exceed 25 percent of the total cementious weight), and fly ash (not to exceed 25 percent of the total cementious weight).

6.1.3 *Aggregates*—Aggregates shall conform to the requirements of M 6 and M 80, except that the requirements for gradation shall not apply.

6.1.4 *Admixtures and Blends*—Admixtures and blends shall be allowed to be used unless prohibited by the owner.

6.1.5 *Steel Reinforcement*—Reinforcement shall consist of wire conforming to M 32M/M 32 or M 225M/M 222, or of wire fabric conforming to M 55M/M 55 or M 221M/M 221, or of bars of Grade 300 [40] steel conforming to M 31M/M 31.

6.2 *Manufacture*:

6.2.1 *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious materials ratio not exceeding 0.53 by mass. Cementitious materials shall be as specified in Section 6.1 and shall be added to the mix in a proportion not less than 280 kg/m^3 [470 lb/yd^3] unless mix designs with a lower cementitious material content demonstrate that the quality and performance of the pipe meet the requirements of this specification.

6.2.2 *Reinforcement*:

6.2.2.1 *Placement*—Reinforcement shall be placed as indicated in Section 5.1.6.2, subject to the tolerances given in Sections 5.1.6.2 and 8.2.2. Minimum design protective cover of concrete over the circumferential reinforcement in the barrel of the pipe shall be 25 mm [1 in.] for wall thicknesses of 63 mm [$2^1/_2$ in.] or greater, and 19 mm [$^3/_4$ in.] for wall thicknesses less than 63 mm [$2^1/_2$ in.], subject to the tolerances given in Section 8.2.2.

6.2.2.2 *Splices*—The strength of the pipe shall not be adversely affected by the splice.

6.2.2.3 *Spacing*—The spacing center-to-center of adjacent rings of circumferential reinforcement in a cage shall not exceed 100 mm [4 in.] for pipe with a wall thickness up to and including 100 mm [4 in.] and shall not exceed the wall thickness or 150 mm [6 in.], whichever is smaller, for larger pipe.

6.2.3 *Joints*—The joints shall be of such design and the ends of the concrete pipe sections so formed that when the sections are laid together they will make a continuous line of pipe with a smooth interior free of appreciable irregularities in the flow line, all compatible with the permissible variations given in Section 8.

6.2.4 *Lift Holes*—When agreed upon by the owner, lift eyes or holes are permitted in each pipe for the purpose of handling.

6.3 *Synthetic Fibers*—Collated fibrillated virgin polypropylene fibers shall be allowed to be used, at the owner’s option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be accepted.

7. PHYSICAL REQUIREMENTS

7.1 *Strength*—The design strength designation of the pipe shall be the D-load to produce the 0.3 mm [0.01 in.] crack when tested in accordance with T 280. The relationship of ultimate strength D-load to the design strength D-load shall be determined using a factor of 1.5 for design strength designations up to 100 N/m·mm [2000 lbf/ft·ft] of diameter, a factor varying in linear proportions from 1.5 to 1.25 for design strength designations from 100 N/m·mm [2000 lbf/ft·ft] through 150 N/m·mm [3000 lbf/ft·ft], and a factor of 1.25 for design strength designations in excess of 150 N/m·mm [3000 lbf/ft·ft].

Note 3—As used in this specification, the 0.3-mm [0.01-in.] crack is a test criterion for pipe tested in three-edge-bearing test and is not intended as an indication of overstressed or failed pipe under installed conditions.

Note 4—Ultimate strength of concrete pipe in the buried condition is dependent on varying soil bedding factors and varying failure modes and shall not necessarily have a relationship to the ultimate strength as defined under three-edge-bearing conditions.

7.2 *Test Equipment and Facilities*—The manufacturer shall furnish without charge all samples, facilities, and personnel necessary to carry out the tests required by this specification.

7.3 *Pipe Load Tests*—The tests for crushing strength, when required, shall be made in accordance with T 280. When alternative methods of load testing are specified, tests shall be made in accordance with the alternative requirements.

8. DIMENSIONS AND PERMISSIBLE VARIATIONS

8.1 *Standard Diameters*—Pipe shall be manufactured in the standard inside diameters listed in Table 1.

Note 5—Diameters other than those shown in Table 1 and diameters larger than 3600 mm [144 in.] are possibly available. When such sizes are required, the owner should contact the manufacturers in the area.

Table 1—Standard Designated Inside Diameters, mm [in.]

mm	[in.]	mm	[in.]	mm	[in.]	mm	[in.]	mm	[in.]	mm	[in.]	mm	[in.]
300	12	600	24	900	26	1500	60	2100	84	2700	108	3300	132
375	15	675	27	1050	42	1650	66	2250	90	2850	114	3450	138
450	18	750	30	1200	48	1800	72	2400	96	3000	120	3600	144
525	21	825	33	1350	54	1950	78	2500	102	3150	126		

8.2 *Design Tolerances*—Except as specified in this section, all permissible design tolerances shall be given in Section 5.

8.2.1 *Internal Diameters*—The permissible variations in the internal diameter are as prescribed in Table 2. These diameter requirements are based on the average of four diameter measurements at a distance of 12-in. from the end of the bell or spigot of the pipe. Diameter verification shall be made on the number of pipe selected for test per Section 11.

Table 2—Permissible Variation in Internal Diameter

Designated Diameter of Pipe		Permissible Variation, Internal Diameter of Pipe			
		Minimum		Maximum	
mm	[in.]	mm	[in.]	mm	[in.]
300	12	300	$11^{3}/_{4}$	310	$12^{1}/_{4}$
375	15	375	$14^{23}/_{32}$	390	$15^{9}/_{32}$
450	18	450	$17^{11}/_{16}$	465	$18^{5}/_{16}$
525	21	525	$20^{21}/_{32}$	545	$21^{11}/_{32}$
600	24	600	$23^{5}/_{8}$	620	$24^{3}/_{8}$
675	27	675	$26^{5}/_{8}$	695	$27^{3}/_{8}$
750	30	750	$29^{5}/_{8}$	775	$30^{3}/_{8}$
825	33	825	$32^{5}/_{8}$	850	$33^{3}/_{8}$
900	36	900	$35^{5}/_{8}$	925	$36^{3}/_{8}$
1050	42	1050	$41^{9}/_{16}$	1080	$42^{7}/_{16}$
1200	48	1200	$47^{1}/_{2}$	1230	$48^{1}/_{2}$
1350	54	1350	$53^{7}/_{16}$	1385	$54^{9}/_{16}$
1500	60	1500	$59^{3}/_{8}$	1540	$60^{5}/_{8}$
1650	66	1650	$65^{5}/_{16}$	1695	$66^{11}/_{16}$
1800	72	1800	$71^{1}/_{4}$	1850	$72^{3}/_{4}$
1950	78	1950	$77^{1}/_{4}$	2000	$78^{3}/_{4}$
2100	84	2100	$83^{3}/_{16}$	2155	$84^{13}/_{16}$
2250	90	2250	$89^{1}/_{8}$	2310	$90^{7}/_{8}$
2400	96	2400	$95^{1}/_{16}$	2465	$96^{15}/_{16}$
2550	102	2550	101	2620	103
2700	108	2700	$106^{15}/_{16}$	2770	$109^{1}/_{16}$
2850	114	2850	$112^{7}/_{8}$	2925	$115^{1}/_{8}$
3000	120	3000	$118^{13}/_{16}$	3080	$121^{3}/_{16}$
3150	126	3150	$124^{3}/_{4}$	3235	$127^{1}/_{4}$
3300	132	3300	$130^{11}/_{16}$	3390	$133^{5}/_{16}$
3450	138	3450	$136^{5}/_{8}$	3540	$139^{3}/_{8}$
3600	144	3600	$142^{9}/_{16}$	3695	$145^{7}/_{16}$

8.2.2 *Reinforcement Placement Tolerances*—The maximum variation in the nominal position of the reinforcement shall be ±10 percent of the wall thickness or ±16 mm [±$^{5}/_{8}$ in.], whichever is greater. Pipe having variations in the position of the reinforcement exceeding those specified above shall be accepted if the three-edge-bearing strength requirements obtained on a representative sample are met. In no case, however, shall the cover over the circumferential reinforcement be less than 16 mm [$^{5}/_{8}$ in.].

8.2.3 *Length of Two Opposite Sides*—Variations in the laying length of two opposite sides of pipe shall not be more than 6 mm [$^{1}/_{4}$ in.] for all sizes through 600 mm [24-in.] internal diameter, and not more than 10 mm/m [$^{1}/_{8}$ in./ft] of internal diameter for all larger sizes, with a maximum of 16 mm [$^{5}/_{8}$ in.] in any pipe through 2100 mm [84-in.] internal diameter, and a maximum of 19 mm [$^{3}/_{4}$ in.] for 2250 mm [90-in.] internal diameter or larger, except where beveled-end pipe for laying on curves is specified by the owner.

8.2.4 *Length of Pipe*—The underrun in length of a section of pipe shall not be more than 10 mm/m [$^{1}/_{8}$ in./ft] with a maximum of 13 mm [$^{1}/_{2}$ in.] in any length of pipe.

8.2.5 *Wall Thickness Tolerances*—The wall thickness shall not be less than the nominal specified in the design given in Section 5.1.3.1 by more than 5 percent or 5 mm [$^{3}/_{16}$ in.], whichever is greater.

A wall thickness more than that required in the design is not a cause for rejection except that such pipe shall not be used for the tests required in Section 7.3.

9. ACCEPTANCE OF DESIGN

9.1 *Acceptance by Tests of Specimens*—Three to five representative specimens, or special test pipe that are shorter than standard production pipe, as agreed upon by the owner and manufacturer, shall be tested to the 0.3 mm [0.01 in.] crack and to ultimate strength and the results recorded. Compute the values in Sections 9.1.1 and 9.1.2 for both the 0.3 mm [0.01 in.] crack and the ultimate strength.

9.1.1 Compute the estimated standard deviation, *s*, by Equation 1 or Equation 2, which yield identical values.

$$s = \sqrt{[\Sigma\left(X_i - \overline{X}\right)^2]\Big/(n-1)} \tag{1}$$

$$s = \sqrt{[\Sigma X_i^2 - \left(\Sigma X_i\right)^2\big/n]\Big/(n-1)} \tag{2}$$

where:

X_i = observed value of the load to produce the 0.3 mm [0.01 in.] crack (and the load to develop the ultimate strength)

$\overline{X}$ = average (arithmetic mean) of the values of x_i, and

n = number of observed values.

9.1.2 Compute the minimum allowable arithmetic mean, $\overline{X}_s$, by Equation 3. In Equation 3, the value of the estimated standard deviation, *s*, shall be as calculated by Equations 1 or 2 or equal to 0.07*L*, whichever is greater.

$$\overline{X}_s = L + 1.07s \tag{3}$$

where:

L = specification limit (specified D-load).

9.1.3 The pipe design shall be acceptable if the arithmetic mean $\overline{X}$ for the 0.3 mm [0.01 in.] crack and ultimate strength is equal to or greater than the computed values of $\overline{X}_s$, and if all the tested specimens meet or exceed the specification limit.

9.2 *Alternative Acceptance Method*—The manufacturer shall be allowed to request approval of designs based on empirical evaluations of the strength of the pipe, including, but not limited to, designs based on interpolation between designs approved in accordance with Section 9.1, or designs evaluated on the basis of tests other than the three-edge-bearing test method. Acceptance of design tests need not be performed for each contract or order.

10. ACCEPTANCE OF PIPE BY LOAD TESTING

10.1 *Lot Sampling*—When the acceptance is to be in accordance with Section 4.1.1, randomly select from the lot a sample of the size listed in Table 3 and test each specimen to the design strength. When all specimen test strengths are greater than the minimum design strength D-load, the lot shall be accepted. When one or more specimen test strengths are less than the minimum design strength D-load, the values for $\overline{X}$ and *s* shall be computed and *s* shall be substituted into the applicable equation given in Table 3. When the arithmetic mean $\overline{X}$ is equal to or greater than the computed value of $\overline{X}_s$, the lot of pipe shall be acceptable. When the arithmetic mean $\overline{X}$ is less than the computed value of $\overline{X}_s$, the lot of pipe shall be rejected for that design strength D-load strength.

Table 3—Sample Size

Lot Size	Sample Size	Equation	Equation Number
0 to 300	3	$\overline{X}_S = L + 1.08s$	*(4)*
301 to 500	4	$\overline{X}_S = L + 1.09s$	*(5)*
501 to 800	5	$\overline{X}_S = L + 1.10s$	*(6)*
801 to 1300	7	$\overline{X}_S = L + 1.16s$	*(7)*

10.2 *Use of Design Test Pipe*—When the pipe tested in Section 9 were selected at random from a production lot, the test data may be used in the acceptance analysis of that lot.

10.3 *Use of Pipe Tested to 0.3mm [0.01 in.] Crack*—Pipe that have been tested only to the formation of the 0.3mm [0.01 in.] crack and that meet the design strength requirements shall be acceptable for use. All pipe that test less than the design strength shall be removed from the lot and marked so that they will not be shipped.

11. ACCEPTANCE OF PIPE BY CONCRETE COMPRESSION TESTING

11.1 *Type of Specimen*—Compression tests for determining concrete compressive strength shall be allowed to be made on either concrete cylinders or on cores drilled from the pipe. Pipe that fails to meet the strength requirements as determined by the selected test type shall not be retested using one of the other test types without approval of the owner.

11.2 *Compression Testing of Cylinders*:

11.2.1 *Cylinder Production*—Cylinders shall be prepared in accordance with the Cylinder Strength Test Method of T 280.

11.2.2 *Number of Cylinders*—Prepare not fewer than five test cylinders from each concrete mix used within a group (one day’s production) of pipe sections.

11.2.3 *Acceptability on the Basis of Cylinder Test Results*:

11.2.3.1 When the compressive strengths of all cylinders tested for a group are equal to or greater than the design concrete strength, the compressive strength of concrete in the group of pipe sections shall be accepted.

11.2.3.2 When the average compressive strength of all cylinders tested is equal to or greater than the design concrete strength, not more than 10 percent of the cylinders tested have a compressive strength less than the design concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the design concrete strength, then the group shall be accepted.

11.2.3.3 The group of pipe shall be acceptable only when the compressive strength of the cylinders tested conforms to the acceptance criteria stated in Section 11.2.3.1 or Section 11.2.3.2.

11.3 *Compression Testing of Cores*:

11.3.1 *Obtaining Cores*—Cores shall be obtained, prepared, and tested in accordance with the Core Strength Test Method of T 280.

11.3.2 *Number of Cores*—One core shall be cut from a pipe section selected at random from each day’s production run of a single concrete strength.

11.4 *Acceptability on the Basis of Core Test Results*:

11.4.1 When the compressive strengths of a core tested for a group of pipe sections is equal to or greater than the design concrete strength, the compressive strength of the concrete for the group is acceptable.

11.4.2 If the compressive strength of the core tested is less than the design concrete strength, two additional cores shall be taken from that pipe section and tested. The group of pipe represented by these core tests shall be considered acceptable if: (1) the average of three cores is equal to at least 85 percent of the required strength , and (2) no single core is less than 75 percent of the required strength.

11.4.3 If the compressive strength of the three cores does not meet the requirements of Section 11.4.2, the pipe section from which the cores were taken shall be rejected. Two pipe sections from the remainder of the group shall be selected at random and cored and tested for conformance with either Section 11.4.1 or Section 11.4.2. If both pipe sections meet the core strength requirements of Section 11.4.1 or Section 11.4.2, the remainder of the group shall be acceptable. If either or both pipe sections do not meet the strength test requirements, then the remainder of the group shall be either rejected or, at the option of the manufacturer, each pipe section of the remainder of the group shall be cored and accepted individually, and any of the pipe sections that have core strengths less than the requirements of Section 11.4.1 or Section 11.4.2 shall be rejected.

11.5 *Plugging Core Holes*—Core holes shall be plugged and sealed by the manufacturer in a manner such that the pipe section will meet all of the requirements of this specification. Pipe sections so plugged and sealed shall be considered satisfactory for use.

11.6 *Retests of Pipe*—When not more than 20 percent of the concrete specimens fail to pass the requirements of this specification, the manufacturer may cull the project stock and may eliminate whatever quantity of pipe is desired. The manufacturer shall mark those pipe so that they will not be shipped. The required tests shall be made on the balance of the order and the pipe shall be accepted if they conform to the requirements of this specification.

12. INSPECTION

12.1 The quality of materials, process of manufacture, and the finished pipe shall be subject to inspection by the owner.

13. REJECTION

13.1 Pipe shall be subject to rejection for failure to conform to any of the specification requirements. Individual sections of pipe are subject to rejection because of any of the following:

13.1.1 Fractures or cracks passing through the wall, except for a single-end crack that does not exceed the depth of the joint;

13.1.2 Defects that indicate mixing and molding not in compliance with Section 6.2;

13.1.3 The ends of the pipe are not normal to the walls and centerline of the pipe, within the limits of variations given in Section 8.2.3;

13.1.4 Damaged ends where such damage would prevent making a satisfactory joint; or

13.1.5 Surface defects that indicate honeycombed or open texture that would adversely affect the function of the pipe.

13.2 The exposure of the ends of longitudinals, stirrups, or spacers that have been used to position the cages during the placement of the concrete is not a cause for rejection.

14. DISPOSITION OF A REJECTED LOT

14.1 A lot of pipe which fails to meet the criteria for acceptability shall be allowed to be utilized in accordance with a procedure mutually agreed upon by the manufacturer and the owner. The procedure shall demonstrate improvement in the lot, statistically calculate a reduced D-load strength for the lot, or develop an acceptable disposition. The manufacturer shall bear all expenses incurred by the procedure.

15. REPAIRS

15.1 Pipe shall be repaired, if necessary, because of imperfections in manufacture, damage during handling, or pipes that have been cored for testing, and will be acceptable if, in the opinion of the owner, the repairs are sound and properly finished and cured and the repaired pipe conforms to the requirements of this specification.

16. CERTIFICATION

16.1 When agreed upon in writing by the owner and the manufacturer, a certification shall be made the basis of acceptance. This shall consist of a copy of the manufacturer's test report or a statement by the manufacturer, accompanied by a copy of the test results, that the pipe has been sampled, tested, and inspected in accordance with the provisions of Section 4. Each certification so furnished shall be signed by an authorized agent of the manufacturer.

17. PRODUCT MARKING

17.1 The following information shall be legibly marked on each section of pipe:

17.1.1 The pipe design strength shall be indicated by the 0.3 mm [0.01 in.] crack D-load designated in Section 5.1.2, followed by the capital letter D and specification designation;

17.1.2 Date of manufacture;

17.1.3 Name or trademark of the manufacturer;

17.1.4 Plant identification; and

17.1.5 One end of each section of pipe designed to be installed with a particular axis of orientation shall be clearly marked during the process of manufacturing or immediately thereafter on the inside and outside of opposite walls on the vertical axis or shall be designated by location of lift holes.

17.2 Markings shall be indented on the pipe section or painted thereon with waterproof paint.

18. KEYWORDS

18.1 *Concrete pipe*—reinforced; culvert; D-load; sewer pipe; storm drains; three-edge-bearing strength.

APPENDIX

(Nonmandatory Information)

X1. EXAMPLE CALCULATION

X1.1. As required by Section 10.1, the acceptability of a lot of 520 sections of 1350 mm [54 in.] designated inside diameter pipe will be determined in accordance with Section 4.1.1. The design strength (0.3 mm [0.01 in.] crack) D-load is specified as 62 N/linear m per mm [1250 lbf/linear ft per ft] of designated inside diameter (62 [1250] D pipe).

X1.2. From the lot, randomly select a sample of five specimens ($n = 5$) each 1.8 m [6 ft] long as shown in Table 2.

X1.3. Test the pipe and record the observed values of X_i, in kilonewtons [pounds-force], which produce the 0.3 mm [0.01 in.] crack: 213.51 [48,000], 144.57 [32,500], 191.27 [43,000], 200.17 [45,000], and 180.15 [40,500].

X1.4. *Example Computations*—choose the appropriate example for either SI or inch-pound units;

(a) In this example X_i, is in kilonewtons, convert the specification limit L (design strength D-load) to kilonewtons by multiplying the D-load times the designated inside diameter in millimeters times the pipe length in meters, or

$$L = 62 \times 1350 \times 1.8 = 150.66 \text{ kN}$$

(b) In this example X_i is in pounds-force, convert the specification limit L (design strength D-load) to pounds by multiplying the D-load times the designated inside diameter in feet times the pipe length in feet, or

$$L = 1250 \times \left({}^{54}\!/\!{}_{12}\right) \times 6 = 33{,}750 \text{ lbf}$$

X1.5. Since an observed value of the test loads (X_i = 144.57 kN [32,500 lbf]) is less than the specification limit (L =150.66 kN [33,750 lbf]), compliance with the acceptability criteria must be determined in accordance with Section 10.

X1.6. The following values for $\bar{X}$ and s must be computed (see Note 6 if computing values using inch-pound units):

$\bar{X}$ = average (arithmetic mean) of the observed values X_i, and

s = estimated standard deviation.

Note X1—The observed inch-pound values of pipe strengths in Table X1.2 are divided by 100 to simplify the computations in accordance with the recommendation made in Section 25 of ASTM STP 15-C, *Manual on Quality Control of Materials*. The effect is to reduce the size of the numbers so they can be computed more readily on a desk calculator.

X1.7. Calculate the values for $\bar{X}$ as follows: (See Table X1.1, for SI Values for $\bar{X}$, see Table X1.2 for inch-pound Values for $\bar{X}$.)

Table X1.1—SI Values for $\overline{X}$

213.51	45 586.52		
144.57	20 900.48	$(\Sigma X_i)^2 =$	$(929.67)^2$
191.27	36 584.21	$=$	864286.31
200.17	40 068.03	$\overline{X} =$	$(\Sigma X_i/n)$
180.15	32 454.02	$\overline{X} =$	(929.67/5)
$\Sigma X_i = 929.67$	$\Sigma X_i^2 = 175593.26$	$\overline{X} =$	185.93 kN

Table X1.2—Inch-Pound Values for $\overline{X}$

Values for $\overline{X}$			
480	230,400	$(\Sigma X_i)^2 =$	$(2090)^2$
325	105,625	$=$	4,368,100
430	184,900	$\overline{X} =$	$(\sum X_i/n)\times 100$
450	202,500	$\overline{X} =$	$(2090/5)\times 100$
405	164,025	$\overline{X} =$	41,800 lbf
$\Sigma X_i = 2090$	$\Sigma X_i^2 = 887,450$		

X1.8. The standard deviation, *s*, may be computed by either Equations 1 or 2. Since Equation 2 is a simpler form for computation, this will be used.

$$s = \sqrt{\left[\sum X_i^2 - \left(\sum X_i\right)^2 / n\right] \Big/ (n-1)}$$

(a) Example computation using SI units:

$$s = \sqrt{(175\ 593.26 - 864\ 286.31/5)/(5-1)}$$

$$s = \sqrt{684.0}$$

$$s = 26.15 \text{ kN}$$

(b) Example computation using inch-pound units;

$$s = \sqrt{(887,450) - (4,368,100/5)/(5-1)}$$

$$s = \sqrt{3458}$$

$s = 5.88$ Multiply by 100 to obtain total pounds-force:

$s = 58.8 \times 100$

$s = 5880$ lbf

X1.9. The required minimum allowable arithmetic mean $\bar{X}_s$ is computed by Equation 3:

(a) SI value computation

$$\bar{X}_s = L + 1.10s$$

$$\bar{X}_s = 150.66 + 1.10 \times 26.15$$

$$\bar{X}_s = 179.43 \text{ kN}$$

Since the actual $\bar{X}$ of 185.93 kN is greater than the required minimum allowable $\bar{X}_s$ of 179.43 kN, the lot of pipe is acceptable.

(b) Inch-pound value computation

$$\bar{X}_s = L + 1.10s$$

$$\bar{X}_s = 33750 + 1.10 \times 5880$$

$$\bar{X}_s = 40,218 \text{ lbf}$$

Since the actual $\bar{X}$ of 41,800 lbf is greater than the required minimum allowable $\bar{X}_s$ of 40,218 lbf, the lot of pipe is acceptable.

X1.10. ASTM MNL 7A (formerly STP 15-D), *Manual on Presentation of Data and Control Chart Analysis*, is a valuable source of information regarding statistical procedures and simplified computational methods.

---

[1] Agrees with ASTM C 655M-07 and C 655-07 except that the use of synthetic fibers is at the option of the owner and the method of acceptance is changed per Sections 11.1, 11.2.2, 11.2.3.3, 11.4.2, and 11.4.3.

Standard Specification for

Field-Applied Coating of Corrugated Metal Structural Plate for Pipe, Pipe-Arches, and Arches

AASHTO Designation: M 243-96 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Field-Applied Coating of Corrugated Metal Structural Plate for Pipe, Pipe-Arches, and Arches

AASHTO Designation: M 243-96 (2008)

1. SCOPE

1.1. This specification covers field-applied asphaltic mastic coating of corrugated metal structural plate for pipe, pipe-arches, and arches to be used for the construction of metal culverts.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 167, Corrugated Steel Structural Plate, Zinc-Coated, for Field-Bolted Pipe, Pipe-Arches, and Arches
- M 219, Corrugated Aluminum Alloy Structural Plate for Field-Bolted Pipe, Pipe-Arches, and Arches

3. DESCRIPTION

3.1. Corrugated metal structural plate for pipe, pipe-arches, and arches shall conform to the requirements of M 167 or M 219 and, in addition, shall be coated as hereinafter described.

3.2. Before applying coating material to metal surfaces, moisture, dirt, oil, unbonded or incompatible paint, grease, residual oils, alkalies, or other foreign matter must be removed from the surface to be coated.

COATING MATERIAL REQUIREMENTS

4. ASPHALT MASTIC

4.1. The material shall be uniformly applied to structural plate for pipe, pipe-arches, or arches in such a manner to attain (both inside and outside) a minimum thickness of 1.27 mm measured on the crest of the corrugations.

4.2. The asphalt mastic shall be furnished in any one of three consistencies depending on the type of application to be employed. In spraying consistency, the material shall be suitable for air gun spraying without the use of additional thinners at temperatures of 4.4ºC and above. In trowel grade consistency, the material shall be suitable for knife or trowel application. In brushing consistency, the material shall be suitable for application with an ordinary roofing brush.

4.3. The asphalt mastic shall be designed as a cold-applied membrane waterproofing for application to aluminum or steel to provide a protective coating with high resistance to corrosion and chemical fumes. It shall not be affected by freezing temperatures and will not flow in hot weather. It shall have high cohesive strength and, after application, readily harden into a tough elastic seal. The material shall be mixed until the mineral stabilizers and fillers are uniformly dispersed.

4.4. The material for coating shall be an asphalt having the following physical characteristics:

Asphalt Base—Oxidized petroleum asphalts

Solvent—Rapid drying petroleum solvents

Fillers—Mineral stabilizers and fillers

Consistency—Made in three consistencies—trowel, brush, and spraying

4.5. *Physical Properties*:

	Trowel Grade		Spraying Grade		Brushing Grade	
	Min	Max	Min	Max	Min	Max
Solids, percent by mass	63	68	61	66	60	65
Density, kg/L	1.04	1.07	0.99	1.11	0.98	1.02
Dry to touch, h		2		2		2
Dry hard		48		48		48

4.6. *Methods of Sampling and Testing*:

4.6.1. A representative sample of approximately 4 L shall be taken from each lot furnished.

4.6.2. *Physical Tests*:

4.6.2.1. *Solids Content*—Approximately a 9-g sample of material is weighed into an aluminum drying dish to an accuracy of 0.01 g. Sample is heated until constant mass is obtained (approximately 24 to 48 h) at 163 ± 3ºC cooled, reweighed, and percentage of solids calculated. Percent of solids is determined by dividing mass of material after heating by mass of material before heating × 100.

4.6.2.2. *Flow Properties at Elevated Temperatures*—A coating of the material is applied approximately 1.6 mm thick, on a degreased steel panel 0.61 mm thick. Parallel lines spaced 12.7 mm apart are scored horizontally across the width of the surface. After air drying for a period of 48 h, the panel shall be suspended in a vertical position in an oven at 66 ± 3ºC for 24 h. After removal of the panel, the surface of the coating is inspected for shifting or sagging of the lines. Any shifting or sagging of the lines shall be cause for rejection.

4.6.2.3. *Acid and Alkali Resistance*—A coating of the material prepared in accordance with Section 4.6.2.2 shall show no signs of attack when immersed for 24 h in each of the following solutions: 10 percent of hydrochloric acid, 10 percent of sulfuric acid, and 10 percent of sodium hydroxide. On removal of the mastic by solvent cleaning, the panel surface shall be free from any pitting or rusting.

4.6.2.4. *Pliability and Adherence Characteristics*—A coating of the material shall be prepared in accordance with Section 4.6.2.2. After air drying for a period of 48 h, followed by baking in an oven for 48 h at 104 ± 3ºC the material shall not crack or peel from the panel when bent at room temperature (22 ± 1ºC) 180 degrees over a 28.6-mm mandrel.

Standard Specification for

Corrugated Steel Pipe, Polymer-Precoated, for Sewers and Drains

AASHTO Designation: M 245-00 (2008)
ASTM Designation: A 762/A 762M-98

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Corrugated Steel Pipe, Polymer-Precoated, for Sewers and Drains

AASHTO Designation: M 245-00 (2008)
ASTM Designation: A 762/A 762M-98

1. SCOPE

1.1. This specification covers polymer-precoated corrugated steel pipe intended for use for storm water drainage, underdrains, the construction of culverts, and similar uses. Pipe covered by this specification is not normally used for the conveyance of sanitary or industrial wastes. The steel sheet used in fabrication of the pipe has a polymer protective coating over a metallic coating of zinc (galvanizing), 55 aluminum-zinc alloy, or zinc-5 percent aluminum-Mischmetal alloy.

1.2. The polymer coating provides a degree of extra protection for the pipe against abrasion and corrosion as compared with metallic-coated pipe without polymer coating. Some severe environments may cause corrosion problems to accessory items such as rivets or coupling band hardware that does not have a polymer coating. Additional protection for polymer-precoated corrugated steel pipe can be provided by use of coatings applied after fabrication of the pipe as described in M 190.

1.3. This specification does not include requirements for bedding, backfill, or the relationship between earth cover load and sheet thickness of the pipe. Experience has shown that the successful performance of this product depends upon the proper selection of sheet thickness, type of bedding and backfill, controlled manufacture in the plant, and care in the installation. The installation procedure is described in the *AASHTO LRFD Bridge Construction Specifications*, Section 26.

- F 568M, Standard Specification for Carbon and Alloy Steel Externally Threaded Metric Fasteners (Metric)

3. DESCRIPTIONS OF TERMS SPECIFIC TO THIS STANDARD

3.1. *fabricator*—the producer of the pipe.

3.2. *manufacturer*—the producer of the sheet.

3.3. *purchaser*—the purchaser of the finished product.

4. CLASSIFICATION

4.1. The corrugated steel pipe covered by this specification is classified as follows:

4.1.1. *Type I*—This pipe shall have a full circular cross section, with a single thickness of corrugated sheet, fabricated with annular (circumferential) or helical corrugations.

4.1.2. *Type IA*—This pipe shall have a full circular cross section with an outer shell of corrugated sheet fabricated with helical corrugations and an inner liner of smooth (uncorrugated) sheet attached to the shell at helical lock seams.

4.1.3. *Type IR*—This pipe shall have a full circular cross section with a single thickness of smooth sheet, fabricated with helical ribs projecting outwardly.

4.1.4. *Type II*—This pipe shall be a Type I pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.5. *Type IIA*—This pipe shall be a Type IA pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.6. *Type IIR*—This pipe shall be a Type IR pipe that has been reformed into a pipe-arch having an approximately flat bottom.

4.1.7. *Type III*—This pipe, intended for use as underdrains or for underground disposal of water, shall be a Type I pipe that has been perforated to permit the inflow or outflow of water.

4.1.8. *Type IIIA*—This pipe, intended for use as underdrains, shall consist of a semicircular cross section having a smooth (uncorrugated) bottom with a corrugated top shield.

4.2. Perforations in Type III pipe are included in two classes as described in Section 8.3.2.

5. ORDERING INFORMATION

5.1. Orders for material to this specification shall include the following information as necessary to adequately describe the desired product:

5.1.1. Name of material (polymer-coated corrugated steel pipe);

5.1.2. Grade of polymer coating indicating thickness on inside and outside (Section 6.1.1);

5.1.3. Type of metallic coating (zinc or aluminum-zinc alloy) (Section 6.1.2);

5.1.4. AASHTO designation and date of issue;

5.1.5. Type of pipe (Section 4.1);

5.1.6. Diameter of circular pipe (Table 8), or span and rise of pipe-arch section (Tables 10, 11, or 12);

5.1.7. Length, either total length or length of each piece and number of pieces;

5.1.8. Description of corrugations (Section 7.2);

5.1.9. Sheet thickness (Section 8.1.2);

5.1.10. For Type I and Type II pipe, the pipe fabrication method, whether with annular corrugations or helical corrugations (Section 7.1.1) (Note 1);

5.1.11. Coupling bands, number, and type (Section 9.1) if special type is required;

5.1.12. Gaskets for coupling bands, if required (Section 9.3);

5.1.13. For Type III pipe, class of perforations, if other than Class 1 (Section 8.3.2);

5.1.14. Certification, if required (Section 14.1); and

5.1.15. Special requirements.

Note 1—Pipe manufactured with annular corrugations may have an element of weakness in the longitudinal seams compared with pipe with helical corrugations. Therefore, consideration of the method of fabrication is important when pipe is installed under certain conditions of loading.

6. MATERIALS

6.1. *Steel Sheet for Pipe*—All pipe fabricated under this specification shall be formed from polymer-precoated sheet conforming to M 246.

6.1.1. The grade of coating shall be stated in the order, and the polymer coating thickness on both inside and outside of the pipe. The polymer coating is classified by grade corresponding to the thickness in micrometers on each side in SI units. (See Table 1.)

Table 1—Grade

Grade	Coating Thickness, μm
250/250	250/250

6.1.1.1. Any combination of polymer coating thickness or other than shown in Table 1 is subject to agreement between the manufacturer and purchaser or fabricator.

6.1.2. The polymer coating is applied to steel sheet having a metallic coating of zinc or aluminum-zinc alloy, as described in M 218, M 289, or ASTM A 929M. The type of metallic coating should be stated in the order, consistent with thickness availability as shown in Table 8. If the type of metallic coating is not stated, zinc-coated sheet conforming to M 218 shall be used. All pipe furnished on the order shall have the same metallic coating unless otherwise specified.

6.2. *Steel Sheet for Coupling Bands*—The sheet used in fabricating coupling bands shall conform to M 246 with the same polymer coating grade as that used for fabrication of the pipe furnished under the order, and having the same metallic coating.

6.2.1. As an alternate, the steel sheet for coupling bands shall conform to M 218, M 289, or ASTM A 929M (with the same metallic coating as the pipe), with the sheet having a bituminous coating according to M 190, except the thickness requirement shall not apply.

6.2.2. When specifically permitted by the purchaser, coupling bands shall be made of steel sheet conforming to the specification listed in Section 6.2.1 having the same metallic coating as the pipe, but without bituminous coating.

6.3. *Rivets*—The rivets used in riveted pipe shall be of the same material as the base metal specified for the corrugated sheets. They shall be thoroughly galvanized or sherardized. If bolts and nuts are substituted for rivets (Section 7.3.1), they shall meet the following requirements. (See Table 2.)

Table 2—Bolts and Nuts

	Bolts	Nuts
For pipe fabrication:		
For M 245 pipe	F 568, Class 8.8	M 291M, Class 12
For coupling bands:		
For M 245 pipe	F 568, Class 4.6	M 291M, Class 5

The bolts and nuts shall be hot-dip galvanized in conformance with M 232M/M 232, or be mechanically galvanized in conformance with M 298, Class 40.

6.3.1. When specified in the order, rivets used in riveted pipe to be installed in severely corrosive environments shall be made of stainless steel conforming to any of the S3xxxx designations in ASTM A 493. Stainless steel rivets may be substituted for those described in Section 6.3 at the fabricator's option.

Note 2—Some polymer-precoated pipe in a severe environment is reported to have failed due to corrosion of rivets conforming to Section 6.3, while the sheet was essentially unaffected. The use of stainless steel rivets is recommended to overcome such problems.

6.4. *Hardware for Coupling Bands*—Bolts and nuts for coupling bands shall conform to the following requirements. (See Table 2.) Bolts, nuts, and other threaded items used with coupling bands shall be zinc coated by one of the following processes: hot-dip process as provided in M 232M/M 232; electroplating process as provided in ASTM B 633, Class Fe/Zn 8; or mechanical process as provided in M 298, Class 8. Other hardware items used with coupling bands shall be zinc coated by one of the following processes: hot-dip process as provided in M 232M/M 232; electroplating process as provided in ASTM B 633, Class Fe/Zn 25; or mechanical process as provided in M 298, Class 25.

6.5. *Gaskets*—If gaskets are used in couplings, they shall be a band of expanded rubber meeting the requirements of ASTM D 1056 for the "RE" closed cell grades, or O-rings meeting the requirements of M 198.

7. FABRICATION

7.1. *General Requirements*—Pipe shall be fabricated in full circular cross section except for Type IIIA, which is described in Section 8.4.

7.1.1. Type I pipe shall have annular corrugations with lap joints fastened with rivets or shall have helical corrugations with a continuous lock seam extending from end to end of each length of pipe. The type of fabrication used shall be the option of the fabricator unless otherwise specified.

7.1.2. Type IA pipe shall be fabricated with a smooth liner and helically corrugated shell integrally attached at helical lock seams extending from end to end of each length of pipe. The shell shall have corrugations of nominal 68- or 75-mm pitch.

7.1.3. Type IR pipe shall be fabricated with helical ribs projecting outward with a continuous lock seam extending from end to end of each length of pipe.

7.2. *Corrugations*—The corrugations shall be either annular or helical as provided in Section 7.1. The direction of the crests and valleys of helical corrugations shall not be less than 60 degrees from the axis of the pipe for pipe diameters larger than 500 mm and not less than 45 degrees from the axis for pipe diameters of 500 mm and smaller.

7.2.1. For Type I and IA pipe, corrugations shall form smooth continuous curves and tangents. The dimensions of the corrugations shall be in accordance with Table 3 for the size indicated in the order, except if the depth measurement of one or more corrugations is less than the minimum depth in Table 3, the depth of all corrugations between adjacent seams shall be measured and the values of Table 4 for minimum average depth and minimum corrugation depth shall apply.

Note 3—Inspection frequently consists of measurement of the depth of one or a few corrugations. If such measurement indicates insufficient depth, application of the requirements in Table 4 provides for acceptance where greater depth of some corrugations compensates for lack of depth of others. These measurements would normally be made at one location between seams on a length of pipe.

Table 3—Corrugation Requirements for Types I, IA, II, IIA, and III Pipe

Nominal Size, mm	Max Pitch,[a] mm	Min Depth,[b] mm	Inside Radius[c]	
			Nominal, mm	Min, mm
38 × 6.5[d]	48	6	7	6.5
68 × 13	73	12	17	12
75 × 25	83	24	14	12
125 × 25	135	24	40	36

[a] Pitch is measured from crest to crest of corrugations, at 90 degrees to the direction of the corrugations.

[b] Depth is measured as the vertical distance from a straightedge resting on the corrugation crests parallel to the axis of the pipe to the bottom of the intervening valley. If the depth measurement of one or more corrugations is less than the value indicated herein, the depth of all corrugations between seams shall be measured, and the requirements of Table 2 shall be applied. (See Section 7.2.1.)

[c] Minimum inside radius requirement does not apply to a corrugation containing a helical lock seam.

[d] The corrugation size of 38 × 6.5 mm is available only in helically corrugated pipe.

Table 4—Referee Requirements for Corrugation Depth[a]

Nominal size, mm	Diameter, mm	Min Average Depth, mm	Min Corrugation Depth, mm
38 × 6.5	All	6.1	5.0
68 × 13	300 through 525	12.1	10.0
68 × 13	Greater than 525	12.4	11.0
75 × 25	All	24.9	23.0
25 × 25	All	24.9	23.0

[a] See Section 7.2.1 for application of Table 2.

7.2.2. For Type IR pipe, the corrugations shall be essentially rectangular ribs projecting outward from the pipe wall. The dimensions and spacing of the ribs shall be in accordance with Table 5 for the size indicated on the order. For the 292-mm rib spacing, if the sheet between the ribs does not include a lock seam, a stiffener shall be included midway between the ribs. This stiffener shall have a nominal radius of 6.4 mm and a minimum height of 5.1 mm toward the outside of the pipe.

Note 4—The nominal dimensions and properties for smooth corrugations and for ribs are given in *AASHTO LRFD Bridge Design Specifications* and in ASTM A 796/A 796M.

Table 5—Rib Requirements for Types IR and IIR Pipe

Nominal Size, mm	Rib			Bottom Outside Radius, Min, mm	Bottom Outside Radius,[d] Max Avg, mm	Top Outside Radius, Min, mm	Top Outside Radius,[d] Max Avg, mm
	Width,[a] Min, mm	Depth,[b] Min, mm	Spacing,[c] Max, mm				
19 × 19 × 190	17	19	197	2.5	6.0	$2.5 + t$	$6.0 + t$
19 × 25 × 292	17	24	298	2.5	6.0	$2.5 + t$	$6.0 + t$

[a] Width is a dimension of the inside of the rib, but is measured on the outside of the pipe (outside of the rib) and shall meet or exceed the stated minimum width plus two times the wall thickness, that is, $2t + 17$ mm.

[b] Depth is an average of three ribs (one sheet width) measured from the inside by placing a straightedge across the open rib and measuring to the bottom of the rib.

[c] Spacing is an average of three ribs (one sheet width) measured center-to-center of the ribs at 90 degrees to the direction of the ribs.

[d] The average of the four rib radii (Top and Bottom) shall be within the minimum and maximum tolerances. The outside radius refers to the surface outside of the pipe.

7.3. *Riveted Seams*—The longitudinal seams shall be staggered to the extent that no more than three thicknesses of sheet are fastened by any rivet. Pipe to be reformed into pipe-arch shape shall have seams meeting the longitudinal seam requirement of Section 8.2.2.

Note 5—Fabrication of pipe without longitudinal seams in 120 degrees of arc, so that the pipe may be installed without longitudinal seams in the invert, is subject to negotiation between the purchaser and fabricator.

7.3.1. The size of rivets, number per corrugation, and width of lap at the longitudinal seam shall be as stated in Table 6, depending on sheet thickness, corrugation size, and diameter of pipe. For pipe with 25-mm deep corrugations, M 12 diameter bolts and nuts may be used in lieu of rivets on a one-for-one replacement ratio. Circumferential seams shall be riveted using rivets of the same size as for longitudinal seams and shall have a maximum rivet spacing of 150 mm, measured on centers, except that six rivets will be sufficient in 300-mm diameter pipe.

Table 6—Riveted Longitudinal Seams

Specified Sheet Thickness, mm	Nominal Corrugation Size		
	68 × 13 mm[a,d]	75 × 25 mm[b,e]	125 × 25 mm[c,e]
	Rivet Diameters, Min, mm		
1.32	8.0	—	—
1.63	8.0	9.5	9.5
2.01	8.0	9.5	9.5
2.77	9.5	11.0	11.0
3.51	9.5	11.0	11.0
4.27	9.5	11.0	11.0

[a] One rivet each valley for pipe diameters 900 mm and smaller. Two rivets each valley for pipe diameters 1000 mm and larger.

[b] Two rivets each valley for all pipe diameters.

[c] Two rivets each crest and valley for all pipe diameters.

[d] Minimum width of lap: 38 mm for pipe diameters 900 mm and smaller, and 75 mm for pipe diameters 1050 mm and larger.

[e] Minimum width of lap: 75 mm for pipe of all diameters.

7.3.2. All rivets shall be driven cold in such a manner that the sheets shall be drawn tightly together throughout the entire lap. The center of a rivet shall be no closer than twice its diameter from the edge of the sheet. All rivets shall have neat, workmanlike, and full hemispherical heads or heads of a form acceptable to the purchaser, shall be driven without bending, and shall completely fill the hole.

7.4. *Helical Lock Seams*—The lock seam for Type I pipe shall be formed in the tangent element of the corrugation profile with its center near the neutral axis of the corrugation profile. The lock seam for Type IA pipe shall be in the valley of the corrugation, shall be spaced not more than 760 mm apart, and shall be formed from both the liner and the shell in the same general manner as Type I helical lock seam pipe. The lock seam for Type IR pipe shall be formed in the flat zone of the pipe wall, midway between two ribs.

7.4.1. The edges of the sheets within the cross section of the lock seam shall lap at least 4.0 mm for pipe 250 mm or less in diameter and at least 7.9 mm for pipe greater than 250 mm in diameter, with an occasional tolerance of –10 percent of lap width allowable. The lapped surfaces shall be in tight contact. The profile of the sheet shall include a retaining offset adjacent to the 180-degree fold (as described in T 249) of one sheet thickness on one side of the lock seam, or one-half sheet thickness on both sides of the lock seam, at the fabricator's option. There shall be no visible cracks in the metal, loss of metal-to-metal contact, or excessive angularity on the interior of the 180-degree fold of metal at the completion of forming the lock seam.

7.4.2. Specimens cut from production pipe normal to and across the lock seam shall develop the tensile strength as provided in Table 7, when tested according to T 249. For Type IA pipe, the lock seam strength shall be as tabulated based on the thickness of the corrugated shell.

Table 7—Lock Seam Tensile Strength

Specified Sheet Thickness,[a] mm	Lock Seam Tensile Strength, per Unit Width, Min, kN/m
1.02	30
1.32	42
1.63	60
2.01	91
2.77	122
3.50	154
4.27	210

[a] For Type IA pipe, the thickness shall be that of the corrugated shell.

7.4.3. When the ends of helically corrugated lock seam pipe have been rerolled to form annular corrugations, either with or without a flanged end finish, the lock seam in the rerolled end shall not contain any visible cracks in the base metal and the tensile strength of the lock seam shall be not less than 60 percent of that required in Section 7.4.2.

7.5. *End Finish*:

7.5.1. To facilitate field jointing, the ends of the individual pipe sections with helical corrugations may be rerolled to form annular corrugations extending at least two corrugations from the pipe end, or to form an upturned flange meeting the requirements in Section 7.5.2, or both. The diameter of ends shall not exceed that of the pipe barrel by more than the depth of the corrugation. All types of pipe ends, whether rerolled or not, shall be matched in a joint such that the maximum difference in the diameter of abutting pipe ends is 13 mm.

7.5.1.1. When pipe with any size helical corrugation or rib is rerolled to form annular corrugations in the ends, the usual size of the annular corrugations is 68 by 13 mm.

7.5.2. If a flanged finish is used on the ends of individual pipe sections to facilitate field jointing, the flange shall be uniform in width, not less than 13 mm wide, and square to the longitudinal axis of the pipe.

7.5.3. The ends of all pipe that will form the inlet and outlet of culverts, fabricated of sheets having nominal thicknesses of 2.01 mm and less, shall be reinforced in a manner approved by the purchaser, when specified.

8. PIPE REQUIREMENTS

8.1. *Type I, Type IA, and Type IR Pipe*:

8.1.1. *Pipe Dimensions*—The nominal diameter of the pipe shall be as stated in the order, selected from the sizes listed in Table 8. The size of corrugations, which are standard for each size of pipe, are also shown in Table 8. The average inside diameter of circular pipe and pipe to be reformed into pipe-arches shall not vary more than 1 percent or 13 mm, whichever is greater, from the nominal diameter when measured on the inside crest of the corrugations. Alternately, for pipe having annular corrugations, conformance with the inside diameter requirement may be determined by measuring the outside circumference, for which minimum values are given in Table 8.

Note 6—The outside circumference of helically corrugated pipe is influenced by the corrugation size and the angle of the corrugations, affecting the number of corrugations crossed; therefore, no minimum circumferential measurement can be specified.

Table 8—Pipe Sizes

Nominal Inside Diameter, mm	Corrugation Sizes[a]					Min Outside Circumference,[b] mm
	38 × 6.5 mm	68 × 13 mm	75 × 25 mm	125 × 25 mm	Ribbed Pipe[c]	
100	X					284
150	X					441
200	X					598
250	X					755
300	X	X				912
375	X	X				1148
450	X	X			X	1383
525		X			X	1620
600		X			X	1854
675		X			X	2091
750		X			X	2483
825		X			X	2561
900		X	X	X	X	2797
1050		X	X	X	X	3269
1200		X	X	X	X	3739
1350		X	X	X	X	4209
1500		X	X	X	X	4675
1650		X	X	X	X	5142
1800		X	X	X	X	5609
1950		X	X	X	X	6075
2100		X	X	X	X	6542
2250			X	X	X	7008
2400			X	X	X	7475
2550			X	X	X	7941
2700			X	X	X	8408
2850			X	X		8874
3000			X	X		9341
3150			X	X		9807
3300			X	X		10274
3450			X	X		10740
3600			X	X		11207

[a] An "X" indicates standard corrugation sizes for each nominal diameter of pipe.

[b] Measured in valley of annular corrugations. Not applicable to helically corrugated pipe.

[c] Rib sizes 19 × 19 × 190 mm and 19 × 25 × 292 mm.

8.1.2. *Sheet Thickness*—Sheet thickness shall be specified by the purchaser from the specified sheet thicknesses listed in Table 9 (Notes 7 and 8). For Type IA pipe, the thickness of both the shell and the liner shall be given; the thickness of the corrugated shell shall not be less than 60 percent of the thickness of the equivalent Type I pipe; the liner shall have a nominal thickness of at least 1.02 mm; and the sum of the specified thicknesses of shell and liner shall equal or exceed the specified thickness of an equivalent pipe with corrugations identical to the shell according to the design criteria in *AASHTO LRFD Bridge Design Specifications*.

Note 7—The sheet thicknesses indicated in Table 9 are the thicknesses listed as available in M 246. The specified thickness is based on the thickness of the metallic-coated sheet, not including the thickness of polymer coating.

Note 8—The purchaser should determine the required thickness for each of the types of pipe described in Sections 4.1.1 through 4.1.6, according to the design criteria in *AASHTO LRFD Bridge Design Specifications*, Section 12, or other appropriate guidelines.

Table 9—Thickness of Metallic-Coated Steel Sheet[a]

Specified Thickness		Specification Designation	
mm	ASTM A 929M Zn-5A1 MM, Alloy Coated	M 218, Zinc-Coated	M 289, 55 Aluminum-Zinc Alloy Coated
1.02	X	X	X
1.32	X	X	X
1.63	X	X	X
2.01	X	X	X
2.77	X	X	X
3.51	X	X	X
4.27	X	X	

[a] An "X" indicates sheet thickness included in the applicable specifications which are referenced in M 246. The specified thickness is the thickness of the metallic-coated steel sheet and does not include the thickness of the polymer coating.

8.1.3. When specified by the purchaser, the finished pipe shall be factory elongated to the extent specified. The elongation shall be accomplished by the use of a mechanical apparatus that will produce a uniform deformation throughout the length of the section.

8.2. *Type II, IIA, and IIR Pipe*:

8.2.1. *Pipe-Arch Dimensions*—Pipe furnished as Type II, IIA, or IIR shall be made from Type I, IA, or IR pipe, respectively, and shall be reformed to provide a pipe-arch shape. All applicable requirements for Types I, IA, and IR pipe shall be met by finished Types II, IIA, and IIR pipe, respectively. Pipe-arches shall conform to the dimensional requirements of Tables 10, 11, or 12. All dimensions shall be measured from the inside crests of corrugations for Type II pipe or from the inside liner or surface for Types IIA or IIR pipe, respectively.

Table 10—Pipe Arch Requirements—68 × 13 mm Corrugations

Pipe-Arch Size, mm	Equivalent Dia, mm	Span,[a] mm	Rise,[a] mm	Min Corner Radius, mm	Max B,[b] mm
430 × 330	375	430	330	75	135
530 × 380	450	530	380	75	155
610 × 460	525	610	460	75	185
710 × 510	600	710	510	75	205
780 × 560	675	780	560	75	225
885 × 610	750	870	630	75	240
970 × 690	825	970	690	75	255
1060 × 740	900	1060	740	90	265
1240 × 840	1050	1240	840	100	290
1440 × 970	1200	1440	970	130	345
1620 × 1100	1350	1620	1100	155	380
1800 × 1200	1500	1800	1200	180	420
1950 × 1320	1650	1950	1320	205	460
2100 × 1450	1800	2100	1450	230	510

[a] A tolerance of 25 mm or 2 percent of equivalent diameter, whichever is greater, will be permissible in span and rise.

[b] B is defined as the vertical dimension from a horizontal line across the widest portion of the arch to the lowest portion of the base.

Table 11—Pipe-Arch Requirements—75 × 25 mm Corrugations

Pipe-Arch Size, mm	Equiv Dia, mm	Span,[a] mm	Rise,[a] mm	Min Corner Radius, mm
1010 × 790	900	1010 – 45	790 + 45	130
1160 × 920	1050	1160 – 55	920 + 55	155
1340 × 1050	1200	1340 – 60	1050 + 60	180
1520 × 1170	1350	1520 – 70	1170 + 70	205
1670 × 1300	1500	1670 – 75	1300 + 75	230
1850 × 1400	1650	1850 – 85	1400 + 85	305
2050 × 1500	1800	2050 – 95	1500 + 95	355
2200 × 1620	1950	2200 – 110	1620 + 110	355
2400 × 1720	2100	2400 – 120	1720 + 120	410
2600 × 1820	2250	2600 – 130	1820 + 130	410
2840 × 1920	2400	2840 – 145	1920 + 145	460
2970 × 2020	2550	2970 – 150	2020 + 150	460
3240 × 2120	2700	3240 – 165	2120 + 165	460
3470 × 2220	2850	3470 – 175	2220 + 175	460
3600 × 2320	3000	3600 – 180	2320 + 180	460

[a] Negative and positive numbers listed with span and rise dimensions are negative and positive tolerances, no tolerance in opposite direction.

Table 12—Pipe-Arch Requirements—19 × 19 mm and 19 × 25 × 292 mm Rib Corrugations

Pipe-Arch Size, mm	Equiv Dia, mm	Span,*a* mm	Rise,[a] mm	Min Corner Radius, mm
500 × 400	450	500 – 25	410 + 25	130
580 × 490	525	580 – 25	490 + 25	130
680 × 540	600	680 – 40	540 + 40	130
750 × 620	675	750 – 40	620 + 40	130
830 × 670	750	830 – 40	670 + 40	130
900 × 750	825	900 – 45	750 + 45	130
1010 × 790	900	1010 – 45	790 + 45	130
1160 × 920	1050	1160 – 55	920 + 55	155
1340 × 1050	1200	1340 – 60	1050 + 60	180
1520 × 1170	1350	1520 – 70	1170 + 70	205
1670 × 1300	1500	1670 – 75	1300 + 75	230
1850 × 1400	1650	1850 – 85	1400 + 85	305
2050 × 1500	1800	2050 – 95	1500 + 95	355

[a] Negative and positive numbers listed with span and rise dimensions are negative and positive tolerances, no tolerance in opposite direction.

8.2.2. *Longitudinal Seams*—Longitudinal seams of riveted pipe arches shall not be placed in the corner radius.

8.2.3. Reforming Type IR into Type IIR pipe shall be done in a manner that avoids damage to the external ribs.

8.3. *Type III Pipe*:

8.3.1. Type III pipe shall have a full circular cross section and shall conform to the requirements for Type I pipe and, in addition, shall contain perforations conforming to one of the classes described in Section 8.3.2.

8.3.2. *Perforations*—The perforations shall conform to the requirements for Class 1, unless otherwise specified in the order. Class 1 perforations are for pipe intended to be used for subsurface drainage. Class 2 perforations are for pipe intended to be used for subsurface disposal of water, but pipe containing Class 2 perforations may also be used for subsurface drainage.

8.3.2.1. *Class 1 Perforations*—The perforations shall be approximately circular and cleanly cut; shall have nominal diameters of not less than 4.8 mm nor greater than 9.5 mm, and shall be arranged in rows parallel to the axis of the pipe. The perforations shall be located on the inside crests or along the neutral axis of the corrugations, with one perforation in each row for each corrugation. Pipe connected by couplings or bands may be unperforated within 100 mm of each end of each length of pipe. The rows of perforations shall be arranged in two equal groups placed symmetrically on either side of a lower unperforated segment corresponding to the flow line of the pipe. The spacing of the rows shall be uniform. The distance between the centerlines of rows shall be not less than 25 mm. The minimum number of longitudinal rows of perforations, the maximum heights of the centerlines of the uppermost rows above the bottom of the invert, and the inside chord lengths of the unperforated segments illustrated in Figure 1 shall be as specified in Table 13.

Note 9—Pipe with Class 1 perforations is generally available in diameters from 100 to 525 mm inclusive, although perforated pipe in larger sizes may be obtained.

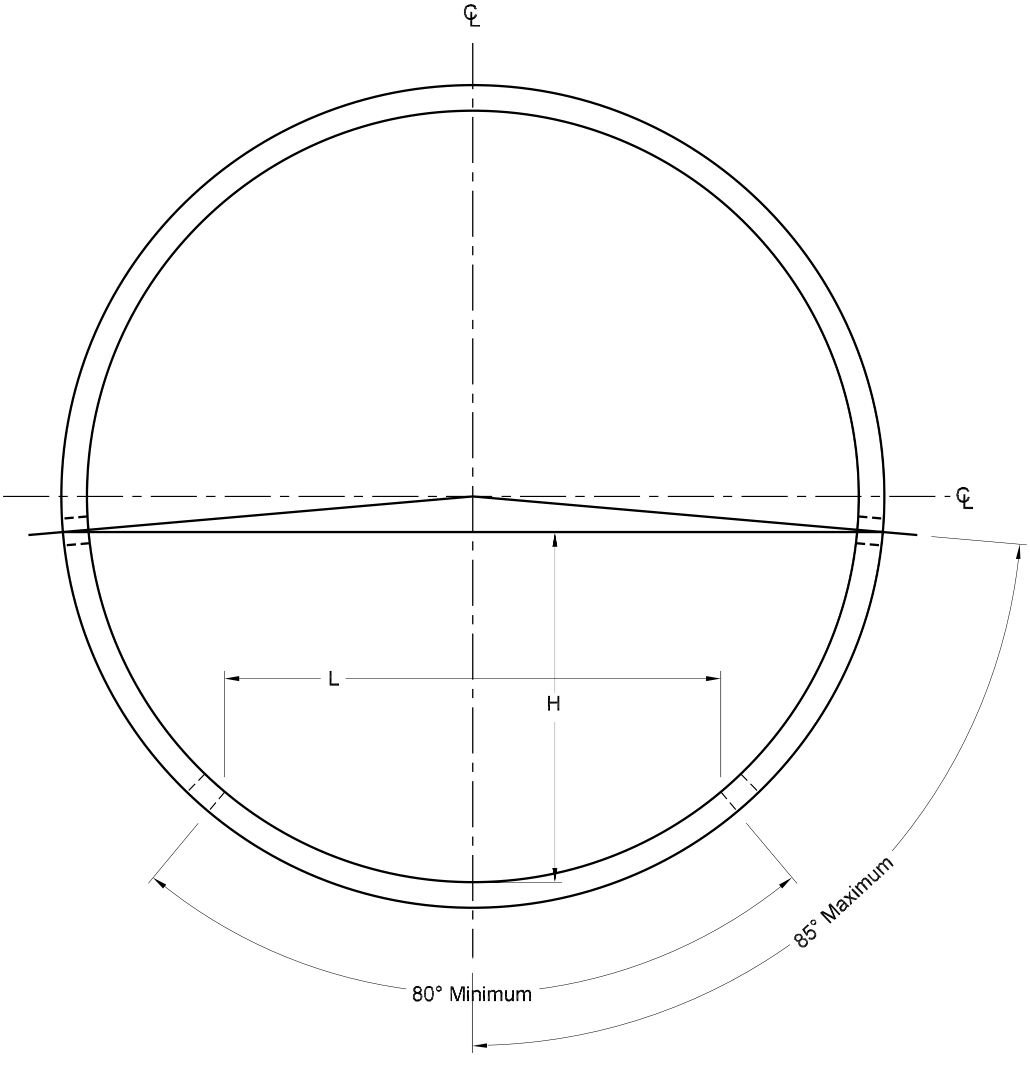

Figure 1—Requirements for Perforations

Table 13—Rows of Perforations, Height *H* of the Centerline of the Uppermost Rows above the Invert, and Chord Length *L* of the Unperforated Segment, for Class 1 Perforations

Internal Diameter of Pipe, mm	Rows of Perforations[a]	*H*, Max,[b] mm	*L*, Min,[b] mm
100	2	46	64
150	4	69	96
200	4	92	128
250	4	115	160
300	6[c]	138	192
375	6[c]	172	240
450	6[c]	207	288
525	6	241	338
600 and larger	8	(d)	(d)

[a] Minimum number of rows. A greater number of rows for increased inlet area shall be subject to agreement between purchaser and fabricator. Note that the number of perforations per unit length in each row (and inlet area) is dependent on the corrugation pitch.

[b] See Figure 1 for location of dimensions *H* and *L*.

[c] Minimum of four rows permitted in pipe with 38 × 6.5 mm corrugations.

[d] H(max) = 0.46D; L(min) = 0.64D, where D = internal diameter of pipe, millimeters or inches, as appropriate.

8.3.2.2. *Class 2 Perforations*—The perforations shall be circular holes with nominal diameters of 8.0 to 9.5 mm or slots with nominal width of 4.8 to 8.0 mm and not to exceed 13 mm in length. The perforations shall be uniformly spaced around the full periphery of the pipe. The perforations shall provide an opening area of not less than 230 square centimeters per square meter of pipe surface based on nominal diameter and length of pipe.

Note 10—323 perforations, 9.5-mm diameter, per square meter satisfies this requirement.

8.4. *Type IIIA Pipe*:

8.4.1. Type IIIA pipe shall be fabricated of an unperforated semicircular bottom section with a top shield of corrugated steel, both of nominal 1.32-mm thickness or greater. The smooth semicircular bottom section shall be approximately 120 mm in diameter and shall have a continuous lip extending outward along each side; the corrugated top shield shall be approximately 160 mm wide including a 19 mm sloping overhang on each side and shall be secured to the lip of the bottom section by integral tabs spaced at about 90 mm center-to-center. The top shield shall have corrugations approximately 22 mm center-to-center and approximately 8.0-mm depth.

9. COUPLING BANDS

9.1. *Types of Coupling Bands*—Field joints for each type of corrugated steel pipe shall maintain pipe alignment during construction and prevent infiltration of fill material during the life of the installation. Coupling bands may be of the following types:

9.1.1. *Coupling bands may be of the following types*:

9.1.1.1. Bands with annular corrugations;

9.1.1.2. Bands with helical corrugations;

9.1.1.3. Bands with projections (dimples);

9.1.1.4. Channel bands for upturned flanges, with or without annular corrugations;

9.1.1.5. Flat bands; and

9.1.1.6. Smooth sleeve-type couplers.

9.1.2. Except as provided in Sections 9.1.1 through 9.1.4, the type of coupling furnished shall be at the option of the fabricator unless the type is specified in the order.

Note 11—Bands are classified according to their ability to resist shear, moment, and tensile forces as described in *AASHTO LRFD Bridge Construction Specifications*, Section 26, and identified as "standard joints" and "special joints." The first four types of bands listed in Section 9.1, and meeting the requirements of Section 9.2, are expected to meet the requirements for "standard joints." Some may also be able to meet the requirements for "special joints," but such capability should be determined by analysis or test.

9.1.3. Coupling bands with annular corrugations shall be used only with pipe with annular corrugations, or helical pipe in which the ends have been rerolled to form annular corrugations. The corrugations in the band shall have the same dimensions as the corrugations in the pipe end, or may be of a special design to engage only the first or second corrugation from the end of each pipe. The band may also include a U-shaped channel to accommodate upturned flanges on the pipe.

9.1.4. Coupling bands with helical corrugations shall be used only with pipe with helically corrugated ends. The corrugations in the bands shall be designed to properly mesh with the corrugations in the pipe.

9.1.5. Coupling bands with projections (dimples) may be used with pipe with either annular or helical corrugations. The bands shall be formed with the projections in annular rows with one projection for each corrugation of helical pipe. Bands 265 or 300 mm wide shall have two annular rows of projections, and bands 415 or 560 mm wide shall have four annular rows of projections.

9.1.6. Channel bands may be used only with pipe having upturned flanges on the pipe ends.

9.1.7. Smooth sleeve-type couplers and flat bands may be used only with Type III and IIIA pipe of 300-mm diameter or smaller.

9.2. *Requirements*—Coupling bands shall be fabricated to lap on an equal portion of each of the pipe sections to be connected. The ends of the bands shall lap or be fabricated to form a tightly closed joint upon installation. Coupling band thickness shall conform to the requirements in Table 14, based on the sheet thickness of the pipe to be connected except as provided in Sections 9.2.1 and 9.2.2. The bandwidth shall be not less than as shown in Table 15. The bands shall be connected in a manner approved by the purchaser with suitable galvanized devices, such as angles or integrally or separately formed and attached flanges, bolted with zinc-coated bolts; bars and straps; wedge lock and straps; or lugs. Coupling bands shall be fastened with the following size of bolts:

- Pipe diameters 450 mm and less—M10 diameter;
- Pipe diameters 525 mm and greater—M12 diameter;
- Type IIIA pipe—M8 diameter.

Table 14—Coupling Band Thickness

Nominal Pipe Thickness, mm	Nominal Coupling Band Thickness, Min, mm
2.77 and thinner	1.32
3.51	1.63
4.27	2.01

Table 15—Coupling Bandwidth Requirements

		Coupling Bandwidth, Min		
Nominal Corrugation Size,[a] mm	Nominal Pipe Inside Diameter,[b] mm	Annular Corrugated Bands, mm	Helically Corrugated Bands, mm	Bands with Projections, mm
38 × 6.5	100 to 450	285	180	285
68 × 13	300 to 900	180	300	285
	1050 to 1800	285	300	285
	1950 to 2100[c]	285	300	415
75 × 25	900 to 1800	300	350	285
	1950 to 3600	300	350	415
125 × 25	900 to 1800	500	560	300
	1950 to 3600	500	560	560

[a] For helically corrugated pipe with rerolled ends, the nominal corrugation size refers to the dimensions of the end corrugations in the pipe.

[b] Equivalent diameter for Type II, IIA, and IIR pipe.

[c] Diameters through 3600 mm for annular corrugated bands used on rerolled ends of helically corrugated pipe.

9.2.1. If flanges are provided on the pipe ends, the coupling may also be made by interlocking the flanges with a preformed channel band or other band incorporating a locking channel not less than 19 mm in width. The depth of the channel shall be not less than 13 mm. The channel band shall have a minimum nominal thickness of 2.01 mm.

9.2.2. Smooth sleeve-type couplings and flat bands shall be steel having a nominal thickness of not less than 1.02 mm or, as an option, may be a plastic sleeve to provide equivalent strength. The coupling shall be close-fitting to hold the pipe firmly in alignment without the use of sealing compounds or gaskets. The coupling or flat band shall contain a device so that the band or coupling will lap equally on the two pipes being joined. The overall length of the coupling shall be equal to or greater than the nominal diameter of the pipe.

9.3. *Gaskets*—Where infiltration or exfiltration is a concern, the couplings may be required to have gaskets. The closed-cell expanded rubber gaskets shall be a continuous band, approximately 180 mm wide and approximately 9.5 mm thick. Rubber O-ring gaskets shall be 20-mm diameter for pipe diameters of 900 mm or smaller, and 22-mm diameter for larger pipe diameters, having 13-mm deep end corrugations. Rubber O-ring gaskets shall be 35-mm diameter for pipe having 25-mm deep end corrugations.

Note 12—Riveted pipe is not watertight, having small openings at the intersection of longitudinal and circumferential seams. Therefore, this type of fabrication should not be used where watertightness is a concern unless the pipe is bituminous coated or lined prior to installation.

9.4. Other types of coupling bands or fastening devices, which are as equally effective as those described, and which comply with the joint performance criteria of *AASHTO LRFD Bridge Construction Specifications*, Section 26 may be used when approved by the purchaser.

10. WORKMANSHIP

10.1. The completed pipe shall show careful, finished workmanship in all particulars. Pipe that has been damaged, either during fabrication or in shipping, may be rejected unless repairs are made that are satisfactory to the purchaser. Among others, the following defects shall be considered as constituting poor workmanship:

- Variation from a straight centerline;
- Elliptical shape in pipe intended to be round;
- Dents or bends in the metal;
- Polymer coating or metallic coating that has been bruised, broken, disbonded, or otherwise damaged;
- Lack of rigidity;
- Illegible markings on the steel sheet;
- Ragged or diagonal sheared edges;
- Uneven laps in riveted pipe;
- Loose, unevenly lined, or unevenly spaced rivets;
- Loosely formed lock seams.

11. REPAIR OF DAMAGED COATINGS

11.1. Pipe on which either the polymer coating or the underlying metallic coating has been damaged in fabrication or handling shall be repaired. Damage to the metallic coating shall be repaired as described in Sections 11.2 through 11.4. Damage to the polymer coating shall be repaired as described in Section 11.5. The repair shall be done so that the completed pipe shall show careful finished workmanship in all particulars. Pipe which, in the opinion of the purchaser, has not been cleaned or coated satisfactorily may be rejected. If the purchaser so elects, the repair shall be done in his presence.

11.2. Damage to the metallic coating shall be repaired as provided in ASTM A 780 (Note 13) except as described herein. The damaged area shall be cleaned to bright metal by blast cleaning, power disk sanding, or wire brushing. The cleaned area shall extend at least 13 mm into the undamaged section of the coating. The cleaned area shall be coated within 24 hours and before any rusting or soiling.

Note 13—While ASTM A 780 specifically refers to repair of damaged zinc coatings, the same procedures are applicable to repair of aluminum-zinc alloy coatings except as described in this section.

11.3. *Zinc-Rich Paint Coating*—Zinc-rich paint shall be applied to a dry film thickness of at least 0.13 mm over the damaged section and surrounding cleaned area. Zinc-rich paint shall be used for repair of damage to both zinc and aluminum-zinc alloy coatings.

11.4. *Metallizing Coating*—The damaged area shall be cleaned as described in Section 11.2, except it shall be cleaned to the near-white condition. The repair coating applied to the cleaned section shall have a thickness of not less than 0.13 mm over the damaged section and shall taper off to zero thickness at the edges of the cleaned undamaged section.

11.4.1. Where zinc coating is to be metallized, it shall be done with zinc wire containing not less than 99.98 percent zinc.

11.4.2. Where aluminum-zinc alloy coating is to be metallized, it shall be done using zinc wire containing not less than 99.98 percent zinc, aluminum wire containing not less than 99 percent aluminum, or an alloy wire of 55 percent aluminum and 45 percent zinc by mass.

11.5. Areas of damaged polymer coating shall be repaired with a polymer coating similar to and compatible with respect to durability, adhesion, and appearance of the original polymer coating.

11.5.1. Polymer coating damaged during shipping or installation may be repaired using materials as described in Section 11.5 or by the application of a protective coating material conforming to M 243.

12. INSPECTION

12.1. The purchaser or his representative shall have free access to the fabricating plant for inspection, and every facility shall be extended to him for this purpose. This inspection shall include an examination of the pipe for the items in Section 10.1 and the specific requirements of this specification applicable to the type of pipe and method of fabrication.

12.2. On a random basis, samples may be taken for chemical analysis and metallic and polymer coating measurements for check purposes. These samples will be secured from fabricated pipe or from sheets or coils of the material used in fabrication of the pipe. The mass of metallic coating shall be determined in accordance with T 65M/T 65 for zinc and the dilute hydrochloric acid method of T 65M/T 65 for aluminum-zinc alloy. The thickness of polymer coating shall be measured according to ASTM D 1005.

13. REJECTION

13.1. Pipe that fails to conform to the specific requirements of this specification, or that shows poor workmanship, may be rejected. This requirement applies not only to the individual pipe, but to any shipment as a whole in which a substantial number of pipes are defective. If the average deficiency in length of any shipment of pipe is greater than 1 percent, the shipment may be rejected.

14. CERTIFICATION

14.1. When specified in the purchase order or contract, a manufacturer’s or fabricator’s certification, or both, shall be furnished to the purchaser stating that samples representing each lot have been tested and inspected in accordance with this specification and have been found to meet the requirements for the material described in the order. When specified in the order, a report of the test results shall be furnished.

Standard Specification for

Steel Sheet, Metallic-Coated and Polymer-Precoated, for Corrugated Steel Pipe

AASHTO Designation: M 246-05
ASTM Designation: A 742/A 742M-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Sheet, Metallic-Coated and Polymer-Precoated, for Corrugated Steel Pipe

AASHTO Designation: M 246-05
ASTM Designation: A 742/A 742M-03

1. SCOPE

1.1. This specification covers polymer-precoated steel sheet for corrugated steel pipe (CSP), which is coated after metallic coating on continuous lines by coil coating (roller coating or laminating) processes. The metallic coating is either zinc or aluminum-zinc alloy. Sheet for this purpose is furnished flat in coils, flat in cut lengths, or corrugated in cut lengths, all being protected by a mill-applied polymer coating on one or both sides.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 218, Steel Sheet, Zinc-Coated (Galvanized), for Corrugated Steel Pipe
- M 289, Aluminum-Zinc Alloy Coated Sheet Steel for Corrugated Steel Pipe

2.2. *ASTM Standards*:

- A 916M, Zinc-5 Percent Aluminum-MM Alloy Coated Steel Pipe
- D 543, Standard Practices for Evaluating the Resistance of Plastics to Chemical Reagents
- D 658, Standard Test Method for Abrasion Resistance of Organic Coatings by Air Blast Abrasive (Withdrawn 1996)
- D 1005, Standard Test Method for Measurement by Dry Film Thickness of Organic Coatings Using Micrometers
- D 2794, Standard Test Method for Resistance of Organic Coatings to the Effects of Rapid Deformation (Impact)
- G 22, Standard Practice for Determining Resistance of Plastics to Bacteria (Withdrawn 2001)
- G 23, Practice for Operating Light-Exposure Apparatus (Carbon-Arc Type) With and Without Water for Exposure of Nonmetallic Materials (Withdrawn 2000)
- G 62, Standard Test Methods for Holiday Detection in Pipeline Coatings

3. CLASSIFICATION

3.1. The polymer coating is classified by grade corresponding to the thickness micrometers on each side in SI units, and the thickness in mils on each side in inch-pound units. (See Table 1.)

Table 1—Polymer Coating

Grade	Coating Thickness, μm
250/250	250/250

3.2. Any combination of polymer coating thickness other than shown in Table 1 is subject to agreement between the manufacturer and purchaser or fabricator.

4. TERMINOLOGY

4.1. In this specification, *manufacturer* refers to the producer of the sheet, *fabricator* refers to the producer of the pipe, and *purchaser* refers to the purchaser of the finished pipe.

5. ORDERING INFORMATION

5.1. The polymer-precoated sheet covered by this specification shall be ordered only to the specified thicknesses listed in Table 2. The specified thickness is based on the thickness of the metallic-coated steel sheet, not including the thickness of the polymer coating.

Table 2—Thicknesses of Metallic-Coated Steel Plate

Specified Thickness		Specification Designation		
mm	in.	M 218, Zinc-Coated	M 289, 55% Aluminum-Zinc Alloy Coated	A 916M, Zn-5 Al-MM Alloy Coated
1.02	0.040	X	X	X
1.32	0.052	X	X	X
1.63	0.064	X	X	X
2.01	0.079	X	X	X
2.77	0.109	X	X	X
3.51	0.138	X	X	X
4.27	0.168	X		X

Note: An "X" indicates sheet thickness included in the applicable specification.

5.2. Orders for material to this specification shall include the following information, as necessary, to adequately describe the desired product:

5.2.1. Name of material (polymer-precoated steel sheet for CSP);

5.2.2. Type of metallic coating (Section 6.1);

5.2.3. AASHTO designation number and date of issue;

5.2.4. Corrugation size, if corrugated (Section 6.3);

5.2.5. Substrate dimensions (specified thickness; width, either flat or overall corrugated; and length, if cut length);

5.2.6. Grade of polymer coating (Section 3) indicating thickness on each side;

5.2.7. Coil size requirements (specify maximum outside diameter (OD), acceptable inside diameter (ID), and maximum mass);

5.2.8. Certification, if required (Section 11.1); and

5.2.9. Special requirements.

Note 1—Typical ordering descriptions are as follows: Polymer-precoated steel sheet, aluminum-zinc alloy coated for CSP, conforming to M 246-____, 2.77 by 700 mm by coil, with Grade 250 polymer coating (0.25 mm); coil 1200 mm max OD, 600 mm ID, 10000 kg max coil mass. [Polymer-precoated steel sheet, zinc-coated for CSP, conforming to M 246-____.]

6. GENERAL REQUIREMENTS

6.1. The metallic-coated steel substrate shall conform to all applicable requirements of the specification listed below for the kind of metallic coating specified. If the type of metallic coating is not stated in the order, zinc-coated sheet as described in Section 6.1.1 shall be furnished.

6.1.1. *Zinc Coating*—Zinc-coated steel sheet shall conform to the requirements of M 218.

6.1.2. *Aluminum-Zinc Alloy Coating 55*—Aluminum-zinc alloy coated steel sheet shall conform to the requirements of M 289 and zinc-5 aluminum-MM alloy coated steel sheets shall conform to the requirements of ASTM A 916M.

6.1.3. The steel sheet shall be thoroughly cleaned of any chromate pretreatment or other passivation using a multi-brush cleaning process. All traces of the caustic cleaning solution shall be immediately rinsed from the sheet following caustic cleaning. After drying, the steel sheet shall be treated with chromic acid solution and heat-cured prior to application of the polymer film. The deposited chromium content shall range from 135 to 190 mg/m^2.

6.2. The polymer coating shall be a film coating composed of at least 85 percent ethylene acrylic acid copolymer and be capable of being applied to the sheet specified in Section 6.1. After application, the polymer coating shall be free of holes, tears, and discontinuities, and shall be sufficiently flexible so that it will withstand the corrugating, forming, and lock-seaming operations, and punching of holes for rivets or perforations.

6.3. If the polymer-coated sheet is to be furnished with corrugations, the corrugations shall conform to the requirements stated in the appropriate specification listed in Section 6.1.

7. REQUIREMENTS FOR POLYMER COATINGS

7.1. *Adhesion*—There shall be no spalling or cracking of the coating when tested in accordance with Section 9.1. There shall be no disbonding of the coating at the cut to be made as described in Section 9.1.

7.2. *Impact*—There shall be no break in the polymer coating when tested in accordance with Section 9.2.

7.3. *Thickness of Coating*—The thickness of the polymer coating shall meet the requirements of Section 3, or as specified in the purchase order, when tested in accordance with Section 9.3.

7.4. *Holidays*—The polymer coating on the steel shall be substantially free of holidays when tested in accordance with Section 9.4. An average of 22 holidays per square meter of actual surface area on the test specimen shall be permitted.

Note 2—Holidays are pinholes or voids in the polymer coating that are not visually discernible.

7.5. *Abrasion Resistance*—The average abrasion coefficient, when tested in accordance with Section 9.5, shall be a minimum of 3.9 (expressed in g/μm of thickness).

7.6. *Imperviousness*—There shall be no loosening or separation of the polymer coating from the metallic-coated steel substrate when tested in accordance with Section 9.6.

7.7. *Freeze–Thaw Resistance*—The specimen shall withstand 100 freeze–thaw cycles, as described in Section 9.7, without spalling, disbonding, or other detrimental effects.

7.8. *Weatherability*—The specimens shall withstand 1000 hours of weathering with no observable delamination or cracking, when tested in accordance with Section 9.8.

7.9. *Resistance to Microbial Attack*—There shall be no effect of microbial attack of the polymer coating when tested in accordance with Section 9.9.

Note 3—Tests 7.1 through 7.4 are suggested as quality control tests. When these tests are used for quality control, they may be run at room temperature only. Tests 7.5 through 7.9 are suggested as qualifying tests. However, the purchaser may use any of the tests listed to verify compliance.

8. SAMPLING AND TESTING

8.1. The manufacturer shall make tests and measurements adequate to ensure that the material produced complies with this specification.

8.1.1. Test results to show compliance with this specification shall be retained by the manufacturer for 7 years and shall be made available to the fabricator and purchaser upon request.

8.2. The purchaser of the sheet (fabricator), or purchaser of the pipe made from the sheet, may make such tests as are deemed necessary to determine the acceptability of the material or to verify the correctness of a certification.

8.3. Flat samples of polymer-precoated steel shall be taken by the manufacturer from each coil or in accordance with the sampling procedure as mutually agreed between manufacturer and purchaser. Each sample shall be at least 600 mm long by the coil width and shall carry an identification to relate it to the coil from which it was taken.

9. TEST METHODS FOR POLYMER COATINGS

9.1. *Adhesion*:

9.1.1. *Scope*—This procedure is to measure the adhesion of the polymer coating to the metallic-coated substrate.

9.1.2. *Significance and Use*—This test indicates the ability of the polymer to withstand forces in fabrication and use tending to disbond the coating from the substrate.

9.1.3. *Procedure*—Cut a 50 by 200 mm coupon from the sample of precoated steel. Bend the coupon 180 degrees over a 12.5-mm diameter mandrel. The surface with the polymer coating to be tested shall be on the outside of the bend. After making the bend, make a cut through the polymer coating along an element on the outside of the bend to check for polymer coating adhesion. Perform this test at –18ºC, 25ºC, and 50ºC ± 1ºC. Check for spalling or cracking of the polymer coating, or for disbonding from the metallic-coated substrate.

9.1.4. *Precision and Bias*—No statement is made about either the precision or the bias of the procedure for measuring adhesion since the result merely states whether there is conformance to the criteria for success specified in the procedure.

9.2. *Impact*:

9.2.1. *Scope*—This procedure is to measure the ability of the polymer coating to withstand impact.

9.2.2. *Significance and Use*—This test provides a measure of the ability of the polymer coating to resist damage by impact, to which it may be subjected in service, in order to determine brittleness of the polymer coating.

9.2.3. *Procedure*—Cut a 150 by 150 mm coupon from the sample of precoated steel to be used for fabrication of the pipe. Direct impact the coating with an energy of 4.0 J using an impact tester[1] with a 15.88-mm diameter punch and with the specimen set on a 16.26-mm diameter punch die. Test at approximately 25ºC (Note 4). Check for breaks in the polymer coating.

Note 4—This test procedure is described in detail in ASTM D 2794.

9.2.4. *Precision and Bias*—No statement is made about either the precision or the bias of the procedure for measuring impact resistance since the result merely states whether there is conformance to the criteria for success specified in the procedure.

9.3. *Thickness of Coating*—Measure polymer coating thickness in accordance with ASTM D 1005.

9.4. *Holidays*—Test a specimen that is at least 300 mm long and the full coil width in accordance with ASTM G 62, Method A, using a nominal voltage of 67.5 volts.

9.5. *Abrasion Resistance*—Determine the abrasion coefficient in accordance with ASTM D 658 except use a silicon carbide grain passing a 106-µm sieve and retained on a 90-µm sieve, and an air test pressure of 33.25 kPa (250 mm Hg).

9.5.1. The modifications to the procedure in ASTM D 658 are not expected to have an effect on the precision and bias as indicated in ASTM D 658.

9.6. *Imperviousness*—Test the polymer coating for imperviousness to chemical reagents in accordance with the applicable sections of ASTM D 543 using a 10 percent solution of sodium chloride, a 10 percent solution of sodium hydroxide, and a 30 percent solution of sulfuric acid. Hold each reagent in a separate confined area of the polymer-precoated sheet for a period of 48 hours. Avoid excessive evaporation of the test solutions.

9.7. *Freeze–Thaw Resistance*:

9.7.1. *Scope*—This procedure is to evaluate the ability of the polymer coating to resist freeze–thaw cycling.

9.7.2. *Significance and Use*—As pipe fabricated from polymer-coated steel sheet will be exposed to freeze-thaw action while saturated, the procedure will measure ability to withstand such action without damage to the polymer coating.

9.7.3. *Procedure*—Cut a minimum of three 150 by 150 mm coupons from the sample of precoated metal. Immerse the coupons in water at room temperature for 2 weeks and then subject them to freeze–thaw cycling. One (1) cycle shall consist of 8 hours at –18ºC followed immediately by immersion in water at room temperature for 16 hours. Cycle time may be interrupted over weekends and holidays, but the specimens shall be maintained in water at room temperature, and such interruptions should be noted. Make observations during the cycling and note any visible changes in the coating, such as spalling, disbonding, etc. After 100 cycles, make a final examination of the effects as a result of freezing and thawing.

9.7.4. *Precision and Bias*—No statement is made about either the precision or the bias of the procedure for measuring freeze–thaw resistance since the result merely states whether there is conformance to the criteria for success specified in the procedure.

9.8. *Weatherability*—Subject coupons of the precoated metal to accelerated weathering in accordance with ASTM G 23 using the specimen spray arrangement for Type E, Single Open-Flame Sunshine Carbon-Arc Lamp Apparatus. Test conditions shall consist of a 2-hour cycle including 18 minutes of water spray and a maximum temperature of 60ºC.

9.9. *Resistance to Microbial Attack*—Subject test specimens of the polymer coating to conditions described in ASTM G 22, Procedure B. There shall be no visible effects of bacterial attack on the polymer coating after the prescribed incubation period (21 days minimum).

10. REJECTION

10.1. Material tested by the purchaser and found not conforming to this specification may be rejected.

11. CERTIFICATION

11.1. When specified in the purchase order or contract, a manufacturer's certification shall be furnished to the purchaser of the sheet (fabricator) or to the purchaser of the finished pipe stating that samples representing each lot have been tested and inspected in accordance with this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished. The results of tests suggested in Section 7 as qualifying tests may be typical results rather than results of tests on the specific lot of material.

12. MARKING

12.1. Each 0.6 to 1.5 m of sheet in coils or cut lengths shall be identified by marking as follows:

12.1.1. Name of sheet producer,

12.1.2. Brand name,

12.1.3. Specified thickness of metallic-coated sheet,

12.1.4. Type of metallic coating,

12.1.5. Type or thickness of polymer coating,

12.1.6. Identification symbols relating to a specific heat number and coating lot number, and

12.1.7. AASHTO designation number.

12.2. The brand shall be removed, obliterated, or the sheet rebranded "Non-Specification" on each 0.6 to 1.5 m of material in a coating lot or heat for which control tests, as prescribed herein, show nonconformance to this specification, or where the metallic-coated steel substrate shows nonconformance to the appropriate sheet specification.

COMMENTARY (NOT PART OF THE SPECIFICATION)

C1. PRINCIPAL CHANGES IN THIS REVISION RECORDED FOR THE CONVENIENCE OF THE USER

C1.1. Aluminum-coated steel sheet has been deleted as an acceptable material since it is not produced with polymer coating.

C1.2. The classification, based on polymer coating thickness, has been changed from arbitrary Types A, B, and C to Grades with the numbers expressing the polymer thickness (Section 3).

C1.3. The polymer coating thickness requirement has been clarified (Section 7.3).

C1.4. Test methods contained in the specification have been revised to add scope, significance and use, and precision statements as required by ASTM (Sections 9.1, 9.2, 9.7). Clarifying details have been added in Sections 9.4 and 9.8.

C1.5. The certification provisions have been revised in accordance with the Form and Style for ASTM Standards.

---

[1] The Gardner-Impact Tester, Variable, Model IG 1120, available from Pacific Scientific Company, Gardner/Neotec Instrument Division, 2431 Linden Lane, Silver Spring, MD 20910, has been found suitable for this purpose.

Standard Specification for

Corrugated Polyethylene Drainage Pipe

AASHTO Designation: M 252-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Corrugated Polyethylene Drainage Pipe

AASHTO Designation: M 252-09

1. SCOPE

1.1. This specification covers the requirements and methods of test for corrugated polyethylene (PE) pipe, couplings and fittings for use in subsurface drainage systems, storm sewers, and in surface drainage (culverts), where soil support is given to the pipe's flexible walls in all applications.

1.1.1. Nominal sizes of 75 to 250 mm (3 to 10 in.) are included.

1.1.2. Materials, dimensions, pipe stiffness, environmental stress-crack resistance, perforations, joining systems, and forms of marking are specified.

Note 1—When PE pipe is to be used in locations where the ends may be exposed, consideration should be given to combustibility of the PE and the deteriorating effects of prolonged exposure to ultraviolet radiation.

1.2. *Units*—The values stated in SI units are to be regarded as standard. Within the text, the U.S. customary units are shown in parentheses, and may not be exact equivalents.

1.3. The following precautionary caveat pertains only to the test method portion, Section 9.3 of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

---

3. TERMINOLOGY

3.1. The terminology used in this standard is in accordance with the definitions given in ASTM D 883 and ASTM F 412 unless otherwise specified.

3.2. *crack*—Any break or split that extends through the wall.

3.3. *crease*—An irrecoverable indentation; generally associated with wall buckling.

3.4. *reworked material*—A plastic from a processor's own production that has been reground, pelletized, or solvated after having been previously processed by molding, extrusion, etc. (ASTM D 883).

4. CLASSIFICATION

4.1. The corrugated PE pipe covered by this specification is classified as follows:

4.1.1. *Type C*—This pipe shall have a full circular cross section, with a corrugated surface both inside and outside. Corrugations may be either annular or helical.

4.1.1.1. *Type CP*—This pipe shall be Type C with Class 2 perforations.

4.1.2. *Type S*—This pipe shall have a full circular cross section, with an outer corrugated pipe wall and a smooth inner liner. Corrugations may be either annular or helical. Type S pipe is not available in nominal sizes of less than 100 mm (4 in.).

4.1.2.1. *Type SP*—This pipe shall be Type S with either Class 1 or Class 2 perforations.

4.2. Class 1 and Class 2 perforations are as described in Sections 7.4.1 and 7.4.2.

5. ORDERING INFORMATION

5.1. Orders using this specification shall include the following information as necessary to adequately describe the desired product:

5.1.1. AASHTO designation and year of issue;

5.1.2. Type of pipe (Section 4.1);

5.1.3. Diameter and length required, either total length or length of each piece and number of pieces;

Note 2—Type C and CP pipe less than 200 mm (8 in.) in diameter may be supplied coiled; coiling of Type C and CP pipe 200 mm (8 in.) or greater is not recommended; Type S and SP pipe is not supplied in coils.

5.1.4. Number of couplings;

5.1.5. For Type SP pipe, class of perforations (Class 2 is furnished if not specified) (Section 7.4); and

5.1.6. Certification, if desired (Section 12.1).

6. MATERIALS

6.1. *Basic Materials*:

6.1.1. *Extruded Pipe and Blow Molded Fittings*—Pipe and fittings shall be made of virgin PE resin compounds meeting the requirements of ASTM D 3350 and cell classification 424420C, except that the carbon black content shall not exceed 5 percent. Resins that have higher cell classifications in one or more properties are acceptable provided product requirements are met.

6.1.2. *Rotational Molded Fittings and Couplings*—Fittings and couplings shall be made of virgin PE resins meeting the requirements of ASTM D 3350 and cell classification 213320C, except that the carbon black content shall not exceed 5 percent. Resins that have higher cell classifications in one or more properties are acceptable provided product requirements are met.

6.1.3. *Injection Molded Fittings and Couplings*—Fittings and couplings shall be made of virgin PE resins meeting the requirements of ASTM D 3350 and cell classification 314420C, except that the carbon black content shall not exceed 5 percent. Resins that have higher cell classifications in one or more properties are acceptable provided product requirements are met.

6.2. *Reworked Material*—In lieu of virgin PE, clean reworked material may be used, provided that it meets the cell class requirements as described in Section 6.1.

7. REQUIREMENTS

7.1. *Workmanship*—The pipe and fittings shall be free of foreign inclusions and visible defects as defined herein. The ends of the pipe shall be cut squarely and cleanly so as not to adversely affect joining or connecting.

7.1.1. *Visible Defects*—Cracks, creases, unpigmented or nonuniformly pigmented pipe are not permissible.

7.1.2. *Inner Liner*—For Type S and SP pipe, the inner liner shall be fused to the outer corrugated wall at all internal corrugation crests.

7.2. *Pipe Dimensions*:

7.2.1. *Nominal Size*—The nominal size for the pipe and fittings is based on the nominal inside diameter of the pipe. Nominal diameters shall be sized for Type C and CP pipe in not less than 25-mm (1 in.) increments from 75 to 250 mm (3 to 10 in.). Nominal sizes shall be sized for Type S and SP pipe in not less than 50-mm (2 in.) increments from 100 to 250 mm (4 to 10 in.).

7.2.2. *Inner Liner*—For Type S and SP pipe, the inner liner shall have a minimum thickness of 0.5 mm (0.02 in.) for pipe of 100 mm (4 in.) and 150 mm (6 in.) nominal size and a minimum thickness of 0.6 mm (0.025 in.) for pipe of 200 mm (8 in.) and 250 mm (10 in.) nominal size, when measured in accordance with Section 9.5.4.

7.2.3. *Inside Diameter Tolerances*—The tolerance on the specified inside diameter shall be +4.5, –1.5 percent when measured in accordance with Section 9.5.1.

7.2.4. *Length*—Corrugated PE pipe is an extruded product and may be sold in any length agreeable to the user. Lengths shall not be less than 99 percent of the stated quantity when measured in accordance with Section 9.5.2.

7.3. *Fitting and Coupling Dimensions*:

7.3.1. The maximum allowable gap between fitting or coupling and pipe shall not exceed 3 mm (0.1 in.) unless otherwise specified.

7.3.2. All fittings and couplings shall be within an overall length dimensional tolerance of ±12 mm (0.5 in.) of the manufacturer's specified dimensions.

7.4. *Perforations*—When perforated pipe is specified, the perforations shall conform to the requirements of Class 2, unless otherwise specified in the order. Class 1 perforations are for pipe intended to be used for subsurface drainage or combination storm and underdrain. Class 2 perforations are for pipe intended to be used for subsurface drainage only. The perforations shall be cleanly cut so as not to restrict the inflow of water. Where circular perforations are preferred, the drill shall not penetrate the side walls of the corrugations. Pipe connected by couplings or bands may be unperforated within 100 mm (4 in.) of each end of each length of pipe.

Note 3—Pipe ordered under Class 1 perforations has no requirement as to inlet area because it specifies size, number, and location of holes. Alternate perforation patterns should be agreed to between the purchaser and manufacturer.

7.4.1. *Class 1 Perforations*—The perforations shall be approximately circular and shall have nominal diameters of not more than 5 mm (0.2 in.) for 100- and 150-mm (4- and 6-in.) diameter pipe and not greater than 10 mm (0.4 in.) for 200- and 250-mm (8- and 10-in.) diameter pipe. The holes shall be arranged in rows parallel to the axis of the pipe. The location of the perforations shall be in the valley of the outside corrugation and in each corrugation. The rows of perforations shall be arranged in two equal groups placed symmetrically on either side of the lower unperforated segment corresponding to the flow line of the pipe. The spacing of the rows shall be uniform. The distance of the centerlines of the uppermost rows above the bottom of the invert, and the inside chord lengths of the unperforated segments illustrated in Figure 1 shall be as specified in Table 1. All measurements shall be made in accordance with Section 9.5.3.

Table 1—Rows of Perforations, Height *H* of the Centerline of the Uppermost Rows above the Invert, and Chord Length *L* of Unperforated Segment, for Class 1 Perforations

Nominal Diameter, mm (in.)	Rows of Perforations[a]	*H*, Max,[b,] mm (in.)	*L*, Min,[b] mm (in.)
75 (3)	2	35 (1.4)	50 (2)
100 (4)	2	45 (1.75)	65 (2.5)
150 (6)	4	70 (2.75)	95 (3.75)
200 (8)	4	94 (3.7)	130 (5.1)
250 (10)	4	120 (4.7)	160 (6.3)

[a] Minimum number of rows. A greater number of rows for increased inlet area shall be subject to agreement between purchaser and manufacture. Note that the number of perforations per meter in each row (and inlet area) is dependent on the corrugation pitch.

[b] See Figure 1 for location of dimensions *H* and *L*.

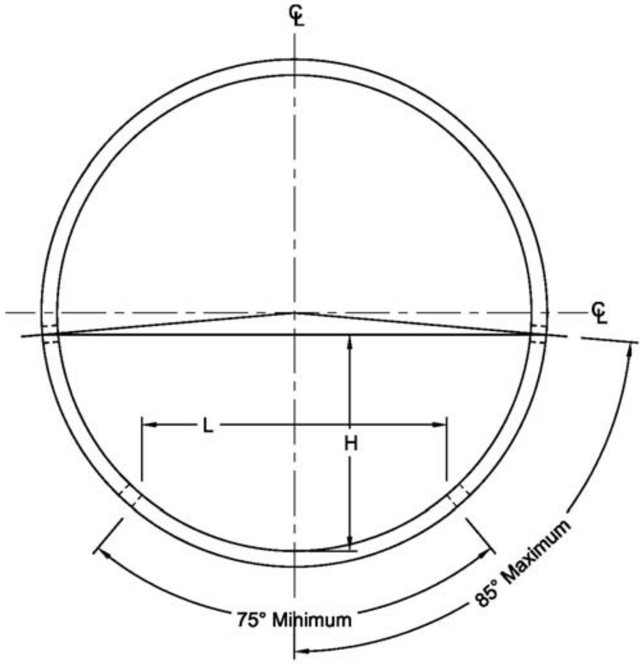

Figure 1—Requirements for Perforations

7.4.2. *Class 2 Perforations*—Circular and slotted perforations shall conform to the maximum dimensions as shown in Table 2. Perforations shall be placed in the outside valleys of the corrugations. The water inlet area shall be a minimum of 20 cm^2/m (1 $in.^2$/ft) of pipe. All measurements shall be made in accordance with Section 9.5.3.

Table 2—Maximum Perforation Dimensions

Nominal Pipe Diameter, mm (in.)	Drilled Hole Diameter, mm (in.)	Slotted Holes	
		Width, mm (in.)	Length, mm (in.)
75 (3)	4.75 (0.19)	3 (0.12)	25 (1)
100 (4)	4.75 (0.19)	3 (0.12)	25 (1)
150 (6)	4.75 (0.19)	3 (0.12)	25 (1)
200 (8)	6.25 (0.25)	3 (0.12)	30 (1.2)
250 (10)	8.00 (0.3)	3 (0.12)	30 (1.2)

7.5. *Pipe Stiffness*—Type C pipe, as described in Section 4.1.1, shall have a minimum pipe stiffness (PS) of 240 kPa (35 psi) at 5 percent deflection; and Type S pipe, as described in Section 4.1.2, shall have a minimum PS of 340 kPa (50 psi) at 5 percent deflection when tested in accordance with Section 9.1. The pipe tested shall contain perforations, if specified.

7.6. *Pipe Flattening*—There shall be no evidence of wall buckling, cracking, splitting, delamination, or decrease or downward deviation in the load-deflection curve when the pipe is tested in accordance with Section 9.2.

7.7. *Environmental Stress Cracking*—There shall be no cracking of the pipe when tested in accordance with Section 9.3.

7.8. *Brittleness*—There shall be no cracking of the pipe wall when tested in accordance with Section 9.4 except as specified in Sections 7.8.1 and 7.8.2.

Note 4—The brittleness test is similar to that described in ASTM F 405.

7.8.1. Cracks with a maximum chord length of 10 mm (0.4 in.) that originate at a perforation or at either end of the sample shall not be cause for rejection.

7.8.2. Splitting along a seam or mold parting line is not caused by brittleness and should be evaluated as a workmanship defect as described in Section 7.1.1 if no split exceeds 50 mm (2 in.) in chord length.

7.9. *Fitting and Coupling Requirements*:

7.9.1. The fittings and couplings shall not reduce or impair the overall integrity or function of the pipe line.

7.9.2. Common corrugated fittings include reducers, tees, wyes, and end caps.

Note 5—Only fittings and couplings supplied or recommended by the pipe manufacturer should be used.

7.9.3. Fittings and couplings shall not reduce the inside diameter of the pipe being joined by more than 5 percent of the nominal inside diameter. Reducer fittings shall not reduce the cross-sectional area of the smaller size.

7.9.4. Pipe connected by in-line couplers shall not separate when tested in accordance with Section 9.6.1.

7.9.5. The coupling shall not crack or crease when tested in accordance with Section 9.6.2.

7.9.6. The design of the couplers shall be such that when connected with the pipe, the axis of the assembly will be level and true when tested in accordance with Section 9.6.3.

8. CONDITIONING

8.1. *Conditioning*—Condition the specimen prior to test at 23 ± 2ºC (73.4 ± 3.6°F) for not less than 24 hours in accordance with Procedure A in ASTM D 618 for those tests where conditioning is required, and unless otherwise specified.

8.2. *Conditions*—Conduct the test in a laboratory temperature of 23 ± 2ºC (73.4 ± 3.6°F) unless otherwise specified herein.

9. TEST METHODS

9.1. *Pipe Stiffness*—Select a pipe specimen and test for PS as described in ASTM D 2412, with the following exceptions.

9.1.1. The test specimen shall be 300 ± 10 mm (12 ± 0.4 in.) long, cut to include full corrugations.

9.1.2. Locate the specimen in the loading machine with an imaginary line connecting the two seams formed by the corrugation mold (end view) parallel to the loading plates. The specimen must lie flat on the plate within 1 mm (0.04 in.) and may be straightened by hand bending at room temperature to accomplish this.

9.1.3. The deflection indicator shall be readable and accurate to ±0.03 mm (0.001 in.).

9.1.4. The residual curvature found in corrugated pipe, especially that furnished in coils, frequently results in an erratic load-deflection curve. When this occurs, the beginning point for deflection measurements shall be at a load of 20 ± 5 newtons (4.5 ± 1 lbf). This point shall be considered as the origin of the load-deflection curve.

Note 6—The parallel plates must exceed the length of the test specimen as specified above.

Note 7—Additional pipe specimens may be tested at other orientations for PS and flattening if desired.

9.2. *Pipe Flattening*—Flatten the pipe specimen from Section 9.1 until the vertical inside diameter is reduced by 20 percent. The rate of loading shall be the same as in Section 9.1. The specimen shall fail if wall buckling, cracking, splitting, or delamination is observed with the unaided eye or if there is a decrease or downward deviation in load-deflection curve at 20 percent or less deflection. The load-deflection curve shall be carried beyond 20 percent deflection so that the shape of the curve at 20 percent deflection can be determined.

9.3. *Environmental Stress Cracking*—Test sections of the pipe for environmental stress cracking in accordance with ASTM D 1693, except for the following modification:

9.3.1. Two specimens shall be tested.

9.3.2. Each specimen shall consist of a 90-degree arc length of pipe without perforations as shown in Figure 2.

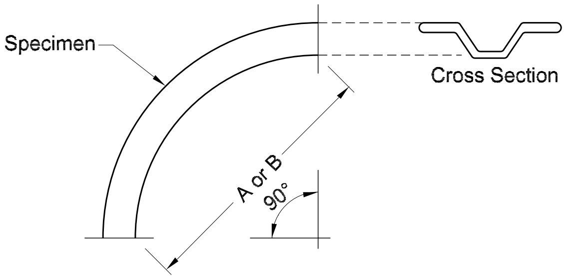

Figure 2—Specimen Configuration for Environmental Stress Cracking

9.3.3. Bend the specimens to shorten the inside chord length 20 ± 1 percent and retain in this position using a suitable holding device. Determine the arc chord dimension (B) of the specimen under test as follows:

$$B = 0.8A \qquad (1)$$

where:

A = the inside chord dimension before bending, and

B = the same dimension taken after bending. (See Figure 2.)

9.3.4. Place the bent specimen in a container of suitable size and cover completely with the preheated wetting agent 100 percent "Igepal CO-630," a trade name for nonylphenoxy poly (ethyleneoxy) ethanol, at 50ºC ± 2ºC (122°F ± 3.6°F). Maintain this temperature for 24 hours, and then remove the sample and inspect immediately. For recommended practices on using specific chemicals to test plastic pipe, refer to R 16.

9.4. *Brittleness*—Test two samples of pipe at an impact of 45 joules (35 ft-lbf) between two flat parallel plates using the apparatus depicted in Figure 3.

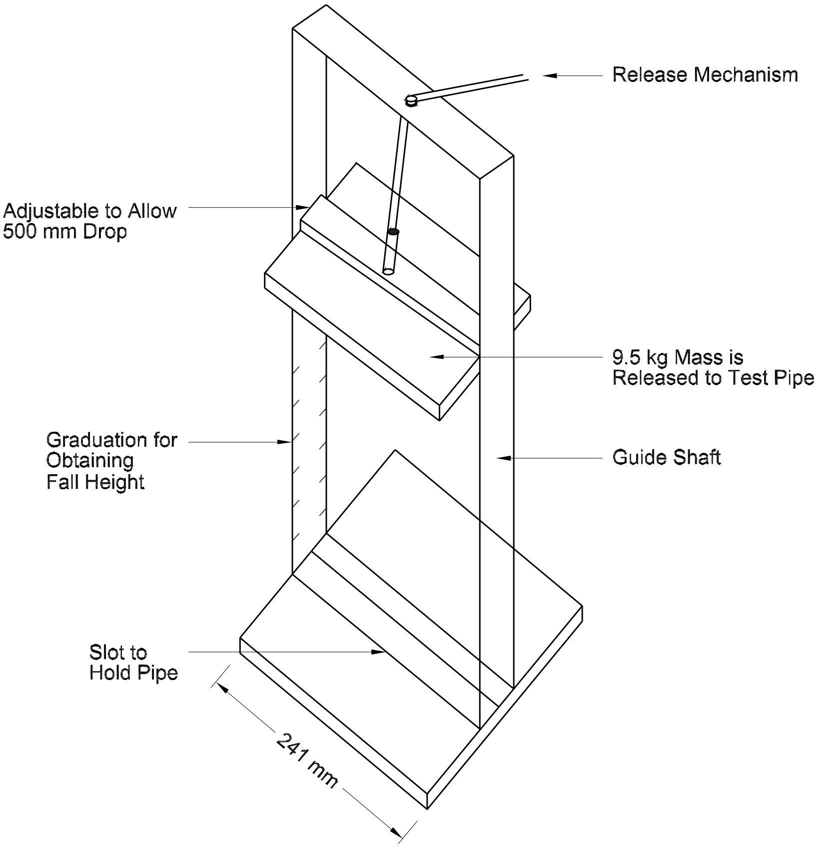

Figure 3—Brittleness Test Device

9.4.1. Cut the sample specimens 150 mm (6 in.) long from one continuous length.

9.4.2. Condition specimens at –4ºC ± 2ºC (25°F ± 3.6°F) for a minimum of 1 hour.

9.4.3. Set the 9.5-kg (20 lb) top plate for a free fall of 500 mm (20 in.) to the uppermost surface of the specimen.

9.4.4. Locate the specimen on the bottom plate with the plane of the corrugated seams parallel to the plate.

9.4.5. Drop the upper plate and impact test the specimen within 30 seconds of removal from the conditioning environment.

9.4.6. Remove and inspect in accordance with the requirements of Section 7.8.

9.5. *Pipe Dimensions*:

9.5.1. *Inside Diameter*—Measure the inside diameter of two sections of pipe with a tapered plug in accordance with ASTM D 2122. Alternatively, measure the inside diameter of two sections, with a suitable device accurate to ±0.2 mm (0.008 in.) the mold part-line and 90 degrees to it, and average the measurements.

9.5.2. *Length*—Measure pipe with any suitable device accurate to 0.2 percent. Make all measurements on the pipe while it is stress-free and at rest on a flat surface in a straight line. The length measurements may be taken at ambient temperature.

9.5.3. *Perforations*—Measure dimensions of perforations on a straight specimen with no external forces applied. Make linear measurements with instruments accurate to 0.2 mm (0.008 in.).

9.5.4. *Inner Liner*—Measure the thickness of the inner liner with a digital micrometer or ultrasonic thickness gauge in accordance with ASTM D 2122.

9.6. *Couplings*:

9.6.1. *Joint Integrity*—This test is limited to Type C and Type CP pipe supplied in coils. Assemble couplings to appropriate pipe in accordance with the manufacturer’s recommendations. Use pipe samples at least 150 mm (6 in.) in length. Vertically suspend two pipe lengths connected by the joint couplings along their longitudinal axis. Then hang a tare mass from the lower end of the assembled pipe specimen for 3 minutes. Apply the test mass gently. Verify that the joint will support a mass along the pipe axis equal to 0.090 kg/mm (60 lb/ft) of the nominal inside diameter, without separating. Test two coupling of each type.

9.6.2. *Strength*—Assemble each coupling to the appropriate pipe in accordance with the manufacturer’s recommendations. Use pipe samples at least 150 mm (6 in.) in length. Load the connected pipe and coupling between parallel plates at the rate of 12.5 mm/minute (0.5 in./min) until the vertical inside diameter is reduced by at least 20 percent of the nominal diameter of the coupling. Inspect for damage while at the specified deflection and after load removal, and report the results of this inspection.

9.6.3. *Alignment*—Assure that the assembly or joint is correct and complete; if the pipe is bent, it should be hand-straightened prior to performing this test. Lay the assembly or joint on a flat surface and verify that it will accommodate straight-line flow.

10. INSPECTION AND RETEST

10.1. *Inspection*—Inspection of the material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

10.2. *Retest and Rejection*—If any failure to conform to these specifications occurs, the pipe or fittings or couplings may be retested to establish conformity in accordance with agreement between the purchaser and seller. Individual results, not averages, constitute failure.

11. MARKING

11.1. All pipe shall be clearly marked at intervals of not more than 3.5 m (10 ft), and fittings and couplings shall be clearly marked, as follows:

11.1.1. Manufacturer’s name or trademark,

11.1.2. Nominal size,

11.1.3. The specification designation AASHTO M 252,

11.1.4. The plant designation code, and

11.1.5. The date of manufacture or an appropriate code. If a date code is used, a durable manufacturer sticker that identifies the actual date of manufacture shall be adhered to the inside of each length of pipe.

Note 8—A durable sticker is one that is substantial enough to remain in place and be legible through installation of the pipe.

12. QUALITY ASSURANCE

12.1. A manufacturer’s certification that the product was manufactured, tested, and supplied in accordance with this specification shall be signed by a person authorized by the manufacturer.

Standard Specification for

Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers

AASHTO Designation: M 259-98 (2006)[1]
ASTM Designation: C 789-95a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers

AASHTO Designation: M 259-98 (2006)[1]
ASTM Designation: C 789-95a

1. SCOPE

1.1. This specification covers single-cell precast reinforced concrete box sections intended to be used for the construction of culverts and for the conveyance of storm water, industrial wastes, and sewage.

1.2. A complete metric companion to M 259 has been developed—M 259M; therefore, no metric equivalents are presented in this specification.

Note 1—This specification is primarily a manufacturing and purchasing specification. However, standard designs are included and the criteria used to develop these designs are given in the Appendices. The successful performance of this product depends upon the proper selection of the box section, bedding, and backfill, and care that the installation conforms to the construction specifications. The owner of the precast reinforced concrete box sections specified herein is cautioned that the loading conditions and the field requirements must properly correlate with the box section specified and that inspection at the construction site must be provided.

Note 2—AASHTO M 273 is to be used for box sections with less than 2 ft of cover subjected to highway loading.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 32M/M 32, Steel Wire, Plain, for Concrete Reinforcement
- M 55M/M 55, Steel Welded Wire Reinforcement, Plain, for Concrete
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 85, Portland Cement
- M 148, Liquid Membrane-Forming Compounds for Curing Concrete (Discontinued)
- M 154, Air-Entraining Admixtures for Concrete
- M 221M/M 221, Steel Welded Wire Reinforcement, Deformed, for Concrete
- M 225M/M 225, Steel Wire, Deformed, for Concrete Reinforcement
- M 240, Blended Hydraulic Cement
- M 262, Concrete Pipe and Related Products
- M 273, Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers with Less Than 2 ft of Cover Subjected to Highway Loadings
- M 295, Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

- T 280, Concrete Pipe, Manhole Sections, or Tile
- *Standard Specifications for Highway Bridges*

2.2. *ASTM Standards*:

- C 1116, Standard Specification for Fiber-Reinforced Concrete

3. DEFINITIONS

3.1. *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. TYPES

4.1. Precast reinforced concrete box sections manufactured in accordance with this specification shall be of three types identified in Tables 1, 2, and 3, and shall be designated by type, span, rise, and design earth cover.

5. BASIS OF ACCEPTANCE

5.1. Acceptability of the box sections produced in accordance with Section 7 shall be determined by the results of the concrete compressive strength tests described in Section 10, by the material requirements described in Section 6, and by inspection of the finished box sections.

5.2. Box sections shall be considered ready for acceptance when they conform to the requirements of this specification.

6. MATERIALS

6.1. *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water in which steel has been embedded in such a manner that the steel and concrete act together.

6.2. *Cementitious Materials*:

6.2.1. *Cement*—Cement shall conform to the requirements for portland cement of M 85 or shall be portland blast-furnace slag cement or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash and shall not exceed 25 percent by weight.

6.2.2. *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.3. *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

6.2.3.1. Portland cement only,

6.2.3.2. Portland blast-furnace slag cement only,

14	42	0.44	0.70	0.77	0.29^d

[a] The design earth cover indicated is the height of fill above the top of the box section. Design requirements are based on the material and soil properties, loading data, and typical section as included in Appendix X1. For alternative or special designs, see Section 7.2.

[b] Design steel area in square inches per linear foot of box section at those locations that are indicated on the typical section included in Appendix X1.

[c] The box section designation, for example, 3 ft by 2 ft by 2 in. indicates (interior horizontal span in feet) by (interior vertical rise in feet) by (wall and slab thickness in inches).

[d] Minimum practical steel area is specified.

Notes:

1. Design earth covers and reinforcement areas are based on the weight of a column of earth over the width of the box section as defined in Appendix X1. See Appendix X2 for modification to reinforcement areas for other earth load conditions.
2. Concrete design strength, 5000 psi.

14	42	0.45	0.72	0.79	0.29[d]

[a] The design earth cover indicated is the height of fill above the top of the box section. Design requirements are based on the material and soil properties, loading data, and typical section as included in Appendix X1. For alternative or special designs, see Section 7.2.

[b] Design steel area in square inches per linear foot of box section at those locations that are indicated on the typical section included in Appendix X1.

[c] The box section designation, for example, 3 ft by 2 ft by 2 in. indicates (interior horizontal span in feet) by (interior vertical rise in feet) by (wall and slab thickness in inches).

[d] Minimum practical steel area is specified.

Notes:

1. Design earth covers and reinforcement areas are based on the weight of a column of earth over the width of the box section as defined in Appendix X1. See Appendix X2 for modification to reinforcement areas for other earth load conditions.
2. Concrete design strength, 5000 psi.

[a] The design earth cover indicated is the height of fill above the top of the box section. Design requirements are based on the material and soil properties, loading data, and typical section as included in Appendix X1. For alternative or special designs, see Section 7.2.

[b] Design steel area in square inches per linear foot of box section at those locations that are indicated on the typical section included in Appendix X1.

[c] The box section designation, for example, 3 ft by 2 ft by 2 in. indicates (Interior Horizontal Span in feet) by (interior vertical rise in feet) by (wall and slab thickness in inches).

[d] Minimum practical steel area is specified.

Notes:
1. Design earth covers and reinforcement areas are based on the weight of a column of earth over the width of the box section as defined in Appendix X1. See Appendix X2 for modification to reinforcement areas for other earth load conditions.
2. Concrete design strength, 5000 psi.

6.2.3.3. Portland-pozzolan cement only, and

6.2.3.4. A combination of portland cement and fly ash wherein the proportion of fly ash is between 5 and 25 percent by weight of total cementitious materials (portland cement plus fly ash).

6.3. *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirements for gradation shall not apply.

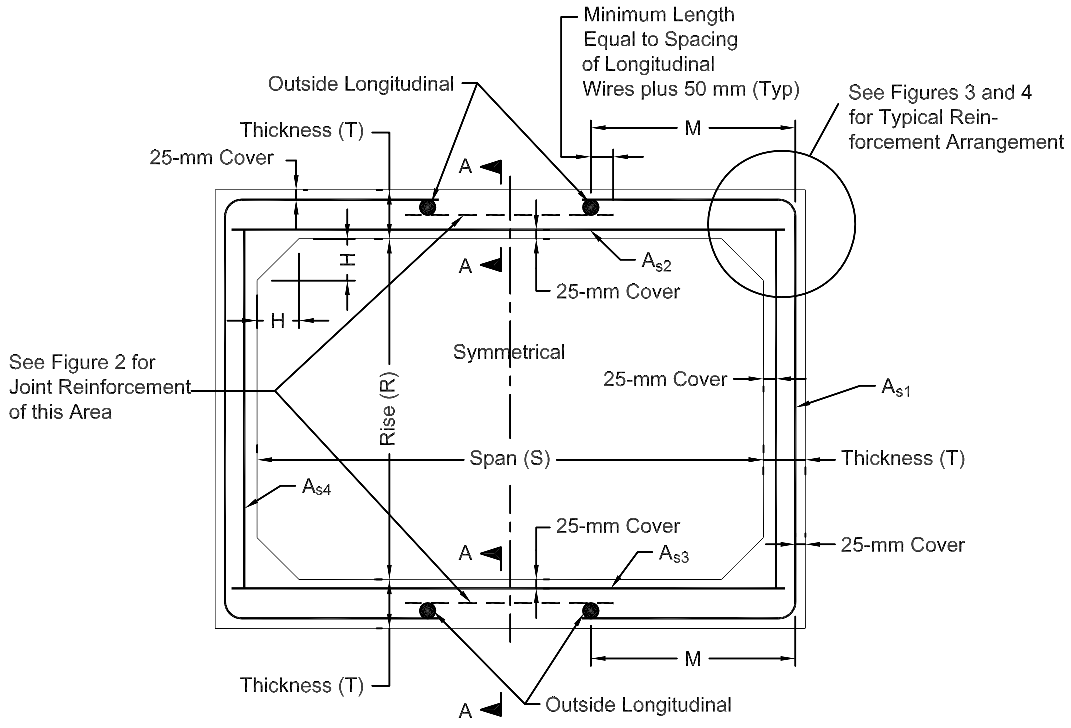
6.4. *Admixtures and Blends*—Admixtures and blends may be used with the approval of the owner.

6.5. *Steel Reinforcement*—Reinforcement shall consist of welded wire fabric conforming to M 55M/M 55 or M 221M/M 221.

6.6. *Synthetic Fibers*—Collated fibrillated virgin polypropylene fibers may be used, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be accepted.

7. DESIGN

7.1. *Design Tables*—The box section dimensions, compressive strength of the concrete, and reinforcement details shall be as prescribed in Tables 1, 2, or 3 and Figures 1, 2, and 3, subject to the provisions of Section 11. Table 1 sections are designed for combined earth dead load and AASHTO HS20 live load conditions. Table 2 sections are designed for combined earth dead load and Interstate live load conditions when the Interstate live loading exceeds the HS20 live loading. Table 3 sections are designed for earth dead load conditions only. Criteria used to develop Tables 1, 2, and 3 are given in Appendix X1. For modifications to the designs shown in Tables 1, 2, and 3 due to anticipated earth and surcharge loads different from those used to develop the tables, see Appendix X2.



Notes: 1. The dimension *M* is the total of the theoretical cutoff length plus the required anchorage.
2. The haunch dimension *H* is equal to the thickness *T*.

Figure 1—Typical Box Section

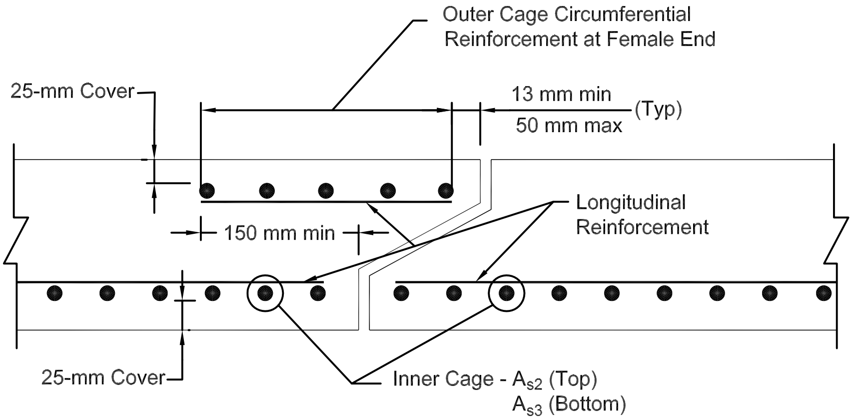


Figure 2—Section A-A Top and Bottom Slab Joint Reinforcement

7.2. *Modified and Special Designs*—The manufacturer may request approval by the owner of modified designs that differ from the designs in Section 7; or special designs for sizes and loads other than those shown in Tables 1, 2, and 3.

Note 3—The tabular designs in this specification were prepared according to AASHTO's *Standard Specifications for Highway Bridges*, 1973 Edition. The current AASHTO *Standard Specifications for Highway Bridges* allows concrete shear stress criteria that differ from the

1973 criteria. The use of current AASHTO concrete shear stress criteria shall be acceptable by this specification for modified or special designs.

7.3. *Placement of Reinforcement*—The cover of concrete over the circumferential reinforcement shall be 1 in., subject to the provisions of Section 11. The inside circumferential reinforcement shall extend into the male portion of the joint and the outside circumferential reinforcement shall extend into the female portion of the joint. The clear distance of the end circumferential wires shall be not less than $^1/_2$ in. or more than 2 in. from the ends of the box section. Reinforcement shall be assembled utilizing any combination of single or multiple layers of welded-wire fabric. A common reinforcement unit may be utilized for both A_{s2} (or A_{s3}) and A_{s4}, with the largest area requirement governing, bending the reinforcement 90 degrees at the corners and waiving the extension requirements of Figure 3. See Figure 4. The welded-wire fabric shall be composed of circumferential and longitudinal wires meeting the spacing requirements of Section 7.4 and shall contain sufficient longitudinal wires extending through the box section to maintain the shape and position of reinforcement. The exposure of the ends of longitudinals, stirrups, and spacers used to position the reinforcement shall not be a cause for rejection.

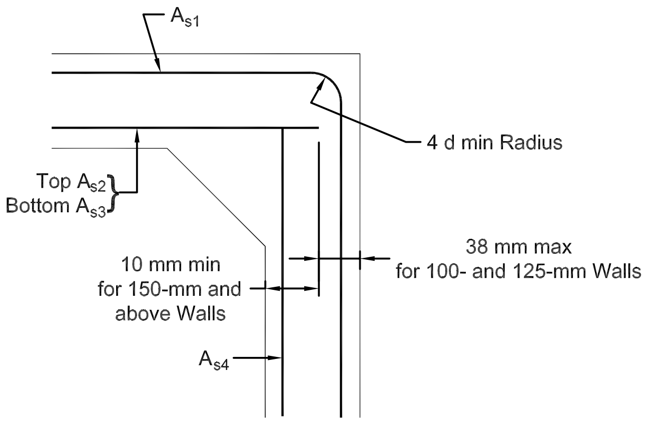

Figure 3—Detail Inner Reinforcement

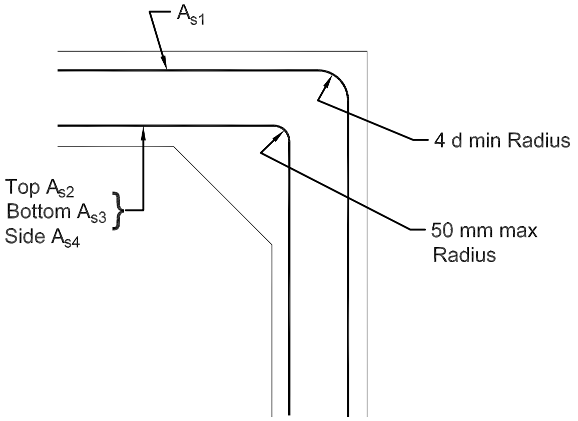

Figure 4—Detail Option

7.4. *Laps, Welds, and Spacing*—Splices in the circumferential reinforcement shall be made by lapping. The overlap measured between the outermost longitudinal wires of each fabric sheet shall not be less than the spacing of the longitudinal wires plus 2 in. If A_{s1} is extended and connected, welded splices shall be allowed in the connection. A_{s4} may be lapped and welded at any location or connected by welding at the corners to A_{s2} and A_{s3}. The spacing center-to-center of the circumferential wires shall not be less than 2 in. nor more than 4 in. The spacing center-to-center of the longitudinal wires shall not be more than 8 in.

8. JOINTS

8.1. The precast reinforced concrete box sections shall be produced with male and female ends. The ends shall be of such design and the ends of the box sections so formed that the sections can be laid together to make a continuous line of box sections compatible with the permissible variations given in Section 11.

8.2. Outer cage circumferential reinforcement as shown in Figures 1 and 2 shall be placed in the top and bottom slabs at the female portion of the joint when A_{s1} is not continuous over the span. The minimum area of such reinforcement in square inches per linear foot of box section length shall be the same as the areas specified for A_{s4} in Tables 1, 2, and 3.

9. MANUFACTURE

9.1. *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious materials ratio not exceeding 0.53 by weight. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 470 lb/yd^3 unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this specification.

9.2. *Curing*—The box sections shall be cured for a sufficient length of time so that the concrete will develop the specified compressive strength in 28 days or less. Any one of the following methods of curing or combinations thereof may be used:

9.2.1. *Steam Curing*—The box sections may be low pressure, steam cured by a system that will maintain a moist atmosphere.

9.2.2. *Water Curing*—The box sections may be water cured by any method that will keep the sections moist.

9.2.3. *Membrane Curing*—A sealing membrane conforming to the requirements of M 148 may be applied and shall be left intact until the required concrete compressive strength is attained. The concrete temperature at the time of application shall be within 10ºF of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

9.3. *Forms*—The forms used in manufacture shall be sufficiently rigid and accurate to maintain the box section dimensions within the permissible variations given in Section 11. All casting surfaces shall be of smooth nonporous material.

9.4. *Handling*—Handling devices or holes shall be permitted in each box section for the purpose of handling and laying.

10. PHYSICAL REQUIREMENTS

10.1. *Type of Specimen*—Compression tests for determining concrete compressive strength may be made on either concrete cylinders or on cores drilled from the boxed section.

10.2. *Compression Testing of Cylinders*:

10.2.1. *Cylinder Production*—Cylinders shall be prepared in accordance with the Cylinder Strength Test Method of T 280.

10.2.2. *Number of Cylinders*—Prepare not fewer than five test cylinders from a group (1 day's production of each concrete strength) of box sections.

10.2.3. *Acceptability on the Basis of Cylinder Test Results*:

10.2.3.1. When the compressive strengths of all cylinders tested for a group are equal to or greater than the design concrete strength, the compressive strength in the group of box sections shall be accepted.

10.2.3.2. When the average compressive strength of all cylinders tested is equal to or greater than the design concrete strength, not more than 10 percent of the cylinders tested have a compressive strength less than the design concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the design concrete strength, then the compressive strength of the concrete in the group of box sections shall be accepted.

10.2.3.3. When the compressive strength of the cylinders tested does not conform to the acceptance criteria stated in Section 10.2.3.1 or Section 10.2.3.2, the acceptability of the group shall be determined in accordance with the provisions of Section 10.2.

10.3. *Compression Testing of Cores*:

10.3.1. *Obtaining Cores*—Cores shall be obtained and prepared in accordance with the Core Strength Test Method of T 280.

10.3.2. *Number of Cores*—One core shall be taken from a box section selected at random from each group of 15 box sections of a single size or fraction of such a group from each continuous production run.

10.4. *Acceptability on the Basis of Core Test Results*:

10.4.1. When the compressive strengths of cores tested for a group of box sections is equal to or greater than the design concrete strength, the compressive strength of the concrete for the group is acceptable.

10.4.2. If the compressive strength of the core tested is less than the design concrete strength, the box section from which that core was taken may be re-cored. If the compressive strength of the re-core is equal to or greater than the design concrete compressive strength, the compressive strength of the concrete for the group is acceptable.

10.4.3. If the compressive strength of the re-core is less than the design concrete strength, the box section from which the core was taken shall be rejected. Two box sections from the remainder of the group shall be selected at random and one core shall be taken from each box section. If the compressive strength of both cores is equal to or greater than the design concrete compressive strength, the concrete compressive strength of the remainder of the group shall be acceptable. If the compressive strength of either of the two cores tested is less than the design concrete compressive strength, then the remainder of the group shall be either rejected or, at the option of the manufacturer, each box section of the remainder of the group shall be cored and accepted individually, and any of the box sections that have a core with less than the design concrete compressive strength shall be rejected.

10.5. *Plugging Core Holes*—The core holes shall be plugged and sealed by the manufacturer in a manner such that the box section will meet all of the test requirements of this specification. Box sections so sealed shall be considered satisfactory for use.

10.6. *Test Equipment*—Every manufacturer furnishing box sections under this specification shall furnish all facilities and personnel necessary to carry out the tests required.

11. PERMISSIBLE VARIATIONS

11.1. *Internal Dimensions*—The internal dimensions shall not vary more than one percent from the design dimensions. The haunch dimensions shall not vary more than $^1/_4$ in. from the design dimensions.

11.2. *Slab and Wall Thickness*—The slab and wall thickness shall not be less than that shown in the design by more than 5 percent or $^3/_{16}$ in., whichever is greater. A thickness more than that required in the design shall not be a cause for rejection.

11.3. *Length of Opposite Surfaces*—Variations in laying lengths of two opposite surfaces of the box section shall not be more than $^1/_8$ in./ft of internal span, with a maximum of $^5/_8$ in. for all sizes through 7-ft internal span, and a maximum of $^3/_4$ in. for internal spans greater than 7 ft, except where beveled ends for laying on curves are specified by the owner.

11.4. *Length of Section*—The underrun in length of a section shall not be more than $^1/_8$ in./ft of length with a maximum of $^1/_2$ in. in any box section.

11.5. *Position of Reinforcement*—The maximum variation in the position of the reinforcement for 5 in. or less slab and wall thicknesses shall be $\pm^3/_8$ in., and for greater than 5-in. slab and wall thicknesses shall be $\pm^1/_2$ in. In no case, however, shall the cover over the reinforcement be less than $^5/_8$ in., as measured to the internal surface or the external surface. The preceding minimum cover limitation does not apply at the mating surfaces of the joint.

11.6. *Area of Reinforcement*—The areas of steel reinforcement shall be the design steel areas as shown in Tables 1, 2, or 3. Steel areas greater than those required shall not be cause for rejection. The permissible variation in diameter of any wire in finished fabric shall conform to the tolerances prescribed for the wire before fabrication by either M 32M/M 32 or M 225M/M 225 as applicable.

12. REPAIRS

12.1. Box sections may be repaired, if necessary, because of imperfections in manufacture or handling damage and will be acceptable if, in the opinion of the owner, the repaired box section conforms to the requirements of this specification.

13. INSPECTION

13.1. The quality of materials, the process of manufacture, and the finished box sections shall be subject to inspection by the owner.

14. REJECTION

14.1. Box sections shall be subject to rejection if it fails to conform to any of the specification requirements. Individual box sections may be rejected because of any of the following:

14.1.1. Fractures or cracks passing through the wall, except for a single-end crack that does not exceed the depth of the joint.

14.1.2. Defects that indicate mixing and molding, not in compliance with Section 9.1, or honeycombed or open texture that would adversely affect the function of the box sections.

14.1.3. The ends of the box sections are not normal to the walls and centerline of the box section, within the limits of variations given in Section 11, except where beveled ends are specified.

14.1.4. Damaged ends, where such damage would prevent making a satisfactory joint.

15. MARKING

15.1. The following information shall be clearly marked on each box section by indentation, waterproof paint, or other approved means:

15.1.1. Box section span, rise, table number, maximum and minimum design earth cover, and specification designation;

15.1.2. Date of manufacture;

15.1.3. Name or trademark of the manufacturer; and

15.1.4. Each section shall be clearly marked by indentation on either the inner or outer surface during the process of manufacture so that the location of the top will be evident immediately after the forms are stripped. In addition, the word “top” shall be lettered with waterproof paint on the inside top surface.

16. KEYWORDS

16.1. Concrete box—precast; culvert.

APPENDIXES

(Nonmandatory Information)

X1. DESIGN CRITERIA USED TO DEVELOP TABLES 1, 2, AND 3

X1.1. *Bedding and Backfill Assumptions*:

X1.1.1. The bedding is assumed to provide a slightly yielding, uniformly distributed support over the bottom width of the box section.

X1.1.2. The design earth covers and reinforcement areas are based on the weight of a column of earth over the width of the box section.

X1.1.3. Refer to Appendix X2 for other bedding and backfill conditions.

X1.2. *Criteria for Loads*:

X1.2.1. Design loads are based on the American Association of State Highway and Transportation Officials (AASHTO) *Standard Specifications for Highway Bridges*, Thirteenth Edition.

X1.2.2. Live loads for designs given in Table 1 are H20 truck wheel loads as defined in the AASHTO specifications. Live loads for designs given in Table 2 are either the H20 truck wheel loads, or interstate truck wheel loads as defined in U.S. Department of Commerce, Bureau of Public Roads Circular Memorandum 22-40, 22 April 1957, depending upon which produces the more severe design strength requirements. Distribution of truck wheel loads through earth fills is in accordance with Article 1.3.3 of the AASHTO specifications. Earth cover loads for designs given in Tables 1, 2, and 3 are the weight of a column of earth of a width equal to the outside width dimension of the box section and a height equal to the depth of earth cover over the top of the section. This earth load is recommended in Article 1.2.2 (A) of the AASHTO Bridge Specifications for the normal case of box culverts on “yielding” subgrade. The AASHTO specifications define an “unyielding” subgrade as “rock or piles” and require the use of the Iowa formulas for this case. See Appendix X2 for a method to modify the designs given in Tables 1, 2, and 3 when the anticipated earth load, or earth load plus uniformly distributed surface surcharge load, is greater (or less) than the weight of the column of earth directly above the out-to-out width of the box sections.

X1.2.3. Article 1.2.2 of the AASHTO specification allows the design of buried structures, such as box section culverts, for 70 percent of the weight of earth directly above the out-to-out width of structures. On the other hand, the Marston-Spangler theory of earth loads on buried pipe gives a total earth load greater than the weight of the column of earth directly over the structure for most “positive projecting” culverts, and less than the weight of the column of earth over the structure for “trench type” installations, “negative projecting” culverts, and “induced trench” culverts. In view of the number of different installation conditions that may be encountered and the use of higher reinforcing steel stresses associated with the ultimate strength design method (Section X1.2), the 30 percent reduction in weight of supported earth load permitted in Article 1.2.2 of the AASHTO specification is not utilized for the tabulated designs, and a method of modifying designs for anticipated earth loads that differs from the above described “standard earth load” is given in Appendix X2.

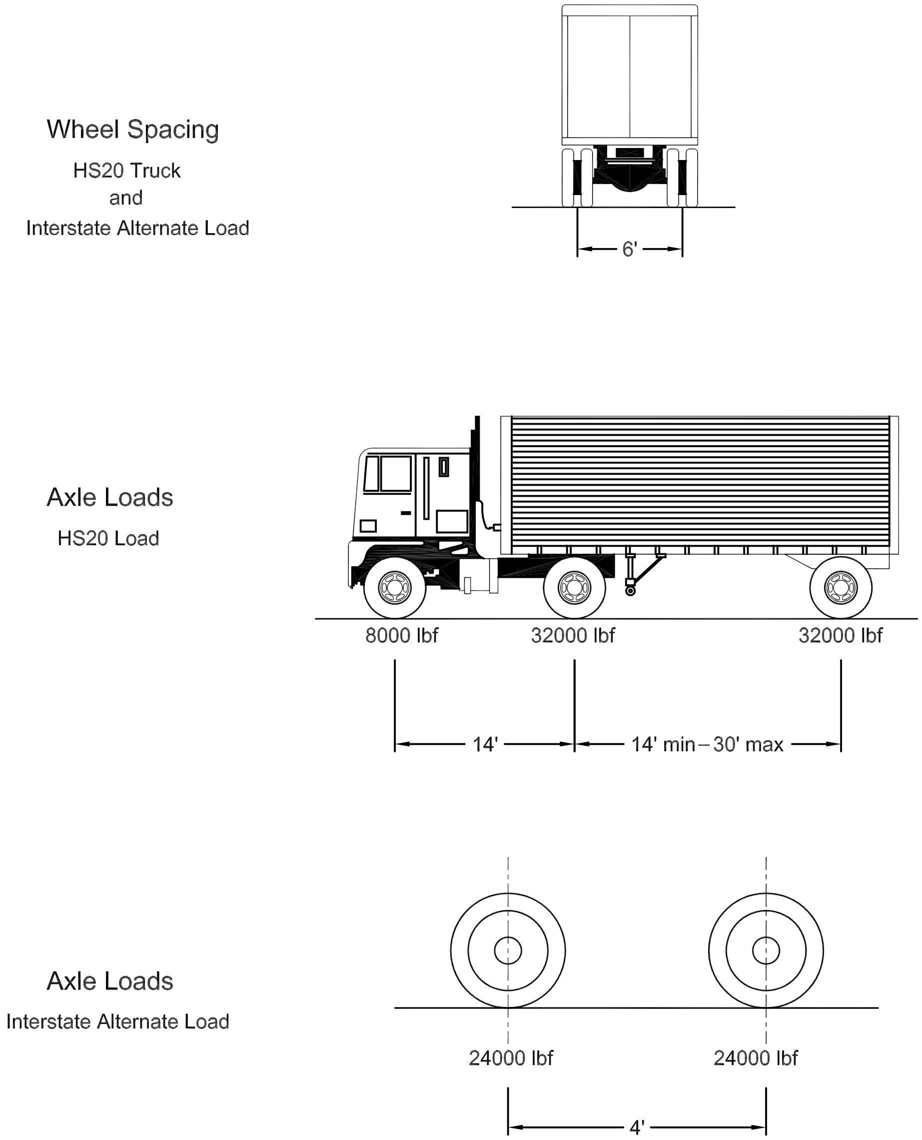

Figure X1.1—Axle Loads for Box Section Standard Designs

X1.2.4. Lateral earth pressure from weight of earth above and adjacent to a box section is taken as a minimum of 0.25 times vertical pressure, and an additional 0.25 times vertical pressure is added when determining steel areas only when areas are increased by such increased lateral pressure. For Tables 1 and 2, additional lateral pressure in lbf/ft^2 from approaching truck wheel loads is taken as 700 divided by depth of earth cover in feet and is added when determining steel areas only at sections where area is increased by increased lateral pressure.

X1.3. *Methods of Analysis*:

X1.3.1. The structural effects of the loads described in Section X1.2 are evaluated based on the elastic method of structural analysis. Design moments, shears, and thrusts are determined by computer analysis using the stiffness matrix method, and design is based on maximum stress resultants at critical sections caused by the most severe combination of design loads.

X1.4. *Method of Design*:

X1.4.1. Design heights of earth cover, wall thicknesses, and reinforcing steel areas are determined based on the elastic method structural analysis and the ultimate strength method of reinforced concrete design given in the 1971 ACI Building Code (ACI 318-71).[2] Steel areas are governed by ultimate flexural strength. The steel areas and the size and spacing of circumferential wires are proportioned to limit the maximum crack width to 0.01 in. under design load conditions. Evaluation of crack control with the welded wire fabric reinforcement specified for the tabulated designs is based on the results of research by Lloyd, Rejali, and Kesler[3] at the University of Illinois, and is significantly more conservative than the crack control provisions given in ACI 318-71. This is because it is recognized that approximations that were used to simplify the ACI crack control provisions can result in unconservative designs for thin elements such as slabs. Standard designs do not cover installations that must resist significant external water pressure. Furthermore, installations that are subject to high external water pressure may require vertical reinforcement for the inside face of the side walls. Lloyd, Rejali, and Kesler suggest that crack control equations developed for deformed bar reinforcement may also be used for both welded smooth wire fabric and deformed wire fabric reinforcement.

X1.4.2. Note that some box section designs shown in the tables have steel area requirements designated by "D" as minimum practical steel area. For such designs, the steel areas calculated for support of design loads are less than the minimum steel area that is specified for slabs in AASHTO Specification, 0.002 bt, and thus, the minimum reinforcement areas are shown in the tables.

X1.4.3. For specific criteria used in Tables 1, 2, and 3, refer to Table X1.1.

Table X1.1—Update on AASHTO Bridge Specification Edition Impact (variable with depth) (see AASHTO Bridge Specifications, 1977)

Material Properties:	
Welded wire fabric, minimum specified yield stress	65000 psi
Concrete, minimum specified compressive strength	5000 psi
Soil Data:	
Unit weight	120 lbf/ft^3
Ratio of lateral to vertical pressure from weight of earth	0.25 min to 0.50 max
Additional lateral pressure from approaching truck wheels	700 ÷ H, lbf/ft^2 where H =earth cover, ft
External water table	below box section invert
Effective weight coefficient	1.0
—	
Uniform internal pressure	0.0
Depth of water in box section	equal to inside height
External ground water pressure	0.0
Structural Arrangement:	
Concrete cover over steel	1.0 in.
Slab thickness	$^1/_{12}$ times inside span plus 1.0 in. up to 7-ft span—$^1/_{12}$ inside span above 7-ft span
Side Wall thickness	equal to slab thickness
Haunch dimensions	vertical and horizontal dimensions both equal to slab thickness
Minimum reinforcing inside face slabs and side walls, outside face side walls and corners of slabs	0.002 bt
The structural arrangement and details are shown in Figure 1	

[a] See ACI 318-71, Section 9.2.1(c).

X1.4.4. The maximum height of earth cover shown in the tables is determined by the shear strength of the box section without the use of special shear reinforcement, as given in Sections 11.2.1, 11.2.2, and 11.4.1 of ACI 318-71, and by the "standard weight" of the column of earth directly above the box section. See Table X1.2 for the maximum loads that can be carried on the standard box sections. These loads can be used to determine maximum earth cover heights when the anticipated weight of earth supported by the section is greater than (or less than) the above "standard weight" of earth cover.

Table X1.2—Design Information for Revising Tabulated Reinforcing Steel Areas

	Change in Reinforcing Steel Area per 1000 lbf/ft Change in Total Weight on Box Section				Change in Reinforcing Steel Area per 1000 lbf/ft Change in Total Weight on Box Section		
Culvert Size	ΔA_{s1}, in.^{2}/ft	ΔA_{s2} ΔA_{s3}, in.^{2}/ft	Maximum W, lbf/ft[a]	Culvert Size	ΔA_{s1}, in.^{2}/ft	ΔA_{s2} ΔA_{s3}, in.^{2}/ft	Maximum W, lbf/ft[a]

[a] Maximum allowable total weight on box section as governed by shear strength of box section without stirrups.

X1.5. *Multiple-Cell Installations*:

X1.5.1. The designs given herein are for single cell precast reinforced concrete box sections. The units may be used in parallel for multicell installations if means of positive lateral bearing by continuous contact between the sides of adjacent boxes are provided. Compacted earth fill, granular backfill, or grouting between the units are considered means of providing such positive bearing.

X2. MODIFICATION OF “STANDARD” BOX SECTION DESIGNS FOR EARTH LOADS DIFFERENT FROM THE “STANDARD” EARTH LOAD

X2.1. The heights of cover given in Tables 1, 2, and 3 are based on a “standard weight of earth fill” equal to the weight of a column of earth with a unit weight of 120 lb/ft^3 and a width equal to the out-to-out width of the box section. For some installations, the design engineer may determine that for a given height of cover, the weight of earth to be supported by the box section is more or less than the above “standard weight of earth fill” used to develop the designs given in the tables.

X2.1.1. For example, the Marston-Spangler theory for loads on buried structures indicates that the weight of earth that must be supported by most “positive projecting” conduits is greater than the weight of a column of earth directly over the conduit, while the weight of earth that must be supported by “trench-type” conduits, “negative-projecting” conduits, and “induced-trench” conduits is less than the weight of earth over the conduits. Also, the designer may wish to use a unit weight of earth more or less than the 120 lb/ft^3 used in the “standard weight,” or may wish to include a particular uniformly distributed surface surcharge loading.

X2.2. Incremental reinforcing steel areas are given in Table X1.1 for each box section type. Where installation conditions warrant the use of a weight of earth more or less than the “standard weight,” the designer may utilize these incremental areas to modify the steel areas given in Tables 1, 2, or 3 for a particular height of cover. The maximum total weight of earth fill that may be supported over the out-to-out width of each standard box section size, as governed by shear strength without shear reinforcing, is also given in Table X1.2. Thus, for any weight of earth or surface surcharge, or both, a designer can use Tables 1, 2, 3, and X1.2, to determine the required area of reinforcing steel for various heights of earth cover, or the maximum height of earth cover without special shear reinforcing, for any of the standard box section sizes shown in these tables.

X2.3. The following design example illustrates how the previously mentioned tables may be used to obtain a suitable design for a box section to support an earth load that is greater than the “standard weight of earth” used to develop Tables 1, 2, and 3.

X2.3.1. *Example*:

X2.3.1.1. *Given*—A 6 ft by 6 ft by 7 in. Table 1 precast concrete box section under 14 ft of cover with 110 lb/ft^3 earth and an effective weight of earth supported by the section of 1.36 times the weight of the column of earth directly over the section instead of the standard 120 lb/ft^3 earth.

X2.3.1.2. *Find*—The required A_{s1}, A_{s2}, and A_{s3} circumferential reinforcement areas. In all cases A_{s4} is governed by the minimum steel areas as described in X1.4.2 and is not changed by increased vertical loads.

X2.3.2. *Solution*:

X2.3.2.1. Effective unit weight of soil = 110 × 1.36 = 150 lb/ft^3

X2.3.2.2. Determine change in total weight of earth on culvert in kps force/linear ft (1000 lbf):

$$W = H \times B \times w \qquad (X2.1)$$

where:

W = total weight of earth on culvert, kf/linear ft;
H = height of earth cover, ft;
B = outside span, ft;
w = unit weight of earth, kf/ft^3;
W_{120} = 14 × 7.167 × 0.120 = 12.040 kf/ft;
W_{150} = 14 × 7.167 × 0.150 = 15.051 kf/ft; and
W = $W_{150} - W_{120}$ = 3.011 kf/ft

X2.3.2.3. Determine the change in circumferential reinforcement areas. From Table 1, for a 6 ft by 6 ft by 7 in. section under 14 ft of cover A_{s1} = 0.17, A_{s2} = 0.32, and A_{s3} = 0.33 in.^{2}/ft. From Table X1.2, for a 6 ft by 6 ft by 7 in. section, the changes in reinforcing areas are for A_{s1} = 0.013, A_{s2} and A_{s3} = 0.02B in.^{2}/ft for each 1000 lbf/ft of load change. Therefore:

$$\Delta A_{s1} = 3.011 \times 0.013 = 0.039$$

$$\Delta A_{s2} = 3.011 \times 0.028 = 0.084$$

$$\Delta A_{s3} = 3.011 \times 0.028 = 0.084$$

Therefore, the correct reinforcement areas are as follows:

$$A_{s1} = 0.17 + 0.04 = 0.21 \text{ in.}^2/\text{ft}$$

$$A_{s2} = 0.32 + 0.08 = 0.40 \text{ in.}^2/\text{ft}$$

$$A_{s3} = 0.33 + 0.08 = 0.41 \text{ in.}^2/\text{ft}$$

X2.3.2.4. Determine if the total weight of earth on the culvert is less than the maximum as governed by the shear strength of culvert without stirrups.

From Table X1.2, the maximum allowable weight = 16 900 lbf/ft. From Section X2.3.2.2,

W_{150} = 15 051 lbf/ft

The approximate equivalent uniform load from an HS20 live-load at 14-ft burial depth is about 160 lbf/ft^2 or a total load of 1150 lbf/ft (160 × 7.167). Therefore, the total weight on the box section is 16 200 lbf/ft (15 050 + 1150), which is less than the maximum allowable; therefore, the design is satisfactory.

---

[1] Standard designs and criteria used to develop designs included in this specification are under the jurisdiction of the AASHTO Subcommittee on Bridges and Structures.

Standard Specification for

Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers [Metric]

AASHTO Designation: M 259M-00 (2008)[1]
ASTM Designation: C 789M-98

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers [Metric]

AASHTO Designation: M 259M-00 (2008)[1]
ASTM Designation: C 789M-98

1. SCOPE

1.1. This specification covers single-cell precast reinforced concrete box sections intended to be used for the construction of culverts and for the conveyance of storm water, industrial wastes, and sewage.

1.2. This specification is the metric counterpart of M 259.

Note 1—This specification is primarily a manufacturing and purchasing specification. However, standard designs are included and the criteria used to develop these designs are given in the Appendices. The successful performance of this product depends upon the proper selection of the box section, bedding, and backfill, and care that the installation conforms to the construction specifications. The owner of the precast reinforced concrete box sections specified herein is cautioned that the loading conditions and field requirements must properly correlate with the box section specified and that inspection at the construction site must be provided.

Note 2—AASHTO M 273M is to be used for box sections with less than 0.6 m of cover subjected to highway loading.

4. TYPES

4.1. Precast reinforced concrete box sections manufactured in accordance with this specification shall be of three types identified in Tables 1, 2, and 3, and shall be designated by type, span, rise, and design earth cover.

4.3	1070	930	1480	1630	610[d]

[a] The design earth cover indicated is the height of fill above the top of the box section. Design requirements are based on the material and soil properties, loading data, and typical section as included in Appendix X1. For alternative or special designs, see Section 7.2.

[b] Design steel area in square millimeters per linear meter of box section at those locations that are indicated on the typical section included in Appendix X1.

[c] The box section designation, for example, 900 mm by 600 mm by 100 mm indicates (interior horizontal span, in millimeters) by (interior vertical rise, in millimeters) by (wall and slab thickness, in millimeters).

[d] Minimum practical steel area is specified.

Notes:
1. Design earth covers and reinforcement areas are based on the mass of a column of earth over the width of the box section as defined in Appendix X1. See Appendix X2 for modification to reinforcement areas for other earth load conditions.
2. Concrete design strength, 35 MPa.

[a] The design earth cover indicated is the height of fill above the top of the box section. Design requirements are based on the material and soil properties, loading data, and typical section as included in Appendix X1. For alternative or special designs, see Section 7.2.

[b] Design steel area in square millimeters per linear meter of box section at those locations that are indicated on the typical section included in Appendix X1.

[c] The box section designation, for example, 900 mm by 600 mm by 100 mm indicates (interior horizontal span, in millimeters) by (interior vertical rise, in millimeters) by (wall and slab thickness, in millimeters).

[d] Minimum practical steel area is specified.

Notes:
1. Design earth covers and reinforcement areas are based on the mass of a column of earth over the width of the box section as defined in Appendix X1. See Appendix X2 for modification to reinforcement areas for other earth load conditions.
2. Concrete design strength, 35 MPa.

[a] The design earth cover indicated is the height of fill above the top of the box section. Design requirements are based on the material and soil properties, loading data, and typical section as included in Appendix X1. For alternative or special designs, see Section 7.2.

[b] Design steel area in square millimeters per linear meter of box section at those locations that are indicated on the typical section included in Appendix X1.

[c] The box section designation, for example, 900 mm by 600 mm by 100 mm indicates (interior horizontal span, in millimeters) by (interior vertical rise, in millimeters) by (wall and slab thickness, in millimeters).

[d] Minimum practical steel area is specified.

Notes:
1. Design earth covers and reinforcement areas are based on the mass of a column of earth over the width of the box section as defined in Appendix X1. See Appendix X2 for modification to reinforcement areas for other earth load conditions.
2. Concrete design strength, 35 MPa.

5. BASIS OF ACCEPTANCE

5.1. Acceptability of the box sections produced in accordance with Section 7 shall be determined by the results of the concrete compressive strength tests described in Section 10, by the material requirements described in Section 6, and by inspection of the finished box sections.

5.2. Box sections shall be considered ready for acceptance when they conform to the requirements of this specification.

6. MATERIALS

6.1.1. *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water in which steel has been embedded in such a manner that the steel and concrete act together.

6.2. *Cementitious Materials*:

6.2.1. *Cement*—Cement shall conform to the requirements for portland cement of M 85 or shall be portland blast-furnace slag cement or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash and shall not exceed 25 percent by mass.

6.2.2. *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.3. *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in the concrete shall be one of the following:

6.2.3.1. Portland cement only.

6.2.3.2. Portland blast-furnace slag cement only.

6.2.3.3. Portland-pozzolan cement only.

6.2.3.4. A combination of portland cement and fly ash wherein the proportion of fly ash is between 5 and 25 percent by mass of total cementitious materials (portland cement plus fly ash).

6.3. *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirements for gradation shall not apply.

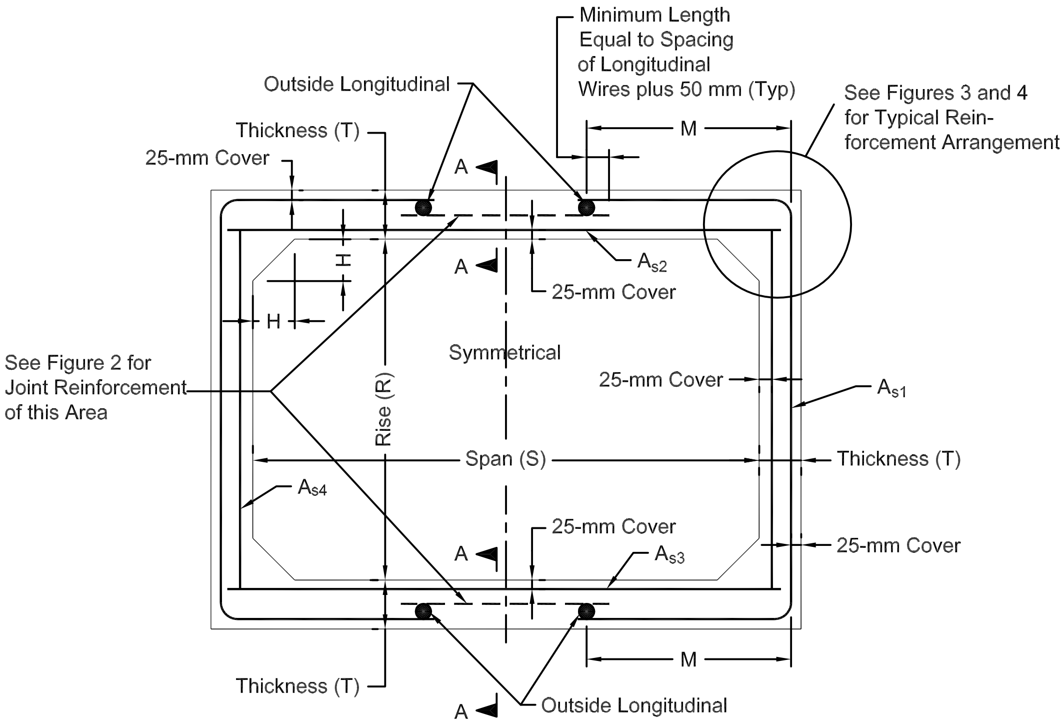
6.4. *Admixtures and Blends*—Admixtures and blends may be used with the approval of the owner.

6.5. *Steel Reinforcement*—Reinforcement shall consist of welded wire fabric conforming to M 55M/M 55 or M 221M/M 221.

6.6. *Synthetic Fibers*—Collated fibrillated virgin polypropylene fibers may be used, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be accepted.

7. DESIGN

7.1. *Design Tables*—The box section dimensions, compressive strength of the concrete, and reinforcement details shall be as prescribed in Tables 1, 2, or 3 and Figures 1, 2, and 3, subject to the provisions of Section 11. Table 1 sections are designed for combined earth dead load and AASHTO HS20 live load conditions. Table 2 sections are designed for combined earth dead load and Interstate live load conditions when the Interstate live loading exceeds the HS20 live loading. Table 3 sections are designed for earth dead load conditions only. Criteria used to develop Tables 1, 2, and 3 are given in Appendix X1. For modifications to the designs shown in Tables 1, 2, and 3 due to anticipated earth and surcharge loads different from those used to develop the tables, see Appendix X2.



Notes: 1. The dimension *M* is the total of the theoretical cutoff length plus the required anchorage.
2. The haunch dimension *H* is equal to the thickness *T*.

Figure 1—Typical Box Section

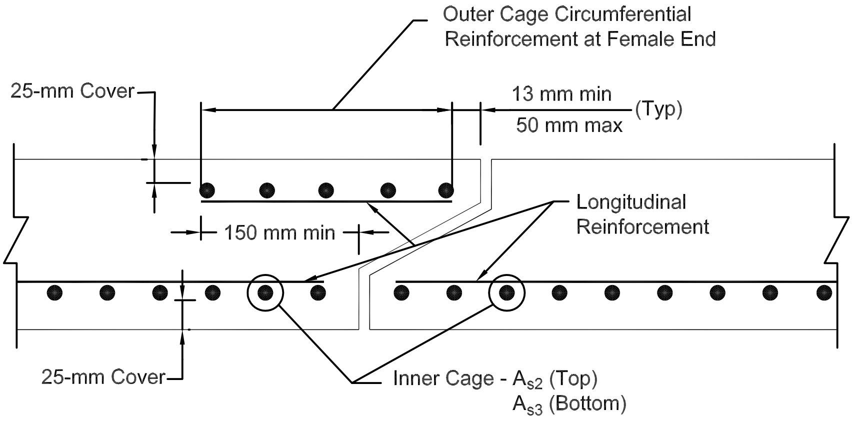


Figure 2—Section A-A Top and Bottom Slab Joint Reinforcement

7.2. *Modified and Special Designs*—The manufacturer may request approval by the owner of modified designs that differ from the designs in Section 7, or special designs for sizes and loads other than those shown in Tables 1, 2, and 3.

Note 3—The tabular designs in this specification were prepared according to AASHTO *Standard Specifications for Highway Bridges*, 1973 Edition. The current AASHTO *Standard Specifications for Highway Bridges* allows concrete shear stress criteria that differ from the 1973 criteria. The use of current AASHTO concrete shear stress criteria shall be acceptable by this specification for modified or special designs.

7.3. *Placement of Reinforcement*—The cover of concrete over the circumferential reinforcement shall be 25 mm, subject to the provisions of Section 11. The inside circumferential reinforcement shall extend into the male portion of the joint and the outside circumferential reinforcement shall extend into the female portion of the joint. The clear distance of the end circumferential wires shall be not less than 13 mm or more than 50 mm from the ends of the box section. Reinforcement shall be assembled utilizing any combination of single or multiple layers of welded-wire fabric. A common reinforcement unit may be utilized for both A_{s2} (or A_{s3}) and A_{s4}, with the largest area requirement governing, bending the reinforcement 90 degrees at the corners and waiving the extension requirements of Figure 3. (See Figure 4.) The welded-wire fabric shall be composed of circumferential and longitudinal wires meeting the spacing requirements of Section 7.4 and shall contain sufficient longitudinal wires extending through the box section to maintain the shape and position of reinforcement. The exposure of the ends of longitudinals, stirrups, and spacers used to position the reinforcement shall not be a cause for rejection.

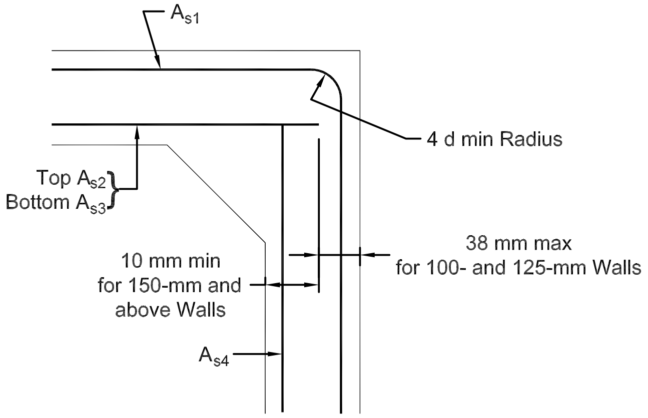

Figure 3—Detail Inner Reinforcement

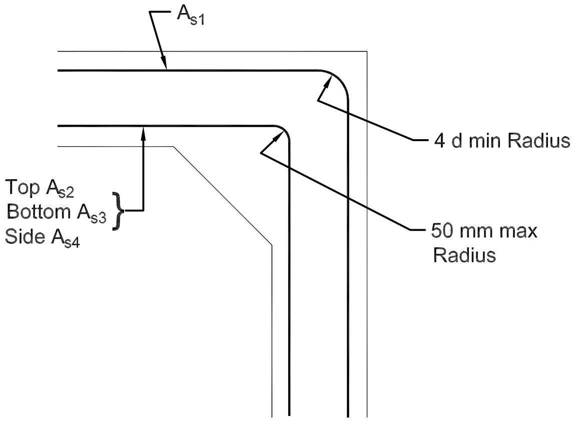

Figure 4—Detail Option

7.4. *Laps, Welds, and Spacing*—Splices in the circumferential reinforcement shall be made by lapping. The overlap measured between the outermost longitudinal wires of each fabric sheet shall not be less than the spacing of the longitudinal wires plus 50 mm. If A_{s1} is extended and connected, welded splices shall be allowed in the connection. A_{s4} may be lapped and welded at any location or connected by welding at the corners to A_{s2} and A_{s3}. The spacing center-to-center of the circumferential wires shall not be less than 50 mm nor more than 100 mm. The spacing center-to-center of the longitudinal wires shall not be more than 200 mm.

8. JOINTS

8.1. The precast reinforced concrete box sections shall be produced with male and female ends. The ends shall be of such design and the ends of the box sections so formed that the sections can be laid together to make a continuous line of box sections compatible with the permissible variations given in Section 11.

8.2. Outer cage circumferential reinforcement as shown in Figures 1 and 2 shall be placed in the top and bottom slabs at the female portion of the joint when A_{s1} is not continuous over the span. The minimum area of such reinforcement in square millimeters per linear meter of box section length shall be the same as the areas specified for A_{s4} in Tables 1, 2, and 3.

9. MANUFACTURE

9.1. *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious materials ratio not exceeding 0.53 by mass. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 280 kg/m^3 unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this specification.

9.2. *Curing*—The box sections shall be cured for a sufficient length of time so that the concrete will develop the specified compressive strength in 28 days or less. Any one of the following methods of curing or combinations thereof may be used:

9.2.1. *Steam Curing*—The box sections may be low pressure, steam cured by a system that will maintain a moist atmosphere.

9.2.2. *Water Curing*—The box sections may be water cured by any method that will keep the sections moist.

9.2.3. *Membrane Curing*—A sealing membrane conforming to the requirements of M 148 may be applied and shall be left intact until the required concrete compressive strength is attained. The concrete temperature at the time of application shall be within 6ºC of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

9.3. *Forms*—The forms used in manufacture shall be sufficiently rigid and accurate to maintain the box section dimensions within the permissible variations given in Section 11. All casting surfaces shall be of smooth nonporous material.

9.4. *Handling*—Handling devices or holes shall be permitted in each box section for the purpose of handling and laying.

10. PHYSICAL REQUIREMENTS

10.1. *Type of Specimen*—Compression tests for determining concrete compressive strength may be made on either concrete cylinders or on cores drilled from the boxed section.

10.2. *Compression Testing of Cylinders*:

10.2.1. *Cylinder Production*—Cylinders shall be prepared in accordance with the Cylinder Strength Test Method of T 280.

10.2.2. *Number of Cylinders*—Prepare not fewer than five test cylinders from a group (1 day's production of each concrete strength) of box sections.

10.2.3. *Acceptability on the Basis of Cylinder Test Results*:

10.2.3.1. When the compressive strengths of all cylinders tested for a group are equal to or greater than the design concrete strength, the compressive strength in the group of box sections shall be accepted.

10.2.3.2. When the average compressive strength of all cylinders tested is equal to or greater than the design concrete strength, not more than 10 percent of the cylinders tested have a compressive strength less than the design concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the design concrete strength, then the compressive strength of the concrete in the group of box sections shall be accepted.

10.2.3.3. When the compressive strength of the cylinders tested does not conform to the acceptance criteria stated in Sections 10.2.3.1 or 10.2.3.2, the acceptability of the group shall be determined in accordance with the provisions of Section 10.2.

10.3. *Compression Testing of Cores*:

10.3.1. *Obtaining Cores*—Cores shall be obtained and prepared in accordance with the Core Strength Test Method of T 280.

10.3.2. *Number of Cores*—One core shall be taken from a box section selected at random from each group of 15 box sections of a single size or fraction of such a group from each continuous production run.

10.4. *Acceptability on the Basis of Core Test Results*:

10.4.1. When the compressive strengths of cores tested for a group of box sections is equal to or greater than the design concrete strength, the compressive strength of the concrete for the group is acceptable.

10.4.2. If the compressive strength of the core tested is less than the design concrete strength, the box section from which that core was taken may be re-cored. If the compressive strength of the re-core is equal to or greater than the design concrete compressive strength, the compressive strength of the concrete for the group is acceptable.

10.4.3. If the compressive strength of the re-core is less than the design concrete strength, the box section from which the core was taken shall be rejected. Two box sections from the remainder of the group shall be selected at random and one core shall be taken from each box section. If the compressive strength of both cores is equal to or greater than the design concrete compressive strength, the concrete compressive strength of the remainder of the group shall be acceptable. If the compressive strength of either of the two cores tested is less than the design concrete compressive strength, then the remainder of the group shall be either rejected or, at the option of the manufacturer, each box section of the remainder of the group shall be cored and accepted individually, and any of the box sections that have a core with less than the design concrete compressive strength shall be rejected.

10.5. *Plugging Core Holes*—The core holes shall be plugged and sealed by the manufacturer in a manner such that the box section will meet all of the test requirements of this specification. Box sections so sealed shall be considered as satisfactory for use.

10.6. *Test Equipment*—Every manufacturer furnishing box sections under this specification shall furnish all facilities and personnel necessary to carry out the tests required.

11. PERMISSIBLE VARIATIONS

11.1. *Internal Dimensions*—The box culvert manufacturer shall establish the rise and span of the existing equipment to the nearest millimeter and verify that it is within the limits given in Table 4. The internal dimensions shall not vary more than 1 percent from the manufacturer's established metric size.

Table 4—Permissible Variation in Internal Size (Span or Rise)

Designated Size, mm	Permissible Variation, Internal Size, mm	
	Min	Max
600	600	620
900	900	920
1200	1200	1230
1500	1500	1540
1800	1810	1850
2100	2110	2160
2400	2410	2460
2700	2710	2770
3000	3020	3080
3300	3320	3390
3600	3620	3690

11.2. *Slab and Wall Thickness*—The slab and wall thickness shall not be less than that shown in the design by more than 5 percent or 5 mm, whichever is greater. A thickness more than that required in the design shall not be a cause for rejection.

11.3. *Length of Opposite Surfaces*—Variations in laying lengths of two opposite surfaces of the box section shall not be more than 10 mm/m of internal span, with a maximum of 16 mm for all sizes through 2100-mm internal span, and a maximum of 19 mm for internal spans greater than 2100 mm, except where beveled ends for laying on curves are specified by the owner.

11.4. *Length of Section*—The underrun in length of a section shall not be more than 10 mm/m of length with a maximum of 13 mm in any box section.

11.5. *Position of Reinforcement*—The maximum variation in the position of the reinforcement for 130 mm or less slab and wall thicknesses shall be ±10 mm and for greater than 130-mm slab and wall thicknesses shall be ±13 mm. In no case, however, shall the cover over the reinforcement be less than 16 mm, as measured to the internal surface or the external surface. The preceding minimum cover limitation does not apply at the mating surfaces of the joint.

11.6. *Area of Reinforcement*—The areas of steel reinforcement shall be the design steel areas as shown in Tables 1, 2, or 3. Steel areas greater than those required shall not be cause for rejection. The permissible variation in diameter of any wire in finished fabric shall conform to the tolerances prescribed for the wire before fabrication by either M 32M/M 32 or M 225M/M 225 as applicable.

12. REPAIRS

12.1. Box sections may be repaired, if necessary, because of imperfections in manufacture or handling damage and will be acceptable if, in the opinion of the owner, the repaired box section conforms to the requirements of this specification.

13. INSPECTION

13.1. The quality of materials, the process of manufacture, and the finished box sections shall be subject to inspection by the owner.

14. REJECTION

14.1. Box sections shall be subject to rejection if it fails to conform to any of the specification requirements. Individual box sections may be rejected because of any of the following:

14.1.1. Fractures or cracks passing through the wall, except for a single end crack that does not exceed the depth of the joint.

14.1.2. Defects that indicate mixing and molding, not in compliance with Section 9.1, or honeycombed or open texture that would adversely affect the function of the box sections.

14.1.3. The ends of the box sections are not normal to the walls and centerline of the box section, within the limits of variations given in Section 11, except where beveled ends are specified.

14.1.4. Damaged ends, where such damage would prevent making a satisfactory joint.

15. MARKING

15.1. The following information shall be clearly marked on each box section by indentation, waterproof paint, or other approved means:

15.1.1. Box section span, rise, table number, maximum and minimum design earth cover, and specification designation;

15.1.2. Date of manufacture;

15.1.3. Name or trademark of the manufacturer; and

15.1.4. Each section shall be clearly marked by indentation on either the inner or outer surface during the process of manufacture so that the location of the top will be evident immediately after the forms are stripped. In addition, the word “top” shall be lettered with waterproof paint on the inside top surface.

16. KEYWORDS

16.1. Concrete box—precast; culvert.

APPENDIX

(Nonmandatory Information)

X1. DESIGN CRITERIA USED TO DEVELOP TABLES 1, 2, AND 3

X1.1. *Bedding and Backfill Assumptions*:

X1.1.1. The bedding is assumed to provide a slightly yielding, uniformly distributed support over the bottom width of the box section.

X1.1.2. The design earth covers and reinforcement areas are based on the mass of a column of earth over the width of the box section.

X1.1.3. Refer to Appendix X2 for other bedding and backfill conditions.

X1.2. *Criteria for Loads*:

X1.2.1. Design loads are based on the American Association of State Highway and Transportation Officials (AASHTO) *Standard Specifications for Highway Bridges*, Thirteenth Edition, 1973.

X1.2.2. Live loads for designs given in Table 1 are H20 truck wheel loads as defined in the AASHTO specifications. Live loads for designs given in Table 2 are either the H20 truck wheel loads, or interstate truck wheel loads as defined in U.S. Department of Commerce, Bureau of Public Roads Circular Memorandum 22-40, 22 April 1957, depending upon whichever produces the more severe design strength requirements. Distribution of truck wheel loads through earth fills is in accordance with Article 1.3.3 in the AASHTO specifications. Earth cover loads for designs given in Tables 1, 2, and 3 are the mass of a column of earth of a width equal to the outside width dimension of the box section and a height equal to the depth of earth cover over the top of the section. This earth load is recommended in Article 1.2.2 (A) of the AASHTO Bridge Specifications for the normal case of box culverts on “yielding” subgrade. The AASHTO specifications define an “unyielding” subgrade as “rock or piles” and requires the use of the Iowa formulas for this case. See Appendix X2 for a method to modify the designs given in Tables 1, 2, and 3 when the anticipated earth load, or earth load plus uniformly distributed surface surcharge load, is greater (or less) than the mass of the column of earth directly above the out-to-out width of the box sections.

X1.2.3. Article 1.2.2 of the AASHTO specification allows the design of buried structures, such as box section culverts, for 70 percent of the mass of earth directly above the out-to-out width of structure. On the other hand, the Marston-Spangler theory of earth loads on buried pipe gives a total earth load greater than the mass of the column of earth directly over the structure for most “positive projecting” culverts, and less than the mass of the column of earth over the structure for “trench type” installations, “negative projecting” culverts, and “induced trench” culverts. In view of the number of different installation conditions that may be encountered and the use of higher reinforcing steel stresses associated with the ultimate strength design method (see Section X1.2), the 30 percent reduction in mass of supported earth load permitted in Article 1.2.2 of the AASHTO specification is not utilized for the tabulated designs, and a method of modifying designs for anticipated earth loads that differ from the above described "standard earth load" is given in Appendix X2.

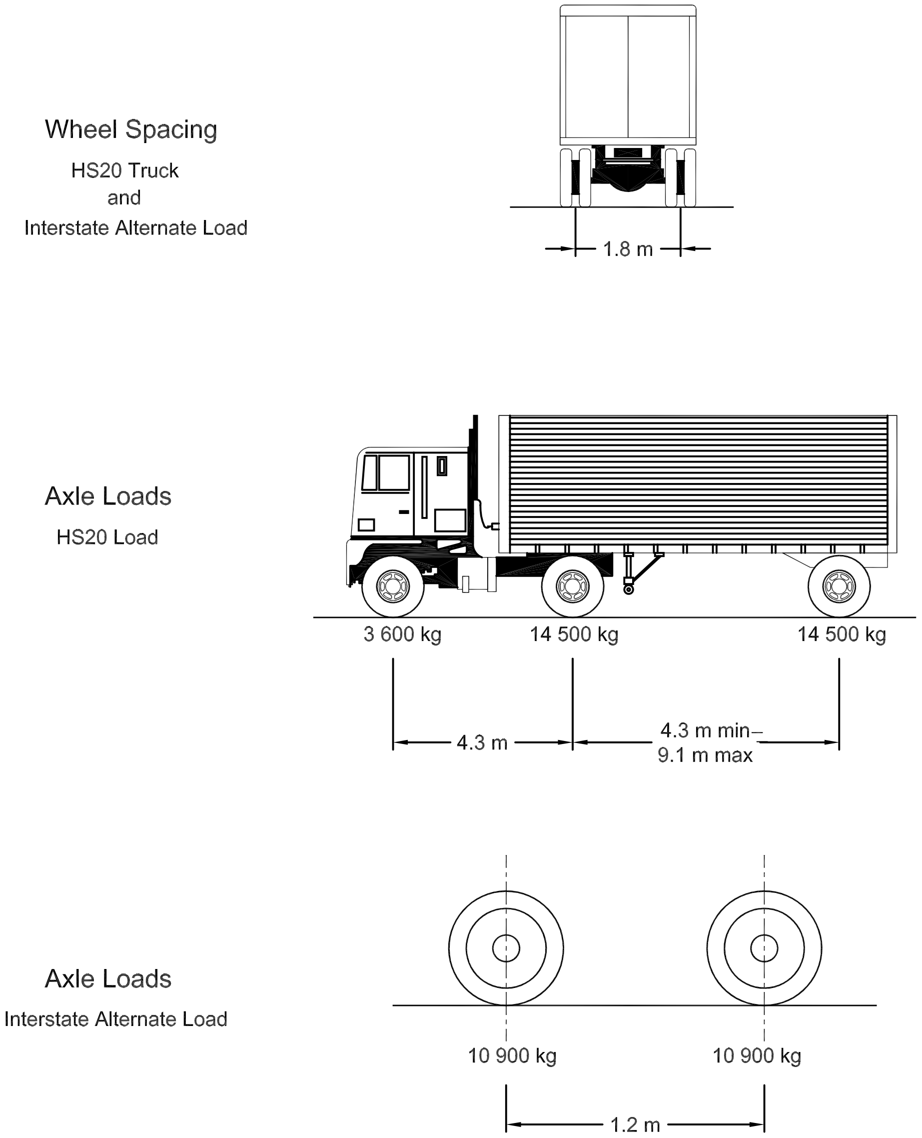

Figure X1.1—Axle Loads for Box Section Standard Designs

X1.2.4. Lateral earth pressure from mass of earth above and adjacent to a box section is taken as a minimum of 0.25 times vertical pressure, and an additional 0.25 times vertical pressure is added when determining steel areas only when areas are increased by such increased lateral pressure. For Tables 1 and 2, additional lateral pressure in pascals per square meter from approaching truck wheel loads is taken as 15 divided by depth of earth cover in meters and is added when determining steel areas only at sections where area is increased by lateral pressure.

X1.3. *Methods of Analysis*:

X1.3.1. The structural effects of the loads described in Section X1.2 are evaluated based on the elastic method of structural analysis. Design moments, shears, and thrusts are determined by computer analysis using the stiffness matrix method, and design is based on maximum stress resultants at critical sections caused by the most severe combination of design loads.

X1.4. *Method of Design*:

X1.4.1. Design heights of earth cover, wall thicknesses, and reinforcing steel areas are determined based on the elastic method of structural analysis and the ultimate strength method of reinforced concrete design given in the 1971 ACI Building Code (ACI 318-71).[2] Steel areas are governed by ultimate flexural strength. The steel areas and the size and spacing of circumferential wires are proportioned to limit the maximum crack width to 0.3 mm under design load conditions. Evaluation of crack control with the welded wire fabric reinforcement specified for the tabulated designs is based on the results of research by Lloyd, Rejali, and Kesler[3] at the University of Illinois, and is significantly more conservative than the crack control provisions given in ACI 318-71. This is because it is recognized that approximations that were used to simplify the ACI crack control provisions can result in unconservative designs for thin elements such as slabs. Standard designs do not cover installations that must resist significant external water pressure. Furthermore, installations that are subject to high external water pressure may require vertical reinforcement for the inside face of the side walls. Lloyd, Rejali, and Kesler suggest that crack control equations developed for deformed bar reinforcement may also be used for both welded smooth wire fabric and deformed wire fabric reinforcement.

X1.4.2. Note that some box section designs shown in the tables have steel area requirements designated by "D" as minimum practical steel area. For such designs, the steel areas calculated for support of design loads are less than the minimum steel area that is specified for slabs in AASHTO Specification, 0.002 bt, and thus, the minimum reinforcement areas are shown in the tables.

X1.4.3. For specific criteria used in Tables 1, 2, and 3, refer to Table X1.1.

X1.4.4. The maximum height of earth cover shown in the tables is determined by the shear strength of the box section without the use of special shear reinforcement, as given in Sections 11.2.1, 11.2.2, and 11.4.1 of ACI 318-71, and by the "standard mass" of the column of earth directly above the box section. See Table X1.2 for the maximum loads that can be carried on the standard box sections. These loads can be used to determine maximum earth cover heights, when the anticipated mass of earth supported by the section is greater than (or less than) the above "standard mass" of earth cover.

X1.5. *Multiple-Cell Installations*:

X1.5.1. The designs given herein are for single cell precast reinforced concrete box sections. The units may be used in parallel for multicell installations if means of positive lateral bearing by continuous contact between the sides of adjacent boxes are provided. Compacted earth fill, granular backfill, or grouting between the units are considered means of providing such positive bearing.

Table X1.1—Specific Criteria Used for Tables 1, 2, and 3

Material Properties:	
Welded wire fabric, minimum specified yield stress	445 MPa
Concrete, minimum specified compressive strength	35 MPa
Soil Data:	
Unit mass	1920 kg/m^3
Ratio of lateral to vertical pressure from mass of earth	0.25 min to 0.50 max
Additional lateral pressure from approaching truck wheels	33.5 ÷ H, kPa where H = earth cover, m
External water table	below box section invert
Effective mass coefficient	1.0
Capacity Reduction Factors (from ACI 318-71):	
Shear	0.85
Axial compression combined with bending[a]	0.70 to 0.90
Loading Data:	
Load factor—dead load	1.5
Load factor—live load	2.2
Truck axle load: H20 (Table 1)	14500 kg
Interstate (Table 2)	2 @ 10900 kg
None (Table 3)	—
Loading Data:	
Impact (variable with depth) (See AASHTO Bridge Specifications, 1969	0 to 20 percent
Uniform internal pressure	0.0
Depth of water in box section	equal to inside height
External groundwater pressure	0.0
Structural Arrangement:	
Concrete cover over steel	25 mm
Slab thickness	$^{1}/_{12}$ times inside span plus 25 mm up to 2100-mm span—$^{1}/_{12}$ inside span above 2100-mm span
Side wall thickness	equal to slab thickness
Haunch dimensions	vertical and horizontal dimensions both equal to slab thickness
Minimum reinforcing inside face slabs and side walls, outside face side walls and corners of slabs	0.002 bt
The structural arrangement and details are shown in Figure 1	

Table X1.2—Design Information for Revising Tabulated Reinforcing Steel

Box Section Designated Span × Rise × Wall Thickness, mm	Change in Reinforcing Steel Area per kg/m, Change in Total Mass on Box Section		Maximum W, kg/m[a]	Box Section Designated Span × Rise × Wall Thickness, mm	Change in Reinforcing Steel Area per kg/m, Change in Total Mass on Box Section		Maximum W, kg/m[a]

[a] Maximum allowable total mass on box section as governed by shear strength of box section without stirrups.

X2. MODIFICATION OF “STANDARD’’ BOX SECTION DESIGNS FOR EARTH LOADS DIFFERENT FROM THE “STANDARD” EARTH LOAD

X2.1. The heights of cover given in Tables 1, 2, and 3 are based on a “standard mass of earth fill” equal to the mass of a column of earth with a unit mass of 1920 kg/m^3 and a width equal to the out-to-out width of the box section. For some installations, the design engineer may determine that for a given height of cover, the mass of earth to be supported by the box section is more or less than the above “standard mass of earth fill” used to develop the designs given in the tables.

X2.1.1. For example, the Marston-Spangler theory for loads on buried structures indicates that the mass of earth that must be supported by most “positive projecting” conduits is greater than the mass of a column of earth directly over the conduit, while the mass of earth that must be supported by “trench-type” conduits, “negative-projecting” conduits, and “induced-trench” conduits is less than the mass of earth over the conduits. Also, the designer may wish to use a unit mass of earth more or less than the 1920 kg/m^3 used in the “standard mass,” or may wish to include a particular uniformly distributed surface surcharge loading.

X2.2. Incremental reinforcing steel areas are given in Table X1.2 for each box section type. Where installation conditions warrant the use of a mass of earth more or less than the “standard mass,” the designer may utilize these incremental areas to modify the steel areas given in Tables 1, 2, or 3 for a particular height of cover. The maximum total mass of earth fill that may be supported over the out-to-out width of each standard box section size, as governed by shear strength without shear reinforcing, is also given in Table X1.2. Thus, for any mass of earth or surface surcharge, or both, a designer can use Tables 1, 2, 3, and X1.2, to determine the required area of reinforcing steel for various heights of earth cover, or the maximum height of earth cover without special shear reinforcing, for any of the standard box section sizes shown in these tables.

X2.3. The following design example illustrates how the previously mentioned tables may be used to obtain a suitable design for a box section to support an earth load that is greater than the "standard mass of earth" used to develop Tables 1, 2, and 3.

X2.3.1. *Example*:

X2.3.1.1. *Given*—A 1800 by 1800 by 175 mm. Table 1 precast concrete box section under 4.3 m of cover with 1760 kg/m^3 earth and an effective mass of earth supported by the section of 1.36 times the mass of the column of earth directly over the section instead of the standard 1920 kg/m^3 earth.

X2.3.1.2. *Find*—The required A_{s1}, A_{s2}, and A_{s3} circumferential reinforcement areas. In all cases A_{s4} is governed by the minimum steel areas as described in X1.4.2 and is not changed by increased vertical loads.

X2.3.2. *Solution*:

X2.3.2.1. Effective unit mass of soil = 1760 + 1.36 = 2400 kg/m^3

X2.3.2.2. Determine change in total mass of earth on culvert in kilograms per linear meter:

$$W = H \times B \times w \tag{X2.1}$$

where:

W = total mass of earth on culvert, kg/linear m;

H = height of earth cover, m;

B = outside span, m;

w = unit weight of earth, kg/m^3;

W_{1920} = $4.3 \times 2.2 \times 1920 = 18200$ kg/m;

W_{2400} = $4.3 \times 2.2 \times 2400 = 22700$ kg/m;

W = $W_{2400} - W_{1920} = 4500$ kg/m.

X2.3.2.3. Determine the change in circumferential reinforcement areas. From Table 1, for an 1800 by 1800 by 175 mm section under 4.3 m of cover, A_{s1} = 360, A_{s2} = 680, and A_{s3} = 700 mm^2/m. From Table 6, for an 1800 by 1800 by 175 mm section, the changes in reinforcing areas are A_{s1} = 0.018; A_{s2} and A_{s3} = 0.040 mm^2/m for each kilogram per meter of load change. Therefore:

$$\Delta A_{s1} = 4500 \times 0.018 = 81$$

$$\Delta A_{s2} = 4500 \times 0.040 = 180$$

$$\Delta A_{s3} = 4500 \times 0.040 = 180$$

Therefore, the correct reinforcement areas are as follows:

$$A_{s1} = 360 + 81 = 441 \text{ mm}^2/\text{m}$$

$$A_{s2} = 680 + 180 = 860 \text{ mm}^2/\text{m}$$

$$A_{s3} = 700 + 180 = 880 \text{ mm}^2/\text{m}$$

X2.3.2.4. Determine if the total mass of earth on the culvert is less than maximum as governed by the shear strength of culvert without stirrups.

From Table 6, the maximum allowable mass = 25 200 kg/m. From Section X2.3.2.2,

$$W_{2400} = 22\,700 \text{ kg/m}$$

The approximate equivalent uniform load from an HS20 live load at 4.3-m burial depth is about 780 kg/m^2 or a total load 1720 kg/m (780 × 2.2). Therefore, the total mass on the box section is 24 400 kg/m (22 700 + 1720), which is less than the maximum allowable; therefore, the design is satisfactory.

---

[1] Standard designs and criteria used to develop designs included in this specification are under the jurisdiction of the AASHTO Subcommittee on Bridges and Structures. Agrees with ASTM C 507-98 except that the use of synthetic fibers will be at the owner's option.

Standard Definitions of Terms Relating to

Concrete Pipe and Related Products

AASHTO Designation: M 262-10[1]
ASTM Designation: C 822-08b

1. TERMINOLOGY

1.1 *absorption*—the increase in mass of concrete resulting from the penetration of water into the concrete.

1.2 *absorption test*—a test made to determine the absorption of concrete.

1.3 *admixture*—a material other than water, aggregates, and cement used as an ingredient of concrete and added to the batch immediately before or during its mixture.

1.4 *annular space*—the space between the inner surface of the female end and the outer surface of the male end of an assembled pipe joint.

1.5 *bell*—see *female end of pipe.*

1.6 *blend*—a combining of various cementitious materials.

1.7 *box section*—a concrete pipe with a rectangular cross section.

1.8 *box section bottom slab*—lower horizontal portion of a box section in the installed condition (M 259, M 273).

1.9 *box section top slab*—upper horizontal portion of a box section in the installed condition (M 259, M 273).

1.10 *box section wall*—vertical sides of a box section in the installed condition (M 259, M 273).

1.11 *cage*—an assembled unit of steel reinforcement consisting of circumferential and longitudinal bars or wires.

1.12 *circular reinforcement*—a circular-shaped line of reinforcement.

1.13 *circumferential reinforcement*—reinforcement that is approximately perpendicular to the longitudinal axis of the concrete pipe, box, or structure.

1.14 *combined sewer*—a pipeline intended to convey sewage and storm water.

1.15 *compressive strength*—the maximum resistance of a concrete specimen to axial compressive loading; or the specified resistance used in design calculations.

1.16 *compression test*—a test made on a concrete specimen to determine the compressive strength.

1.17 *concrete*—a homogeneous mixture of portland cement, fine aggregate, coarse aggregate, and water. The mixture may also contain admixtures or other cementitious materials or both.

1.18 *core*—a cylinder of concrete obtained from concrete by means of a core drill.

1.19 *crown*—the top or highest point of the internal surface of the transverse cross section of a pipe.

1.20 *culvert*—a pipeline intended to convey water under a highway, railroad, canal, or similar facility.

1.21 *cylinder (test)*—a cast cylindrical specimen of concrete.

1.22 *designated size*—the dimensional name for a particular size that may or may not be equal to or related to the dimensions used for design purposes or dimensions of the manufactured product.

1.23 *design strength*—the minimum acceptable 0.3-mm (0.01-in.) crack D-load.

1.24 *D-load*—the supporting strength of a pipe loaded under three-edge-bearing test conditions expressed in newtons per linear meter per millimeter of inside diameter or horizontal span (pounds per linear foot per foot of inside diameter or horizontal span).

1.25 *D-load, 0.3-mm (0.01-in.) crack*—the maximum three-edge-bearing test load supported by a concrete pipe before a crack having a width of 0.3 mm (0.01 in.) occurs, measured at close intervals, throughout a continuous length of 300 mm (1 ft) or more measured parallel to the longitudinal axis of pipe barrel expressed as D-load.

1.26 *D-load ultimate (Du)*—the maximum three-edge-bearing test load supported by a pipe, expressed as D-load.

1.27 *distribution reinforcement*—reinforcement, typically running 90 degrees to the main or circumferential reinforcement, intended to disperse concentrated loads to larger areas of a structural member.

1.28 *drain tile*—pipe for collecting and conveying surface and subsurface water from an area.

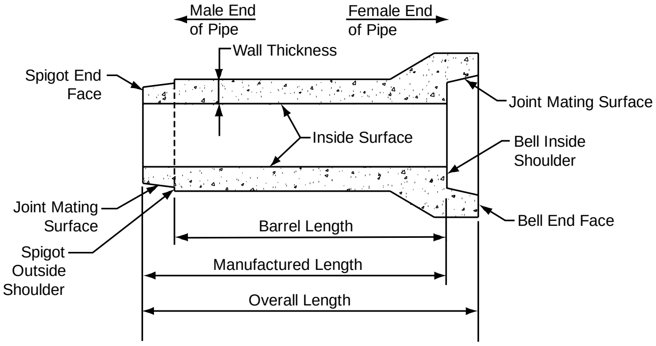
1.29 *elliptical reinforcement*—a line of reinforcement in the approximate shape of an ellipse.

1.30 *exfiltration*—the volume of pipeline flow leaving a sewer and its connections into the soil from pipe, joints, connections, and appurtenances.

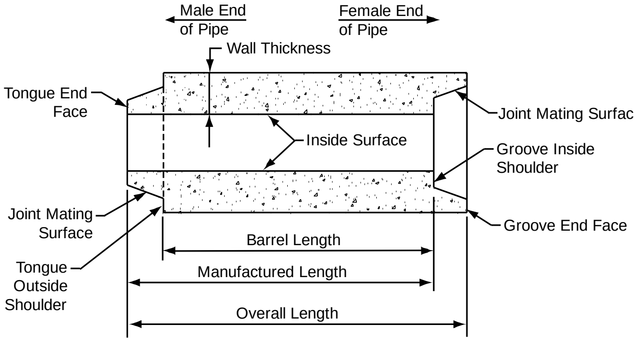
1.31 *external load-crushing strength test*—a test of the pipe in which external crushing forces are exerted in specified directions and locations on a specified length of pipe.

1.32 *external sealing bands*—flexible wrappings that are applied to the outside of a concrete pipe, box section, or manhole section joint intended to control the movement of fluids or solids through the joint.

1.33 *female end of pipe (bell, socket, groove, modified groove)*—that portion of the end of the pipe, regardless of its shape or dimensions, that overlaps a portion of the end of the adjoining pipe.



Bell and Spigot Pipe



Tongue and Groove Pipe

Notes:
1. This is a schematic drawing that only defines nomenclatures and cannot be used for joint designs.
2. Laying length is not shown and shall be as recommended by the pipe manufacturer when developing a pipe layout for field installations.
3. The length of the pipe used in the calculations for three-edge-bearing strength test results is defined as laying length in the Calculations section of T 280 and may not equal field laying length.

Figure 1—Pipe Nomenclature

1.34 *flow line*—a line formed by the inverts of pipe.

1.35 *gradation*—the distribution of particles of granular material among standard sizes usually expressed in terms of cumulative percentages larger or smaller than each of a series of sieve openings.

1.36 *grade rings*—precast concrete rings used for vertical adjustment at the top of a manhole to set manhole casting to proper grade.

1.37 *groove*—see *female end of pipe*.

1.38 *handling reinforcement*—reinforcement intended to reduce the risk of collapse of the pipe or section during handling or storage prior to and during final placement.

1.39 *hydrostatic pressure*—the pressure exerted by water at rest.

1.40 *hydrostatic test*—a test of the ability of a pipe or its joint to withstand internal hydrostatic pressure.

1.41 *infiltration*—the volume of groundwater entering a sewer and its connections from the soil through pipe, joints, connections, or appurtenances.

1.42 *inflow*—the volume of any kind of water entering a sewer and its connections from outside sources not including those sources described under "infiltration."

1.43 *installed length*—final length, along the centerline, of a pipe or box section in place including the longitudinal joint separation between the section and the last section placed.

1.44 *invert*—the bottom or lowest point of the internal surface of the transverse cross section of a pipe.

1.45 *irrigation pipe*—pipe intended for the distribution of irrigation water by pumping or gravity.

1.46 *joint*—a connection of two pipe, manhole, or box section ends, made either with or without the use of additional parts or materials, or both.

1.47 *joint angular deflection*—change in alignment commencing in the joint caused by opening or closing one side of the joint.

1.48 *joint at normal (design) closure*—position of the joint when closed to the manufacturer's recommended inside longitudinal separation without joint angular deflection.

1.49 *joint in off-center position*—with the joint at normal or design closure, without joint angular deflection, when the spigot or bell has been moved in a radial direction. The maximum off-center position occurs when the outer surface of the spigot and the inner surface of the bell are in contact.

1.50 *joint leakage test*—test procedure, utilizing water pressure, air pressure or a vacuum, intended to determine the acceptability of an individual joint relative to leakage.

1.51 *joint leakage test apparatus*—sealing device used to isolate a single joint so that the joint can be tested for leakage. See *joint leakage test.*

1.52 *joint reinforcement*—reinforcement, in or near the joint, intended to enhance the structural characteristics of the joint area of a concrete pipe or box section.

1.53 *joint shear test*—a proof-of-design test procedure to determine minimum shear strength of a joint.

1.54 *layer of reinforcement*—circumferential reinforcement that is one bar or wire in thickness.

1.55 *laying length*—pipe section centerline dimension used for preparing pipeline layout plans. The length as measured from a point on a pipe to an identical point of an adjacent pipe of an installed pipeline.

1.56 *lift hole*—a small hole cast or drilled in the wall of the pipe or section for inserting a bolt, loop of cable or other device used in handling the pipe or section.

1.57 *line of reinforcement*—circumferential reinforcement comprised of one or more layers.

1.58 *longitudinal reinforcement*—reinforcement, in a concrete pipe or box section, running parallel to the intended flow.

1.59 *lot*—an assemblage of concrete pipe, all being of like size, material, and strength designation, manufactured by the same process. The lot size may differ from the quantity designated in the contract or order.

1.60 *low-pressure air test*—testing procedure, utilizing compressed air, intended to determine the acceptability of a pipe section, joint, or pipeline.

1.61 *male end of pipe (spigot, tongue, modified tongue)*—that portion of the end of the pipe, regardless of its shape or dimensions, that is overlapped by a portion of the end of the adjoining pipe.

1.62 *manhole*—a precast concrete structure for vertical access to a pipeline or other closed structure.

1.63 *manhole base*—a concrete slab foundation and the bottom manhole riser section or a bottom manhole riser section with a connected concrete slab.

1.64 *manhole base section*—precast concrete slab foundation and the bottom manhole rise section, or the bottom riser section with precast monolithic or integral slab. A monolithic base section is cast as a single unit. An integral base section is made into a single unit by interconnecting precast manhole components such as a riser section and base slab.

1.65 *manhole reducer section*—a concrete pipe section used as a transition between different-diameter manhole riser sections

1.66 *manhole riser section*—a concrete pipe section used to construct a manhole exclusive of the base, reducers, and top section.

1.67 *manhole top*—the concrete slab top or conical top used to reduce the manhole riser diameter to that of the desired access hole.

1.68 *manufactured length*—the length from spigot/tongue end face to bell/groove inside shoulder.

1.69 *manufacturer*—the group, corporation, partnership, or individual that manufactures or supplies a product.

1.70 *mat reinforcement*—see *quadrant mat.*

1.71 *material tests*—the quality and property tests of component materials.

1.72 *modified design*—a concrete pipe design changed from a standard design.

1.73 *modified groove*—see *female end of pipe*.

1.74 *modified tongue*—see *male end of pipe*.

1.75 *negative air pressure (vacuum) test*—test procedure utilizing air at a pressure less than atmospheric pressure, intended to determine the acceptability of a pipe section or multiple pipe sections, or an installed pipeline or manhole before or after backfill.

1.76 *nonreinforced pipe*—concrete pipe designed without reinforcement.

1.77 *O-ring gasket*—a solid gasket of circular cross section.

1.78 *overall length*—the length from the spigot/tongue end face to bell/groove end face.

1.79 *owner*—the public agency or authority, group, corporation, partnership, or individual that specifies products or services for use on a project that it presently or eventually will own or administrate.

1.80 *permeability*—that property that permits movement of a liquid through the pores and interstices of the concrete.

1.81 *permeability test*—a test to determine the movement of a liquid through concrete under a hydraulic or pressure gradient.

1.82 *pipe*—a tube or elongated hollow concrete structure intended to transmit flow between locations.

1.83 *pipe diameter*—the inside diameter of a concrete pipe.

1.84 *pipe section*—a single pipe.

1.85 *pipeline*—pipe sections joined together.

1.86 *plant tests*—the quality assurance tests performed prior to delivery as a basis of acceptance.

1.87 *preformed flexible joint sealant*—pliable material, formed into a defined cross section, that is applied to the surface of a pipe, box section, or manhole section joint, intended to control the movement of fluids or solids through the joint.

1.88 *quadrant mat*—additional tension zone circumferential reinforcement secured to a layer of reinforcement in the concrete pipe wall.

1.89 *reinforced concrete pipe*—a pipe structure comprised of concrete and steel reinforcement. Such reinforcement is composed of steel wire, welded wire fabric, or bars, of known strength, formed into a cage and positioned in the concrete wall in a specific location in such a manner that the two materials act together to resist stresses.

1.90 *reinforcement*—steel in the form of continuous wire, welded wire fabric, or bars embedded in concrete in such a manner that the above referenced concrete and steel act together to resist stresses.

1.91 *resilient connector*—a flexible connection for joining pipe to structures capable of being deformed and deflected without rupture or leakage.

1.92 *rubber gasket*—rubber formed and used as a seal in concrete pipe joints.

1.93 *sample*—the number of specimens drawn from a lot.

1.94 *sewage (wastewater)*—the spent water of a community that is a combination of liquid and water-carried wastes.

1.95 *sewer*—a pipeline intended to convey sewage.

1.96 *special design*—a concrete pipe design for sizes, loads, or service conditions not covered by a standard design.

1.97 *specimen*—an individual unit on which a test can be made.

1.98 *spigot*—see *male end of pipe*.

1.99 *splice (reinforcement)*—junction of two sections of parallel reinforcement intended to provide continuity and to transfer forces between the two sections.

1.100 *springline*—the points on the internal surface of the transverse cross section of a pipe intersected by the line of maximum horizontal dimension; or in box sections, the mid-height of the internal vertical wall.

1.101 *standard design*—a published and proven concrete pipe design.

1.102 *storm drain*—a pipeline intended to convey storm water.

1.103 *storm sewer*—a pipeline intended to convey storm water.

1.104 *stormwater*—precipitation run-off.

1.105 *three-edge-bearing method*—a method for applying the load to a pipe in an external load-crushing strength test.

1.106 *tongue*—see *male end of pipe*.

1.107 *ultimate strength*—the maximum three-edge-bearing test load supported by a pipe.

1.108 *wall (pipe)*—the structural element composed of concrete or concrete and steel between the inside and outside surfaces of a concrete pipe.

1.109 *watertight*—will restrain the passage of water to not exceed a specified limit.

---

[1] Agrees with ASTM C 822-08b except for the definition of "admixture."

Standard Specification for

Acrylonitrile-Butadiene-Styrene (ABS) and Poly(Vinyl Chloride) (PVC) Composite Sewer Piping

AASHTO Designation: M 264-03 (2007)
ASTM Designation: D 2680-01

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Acrylonitrile-Butadiene-Styrene (ABS) and Poly(Vinyl Chloride) (PVC) Composite Sewer Piping

AASHTO Designation: M 264-03 (2007)
ASTM Designation: D 2680-01

AASHTO M 264-03 (2007) is identical to ASTM D 2680-01 except for the following provisions:

1. Add the following to Section 2.1 of ASTM D 2680-01:
   - D 883, Standard Terminology Relating to Plastics
2. Replace the first sentence of Section 3.1.1 of ASTM D 2680-01 with the following:

   Definitions are in accordance with ASTM D 883 and F 412 and abbreviations are in accordance with ASTM D 1600, unless otherwise indicated.
3. Replace the first sentence of Section 5.2.2 of ASTM D 2680-01 with the following:

   The thermoplastic material shall be a rigid PVC plastic and shall meet or exceed the requirements of ASTM D 4396, for a minimum cell classification of 11432.

Standard Specification for

Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers with Less Than 2 ft of Cover Subjected to Highway Loadings

AASHTO Designation: M 273-00 (2008)[1]
ASTM Designation: C 850-95a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers with Less Than 2 ft of Cover Subjected to Highway Loadings

AASHTO Designation: M 273-00 (2008)[1]
ASTM Designation: C 850-95a

1. SCOPE

1.1. This specification covers single-cell, precast reinforced concrete box sections with less than 2 ft of cover subjected to highway loadings and intended to be used for the construction of culverts and for the conveyance of storm water, industrial wastes, and sewage.

1.2. A complete metric companion to M 273 has been developed—M 273M; therefore, no metric equivalents are presented in this specification.

Note 1—This specification is primarily a manufacturing and purchasing specification. However, standard designs are included and the criteria used to develop these designs are given in Appendix X1. The successful performance of this product depends upon the proper selection of the box section, bedding, backfill, controlled manufacture in the plant, and care that the installation conforms to the construction specifications. The owner of the precast reinforced concrete box sections specified herein is cautioned that the loading conditions and the field requirements must be correlated with the box sections specified and that inspection at the construction site must be provided.

Note 2—AASHTO M 259 is to be used for box sections subjected to highway loading with 2 ft or more earth cover, or subjected to dead load only.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 31M/M 31, Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement
- M 32M/M 32, Steel Wire, Plain, for Concrete Reinforcement

- *Standard Specifications for Highway Bridges*

2.2. *ASTM Standard*:

- C 1116, Standard Specification for Fiber-Reinforced Concrete

3. TERMINOLOGY

3.1. *Definitions*—For definitions of terms relating to concrete pipe, see M 262.

4. TYPES

4.1. Precast reinforced concrete box sections manufactured in accordance with this specification shall be of the types identified in Tables 1 and 2, and shall be designated by type, span, and rise.

5. BASIS OF ACCEPTANCE

5.1. Acceptability of the box sections produced in accordance with Section 7 shall be determined by the results of the concrete compressive strength tests described in Section 10, by the material requirements described in Section 6, and by inspection of the finished box sections.

5.2. Box sections shall be considered ready for acceptance when they conform to the requirements of this specification.

6. MATERIALS

6.1. *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water, in which steel has been embedded in such a manner that the steel and concrete act together.

6.2. *Cementitious Materials*:

6.2.1. *Cement*—Cement shall conform to the requirements for portland cement of M 85 or shall be portland blast-furnace slag cement or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash and shall not exceed 25 percent by weight.

Table 1—Design Requirements for Precast Reinforced Concrete Box Sections with Less Than 2 ft of Cover Subjected to HS20 Loading[a]

Box Section	Thickness, in.			Circumferential Reinforcement Areas[c]						Distribution Reinforcement Areas[d]

[a] Design requirements are based on maximum effects resulting from cover conditions ranging from 0 to 2 ft and the material and soil properties and loading data shown in Appendix X1. For modified or special designs, see Section 7.2.

[b] The box section designation, for example 3 by 2, indicates interior horizontal span, in feet, by interior vertical rise, in feet.

[c] Design reinforcement areas in square inches per linear foot of box section length at those locations as shown in Figure 1.

[d] Design reinforcement areas in square inches per linear foot of box section width at those locations as shown in Figure 1.

[e] Minimum reinforcement area is specified.

Notes:
1. Reinforcement areas are based on the weight of a column of earth over the width of the box section plus live loads as defined in Appendix X1.
2. Concrete design strength, 5000 psi.

Table 2—Design Requirements for Precast Reinforced Concrete Box Sections with Less Than 2 ft of Cover Subjected to Interstate Loading[a]

[a] Design requirements are based on maximum effects resulting from cover conditions ranging from 0 to 2 ft and the material and soil properties and loading data shown in Appendix X1. For modified or special designs, see Section 7.2.

[b] The box section designation, for example 3 by 2, indicates interior horizontal span, in feet, by interior vertical rise, in feet.

[c] Design reinforcement areas in square inches per linear foot of box section length at those locations as shown in Figure 1.

[d] Design reinforcement areas in square inches per linear foot of box section width at those locations as shown in Figure 1.

[e] Minimum reinforcement area is specified.

Notes:
1. Reinforcement areas are based on the weight of a column of earth over the width of the box section plus live loads as defined in Appendix X1.
2. Concrete design strength 5000 psi.

6.2.2. *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.3. *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in concrete shall be one of the following:

6.2.3.1. Portland cement only,

6.2.3.2. Portland blast-furnace slag cement only,

6.2.3.3. Portland-pozzolan cement only, and

6.2.3.4. A combination of portland cement and fly ash wherein the proportion of fly ash is between 5 and 25 percent by weight of total cementitious material (portland cement plus fly ash).

6.3. *Aggregates*—Aggregates shall conform to M 6 and M 80 except that the requirements for gradation shall not apply.

6.4. *Admixtures and Blends*—Admixtures and blends may be used with the approval of the owner.

6.5. *Steel Reinforcement*—Reinforcement shall consist of welded wire fabric conforming to M 55M/M 55 or M 221M/M 221. Longitudinal distribution reinforcement may consist of welded wire fabric or deformed billet-steel bars conforming to M 31M/M 31, Grade 60.

6.6. *Synthetic Fibers*—Polypropylene fibers may be used, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be accepted.

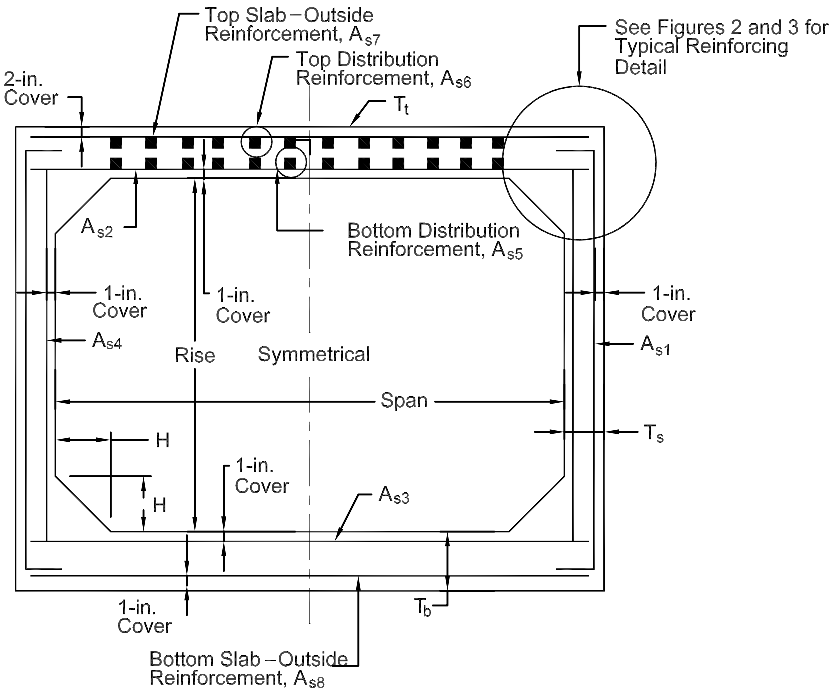
7. DESIGN

7.1. *Design Tables*—The box section dimensions, compressive strength of the concrete, and reinforcement details shall be as prescribed in Tables 1 or 2 and Figures 1 and 2, subject to the provisions of Section 11. Table 1 sections are designed for a cover range from 0 to 2 ft plus AASHTO HS20 live load conditions. Table 2 sections are designed for a cover range from 0 to 2 ft plus Interstate live load conditions. Criteria used to develop Tables 1 and 2 are given in the Appendix X1.

7.2. *Modified and Special Designs*—The manufacturer may request approval by the owner of modified designs that differ from the designs in Section 7.1; or special designs for sizes and loads other than those shown in Tables 1 and 2.

7.3. *Placement of Reinforcement*—The cover of concrete over the circumferential reinforcement shall be 1 in. except in the outside top of the top slab where it shall be 2 in., subject to the provisions of Section 11. The inside circumferential and longitudinal reinforcement shall extend into the male portion of the joint and the outside circumferential and longitudinal reinforcement shall extend into the female portion of the joint. The clear distance of the end circumferential wires shall be not less than $^1/_2$ in. or more than 2 in. from the ends of the box section. Reinforcement shall be assembled utilizing any combination of single or multiple layers of welded-wire fabric. Common reinforcement units may be utilized for both A_{s2} (or A_{s3}) and A_{s4}, and also for both A_{s7} (or A_{s8}) and A_{s1}, with the largest area requirement of each combination governing, bending the reinforcement

90 degrees at the corners, and waiving the extension requirements of Figure 2. See Figure 3. The welded-wire fabric shall be composed of circumferential and longitudinal wires meeting the spacing requirements of Section 7.4 and shall contain sufficient longitudinal wires extending through the box section to maintain the shape and position of reinforcement. Longitudinal distribution reinforcement may be welded-wire fabric or deformed billet-steel bars and shall meet the spacing requirements of Section 7.4. The ends of the longitudinal distribution reinforcement shall be not more than 2 in. from the ends of the box section. The exposure of the ends of longitudinals, stirrups, and spacers used to position the reinforcement shall not be a cause for rejection.



Note: The haunch dimension *H* is equal to the thickness T_s.

Figure 1—Typical Box Section

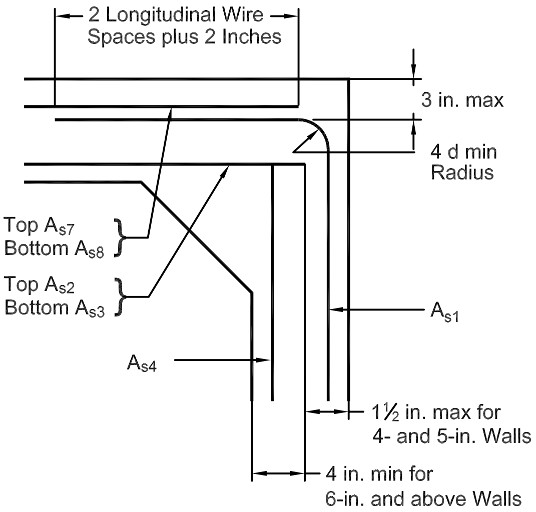


Figure 2—Detail Reinforcement Arrangement

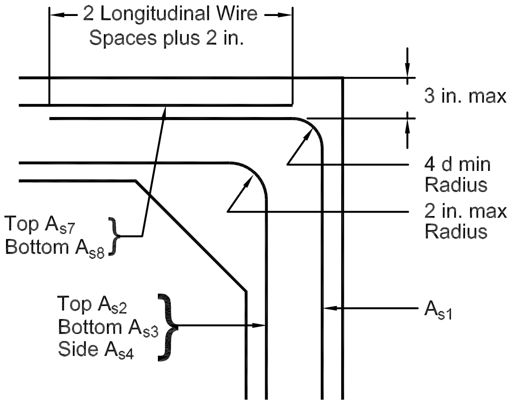

Figure 3—Detail Option

7.4. *Laps, Welds, and Spacing*—Splices in the circumferential reinforcement shall be made by lapping. The overlap measured between the outermost longitudinal wires of each fabric sheet shall be not less than the spacing of the longitudinal wires plus 2 in. A_{s1} shall be lapped with A_{s7} and A_{s8} as shown in Figure 2 or Figure 3 and may be connected by welding. A_{s4} may be lapped and welded at any location or connected by welding the corners to A_{s2} and A_{s3}. The spacing center-to-center of the circumferential wires shall not be less than 2 in. nor more than 4 in. The spacing center to center of the longitudinal wires shall not be more than 8 in. The spacing center-to-center of the longitudinal distribution wires or bars for either line of reinforcing in the top slab shall not be more than 8 in.

8. JOINTS

8.1. The precast reinforced concrete box sections shall be produced with male and female ends. The ends shall be of such design and the ends of the box sections so formed that the sections can be laid together to make a continuous line of box sections compatible with the permissible variations given in Section 11.

9. MANUFACTURE

9.1. *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious materials ratio not exceeding 0.53 by weight. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 470 lb/yd^3, unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this standard.

9.2. *Curing*—The box sections shall be cured for a sufficient length of time so that the concrete will develop the specified compressive strength in 28 days or less. Any one of the following methods of curing or combinations thereof may be used:

9.2.1. *Steam Curing*—The box sections may be low pressure, steam cured by a system that will maintain a moist atmosphere.

9.2.2. *Water Curing*—The box sections may be water cured by any method that will keep the section moist.

9.2.3. *Membrane Curing*—A sealing membrane conforming to the requirements of M 148 may be applied and shall be left intact until the required concrete compressive strength is attained. The concrete temperature at the time of the application shall be within ±10ºF of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

9.3. *Forms*—The forms used in manufacture shall be sufficiently rigid and accurate to maintain the box section dimensions within the permissible variations given in Section 11. All casting surfaces shall be of smooth, nonporous material.

9.4. *Handling*—Handling devices or holes shall be permitted in each box section for the purpose of handling and laying.

10. PHYSICAL REQUIREMENTS

10.1. *Type of Specimen*—Compression tests for determining concrete compressive strength may be made on either concrete cylinders or on cores drilled from the boxed section. (See T 22.)

10.2. *Compression Testing of Cylinders*:

10.2.1. *Cylinder Production*—Cylinders shall be prepared in accordance with the Cylinder Strength Test Method of T 280.

10.2.2. *Number of Cylinders*—Prepare not fewer than five test cylinders from a group (1 day's production of each concrete strength) of box sections.

10.2.3. *Acceptability on the Basis of Cylinder Test Results*:

10.2.3.1. When the compressive strengths of all cylinders tested for a group are equal to or greater than the design concrete strength, the compressive strength in the group of box sections shall be accepted.

10.2.3.2. When the average compressive strength of all cylinders tested is equal to or greater than the design concrete strength, not more than 10 percent of the cylinders tested have a compressive strength less than the design concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the design concrete strength, then the compressive strength of the concrete in the group of box sections shall be accepted.

10.2.3.3. When the compressive strength of the cylinders tested does not conform to the acceptance criteria stated in Section 10.2.3.1 or Section 10.2.3.2, the acceptability of the group shall be determined in accordance with the provisions of Section 10.2.

10.3. *Compression Testing of Cores*:

10.3.1. *Obtaining Cores*—Cores shall be obtained and prepared in accordance with the Core Strength Test Method of T 280.

10.3.2. *Number of Cores*—One core shall be taken from a box section selected at random from each group of 15 box sections of a single size or fraction of such a group from each continuous production run.

10.4. *Acceptability on the Basis of Core Test Results*:

10.4.1. When the compressive strengths of cores tested for a group of box sections is equal to or greater than the design concrete strength, the compressive strength of the concrete for the group is acceptable.

10.4.2. If the compressive strength of the core tested is less than the design concrete strength, the box section from which that core was taken may be re-cored. If the compressive strength of the re-core is equal to or greater than the design concrete compressive strength, the compressive strength of the concrete for the group is acceptable.

10.4.3. If the compressive strength of the re-core is less than the design concrete strength, the box section from which the core was taken shall be rejected. Two box sections from the remainder of the group shall be selected at random and one core shall be taken from each box section. If the compressive strength of both cores is equal to or greater than the design concrete compressive strength, the concrete compressive strength of the remainder of the group shall be acceptable. If the compressive strength of either of the two cores tested is less than the design concrete compressive strength, then the remainder of the group shall be either rejected or, at the option of the manufacturer, each box section of the remainder of the group shall be cored and accepted individually, and any of the box sections that have a core with less than the design concrete compressive strength shall be rejected.

10.5. *Plugging Core Holes*—The core holes shall be plugged and sealed by the manufacturer in a manner such that the box section will meet all of the test requirements of this specification. Box sections so sealed shall be considered satisfactory for use.

10.6. *Test Equipment*—Every manufacturer furnishing box sections under this specification shall furnish all facilities and personnel necessary to carry out the test required.

11. PERMISSIBLE VARIATIONS

11.1. *Internal Dimensions*—The internal dimensions shall vary not more than 1 percent from the design dimensions. The haunch dimensions shall vary not more than $^1/_4$ in. from the design dimensions.

11.2. *Slab and Wall Thickness*—The slab and wall thickness shall not be less than that shown in the design by more than 5 percent or $^3/_{16}$ in., whichever is greater. A thickness more than that required in the design shall not be cause for rejection.

11.3. *Length of Opposite Surfaces*—Variations in laying lengths of two opposite surfaces of the box section shall not be more than $^1/_8$ in./ft of span with a maximum of $^5/_8$ in. for all sizes through 7-ft internal span, and a maximum of $^3/_4$ in. for internal spans greater than 7 ft, except where beveled ends for laying on curves are specified by the owner.

11.4. *Length of Section*—The underrun in length of a section shall not be more than $^1/_8$ in./ft of length with a maximum of $^1/_2$ in. any box section.

11.5. *Position of Reinforcement*—The maximum variation in the position of the reinforcement for 5 in. or less wall thicknesses shall be $\pm^3/_8$ in., and for greater than 5-in. slab and wall thicknesses shall be $\pm^1/_2$ in. In no case, however, shall the cover over the reinforcement be less than $^5/_8$ in., as measured to the internal surface or the external surface of the box section except the cover over the reinforcement for the external surface of the top slab shall not be less than $1^5/_8$ in. The preceding minimum cover limitation does not apply at the mating surfaces of the joint.

11.6. *Area of Reinforcement*—The areas of steel reinforcement shall be the design steel areas as shown in Tables 1 and 2. Steel areas greater than those required shall not be cause for rejection. The permissible variation in diameter of any reinforcement shall conform to the tolerances prescribed in the AASHTO specification for that type of reinforcement.

12. REPAIRS

12.1. Box sections may be repaired, if necessary, because of imperfections in manufacture or handling damage and will be acceptable if, in the opinion of the owner, the repaired box section conforms to the requirements of this specification.

13. INSPECTION

13.1. The quality of materials, the process of manufacture, and the finished box sections shall be subject to inspection by the owner.

14. REJECTION

14.1. Box sections shall be subject to rejection if it fails to conform to any of the specification requirements. Individual box sections may be rejected because of any of the following:

14.1.1. Fractures or cracks passing through the wall, except for a single-end crack that does not exceed the depth of the joint;

14.1.2. Defects that indicate mixing and molding, not in compliance with Section 9.1, or honeycombed or open texture, that would adversely affect the function of the box;

14.1.3. The ends of the box sections are not normal to the walls and centerline of the box section, within the limits of variations given in Section 11, except where beveled ends are specified; and

14.1.4. Damaged ends, where such damage would prevent making a satisfactory joint.

15. PRODUCT MARKING

15.1. The following information shall be legibly marked on each box section by indentation, waterproof paint, or other approved means:

15.1.1. Box section span, rise, table number, and specification designation,

15.1.2. Date of manufacture,

15.1.3. Name or trademark of the manufacturer,

15.1.4. Identification of the plant, and

15.1.5. Each section shall be clearly marked by indentation on either the inner or outer surface during the process of manufacture so that the location of the top will be evident immediately after the forms are stripped. In addition, the word "top" shall be lettered with waterproof paint on the inside top surface.

16. KEYWORDS

16.1. Concrete box—precast; culvert; sewer pipe; storm drain.

APPENDIX

(Nonmandatory Information)

X1. DESIGN CRITERIA USED TO DEVELOP TABLES 1 AND 2

X1.1. *Bedding and Backfill Assumptions*:

X1.1.1. The bedding is assumed to provide a slightly yielding, uniformly distributed support over the bottom width of the box section.

X1.1.2. The cover over the top of the box section may vary from 0 to 2 ft.

X1.2. *Criteria for Loads*:

X1.2.1. Design loads are based on the American Association of State Highway and Transportation Officials (AASHTO) *Standard Specifications for Highway Bridges*.

X1.2.2. Live loads for designs given in Table 1 are HS20 loadings as defined in the AASHTO specifications. Live loads for designs given in Table 2 are interstate loadings as defined in U.S. Department of Commerce, Bureau of Public Roads Circular Memorandum 22-40, 22 April 1957. Impact allowances are in accordance with AASHTO specifications. Wheel loads are distributed over a width of [48 + 0.06 × (span minus one haunch)], in inches, perpendicular to the span by use of longitudinal distribution reinforcement in top and bottom of top slab. Loads are spread parallel to span over a length equal to (8 + 1.75 H cover) in inches. Cover loads for designs given in Tables 1 and 2 are the mass of a column of earth of a width equal to the outside width dimension of the box section and a height equal to the depth of cover over the top of the section.

X1.2.3. Lateral earth pressure from mass of earth above and adjacent to a box section is taken as a minimum of 0.25 times vertical pressure, and an additional 0.25 times vertical pressure is added in determining reinforcement areas only when areas are increased by such increased lateral pressure. Additional lateral pressure in lbf/ft^2 from approaching wheel loads is taken as 700 divided by depth to surface in feet, or 800 where depth to surface is less than 1 ft, and is added when determining reinforcement areas only at sections where areas are increased by increased lateral pressure.

X1.3. *Method of Analysis*:

X1.3.1. The structural effects of the loads described in Section X1.2 are evaluated based on the elastic method of structural analysis. Design moments, shears, and thrusts are determined by computer analysis using the stiffness matrix method, and design is based on maximum stress resultants at critical sections caused by the most severe combination of design loads.

X1.4. *Method of Design*:

X1.4.1. Box section design is based on load factor design provisions given in AASHTO's *Standard Specifications for Highway Bridges*. The load factor for dead load is increased from 1.3 to 1.5 for consistency with M 259. Reinforcement areas are governed by either service live load fatigue stress limitation of 21 000 lbf/in.^{2}, or service total load stress limitation of 36 000 lbf/in.^{2}, or ultimate total load yield stress limitation of 60 000 lbf/in.^{2} Crack width is controlled by limiting maximum spacing of circumferential reinforcement (welded wire fabric) to 4 in. and longitudinal distribution reinforcement (welded wire fabric or deformed grade 60 bars) to 8 in. Longitudinal distribution reinforcement called for in Tables 1 and 2 for top slab inside face is in accordance with distribution reinforcement formulas given in AASHTO specification for bridge decks. Longitudinal distribution reinforcement is also required in the top of the top slab, when wheel loads are adjacent to joints that provide only shear connections between box section units. These requirements were determined by evaluating analyses with loads in various positions on and near the edge of slabs having various length-to-width ratios and various conditions of edge restraint.

X1.4.2. Some box section designs shown in Tables 1 and 2 have reinforcement area requirements designated by "E" as minimum reinforcement area. For such cases, the reinforcement areas calculated for support of design loads are less than the minimum area that is specified in AASHTO bridge specifications, 0.002 Ag or 0.125 in.^{2}/ft whichever is greater.

X1.4.3. For specific criteria used to develop Tables 1 and 2, refer to Table X1.1.

X1.4.4. The top and bottom slab and sidewall thicknesses given in Tables 1 and 2 either conform to the dimensions used in M 259 or provide the minimum thickness required because of shear requirements given in the AASHTO bridge specification. The effective width of top or bottom slab for distribution of shear stress resulting from wheel loads is the same width used for determining maximum bending moments per unit of box section length.

X1.4.5. Haunch dimensions are the values used in M 259 and are the same as the sidewall thickness as shown in Tables 1 and 2.

Table X1.1—Specific Criteria Used to Develop Tables 1 and 2

Material Properties:	
Welded wire fabric, (circumferential or longitudinal distribution reinforcement), specified yield stress	60 000 psi
Deformed bars (longitudinal distribution reinforcement) specified yield stress	60 000 psi
Length of box section resisting truck wheel load	48 + 0.06 (span minus haunches), in.
Length of wheel bearing area parallel to slab span	(8 + 1.75H) in.
Concrete, minimum specified compressive strength	5000 psi
Soil Data:	
Unit weight	120 lb/ft^3
Ratio of lateral to vertical pressure from weight of earth	0.25 min to 0.50 max
External water table	below box section invert
Effective weight coefficient for soil load	1.0
Capacity Reduction Factors:	
Shear	0.85
Axial compression combined with bending	0.70 to 0.90
Loading Data:	
Load factor—dead load	1.5
Load factor—live load	2.2
Truck axle load:	
HS20 (Table 1)	32 000 lbf (See Figure 4.)
Interstate (Table 2)	2 @ 24 000 lbf each (See Figure 4.)
Lateral earth pressure from approaching wheel	800 lbf/ft^2 to 1 ft earth cover; 700/H lbf/ft^2 where H is depth of earth cover, ft, when depth exceeds 1 ft
Impact (variable with depth) see AASHTO Bridge Specifications, 1977	30 percent to 20 percent
Uniform internal pressure	0.0
Depth of water in box section external groundwater pressure	Equal to inside height 0.0
Structural Arrangements:	
Concrete cover over steel:	
Top of top slab	2 in.
All other surfaces	1 in.
Slab thickness	See Tables 1 and 2.
Side wall thickness	See Tables 1 and 2.
Haunch dimensions	Vertical and horizontal dimensions both equal to side wall thickness.
Minimum reinforcement	0.002 Ag or 0.125 in.^{2}/ft, whichever is greater
The structural arrangement and details are shown in Figures 1 and 2.	

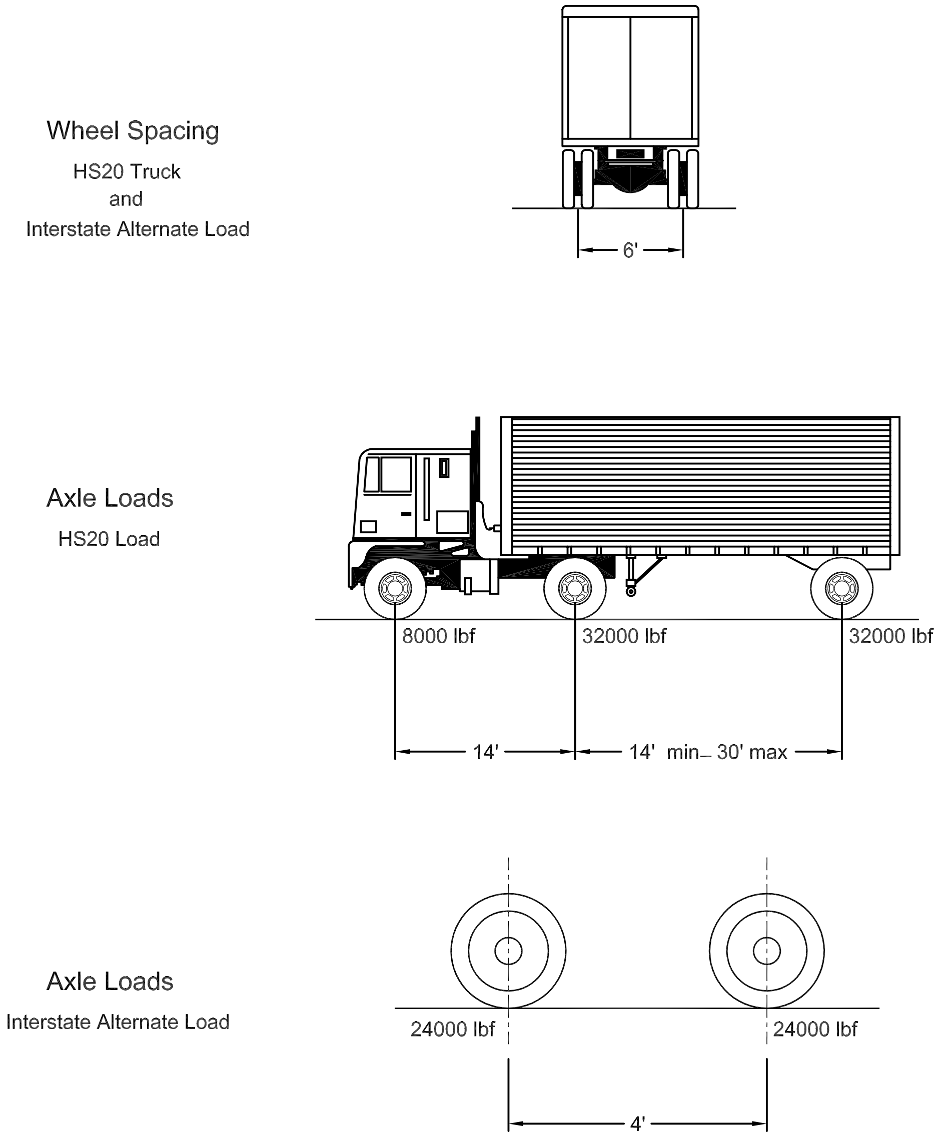

Figure X1.1—Axle Loads for Box Section Standard Designs

X1.5. *Multiple-Cell Installations*:

X1.5.1. The designs given herein are for single cell precast reinforced concrete box sections. The units may be used in parallel for multicell installations if means of positive lateral bearing by continuous contact between the sides of adjacent boxes are provided. Compacted earth fill, granular backfill, or grouting between the units are considered means of providing such positive bearing.

---

[1] Standard Designs and Criteria used to develop the designs that are included in this specification are under the jurisdiction of the AASHTO Subcommittee on Bridges and Structures. Agrees with ASTM C 850-95a except that the use of synthetic fibers will be at the owner’s option.

Standard Specification for

Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers with Less Than 0.6 m of Cover Subjected to Highway Loadings [Metric]

AASHTO Designation: M 273M-00 (2008)[1]
ASTM Designation: C 850M-98

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Precast Reinforced Concrete Box Sections for Culverts, Storm Drains, and Sewers with Less Than 0.6 m of Cover Subjected to Highway Loadings [Metric]

AASHTO Designation: M 273M-00 (2008)[1]
ASTM Designation: C 850M-98

1. SCOPE

1.1. This specification covers single-cell, precast reinforced concrete box sections with less than 0.6 m of cover subjected to highway loadings and intended to be used for the construction of culverts and for the conveyance of storm water, industrial wastes, and sewage.

1.2. This metric specification is equivalent to M 273 and is compatible in technical content.

Note 1—This specification is primarily a manufacturing and purchasing specification. However, standard designs are included and the criteria used to develop these designs are given in Appendix X1. The successful performance of this product depends upon the proper selection of the box section, bedding, backfill, controlled manufacture in the plant, and care that the installation conforms to the construction specifications. The owner of the precast reinforced concrete box sections specified herein is cautioned that the loading conditions and the field requirements must be correlated with the box sections specified and inspection must be provided at the construction site.

Note 2—AASHTO M 259M is to be used for box sections subjected to highway loading with 0.6 m or more earth cover, or subjected to dead load only.

[a] Design requirements are based on maximum effects resulting from cover conditions ranging from 0 to 0.6 m and the material and soil properties and loading data shown in Appendix X1. For modified or special designs, see Section 7.2.

[b] The box section designation, for example 900 by 600, indicates interior horizontal span, in millimeters, by interior vertical rise, in millimeters.

[c] Design reinforcement areas in square millimeters per linear meter of box section length at those locations as shown in Figure 1.

[d] Design reinforcement areas in square millimeters per linear meter of box section width at those locations as shown in Figure 1.

[e] Minimum reinforcement area is specified.

Notes:
1. Reinforcement areas are based on the mass of column of earth over the width of the box section plus live loads as defined in Appendix X1.
2. Concrete design strength, 35 MPa.

[a] Design requirements are based on maximum effects resulting from cover conditions ranging from 0 to 0.6 m and the material and soil properties and loading data shown in Appendix X1. For modified or special designs, see Section 7.2.

[b] The box section designation, for example 900 by 600, indicates interior horizontal span, in millimeters, by interior vertical rise, in millimeters.

[c] Design reinforcement areas in square millimeters per linear meter of box section length at those locations as shown in Figure 1.

[d] Design reinforcement areas in square millimeters per linear meter of box section width at those locations as shown in Figure 1.

[e] Minimum reinforcement area is specified.

Notes:
1. Reinforcement areas are based on the mass of column of earth over the width of the box section plus live loads as defined in Appendix X1.
2. Concrete design strength, 35 MPa.

5. BASIS OF ACCEPTANCE

5.1. Acceptability of the box sections produced in accordance with Section 7 shall be determined by the results of the concrete compressive strength tests described in Section 10, by the material requirements described in Section 6, and by inspection of the finished box sections.

5.2. Box sections shall be considered ready for acceptance when they conform to the requirements of this specification.

6. MATERIALS

6.1. *Reinforced Concrete*—The reinforced concrete shall consist of cementitious materials, mineral aggregates, and water, in which steel has been embedded in such a manner that the steel and concrete act together.

6.2. *Cementitious Materials*:

6.2.1. *Cement*—Cement shall conform to the requirements for portland cement of M 85 or shall be portland blast-furnace slag cement or portland-pozzolan cement conforming to the requirements of M 240, except that the pozzolan constituent in the Type IP portland-pozzolan cement shall be fly ash and shall not exceed 25 percent by mass.

6.2.2. *Fly Ash*—Fly ash shall conform to the requirements of M 295, Class F or Class C.

6.2.3. *Allowable Combinations of Cementitious Materials*—The combination of cementitious materials used in concrete shall be one of the following:

6.2.3.1. Portland cement only,

6.2.3.2. Portland blast-furnace slag cement only,

6.2.3.3. Portland-pozzolan cement only, and

6.2.3.4. A combination of portland cement and fly ash wherein the proportion of fly ash is between 5 and 25 percent by mass of total cementitious material (portland cement plus fly ash).

6.3. *Aggregates*—Aggregates shall conform to M 6 and M 80, except that the requirements for gradation shall not apply.

6.4. *Admixtures and Blends*—Admixtures and blends may be used with the approval of the owner.

6.5. *Steel Reinforcement*—Reinforcement shall consist of welded wire fabric conforming to M 55M/M 55 or M 221M/M 221. Longitudinal distribution reinforcement may consist of welded wire fabric or deformed billet-steel bars conforming to M 31M/M 31, Grade 400.

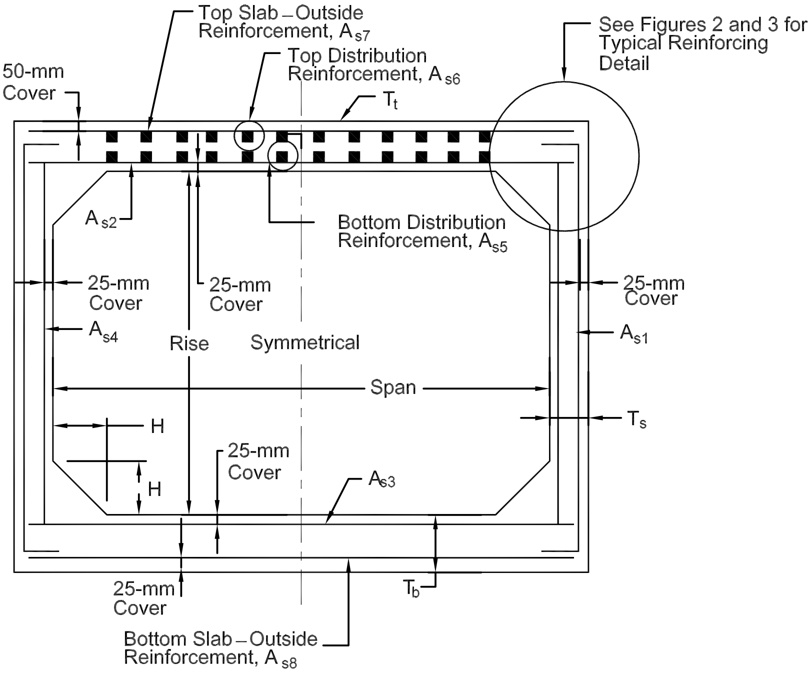
6.6. *Synthetic Fibers*—Polypropylene fibers may be used, at the owner's option, in concrete pipe as a nonstructural manufacturing material. Only Type III synthetic fibers designed and manufactured specifically for use in concrete and conforming to the requirements of ASTM C 1116 shall be accepted.

7. DESIGN

7.1. *Design Tables*—The box section dimensions, compressive strength of the concrete, and reinforcement details shall be as prescribed in Tables 1 or 2 and Figures 1 and 2, subject to the provisions of Section 11. Table 1 sections are designed for a cover range from 0 to 0.6 m plus AASHTO HS20 live load conditions. Table 2 sections are designed for a cover range from 0 to 0.6 m plus Interstate live load conditions. Criteria used to develop Tables 1 and 2 are given in the Appendix X1.

7.2. *Modified and Special Designs*—The manufacturer may request approval by the owner of modified designs that differ from the designs in Section 7.1; or special designs for sizes and loads other than those shown in Tables 1 and 2.

7.3. *Placement of Reinforcement*—The cover of concrete over the circumferential reinforcement shall be 25 mm except in the outside top of the top slab where it shall be 50 mm, subject to the provisions of Section 11. The inside circumferential and longitudinal reinforcement shall extend into the male portion of the joint and the outside circumferential and longitudinal reinforcement shall extend into the female portion of the joint. The clear distance of the end circumferential wires shall not be less than 13 mm or more than 50 mm from the ends of the box section. Reinforcement shall be assembled utilizing any combination of single or multiple layers of welded-wire fabric. Common reinforcement units may be utilized for both A_{s2} (or A_{s3}) and A_{s4}, and also for both A_{s7} (or A_{s8}) and A_{s1}, with the largest area requirement of each combination governing, bending the reinforcement 90 degrees at the corners, and waiving the extension requirements of Figure 2. See Figure 3. The welded-wire fabric shall be composed of circumferential and longitudinal wires meeting the spacing requirements of Section 7.4 and shall contain sufficient longitudinal wires extending through the box section to maintain the shape and position of reinforcement. Longitudinal distribution reinforcement may be welded-wire fabric or deformed billet-steel bars and shall meet the spacing requirements of Section 7.4. The ends of the longitudinal distribution reinforcement shall be not more than 50 mm from the ends of the box section. The exposure of the ends of longitudinals, stirrups, and spacers used to position the reinforcement shall not be a cause for rejection.



Note: The haunch dimension *H* is equal to the thickness T_s.

Figure 1—Typical Box Section

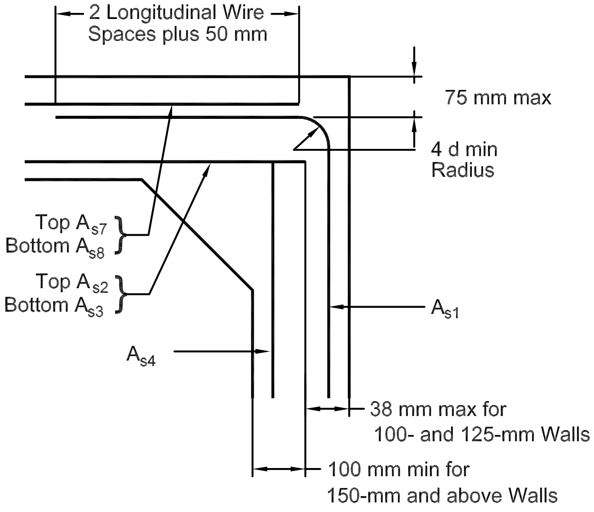


Figure 2—Detail Reinforcement Arrangement

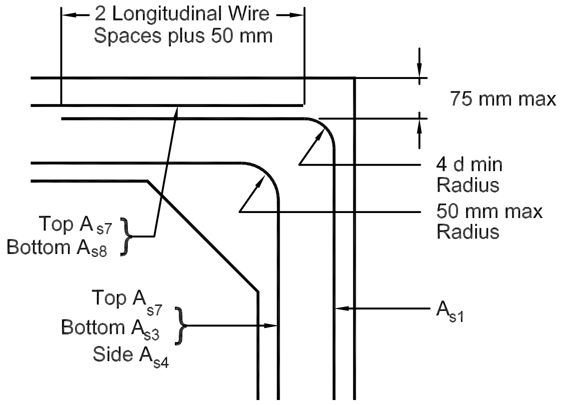

Figure 3—Detail Option

7.4. *Laps, Welds, and Spacing*—Splices in the circumferential reinforcement shall be made by lapping. The overlap measured between the outermost longitudinal wires of each fabric sheet shall not be less than the spacing of the longitudinal wires plus 50 mm. A_{s1} shall be lapped with A_{s7} and A_{s8} as shown in Figure 2 or Figure 3 and may be connected by welding. A_{s4} may be lapped and welded at any location or connected by welding at the corners to A_{s2} and A_{s3}. The spacing center to center of the circumferential wires shall not be less than 50 mm nor more than 100 mm. The spacing center-to-center of the longitudinal wires shall not be more than 200 mm. The spacing center-to-center of the longitudinal distribution wires or bars for either line of reinforcing in the top slab shall not be more than 200 mm.

8. JOINTS

8.1. The precast reinforced concrete box sections shall be produced with male and female ends. The ends shall be of such design and the ends of the box sections so formed that the sections can be laid together to make a continuous line of box sections compatible with the permissible variations given in Section 11.

9. MANUFACTURE

9.1. *Mixture*—The aggregates shall be sized, graded, proportioned, and mixed in a batch mixer with such proportions of cementitious materials and water as will produce a homogeneous concrete mixture of such quality that the pipe will conform to the test and design requirements of this specification. All concrete shall have a water-cementitious materials ratio not exceeding 0.53 by mass. Cementitious materials shall be as specified in Section 6.2 and shall be added to the mix in a proportion not less than 280 kg/m^3 unless mix designs with a lower cementitious materials content demonstrate that the quality and performance of the pipe meet the requirements of this standard.

9.2. *Curing*—The box sections shall be cured for a sufficient length of time so that the concrete will develop the specified compressive strength in 28 days or less. Any one of the following methods of curing or combinations thereof may be used:

9.2.1. *Steam Curing*—The box sections may be low pressure, steam cured by a system that will maintain a moist atmosphere.

9.2.2. *Water Curing*—The box sections may be water cured by any method that will keep the section moist.

9.2.3. *Membrane Curing*—A sealing membrane conforming to the requirements of M 148 may be applied and shall be left intact until the required concrete compressive strength is attained. The concrete temperature at the time of the application shall be within ±6ºC of the atmospheric temperature. All surfaces shall be kept moist prior to the application of the compounds and shall be damp when the compound is applied.

9.3. *Forms*—The forms used in manufacture shall be sufficiently rigid and accurate to maintain the box section dimensions within the permissible variations given in Section 11. All casting surfaces shall be of smooth, nonporous material.

9.4. *Handling*—Handling devices or holes shall be permitted in each box section for the purpose of handling and laying.

---

10. PHYSICAL REQUIREMENTS

10.1. *Type of Specimen*—Compression tests for determining concrete compressive strength may be made on either concrete cylinders or on cores drilled from the boxed section. (See T 22.)

10.2. *Compression Testing of Cylinders*:

10.2.1. *Cylinder Production*—Cylinders shall be prepared in accordance with the Cylinder Strength Test Method of T 280.

10.2.2. *Number of Cylinders*—Prepare not fewer than five test cylinders from a group (1 day’s production of each concrete strength) of box sections.

10.2.3. *Acceptability on the Basis of Cylinder Test Results*:

10.2.3.1. When the compressive strengths of all cylinders tested for a group are equal to or greater than the design concrete strength, the compressive strength in the group of box sections shall be accepted.

10.2.3.2. When the average compressive strength of all cylinders tested is equal to or greater than the design concrete strength, not more than 10 percent of the cylinders tested have a compressive strength less than the design concrete strength, and no cylinder tested has a compressive strength less than 80 percent of the design concrete strength, then the compressive strength of the concrete in the group of box sections shall be accepted.

10.2.3.3. When the compressive strength of the cylinders tested does not conform to the acceptance criteria stated in Section 10.2.3.1 or Section 10.2.3.2, the acceptability of the group shall be determined in accordance with the provisions of Section 10.2.

10.3. *Compression Testing of Cores*:

10.3.1. *Obtaining Cores*—Cores shall be obtained and prepared in accordance with the Core Strength Test Method of T 280.

10.3.2. *Number of Cores*—One core shall be taken from a box section selected at random from each group of 15 box sections of a single size or fraction of such a group from each continuous production run.

10.4. *Acceptability on the Basis of Core Test Results*:

10.4.1. When the compressive strengths of cores tested for a group of box sections is equal to or greater than the design concrete strength, the compressive strength of the concrete for the group is acceptable.

10.4.2. If the compressive strength of the core tested is less than the design concrete strength, the box section from which that core was taken may be re-cored. If the compressive strength of the re-core is equal to or greater than the design concrete compressive strength, the compressive strength of the concrete for the group is acceptable.

10.4.3. If the compressive strength of the re-core is less than the design concrete strength, the box section from which the core was taken shall be rejected. Two box sections from the remainder of the group shall be selected at random and one core shall be taken from each box section. If the compressive strength of both cores is equal to or greater than the design concrete compressive strength, the concrete compressive strength of the remainder of the group shall be acceptable. If the compressive strength of either of the two cores tested is less than the design concrete compressive strength, then the remainder of the group shall be either rejected or, at the option of the manufacturer, each box section of the remainder of the group shall be cored and accepted individually, and any of the box sections that have a core with less than the design concrete compressive strength shall be rejected.

10.5. *Plugging Core Holes*—The core holes shall be plugged and sealed by the manufacturer in a manner such that the box section will meet all of the test requirements of this specification. Box sections so sealed shall be considered satisfactory for use.

10.6. *Test Equipment*—Every manufacturer furnishing box sections under this specification shall furnish all facilities and personnel necessary to carry out the test required.

11. PERMISSIBLE VARIATIONS

11.1. *Internal Dimensions*—The box culvert manufacturer shall establish the rise and span of the existing equipment to the nearest millimeter and verify that it is within the limits given in Table 3. The internal dimensions shall not vary more than 1 percent from the manufacturer's established metric size. The haunch dimensions shall vary not more than 6 mm from the design dimensions.

Table 3—Permissible Variation in Internal Size (Span or Rise)

Designated Size, mm	Permissible Variation, Internal Size, mm	
	Min	Max
600	600	620
900	900	920
1200	1200	1230
1500	1500	1540
1800	1810	1850
2100	2110	2160
2400	2410	2460
2700	2710	2770
3000	3020	3080
3330	3320	3390
3600	3620	3690

11.2. *Slab and Wall Thickness*—The slab and wall thickness shall not be less than that shown in the design by more than 5 percent or 5 mm, whichever is greater. A thickness more than that required in the design shall not be cause for rejection.

11.3. *Length of Opposite Surfaces*—Variations in laying lengths of two opposite surfaces of the box section shall not be more than 10 mm/m of internal span, with a maximum of 16 mm for all sizes through 2100-mm internal span, and a maximum of 19 mm for internal spans greater than 2100 mm, except where beveled ends for laying on curves are specified by the owner.

11.4. *Length of Section*—The underrun in length of a section shall not be more than 10 mm/m of length with a maximum of 13 mm in any box section.

11.5. *Position of Reinforcement*—The maximum variation in the position of the reinforcement for 130 mm or less wall thicknesses shall be ±10 mm, and for greater than 130-mm slab and wall thicknesses shall be ±13 mm. In no case, however, shall the cover over the reinforcement be less than 16 mm, as measured to the internal surface or the external surface of the box section except the cover over the reinforcement for the external surface of the top slab shall not be less than 42 mm. The preceding minimum cover limitation does not apply at the mating surfaces of the joint.

11.6. *Area of Reinforcement*—The areas of steel reinforcement shall be the design steel areas as shown in Tables 1 and 2. Steel areas greater than those required shall not be cause for rejection. The permissible variation in diameter of any reinforcement shall conform to the tolerances prescribed in the AASHTO specification for that type of reinforcement.

12. REPAIRS

12.1. Box sections may be repaired, if necessary, because of imperfections in manufacture or handling damage and will be acceptable if, in the opinion of the owner, the repaired box section conforms to the requirements of this specification.

13. INSPECTION

13.1. The quality of materials, the process of manufacture, and the finished box sections shall be subject to inspection by the owner.

14. REJECTION

14.1. Box sections shall be subject to rejection if it fails to conform to any of the specification requirements. Individual box sections may be rejected because of any of the following:

14.1.1. Fractures or cracks passing through the wall, except for a single-end crack that does not exceed the depth of the joint;

14.1.2. Defects that indicate mixing and molding, not in compliance with Section 9.1, or honeycombed or open texture, that would adversely affect the function of the box;

14.1.3. The ends of the box sections are not normal to the walls and centerline of the box section, within the limits of variations given in Section 11, except where beveled ends are specified; and

14.1.4. Damaged ends, where such damage would prevent making a satisfactory joint.

15. PRODUCT MARKING

15.1. The following information shall be legibly marked on each box section by indentation, waterproof paint, or other approved means:

15.1.1. Box section span, rise, table number, and specification designation,

15.1.2. Date of manufacture,

15.1.3. Name or trademark of the manufacturer,

15.1.4. Identification of the plant, and

15.1.5. Each section shall be clearly marked by indentation on either the inner or outer surface during the process of manufacture so that the location of the top will be evident immediately after the forms are stripped. In addition, the word "top" shall be lettered with waterproof paint on the inside top surface.

16. KEYWORDS

16.1. Concrete box—precast; culvert; sewer pipe; storm drain.

APPENDIX

(Nonmandatory Information)

X1. DESIGN CRITERIA USED TO DEVELOP TABLES 1 AND 2

X1.1. *Bedding and Backfill Assumptions*:

X1.1.1. The bedding is assumed to provide a slightly yielding, uniformly distributed support over the bottom width of the box section.

X1.1.2. The cover over the top of the box section may vary from 0 to 0.6 m.

X1.2. *Criteria for Loads*:

X1.2.1. Design loads are based on the AASHTO *Standard Specifications for Highway Bridges*.

X1.2.2. Live loads for designs given in Table 1 are HS20 loadings as defined in the AASHTO specifications. Live loads for designs given in Table 2 are interstate loadings as defined in U.S. Department of Commerce, Bureau of Public Roads Circular Memorandum 22-40, 22 April 1957. Impact allowances are in accordance with AASHTO specifications. Wheel loads are distributed over a width of [1200 + 0.06 × (span minus one haunch)], in millimeters, perpendicular to the span by use of longitudinal distribution reinforcement in top and bottom of top slab. Loads are spread parallel to span over a length equal to (200 + 1.75 *H* cover) in millimeters. Cover loads for designs given in Tables 1 and 2 are the mass of a column of earth of a width equal to the outside width dimension of the box section and a height equal to the depth of cover over the top of the section.

X1.2.3. Lateral earth pressure from mass of earth above and adjacent to a box section is taken as a minimum of 0.25 times vertical pressure, and an additional 0.25 times vertical pressure is added in determining reinforcement areas only when areas are increased by such increased lateral pressure. Additional lateral pressure in kilopascals from approaching wheel loads is taken as 33.5 divided by depth to surface in meters, or 38.3 where depth to surface is less than 0.6 m, and is added when determining reinforcement areas only at sections where areas are increased by increased lateral pressure.

X1.3. *Method of Analysis*:

X1.3.1. The structural effects of the loads described in Section X1.2 are evaluated based on the elastic method of structural analysis. Design moments, shears, and thrusts are determined by computer analysis using the stiffness matrix method, and design is based on maximum stress resultants at critical sections caused by the most severe combination of design loads.

X1.4. *Method of Design*:

X1.4.1. Box section design is based on load factor design provisions given in AASHTO's *Standard Specifications for Highway Bridges*. The load factor for dead load is increased from 1.3 to 1.5 for consistency with AASHTO M 259M. Reinforcement areas are governed by either service live load fatigue stress limitation of 145 MPa, or service total load stress limitation of 248 MPa, or ultimate total load yield stress limitation of 414 MPa. Crack width is controlled by limiting maximum spacing of circumferential reinforcement (welded wire fabric) to 100 mm and longitudinal distribution reinforcement (welded wire fabric or deformed grade 60 bars) to 200 mm. Longitudinal distribution reinforcement called for in Tables 1 and 2 for top slab inside face is in accordance with distribution reinforcement formulas given in AASHTO specification for bridge decks. Longitudinal distribution reinforcement is also required in the top of the top slab, when wheel loads are adjacent to joints that provide only shear connections between box section units. These requirements were determined by evaluating analyses with loads in various positions on and near the edge of slabs having various length-to-width ratios and various conditions of edge restraint.

X1.4.2. Some box section designs shown in Tables 1 and 2 have reinforcement area requirements designated by "E" as minimum reinforcement area. For such cases, the reinforcement areas calculated for support of design loads are less than the minimum area that is specified in AASHTO bridge specifications, 0.002 Ag or 265 mm^2/m whichever is greater.

X1.4.3. For specific criteria used to develop Tables 1 and 2, refer to Table X1.1.

X1.4.4. The top and bottom slab and sidewall thicknesses given in Tables 1 and 2 either conform to the dimensions used in M 259M or provide the minimum thickness required because of shear requirements given in the AASHTO bridge specification. The effective width of top or bottom slab for distribution of shear stress resulting from wheel loads is the same width used for determining maximum bending moments per unit of box section length.

X1.4.5. Haunch dimensions are the values used in M 259M and are the same as the sidewall thickness shown in Tables 1 and 2.

Table X1.1—Specific Criteria Used to Develop Tables 1 and 2

Material Properties:	
Welded wire fabric, (circumferential or longitudinal distribution reinforcement), specified yield stress	414 MPa
Deformed bars (longitudinal distribution reinforcement) specified yield stress	414 MPa
Length of box section resisting truck wheel load	1200 + 0.06 (span minus haunches), mm
Length of wheel bearing area parallel to slab span	(200 + 1.75H) mm
Concrete, minimum specified compressive strength	35 MPa
Soil Data:	
Unit weight	1920 kg/mm^3
Ratio of lateral to vertical pressure from weight of earth	0.25 min to 0.50 max
External water table	below box section invert
Effective weight coefficient for soil load	1.0
Capacity Reduction Factors:	
Shear	0.85
Axial compression combined with bending	0.70 to 0.90
Loading Data:	
Load factor—dead load	1.5
Load factor—live load	2.2
Truck axle load: HS20 (Table 1)	14 500 (See Figure 4.)
Interstate (Table 2)	2 @ 10 900 kg each (See Figure 4.)
Lateral earth pressure from approaching wheel	38.3 kPa to 0.6 m earth cover; 33.5/H kPa where H is depth of earth cover, m, when depth exceeds 0.6 m
Impact (variable with depth) see AASHTO Bridge Specifications, 1977	30 percent to 20 percent
Uniform internal pressure	0.0
Depth of water in box section	Equal to inside height
External ground water pressure	0.0
Structural Arrangements:	
Concrete cover over steel:	
Top of top slab	50 mm
All other surfaces	25 mm
Slab thickness	See Tables 1 and 2.
Side wall thickness	See Tables 1 and 2.
Haunch dimensions	Vertical and horizontal dimensions both equal to side wall thickness
Minimum reinforcement	0.002 Ag or 265 mm^2/m, whichever is greater
The structural arrangement and details are shown in Figures 1 and 2.	

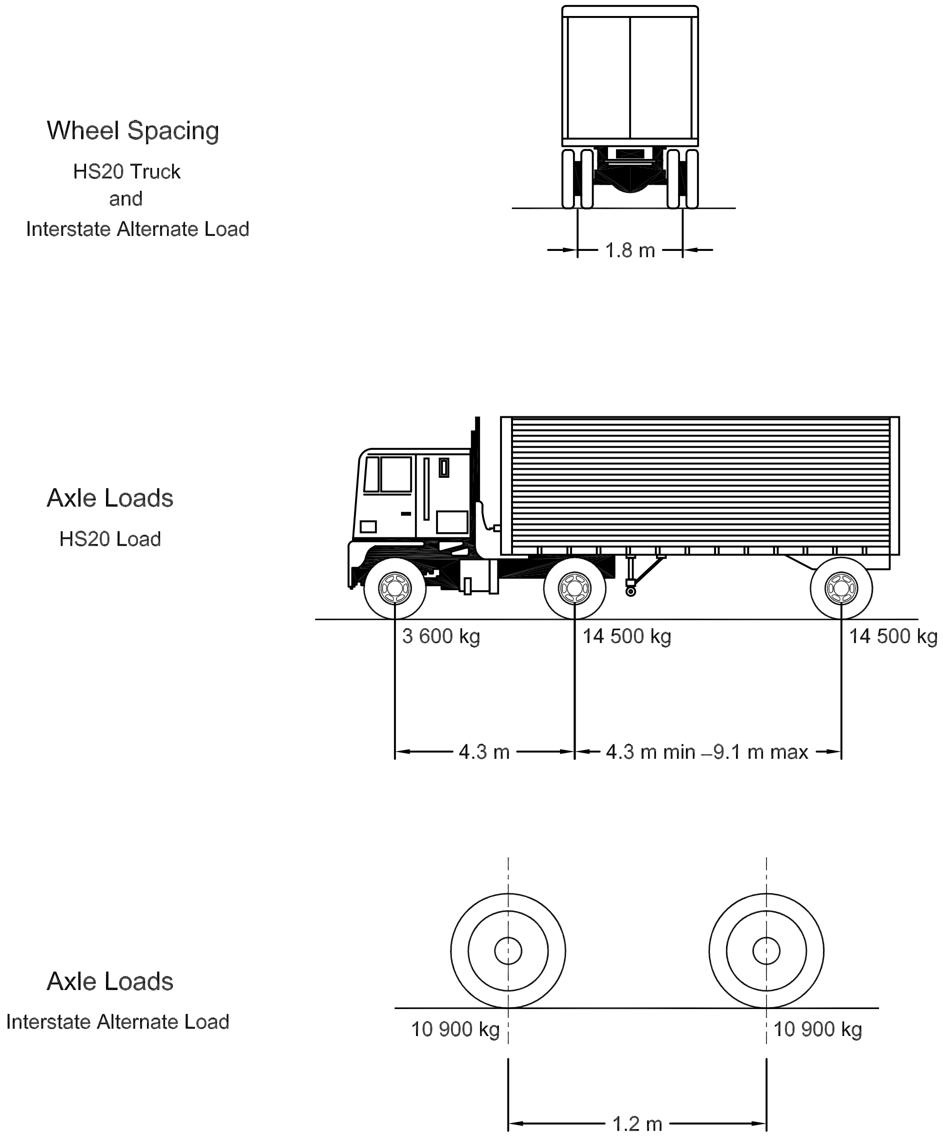

Figure X1.1—Axle Loads for Box Section Standard Designs

X1.5. *Multiple-Cell Installations*:

X1.5.1. The designs given herein are for single cell precast reinforced concrete box sections. The units may be used in parallel for multicell installations if means of positive lateral bearing by continuous contact between the sides of adjacent boxes are provided. Compacted earth fill, granular backfill, or grouting between the units are considered means of providing such positive bearing.

---

[1] Standard Designs and Criteria used to develop the designs that are included in this specification are under the jurisdiction of the AASHTO Subcommittee on Bridges and Structures. Agrees with ASTM C 850M-98 except that the use of synthetic fibers will be at the owner’s option.

Standard Specification for

Steel Sheet, Aluminum-Coated (Type 2), for Corrugated Steel Pipe

AASHTO Designation: M 274-87 (2008)

American Association of State Highway and Transportation Officials

Washington, D.C. 20001

Standard Specification for

Steel Sheet, Aluminum-Coated (Type 2), for Corrugated Steel Pipe

AASHTO Designation: M 274-87 (2008)

1. SCOPE

1.1. This specification covers steel sheet used in the fabrication of corrugated steel pipe (CSP) used for drainage pipe and underdrains. The steel sheet is coated with commercially pure aluminum (referred to as Type 2) on continuous lines by the hot-dip process, and is produced in one coating mass only. The material is furnished flat in coils and cut lengths, and corrugated in cut lengths.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 213M/T 213, Mass [Weight] of Coating on Aluminum-Coated Iron or Steel Articles

2.2. *ASTM Standards*:

- A 463M, Standard Specification for Steel Sheet, Aluminum-Coated, by the Hot-Dip Process
- A 754, Standard Test Method for Coating Weight (Mass) of Metallic Coatings on Steel by X-Ray Fluorescence
- E 376, Standard Practice for Measuring Coating Thickness by Magnetic-Field or Eddy-Current (Electromagnetic) Examination Methods

3. TERMINOLOGY

3.1. In this specification, *manufacturer* refers to the producer of the sheet, *fabricator* refers to the producer of the pipe, and *purchaser* refers to the purchaser of the finished pipe.

4. ORDERING INFORMATION

4.1. All sheet covered by this specification shall be ordered only to the specified thicknesses listed in Table 5.

4.2. Unless otherwise specified in the purchase order, all material furnished to this specification will be chemically treated, dry or oiled.

4.3. Orders for material to this specification shall include the following information, as necessary, to adequately describe the desired product:

4.3.1. Name of material (aluminum-coated steel sheet for CSP);

4.3.2. AASHTO designation number and date of issue;

4.3.3. Corrugation size, if corrugated (Section 8.3);

4.3.4. Dimensions (thickness; width, either flat or overall corrugated; and length, if cut length);

4.3.5. Coil size requirements (specify maximum outside diameter (OD), acceptable inside diameter (ID), and maximum mass);

4.3.6. Certification, if required (Section 11.1); and

4.3.7. Special Requirements.

Note 1—Typical ordering descriptions are as follow:

- Aluminum-coated steel sheet for CSP conforming to M 274-___, 68 by 13 mm corrugations, 1.63 by 648 by 1500 m.
- Aluminum-coated steel sheet for CSP conforming to M 274-___, 2.01 by 699 mm by coil, 1200 mm OD, 600 mm ID, 9000 kg max. certified with test report.

---

5. GENERAL REQUIREMENTS

5.1. Steel sheet material supplied under this specification shall meet the applicable requirements of ASTM A 463M unless otherwise specified herein. ASTM A 463M applies to aluminum-coated sheet; however, tolerances, sampling, sample preparation, and methods of testing (except for mass of coating) all are applicable to aluminum-coated sheet.

---

6. CHEMICAL COMPOSITION

6.1. The base metal composition shall conform to the requirements of Table 1.

Table 1—Base Metal Chemical Composition by Cast Analysis

	Composition, percent	Tolerance Over the Max Limit by Product Analysis, percent
Sulfur, max	0.05	+0.01
Sum of carbon, manganese, phosphorus, silicon, and sulfur, max	0.70	+0.04

6.2. *Aluminum Bath Analysis*—The bath shall be produced from commercially pure aluminum and the bath analysis shall conform to the limits given in Table 2.

Table 2—Aluminum Bath Analysis

	Composition, percent
Iron, max	3.0
Silicon, max	0.35
Magnesium, max	0.50
Other—each max	0.05
Other—total max	0.20

7. PHYSICAL PROPERTIES

7.1. The aluminum-coated steel sheet shall conform to the mechanical properties shown in Table 3, when tested prior to corrugating or other fabrication.

Table 3—Mechanical Requirements (Properties of Flat Material Prior to Fabrication)

Tensile strength, min, MPa	310
Yield point, min, MPa	230
Elongation in 50 mm, min, percent	20

Note 2—Steel sheet tested after corrugating and other fabricating should conform to the tensile and yield strength requirements in Table 3, but due to cold working, conformance to the elongation requirement may not be obtained.

7.2. The mass of aluminum coating shall conform to the requirements prescribed in Table 4. The mass of coating is the total amount on both surfaces of the sheet expressed in g/m^2 of sheet.

Table 4—Mass of Coating

Min Check Limit Triple Spot Test, g/m^2	Min Check Limit Single-Spot Test, g/m^2
300	270

7.3. Adherence of coating shall be such that no peeling occurs while the material is being corrugated and formed into pipe.

8. DIMENSIONS AND TOLERANCES

8.1. Sheet thickness shall conform to dimensions prescribed in Table 5. The thickness of the sheet includes both the base steel and the aluminum coating.

Table 5—Sheet Thickness[a]

Specified Thickness, mm	Min Thickness, mm
1.32	1.17
1.63	1.45
2.01	1.83
2.77	2.57
3.51	3.28

[a] Thickness is measured at any point on the sheet not less than 10 mm from an edge, and if corrugated, on the tangents of corrugation.

8.2. Permissible variations in width, length, and camber of flat material shall be in accordance with ASTM A 463M. Flatness tolerances of uncorrugated sheet shall conform to the dimensions prescribed in Table 6.

Table 6—Flatness Tolerances (Cut Lengths Only)

Specified Thickness, mm	Specified Width, mm	Flatness Tolerance (Max Deviation from a Horizontal Flat Surface), mm
1.32	To 900 incl	12.7
	More than 900 to 1500 incl	19
1.63 and thicker	To 1500 incl	12.7

Note: This table also applies to sheets cut to length from coils by the user when adequate flattening measures are performed.

8.3. Corrugations shall form smooth continuous curves and tangents. The dimensions of the corrugations shall be in accordance with Table 7 (Note 3).

Table 7—Corrugated Requirements

Nominal Size, mm	Max Pitch,[a] mm	Min Depth,[b] mm	Inside Radius	
			Nominal, mm	Min, mm
38 × 6.5	48	6	7	6.5
68 × 13	73	12	17	12
75 × 25	83	24	14	12
125 × 25	135	24	40	36

[a] Pitch is measured from crest to crest of corrugation, at 90 degrees to the direction of the corrugations.

[b] Depth is measured as the vertical distance from a straightedge resting on the corrugation crests to the bottom of the intervening valley.

Note 3—Some sizes of corrugations shown in Table 7 may not be available in cut-length sheets. The 38- by 6.5-mm size, especially, is generally used only for helically corrugated pipe.

8.4. Covering width of corrugated sheet shall be in accordance with Table 8. Covering width is the distance between the crests of the extreme corrugations. There is no established tolerance for overall width since the covering width and lip dimensions are the governing factors for the formed product. The lip dimension of corrugated sheets shall be in accordance with Table 9. This dimension is measured along the radial curvature from the crest of the corrugation to the edge of the sheet.

Table 8—Covering Width Tolerance for Corrugated Sheet

Covering Width, mm	Tolerance Over and Under, mm
To 600 inclusive	6.4
Over 600 to 900 inclusive	9.5
Over 900 to 1200 inclusive	12.7

Table 9—Corrugated Sheet Lip Dimensions

Nominal Corrugation Size, mm	For Riveted Pipe Construction,[a] mm	For Spot Welded Pipe Construction, Min, mm
68 × 13	19	11
75 × 25	22	13
125 × 25	22	13

[a] Tolerances, +4.8 mm, – 0.

9. SAMPLING AND TESTING

9.1. Except as specified below, the manufacturer shall make adequate tests and measurements to ensure that the material produced complies with this specification.

9.1.1. Test results, including chemical composition, mechanical properties, and mass of coating for each heat and coating lot, shall be maintained by the sheet manufacturer for 7 years and shall be made available to the fabricator and purchaser upon request.

9.2. The purchaser of the sheet (fabricator), or purchaser of the pipe made from the sheet, may make such tests as are deemed necessary to determine the acceptability of the material or to verify the correctness of a certification.

9.3. Mechanical properties shall be determined on sheet prior to corrugating or other fabricating, except tests may be made after fabrication by the purchaser for tensile strength and yield point.

9.3.1. Two tension tests shall be made on random samples of finished material from each cast or heat. When the finished material from said cast or heat is less than 45 Mg, one test is sufficient. When material rolled from one cast or heat differs 1.27 mm or more in thickness, one tension test shall be made from both the thickest and thinnest material rolled regardless of the mass represented. The samples shall be prepared and tested in accordance with the method specified in ASTM A 463M.

9.4. *Mass of Coating*—Sampling for mass of coating shall be as prescribed in ASTM A 463M. The mass of coating shall be determined according to T 213M/T 213.

9.4.1. The mass may be converted from the sum of readings of both surfaces of the sheet by a magnetic thickness gauge suitably checked and demonstrated for accuracy (Note 4) (1 μm = 3.2 g/m^2 each surface). When a magnetic thickness gauge is used and a dispute arises, the mass shall be determined by the stripping test in T 213M/T 213.

Note 4—Several magnetic and electromagnetic types of coating thickness gauges are commercially available and are a satisfactory basis for acceptance when properly calibrated just prior to inspection use. (See ASTM E 376.)

9.4.2. The mass of coating may be determined from the coating thickness measured by the x-ray fluorescence method, according to ASTM A 754. When this method is used and a dispute arises, the mass shall be determined by the stripping test in T 213M/T 213.

10. REJECTION

10.1. Material tested by the purchaser and found not conforming to this specification may be rejected.

11. CERTIFICATION

11.1. When specified in the purchase order or contract, a manufacturer’s certification shall be furnished to the purchaser of the sheet (fabricator) or to the purchaser of the finished pipe stating that the material was manufactured, sampled, tested, and inspected in accordance with this specification and has been found to meet the requirements for the material described in the purchase order or contract. When specified in the purchase order or contract, a report of the test results shall be furnished.

12. MARKING

12.1. Each 0.6 to 1.5 m of sheet in coils or cut lengths shall be identified by showing the following:

12.1.1. Name of sheet manufacturer,

12.1.2. Brand name,

12.1.3. Specified thickness,

12.1.4. Specified mass of coating,

12.1.5. Identification symbols relating to a specific heat number and lot number, and

12.1.6. AASHTO designation number.

12.2. The brand shall be removed, obliterated, or rebranded “Non-Specification Material” on each 0.6 to 1.5 m of material in a lot or heat for which control tests do not show conformance to this specification.

Standard Specification for

Class PS46 Poly(Vinyl Chloride) (PVC) Pipe

AASHTO Designation: M 278-02 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Class PS46 Poly(Vinyl Chloride) (PVC) Pipe

AASHTO Designation: M 278-02 (2007)

1. SCOPE

1.1. This specification covers the requirements and methods of test for smooth-wall perforated and unperforated poly(vinyl chloride) (PVC) plastic pipe, couplings, and fittings for use in subsurface drainage and surface drainage (culverts) of transportation facilities, where soil support is given to its flexible walls in all applications.

1.1.1. Nominal sizes of 100 to 375 mm in a stiffness class designated as PS46 are included.

1.1.2. Materials, dimensions, flattening, impact resistance, pipe stiffness, extrusion quality, joining systems, perforations, and form of marking are specified.

1.2. The following precautionary caveat pertains only to the test method portion, Section 6.8, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. NOMENCLATURE

3.1. *General*—The nomenclature used in this specification is in accordance with the definitions given in Definitions ASTM D 883 and Definitions ASTM F 412, unless otherwise specified. The abbreviation for polyvinyl chloride is PVC.

4. MATERIALS

4.1. *Basic Materials*—Pipe and fittings shall be made of virgin PVC plastic having a cell classification of 12454-B as defined in ASTM D 1784. Compounds shall be tested in accordance with ASTM D 1598 and provide a minimum hydrostatic design basis (HDB) of 30 MPa in water. Minimum HDB shall be evaluated in accordance with ASTM D 2837.

4.2. *Rework Materials*—Rework material from the manufacturer's own pipe or fittings production may be used by the same manufacturer, provided that the pipe or fabricated fittings produced meet all the requirements of this specification.

4.3. *Solvent Cement*—The PVC solvent cement used in joining the pipe and fittings for solvent cement joints shall comply with the requirements of ASTM D 2564.

4.4. *Gaskets*—Elastomeric seals (gaskets) shall comply with the requirements of ASTM F 477. The lubricant used for assembly shall have no detrimental effect on the gasket or on the pipe or fittings.

5. JOINING SYSTEMS

5.1. *Gasketed Joints*—The joint shall be designed so that, when assembled, the gasket inside the bell will be compressed radially on the pipe spigot to form a watertight seal.

5.1.1. The joint shall be designed to avoid displacement of the gasket when installed in accordance with the manufacturer's recommendations.

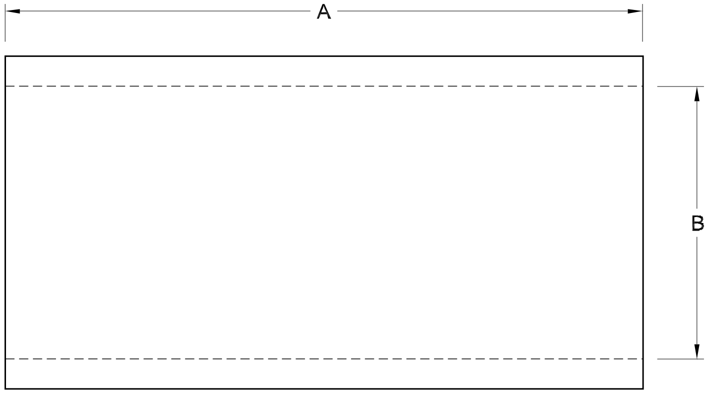
5.1.2. The assembly of joints shall be in accordance with the pipe manufacturer's recommendations.

5.2. *Solvent Cement Joints*—In the solvent cement joint, the pipe spigot wedges into the tapered socket and the surfaces fuse together. The tapered socket may be a portion of a molded fitting or it may be a belled end of a pipe section.

5.2.1. The assembly of joints shall be in accordance with ASTM D 2855 and taking cognizance of ASTM F 402.

Note 1—Difficulty may be encountered in obtaining watertight joints when solvent cementing joints in pipe diameters greater than 150 mm.

5.3. *Unsealed Joints*—Perforated pipe may be connected with stop-type couplings (as described in ASTM D 3034, Figure 9) or belled-ends of pipe conforming to Section 6.2.5 without the use of solvent cement. If sleeve couplings as described in Figure 1 are used, the coupling shall be solvent cemented to one length of pipe, lapping 40 to 50 percent of the coupling length.



Nominal Size, mm	Length (A)		Inside Diameter (B)	
	Average, mm	Tolerance, mm	Average, mm	Tolerance, mm
100	88.9	+6.35, –0	107.44	±0.13
150	152.4	+6.35, –0	159.77	±0.13
200	203.2	+6.35, –0	213.74	±0.15
250	254.0	+6.34, –0	267.21	±0.18
300	304.8	+6.35, –0	318.13	±0.20
375	381.0	+6.35, –0	389.51	±0.23

Figure 1—Sleeve Coupling Dimensions

6. REQUIREMENTS

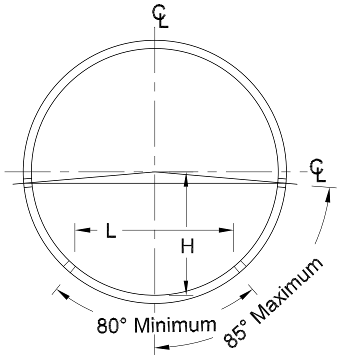
6.1. *Workmanship*—The pipe and fittings shall be homogeneous throughout, and free from visible cracks, flaws, foreign inclusions, or other injurious defects. The pipe shall be as uniform as commercially practical in color, opacity, and other physical properties.

6.2. *Pipe Dimensions*:

6.2.1. *Diameter*—The average outside diameter of the pipe shall be as specified in Figure 2 when measured in accordance with ASTM D 2122.

6.2.2. *Wall Thickness*—The minimum wall thickness shall be as specified in Figure 2 when measured in accordance with ASTM D 2122.

6.2.3. *Length*—Laying length shall be 6 m for diameters up to 200 mm and no less than 3 m for larger sizes; or as mutually agreed upon between purchaser and manufacturer. A tolerance of ±25 mm shall be permitted.



Pipe Dimensions

Nominal Size, mm	Outside Diameter		Out-of-Roundness		Minimum Wall Thickness, mm
	Average, mm	Tolerance, mm	Min, mm	Max, mm	
100	107.06	±0.22	105.80	108.34	3.08
150	159.38	±0.28	158.12	160.66	4.58
200	213.36	±0.30	212.08	214.62	6.10
250	266.70	±0.38	263.66	269.75	7.65
300	317.50	±0.46	313.87	321.14	9.09
375	388.62	±0.58	384.16	393.09	11.13

Figure 2—Requirements for Perforations

6.2.4. *Perforations*—Perforations, when required, shall be circular holes, 4.8 to 9.5 mm in diameter, arranged in rows parallel to the axis of the pipe. Perforations shall be approximately 75 mm center-to-center, along the rows. The rows of perforations shall be arranged in two equal groups placed symmetrically on either side of a lower unperforated segment, corresponding to the flowline of the pipe. The spacing of the rows shall be uniform. The distance between the centerlines of rows shall be not less than 25 mm. The minimum number of longitudinal rows of perforations, the maximum heights of the centerlines of the uppermost rows above the bottom of the inverts, and the inside chord lengths of the unperforated segments shall be as specified in Table 1.

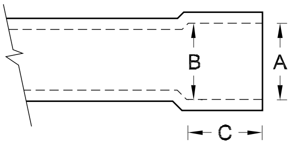
Table 1—Rows of Perforations, Height *H* of the Centerline of the Uppermost Rows above the Invert, and Chord Length *L* of the Unperforated Segment

Internal Diameter of Pipe, mm	Rows of Perforations	*H*, Max, mm	*L*, Min, mm
100	2	46	65
150	4	70	98
200	4	94	130
250	4	116	164
300	6	140	195
375	6	175	244

6.2.5. *Integral Bell Dimensions*—The thickness of the wall shall be considered satisfactory if the bell was formed from pipe meeting the requirements of this specification.

6.2.5.1. *Elastomeric Joints*—Integral bells for elastomeric seal joint shall meet dimensions recommended by the manufacturer.

6.2.5.2. *Solvent Cement Joints*—Socket-type bell dimensions for solvent cement joints shall comply with Figure 3.

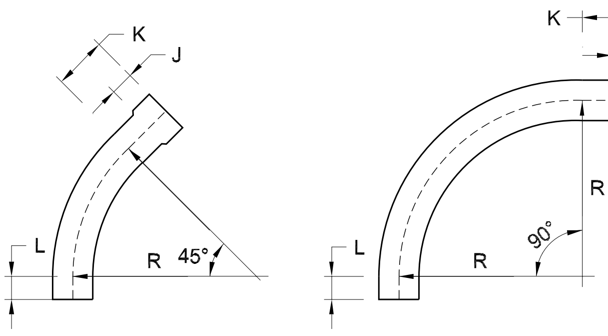


Nominal Size, mm	Entrance (A)		Socket Bottom (B)		Min Bell Depth (C)
	Diameter, mm	Tolerance, mm	Diameter, mm	Tolerance, mm	
100	107.57	±0.22	106.93	±0.22	44.44
150	160.15	±0.28	159.26	±0.28	76.20
200	213.97	±0.30	213.06	±0.30	101.60
250	267.47	±0.38	286.32	±0.38	127.00
300	318.41	±0.46	317.04	±0.46	152.40
375	369.79	±0.58	388.04	±0.58	190.50

Figure 3—Pipe Integral Bell for Solvent Cement Joints

6.3. *Fitting Dimensions*:

6.3.1. *Fitting Wall Thickness*—The minimum wall thickness of sleeve-type couplings and molded fittings shall be no less than the respective minimum thicknesses listed for the equivalent pipe in Figure 2. The wall thickness of bends manufactured from pipe (Figure 4) shall be considered satisfactory, providing the bend was formed from pipe meeting the requirements of this specification. For reducing fittings or those with smaller inlets, the minimum wall thickness of each inlet shall not be less than the minimum wall thickness for that size pipe.



Nominal Size, mm	Dimensions (Min)			
	Radius (R), mm	(J), mm	(K), mm	(L), mm
100	406.4, 609.6, or 914.4	44.44	88.90	50.80
150	609.6 or 914.4	76.20	152.40	88.90
200	609.6 or 914.4	101.60	203.20	127.00

Figure 4—Laying Lengths of Bends Manufactured from Pipe

6.3.2. *Laying Length*—The laying length of fittings shall meet the requirements of Figures 1 and 4 of this specification or Tables 3 to 11 of ASTM D 3034.

6.4. *Minimum Pipe Stiffness*—The minimum pipe stiffness (PS) values shall be 320 kPa when tested in accordance with Section 8.3. Three specimens shall be tested; all shall meet the requirements.

6.5. *Pipe Flattening*—There shall be no evidence of splitting, cracking, or breaking when pipe and couplings tested in accordance with Section 8.4 are examined without the use of magnification equipment.

6.6. *Impact Strength*—The minimum drop weight impact strength for pipe and couplings shall meet the requirements of Table 2, when tested in accordance with Section 8.1.

Table 2—Impact Strength at 0°C

Nominal Size, mm	J
100	90
150	115
200	130
250	130
300	130
375	130

6.7. *Joint Tightness:*

6.7.1. *Elastomeric Seal (Gasketed) Joints*—Joints made with pipe and fittings having elastomeric seals shall show no sign of leakage when tested in accordance with ASTM D 3212. All surfaces of the joint upon which the gasket bears shall be smooth and free of imperfections, ridges, fractures, or cracks that could adversely affect the seal.

6.7.2. *Solvent Cement Joints*—Joints made with solvent cement joining shall show no sign of leakage when tested in accordance with Section 8.2.

Note 2—These requirements are qualifying requirements for joint design and fabrication and are not necessarily indicative of performance in field assembly.

6.8. *Extrusion Quality*—The pipe and fittings shall not flake or disintegrate when tested in accordance with ASTM D 2152. For recommended practices on using specific chemicals to test plastic pipe, refer to R 16.

7. CONDITIONING

7.1. *Referee Test*—When conditioning is required for tests, the specimens shall be conditioned in accordance with Procedure A in ASTM D 618 at 20 to 21ºC and 50 ± 5 percent relative humidity for not less than 40 hours prior to test. Tests shall be conducted under the same conditions of temperature and humidity, unless otherwise specified.

7.2. *Quality Control*—For quality control tests, except impact, specimens shall be conditioned for a minimum of 3 hours in air or 1 hour in liquid at 20 to 25ºC. They shall be tested at 20 to 25ºC without regard to relative humidity.

7.3. *Impact Tests*—For the impact test described in Section 8.1, the specimen and the surrounding conditioning medium are to be in thermal equilibrium with one another at a temperature of 0 to 2ºC.

8. TEST METHODS

8.1. *Impact Resistance*—Five specimens, each 150 ± 2 mm long, shall be tested in accordance with ASTM D 2444, using a 10-kg Tup A, and the Flat plate (holder B). When testing is performed at temperatures above 0ºC, no more than 15 seconds shall elapse from the time of removal of the specimen from the conditioning medium until completion of that test. Perforated specimens must be positioned with the print marking, as described in Section 10, uppermost; other specimens may be positioned with a random surface uppermost. All specimens must be located so that the contact point is centered. All five specimens shall pass. If one specimen fails, another five specimens shall be tested; nine out of ten specimens passing shall be acceptable.

8.2. *Joint Tightness of Solvent Cemented Joints*—A section of unperforated pipe shall be cemented to a bell or coupling, using the manufacturer's recommendations, or, in their absence, the methods described in ASTM D 2855. Unless otherwise specified, the assembly shall be allowed to stand for at least 24 hours. It shall then be subjected to an internal pressure of 0.17 MPa, using water as the test medium. The pressure shall be maintained for at least 1 hour. Examine the joint for leakage.

8.3. *Pipe Stiffness*—Determine the PS at 5 percent deflection of the initial inside diameter, as described in ASTM D 2412. Test three specimens, each 150 ± 2 mm long. Unperforated pipe samples shall be placed so that the minimum wall thickness is uppermost (adjacent to the top bearing plate). Perforated pipe samples shall be placed with the marking, as described in Section 10, uppermost.

8.4. *Pipe Flattening*—Flatten three specimens of pipe, each 150 ± 2 mm long, between parallel plates in a suitable press until the distance between the plates is twice the wall thickness plus 5 percent of the nominal diameter of the pipe. The rate of loading shall be uniform and such that the compression is completed within 2 to 5 minutes. Remove the load and examine the specimens.

8.5. *Dimensions*—Measurements shall be made in accordance with applicable sections of ASTM D 2122.

9. INSPECTION AND RETEST

9.1. *Inspection*—The material shall be inspected as agreed upon by the purchaser and the seller as part of the purchase contract.

9.2. *Retest and Rejection*—If the material fails to meet the requirement of Section 6 when tested in accordance with Section 8, the material may be retested to establish conformity in accordance with agreement between the purchaser and seller.

10. MARKING

10.1. All pipe shall be clearly marked at intervals of no more than 3.0 m, with 9.5 mm or larger letters, and fittings shall be clearly marked, as follows:

10.1.1. Manufacturer's name or trademark,

10.1.2. Nominal size,

10.1.3. The specification designation M 278, and

10.1.4. The plant designation code.

10.2. Pipe shall be tagged with the date of manufacture.

10.3. In addition to the above, all bends made from the pipe shall be marked to show the angle and radius of curvature.

10.4. The marking on perforated pipe shall be 180 degrees from a point equidistant between the bottom row of holes as shown in Table 1.

10.5. When exposed, a "home" mark, located at spigot ends, indicates the proper position of the bell end, when the spigot end is fully inserted.

11. QUALITY ASSURANCE

11.1. A manufacturer's certification that the product was manufactured, tested, and supplied in accordance with this specification, together with a report of the test results and the date each test was completed, shall be furnished upon request. Each certification so furnished shall be signed by a person authorized by the manufacturer.

Standard Specification for

Aluminum-Zinc Alloy Coated Sheet Steel for Corrugated Steel Pipe

AASHTO Designation: M 289-91 (2008)

Standard Specification for

Aluminum-Zinc Alloy Coated Sheet Steel for Corrugated Steel Pipe

AASHTO Designation: M 289-91 (2008)

1. SCOPE

1.1. This specification covers sheet steel for corrugated steel pipe, which is coated with a 55 percent aluminum-zinc alloy on continuous lines by the hot-dip process. The material is furnished in coils, flat cut lengths, and corrugated cut lengths. The standard corrugations available in cut lengths (pitch by depth) are 68 by 13 mm, 75 by 25 mm, and 125 by 25 mm. Aluminum-zinc alloy coated steel sheet for corrugated pipe is produced in one coating mass only, designated as 210 g/m^2.

1.2. Steel sheets or coils furnished under this specification shall meet the applicable requirements of ASTM A 792M unless otherwise specified herein.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- A 754/A754M, Standard Test Method for Coating Weight (Mass) of Metallic Coatings on Steel by X-Ray Fluorescence
- E 8/E 8M, Standard Test Methods for Tension Testing of Metallic Materials
- E 376, Standard Practice for Measuring Coating Thickness by Magnetic-Field or Eddy-Current (Electromagnetic) Examination Methods

3. DESCRIPTION OF TERMS

3.1. In this specification, *manufacturer* refers to the producer of the sheet, *fabricator* refers to the producer of the pipe, and *purchaser* refers to the purchaser of the finished product.

4. ORDERING INFORMATION

4.1. All sheet, both flat and formed, covered by this specification is ordered only to the specified thicknesses listed in Table 4. The thickness of the sheet includes both the base steel and the coating.

4.2. Unless otherwise specified in the purchase order, all material furnished to this specification will be chemically treated.

4.3. Orders for material to this specification shall include the following information, as necessary, to adequately describe the desired product:

4.3.1. Name of material (aluminum-zinc alloy coated sheet for corrugated steel pipe, or corrugated aluminum-zinc alloy coated sheet for corrugated steel pipe);

4.3.2. Description of corrugations, if corrugated (Section 10);

4.3.3. Mass of aluminum-zinc alloy coating (210 g/m^2) (Note 1);

4.3.4. AASHTO designation number and date of issue;

4.3.5. Dimensions: thickness, flat width (if flat) or overall corrugated width (if corrugated), and length (if cut length) (Section 10);

4.3.6. Coil size requirements (specify maximum outside diameter (OD), acceptable inside diameter (ID), and maximum mass); and

4.3.7. Special requirements.

4.4. If a certification by the manufacturer is required, it shall be specified in the purchase order (Section 12).

Note 1—The coating mass should be shown in the order to eliminate possible confusion with coating masses permitted by other specifications.

Note 2—Typical ordering descriptions are as follow:

- Aluminum-zinc alloy coated steel sheet for corrugated steel pipe 68 by 13 mm corrugated, 210-g/m^2 coating, 1.63 by 648 by 1524 mm, in accordance with M 289-___.
- Aluminum-zinc alloy coated steel sheet for corrugated steel pipe, 210-g/m^2 coating, 2.01 by 686 mm by coil, 1200 mm max OD, 600 mm ID, 5445 kg max coils, in accordance with M 289-___.

5. CHEMICAL REQUIREMENTS

5.1. *Cast or Heat (formerly Ladle) Analysis*—The base metal cast or heat (formerly ladle) analysis shall conform to the chemical requirements of Table 1.

Table 1—Chemical Composition by Cast Analysis

	Composition, percent	Tolerance Over the Max Limit by Product Analysis, percent
Carbon, max	—	—
Manganese, max	—	—
Phosphorus, max	—	—
Sulfur, max	0.05	+0.01
Silicon, max	—	—
Sum of first five elements, max	0.07	+0.04

Note: Copper bearing steel availability subject to inquiry.

6. MECHANICAL REQUIREMENTS

6.1. The aluminum-zinc alloy coated sheet steel shall conform to the mechanical properties of Table 2.

Table 2—Mechanical Requirements
(Properties of Flat Material Prior to Fabrication)

Tensile Strength, min, MPa	310
Yield Point, min, MPa	230
Elongation in 50 mm, min percent	20

6.2. Two tension tests shall be made on random samples of finished material from each cast or heat. When the finished material from said cast or heat is less than 45 Mg, one test is sufficient. When material rolled from one cast or heat differs 1.27 mm or more in thickness, one tension test shall be made from both the thickest and thinnest material rolled regardless of the mass represented. The samples shall be prepared and tested in accordance with the method specified in ASTM A 792M and E 8/E 8M.

7. ALUMINUM-ZINC ALLOY COATING

7.1. The coating shall have a nominal composition of 55.0 percent aluminum, 1.6 percent silicon, and the remainder zinc (Note 3). The mass of coating shall conform to the requirements prescribed in Table 3. The mass of coating is the total amount on both surfaces of the sheet expressed in g/m^2 of sheet.

Table 3—Mass of Coating (Total Both Sides)

Min Check Limit Triple-Spot Test, g/m^2 of Sheet	Min Check Limit Single-Spot Test, g/m^2 of Sheet
210	180

Note 3—Chemical Analysis of the coating will typically agree with the nominal composition within ±3 percent for aluminum and zinc, and within ±0.5 percent for silicon.

7.2. Sampling and methods of testing shall be as prescribed in T 65M/T 65 and ASTM A 792M, using the dilute hydrochloric acid method (Note 4).

Note 4—T 65M/T 65 is a method for determining mass of zinc coating on steel, but the dilute hydrochloric acid method is satisfactory for determining the mass of aluminum-zinc alloy coating.

7.2.1. The mass of coating may be determined from the coating thickness measured by the x-ray fluorescence method, according to ASTM A 754. When this method is used and a dispute arises, the mass shall be determined by the stripping test in T 65M/T 65.

7.3. Adherence of coating shall be such that no peeling occurs while the material is being corrugated and formed into pipe.

8. TESTS BY MANUFACTURER

8.1. The manufacturer shall make such tests and measurements as are deemed necessary to ensure that the material produced complies with this specification.

9. SAMPLING BY PURCHASER

9.1. *Product, Check, or Verification Analysis*—Base metal analysis may be made by the purchaser in accordance with ASTM A 792M.

9.2. *Mechanical Testing*—Test for mechanical properties may be made by the purchaser. Testing of flat material shall be made prior to corrugating or other fabrication and shall be in accordance with ASTM A 792M and E 8/E 8M.

9.3. *Mass of Coating*—The purchaser may make random checks of coating masses to assure compliance of minimum values specified in Table 3. The mass may be converted from the sum of the readings on both surfaces of the sheet by a magnetic coating thickness gauge suitably checked and demonstrated for accuracy (Notes 5 and 6). In case of dispute, additional samples shall be taken and tested in accordance with the procedure outlined in T 65M/T 65 and ASTM A 792M, using the dilute hydrochloric acid method (Note 4).

Note 5—Several magnetic types of coating thickness gauges are commercially available and are a satisfactory basis for acceptance when properly calibrated just prior to inspection use. (See ASTM E 376.)

Note 6—An aluminum-zinc alloy coating mass of 210 g/m^2 total both sides is equivalent to an average thickness of 28 μm each side.

9.4. *Rejection and Rehearing*—Material tested by the purchaser and found not conforming to this specification may be rejected, subject to the rejection and rehearing provisions of ASTM A 792M.

10. DIMENSIONS AND TOLERANCES

10.1. Sheet thickness shall conform to dimensions prescribed in Table 4. If corrugated, thickness shall be measured on the tangents of the corrugations.

Table 4—Sheet Thickness for Corrugated Steel Pipe

Specified Thickness, mm	Min Thickness, mm
1.02	0.91
1.32	1.17
1.63	1.45
2.01	1.83
2.77	2.57
3.51	3.28
4.27	4.04

Note: Thickness is measured on the tangents of corrugations on the sheet not less than 10 mm from an edge.

10.2. Permissible variations in width, length, and camber of flat material shall be in accordance with ASTM A 792M.

10.3. Corrugations shall form smooth continuous curves and tangents. The dimensions of the corrugations shall be in accordance with Table 5 (Note 7).

Note 7—Some sizes of corrugations shown in Table 5 may not be available in cut-length sheets. The 38 by 6.5 mm size, especially, is generally used only for helically corrugated pipe.

Table 5—Corrugation Requirements

Nominal Size, mm	Max Pitch,[a] mm	Min Depth,[b] mm	Inside Radius	
			Nominal, mm	Min, mm
38 × 6.5	48	6.0	7	6.5
68 × 13	73	12	17	12
75 × 25	83	24	14	12
125 × 25	135	24	40	36

[a] Pitch is measured from crest to crest of corrugation, at 90 degrees to the direction of the corrugations.

[b] Depth is measured as the vertical distance from a straightedge resting on the corrugation crests to the bottom of the intervening valley.

10.4. Covering width of corrugated sheet shall be in accordance with Table 6. Covering width is the distance between the crests of the extreme corrugations. There is no established tolerance for overall width since the covering width and lip dimensions are the governing factors for the formed product. The lip dimension of corrugated sheet shall be in accordance with Table 7. This dimension is measured along the radial curvature from the crest of the corrugation to the edge of the sheet.

Table 6—Covering Width Tolerances for Corrugated Sheet

Covering Width, mm	Tolerance Over and Under, mm
To 600 incl	6
Over 600 to 900 incl	10
Over 900 to 1200 incl	13

Table 7—Corrugated Sheet Lip Dimensions

Nominal Corrugation Size, mm	For Riveted Pipe Construction,[a] mm	For Spot Welded Pipe Construction, Min, mm
68 by 13	19	11
75 by 25	22	13
125 by 25	22	13

[a] Tolerances, +5 mm, –0.

11. RECORDS

11.1. Test results, including chemical compositions, tensile strength, and mass of coating for each heat and coating lot, shall be maintained by the sheet manufacturer for 7 years and shall be made available to the fabricator and purchaser upon request.

12. CERTIFICATION

12.1. When specified in the purchase order, a manufacturer's certification shall be furnished to the purchaser. The certification shall show results of tests conducted on samples from each lot from which sheet is furnished. A statement shall be included that the test results conform to the requirements of M 289. The certification shall provide information necessary to identify the sheet represented, such as manufacturer's name or brand, heat number, lot number, sheet thickness, coating mass, corrugation size (if corrugated), and sheet size (if cut lengths). Furnishing a certification shall not restrict the right of the purchaser of the sheet (fabricator) or ultimate purchaser of the pipe made from the sheet to sample and test the material furnished.

13. MARKING

13.1. Each 0.5 to 1.5 m of sheet in coils or cut lengths shall be identified by showing the following:

13.1.1. Name of sheet manufacturer,

13.1.2. Brand name,

13.1.3. Specified thickness,

13.1.4. Specified mass of coating,

13.1.5. Identification symbols relating to a specific heat number and coating lot number, and

13.1.6. AASHTO designation number.

13.2. The brand shall be removed, obliterated, or the sheet rebranded "Non Specification" on each 0.5 to 1.5 m of material in a coating lot or heat where control tests, as prescribed herein, show nonconformance to this specification.

Standard Specification for

Corrugated Polyethylene Pipe, 300- to 1500-mm (12- to 60-in.) Diameter

AASHTO Designation: M 294-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Corrugated Polyethylene Pipe, 300- to 1500-mm (12- to 60-in.) Diameter

AASHTO Designation: M 294-10

1. SCOPE

1.1 This specification covers the requirements and methods of tests for corrugated polyethylene (PE) pipe, couplings, and fittings for use in surface and subsurface drainage applications.

1.1.1 Nominal sizes of 300 to 1500 mm (12 to 60 in.) are included.

1.1.2 Materials, workmanship, dimensions, pipe stiffness, slow crack growth resistance, joining systems, brittleness, and form of markings are specified.

1.2 Corrugated PE pipe is intended for surface and subsurface drainage applications where soil provides support to its flexible walls. Its major use is to collect or convey drainage water by open gravity flow, as culverts, storm drains, etc.

Note 1—When PE pipe is to be used in locations where the ends may be exposed, consideration should be given to protection of the exposed portions due to combustibility of the PE and the deteriorating effects of prolonged exposure to ultraviolet radiation.

1.3 *Units*—The values stated in SI units are to be regarded as standard. Within the text, the U.S. customary units are shown in parentheses, and may not be exact equivalents.

1.4 This specification does not include requirements for bedding, backfill, or earth cover load. Successful performance of this product depends upon proper type of bedding and backfill, and care in installation. The structural design of corrugated PE pipe and the proper installation procedures are given in *AASHTO LRFD Bridge Design Specifications,* Section 12, and *LFRD Bridge Construction Specifications,* Section 30, respectively. Upon request of the user or engineer, the manufacturer shall provide profile wall section detail required for a full engineering evaluation.

1.5 The following precautionary caveat pertains only to the test method portion, Section 9.4, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1 The terminology used in this standard is in accordance with the definitions given in ASTM D 883 and ASTM F 412 unless otherwise specified.

3.2 *crack*—any break or split that extends through the wall.

3.3 *crease*—an irrecoverable indentation, generally associated with wall buckling.

3.4 *buckling*—any reverse curvature or deformation in the pipe wall that reduces the load-carrying capability of the pipe. Any decrease or downward deviation in the pipe stiffness test curve shall be considered a wall-buckling point.

3.5 *polyethylene (PE) plastics*—plastics based on polymers made with ethylene as essentially the sole monomer (ASTM D 883).

3.6 *reworked plastic*—A plastic from a processor’s own production that has been reground, pelletized, or solvated after having been previously processed by molding, extrusion, etc. (ASTM D 883).

3.7 *virgin polyethylene material*—PE plastic material in the form of pellets, granules, powder, floc, or liquid that has not been subject to use or processing other than required for initial manufacture.

3.8 *slow crack growth*—A phenomenon by which a stress crack may form. A stress crack is an external or internal crack in plastic caused by tensile stresses less than its short-time mechanical strength.

3.9 *delamination*—A separation between the inner liner and outer corrugated wall of Type S pipe as evidenced by a visible gap extending completely through at least one corrugation valley at any point around the circumference of the pipe. For Type D pipe, delamination is a separation of the inner and outer wall as evidenced by a visible gap extending completely between the internal supports and inner or outer wall at any point around the circumference of the pipe.

4. CLASSIFICATION

4.1 The corrugated PE pipe covered by this specification is classified as follows:

4.1.1 *Type C*—This pipe shall have a full circular cross section, with a corrugated surface both inside and outside. Corrugations shall be annular.

4.1.1.1 *Type CP*—This pipe shall be Type C with perforations.

4.1.2 *Type S*—This pipe shall have a full circular cross section, with an outer corrugated pipe wall and a smooth inner liner. Corrugations shall be annular.

4.1.2.1 *Type SP*—This pipe shall be Type S with perforations.

4.1.3 *Type D*—This pipe shall consist of an essentially smooth inner wall/liner braced circumferentially or spirally with projections or ribs joined to an essentially smooth outer wall.

4.1.3.1 *Type DP*—This pipe shall be Type D with perforations.

4.2 Two classes of perforations are as described in Sections 7.3.1 and 7.3.2.

5. ORDERING INFORMATION

5.1 Orders using this specification shall include the following information, as necessary, to adequately describe the desired product:

5.1.1 AASHTO designation and year of issue;

5.1.2 Type of pipe (Section 4.1);

5.1.3 Diameter and length required, either total length or length of each piece and number of pieces;

5.1.4 Number of couplings;

5.1.5 Class of perforations (Class 2 is furnished if not specified) (Section 7.3); and

5.1.6 Certification, if desired (Section 12.1).

6. MATERIALS

6.1 *Basic Materials*:

6.1.1 *Extruded Pipe and Blow Molded Fittings*—Pipe and fittings shall be made of virgin PE resin compounds meeting the requirements of ASTM D 3350 and cell classification 435400C, except that the carbon black content shall not exceed 5 percent, and the density shall not be less than 0.948 gm/cc nor greater than 0.955 gm/cc. The cell classification shall be based on the virgin PE resin compounds without carbon black. Resins that have higher cell classifications in one or more properties, with the exception of density, are acceptable provided product requirements are met. For slow crack growth resistance, acceptance of resins shall be determined by using the notched constant ligament-stress (NCLS) test according to the procedure described in Section 9.4. For slow crack growth resistance, acceptance of pipe shall be determined by tests on the finished pipe using the NCLS test according to the procedure described in Section 9.4. The average failure time of the pipe liner shall not be less than 18 hours. If profile geometries do not have a flat portion of sufficient length to produce an NCLS tensile specimen of 25 mm (1 in.) length, the pipe sample shall be ground and a test plaque made in accordance with ASTM D 4703 Procedure C at a cooling rate of 15ºC/min (27°F/min) and tested per ASTM F 2136. The average failure time of test specimens from plaques shall not be less than 24 hours.

6.1.2 *Rotational Molded Fittings and Couplings*—Fittings and couplings shall be made of virgin PE resins meeting the requirements of ASTM D 3350 and cell classification 213320C, except that the carbon black content shall not exceed 5 percent. Resins that have higher cell classifications in one or more properties are acceptable provided product requirements are met.

6.1.3 *Injection Molded Fittings and Couplings*—Fittings and couplings shall be made of virgin PE resins meeting the requirements of ASTM D 3350 and cell classification 314420C, except that the carbon black content shall not exceed 5 percent. Resins that have higher cell classifications in one or more properties are acceptable provided product requirements are met.

6.2 *Reworked Plastic*—In lieu of virgin PE, clean reworked plastic may be used by the manufacturer, provided that it meets the cell class requirements as described in Section 6.1.

6.3 *Resin Blending*—When blended resins are used, the components of the blend must be virgin PE and the final blend must meet all of the requirements of Section 6.1.1 for extruded pipe and blow molded fittings, Section 6.1.2 for rotational molded fittings and couplings, and Section 6.1.3 for injection molded fittings and couplings.

7. REQUIREMENTS

7.1 *Workmanship*—The pipe and fittings shall be free of foreign inclusions and visible defects as defined herein. The ends of the pipe shall be cut squarely and cleanly so as not to adversely affect joining or connecting.

7.1.1 *Visible Defects*—Cracks, creases, delaminations, and unpigmented or nonuniformly pigmented pipe are not permissible in the pipe or fittings as furnished. There shall be no evidence of delamination when tested in accordance with Section 9.7.

7.2 *Pipe Dimensions*:

7.2.1 *Nominal Size*—The nominal size for the pipe and fittings is based on the nominal inside diameter of the pipe. Nominal diameters shall be 300, 375, 450, 525, 600, 675, 750, 900, 1050, 1200, 1350, and 1500 mm (12, 15, 18, 21, 24, 27, 30, 36, 42, 48, 54, and 60 in.).

7.2.2 *Wall Thickness*—The inner wall of Type S pipe, and both inner and outer walls of Type D, pipe shall have the following minimum thicknesses, when measured in accordance with Section 9.6.4.

Diameter, mm (in.)	Wall Thickness, mm (in.)
300 (12)	0.9 (0.035)
375 (15)	1.0 (0.04)
450 (18)	1.3 (0.05)
525 (21)	1.5 (0.06)
600 (24)	1.5 (0.06)
675 (27)	1.5 (0.06)
750 (30)	1.5 (0.06)
900 (36)	1.7 (0.07)
1050 (42)	1.8 (0.07)
1200 (48)	1.8 (0.07)
1350 (54)	2.0 (0.08)
1500 (60)	2.0 (0.08)

7.2.3 *Inside Diameter Tolerances*—The tolerance on the specified inside diameter shall be 4.5 percent oversize and 1.5 percent undersize, but not more than 37 mm (1.5 in.) oversize when measured in accordance with Section 9.6.1.

7.2.4 *Length*—Corrugated PE pipe may be sold in any length agreeable to the user. Lengths shall not be less than 99 percent of the stated quantity when measured in accordance with Section 9.6.2.

7.3 *Perforations*—When perforated pipe is specified, the perforations shall conform to the requirements of Class 2, unless otherwise specified in the order. Class 1 perforations are for pipe intended to be used for subsurface drainage or combination storm and underdrain. Class 2 perforations are for pipe intended to be used for subsurface drainage only. The perforations shall be cleanly cut so as not to restrict the inflow of water. Pipe connected by couplings or bands may be unperforated within 100 mm (4 in.) of each end of each length of pipe. Pipe connected by bell and spigot joints may not be perforated in the area of the bells and spigots.

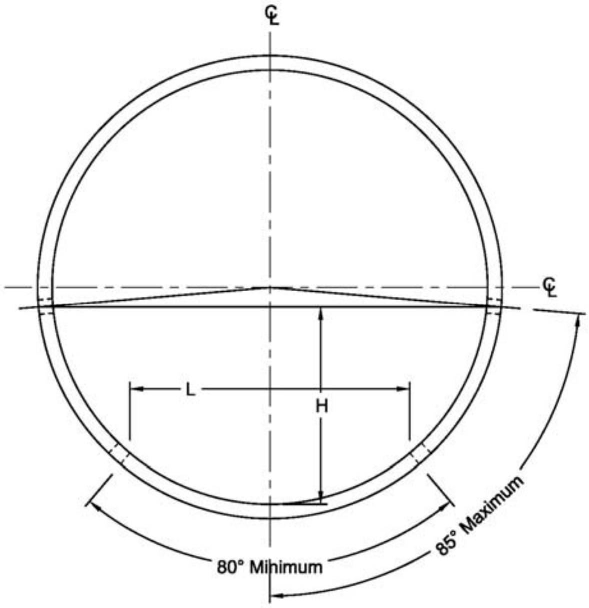

Figure 1—Requirements for Perforations

Table 1—Rows of Perforations, Height *H* of the Centerline of the Uppermost Rows above the Invert, and Chord Length *L* of Unperforated Segment, for Class 1 Perforations

Nominal Diameter, mm (in.)	Rows of Perforations[a]	*H*, Max,[b] mm (in.)	*L*, Min,[b] mm (in.)
300 (12)	6	138 (5.4)	192 (7.5)
375 (15)	6	172 (6.75)	240 (9.5)
450 (18)	6	207 (8.15)	288 (11.3)
525 (21)	6	241 (9.5)	336 (13.2)
600 and larger (24 and larger)	8	[c]	[c]

[a] Minimum number of rows. A greater number of rows for increased inlet area shall be subject to agreement between purchaser and manufacturer. Note that the number of perforations per meter in each row (and inlet area) is dependent on the corrugation pitch.

[b] See Figure 1 for location of dimensions *H* and *L*.

[c] *H*(max) = 0.46*D*; *L*(min) = 0.64D, where *D* = nominal diameter of pipe, mm.

7.3.1 *Class 1 Perforations*—The perforations shall be approximately circular and shall have nominal diameters of not less than 5 mm (0.2 in.) nor greater than 10 mm (0.4 in.) and shall be arranged in rows parallel to the axis of the pipe. For Type CP and SP pipe, the perforations shall be located in the external valleys with perforations in each row for each corrugation. (The perforations shall not cut into the corrugation sidewalls.) For Type DP pipe, perforations shall be located in the center of the cells. The perforations shall not cut into the vertical sections of the cells. The rows of perforations shall be arranged in two equal groups placed symmetrically on either side of the lower unperforated segment corresponding to the flow line of the pipe. The spacing of the rows shall be uniform. The distance between the centerlines of the rows shall not be less than 25 mm (1 in.). The minimum number of longitudinal rows of perforations, the maximum height of the centerlines of the uppermost rows of perforations above the bottom of the invert, and the inside chord lengths of the unperforated segments illustrated in Figure 1 shall be as specified in Table 1.

7.3.2 *Class 2 Perforations*—Circular perforations shall be a minimum of 5 mm (0.2 in.) and shall not exceed 10 mm (0.4 in.) in diameter. The width of slots shall not exceed 3 mm (0.1 in.). The length of slots shall not exceed 70 mm (2.75 in.) for 300 mm (12 in.) and 375 mm (15 in.) pipe and 75 mm (3 in.) for 450 mm (18 in.) and larger pipe. Perforations shall be placed in the external valleys for Type CP and SP pipe and in the center of the cells for Type DP pipe. Perforations shall be uniformly spaced along the length and circumference of the pipe. The water inlet area shall be a minimum of 30 cm^2/m (1.5 $in.^2$/ft) for pipe sizes 300 to 450 mm (12 to 18 in.) and 40 cm^2/m (2 $in.^2$/ft) for pipe sizes larger than 450 mm (18 in.). All measurements shall be made in accordance with Section 9.6.3.

7.4 *Pipe Stiffness*—The pipe shall have a minimum pipe stiffness at 5 percent deflection as follows when tested in accordance with Section 9.1.

Diameter, mm (in.)	Pipe Stiffness, kPa (psi)
300 (12)	345 (50)
375 (15)	290 (42)
450 (18)	275 (40)
525 (21)	260 (38)
600 (24)	235 (34)
675 (27)	205 (30)[a]
750 (30)	200 (29)[a]
900 (36)	155 (22.5)[a]
1050 (42)	145 (21)[a]
1200 (48)	135 (20)[a]
1350 (54)	120 (18)[a]
1500 (60)	105 (15)[a]

[a] For diameters 675 mm (27 in.) and larger, the stiffness test is conducted at a higher loading rate than ASTM D 2412 as described in Section 9.7.3.

7.5 *Pipe Flattening*—There shall be no evidence of wall buckling, cracking, splitting, delamination, or decrease or downward deviation in the load-deflection curve when the pipe is tested in accordance with Section 9.2.

7.6 *Brittleness*—Pipe specimens shall not crack or split when tested in accordance with Section 9.3. Five non-failures out of six impacts will be acceptable.

7.7 *Stub Compression Test*—Profile compression capacity in any specimen in the stub compression test shall not be less than 50 percent of the gross cross section area times the minimum specified yield strength when tested in accordance with Section 9.8. The stub compression test, AASHTO T 341, shall be a material and wall design qualification test conducted once a year or whenever there are changes in wall design or material distribution. Computing the minimum capacity requires determining the cross-sectional area of the pipe wall. This can be accomplished conveniently by optically scanning the profile and determining the section properties using a computer drafting program.

7.8 *Fitting Requirements*:

7.8.1 The fittings shall not reduce or impair the overall integrity or function of the pipe line.

7.8.2 Common corrugated fittings include in-line joint fittings, such as couplings and reducers, and branch or complimentary assembly fittings such as tees, wyes, and end caps. These fittings are installed by various methods.

7.8.3 All fittings shall be within an overall length dimensional tolerance ±12 mm (0.5 in.) of the manufacturer's specified dimensions when measured in accordance with Section 9.6.2.

7.8.4 Fittings shall not reduce the inside diameter of the pipe being joined by more than 12 mm (0.5 in.). Reducer fittings shall not reduce the cross-sectional area of the small size.

7.8.5 Couplings shall be corrugated to match the pipe corrugations and shall provide sufficient longitudinal strength to preserve pipe alignment and prevent separation at the joints. Couplings shall be bell and spigot or split collar. Split couplings shall engage at least two full corrugations on each pipe section.

7.8.6 The design of the fittings shall be such that when connected with the pipe, the axis of the assembly will be level and true when tested in accordance with Section 9.5.2.

7.8.7 Other types of coupling bands or fastening devices that are equally effective as those described, and that comply with the joint performance criteria of *AASHTO LRFD Bridge Construction Specifications*, Section 30, may be used when approved by the purchaser.

7.9 Only fittings supplied or recommended by the pipe manufacturer should be used. Fabricated fittings should be supplied with joints compatible with the overall system. All joints shall meet the requirements of a soiltight joint unless otherwise specified by the owner/designer.

7.9.1 *Soiltight joints* are specified as a function of opening size, channel length and backfill particle size. If the size of the opening exceeds 3 mm (0.12 in.), the length of the channel must be at least four times the size of the opening. A backfill material containing a high percentage of fine-graded soils requires investigation for the specific type of joint to be used to guard against soil infiltration. Information regarding joint soiltightness criteria can be found in *AASHTO LRFD Bridge Construction Specifications*, Section 30, “Thermoplastic Pipe.”

7.9.2 *Silt-tight joints* should be used where the backfill material has a high percentage of fines. Silt-tight bell and spigot joints will utilize an elastomeric rubber seal meeting ASTM F 477. Silt-tight joints must be designated to pass a laboratory pressure test of at least 14 kPa (2 psi).

7.9.3 *Watertight joints* must meet a 74 kPa (10.8 psi) laboratory test per ASTM D 3212 and utilize a bell and spigot design with a gasket meeting ASTM F 477.

8. CONDITIONING

8.1 *Conditioning*—Condition the specimen prior to test at 21 to 25ºC (70 to 77°F) for not fewer than 24 hours in accordance with Procedure A in ASTM D 618 for those tests for which conditioning is required, and unless otherwise specified.

8.2 *Conditions*—Conduct all tests at a laboratory temperature of 21 to 25ºC (70 to 77°F) unless otherwise specified herein.

9. TEST METHODS

9.1 *Pipe Stiffness*—Select a minimum of two (2) pipe specimens and test for pipe stiffness (PS), as described in ASTM D 2412 except for the following: (1) the test specimens shall be a minimum of one diameter length for 300-mm (12-in.) to 600-mm (24-in.) diameter pipe, and one half diameter length for pipe diameters greater than 600 mm (24 in.); (2) locate the first specimen in the loading machine with an imaginary line connecting the two seams formed by the corrugation mold (end view) parallel to the loading plates, when applicable. The specimen must lie flat on the plate within 3 mm (0.12 in.) and may be straightened by hand bending at room temperature to accomplish this. Use the first location as a reference point for rotation and testing of the other specimen. Rotate the second specimen 90 degrees from the orientation of the first specimen and test. Test each specimen in one position only; (3) the deflection indicator shall be readable and accurate to ±0.02 mm (0.001 in.); (4) the residual curvature found in tubing frequently results in an erratic initial load-deflection curve. When this occurs, the beginning point for deflection measurement shall be at a load of 20 ± 5 newtons (4.5 lbf ± 1.1 lbf). The point shall be considered as the origin of the load-deflection curve; (5) the crosshead speed shall be the faster of 12.7 mm per minute (0.5 in. per minute) or 2 percent of the nominal inside diameter per minute.

Note 2—The parallel plates must exceed the length of the test specimen as specified above.

Note 3—Additional pipe specimens may be tested at other orientations for pipe stiffness and flattening if desired.

9.2 *Pipe Flattening*—Flatten the two-pipe specimens from Section 9.1 until the vertical inside diameter is reduced by 20 percent. The rate of loading shall be the same as in Section 9.1. Examine the specimen with the unaided eye for cracking, splitting, or delamination. The specimen shall fail if wall buckling, cracking, splitting, or delamination is observed with the unaided eye or if there is a decrease or downward deviation in load-deflection curve at 20 percent or less deflection. The load-deflection curve shall be carried beyond 20 percent deflection so that the shape of the curve at 20 percent deflection can be determined.

9.3 *Brittleness*—Test pipe specimens in accordance with ASTM D 2444 except six specimens shall be tested, or six impacts shall be made on one specimen. In the latter case, successive impacts shall be separated by 120 ± 10 degrees for impacts made on one circle, or at least 300 mm (12 in.) longitudinally for impacts made on one element. Impact points shall be at least 150 mm (6 in.) from the end of the specimen. Tup B shall be used, with a mass of 4.5 kg (10 lb). The height of drop shall be 3.0 m (10 ft). Use a flat plate specimen holder. Condition the specimens for 24 hours at a temperature of –4 ± 2ºC (25 ± 3.6°F), and conduct all tests within 60 seconds of removal from this atmosphere. The center of the falling tup shall strike on a corrugation crown for all impacts.

9.4 *Slow Crack Growth Resistance of Polyethylene Pipe* —Test specimens from the pipe liner for stress crack resistance in accordance with ASTM F 2136, the NCLS test, except for the following modifications:

9.4.1 The applied stress for the NCLS test shall be 4100 kPa (600 psi).

Note 4—The notched depth of 20 percent of the nominal thickness of the specimen is critical to this procedure.

9.4.2 When the pipe liner cannot be sampled, then a specimen may be taken from the profile wall of the pipe. Where the pipe wall profile does not have flat longitudinal sections of sufficient size to obtain a tensile specimen, a sample of the pipe wall shall be ground, made into plaques per ASTM D 4703 Procedure C , samples cut from those plaques and tested as noted in 6.1.1.

9.5 *Joints and Fittings*:

9.5.1 *Joint Integrity*—Pipes that have a welded bell shall be tested to verify the strength of the weld as follows: Assemble the joint in accordance with the manufacturer’s recommendations. Use pipe samples at least 300 mm (12 in.) in length. Assemble a specimen at least 600 mm (24 in.) in length with the connection at the center. Load the connected pipe and joint between parallel plates at the rate of 12.5 mm per minute (0.5 in/min) until the vertical inside diameter is reduced by at least 20 percent of the nominal diameter of the pipe. Inspect for damage while at the specified deflection and after load removal.

9.5.2 *Alignment*—Assure that the assembly or joint is correct and complete. If the pipe is bent, it should be straightened prior to performing this test. Lay the assembly or joint on a flat surface and verify that it will accommodate straight-line flow.

9.6 *Dimensions*:

9.6.1 *Inside Diameter*—Measure the inside diameter of the pipe with a tapered plug in accordance with ASTM D 2122. As an alternative, measure the inside diameter with a suitable device accurate to ±3.0 mm (0.12 in.) by taking two inside diameter measurements, the first at the seam and the second 90 degrees from the seam, and averaging the two measurements. The average inside diameter shall meet the requirements of Section 7.2.3.

9.6.2 *Length*—Measure pipe with any suitable device accurate to ±6.0 mm in 3 m (0.25 in. in 10 ft). Make all measurements on the pipe while it is stress-free and at rest on a flat surface in a straight line. These measurements may be taken at ambient temperature.

9.6.3 *Perforations*—Measure dimensions of perforations on a straight specimen with no external forces applied. Make linear measurements with instruments accurate to 0.2 mm (0.008 in.).

9.6.4 *Wall Thickness*—Measure the wall thickness in accordance with ASTM D 2122.

9.7 *Delamination*—Examine Type S pipe for evidence of delamination as defined and described in Section 3.9 by cutting the pipe at the corrugation crest as shown in Figure 3 and attempting to insert a feeler gauge between the inner and outer corrugated wall at the corrugation valley as shown in Figure 4. The feeler gauge should not pass through the corrugation valley into a void at any location along the circumference of the pipe.

Examine Type D pipe for evidence of delamination as defined and described in Section 3.9 by cutting a section through the pipe as shown in Figure 3 and attempting to insert a feeler gauge between the internal supports and the inner and outer walls as shown in Figure 4. The feeler gauge should not pass between the internal support and the inner or outer wall at any point along the circumference of the pipe.

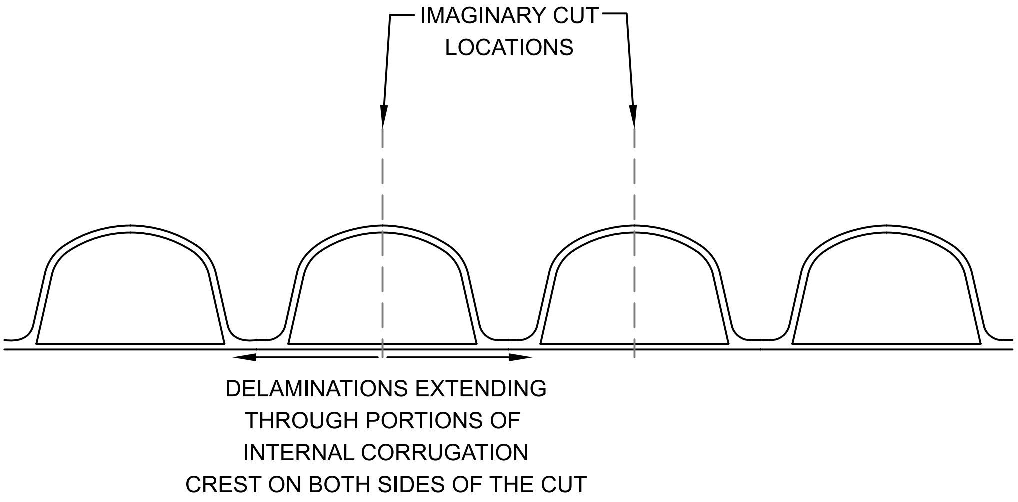

Figure 3—Location of Pipe Cut

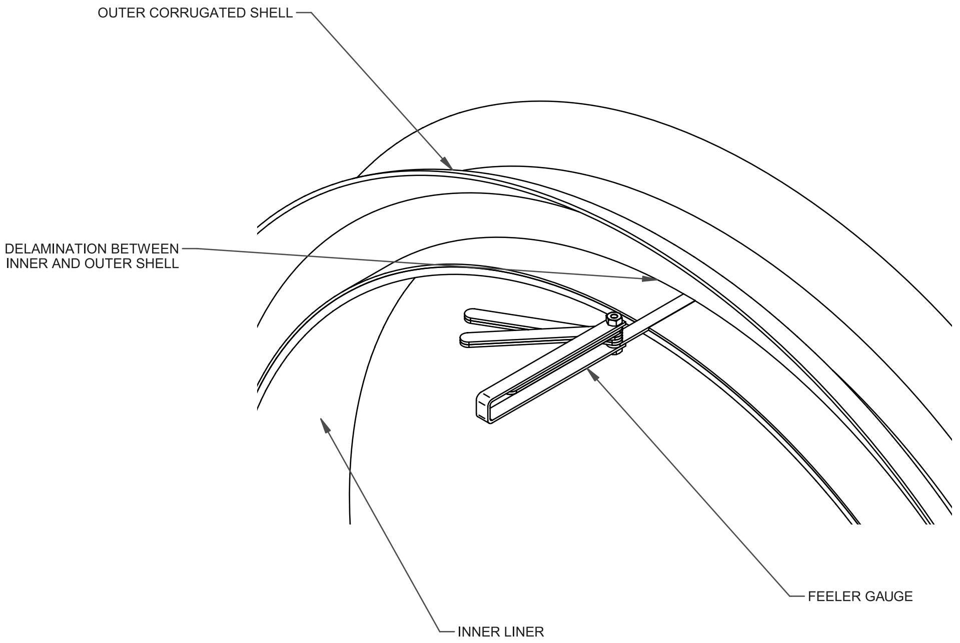

Figure 4—Feeler Gauge Insertion

9.8 *Stub Compression Capacity*—Determine the stub compression capacity of the pipe section in accordance with AASHTO Test Standard T 341. Conduct four tests on specimens cut from the same ring of pipe at 90-degree intervals around the circumference.

10. INSPECTION AND RETEST

10.1 *Inspection*—Inspection of the material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

10.2 *Retest and Rejection*—If any failure to conform to these specifications occurs, the pipe or fittings may be retested to establish conformity in accordance with agreement between the purchaser and seller. Individual results, not averages, constitute failure.

11. MARKING

11.1 All pipe shall be clearly marked at intervals of no more than 3 m (10 ft) as follows:

11.1.1 Manufacturer’s name or trademark;

11.1.2 Nominal size;

11.1.3 This specification designation, M 294;

11.1.4 The plant designation code; and

11.1.5 The date of manufacture or an appropriate code. If a date code is used, a durable manufacturer sticker that identifies the actual date of manufacture shall be adhered to the inside of each length of pipe.

Note 5—A durable sticker is one that is substantial enough to remain in place and be legible through installation of the pipe.

11.2 Fittings shall be marked with the designation number of this specification, M 294, and with the manufacturer's identification symbol.

12. QUALITY ASSURANCE

12.1 A manufacturer's certificate that the product was manufactured, tested, and supplied in accordance with this specification, together with a report of the test results, and the date each test was completed, shall be furnished upon request. Each certification so furnished shall be signed by a person authorized by the manufacturer.

12.2 Manufacturer records—Manufacturers shall keep records of the following: (1) resin manufacturer's data sheets and certification that the base resin meets minimum cell class requirements of the product specification; (2) manufacturer's data sheets and quantities for all additives blended with the resin by the pipe manufacturer; (3) test results to demonstrate that, if resins of two different cell classifications are blended, the resulting mixture meets the requirements of the specified cell classification; (4) correlation of resin shipment source with pipe markings.

ANNEX

(Mandatory Information)

A1. GUIDELINES FOR PIPE MADE FROM BLENDED RESINS

A1.1. If pipe is made from a blend of component resins or from off-prime resin or blends, the manufacturer of each component resin should supply a certificate of analysis for each lot that includes the lot-specific melt index and density. The pipe manufacturer should have a resin testing program in place that includes the testing of each resin blend lot for density and melt index and have the means of conducting (in-house or contract lab) the remaining cell class and NCLS testing as specified in this standard. The manufacturer shall test each resin or resin blend lot for full cell class and NCLS, unless a regular quality assurance program is in place to correlate cell class results to density and melt index. In any case, full cell class and NCLS testing should be performed on all approved/certified resin blends at least quarterly. Additionally, the pipe manufacturer shall have the resin blend independently tested and pre-qualified based on a "recipe" with component percentage tolerances of no more than ±1.5 percent substantiated by independent testing.

A1.2. When blends of virgin resins are used for pipe manufacture, the final blended resin must meet the requirements of the standard. It is not necessary for the individual components of the blend to meet the cell class or NCLS requirements of this standard, provided that the final blend meets all the requirements.

A1.2.1. Sampling and testing of the final blended resin shall be performed as follows:

A1.2.1.1. The sample shall be prepared either by direct sampling from the feed hopper of the extruder (after the material has already been weigh-blended by the blenders or other means), or by manually weigh-blending the individual components to the specified finished blend ratios. The manufacturer shall have current calibration records for the automated or manual weigh blending equipment.

A1.2.1.2. The blended sample shall not contain carbon black concentrate. If carbon black concentrate is present in the sampled material, the carbon black concentrate shall be removed prior to further sample preparation.

A1.2.1.3. The dry-blended sample shall be fully homogenized by melt blending via a twin screw lab extruder prior to testing for physical properties.

A1.2.1.4. The melt-blended sample shall be tested for melt index, density, and NCLS in accordance with the number of hours per the requirements of the standard.

APPENDIX

(Nonmandatory Information)

X1. QUALITY CONTROL/QUALITY ASSURANCE PROGRAM

X1.1. *Scope*:

X1.1.1. As required in Sections 10 and 12, the acceptance of these products relies on the adequate inspection and certification agreed to between the buyer and the seller/producer. This appendix should serve as a guide for both the manufacturer and the user. It places the responsibility on the producer to control the quality of the material they produce and to provide the quality control information needed for acceptance by the buyer/user. The producer is required to perform quality control sampling, testing and record keeping on materials they ship. It also sets forth quality assurance sampling, testing and record keeping that should be performed by the buyer/user to confirm the performance of the producer's control plan.

X1.2. *Program Requirements*:

X1.2.1. The producing company must have a quality control plan approved by the specifying agency.

X1.2.2. The producing plant must have an approved quality control plan.

X1.2.3. The plant must have an approved laboratory, either within the company or an independent laboratory.

X1.2.4. The producing plant(s) must have a designated quality control technician.

X1.3. *Quality Control Plan*:

X1.3.1. The producer must supply to the specifying agency a written quality control plan that shows how the producer will control the equipment, materials, and production methods to ensure that the specified products are supplied. The following information must be included in the plan:

X1.3.1.1. Titles of the personnel responsible for production quality at the plant(s);

X1.3.1.2. The physical location of the plant(s);

X1.3.1.3. The methods of identification for each lot of material during manufacture, testing, storage, and shipment. The method of identification shall allow the specifying agency to trace the finished product to the material provider;

X1.3.1.4. The method of sampling and testing of raw materials and finished product, including lot sizes and types of tests performed; and

X1.3.1.5. A plan for dealing with nonconforming product, including how the producer plans to initiate immediate investigation and how corrective action will be implemented to remedy the cause of the problem.

X1.4. *Approved Laboratory*:

X1.4.1. All tests must be conducted at laboratories approved by the specifier. Each manufacturer may establish and maintain its own laboratory for performance of quality control testing or may utilize an approved independent laboratory. Records of instrument calibration and maintenance and sample collection and analysis must be maintained at the laboratory.

X1.5. *Quality Control Technician*:

X1.5.1. All samples must be taken and tested by the quality control technician designated by the producer. The designated quality control technicians will be responsible for overall quality control at the producing plant.

X1.6. *Annual Update*:

X1.6.1. An annual update may be required. The annual update may be submitted by the manufacturer to the specifying agency by December 31st of each calendar year.

X1.7. *Plant Approval*:

X1.7.1. The plant approval process requires the manufacturer to submit an annual update to the specifying agency. The update must identify the specific product manufactured at the plant.

X1.7.2. The specifying agency will review the manufacturer's written quality control plan and a plant inspection may be scheduled. This inspection will verify that the quality control plan has been implemented and is being followed and that at least one designated quality control technician is on-site and will be present when material is being produced under this program. The laboratory will be inspected and approved if it meets the requirements.

X1.8. *Sampling and Testing*:

X1.8.1. The quality assurance plan approved for each manufacturer, and/or manufacturer's location, shall detail the methods and frequency of sampling and testing for all raw materials and products purchased or manufactured at that location. All testing shall be in accordance with current specifications and procedures referenced in M 294.

X1.8.2. Samples of materials and pipe may be taken by the specifying agency.

X1.8.3. The specifying agency may require an annual third-party independent assurance test.

X1.9. *Sample Identification and Record Keeping*:

X1.9.1. Manufacturer's Quality Control samples are to be uniquely identified by the producing plant.

X1.9.2. Quality control and quality assurance data are to be retained by the manufacturer for 2 years and made available to the specifying agency upon request.

X1.9.3. Quality control test reports shall include the lot identification.

X1.9.4. Unless requested at the time of ordering, test reports do not have to be filed for specific projects.

X1.9.5. Reports shall indicate the action taken to resolve nonconforming product.

Standard Specification for

Poly(Vinyl Chloride) (PVC) Profile Wall Drain Pipe and Fittings Based on Controlled Inside Diameter

AASHTO Designation: M 304-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Poly(Vinyl Chloride) (PVC) Profile Wall Drain Pipe and Fittings Based on Controlled Inside Diameter

AASHTO Designation: M 304-10

1. SCOPE

1.1. This specification covers poly(vinyl chloride) (PVC) profile wall perforated and non-perforated pipe and fittings, 100 to 1200 mm (4 to 48 in.) nominal inside diameter, for use in non-pressure storm drains, culverts, underdrains, and other subsurface drainage systems providing either soiltight or watertight joints.

1.2. Industrial waste disposal lines should be installed only with the specific approval of the governing code authority since chemicals not commonly found in drains and temperatures in excess of 60ºC (140ºF) may be encountered.

1.3. Pipe and fittings produced to this specification should be installed in accordance with ASTM D 2321 and the manufacturer’s recommendation.

1.4. *Units*—The values stated in SI units are to be regarded as standard. Within the text, the U.S. customary units are shown in parentheses for informational purposes, and may not be exact equivalents.

1.5. The following precautionary caveat pertains only to the test method portion, Section 8, of this specification. *This standard does not purport to address the safety concerns associated with its use. It is the responsibility of whoever uses this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *General*—Definitions used in this specification are in accordance with definitions given in ASTM D 883 and ASTM F 412 unless otherwise indicated.

3.2. *profile wall pipe*—a pipe product consisting of an essentially smooth wall waterway braced with annular or helical projections or ribs on the outside of the pipe, or with annular or helical bracing between essentially smooth outer and inner walls. (See Figure 1.)

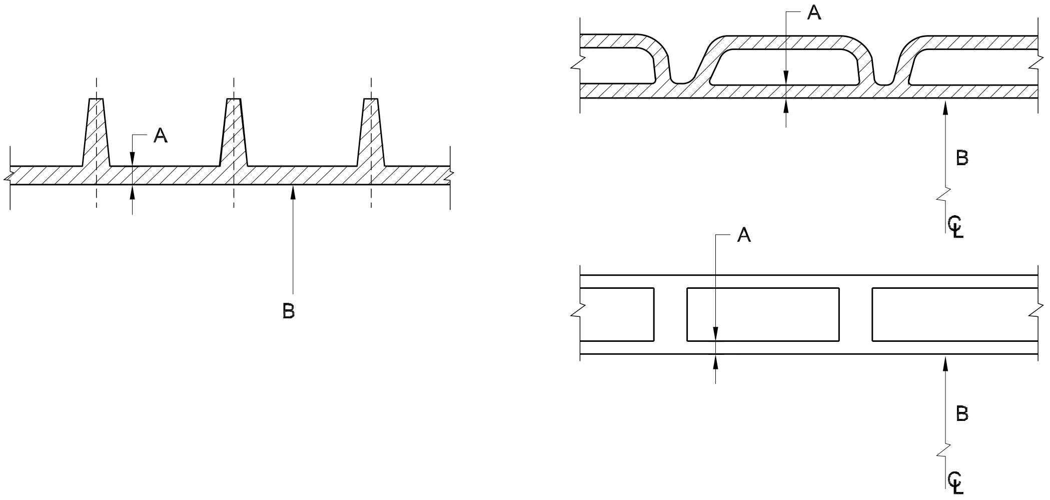

Figure 1—Typical Profiles (Cross Section): A–Waterway Minimum Wall, B–Average Inside Diameter (Other Configurations of Ribs and Spacing Are Permissible)

3.3. *soiltight joints*—joints that do not allow soil migration through the joint into the pipe are deemed soiltight. Both the size of any opening or flow channel into the joint and the soil particle size determine soil tightness.

4. ORDERING INFORMATION

4.1. *Orders*—Orders for materials to this specification shall include the following information as necessary to adequately describe the desired product:

4.1.1. Name of material (PVC ribbed drain pipe);

4.1.2. AASHTO designation, including year;

4.1.3. Perforations, when perforations are required;

4.1.4. Diameter of pipe;

4.1.5. Length, either total length or length of each piece and number of pieces; and

4.1.6. Special requirements.

5. MATERIALS

5.1. *Basic Materials*—The pipe, internal sleeves, and fittings shall be made of PVC plastic having a minimum cell classification of 12454C or 12364C as defined in ASTM D 1784. Homopolymer PVC compounds must meet or exceed the requirements of the above listed minimum cell classification number.

5.2. *Reworked Material*—Clean reworked material generated from the manufacturer's own production, when used by the manufacturer, shall meet the requirements for minimum cell classification as described in Section 5.1.

5.3. *Gaskets*—Elastomeric gaskets shall comply with low head-application requirements described in ASTM F 477.

5.4. *Lubricant*—The lubricant used for assembly shall have no detrimental effect on the gasket or on the pipe. Only lubricant recommended by the manufacturer shall be used.

6. JOINT SYSTEMS

6.1. *Joint Types*—Joints may consist of bells, external sleeves, internal sleeves, or band couplers.

6.2. *Joint Classifications*—Joints shall be classified as soiltight or watertight. Soiltight joints must meet the requirements of Section 7.6. Watertight joints must meet the requirements of Section 7.7.

Note 1—The outside diameters of products of different manufacturers are not specified and therefore compatibility should be reviewed.

7. REQUIREMENTS

7.1. *Workmanship*—The pipe and fittings shall be homogeneous throughout and free from visible cracks, holes, foreign inclusions, or other injurious defects. The pipe shall be as uniform as commercially practical in color, opacity, density, and other physical properties.

7.2. *Pipe Dimensions*:

7.2.1. *Diameter*—The inside diameter of the pipe shall meet the requirements given in Table 1 when measured in accordance with Section 8.3.1.

7.2.2. *Wall Thickness*—The minimum wall thickness of the waterway of ribbed pipe and fitting shall meet the requirement given in Table 1 when measured in accordance with Section 8.3.2.

Table 1—Pipe Requirements

Nominal Pipe Size, mm (in.)	Min Average Inside Diameter,[a] mm (in.)	Min Waterway Wall, mm (in.)	Min Pipe Impact Strength, J(ft-lbf)	Min Pipe Stiffness, kPa (psi)
100 (4)	100.0 (3.9)	0.56 (0.022)	108 (80)	318 (46)
150 (6)	149.7 (5.9)	0.64 (0.025)	108 (80)	318 (46)
200 (8)	199.7 (7.9)	0.89 (0.035)	136 (100)	318 (46)
250 (10)	249.6 (9.8)	1.14 (0.044)	136 (100)	318 (46)
300 (12)	296.8 (11.7)	1.52 (0.06)	136 (100)	318 (46)
375 (15)	363.3 (14.3)	1.90 (0.07)	136 (100)	262 (38)
450 (18)	444.8 (17.5)	2.16 (0.08)	136 (100)	221 (32)
525 (21)	524.7 (20.7)	2.54 (0.10)	136 (100)	193 (28)
600 (24)	594.7 (23.4)	2.92 (0.11)	136 (100)	165 (24)
675 (27)	669.8 (26.4)	3.18 (0.12)	136 (100)	152 (22)
750 (30)	746.4 (29.4)	3.43 (0.14)	163 (120)	131 (19)
900 (36)	898.4 (35.4)	3.94 (0.15)	163 (120)	110 (16)
1050 (42)	1050.9 (41.4)	4.32 (0.17)	163 (120)	97 (14)
1200 (48)	1202.9 (47.4)	4.83 (0.19)	163 (120)	83 (12)

[a] Tolerance on inside diameter shall be +2 percent of nominal pipe size, but not to exceed 13 mm (0.5 in.).

7.2.3. *Bell Wall Thickness*—In the case of belled pipe and fittings fabricated from pipe sections, the thickness of the wall in the bell shall be considered satisfactory if it was formed from pipe meeting the requirements in Table 1. For reducing fittings or those with smaller inlets, the minimum wall thickness for each inlet shall be no less than the minimum wall thickness for that size pipe.

Note 2—Due to the present state of technology in the industry, some fittings are fabricated fittings. Fabricated fittings made from pipe meeting the requirements of the pipe specification should be acceptable providing that the joints are adequately lapped or reinforced. Unreinforced mitered joints should not be used. Laying lengths of fittings should be in accordance with manufacturer's requirements.

7.3. *Pipe Flattening*—There shall be no evidence of splitting, cracking, breaking, or separation of ribs or seams, when pipe is tested in accordance with Section 8.4, and the load on the pipe shall not decrease until the pipe inside diameter is reduced by 20 percent of its original dimension.

7.4. *Pipe Impact Strength*—The impact strength shall not be less than values shown in Table 1 when tested in accordance with Section 8.5.

Note 3—This requirement is intended only for use as a quality control test, not as a simulated service test.

7.5. *Pipe Stiffness*—The pipe shall have a minimum pipe stiffness at 5 percent deflection as listed in Table 1 when tested in accordance with Section 8.6.

Note 4—Pipe meeting the test requirements for stiffness of this specification will provide a flexibility factor not exceeding 0.54 mm/N (0.095 in/lbf) for all pipe diameters above 300 mm

(12 in.). For nominal pipe sizes 300 mm (12 in.) and smaller, the minimum pipe stiffness is 320 kPa (46 psi).

7.6. *Soiltight Joints*—Joints classified as soiltight shall meet the requirements of *AASHTO LRFD Bridge Construction Specifications*, Section 26 when measured in accordance with Section 8.8. The ratio of the D_{85} soil size to the size of the opening must be greater than 0.3 for medium to fine sand and greater than 0.2 for uniform sand.

7.7. *Watertight Joints*—Gasketed joints classified as watertight shall show no sign of leakage when tested in accordance with Section 8.9.

7.8. *Gaskets*—When a gasketed joint is used, gaskets shall meet the low head application requirements of ASTM F 477 and be molded into a circular form or extruded to the proper section and then spliced into circular form.

7.9. *Extrusion Quality*:

7.9.1. *Acetone Immersion*—The pipe shall meet the requirements as defined in ASTM D 2152 when tested in accordance with Section 8.7.1.

Note 5—This is intended only for use as a quality control test and not for use as a simulated service test.

7.9.2. *Heat reversion*—The pipe shall not exhibit any of the effects listed in the suggested interpretation of results of the ASTM Practice F1057 when tested in accordance with Section 8.7.2.

7.10. *Internal Sleeve Dimensions*—The dimensions of the internal sleeve shall be such that they provide a minimum interference to internal flow and provide a soiltight joint with the pipe. The internal sleeve shall lap a minimum of 50 mm (2 in.) on each pipe, and shall contain a device so that the sleeve is centered on the joint. (See Figure 2.)

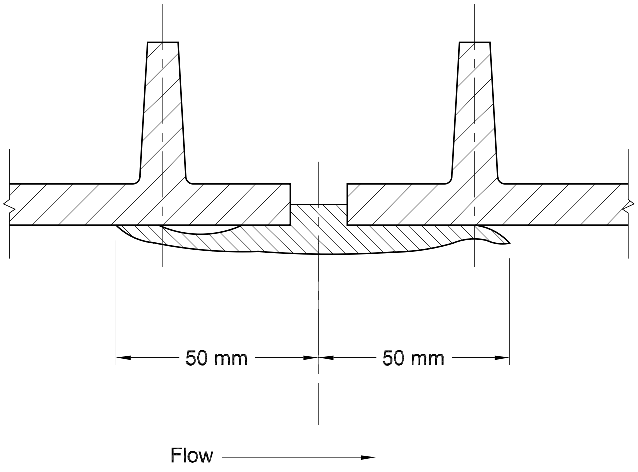

Figure 2—Typical Internal Sleeve Profile (Cross Section). (Other Configurations of Internal Sleeve Are Permissible.)

7.11. *Perforations*—Perforations, when required, shall be circular holes 5 to 10 mm (0.2 to 0.4 in.) in diameter, or slots not to exceed 3 mm (0.12 in.) in width and limited in length to 10 percent of pipe circumference or 75 mm (3 in.), whichever is less, to provide an inlet area as follows:

Pipe Size, mm (in.)	Inlet Area, Min, cm^2/m (in.^2/ft)
100 (4)	11 (0.5)
150 to 250 (6 to 10)	21 (1.0)
300 to 525 (12 to 21)	32 (1.5)
600 (24) and over	42 (2.0)

Perforations shall be arranged in rows parallel to the axis of the pipe. Perforations shall not occur within the rib structure itself but between. The rows of perforations shall be arranged in two equal groups placed symmetrically on either side of a lower unperforated segment, corresponding to the flowline of the pipe. The spacing of the rows shall be uniform. The distance between the centerlines of rows shall be not less than 25 mm (1 in.). The maximum heights (*H*) of the centerlines of the uppermost rows (or upper end of slots) above the bottom of the invert shall be 0.46*D*, and the minimum chord lengths (*L*) of the unperforated invert segment shall be 0.64*D*, where *D* equals the nominal pipe diameter. (See Figure 3.)

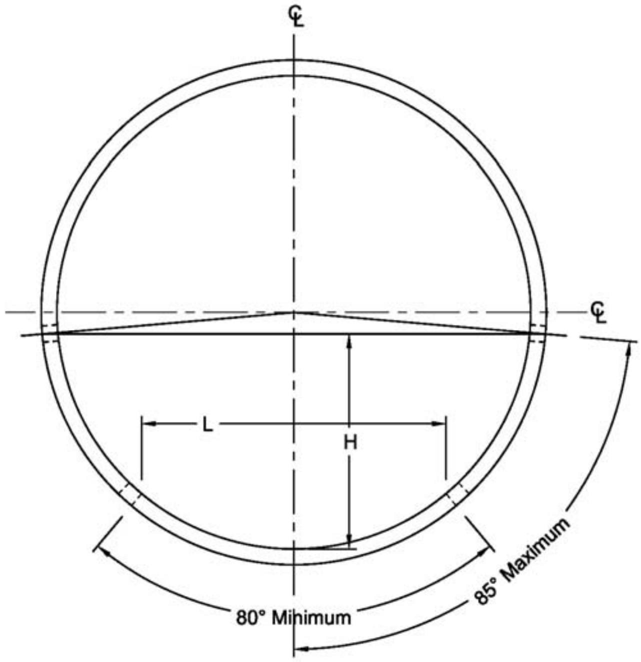

Figure 3—Requirements for Perforations

7.12. *Stub Compression Test*—Profile compression capacity in any specimen in the stub compression test T 341 shall not be less than 75 percent of the gross section area times the minimum specified yield strength when tested in accordance with Section 8.10. The stub compression test, AASHTO T 341, shall be a material and wall design qualification test conducted once a year or whenever there are changes in wall design or material distribution. Computing the minimum capacity requires determining the cross-sectional area of the pipe wall. This can be conveniently accomplished by optically scanning the profile and determining the section properties using computer drafting program.

7.13. *Manufacturer Records*—Manufacturers shall keep records of the following: (1) resin manufacturer's data sheets and certification that the base resin meets cell class requirements of the product specifications; (2) manufacturer's data sheets and quantities for all additives: (3) test results to demonstrate that if resins of two different cell classifications are blended, the resulting mixture meets the requirements of the specified cell class; (4) correlation of the resin shipment source with pipe markings.

8. TEST METHODS

8.1. *Conditioning*:

8.1.1. *Referee Testing*—When conditioning is required for referee tests, condition the specimens in accordance with Procedure A of ASTM D 618 at 23 ± 2ºC (73.5 ± 3.5°F) and 50 percent ±5 percent relative humidity for not less than 40 hours prior to test. Conduct tests under the same conditions of temperature and humidity, unless otherwise specified.

8.1.2. *Quality Control Testing*—Condition specimens for a minimum of 4 hours in air or 1 hour in water at 23 ± 2ºC (73.5 ± 3.5°F). Test the specimens at 23 ± 2ºC (73.5 ± 3.5°F) without regard to relative humidity.

8.2. *Sampling*—The selection of the samples of pipe shall be as agreed upon between the purchaser and seller. In case of no prior agreement, any sample selected by the testing laboratory shall be deemed adequate.

8.3. *Dimensions*:

8.3.1. *Inside Diameter*—Determine the average inside diameter using an internal micrometer telescoping gauge or metal rule accurate to 1 mm ($^1/_{32}$ in.). Take sufficient readings, a minimum of four, in at least two locations and determine the average diameter.

8.3.2. *Wall Thickness*—Measure the wall thickness of the waterway in the gaps between ribs in accordance with ASTM D 2122. Make sufficient readings, a minimum of eight, to ensure that the minimum thickness has been determined.

8.4. *Flattening*—Flatten three specimens of pipe, each with a length equal to one pipe diameter (but not less than 300 mm (12 in.) nor greater than 900 mm (36 in.)) between parallel plates in a suitable press until the pipe inside diameter is reduced by 60 percent of its original dimension for pipes with a measured pipe stiffness less than 318 kPa (46 psi). Pipes with a pipe stiffness of 318 kPa (46 psi) or greater shall be flattened until the pipe inside diameter is reduced by an amount determined by [3.43(OD)/(OD-ID)], expressed as a percent, where OD and ID are the measured outside and inside diameters of the pipe. Record the deflection at which the peak load occurs. The rate of loading shall be uniform and such that the compression is completed within 120 to 300 seconds. The specimen shall pass if no splitting, cracking, breaking, or separation of ribs or seams, or both, is observed under normal light with the unaided eye. Small tears initiated at the cut end of the rib shall not constitute failure.

Note 6—Small tears, observable after test, may be up to approximately 10 percent of nominal diameter in length.

8.5. *Impact Resistance*—Determine the impact resistance of the pipe in accordance with conditions and apparatus in ASTM D 2444 using Tup B and flat plate holder B. Test temperature shall be 23 ± 2ºC (73.5 ± 3.5°F). Test six specimens; all six specimens shall pass. If one specimen fails, test another six specimens. Eleven passes out of 12 tested shall be acceptable. If a rib is chipped by an indirect hit, the specimen may be replaced in the test.

8.5.1. In sizes 100 mm (4 in.) through 375 mm (15 in.), each specimen shall be 150 mm (6 in.) long. In sizes 450 mm (18 in.) and greater, each specimen shall be 300 mm (12 in.) long.

8.5.2. For 100- and 150-mm (4- and 6-in.) pipe, use a 10-kg Tup B. For larger sizes, use either a 10-kg (22-lb) or 15-kg (33-lb) Tup B.

8.5.3. Orient the specimens so the tup will strike the area between the ribs if the physical spacing is such that a clean hit can be made. Where this is not possible, orient the specimens so that one of the ribs receives the strike essentially centered on the tup face. Failure of the test specimen shall be any crack, split, shattering, or separation on ribs, body, or seam.

8.6. *Pipe Stiffness*—Determine the pipe stiffness at 5 percent deflection in accordance with ASTM D 2412, except that the crosshead speed shall be the faster of 12.7 mm per minute (0.5 in. per minute) or 2 percent of the nominal inside diameter per minute. Test three specimens, each with a length equal to one pipe diameter (but not less than 300 mm (12 in.) nor greater than 900 mm (36 in.)) and determine the average pipe stiffness.

Note 7—The 5 percent deflection criterion, which was arbitrarily selected for testing convenience, should not be considered as a limitation with respect to in-use deflection. The Engineer is responsible for establishing the acceptable deflection limit.

8.7. *Extrusion Quality*:

8.7.1. *Acetone Immersion*—Conduct this test in accordance with ASTM D 2152. This procedure is used to determine the degree of fusion of extruded PVC plastic pipe as indicated by reaction to immersion in anhydrous acetone. It is applicable only for distinguishing between unfused and properly fused PVC.

8.7.2. *Heat Reversion*—Conduct this test in accordance with ASTM Practice F 1057. This procedure is used for estimating the quality of extruded PVC plastic pipes by observing the reaction of pipe specimens after exposure to heat.

8.8. *Soiltightness*—Assemble the joint in accordance with the manufacturer’s recommendations. Using a measuring device accurate to 0.4 mm (0.016 in.), locate the maximum size opening between the pipe and jointing device by measuring the opening radially from the pipe wall. No opening may exceed 25 mm (1 in.). For openings exceeding 3 mm (0.12 in.), the length of the channel must exceed four times the size of the opening.

8.9. *Watertightness*—Conduct the internal pressure test in accordance with ASTM D 3212 using 74 kPa (10.8 psi) water pressure.

8.10. *Stub Compression Test for Finished Pipe*—Determine the stub compression capacity of the pipe section in accordance with AASHTO Test Standard T 341. Conduct four tests on specimens cut from the same ring of pipe at 90 degree intervals around the circumference.

9. RETEST AND REJECTION

9.1. *Material Failure*—Material failing to conform to the requirements of this specification may be rejected. Material may be retested to establish conformity in accordance with agreement between the purchaser and seller.

10. PRODUCT MARKING

10.1. *Pipe Marking*—Each standard and random length of pipe compliant with this specification shall be clearly marked by the producer per the following example at intervals of 1.5 m (4.9 ft) or less:

10.1.1. Manufacturer's name, trade name or trademark, and code;

10.1.2. Nominal pipe size in millimeters;

10.1.3. The PVC minimum cell classification as listed in Table 1, ASTM D 1784; for example, 12364C;

10.1.4. The legend "DRAIN PIPE"; and

10.1.5. This specification designation, AASHTO M 304.

10.2. *Fittings Marking*—The fittings in compliance with this specification shall be clearly marked per the following example:

10.2.1. Manufacturer's name or trademark and code;

10.2.2. Nominal size in millimeters;

10.2.3. The material designation "PVC" and ASTM Cell Class; and

10.2.4. This specification designation, AASHTO M 304, and manufacturer's code to include day, month, year, shift, and plant of manufacturer.

10.3. *Markings*—The markings shall be applied to the pipe in such a manner that they remain legible after installation and inspection have been completed.

10.4. *Quality Assurance*—When the product is marked with M 304, it affirms that the product was manufactured, inspected, sampled, and tested in accordance with this specification and has been found to meet the requirements of this specification.

10.4.1. *Notification*—If inspection is specified by the purchaser, the manufacturer shall notify the purchaser in advance of the date, time, and place of testing of the pipe in order that the purchaser may be represented.

10.4.2. *Access*—The inspector shall have free access to those parts of the manufacturer's plant that are involved in work performed under this specification. The manufacturer shall afford the inspector all reasonable facilities for determining whether the pipe meets the requirements of this specification.

10.5. *Certification*—When agreed upon in writing by the purchaser and the seller, a certification shall be made on the basis of acceptance of material. This shall consist of a copy of the manufacturer's test report or a statement by the seller that the material has been sampled, tested, and inspected in accordance with the provisions of this specification. Each certification, so furnished, shall be signed by an authorized agent of the seller or manufacturer.

11. DELIVERY

11.1. *Packaging*—All pipe and couplings and fittings shall, unless otherwise specified, be packaged for standard commercial shipment.

Standard Specification for

Drainage, Sewer, Utility, and Related Castings

AASHTO Designation: M 306-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Drainage, Sewer, Utility, and Related Castings

AASHTO Designation: M 306-10

1. SCOPE

1.1. This specification is applicable to frames, grates, rings, and covers for inlets, manholes, and other structures for civil engineering use where items may be placed in traffic service and load bearing is a consideration.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 105, Gray Iron Castings
- *LRFD Bridge Design Specifications*, Fifth Edition

2.2. *ASTM Standards*:

- A 48/A 48M, Standard Specification for Gray Iron Castings
- A 536, Standard Specification for Ductile Iron Castings

2.3. *Federal Specification*:

- CID A-A-60005, Frames, Covers, Gratings, Steps, Sump and Catch Basin Manhole

3. TERMINOLOGY

3.1. *Definitions of Terms Specific to This Standard*:

3.1.1. *manufacturer*—a producing foundry/facility where iron is melted and poured into molds.

3.1.2. *supplier*—an agent, representative, or organization that provides castings that it did not manufacture.

3.1.3. *purchaser*—the end user of the casting.

3.2. The preceding terms and definitions are specific to this specification. ASTM A 644 contains other terms and definitions relating to gray iron castings.

4. MATERIALS

4.1. Gray Iron Castings shall conform to the requirements of M 105 Class 35B or ASTM A 48 Class 35B.

4.2. Ductile Iron Castings shall conform to the requirements of ASTM A 536 Grade 80-55-06, unless otherwise specified by the customer.

5. MANUFACTURE

5.1. Castings shall be manufactured true to pattern and component parts shall fit together in a satisfactory manner. They shall be smooth and well cleaned by shotblasting. Circular manhole frames, covers, and grates shall be furnished with machined horizontal bearing surfaces unless otherwise specified. All square and rectangular units shall be furnished with an as-cast bearing surface unless otherwise specified.

5.2. *Permissible Variations*:

5.2.1. As-cast dimensions may vary one-half the maximum shrinkage possessed by the metal or ±5.21 mm/m [$\pm^{1}/_{16}$ in./ft].

5.2.2. Mass [weight] ±5 percent drawing/specification mass [weight].

5.3. *Performance and other Requirements*:

5.3.1. The cover or grate shall not rock when rotated to any position in the frame.

5.3.2. The cover or grate shall sit down into the frame so that the top surface of the cover or grate will be flush with the top surface of the frame.

The difference in the level between the cover or grate shall not exceed 3.2 mm [$^{1}/_{8}$ in.] at any point when placed in the frame. The cover or grate shall not sit higher than 1.6 mm [$^{1}/_{16}$ in.] over more than $^{1}/_{4}$ of the circumference when placed in the frame.

5.3.3. *Welding, Plugging*—Not allowed.

5.3.4. *No Painting*—Unless specified by the customer.

5.4. *Quality and Appearance:*

5.4.1. The finished casting shall show careful finished workmanship in all particulars. Castings which have been damaged either during manufacture or shipping may be rejected. Among others, the following defects may be considered as constituting poor workmanship.

5.4.1.1. *Defects, Major (Items that may affect casting load bearing ability)*—Casting could be rejected or require proof that the defect is not injurious. Examples of such defects include: shrinkage, cracks, cold shuts, large cavities, major porosity episodes, or major sand inclusions.

5.4.1.2. *Defects, Minor (Items that may affect top surface appearance)*—Casting could be reworked and resubmitted. Examples of such defects include: dirt, scab, slag, minor surface porosity, or minor sand inclusions.

6. PROOF-LOAD TESTING

6.1. For first article inspection or when specified for quality conformance inspection, the frames and covers or gratings shall show no detrimental permanent deformation when a proof load of 178 kN [40,000 lb] is concentrated on a 229 mm by 229 mm [9 in. by 9 in.] area placed at the center of the cover or grate. To distribute the load evenly in testing, an intermediate layer of material (i.e., fiberboard, felt, rubber, etc.) can be placed between the test block and the casting to be tested. This layer shall not be larger than the area of the test block. The load shall be applied at a constant rate between 45 kg/sec and 454 kg/sec [between 100 lb/sec and 1000 lb/sec]. The castings shall be tested in a frame. If the product is not installed with a frame, or if proof-load testing in a frame is unfeasible, the cover or grate shall be supported in such a fashion as to simulate how an item would be supported following installation. The specified load shall be applied and held for a period of 1 minute by a suitable testing machine. Upon removal of the load, the cover or grating and frame shall be examined for cracks or detrimental permanent deformation. Permanent deformation shall not exceed 3.2 mm [$^1/_8$ in.]. Any cracks shall be cause for rejection. Any permanent deformation that exceeds 3.2 mm [$^1/_8$ in.] shall be cause for rejection. All testing shall occur in the United States on a testing machine calibrated in accordance with and traceable to National Institute of Standards and Technology (NIST) standards. All castings that are subjected to the proof-load test shall be destroyed.

For items that are smaller than a 229 mm by 229 mm [9 in. by 9 in.] footprint, or where a 229 mm by 229 mm [9 in. by 9 in.] footprint would transfer load directly to the frame, an alternate proof load test shall be used. For H-20 or HS-20 loading, the applied load shall be the product of 3.39 MPa [494 psi] multiplied by the area of the cover/grate, but not to exceed 178 kN [40,000 lb]. For H-25 or HS-25 loading, the applied load shall be the product of 4.23 MPa [617 psi] multiplied by the area of the cover/grate, but not to exceed 222 kN [50,000 lb]. The footprint size shall not exceed 229 mm [9 in.] in any direction and shall be smaller than the corresponding frame clear opening.

Example 1:

Given loading is H-20. Therefore, use 3.39 MPa [494 psi].

Given cover diameter is 203 mm [8 in.], which equates to a cover area of 0.0324 m^2 [50.3 in.^{2}].

Given frame has a clear opening of 152 mm [6 in.].

Therefore, the required loading is 0.0324 m^2 [50.3 in.^{2}] multiplied by 3.39 MPa [494 psi], or 110 kN [24,850 lb]. This value does not exceed the 178 kN [40,000 lb] specified in the standard; therefore, it shall be the applied load. The footprint size must be smaller than 152 mm [6 in.] in diameter for the given frame clear opening.

Example 2:

Given loading is HS-25. Therefore, use 4.23 MPa [617 psi].

Given grate size is 203 mm [8 in.] wide and 610 mm [24 in.] long, which equates to a grate area of 0.124 m^2 [192 in.^{2}].

Given frame has a clear opening of 152 mm [6 in.].

Therefore, the required loading is 0.124 m^2 [192 in.^{2}] multiplied by 4.23 MPa [617 psi], or 525 kN [118,465 lb]. This value exceeds the maximum allowed load of 222 kN [50,000 lb]. As a result, 222 kN [50,000 lb] shall be the applied load. The footprint size shall be smaller than 152 mm [6 in.] by 229 mm [9 in.]. Note that the footprint size cannot exceed 229 mm [9 in.] in any direction; consequently, even though the length is 610 mm [24 in.], the maximum value of 229 mm [9 in.] is used.

6.2. The 178-kN [40,000-lb] proof-load requirement listed in Sections 6.1 and 6.2 represents a safety factor of 2.5 for H-20 or HS-20 loading. A 222-kN [50,000-lb] proof load should be used in Sections 6.1 and 6.2, which represents a safety factor of 2.5 for H-25 or HS-25 loading.

6.3. *Precision and Bias*—No statement is made about the precision or the bias for the proof-load test method described in Sections 6.1 and 6.2 for measuring the ultimate strength of the casting. The result merely states whether there is conformance to the criteria for success specified in the procedure outlined in Sections 6.1 and 6.2.

7. MATERIAL TESTING

7.1. Test bar testing shall be conducted in accordance with the applicable inspection requirements of Section 8. Test bar preparation and tensile testing shall be in accordance with the applicable material specification listed in Section 4. Failure to meet the material specifications shall be cause for rejection.

8. INSPECTION

8.1. Unless otherwise specified in the contract or purchase order, the supplier/manufacturer shall be responsible for carrying out all the tests and inspections required by this specification, using purchaser approved reliable facilities, and he shall maintain complete records of all such tests and inspections. Such records shall be available for review by the purchaser. Three separate and alternative bases of acceptance are permitted: If the producing foundry is located within the United States of America, and operates in accordance with an acceptable Quality System approved by the purchaser, all castings must adhere to the inspection criteria listed in Sections 8.1.1 and 8.1.2. If the producing foundry is not located within the United States of America, or if the producing foundry is located within the United States of America and it is not operating in accordance with an acceptable Quality System approved by the purchaser, all castings must adhere to the inspection criteria listed in Sections 8.1.1 and 8.1.3.

8.1.1. *Acceptance on the Basis of Proof-Load Tests*—Acceptability of the castings produced in accordance with this specification shall be determined by the results of the proof-load test as listed in Sections 6.1, 6.2, and 6.3. The producing foundry shall provide information about the ultimate strength of the castings to the purchaser upon request.

8.1.2. *Acceptance on the Basis of Separately Cast Test Bar*—Before supplying any castings to a purchaser, the manufacturer must first submit to the purchaser for acceptance, documentation that a Quality System is in place to ensure material compliance. Thereafter, acceptability of the castings produced in accordance with this specification shall be by certification of the results of material tests conducted on separately cast test bars, and by inspection of the finished castings for freedom from defects. The manufacturer shall provide certification that the test bars furnished for testing represent the castings furnished for the order. If there are more than three test bar failures in one calendar year, the producing facility shall immediately report the three failing test results to the purchaser and shall discontinue supplying product. In order for the producing foundry to resume supplying product, documentation that a new Quality System is in place to ensure material compliance must be submitted to and accepted by the purchaser. The purchaser shall also have the option of allowing production under Section 8.1.3.

8.1.3. *Acceptance on the Basis of Cast-On Test Bars*—A test bar for determining the class of iron shall be cast on each member at a place where it can be easily broken off with a breakage pattern remaining on the member. Test bars are to be removed only after receipt of permission from the purchaser. Test bars shall be of sufficient size to produce a machined test specimen complying with the dimensional requirements for a Type B test bar as shown in Table 2 of M 105. For lots of

15 or fewer, 30 percent of the test bars selected at random from castings shall be tested by the supplier/manufacturer. For lots of 16 to 100, 10 percent or a minimum of 5 test bars, whichever is greater, selected at random from castings shall be tested by the supplier/manufacturer. For lots greater than 100, a minimum of 10 percent of all test bars selected at random from castings shall be tested by the supplier/manufacturer. All test bars shall conform to the strength requirements specified. If any of those test bars fail to conform to the strength requirements herein specified because of surface or internal defects, additional testing shall be performed at the direction of the purchaser. For lots of 15 or fewer, all remaining test bars must be tested. For larger lots, an additional 10 or 10 percent, whichever is greater, of the remaining test bars selected at random from the entire lot must be tested. All test results from this additional testing must conform to the strength requirements of this specification for the lot of castings to be acceptable. Each casting that has a test bar removed from it and evaluated must be inspected for mass [weight] and dimensions by the supplier/manufacturer. If the casting does not conform to the mass [weight] and dimensional requirements, the casting will be rejected. If a casting fails to conform to the mass [weight] or dimensional requirements, all remaining castings shall be inspected and all must conform to the requirements for the lot of castings to be acceptable. If the purchaser elects to select a casting for verification of test results, the member shall be furnished by the supplier/manufacturer at no cost to the purchaser. All test specimen preparation and testing shall be paid for by the supplier/manufacturer.

9. CERTIFICATION

9.1. All shipments to the purchaser shall include appropriate certification from the producing foundry. The certification shall state that the castings have been produced in facilities operating in accordance with the applicable laws and regulations of the United States and the appropriate state, province, or local unit of government. This certification shall also state that all samples representing each lot have been tested, inspected, and have been found to meet the requirements of this specification and the applicable AASHTO or ASTM material specifications listed in Section 4. Certifications shall also state country of origin of the castings. If specified in the order, a report of the test results shall be furnished.

10. MARKING

10.1. Each individual casting shall be identified by the foundry, showing the following:

10.1.1. Name of producing foundry and country of manufacture preceded by the words “Made in,” such as “Made in USA”;

10.1.2. AASHTO designation or ASTM designation number;

10.1.3. Class by a number followed by a letter indicating the minimum tensile strength and size of test bar;

10.1.4. Heat identification and cast date (MM/DD/YY);

10.1.5. Casting lettering as required by the purchaser; and

10.1.6. Markings as required to meet Federal requirements.

11. RECORDS

11.1. All test results as required by this specification shall be maintained by the producing foundry for 7 years and shall be made available to the purchaser upon request.

11.2. Records of casting certifications issued by a producing foundry shall be maintained by the producing foundry for 7 years and shall be made available upon request.

Standard Specification for

Joints for Concrete Pipe and Manholes, Using Rubber Gaskets

AASHTO Designation: M 315-07
ASTM Designation: C 443-05a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Joints for Concrete Pipe and Manholes, Using Rubber Gaskets

AASHTO Designation: M 315-07
ASTM Designation: C 443-05a

AASHTO M 315-07 is identical to ASTM C 443-05a.

Standard Specification for

Joints for Circular Concrete Sewer and Culvert Pipe, Using Rubber Gaskets [Metric]

AASHTO Designation: M 315M-09
ASTM Designation: C 443M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Joints for Circular Concrete Sewer and Culvert Pipe, Using Rubber Gaskets [Metric]

AASHTO Designation: M 315M-09
ASTM Designation: C 443M-07

AASHTO M 315M-09 is identical to ASTM C 443M-07.

Standard Specification for

Polyethylene (PE) Liner Pipe, 300- to 1600-mm Diameter, Based on Controlled Outside Diameter

AASHTO Designation: M 326-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Polyethylene (PE) Liner Pipe, 300- to 1600-mm Diameter, Based on Controlled Outside Diameter

AASHTO Designation: M 326-08

1. SCOPE

1.1. This specification covers the requirements and methods of tests for outside diameter dimension controlled polyethylene liner pipe (PE liner pipe), jointing, and fittings for use in pipe relining and culvert rehabilitation for industrial wastes, sanitary sewer, and surface and subsurface drainage applications.

1.1.1. Nominal sizes of 300 to 1600 mm are included.

1.1.2. Materials, workmanship, dimensions, pipe stiffness, joining systems, and form of markings are specified.

1.2. This specification is intended for rehabilitation of industrial waste, sanitary sewer, and surface and subsurface drainage applications by the insertion of PE liner pipe through existing pipe. PE liner pipe is designed to minimize traffic disruption and subsurface damage, and rehabilitate existing sewers and culverts with little or no interruption in service or traffic.

Note 1—When polyethylene pipe is to be used in locations where the ends may be exposed, consideration should be given to protection of the exposed portions due to combustibility of the polyethylene and the effects of prolonged exposure to ultraviolet radiation.

1.3. For the PE liner pipe to perform properly, the annular space between existing and PE liner pipe must be filled. This specification does not include methods to fill the annular space between the existing pipe and the PE liner pipe, insertion techniques, and termination techniques. Construction and installation procedures are described in ASTM F 585, *Standard Practice for Insertion of Flexible Polyethylene Pipe into Existing Sewers.*

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. The terminology used in this standard is in accordance with the definitions given in ASTM D 883 and ASTM F 412 unless otherwise specified.

3.2. *Crack*—Any break or split that extends through the wall.

3.3. *Crease*—An irrecoverable indentation, generally associated with wall buckling.

3.4. *Buckling*—Any reverse curvature or deformation in the pipe wall that reduces the load-carrying capability of the pipe. Any decrease or downward deviation in the pipe stiffness test curve shall be considered a wall buckling point.

3.5. *Polyethylene (PE) Plastics*—Plastics based on polymers made with ethylene as essentially the sole monomer (ASTM D 883).

3.6. *Reworked Plastic*—A plastic from a processor’s own production that has been reground, pelletized, or solvated after having been previously processed by molding, extrusion, etc. (ASTM D 883).

3.7. *Virgin Polyethylene Material*—PE plastic material in the form of pellets, granules, powder, floc, or liquid that has not been subject to use or processing other than required for initial manufacture.

4. CLASSIFICATION

4.1. The PE liner pipe covered by this specification is classified by the Standard Dimension Ratio (SDR) system. The relationship between SDR, outside diameter and minimum wall thickness is as follows:

$$SDR = \frac{D_o}{t} \qquad (1)$$

where:

SDR = Standard Dimension Ratio;

D_o = Average Outside Diameter, mm; and

t = minimum wall thickness, mm.

4.2. Standard Dimension Ratios covered by this specification are SDR 41, SDR 32.5, and SDR 26.

4.3. Where existing conditions or special requirements make other SDR classifications necessary, other sizes or dimension ratios or both shall be acceptable for engineering applications when mutually agreed upon by the customer and the manufacturer. This is provided that the pipe is manufactured from plastic compounds meeting the material requirement of this specification.

5. ORDERING INFORMATION

5.1. Orders using this specification shall include the following information as necessary to adequately describe the desired product:

5.2. AASHTO designation and year of issue;

5.2.1. Type of pipe (Section 4.2);

5.2.2. Diameter and length required, either total length or length of each piece and number of pieces;

5.2.3. Certification, if desired (Section 12.1).

6. MATERIALS

6.1. *Basic Materials*:

6.1.1. *Extruded Pipe and Fittings*—Pipe and fittings shall be made of virgin PE conforming with the requirements of cell class 345464C as defined and described in ASTM D 3350. Resins that have higher cell classifications in one or more properties are acceptable provided that product requirements are met.

6.1.2. *Rotational Molded Fittings and Couplings*—Fittings and couplings shall be made of virgin PE resins which conform with the requirements of cell class 213320C as defined and described in ASTM D 3350, except that the carbon black content shall not exceed 3 percent. Resins that have higher cell classifications in one or more properties are acceptable provided that product requirements are met.

6.2. *Reworked Plastic*—In lieu of virgin PE, clean reworked plastic may be used by the manufacturer, provided that it meets the cell class requirements as described in Section 6.1.

6.3. The manufacturer shall not blend resins to meet the cell classification specified in Section 6.1.1 or 6.1.2. Blending of reworked plastic and virgin plastic is allowed provided that both the reworked resin and the virgin resin meet the requirements of Section 6.1.

7. REQUIREMENTS

7.1. *Workmanship*—The pipe and fittings shall be free of foreign inclusions and visible defects as defined herein. The ends of the pipe shall be cut squarely and cleanly so as not to adversely affect joining or connecting. Field cuts shall be de-burred and free of defects.

7.2. *Visible Defects*—Cracks, creases, unpigmented or nonuniformly pigmented pipe are not permissible in the pipe or fittings as furnished.

7.3. *Pipe Dimensions*:

7.3.1. *Nominal Size*—The nominal size for the pipe and fittings is based on the nominal outside diameter of the pipe. Nominal diameters, outside diameters, and tolerance shall be in accordance with Table 1, when measured in accordance with Section 9.5.1.

Table 1—Outside Diameter and Tolerance

Nominal Pipe Size, mm (in.)	Outside Diameter, mm (in.)	Tolerance, ± mm (± in.)
300 (12)	323.8 (12.750)	1.5 (0.057)
325 (13)	339.7 (13.375)	1.5 (0.060)
350 (14)	355.6 (14.000)	1.6 (0.063)
400 (16)	406.4 (16.000)	1.8 (0.072)
450 (18)	457.2 (18.000)	2.1 (0.081)
500 (20)	508.0 (20.000)	2.3 (0.090)
538 (21.5)	546.1 (21.500)	2.5 (0.097)
550 (22)	558.8 (22.000)	2.5 (0.099)
600 (24)	609.6 (24.000)	2.7 (0.108)
650 (26)	660.4 (26.000)	3.0 (0.117)
700 (28)	711.2 (28.000)	3.2 (0.126)
750 (30)	762.0 (30.000)	3.4 (0.135)
800 (32)	812.5 (32.000)	3.7 (0.144)
850 (34)	863.6 (34.000)	3.9 (0.153)
900 (36)	914.4 (36.000)	4.1 (0.162)
1,050 (42)	1,066.8 (42.000)	4.8 (0.189)
1,200 (48)	1,219.2 (48.000)	5.5 (0.216)
1,350 (54)	1,371.6 (54.000)	6.2 (0.243)
1,600 (63)	1,600.2 (63.000)	7.20 (0.284)

7.3.2. *Wall Thickness*—The wall thickness shall have the minimum thicknesses in Table 2 for each standard dimension ratio, when measured in accordance with Section 9.5.3.

Table 2—Minimum Wall Thickness

Nominal Pipe Size, mm (in.)	Outside Diameter, mm (in.)	SDR 41 Wall Thickness, mm (in.)	SDR 32.5 Wall Thickness, mm (in.)	SDR 26 Wall Thickness, mm (in.)
300 (12)	323.8 (12.750)	7.9 (0.310)	10 (0.392)	12.4 (0.490)
325 (13)	339.7 (13.375)	8.2 (0.326)	10.4 (0.412)	13.1 (0.514)
350 (14)	355.6 (14.000)	8.0 (0.314)	10.9 (0.431)	13.6 (0.538)
400 (16)	406.4 (16.000)	9.9 (0.390)	12.5 (0.492)	15.6 (0.615)
450 (18)	457.2 (18.000)	11.2 (0.439)	14.1 (0.554)	17.6 (0.692)
500 (20)	508.0 (20.000)	12.4 (0.488)	15.6 (0.615)	19.5 (0.769)
538 (21.5)	546.1 (21.500)	13.3 (0.524)	16.8 (0.662)	21.0 (0.827)
550 (22)	558.8 (22.000)	13.6 (0.537)	17.2 (0.677)	23.4 (0.846)
600 (24)	609.6 (24.000)	14.9 (0.585)	18.7 (0.738)	23.4 (0.923)
650 (26)	660.4 (26.000)	16.1 (0.634)	20.3 (0.800)	25.4 (1.000)
700 (28)	711.2 (28.000)	17.4 (0.683)	21.9 (0.862)	27.4 (1.077)
750 (30)	762.0 (30.000)	18.6 (0.732)	23.4 (0.923)	29.3 (1.154)
800 (32)	812.5 (32.000)	19.8 (0.780)	25.0 (0.985)	31.3 (1.231)
850 (34)	863.6 (34.000)	21.1 (0.829)	26.6 (1.046)	33.2 (1.308)
900 (36)	914.4 (36.000)	22.3 (0.878)	28.1 (1.108)	35.2 (1.385)
1,050 (42)	1,066.8 (42.000)	26.0 (1.024)	32.8 (1.292)	41.0 (1.615)
1,200 (48)	1,219.2 (48.000)	29.7 (1.171)	37.5 (1.477)	46.9 (1.846)
1,350 (54)	1,371.6 (54.000)	33.4 (1.317)	42.2 (1.662)	52.8 (2.077)
1,600 (63)	1,600.2 (63.000)	Not Available	49.2 (1.938)	61.5 (2.423)

7.3.3. *Average Inside Diameter*—The average inside diameter (*ID*) shall be calculated as follows:

$$AvgID = \frac{OD_{\min} + OD_{\max}}{2} - 2\left(t_{\min} \times 1.06\right) \qquad (2)$$

where:

$AvgID$ = Average inside diameter, mm (in.);

OD_{min} = Minimum outside diameter from Table 1, mm (in.);

OD_{max} = Maximum outside diameter from Table 1, mm (in.); and

t_{min} = Minimum wall thickness from Table 2, mm (in.).

7.3.4. *Length*—PE liner pipe may be sold in any length agreeable to the user. The furnished length shall not be less than the shorter of 99 percent of the agreed length or 12 mm ($^{1}/_{2}$ in.), whichever is less.

7.4. *Pipe Stiffness*—The pipe shall have a minimum pipe stiffness at 5 percent deflection as follows when tested in accordance with Section 9.1. The minimum pipe stiffness shall be as follows:

41 SDR – 55.2 kPa (8 psi)

32.5 SDR – 110.3 kPa (16 psi)

26 SDR – 213.7 kPa (31 psi)

7.4.1. Pipe stiffness test for 600 mm (24 in.) and smaller diameters may be extrapolated to larger sizes of the same SDR classification, provided the manufacturer can document the following equation accurately predicts the pipe stiffness for all sizes and SDR:

$$PS = \frac{C \times E}{\left(SDR - 1\right)^3} \qquad (3)$$

where:

C = Design constant;

= 0.649 in SI units;

= 4.472 in U.S. customary units;

E = Flexural Modulus, kPa (psi); and

SDR = Standard Dimension Ratio (as defined in Section 4).

7.5. *Pipe Flattening*—There shall be no evidence of wall buckling, cracking, or splitting, when the pipe is tested in accordance with Section 9.2.

7.6. *Fitting Requirements*:

7.6.1. The fittings shall not reduce or impair the overall integrity or function of the PE liner pipe.

7.6.2. Common fittings include in-line joint fittings, reducers, and branch or complimentary assembly fittings such as tees and wyes. These fittings shall be installed or coupled to the pipe by various methods in accordance with Section 7.7.

7.6.3. All fittings shall be within an overall length dimensional tolerance ±12 mm ($^{1}/_{2}$ in.) of the manufacturer's specified dimensions when measured in accordance with Section 9.5.2.

7.6.4. Fittings shall not reduce the inside diameter of the pipe being joined by more than 12 mm ($^{1}/_{2}$ in.). Reducer fittings shall not reduce the cross-sectional area of the small size.

7.6.5. Fabricated fittings should be supplied with joints compatible with the overall system.

7.7. *Jointing Requirements*:

7.7.1. Joints shall provide sufficient longitudinal (or axial) strength to preserve pipe alignment, prevent separation at the joints, and maintain integrity while pushing or pulling pipe lengths into existing pipes or culverts. Joints shall be mechanical or male and female joint connections. Mechanical or male and female joints connections shall be an integral part of the PE liner pipe. Alternatively, the mechanical joint, male and female joints, or pipe ends may be heat fused provided that the fusion process meets the requirements of ASTM F 2620 and that the fused connection meets the requirements of Section 7 of this standard.

7.7.2. Joints shall have sufficient longitudinal or axial compression strength to withstand a maximum compressive force of 17.5 newtons per mm (100 lbs force per in.) of outside diameter circumference in compression while maintaining joint integrity when tested in accordance with Section 9.4.1.

7.7.3. Joints shall have sufficient pull apart strength to withstand a maximum tensile force of 17.5 newtons per mm (100 lbs force per in.) of outside diameter circumference in tension without joint disassembly when tested in accordance with Section 9.4.2.

7.7.4. Joints shall not reduce the inside diameter or enlarge the outside diameter of the pipe being joined by more than 6 mm ($^1/_4$ in.). When the pipe is coupled, the axis of the assembly will be level and true when tested in accordance with Section 9.4.3.

7.7.5. Other types of mechanical jointing, which are equally effective as those described and which comply with the joint performance criteria of Section 7.7, may be used when approved by the purchaser.

7.7.6. All joints shall meet the watertight joint requirements of Section 7.8 unless otherwise specified by the owner/designer.

7.8. *Watertight joints* must meet a 74 kPa (10.8 psi) laboratory test per ASTM D 3212. Mechanical coupler or male and female joint design shall use a gasket meeting ASTM F 477.

8. CONDITIONING

8.1. *Conditioning*—Unless otherwise specified, for those tests for which conditioning is required, condition the specimen for not fewer than 24 hours prior to test at 21 to 25ºC (70 to 77 ºF) in accordance with Procedure A in ASTM D 618.

8.2. *Conditions*—Conduct all tests at a laboratory temperature of 21 to 25ºC (70 to 77 ºF) unless otherwise specified herein.

9. TEST METHODS

9.1. *Pipe Stiffness*—Select a minimum of two pipe specimens and test for pipe stiffness, as described in ASTM D 2412 except the test specimens shall be a minimum of 300 mm (12 in.) in length for pipe diameters 300 to 600 mm (12 to 24 in.), and one-half diameter length for diameters greater than 600 mm (24 in.). Use the first location as a reference point for rotation and testing of the other specimen. Rotate subsequent specimen 90 degrees from the original orientation. Test each specimen in one position only. The deflection indicator shall be readable and accurate to ±0.02 mm (0.0008 in.).

Note 2—The parallel plates must exceed the length of the test specimen as specified above.

9.2. *Pipe Flattening*—Flatten the two pipe specimens from Section 9.1 until the vertical inside diameter is reduced by 20 percent. The rate of loading shall be the same as in Section 9.1. Examine the specimen with the unaided eye for cracking or splitting.

9.3. *Slow Crack Growth Resistance of Resin Compounds*—Test PE liner pipe basic resin compounds for stress crack resistance in accordance with ASTM F 1473 PENT test with a minimum time to failure of 100 hours.

9.4. *Jointing Fittings*:

9.4.1. *Joint Integrity Longitudinal Compression*—Assemble each male and female joint to the appropriate pipe in accordance with the manufacturer's recommendations. Use pipe samples at least 300 mm (12 in.) in length. Assemble a specimen at least 600 mm (24 in.) in length with the connection at the center. Load the coupled pipe lengths in axial compression at a rate not to exceed 25.4 mm (1 in.) per second until the total compressive load equals the circumference of the PE liner pipe outside diameter, measured in millimeters (inches), times 17.5 newtons (4 lb). The applied load shall be aligned with the longitudinal axis of the pipe. After 2 minutes, unload the pipe coupler assembly and inspect for damage such as splitting, cracking, tearing, or a reduction to the inside diameter of 6 mm ($^1/_4$ in.) or greater. Any damage and/or reduction to the inside diameter by 6 mm ($^1/_4$ in.) or greater is considered a failure.

9.4.2. *Joint Integrity Pull Apart*—Assemble each male and female jointing to the appropriate pipe in accordance with the manufacturer's recommendations. Use pipe samples at least 300 mm (12 in.) in length. Assemble a specimen at least 600 mm (24 in.) in length with the connection at the center. Pull heads may be heat fused to the pipe lengths. Load the coupled pipe in axial tension at a rate not to exceed 25.4 mm (1 in.) per second until the total tensile load equals the circumference of the PE liner pipe outside diameter, measured in millimeters (inches), times 17.5 newtons (4 lb). After 2 minutes, unload the pipe lengths and inspect for damage. The applied load shall be aligned with the longitudinal axis of the pipe. Damage to the pipe such as splitting, cracking, tearing, or joint separation is considered a failure.

9.4.3. *Alignment*—Assure that the assembly or joint is correct and complete. If the pipe is bent, it should be straightened prior to performing this test. Lay the assembly or joint on a flat surface and verify that it will accommodate straight-line flow.

9.5. *Dimensions*:

9.5.1. *Outside Diameter*—Measure the outside diameter of the pipe with a tapered sleeve gauge or a circumferential wrap tape in accordance with ASTM D 2122. As an alternative, measure the outside diameter with a suitable device accurate to ±3.0 mm ($^1/_8$ in.) on two sections. Take eight measurements equally spaced around the circumference of each section and average these 16 measurements. The average outside diameter shall meet the requirements of Section 7.3.1.

9.5.2. *Length*—Measure pipe with any suitable device accurate to ±6.0 mm ($^1/_4$ in.) in 3 m (10 ft). Make all measurements on the pipe while it is stress-free and at rest on a flat surface in a straight line.

9.5.3. *Wall Thickness*—Measure the wall thickness in accordance with ASTM D 2122.

10. INSPECTION AND RETEST

10.1. *Inspection*—Inspection of the material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

10.2. *Retest and Rejection*—If any failure to conform to these specifications occurs, the pipe or fittings may be retested to establish conformity in accordance with agreement between the purchaser and seller. Individual results, not averages, constitute failure.

10.3. *Pipe Marking*—Pipe marking may include ASTM F 714 marking. However, to ensure conformance with this specification, the PE liner pipe shall include markings described in Section 11 of this specification.

11. MARKING

11.1. All pipe shall be clearly marked at intervals of no more than 3.5 m (12 ft) as follows:

11.1.1. Manufacturer's name or trademark,

11.1.2. Nominal outside size,

11.1.3. Dimensional ratio,

11.1.4. The specification designation, AASHTO M 326,

11.1.5. The plant designation code, and

11.1.6. The date of manufacturer or an appropriate code.

11.1.6.1. If the date code is used, a temporary manufacturer sticker that identifies the actual date of manufacture shall be adhered to the inside of each length of pipe.

11.2. Fittings shall be marked with a designation number of this specification, AASHTO M 326 and with the manufacturer's identification symbol.

12. QUALITY ASSURANCE

12.1. A manufacturer's certificate that the product was manufactured, tested, and supplied in accordance with this specification, together with a report of the test results, and the date each test was completed, shall be furnished upon request. Each certification so furnished shall be signed by a person authorized by the manufacturer.

APPENDIX

(Nonmandatory Information)

X1. QUALITY CONTROL/QUALITY ASSURANCE PROGRAM

X1.1. *Scope*:

X1.1.1. As required in Sections 10 and 12, the acceptance of these products relies on the adequate inspection and certification agreed to between the buyer and the seller/producer. This appendix should serve as a guide for both the manufacturer and the user. It places the responsibility on producers to control the quality of the material they produce and to provide the quality control information needed for acceptance by the buyer/user. Producers are required to perform quality control sampling, testing, and record keeping on materials they ship. It also sets forth quality assurance sampling, testing, and record keeping that should be performed by the buyer/user to confirm the performance of the producer's control plan.

X1.2. *Program Requirements*:

X1.2.1. The producing company must have a quality control plan approved by the specifying agency.

X1.2.2. The producing plant must have an approved quality control plan.

X1.2.3. The plant must have an approved laboratory, either within the company or an independent laboratory.

X1.2.4. The producing plant(s) must have a designated quality control technician.

X1.3. *Quality Control Plan*:

X1.3.1. The producer must supply to the specifying agency a written quality control plan that shows how the producer will control the equipment, materials, and production methods to ensure that the specified products are supplied. The following information must be included in the plan:

X1.3.1.1. Titles of the personnel responsible for production quality at the plant(s);

X1.3.1.2. The physical location of the plant(s);

X1.3.1.3. The methods of identification of each lot of material during manufacture, testing, storage, and shipment. The method of identification shall allow the specifying agency to trace the finished product to the material provider;

X1.3.1.4. The method of sampling and testing of raw materials and of finished product, including lot sizes and types of tests performed; and

X1.3.1.5. A plan for dealing with nonconforming product, including how the producer plans to initiate immediate investigation and how corrective action will be implemented to remedy the cause of the problem.

X1.4. *Approved Laboratory*:

X1.4.1. All tests must be conducted at laboratories approved by the specifier. Each manufacturer may establish and maintain its own laboratory for performance of quality control testing or may utilize an approved independent laboratory. Records of instrument calibration and maintenance and sample collection and analysis must be maintained at the laboratory.

X1.5. *Quality Control Technician*:

X1.5.1. All samples must be taken and tested by quality control technicians designated by the producer. The designated quality control technicians will be responsible for overall quality control at the producing plant.

X1.6. *Annual Update*:

X1.6.1. An annual update may be required. The annual update may be submitted by the manufacturer to the specifying agency by December 31st of each calendar year.

X1.7. *Plant Approval*:

X1.7.1. The plant approval process requires the manufacturer to submit an annual update to the specifying agency. The update must identify the specific product manufactured at the plant.

X1.7.2. The specifying agency will review the manufacturer's written quality control plan and a plant inspection may be scheduled. This inspection will verify that the quality control plan has been implemented and is being followed and that at least one designated quality control technician is on-site and will be present when material is being produced under this program. The laboratory will be inspected and approved if it meets the requirements.

X1.8. *Sampling and Testing*:

X1.8.1. The quality assurance plan approved for each manufacturer, and/or manufacturer's location, shall detail the methods and frequency of sampling and testing for all raw materials and products purchased or manufactured at that location. All testing shall be in accordance with current specifications and procedures referenced in M 326.

X1.8.2. Samples of materials and pipe may be taken by the specifying agency.

X1.8.3. The specifying agency may require an annual third-party independent assurance test.

X1.9. *Sample Identification and Record Keeping*:

X1.9.1. Manufacturer's quality control samples are to be uniquely identified by the producing plant.

X1.9.2. Quality control and quality assurance data are to be retained by the manufacturer for 2 years and made available to the specifying agency upon request.

X1.9.3. Quality control test reports shall include the lot identification.

X1.9.4. Unless requested at the time of ordering, test reports do not have to be filed for specific projects.

X1.9.5. Reports shall indicate the action taken to resolve nonconforming product.

Standard Specification for

Sewer and Manhole Brick (Made from Clay or Shale)

AASHTO Designation: M 91-10
ASTM Designation: C 32-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Sewer and Manhole Brick (Made from Clay or Shale)

AASHTO Designation: M 91-10
ASTM Designation: C 32-09

AASHTO M 91-10 is identical to ASTM C 32-09 except that all references to ASTM C 67 contained in ASTM C 32-09 shall be replaced with T 32.

Standard Specification for

Building Brick (Solid Masonry Units Made from Clay or Shale)

AASHTO Designation: M 114-10
ASTM Designation: C 62-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Building Brick (Solid Masonry Units Made from Clay or Shale)

AASHTO Designation: M 114-10
ASTM Designation: C 62-08

AASHTO M 114-10 is identical to ASTM C 62-08.

Standard Specification for

Liquid Membrane-Forming Compounds for Curing Concrete

AASHTO Designation: M 148-05
ASTM Designation: C 309-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Liquid Membrane-Forming Compounds for Curing Concrete

AASHTO Designation: M 148-05
ASTM Designation: C 309-03

The AASHTO equivalent of this specification has been discontinued. Please refer to ASTM C 309-03 for the information formerly contained in this standard.

Standard Specification for

Air-Entraining Admixtures for Concrete

AASHTO Designation: M 154-06
ASTM Designation: C 260-01

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Air-Entraining Admixtures for Concrete

AASHTO Designation: M 154-06
ASTM Designation: C 260-01

AASHTO M 154-06 is identical to ASTM C 260-01 except for the following provision:

1. All references to the ASTM Standards contained in ASTM C 260-01 listed in the following table shall be replaced with the corresponding AASHTO Standard.

Referenced Standards

ASTM	AASHTO
C 183	T 127
C 185	T 137
C 233	T 157

2. Section 8.1 of ASTM C 260-01 shall be replaced with the following:

   8.1 Determine the properties enumerated in Section 6 in accordance with Test Method C 233. It is recommended that, whenever practicable, tests be made in accordance with the section on Materials for Tests for Specific Uses in Test Method C 233, using the cementitious materials proposed for the specific work.

3. Table 1 Physical Requirements of ASTM C 260-01 shall be revised to include compressive strength and flexural strength at 56 days with the same requirements as listed for 28 days. The 56-days requirements shall be applicable only when specified by the purchaser.

Standard Specification for

Ready-Mixed Concrete

AASHTO Designation: M 157-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Ready-Mixed Concrete

AASHTO Designation: M 157-06

1. SCOPE

1.1. This specification covers ready-mixed concrete manufactured and delivered to a purchaser in a freshly mixed and unhardened state as hereinafter specified. Requirements for quality of concrete shall be either as hereinafter specified or as specified by the purchaser. In any case where the requirements of the purchaser differ from those in this specification, the purchaser's specification shall govern. This specification does not cover the placement, consolidation, curing, or protection of the concrete after delivery to the purchaser.

1.2. The values stated in SI units are the preferred standard. The values given in parentheses are for information only.

1.3. As used throughout this specification the manufacturer shall be the contractor, subcontractor, supplier, or producer who furnishes the ready-mixed concrete. The purchaser shall be the specifying agency and designated representatives thereof. The engineer shall be interpreted to mean the designated representative of the specifying agency.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

3. DEFINITIONS

3.1. For the purpose of this specification, ready-mixed concrete is hydraulic cement concrete manufactured for delivery to a purchaser in a plastic state and delivered as hereinafter specified.

3.2. The volume of freshly mixed and unhardened concrete in a given batch shall be determined from the total mass of the batch divided by the actual mass per cubic foot of the concrete. The total mass of the batch shall be calculated either as the sum of the masses of all materials, including water, entering the batch or as the net mass of the concrete in the batch as delivered. The mass per cubic foot shall be determined in accordance with T 121M/T 121 from the average of at least three measurements, each on a different sample using a 14 L ($^1/_2$-ft^3) container. Each sample shall be taken from the midpoint of each of three different truck loads by the procedure outlined in T 142.

Note 1—It should be understood that the volume of hardened concrete may be, or appear to be, less than expected due to waste and spillage, overexcavation, spreading forms, some loss of entrained air, or settlement of wet mixtures.

4. MATERIALS

4.1. Storage and facilities satisfactory to the engineer shall be provided at the batching plant to permit proper sampling, testing, and control of materials prior to and during use. The following specifications shall apply:

4.1.1. *Cement*—Cement shall conform to M 85 for hydraulic cement, M 240 for blended hydraulic cement, or ASTM C 1157 for blended hydraulic cement. The engineer shall specify the type or types required. If no type is specified, the requirements of Type 1 as specified in M 85 shall apply. These different cements will produce concrete of different properties and should not be used interchangeably. Cement from different sources shall not be used interchangeably without approval of the engineer.

4.1.2. *Other Cementitious Materials*—Cementitious materials other than cement shall meet the requirement of the following specification unless specified otherwise by the purchaser:

- Fly Ash—M 295
- Ground Granulated Blast Furnace Slag—M 302
- Silica Fume—M 307

4.1.3. *Aggregates*—Coarse aggregates shall conform to M 80. Fine aggregates shall conform to M 6. Lightweight aggregates shall conform to M 195.

4.1.4. *Water*—Water shall be clear and free from injurious amounts of oil, acid, alkali, organic matter, or other deleterious substance. It shall not be salty or brackish. It shall be tested in accordance with T 26. Water of questionable quality shall be subject to the acceptance criteria of Tables 1 and 2 or as designated by the purchaser.

Table 1—Acceptance Criteria for Questionable Water Supplies

	Limits	Test Method
Compressive strength, min percent control at 7 days	90	T 106[a]
Time of set, deviation from control	From 1:00 earlier to 1:30 later	T 131[a]

[a] Comparison shall be based on fixed proportions and the same volume of test water compared to control mix using water or distilled water.

Table 2—Chemical Limitations for Wash Water

	Limits	Test Method
Chemical requirements, maximum concentration		
Chloride as $C1^{[-1]}$ expressed as a percent by weight of cement when added to the $C1^{[-1]}$ in the other components of the concrete mixture shall not exceed the following levels:		
1. Prestressed concrete	0.06 percent	T 260
2. Conventionally reinforced concrete in a moist environment and exposed to chloride	0.10 percent	
3. Conventionally reinforced concrete in a moist environment but not exposed to chloride	0.15 percent	
4. Above ground building construction where the concrete will stay dry	No limit for corrosion	
Sulfate as SO_4 ppm[a]	3000	ASTM D 516
Alkalis as (Na_2O + 0.658 K_2O), ppm	600	ASTM D 4191, D 4192
Totals, solids, ppm	50000	T 26

[a] Wash water reused as mixing water in concrete may exceed listed concentrations of sulfate if it can be shown that the concentration calculated in the total mixing water, including mixing water on the aggregate and other sources, does not exceed the stated limits.

4.1.4.1. Wash water from mixer washout may be used only with the purchaser's approval. When wash water is permitted, the producer will provide satisfactory proof or data of nondetrimental effects if potentially reactive aggregates are to be used. Use of wash water will be discontinued if undesirable reaction with admixtures or aggregates occurs.

4.1.5. *Admixtures*—When air entrained concrete is specified and an admixture is used to secure the desired air content, the admixture shall meet the requirements of M 154. Where it is desired to use admixtures for purposes other than entrainment of air, the admixture shall conform to the requirements of M 194.

5. QUALITY OF CONCRETE

5.1. The mix design may be specified by the engineer or submitted to the engineer by the contractor for approval, or a performance based specification can be used. When specified by the engineer, it shall include the following:

5.1.1. Each cementitious materials content in kg/m^3 (lb/yd^3) of concrete, or equivalent units;

5.1.2. Designated size, or sizes, and amount by mass of aggregates;

5.1.3. Maximum water to cementitious materials ratio where water includes surface moisture and water in the admixture, but excludes the absorption water of the aggregates;

5.1.4. Consistency desired at the point of delivery (Section 6.1.1 for acceptable tolerances);

5.1.5. The range of air content of the concrete when air-entraining cement or an air-entraining admixture is specified. The air content shall be determined on samples taken at the point of placement; and

5.1.6. The type and amounts of admixture other than air-entraining agents when such admixtures are specified.

5.2. When submitted by the contractor for approval by the engineer, the mix design shall be within the limitation specified for:

5.2.1. Minimum cement content,

5.2.2. Maximum amount of water,

5.2.3. Range for air content,

5.2.4. Range for consistency, and

5.2.5. Maximum aggregate size.

5.3. When a performance-based specification is used, the engineer shall specify the desired fresh and hardened concrete properties and permit the contractor to design the mixture. The specifying agency may specify the design method to be used by the contractor. The contractor will demonstrate through trial mixtures that the mix designs will provide the specified fresh and hardened properties. Selection of slump for placement shall be the responsibility of the contractor. The contractor shall make trial placements to demonstrate that concrete can be placed without any segregation, and without any difficulty in consolidating and finishing.

6. TOLERANCES IN SLUMP

6.1. Unless other tolerances are included in the project specifications, the following shall apply:

6.1.1. When the project specifications for slump are written as a “maximum” or “not to exceed” requirement, see Table 3. This option is to be used only if one addition of water is permitted on the job provided such addition does not increase the water-cement ratio above the maximum permitted by the specifications.

Table 3—Specified Slump

	If 76 mm (3 in.) or Less	If More Than 76 mm (3 in.)
Plus tolerance	0	0
Minus tolerance	38 mm ($1^1/_2$ in.)	63 mm ($2^1/_2$ in.)

6.1.2. When the project specifications for slump are not written as a “maximum” or “not to exceed” requirement, see Table 4.

Table 4—Tolerances for Nominal Slumps

For Specified Slump of—	Tolerance
51 mm (2 in.) and less	13 mm (± $^1/_2$ in.)
More than 51 to 102 mm (2 through 4 in.)	25 mm (± 1 in.)
More than 102 mm (4 in.)	38 mm (± $1^1/_2$ in.)

7. AIR-ENTRAINED CONCRETE

7.1. The purchaser shall specify or approve the design total air content of the concrete.

7.2. The air content of air-entrained concrete when sampled from the transportation unit at the point of placement shall be within the purchaser specified tolerances. Where it is not practical to test at this point, comparison of values measured at the point of placement and the nearest practical location shall be established.

8. MEASURING MATERIALS

8.1. Except as otherwise specifically permitted, cement shall be measured by mass. When fly ash or other cementitious materials are specified in the mix design, they may be weighed cumulatively with cement. Cement and other cementitious material shall be weighed on a scale and in a weigh hopper, which is separate and distinct from those used for other materials. Cement shall be weighed before other cementitious material. When the quantity of cement exceeds 30 percent of the full capacity of the scale, the quantity of cement, and the cumulative quantity of cement plus other cementitious material, shall be within ±1 percent of the required mass For small batches to a minimum of 1 m^3 (1 yd^3), the quantity of cement, and the quantity of cement plus other cementitious material, used shall not be less than the required amount nor more than 4 percent in excess. Under special circumstances, approved by the purchaser, cement may be measured in bags of standard mass (Note 2). No fraction of a bag of cement shall be used unless weighed.

Note 2—In the United States the standard mass of a bag of portland cement is 42.6 kg (94 lb) ±3 percent.

8.2. Aggregate shall be measured by mass. Batch mass shall be based on dry materials and shall be required mass of dry materials plus the total mass of moisture (both absorbed and surface) contained in the aggregate. The quantity of aggregate used in any batch of concrete as indicated by the scale shall be within ±2 percent of the required mass when weighed in individual weigh batchers. In a cumulative aggregate weigh batcher, the cumulative mass after each successive weighing shall be within ±1 percent of the required cumulative amount when the scale is used in excess of 30 percent of its capacity. For cumulative mass for less than 30 percent of scale capacity, the tolerance shall be ±0.3 percent of scale capacity or ±3 percent of the required cumulative mass, whichever is less.

8.3. Mixing water shall consist of water added to the batch, ice added to the batch, water occurring as surface moisture on the aggregates, and water introduced in the form of admixtures. The added water shall be measured by mass or volume to an accuracy of 1 percent of the required total mixing water. Added ice shall be measured by weight. In the case of truck mixers, any wash water retained in the drum for use in the next batch of concrete shall be accurately measured; if this proves impractical or impossible, the wash water shall be discharged prior to loading the next batch of concrete. Total water (including any wash water) shall be measured or weighed to an accuracy of ±3 percent of the specified total amount.

8.4. Powdered admixtures shall be measured by weight, and paste or liquid admixtures by weight or volume. Accuracy of weighing admixtures shall be within ±3 percent of the required weight. Volumetric measurement shall be within an accuracy of ±3 percent of the total amount required or plus and minus the volume of dose required for one sack of cement, whichever is greater.

Note 3—Admixture dispensers of the mechanical type capable of adjustment for variation of dosage, and of simple calibration, are recommended.

9. BATCHING PLANT

9.1. Bins with adequate separate compartments shall be provided in the batching plant for fine and for each required size of coarse aggregate. Each bin compartment shall be designed and operated so as to discharge efficiently and freely, with minimum segregation, into the weighing hopper. Means of control shall be provided so that, as the quantity desired in the weighing hopper is approached, the material may be shut off with precision. Weighing hoppers shall be constructed so as to eliminate accumulations of tare materials and to discharge fully.

9.2. Indicating devices shall be in full view and near enough to be read accurately by the operator while charging the hopper. The operators shall have convenient access to all controls.

9.3. Scales in use shall be accurate when static load tested to ±0.4 percent of the total capacity of the scale.

9.4. Scales for batching concrete ingredients may be either beam or springless dial scales and shall conform to the applicable sections of the current edition of the *National Bureau of Standards Handbook 44, Specifications, Tolerances, and other Technical Requirements for Commercial Weighing and Measuring Devices*,[1] except as may be otherwise specified. Methods for weighing (electric, hydraulic, load cells, etc.) other than beam or springless dial scales that meet the above weighing tolerances are also acceptable.

9.5. Adequate standard test masses shall be available for checking accuracy. All exposed fulcrums, clevises, and similar working parts of scales shall be kept clean. Beam scales shall be equipped with a balance indicator sensitive enough to show movement when a mass equal to 0.1 percent of the nominal capacity of the scale is placed in the batch hopper. Pointer travel shall be a minimum of 5 percent of the net-rated capacity of the largest weigh beam for underweight and 4 percent for overweight.

9.6. The device for the measurement of the added water shall be capable of delivering to the batch the quantity required within the accuracy required in Section 8.3. The device shall be so arranged that the measurements will not be affected by variable pressure in the water supply line. Measuring tanks shall be equipped with outside taps and valves to provide for checking their calibration unless other means are provided for readily and accurately determining the amount of water in the tank.

Note 4—The scale accuracy limitations of the National Ready Mixed Concrete Association Plant Certification meet the requirements of M 157.

10. MIXERS AND AGITATORS

10.1. Mixers may be stationary mixers or truck mixers. Agitators may be truck mixers or truck agitators.

10.1.1. Stationary mixers shall be equipped with a metal plate or plates on which are plainly marked the mixing speed of the drum or paddles and the maximum capacity in terms of the volume of mixed concrete. When used for the complete mixing of concrete, stationary mixers shall be equipped with an acceptable timing device that will not permit that batch to be discharged until the specified mixing time has elapsed.

10.1.2. Each truck mixer or agitator shall have attached thereto in a prominent place a metal plate or plates on which are plainly marked the gross volume of the drum, the capacity of the drum or container in terms of the volume of mixed concrete, and the minimum and maximum mixing speeds of rotation of the drum, blades, or paddles. When the concrete is truck-mixed as described in Section 11.1.3, or shrink mixed as described in Section 11.1.2, the volume of mixed concrete shall not exceed 63 percent of the total volume of the drum or container. When the concrete is central mixed as described in Section 11.1.1, the volume of concrete in the truck mixer or agitator shall not exceed 80 percent of the total volume of the drum or container. Truck mixers and agitators shall be equipped with means by which the number of revolutions of the drum, blades, or paddles may be readily verified.

10.2. All stationary and truck mixers shall be capable of combining the ingredients of the concrete within the specified time or number of revolutions specified in Section 10.5, into a thoroughly mixed and uniform mass and of discharging the concrete so that no less than five of the six requirements shown in Table 5 shall have been met.

Table 5—Requirements for Uniformity of Concrete

Test Requirement Expressed as Maximum Permissible Difference in Results of Tests of Samples Taken from Two Locations in the Concrete Batch	
Mass per cubic meter (mass per cubic foot) calculated to an air-free basis, kg/m^3 (lb/ft^3)	16 (1.0)
Air content, volume percent of concrete	1.0
Slump:	
If average slump is 102 mm (4 in.) or less, mm (in.)	25 (1.0)
If average slump is 102 to 152 mm (4 to 6 in.), mm (in.)	38 (1.5)
Coarse aggregate content, portion by mass of each sample retained on No. 4 (4.75-mm) sieve, percent	6.0
Unit weight of air-free mortar[a] based on average for all comparative samples tested, percent	1.6
Average compressive strength at 7 days for each sample,[b] based on average strength of all comparative test specimens, percent	7.5[c]

[a] "Test for Variability of Constituents in Concrete." Designation 26, *Bureau of Reclamation Concrete Manual*, 7th Edition. Available from Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402.

[b] No fewer than three cylinders will be molded and tested from each of the samples.

[c] Tentative approval of the mixer may be granted pending results of the 7-day compressive strength tests.

Note 5—The sequence or method of charging the mixer will have an important effect on the uniformity of the concrete.

10.3. The agitator shall be capable of maintaining the mixed concrete in a thoroughly mixed and uniform mass and of discharging the concrete with a satisfactory degree of uniformity as defined by Annex A.

10.4. Slump tests of individual samples taken after discharge of approximately 15 percent and 85 percent of the load may be made for a quick check of the probable degree of uniformity (Note 6). These two samples shall be obtained within an elapsed time of not more than 15 minutes. If these slumps differ more than that specified in Annex A, the mixer or agitator shall not be used unless the condition is corrected, except as provided in Section 10.5.

Note 6—No samples should be taken before 10 percent or after 90 percent of the batch has been discharged. Due to the difficulty of determining the actual quantity of concrete discharged, the intent is to provide samples that are representative of widely separated portions, but not the beginning and end of the load.

10.5. Use of the equipment may be permitted when operation with a longer mixing time, a smaller load, or a more efficient charging sequence will permit the requirements of Annex A to be met.

10.6. Mixers and agitators shall be examined or weighed routinely as frequently as necessary to detect changes in condition due to accumulations of hardened concrete or mortar and examined to detect wear of blades. When such changes are extensive enough to affect the mixer performance, the proof-tests described in Annex A shall be performed to show whether the correction of deficiencies is required.

11. MIXING AND DELIVERY

11.1. Ready-mixed concrete shall be mixed and delivered to the point designated by the purchaser by means of one of the following combinations of operations:

11.1.1. Central-mixed concrete,

11.1.2. Shrink-mixed concrete, and

11.1.3. Truck-mixed concrete.

11.2. Mixers and agitators shall be operated within the limits of capacity and speed of rotation designated by the manufacturer of the equipment.

11.3. *Central-Mixed Concrete*—Concrete that is mixed completely in a stationary mixer and transported to the point of delivery either in a truck agitator, or a truck mixer operating at agitating speed, or in nonagitating equipment approved by the purchaser and meeting the requirements of Section 12, shall conform to the following: the mixing time shall be counted from the time all the solid materials are in the drum. The batch shall be so charged into the mixer that some water will enter in advance of the cement and aggregate, and all water shall be in the drum by the end of the first one-fourth of the specified mixing time.

11.3.1. Where no mixer performance tests are made, the acceptable mixing time for mixers having capacities of 0.76 m^3 (1 yd^3) or less shall be not less than 1 minute. For mixers of greater capacity, this minimum shall be increased 15 seconds for each cubic yard or fraction thereof of additional capacity.

Note 7—HPC mixtures—especially those with stiff consistency having high cementitious material content, low water-cementitious material ratio, and several admixtures—may need longer mixing times and a higher number of revolutions for thorough mixing.

11.3.2. Where mixer performance tests have been made on given concrete mixtures in accordance with the testing program set forth in the following paragraphs, and the mixers have been charged to their rated capacity, the acceptable mixing time may be reduced from those particular circumstances to a point at which satisfactory mixing defined in Section 11.3.3 shall have been accomplished. When the mixing time is so reduced, the maximum time of mixing shall not exceed this reduced time by more than 60 seconds for air-entrained concrete.

11.3.3. *Sampling for Uniformity Tests of Stationary Mixers*—Samples of concrete for comparative purposes shall be obtained immediately after arbitrarily designated mixing times, in accordance with one of the following procedures:

11.3.3.1. *Alternative Procedure 1*—The mixer shall be stopped, and the required samples removed by any suitable means from the concrete at approximately equal distances from the front and back of the drum, or

11.3.3.2. *Alternative Procedure 2*—As the mixer is being emptied, individual samples shall be taken after discharge of approximately 15 percent and 85 percent of the load. Any appropriate method of sampling may be used, provided the samples are representative of widely separated portions, but not the very ends of the batch (Note 6).

11.3.3.3. The samples of concrete shall be tested in accordance with Section 17, and differences in test results for the two samples shall not exceed those given in Annex A. Mixer performance tests shall be repeated whenever the appearance of the concrete or the coarse aggregate content of samples selected as outlined in this section indicates that adequate mixing has not been accomplished.

11.4. *Shrink-Mixed Concrete*—Concrete that is partially mixed in a stationary mixer, and then mixed completely in a truck mixer, shall conform to the following: the time of partial mixing shall be the minimum required to intermingle the ingredients. After transfer to a truck mixer the amount of mixing at the designated mixing speed will be that necessary to meet the requirements for uniformity of concrete as indicated in Annex A. Tests to confirm such performance may be made in accordance with Sections 11.3.3 and 11.3.3.3. Additional turning of the mixer, if any, shall be at a designated agitating speed.

11.5. *Truck-Mixed Concrete*—Concrete that is completely mixed in a truck mixer, 70 to 100 revolutions at the mixing speed designated by the manufacturer to produce the uniformity of concrete indicated in Annex A. Concrete uniformity tests may be made in accordance with Section 11.5.1 and if requirements for uniformity of concrete indicated in Annex A are not met with 100 revolutions of mixing, after all ingredients, including water, are in the drum, that mixer shall not be used until the condition is corrected, except as provided in Section 10.5. When satisfactory performance is found in one truck mixer, the performance of mixers of substantially the same design and condition of blades may be regarded as satisfactory. Additional revolutions of the mixer beyond the number found to produce the required uniformity of concrete shall be at a designated agitating speed. (Also see Note 7.)

11.5.1. *Sampling for Uniformity of Concrete Produced in Truck Mixers*—The samples shall be secured from the concrete discharged at the normal operating rate for the mixer being tested, with care being exercised not to obstruct or retard the discharge. Approximately 0.1 m^3 (2 ft^3 approximately) shall be taken after discharge of approximately 15 percent and 85 percent of the load (Note 6). These samples shall be obtained within an elapsed time of not more than 15 minutes. The samples shall be secured and shall be kept separate to represent specific points in the batch rather than combined to form a composite sample. Between samples, where necessary to maintain slump, the mixer may be turned in mixing direction at agitating speed. During sampling, the receptacle shall receive the full discharge of the chute. Sufficient personnel must be available to perform the required tests promptly. Segregation during sampling and handling must be avoided. Each sample shall be remixed the minimum amount to ensure uniformity before specimens are molded for a particular test.

11.6. When a truck mixer or truck agitator is used for transporting concrete that has been completely mixed in a stationary mixer, the truck mixer or agitator shall be agitated continuously during transport at the speed designated by the manufacturer of the equipment as agitating speed.

11.7. When a truck mixer or agitator is approved for mixing or delivery of concrete, no water from the truck water system or elsewhere shall be added after the initial introduction of mixing water for the batch except when, on arrival at the job site, the slump of the concrete is less than that specified. Such additional water to bring the slump within required limits shall be injected into the mixer under such pressure and direction of flow that the requirements for uniformity specified in Annex A are met. The drum or blades shall be turned an additional 30 revolutions or more if necessary, at mixing speed, until the uniformity of the concrete is within these limits. Water shall not be added to the batch at any later time. Discharge of the concrete shall be completed within $1^{1}/_{2}$ hours or before the drum has revolved 300 revolutions, whichever comes first, after the introduction of the mixing water to the cement and aggregates or the introduction of the cement to the aggregates. These limitations may be waived by the purchaser if the concrete is of such slump after the $1^{1}/_{2}$-hours time or the 300-revolutions limit has been reached that it can be placed without the addition of water to the batch. In hot weather, or under conditions contributing to quick stiffening of the concrete, a time less than $1^{1}/_{2}$ hours may be specified by the purchaser.

11.8. Concrete delivered in cold weather shall have the applicable minimum temperature indicated in Table 6.

Table 6—Minimum Concrete Temperature

	As Delivered Concrete Temperature	
Air Temperature, °C	Thin Sections and Unformed Slabs, °C	Heavy Sections and Mass Concrete, °C
–1 to 7	16	10
–18 to –1	18	13
Below –18	21	16
°F	°F	°F
30 to 45	60	50
0 to 30	65	55
Below 0	70	60

The maximum temperature of concrete produced with heated aggregates, heated water, or both, shall at no time during its production or transportation exceed 32ºC (90ºF).

Note 8—When hot water is used, rapid stiffening may occur if hot water is brought in direct contact with the cement. Additional information on cold weather concreting is contained in ACI 306R.

11.9. Every effort should be made to maintain the temperature of the concrete produced during hot weather as low as practicable. In some situations, difficulty may be encountered when concrete temperatures approach 32ºC (90ºF).

Note 9—Additional information is contained in ACI 305R.

12. USE OF NON-AGITATING EQUIPMENT

12.1. Central-mixed concrete may be transported in suitable nonagitating equipment approved by the purchaser. The proportions of the concrete shall be approved by the purchaser and the following limitations shall apply:

12.1.1. Bodies of nonagitating equipment shall be smooth, watertight, metal containers equipped with gates that will permit control of the discharge of the concrete. Covers shall be provided for protection against the weather when required by the purchaser.

12.1.2. The concrete shall be delivered to the site of the work in a thoroughly mixed and uniform mass and discharged with a satisfactory degree of uniformity as prescribed in Annex A.

12.1.3. Slump tests of individual samples taken after discharge of approximately 15 percent and 85 percent of the load may be made for a quick check of the probable degree of uniformity (Note 6). These two samples shall be obtained within an elapsed time of not more than 15 minutes. If these slumps differ more than that specified in Table 5, the nonagitating equipment shall not be used unless the conditions are corrected as provided in Section 12.5.

12.1.4. If the requirements of Annex A are not met when the nonagitating equipment is operated for the maximum time of haul, and with the concrete mixed the minimum time, the equipment may still be used when operated using shorter hauls, or longer mixing times, or combinations thereof that will result in the requirements of Annex A being met.

13. INSPECTION

13.1. Proper facilities shall be provided for the engineer to inspect ingredients and process used in the manufacture and delivery of the concrete. The manufacturer shall, without charge, afford the inspector representing the engineer all reasonable facilities for securing samples to determine whether the concrete is being furnished in accordance with this inspection.

14. INSPECTION OF FRESH CONCRETE AND SAMPLING

14.1. The contractor shall afford the engineer all reasonable access, without charge, for the procurement of samples of fresh concrete at time of placement to determine conformance of it to this specification.

14.2. Samples of concrete shall be obtained in accordance with T 142, except when taken to determine uniformity of slump within any one batch or load of concrete (Sections 10.4, 11.3.3, 11.5.1, and 12.4).

15. SLUMP, AIR CONTENT, AND DENSITY

15.1. Slump, air-content, and density tests shall be made at the time of placement at the option of the engineer as often as is necessary for control checks and acceptance purposes, and always when strength specimens are made.

15.2. If the measured slump, air content, or density falls outside the specified limits, a check test shall be made immediately on another portion of the same sample. In the event of a second failure, the concrete shall be considered to have failed the requirements of the specification. Density shall be required for lightweight concretes and is recommended for normal weight concretes.

16. BATCH TICKET INFORMATION

16.1. The manufacturer of the concrete shall furnish to the purchaser with each batch of concrete before unloading at the site a delivery ticket on which is printed, stamped, or written information concerning said concrete as follows:

16.1.1. Name of ready-mix batch plant,

16.1.2. Serial number of ticket,

16.1.3. Date,

16.1.4. Truck number,

16.1.5. Name of purchaser,

16.1.6. Specific designation of job (name and location),

16.1.7. Specific class or designation of the concrete in conformance with that employed in job specifications,

16.1.8. Amount of concrete in cubic yards (or cubic meters),

16.1.9. Time loaded or of first mixing of cement and aggregates, and

16.1.10. Water added by receiver of concrete and his initials.

16.2. Additional information for certification purposes as designated by the purchaser and required by the job specifications shall be furnished when requested; such information may include the following:

16.2.1. Reading of revolution counter at the first addition of water;

16.2.2. Type and brand, and amount of cement;

16.2.3. Type and brand, and amount of admixtures;

16.2.4. Information necessary to calculate the total mixing water added by the producer. Total mixing water includes free water on the aggregates, water, and ice batched at the plant, and water added by the truck operator from the mixer tank;

16.2.5. Maximum size of aggregate;

16.2.6. Mass of fine and coarse aggregate;

16.2.7. Ingredients certified as being previously approved; and

16.2.8. Signature or initials of ready-mix representative.

17. METHODS OF SAMPLING AND TESTING

17.1. Test ready-mixed concrete in accordance with the following methods:

17.1.1. *Compression Test Specimens*—T 23, using standard moist curing in accordance with Sections 9.1 and 9.2 of T 23.

17.1.2. *Compression Test*—T 22.

17.1.3. *Yield, Mass per Cubic Foot*—T 121M/T 121 or ASTM C 567.

17.1.4. *Air Content*—T 121M/T 121, T 196, or T 152.

17.1.5. *Slump*—T 119M/T 119.

17.1.6. *Sampling Fresh Concrete*—T 142.

17.2. Tests made for determination of mixer performance or for acceptance of concrete shall be conducted by the specifying agency or, with specifying agency approval, by a testing laboratory meeting the requirements of ASTM E 329.

ANNEX

(Mandatory Information)

A1. CONCRETE UNIFORMITY REQUIREMENTS

A1.1. The variation within a batch as provided in Table 5 shall be determined for each property listed as the difference between the highest value and the lowest value obtained from the different portions of the same batch. For this specification the comparison will be between two samples, representing the first and the last portions of the batch being tested. Test results conforming to the limits of five of the six tests listed in Table 5 shall indicate uniform concrete within the limits of this specification.

A1.2. Coarse Aggregate Content, using the washout test, shall be computed from the following relations:

$$P = (c/b) \times 100 \qquad (1)$$

where:

P = mass percent of coarse aggregate in concrete;

c = saturated surface-dry mass in kg (lb) of aggregate retained on the No. 4 (4.75-mm) sieve, resulting from washing all material finer than this sieve from the fresh concrete; and

b = mass of sample of fresh concrete in unit weight container, kg (lb).

A1.3. Unit Weight of Air Free Mortar shall be calculated as follows:

A1.3.1. *Inch-pound units*:

$$M = \frac{b - c}{V - \left(\frac{V \times A}{100} + \frac{c}{G \times 62.4} \right)} \qquad (2)$$

A1.3.2. *Metric units*:

$$M = \frac{b - c}{V - \left(\frac{V \times A}{100} + \frac{c}{1000\,G} \right)} \qquad (3)$$

where:

M = unit weight of air-free mortar, kg/m^3 (lb/ft^3);

b = mass of concrete sample in unit weight container, kg (lb);

c = saturated surface-dry mass of aggregate retained on No. 4 (4.75-mm) sieve, kg (lb);

V = volume of unit weight container, m^3 (ft^3);

A = air content of concrete, percent, measured in accordance with Section 18.1.4 on the sample being tested; and

G = specific gravity of coarse aggregate (SSD).

Standard Specification for

Burlap Cloth Made from Jute or Kenaf and Cotton Mats

AASHTO Designation: M 182-05 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Burlap Cloth Made from Jute or Kenaf and Cotton Mats

AASHTO Designation: M 182-05 (2009)

1. SCOPE, CLASSIFICATION, AND DEFINITION

1.1. *Scope*—This specification covers requirements for burlap made from jute or kenaf and cotton mats for use in curing concrete.

1.2. *Classifications*—The burlap shall be of one type and four classes [mass based on a 1016 mm (40 in.) width, as specified:

Class 1—233 g/m (7.5 oz/yd)
Class 2—248 g/m (8 oz/yd)
Class 3—310 g/m (10 oz/yd)
Class 4—372 g/m (12 oz/yd)

1.3. *Jute and Kenaf*—Jute is defined as the bast fiber obtained from various species of Corchorus. Kenaf is defined as the bast fiber obtained from Hibiscus Cannabinus.

1.4. *Cotton*—Cotton is a vegetable fiber harvested from the cotton plant. The cotton plant belongs to the genus Gossypium of the family Malvaceae.

1.5. The values stated in SI units are to be regarded as the preferred standard.

2. MATERIAL

2.1. The burlap cloth shall be made of jute or kenaf at the option of the manufacturer. It shall have a plain weave and conform to the physical requirements given in Tables 1 or 2.

Table 1—Physical Requirements (SI)

Class	Mass per Linear Meter (1016 mm Basis), g	Yarns per Meter of Warp	Yarns per Meter of Filling	Mass per Square Meter,[a] g
1	233	315 to 433 inclusive	315 to 433 inclusive	229
2	248	354 to 472 inclusive	354 to 433 inclusive	244
3	310	433 to 512 inclusive	394 to 472 inclusive	305
4	372	433 to 512 inclusive	433 to 512 inclusive	366

[a] A plus or minus tolerance of five percent will be permitted.

Table 2—Physical Requirements (inch-pound)

Class	Weight per Linear Yard (40-Inch Basis), Ounces	Yarns per Inch of Warp	Yarns per Inch of Filling	Weight per Square Yard[a]
1	$7^1/_2$	8 to 11, inclusive	8 to 11, inclusive	6.7
2	8	9 to 12, inclusive	9 to 11, inclusive	7.2
3	10	11 to 13, inclusive	10 to 12, inclusive	9.0
4	12	11 to 13, inclusive	11 to 13, inclusive	10.8

[a] A plus or minus tolerance of five percent will be permitted.

2.2. Unless otherwise specified, the burlap shall have minimum width of 1016 mm (40 in.) inclusive of selvage, and shall be in one continuous piece of not less than 23 m (25 yd).

2.3. The selvages shall be firm and straight, and may contain cotton yarn.

2.4. Cotton mats shall consist of a filling material of cotton "bat" or "bats" of at least 400 g/m^2 (12 oz per yd^2); covered with unsized cloth at a minimum of 200 g/m^2 (6 oz per yd^2); tufted or stitched to maintain stability.

3. FREEDOM FROM DEFECTS

3.1. The burlap and cotton mats shall be clean, evenly woven, and shall conform to the quality and product requirements established by this specification. The occurrence of defects shall not exceed the applicable acceptable quality levels.

3.2. Examine the burlap and cotton mats for visual defects that would impair their suitability for use. Cuts, tears, broken or missing yarns, thin, open, or weak places, uneven weaving, and grease spots or stains shall be noted.

4. SAMPLING AND TESTING

4.1. *Lot*—Unless otherwise specified, cloths and cotton mats of the same class presented at one time shall be considered a lot for purposes of inspection and tests.

4.2. *Sampling for Test*—Unless otherwise specified, take random samples of cloth and cotton mats from each inspection lot in accordance with Table 3.

4.3. *Inspection*—Each of the samples selected in accordance with Table 3, or as specified, shall be visually and dimensionally inspected in accordance with the requirements of Sections 3.1 and 3.2.

Table 3—Sampling for Inspection and Tests

Number of Rolls in Lot	Number of Rolls in Sample[a]	Acceptance Number (Defective)	Rejection Number (Defective)
8 and under	2	0	1
9 to 15	3	0	1
16 to 40	4	0	1
41 and over	5	0	1

[a] One unit of product at least 1 m (1 yd) long and the full width of the cloth shall be taken from each sample roll.

4.4. *Tests*—Samples selected for tests in accordance with Table 3, or as otherwise specified, shall be tested to determine compliance with the requirements given in Tables 1 or 2.

5. BASIS FOR REJECTION

5.1. Any unit of product in the sample failing to conform to the requirements shall be considered defective. If the number of defective units of products in the sample for test exceeds the acceptance number for that sample specified in Table 3, the entire lot of cloth from which the sample was taken shall be considered as having failed to meet the requirements of this specification and may be rejected.

6. PACKING

6.1. Pack the burlap cloth and cotton mats in a manner acceptable to common carriers for safe transportation to point of destination specified in shipping instructions at the lowest transportation rate for such supplies.

6.2. Each roll or cotton mat shall have a ticket attached to the selvage at the inner end of the cloth or cotton mat giving the length and width, and name and address of the manufacturer.

Standard Specification for

Chemical Admixtures for Concrete

AASHTO Designation: M 194M/M 194-06
ASTM Designation: C 494/C 494M-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Chemical Admixtures for Concrete

AASHTO Designation: M 194M/M 194-06
ASTM Designation: C 494/C 494M-05

AASHTO M 194M/M 194-06 agrees with ASTM C 494/C 494M-05 except for the following provisions:

1. All references to ASTM Standards contained in ASTM C 494/C 494M-05 listed in the following table shall be replaced with the corresponding AASHTO Standard.

Referenced Standards

ASTM	AASHTO
C 33	M 43
C 39	T 22
C 78	T 97
C 136	T 27
C 138	T 121M/T 121
C 143	T 119M/T 119
C 150	M 85
C 157	T 160
C 183	T 127
C 192	R 39
C 231	T 152
C 260	M 154
C 403	T 197M/T 197
C 666	T 161

2. Table 1 Physical Requirements of ASTM C 494/C 494M-05 shall be revised to include compressive strength and flexural strength at 56 days with the same requirements as listed for 28 days. The 56-day requirements shall be applicable only when specified by the purchaser.
3. The first word in the last sentence of Paragraph 15.1 of ASTM C 494/C 494M-05 has been modified to “As” in lieu of “If.”

Standard Specification for

Molds for Forming Concrete Test Cylinders Vertically

AASHTO Designation: M 205M/M 205-08
ASTM Designation: C 470/C 470M-02a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Molds for Forming Concrete Test Cylinders Vertically

AASHTO Designation: M 205M/M 205-08
ASTM Designation: C 470/C 470M-02a

AASHTO M 205M/M 205-08 is identical to ASTM C 470/C 470M-02a except for the following provisions:

1. All references to the ASTM Standards contained in ASTM C 470/C 470M-02a listed in the following table shall be replaced with the corresponding AASHTO Standard.

Referenced Standards

ASTM	AASHTO
C 31	T 23
C 33	M 43
C 192	R 39

2. Section 5.1 of ASTM C 470/C 470M-02a shall be replaced with the following:

   5.1 Single use molds may be made of sheet metal, plastic, or other materials and must conform to the requirements of this specification. Paper molds shall not be used.

3. Add new sections to ASTM C 470/C 470M-02a containing the following:

   5.3.4 *Top Cap*. Molds shall be provided with tightly fitting plastic caps to maintain the circular shape at the top of the cylinder and to provide a clearance above the finished concrete surface.

   5.5.5 *Top Cap*. Molds shall be provided with tightly fitting metal caps to maintain the circular shape at the top of the cylinder and to provide a clearance above the finished concrete surface.

4. All references to paper molds in sections 5.4, 5.4.1, 5.4.2, and 5.4.3 shall be considered null.

Standard Specification for

Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

AASHTO Designation: M 210-10[1]
ASTM Designation: C 490-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

AASHTO Designation: M 210-10[1]
ASTM Designation: C 490-08

1. SCOPE

1.1. This practice covers the requirements for the apparatus and equipment used to prepare specimens for the determination of length change in hardened cement paste, mortar, and concrete; the apparatus and equipment used for the determination of these length changes; and the procedures for its use.

1.2. Methods for the preparation and curing of test specimens, conditions of testing and curing, and detailed procedures for calculating and reporting test results are contained in applicable test methods.

1.3. The values stated in either SI units or inch-pound units are to be regarded separately as the standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.4. Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 201, Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

2.2. *ASTM Standard*:

- C 1005, Standard Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements

2.3. *IEEE/ASTM Standard*:

- SI 10, American National Standard for use of the International System of Units (SI): The Modern Metric System

3. TERMINOLOGY

3.1. *length change*—an increase or decrease in the linear dimension of a test specimen, measured along the longitudinal axis, due to causes other than applied load.

4. SIGNIFICANCE AND USE

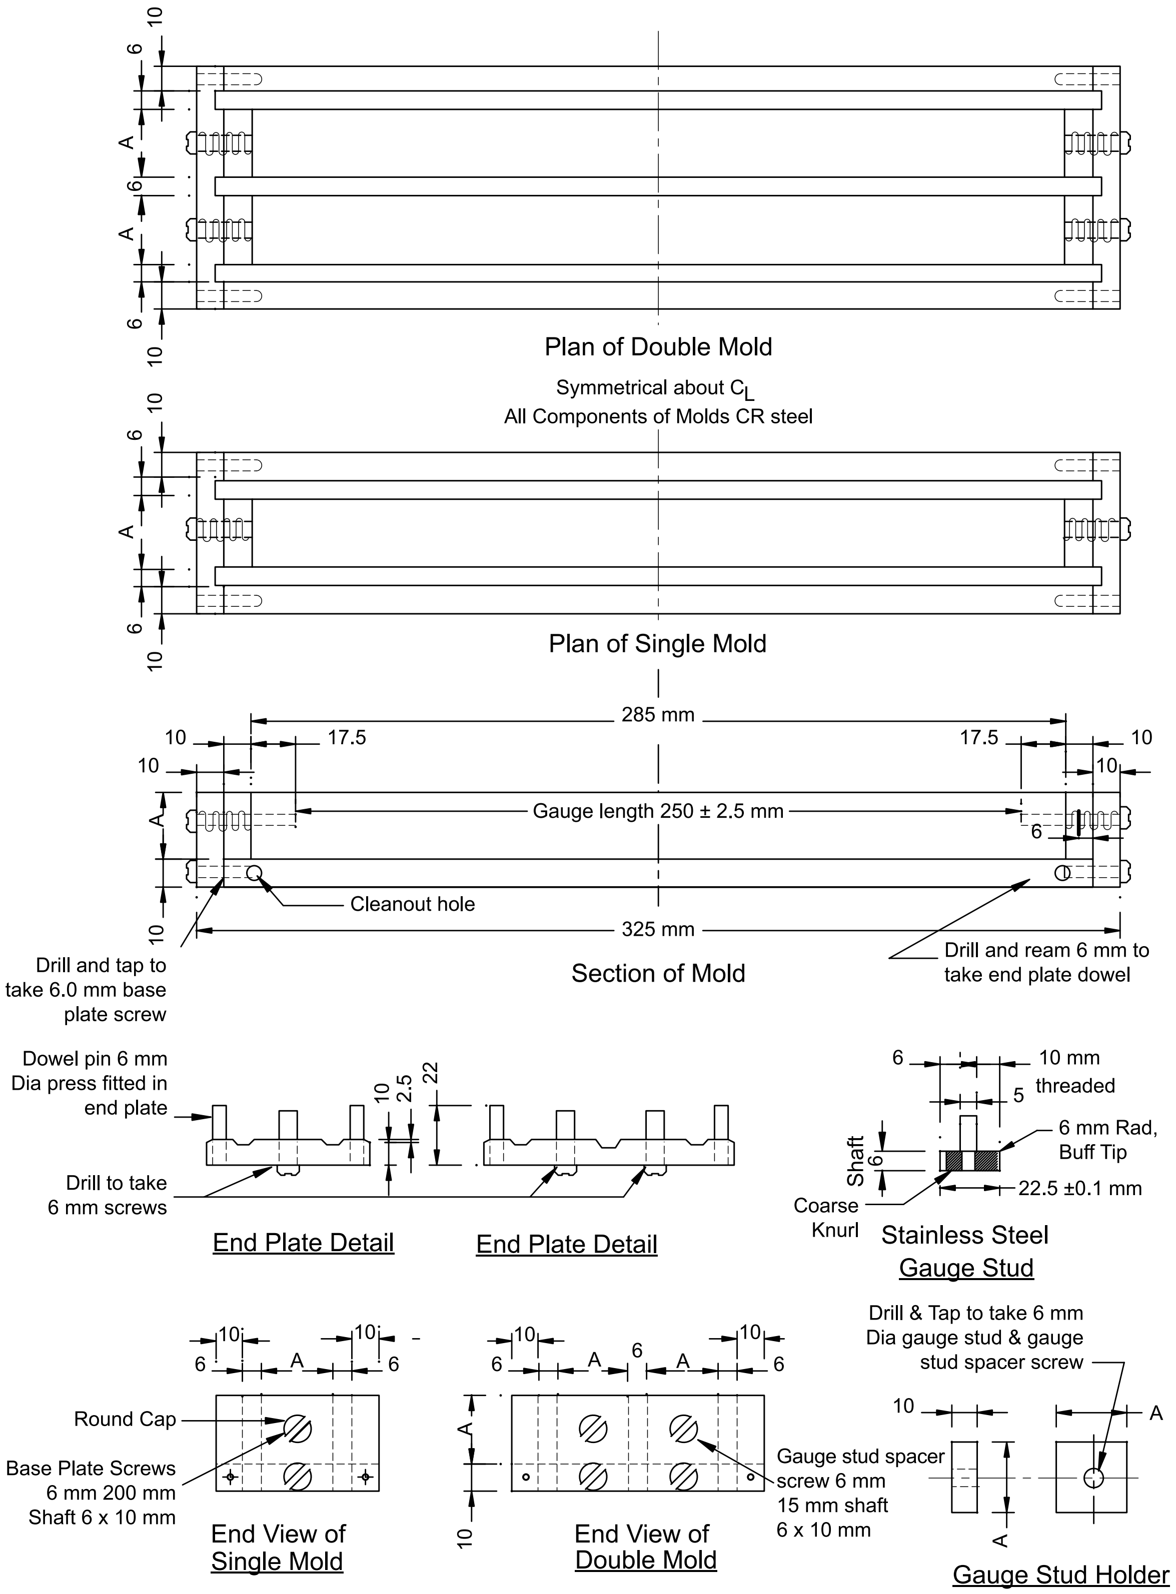
4.1. This practice is intended to provide standard requirements for apparatus common to many test methods used in connection with cement and concrete and standardized procedures for its use. The detailed requirements as to materials, mixtures, specimens, conditioning of specimens, number of specimens, ages at which measurements are to be made, interpretation of results, and precision and bias are left to be dealt with in specific test methods.

5. APPARATUS

5.1. *Reference Masses and Devices for Determining Mass and Volume* shall conform to the requirements of ASTM C 1005.

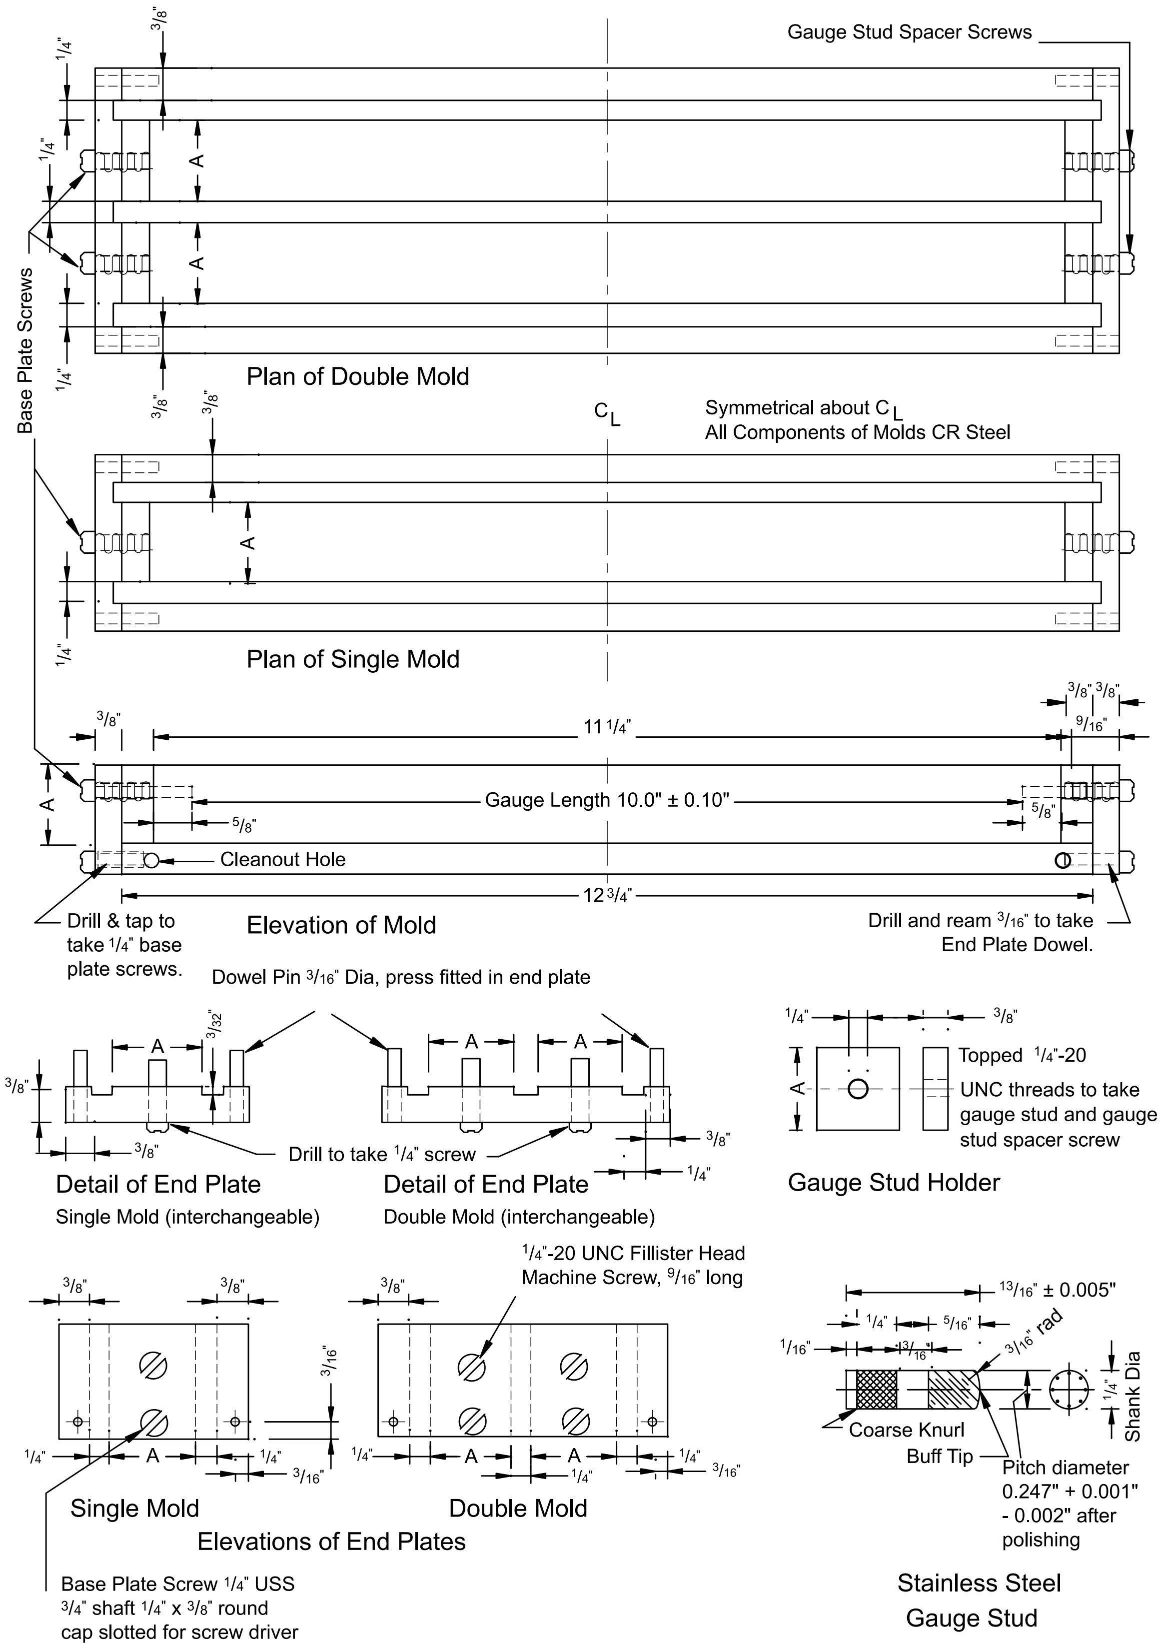
5.2. *Molds* shall have either one or two compartments and shall be constructed as shown in Figures 1 or 2. Molds for test specimens used in determining the length change of cement pastes and mortars shall provide for 25 by 25 by 285-mm prisms having a 250-mm gauge length, or for 1 by 1 by $11^1/_4$-in. prisms having a 10-in. gauge length. Molds for test specimens used in the length change of concretes shall provide for prisms of the desired cross section having a 250-mm or 10-in. gauge length. In some routine tests, 25 by 25 by 160-mm specimens with a gauge length of 125 mm or 1 by 1 by $6^1/_4$-in. specimens with a gauge length of 5 in. are permitted, but in case of dispute, results obtained with specimens of 250-mm (10-in.) gauge length shall govern.

5.2.1. The gauge length shall be considered as the nominal length between the innermost ends of the gauge studs. The parts of the molds shall be tight fitting and firmly held together when assembled, and their surfaces shall be smooth and free of pits. The molds shall be made of steel or other hard metal not readily attacked by the cement paste, mortar, or concrete. The sides of the molds shall be sufficiently rigid to prevent spreading or warping. For the molds shown in Figure 1, the tolerance on dimension A is ±0.7 mm. For the molds shown in Figure 2, the tolerance on dimension A is ±0.03 in.



Note:
1. All dimensions shown in millimeters unless otherwise noted.
2. Dimension "A" to be specified by purchaser.

Figure 1—Molds (SI Units)



Note: Dimension "A" to be specified by purchaser.

Figure 2—Molds (Inch-Pound Units)

5.2.2. Each end plate of the mold shall be equipped to hold properly in place, during the setting period, one of the gauge studs shown in Figures 1 or 2. The gauge studs shall be of American Iron and Steel Institute (AISI)[2] Type 316 stainless steel or other corrosion-resistant metal of similar hardness. Gauge studs of Invar or similar metal shall be used when specimens are tested at widely different temperatures. To prevent restraint of the gauge studs before demolding of the specimen, the device for holding the gauge studs in position shall be so arranged that, if necessary, it can be partially or completely released after the compaction of the paste or mortar into place in the mold. The gauge studs shall be set so that their principal axes coincide with the principal axis of the test specimen. For the molds shown in Figure 1, gauge studs shall extend into the specimen 17.5 ± 0.5 mm and the distance between the inner ends of the gauge studs shall be 250.0 ± 2.5 mm and 250 mm shall be considered the gauge length for calculating length change. For the molds shown in Figure 2, gauge studs shall extend into the specimen 0.625 ± 0.025 in. and the distance between the inner ends of the gauge studs shall be 10.00 ± 0.10 in. and 10 in. shall be considered the gauge length for calculating length change.

5.3. *Length Comparator*, for determining length change of specimens, shall be designed to accommodate the size of specimen employed and to provide or permit a positive means of contact with the gauge studs and the convenient and rapid obtaining of comparator readings (Note 1).

5.3.1. The comparator for determining length changes of specimens produced in the molds shown in Figure 1 shall provide a dial micrometer or other measuring device graduated to read in 0.002-mm units or less, accurate within 0.002 mm in any 0.020-mm range, and within 0.004 mm in any 0.200-mm range, and sufficient range (at least 8.0 mm) in the measuring device to allow for small variations in the actual length of various specimens. The terminals of the comparator shall be plane, polished, and heat-treated. They shall be fitted with collars held in place with set screws. The collars shall extend 1.5 ± 0.1 mm beyond the plane face of the terminal. The collars shall allow free rotation of the gauge stud tips that fit inside the collars and have an inside diameter no more than 0.5 mm larger than the average diameter of that portion of the gauge stud tips that fit into the collars.

5.3.2. The comparator for determining length changes of specimens produced in the molds shown in Figure 2 shall provide a dial micrometer or other measuring device graduated to read in 0.0001-in. units, accurate within 0.0001 in. in any 0.0010-in. range, and within 0.0002 in. in any 0.0100-in. range, and sufficient range (at least 0.3 in.) in the measuring device to allow for small variations in the actual length of various specimens. The terminals of the comparator shall be plane, polished and heat-treated. They shall be fitted with collars held in place with set screws. The collars shall extend 0.062 ± 0.003 in. beyond the plane face of the terminal. The collars shall allow free rotation of the gauge stud tips that fit inside the collars and have an inside diameter no more than 0.02 in. greater than the average diameter of that portion of the gauge stud tips that fit into the collars.

5.3.3. The design shall provide a means for checking the measuring device against a reference bar at regular intervals. The reference bar shall have an overall length of 295.0 ± 3.0 mm or 170.0 ± 3.0 mm ($11^5/_8 \pm {}^1/_8$ in. or $6^5/_8 \pm {}^1/_8$ in.), whichever is appropriate for the specimen in use. The bar shall be of a steel alloy having a coefficient of thermal expansion not greater than two millionths per degree Celsius. Each end of the reference bar shall be fitted with heat-treated, hardened, and polished tips machined to the same shape as the contact end of the gauge studs used in test specimens. Except for the tips, which are attached after heat treatment, no part of the reference bar shall be heat treated. The central 100 mm (4 in.) of the length of the reference bar shall be covered by a rubber tube with a wall at least 3 mm (${}^1/_8$ in.) thick to minimize the effect of temperature change during handling. The reference bar shall be provided near one end with a positioning mark.

Note 1—One type of instrument that has been found satisfactory for use with small prisms is shown in Figure 3. A horizontal comparator should be used with prisms with a cross section greater than 58 cm^2 (9 $in.^2$).

Note 2—Alloys such as Invar lose their low coefficient of thermal expansion properties when heat treated.

5.4. Check and document the bar mold dimension, gauge stud projection into the mold interior, length comparator, and length measuring device for conformance to the design and dimensional requirements of this specification at least every 2 $^1/_2$ years.

Figure 3—Type of Suitable Apparatus for Measurement of Length Changes

6. PROCEDURE

6.1. *Preparation of Molds*—Prior to the molding of specimens, the outside joints of the mold and the contact lines of the molds and base plate shall be sealed to prevent loss of mixing water from a freshly molded specimen. Thinly cover the interior surfaces of the mold with mineral oil. After this operation, set the gauge studs, taking care to keep them clean and free of oil, grease, and foreign matter.

6.2. *Use of Reference Bar*—Place the reference bar in the instrument in the same position each time a comparator reading is taken. Check the dial gauge setting of the measuring device by use of the reference bar at least at the beginning and end of the readings made within a half day when the apparatus is kept in a room maintained at constant temperature. Check it more often when kept in a room where the temperature is not constant.

Note 3—The equation given in the section on calculation of length change contemplates that a comparator reading for the reference bar will be recorded each time the reference bar is used and a difference calculated for each test specimen reading. Alternatively, the dial gauge setting can be reset, if necessary, to its original setting with the reference bar in place each time the reference bar is read. Doing so simplifies the calculation of length change by canceling the comparator reading of the reference bar from the values of L_x and L_i. If this procedure is used, care should be taken to ensure that the dial set screw is tightened adequately each time the dial is reset.

6.3. *Obtaining Comparator Readings*—Rotate specimens slowly in the measuring instrument while the comparator reading is being taken. Record the minimum reading of the dial if the rotation causes a change in the dial reading. Place specimens in the instrument with the same end up each time a comparator reading is taken.

6.3.1. *Obtaining Comparator Readings of Specimens Stored Moist*—Clean the hole in the base of the comparator into which the gauge stud on the lower end of the bar fits. (This hole tends to collect water and sand and should be cleaned after every reading.) Read and record the comparator indication of the length of the reference bar. Take one bar out of immersion, blot the pins, put the bar in the comparator, read, and record the indication. Return the bar to immersion and clean the hole in the base of the comparator. Take out the second bar and treat it in a like manner. Return the second bar to immersion, record the reading, and clean the hole in the base of the comparator. Continue the procedure until all bars have been read, returned to immersion, and the readings recorded, cleaning the hole in the bottom of the comparator each time. After reading the last bar, clean the hole in the comparator base and read and record the reference-bar indication. Blot only around the pins (Note 4).

Note 4—The purpose of the minimal blotting of the pins and no blotting of the bars is to avoid drying and shrinkage of the bars. It has been observed that if the pins are blotted, and the bar placed in the comparator and the dial read, and the bar is then wiped gently with a dry cloth, the bar will shrink measurably. Therefore, drying should be minimized.

7. CALCULATION OF LENGTH CHANGE

7.1. Calculate the length change at any age as follows:

$$L = \frac{(L_x - L_i)}{G} \times 100 \qquad (1)$$

where:

L = change in length at x age, percent,

L_x = comparator reading of specimen at x age minus comparator reading of reference bar at x age, in inches when using Figure 2 apparatus, in millimeters when using Figure 1 apparatus,

L_i = initial comparator reading of specimen minus comparator reading of reference bar at that same time, in inches when using Figure 2 apparatus, in millimeters when using Figure 1 apparatus, and

G = nominal gauge length, 10 in. when using Figure 2 apparatus, 250 mm when using Figure 1 apparatus.

7.2. Calculate length change values for each specimen to the nearest 0.001 percent and report averages to the nearest 0.01 percent.

8. TEMPERATURE, HUMIDITY, AND TIME

8.1. *Molding Room*—The temperature of the molding room and dry materials shall be maintained between 23.0 ± 4°C. The relative humidity shall be not less than 50 percent. The temperature of the mixing water shall not vary from 23.0 ± 2.0°C.

8.2. *Moist Storage Facility*—The temperature and humidity of the air in the moist storage facility shall conform to the requirements of M 201.

8.3. *Time*—Comparator readings shall be taken at specified time intervals or ages. All intervals and ages shall be met within ±2 percent.

9. KEYWORDS

9.1. Cement paste; comparator; concrete; length change apparatus; molds; mortar.

---

[1] Except for the use of SI units, this method agrees with ASTM C 490-08.

[2] Details on this material are available from the American Iron and Steel Institute, 1133 15th St. N.W., Washington, DC 20005.

Standard Specification for

Use of Protective Sealers for Portland Cement Concrete

AASHTO Designation: M 224-91 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Use of Protective Sealers for Portland Cement Concrete

AASHTO Designation: M 224-91 (2009)

1. SCOPE

1.1. This guide includes the selection factors for and use of protective sealers for highway purposes to be applied to hardened concrete for the purpose of protecting new concrete or prolonging the life of sound, in-service concrete. Information in this guide is not applicable to the repair of badly deteriorated concrete.

1.2. Sealers may be divided into two basic types: coatings, which remain on the surface; and penetrants, which penetrate into the concrete to some measurable depth.

1.3. There are strong differences of opinion about the effectiveness and durability of some types of sealers under actual service and conditions as opposed to laboratory tests which may show the sealers to be effective. It must also be understood that there can be considerable differences in performance of material from different manufacturers for the same type of sealer.

1.4. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 200, Epoxy Protective Coatings
- M 233, Boiled Linseed Oil Mixture for Treatment of Portland Cement Concrete

2.2. *ASTM Standard*:

- D 490, Standard Specification for Road Tar

2.3. *Other Reports*:

- Pfeifer, D. W. and M. J. Scali, 1981, *Concrete Sealers for Protection of Bridge Structures*, National Cooperative Highway Research Program Report 244, 138 pp.
- Munshi, Snehal and Leonid Millstein, 1984, *Low Cost Bridge Deck Surface Treatment*, Federal Highway Administration Report No. FHWA/RD-84/001, 70 pp.

3. SELECTION OF THE SEALER

3.1. A number of factors must be carefully considered when choosing a sealer. These factors include the following:

3.1.1. *Purpose*—Will the sealer be used to waterproof the concrete or prevent the ingress of chlorides? A given sealer may be better suited to one or the other of these purposes.

3.1.2. *Effectiveness*—Coatings should form an impervious membrane tightly bonded to the concrete surface, while penetrants should seal the surface pores and fill the capillaries of the concrete. Sealers should maintain their protective properties through wide temperature fluctuations and when subject to all chemical and physical conditions at the site of use.

3.1.3. *Economy*—It is desirable that the chosen sealer be low in initial cost; however, this should not take precedence over life-cycle costs, that is, cost should include consideration of frequency of reapplication necessary to maintain effectiveness.

3.1.4. *Traffic*—Sealers on traveled surfaces must not reduce the frictional properties of the concrete; some types may, with the use of a cover aggregate, increase the frictional properties. Coatings must be resistant to traffic wear; penetrants should be evaluated according to depth of penetration, since they will wear away with the concrete. If an overlay will be placed after sealer application, wear will not be a factor.

3.1.5. *Application and Curing*—Ease and simplicity of application without the use of special skills or equipment is desirable, but not critical. It is usually advantageous for a material to cure or dry in a few hours so that neither damage by rain nor lengthy closure of the facility is necessary.

3.1.6. *Color*—If color of the treated concrete is important, test blocks should be treated with candidate materials for evaluation prior to use.

3.1.7. *Safety*—Safety should be carefully considered. Several of the materials involve toxic or hazardous components. Others may have to be heated. Refer to Section 7 for details.

3.1.8. *Adverse Conditions*—Rarely, it may be necessary to apply the sealer under adverse conditions such as low ambient temperatures or dampness. In these cases, a coating must be chosen that would offer some chance for reasonable success. Experience and the manufacturer’s recommendations should be used in determining whether or not conditions are suitable for application.

4. SEALER TYPES

4.1. Sealers commonly used for concrete are two general types: (1) coatings—those that remain on the surface and tend to build up a layer or membrane of some thickness, and (2) penetrants—those that penetrate the concrete, forming an interior or subsurface barrier. As an aid in the choice of a material suitable for a specific application, the more commonly used sealers are discussed in Sections 4.2 through 4.9.

4.1.1. *References*—additional sources of information regarding sealers are:

4.1.1.1. *AASHTO Standards*—M 200 and M 233.

4.1.1.2. *ASTM Standard*—D 490.

4.1.1.3. *Other Reports*—National Cooperative Highway Research Program Report 244 and Federal Highway Administration Report No. FHWA/RD-84/001.

4.2. *Epoxy Resin*—Epoxy may be considered a coating or penetrant depending on the percent of solids in the formulation. The two component epoxy resin system forms a sealer which is tough, hard, and resistant to chemicals that normally attack roadway surfaces and weathering. Before curing, epoxy has a tendency to "pin-hole," permitting later entrance of water and salt solution into the underlying concrete. Experience indicates the use of suitable primer may alleviate this. Also, application of the material during that part of the day when the concrete is cooling helps prevent "pin-holing." If formulated as a coating, flaking or peeling of the epoxy can occur due to a difference in thermal expansion of the coating and the concrete or to improper surface preparation. The protective film formed by these materials reduces frictional properties. The use of a suitable aggregate spread over the freshly applied coating greatly improves frictional properties. Epoxy systems require skill in handling and application. It is essential that the recommendations of the manufacturer be followed precisely for both application procedures and equipment. Special materials will be required for cleaning of equipment. Most persons are allergic to contact with epoxies. Therefore, recommended safety practices must be followed carefully.

4.3. *Coal Tar Epoxy*—Coal tar resins form surface coatings that are hard and durable. They are relatively resistant to many corrosive and abrasive environments and are durable under exposure to weather. They appear to function best on roadway surfaces when filled with sand and other suitable aggregate. These materials contain curing agents and strong solvents which may cause allergic reactions. They must be handled with caution; recommended safety precautions must be followed. These materials are naturally dark to black in color and may not be desirable in some locations.

4.4. *Linseed Oil*—Linseed oil applied to concrete surfaces penetrates and forms a partial barrier to water. It is, therefore, not subject to traffic abrasion and it does not materially change the original frictional properties of the concrete if applied at the proper rate. Linseed oil may be applied as solution. Experience indicates the solutions are more effective and longer lasting than are emulsions, probably due to redispersion of the linseed oil applied as an emulsion, when subjected to salt solutions. These materials are easily applied with simple, readily available equipment and require no specialized knowledge or skills. Safety hazards are minimal; only routine precautions for handling and using flammable liquids are necessary with the solvent types. For best results on new concrete surfaces, the concrete should be allowed to dry for about 30 days prior to the application of the compound. To remain effective, concrete surfaces should be recoated annually for 2 years followed by a bi-annual or tri-annual schedule of treatment.

4.5. *Tar Primer and Seal*—Tars applied to concrete surfaces form a coating that is an effective surface barrier to water. Usually a primer must be used because of wetting difficulties on concrete. These materials may be applied in solution or softened by heat. Due to relatively poor resistance to sunlight, weather, and abrasion, these materials should be covered by a suitable bituminous mix.

4.6. *Silanes and Siloxanes*—These materials are classified as penetrants. Unlike other sealers, these materials do not truly "seal" the concrete, but react chemically with the concrete, both at the surface and in pores and capillaries, to form a hydrophobic layer which is repellant to water. They can be applied in one coat.

4.7. *Methacrylates*—These materials may be described as a coating or penetrant depending on the formulation. Two coats are usually required to get proper sealing. The surface to be treated must be dry and free of oil, grease, and loose material. Time needed between coats will vary according to ambient temperature conditions.

4.8. *Sodium Silicate*—This material is a penetrant in the form of an aqueous solution. Concrete surfaces must be clean and dry at the time of application. The material should not be applied at temperatures below 4ºC (40ºF) or during rain.

4.9. *Urethane*—This material is classified as a penetrant or a coating depending on formulation. Two coats may be required. The concrete surface should be free of loose material, clean, and dry. Some formulations should not be applied under high humidity conditions. (See manufacturer's recommendation.)

5. SURFACE PREPARATION

5.1. Surfaces to which the sealers are applied may be new concrete or concrete which has been in service for some time.

5.2. Preparation of the surfaces will vary according to the type of sealer being used. In all cases, the surfaces should be clean and free of all dirt, dust, and loose material. Old surfaces should have any oil or paint removed. The required degree of dryness of the concrete will vary accordingly to the material being used, and the manufacturer's literature should be consulted for this and other specific surface requirements.

6. SEALER PREPARATION AND APPLICATION

6.1. For best results, manufacturer's recommendations should be followed in preparing and applying sealers for concrete. Common practices for the different materials follow:

6.1.1. *Epoxy Resins and Coal Tar Epoxy*—All materials should be within applicable temperature ranges before mixing. Thorough mixing of the components in the specified proportions is essential. No more should be mixed than will be used within the pot life of the materials. Small-batch mixing can best be done in clean, dry pails or disposable containers using a mechanical stirrer, although with care, hand mixing is acceptable. For large jobs, specialized continuous mixing equipment is available and should be used.

6.1.1.1. Application on small areas can readily be made by brush, roller, squeegee, hand sprayer, or other means. Power spray equipment is most satisfactory for covering large areas.

6.1.1.2. For most materials, the temperature of the concrete surface should be not less than 15ºC (60ºF). A satisfactory temperature range for the compound at application is 21 to 32ºC (70 to 90ºF).

6.1.1.3. Equipment used in application must be cleaned using solvent wash before setting of the epoxy. The solvent recommended by the manufacturer of the epoxy is best but the others may be satisfactory, such as toluene, trichloroethylene, etc. Use appropriate safety precautions when using these solvents.

6.1.2. *Linseed Oil*—Application of linseed oil may be readily accomplished by brush, squeegee, roller, hand sprayer, or power sprayer. The concrete surface should be dry and at a temperature of not less than 10ºC (50ºF) at the time of application. The rate of application should be specified. Two approximately equal applications are best with a 24-hour minimum drying time between applications. Cleaning of tools and equipment is easily accomplished by use of kerosene or other petroleum solvents.

6.1.3. *Tars*—These materials may be applied by power or hand spray, by brush, or by squeegee. The concrete surface to be treated should be dry and clean. The prime coat should be permitted to dry thoroughly before applying succeeding coats. Depending on the grade of tar selected, temperature of application will vary to provide the proper viscosity for application.

6.1.4. *Silanes and Siloxanes*—These materials should not be applied at temperatures below 0ºC (32ºF) or when the temperature is expected to fall below 0ºC (32ºF) within 12 hours of application. These materials appear to penetrate best on a thoroughly dry surface. Application rate should range between 2.45 and 9.82 m^2/L (100 and 400 ft^2/gallon) depending on surface texture and absorption. The recommended method of application may vary depending on the material. The manufacturer's recommendations should always be followed. The most common method of application is low pressure airless spray and most sealers require enough material to sufficiently saturate the surface of the concrete.

6.1.5. *Methacrylates*—Depending on the formulation, these materials should not be applied when the temperature is below 10ºC (50ºF). A primer is required for some formulations. The concrete surface must be dry. Application rates range from 2.45 to 9.82 m^2/L (100 to 400 ft^2/gallon). Sealers should be applied as the manufacturer recommends. Common methods of application include spray, roller, brush, and squeegee.

6.1.6. *Sodium Silicate*—This material should not be applied at temperatures below 4ºC (40ºF). It may be applied by brush, squeegee, or spraying. After three to six hours, the surface should be flushed with water, the flushing to be repeated at 24-hour intervals for 72 hours. The coverage rate is 4.91 to 7.36 m^2/L (200 to 300 ft^2/gal).

6.1.7. *Urethane*—This material can be applied in the temperature range of 4 to 38ºC (40 to 100ºF) with some formulations having an allowable application temperature as low as –8ºC (18ºF). The surface should be free of moisture. Coverage is in the range of 4.91 to 9.82 m^2/L (200 to 400 ft^2/gal). Sealers are best applied with either air atomized or conventional airless spray—although brush, roller, or squeegee may be used. Manufacturer's recommendations should be followed.

7. SAFETY

7.1. The usual precautions exercised in the working environment should be followed. All waste solvents shall be disposed of in accordance with all applicable federal, state, and local environmental regulations.

7.2. General hazards and cautions for each sealer type are given in Sections 7.2.1 through 7.2.7. See manufacturer's literature for information on specific formulations.

7.2.1. *Epoxy Resins and Coal Tar Epoxy*—These materials almost always cause skin irritation or allergic reactions if allowed to contact the skin. Allergic reactions may not occur immediately. Workers should never think themselves immune to these reactions. Mixing and application should always be in well-ventilated areas. Disposable equipment and clothing should be used whenever possible. Clothing of any kind should not be re-used if soiled by epoxy resin. Safety glasses or goggles are recommended while mixing or applying these materials. The workmen should always wash up thoroughly immediately after completing work. Equipment must be kept clean at all times.

7.2.1.1. In case of direct contact to the body, wash immediately with soap and water until all epoxy compound is removed. If contact is to the eyes, flush with large quantities of water and secure immediate medical attention. Use only soap and water or water-soluble cleaners on the body. The use of solvents for epoxy is to be avoided.

7.2.2. *Linseed Oil*—These oils are not considered toxic or irritating; therefore, the only safety hazard with their use is from burning. Normal precautions indicated for any flammable liquid should be followed.

7.2.3. *Tars*—Caution should be exercised around the hot material and heating equipment.

7.2.4. *Silanes and Siloxanes*—These materials may be flammable, therefore, do not store or use them near heat or open flame. They react chemically with glass, and therefore, should not be stored in glass containers.

7.2.5. *Methacrylates*—These materials are flammable and toxic, and caution should be taken to avoid contact with the skin or breathing concentrated vapors. Safety glasses or goggles should be worn.

7.2.6. *Sodium Silicate*—This material is nontoxic, noncaustic, and nonflammable. It should not be stored in glass containers since it reacts chemically with glass.

7.2.7. *Urethane*—This material is flammable, and some formulations produce vapors. Special protective clothing, including goggles, gloves, and respirators, must be worn when working with urethanes.

Standard Specification for

Boiled Linseed Oil Mixture for Treatment of Portland Cement Concrete

AASHTO Designation: M 233-86 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Boiled Linseed Oil Mixture for Treatment of Portland Cement Concrete

AASHTO Designation: M 233-86 (2009)

1. SCOPE

1.1. This specification covers boiled linseed oil-petroleum spirits mixture to be applied to hardened portland cement concrete as a protection against damage by deicing chemicals.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- D 56, Standard Test Method for Flash Point by Tag Closed Cup Tester
- D 235, Standard Specification for Mineral Spirits (Petroleum Spirits) (Hydrocarbon Dry Cleaning Solvent)
- D 260, Standard Specification for Boiled Linseed Oil
- D 1544, Standard Test Method for Color of Transparent Liquids (Gardner Color Scale)
- D 1639, Standard Test Method for Acid Value of Organic Coating Materials (Withdrawn 2005)
- D 1640, Standard Test Methods for Drying, Curing, or Film Formation of Organic Coatings at Room Temperature
- D 1644, Standard Test Methods for Nonvolatile Content of Varnishes
- D 1959, Standard Test Method for Iodine Value of Drying Oils and Fatty Acids (Withdrawn 2006)
- D 1962, Standard Test Method for Saponification Value of Drying Oils, Fatty Acids, and Polymerized Fatty Acids (Withdrawn 2004)
- D 1963, Standard Test Method for Specific Gravity of Drying Oils, Varnishes, Resins, and Related Materials at 25/25°C (Withdrawn 2004)

3. PROPERTIES

3.1. The compound shall consist of a homogeneous mixture of 50 percent boiled linseed oil and 50 percent petroleum spirits by volume.

3.2. The boiled linseed oil shall conform to the requirements of ASTM D 260, for Boiled Linseed Oil Type 1 or Type 11.

3.3. The petroleum spirits shall conform to the requirements of ASTM D 235, for Petroleum Spirits (Mineral Spirits).

3.4. When requested by the purchaser, the manufacturer shall certify that the boiled linseed oil and petroleum spirits used in the mixture fully conform to the requirements specified in Sections 3.2 and 3.3, respectively.

3.5. The mixture shall have the following properties:

	Minimum	Maximum
Specific gravity 25/25°C	0.84	0.88
Acid value		5
Nonvolatile by mass, percent	55	57
Drying time, h		16
Color, Gardner		13
Iodine value	90	
Saponification	100	
Flash point (T.C.C.) °C (°F)	37.8 (100)	

4. METHODS OF TESTING

4.1. The properties enumerated in this specification shall be determined in accordance with the following methods of test:

4.1.1. *Specific Gravity*—ASTM D 1963.

4.1.2. *Acid Value*—ASTM D 1639.

4.1.3. *Nonvolatile Content*—ASTM D 1644, Method A.

4.1.4. *Drying Time*—ASTM D 1640.

4.1.5. *Color*—ASTM D 1544.

4.1.6. *Iodine Value*—ASTM D 1959.

4.1.7. *Saponification Value*—ASTM D 1962.

4.1.8. *Flash Point*—ASTM D 56.

Standard Specification for

Concrete Made by Volumetric Batching and Continuous Mixing

AASHTO Designation: M 241M/M 241-09
ASTM Designation: C 685/C 685M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Concrete Made by Volumetric Batching and Continuous Mixing

AASHTO Designation: M 241M/M 241-09
ASTM Designation: C 685/C 685M-07

AASHTO M 241M/M 241-09 is identical to ASTM C 685/C 685M-07 except for the following provisions:

1. All references to the ASTM Standards contained in ASTM C 685/C 685M-07 listed in the following table shall be replaced with the corresponding AASHTO Standard.

Referenced Standards

ASTM	AASHTO
C 31	T 23
C 33	M 6 and M 80
C 39	T 22
C 109	T 106
C 138	T 121M/T 121
C 143	T 119M/T 119
C 150	M 85
C 172	T 141
C 173	T 196M/T 196
C 191	T 131
C 231	T 152
C 260	M 154
C 330	M 195
C 494	M 194
C 595	M 240
C 618	M 295

2. Section 6 (Ordering Information), Section 11 (Strength), and Section 12 (Failure to Meet Strength Requirements) are excluded.
3. The following Table 2 shall be used in lieu of Table 2 of ASTM C 685/C 685M-07.

Table 2—Chemical Limitations for Wash Water

	Limits	Test Method
Chemical requirements, max concentration		
Chloride as $Cl^{(-1)}$ expressed as a percent by mass of cement when added to the $Cl^{(-1)}$ in the other components of the concrete mixture shall not exceed the following levels:		
1. Prestressed concrete	0.06 percent	AASHTO T 260
2. Conventionally reinforced concrete in a moist environment and exposed to chloride	0.10 percent	
3. Conventionally reinforced concrete in a moist environment but not exposed to chloride	0.15 percent	
4. Above ground building construction where the concrete will stay dry	No limit for corrosion	
Sulfate as SO_4, ppm[a]	3,000	ASTM D 516
Alkalies as (Na_4O + 0.658 K_2O), ppm	600	ASTM D 516
Total solids, ppm	50,000	AASHTO T 26

[a] Wash water reused as mixing water in concrete may exceed listed concentrations of sulfate if it can be shown that the concentration calculated in the total mixing water, including mixing water on the aggregate and other sources, does not exceed the stated limits.

4. The following referenced document is added to Section 2.3 of ASTM C 685/C 685M-07:
    - M 307, Silica Fume Used in Cementitious Mixtures.
5. Add a new section to ASTM C 685/C 685M-07 as follows:

    5.1.7 Coal fly ash and raw calcined natural pozzolan shall conform to Specification M 295.

    5.1.8 *Silica Fume*—Silica fume shall conform to Specification M 307.

Standard Specification for

Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

AASHTO Designation: M 295-07
ASTM Designation: C 618-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Coal Fly Ash and Raw or Calcined Natural Pozzolan for Use in Concrete

AASHTO Designation: M 295-07
ASTM Designation: C 618-05

1. SCOPE

1.1. This specification covers coal fly ash and raw or calcined natural pozzolan for use in concrete where cementitious or pozzolanic action, or both, is desired, or where other properties normally attributed to finely divided coal fly ash and raw or calcined natural pozzolans may be desired or where both objectives are to be achieved.

Note 1—Finely divided materials may tend to reduce the entrained air content of concrete. Hence, if a fly ash or natural pozzolan is added to any concrete for which entrainment of air is specified, provision should be made to ensure that the specified air content is maintained by air content tests and by use of additional air-entraining admixture or use of an air-entraining admixture in combination with air-entraining hydraulic cement.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates
- C 311, Standard Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. The terms used in this specification are defined in ASTM C 125.

3.1.2. *fly ash*—finely divided residue that results from the combustion of ground or powdered coal and that is transported by flue gasses.

Note 2—This definition of fly ash does not include, among other things, the residue resulting from: (1) the burning of municipal garbage or any other refuse with coal; (2) the injection of lime directly into the boiler for sulfur removal; or (3) the burning of industrial or municipal garbage in incinerators commonly known as "incinerator ash."

4. CLASSIFICATION

4.1. *Class N*—Raw or calcined natural pozzolans that comply with the applicable requirements for the class as given herein, such as some diatomaceous earths; opaline cherts and shales; tuffs and volcanic ashes or pumicites, calcined or uncalcined; and various materials requiring calcination to induce satisfactory properties, such as some clays and shales.

4.2. *Class F*—Fly ash normally produced from burning anthracite or bituminous coal that meets the applicable requirements for this class as given herein. This class fly ash has pozzolanic properties.

4.3. *Class C*—Fly ash normally produced from lignite or subbituminous coal that meets the applicable requirements for this class as given herein. This class of fly ash, in addition to having pozzolanic properties, also has some cementitious properties. Some Class C fly ashes may contain lime contents higher than 10 percent.

5. ORDERING INFORMATION

5.1. The purchaser shall specify any supplementary optional chemical and physical requirements.

5.2. The purchaser shall indicate which procedure, A or B, shall be used when specifying requirements for effectiveness in contribution to sulfate resistance under Table 4.

6. CHEMICAL COMPOSITION

6.1. Fly ash and natural pozzolans shall conform to the requirements as to chemical composition prescribed in Table 1.

Table 1—Chemical Requirements

	Coal Fly Ash and Raw or Calcined Natural Pozzolan Class		
	N	F	C
Silicon dioxide (SiO_2) plus aluminum oxide ($A1_2O_3$) plus iron oxide (Fe_2O_3), min percent	70.0	70.0	50.0
Sulfur trioxide (SO_3), max percent	4.0	5.0	5.0
Moisture content, max percent	3.0	3.0	3.0
Loss on ignition, max percent	5.0	5.0	5.0

Table 2—Supplementary Optional Chemical Requirement

	Coal Fly Ash and Raw or Calcined Natural Pozzolan Class		
	N	F	C
Available alkalies, as equivalent, as Na_2O, max percent[a]	1.5	1.5	1.5

[a] Applicable only when specifically required by the purchaser for mineral admixture to be used in concrete containing reactive aggregate and cement to meet a limitation on content of alkalies.

Note 3—The chemical component determinations and the limits placed on each do not predict the performance of the fly ash or natural pozzolan with hydraulic cement in concrete, but collectively help describe composition and uniformity of the material.

7. PHYSICAL PROPERTIES

7.1. Fly ash and natural pozzolans shall conform to the physical requirements prescribed in Table 3. Supplementary optional physical requirements are shown in Table 4.

Table 3—Physical Requirements

	Coal Fly Ash and Raw or Calcined Natural Pozzolan Class		
	N	F	C
Fineness:			
Amount retained when wet-sieved on 45-μm (No. 325) sieve, max percent[a]	34	34	34
Strength activity index:[b]			
With portland cement, at 7 days, min percent of control	75[e]	75[e]	75[e]
With portland cement, at 28 or 56[c] days, min percent of control	75[e]	75[e]	75[e]
Water requirement, max percent of control	115	105	105
Soundness:[d]			
Autoclave expansion or contraction, max percent	0.8	0.8	0.8
Uniformity requirements:			
The density and fineness of individual samples shall not vary from the average established by the 10 preceding tests, or by all preceding tests if the number is less than 10, by more than:			
Density, max variation from average, percent	5	5	5
Percent retained on 45-μm (No. 325) sieve, max variation, percentage points from average	5	5	5

[a] Care should be taken to avoid the retaining of agglomerations of extremely fine material.

[b] The strength activity index with portland cement is not to be considered a measure of the compressive strength of concrete containing the coal fly ash and raw or calcined natural pozzolan. The strength activity index with portland cement is determined by an accelerated test, and is intended to evaluate the contribution to be expected from the coal fly ash and raw or calcined natural pozzolan to the longer strength development of concrete. The mass of coal fly ash and raw or calcined natural pozzolan specified for the test to determine the strength activity index with portland cement is not considered to be the proportion recommended for the concrete to be used in the work. The optimum amount of coal fly ash and raw or calcined natural pozzolan for any specific project is determined by the required properties of the concrete and other constituents of the concrete and should be established by testing. Strength activity index with portland cement is a measure of reactivity with a given cement and is subject to variation depending on the source of both the coal fly ash and raw or calcined natural pozzolan and the cement.

[c] Only applicable when testing at 56 days is specified.

[d] If the coal fly ash and raw or calcined natural pozzolan will constitute more than 20 percent by mass of the cementitious material in the project mix design, the test specimens for autoclave expansion shall contain that anticipated percentage. Excessive autoclave expansion is highly significant in cases where water to coal fly ash and raw or calcined natural pozzolan and cement ratios are low, for example, in block or shotcrete mixes.

[e] Meeting the 7-day, 28-day, or 56-day (if specified) strength activity index will indicate specification compliance.

Table 4—Supplementary Optional Physical Requirements

	Coal Fly Ash and Raw or Calcined Natural Pozzolan Class		
	N	F	C
Multiple factor, calculated as the product of loss on ignition and fineness, amount retained when wet-sieved on 45-µm (No. 325) sieve, max percent[a]	—	255	—
Increase of drying shrinkage of mortar bars at 28 days, max difference in percent over control[b]	0.03	0.03	0.03
Uniformity requirements:			
In addition, when air-entrained concrete is specified, the quantity of air-entraining agent required to produce an air content of 18.0 vol percent of mortar shall not vary from the average established by the 10 preceding tests or by all preceding tests if less than 10, by more than, percent	20	20	20
Effectiveness in controlling alkali-silica reaction: [c]			
Expansion of test mixture as percentage of low-alkali cement control, at 14 days, max percent	100	100	100
Effectiveness in contributing to sulfate resistance: [d]			
Procedure A:			
Expansion of test mixture:			
For moderate sulfate exposure after 6 months of exposure, max percent	0.10	0.10	0.10
For high sulfate exposure after 6 months of exposure, max percent	0.05	0.05	0.05
Procedure B:			
Expansion of test mixture as a percentage of sulfate resistance cement control after at least 6 months of exposure, max percent	100	100	100

[a] Applicable only for Class F coal fly ash and raw or calcined natural pozzolan since the loss on ignition limitations predominate for Class C.

[b] Determination of compliance or noncompliance with the requirement relating to increase in drying shrinkage will be made only at the request of the owner.

[c] Coal fly ash and raw or calcined natural pozzolans meeting this requirement are considered as effective in controlling alkali aggregate reactions as the use of the low-alkali control cement used in the evaluation. However, the coal fly ash and raw or calcined natural pozzolan shall be considered effective only when the coal fly ash and raw or calcined natural pozzolan are used at percentages by mass of the total cementitious material equal to or exceeding that used in the tests and when the alkali content of the cement to be used with the coal fly ash and raw or calcined natural pozzolan does not exceed that used in the tests by more than 0.05 percent. See Appendix X1, ASTM C 311.

[d] Fly ash or natural pozzolan shall be considered effective only when the fly ash or natural pozzolan is used at percentages, by mass, of the total cementitious material within 2 percent of those that are successful in the test mixtures or between 2 percentages that are successful, and when the C_3A content of the project cement is less than or equal to that which was used in the test mixtures. See Appendix X2 of ASTM C 311.

Note: These optional requirements apply only when specifically requested.

8. METHODS OF SAMPLING AND TESTING

8.1. Sample and test the coal fly ash and raw or calcined natural pozzolan in accordance with the requirements of ASTM C 311.

8.2. Use cement of the type proposed for use in the work and, if available, from the mill proposed as the source of the cement, in all tests requiring the use of hydraulic cement.

9. STORAGE AND INSPECTION

9.1. The coal fly ash and raw or calcined natural pozzolan shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment.

9.2. Inspection of the material shall be made as agreed upon by the purchaser and the seller as part of the purchaser contract.

10. REJECTION

10.1. Material that fails to conform to the requirements of this specification may be rejected. Rejection should be reported to the producer or supplier promptly and in writing.

10.2. Packages varying more than five percent from the stated mass may be rejected. If the average mass of the packages in any shipment, as shown by determining the mass of 50 packages taken at random, is less than that specified, the entire shipment may be rejected.

10.3. Any coal fly ash and raw or calcined natural pozzolan in storage prior to shipment for a period longer than 180 days after testing may be retested and may be rejected if it fails to meet the fineness requirements.

11. PACKAGING AND PACKAGE MARKING

11.1. When the fly ash or natural pozzolan is delivered in packages, the class, name, and brand of the producer and the mass of the material contained therein shall be plainly marked on each package. Similar information shall be provided in the shipping invoices accompanying the shipment of packaged or bulk material.

12. KEYWORDS

12.1. Coal fly ash; raw or calcined natural pozzolan; pozzolans.

Standard Specification for

Ground Granulated Blast-Furnace Slag for Use in Concrete and Mortars

AASHTO Designation: M 302-06
ASTM Designation: C 989-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Ground Granulated Blast-Furnace Slag for Use in Concrete and Mortars

AASHTO Designation: M 302-06
ASTM Designation: C 989-05

1. SCOPE

1.1. This specification covers three strength grades of finely ground granulated blast-furnace slag for use as a cementitious material in concrete and mortar.

1.2. The values stated in SI units are to be regarded as standard. The values given in parentheses are given for information only.

1.3. *The following safety hazards caveat pertains only to the test methods described in this specification. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4. The text of this standard references notes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this standard.

Note 1—The material described in this specification may be used for blending with portland cement to produce a cement meeting the requirements of M 240 or as a separate ingredient in concrete or mortar mixtures. The material may also be useful in a variety of special grouts and mortars and, when used with an appropriate activator, as the principal cementitious material in some applications.

Note 2—Information on technical aspects of the use of the material described in this specification is contained in Appendix A. More detailed information on that subject is contained in ACI 233R-03, formerly ACI 226.1R.

2. REFERENCED DOCUMENTS

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *blast-furnace slag*—the nonmetallic product, consisting essentially of silicates and aluminosilicates of calcium and other bases that is developed in a molten condition simultaneously with iron in a blast furnace. (See ASTM C 125.)

3.2. *Descriptions of Terms Specific to This Standard*:

3.2.1. *granulated blast-furnace slag*—the glassy granular material formed when molten blast-furnace slag is rapidly chilled as by immersion in water. (See ASTM C 125.) Compositional adjustments may be made while the blast-furnace slag is molten.

3.2.2. *slag*—granulated blast-furnace slag, as defined and described in Sections 3.1.1 and 3.2.1 and ground to cement fineness with or without additions meeting the requirements of the section on additions.

4. CLASSIFICATION

4.1. Slag is classified by performance in the slag activity test in three grades: Grade 80, Grade 100, and Grade 120. (See Table 1.)

5. ORDERING INFORMATION

5.1. The purchaser shall specify the grade slag desired and the optional chemical or physical data to be reported.

6. ADDITIONS

6.1. The slag covered by this specification shall contain no additions except as follows:

6.1.1. Calcium sulfate may be added in amounts such that the limits in Table 2 for sulfur trioxide are not exceeded.

6.1.2. Processing additions may be used in the manufacture of the slag, provided such materials, in the amounts used, have been shown to meet the requirements of ASTM C 465 when tested using a 50/50 blend by mass with portland cement.

7. PHYSICAL PROPERTIES

7.1. Slag shall conform to the physical requirements of Table 1.

Table 1—Physical Requirements

Item	
Fineness:	
Amount retained when wet-screened on a 45-µm (No. 325) sieve, max percent	20
Specific surface by air permeability, Method T 153 shall be determined and reported although no limits are required	—
Air content of slag mortar, max percent	12

Slag Activity Index, Min, percent	Average of Last 5 Consecutive Samples	Any Individual Sample
7-Day index:		
Grade 80	—	—
Grade 100	75	70
Grade 120	95	90
28- or 56[a]-Day index:		
Grade 80	75	70
Grade 100	95	90
Grade 120	115	110

[a] Only applicable when testing at 56 days is specified.

8. CHEMICAL COMPOSITION

8.1. Slag shall conform to the chemical requirements prescribed in Table 2.

Table 2—Chemical Requirements

Sulfide sulfur (S), max percent	2.5
Sulfate ion reported as SO_3, max percent	4.0

Note 3—Sulfur in granulated blast-furnace slag is present predominantly as sulfide sulfur. In most cases, instrumental analyses, such as x-ray fluorescence, cannot differentiate sulfide sulfur from sulfate. Determine and report the sulfide sulfur content separately and do not include it in the SO_3 calculations.

9. SAMPLING

9.1. The following sampling and testing procedures shall be used by the purchaser to verify compliance with this specification.

9.2. Take random grab samples either from a delivery unit or at some point in the loading or unloading process so that no sample represents more than 115 Mg (125 tons) (Note 4). If samples are taken from rail cars or trucks, take at least two separate 2-kg (5-lb) portions and thoroughly mix them to obtain a test sample (Note 5). Sample by removing approximately a 300-mm (12-in.) layer of slag. Make a hole before obtaining a sample to avoid dust collector material that may be discharged into the delivery unit after the slag flow ceases. Sample at a rate of 10 samples per month or one sample for each 2300 Mg (2500 tons) of shipments, whichever is more frequent.

Note 4—Standard statistical procedures are recommended for ensuring that samples are selected by a random procedure; see ASTM D 3665. These procedures can be used to select the days within a month or within a week that samples will be taken. The delivery unit or time of day then should be chosen randomly.

Note 5—The quantity of sample specified is more than adequate for the testing required. A 2-kg (5-lb) portion should be retained in a sealed container for retesting if that is considered necessary to verify compliance.

10. TEST METHODS

10.1. *Slag-Activity Tests with Portland Cement*:

10.1.1. Slag activity shall be evaluated by determining the compressive strength of both portland-cement mortars and corresponding mortars made with the same mass of 50/50 mass combinations of slag and portland cement. Appendix X1 discusses the effects of cement, temperature, and amount of slag used on performance with portland cement.

10.1.2. *Reference Cement*—The portland cement used in the slag activity tests shall comply with the standard chemical and physical requirements of M 85 and with the additional requirements of total alkali content and compressive strength limits as shown in Table 3. Sufficient cement shall be reserved to avoid changing reference cement more often than every 2 months. Following the compressive strength requirement of Table 3, the referenced cement shall be re-qualified at intervals no greater than 6 months.

Table 3—Alkali and Strength Limits of Reference Cement for Slag Activity Tests

Total alkalies (Na_2O + 0.658 K_2O),	min percent max percent	0.60 0.90
Compressive strength, MPa, min 28 days[a]		35 (5000 psi)

[a] The minimum strength limit is based solely on the strength of the T 106M/T 106 mortar cubes, as required in specification M 85, regardless of the strength of the flow controlled Specification M 302 mortar cubes.

10.1.3. *Preparation of Specimens*—Prepare mortars in accordance with T 106M/T 106, except that sufficient water shall be used in each batch to produce a flow of 110 ± 5 percent. The proportions shall be as follows:

- Reference Cement Mortar:
  500 g portland cement
  1375 g graded standard sand
- Slag-Reference Cement Mortar:
  250 g portland cement
  250 g slag
  1375 g graded standard sand

10.1.3.1. Mix a reference cement batch each day that a slag-reference cement batch is mixed until at least five batches have been mixed with the reference cement. Thereafter, reference cement batches need not be mixed more often than once a week whenever slag is being produced or shipped.

10.1.4. *Test Ages*—Determine the compressive strength of mortar specimens at 7 and 28 days age in accordance with T 106M/T 106.

10.1.5. *Calculation*—Calculate the slag activity index to the nearest percent for both 7 days and 28 days as follows:

$$\text{Slag Activity Index, percent} = (SP/P) \times 100$$

where:

SP = average compressive strength of slag-reference cement mortar cubes at designated ages, MPa (psi); and

P = average compressive strength of reference cement mortar cubes at designated age, MPa (psi).

The reference cement-mortar strength used to calculate the slag activity index shall, when a reference cement mortar is mixed on the same day as a slag-reference cement mortar, be the result for that batch. Otherwise, the average of tests of the five most recent reference cement-mortar batches shall be used.

10.1.6. *Report*—The report should include the following:

10.1.6.1. Slag activity index, percent;

10.1.6.2. Compressive strength at 7 and 28 days of slag-reference cement mortar;

10.1.6.3. Compressive strength at 7 and 28 days of portland cement mortar;

10.1.6.4. Total alkalies of the reference cement ($Na_2O + 0.658\ K_2O$);

10.1.6.5. Fineness of reference cement; and

10.1.6.6. Potential compound composition of the reference portland cement.

10.1.7. *Precision*—The following precision statements are applicable when the slag activity index with portland cement is based on results of tests of two cubes from single batches of reference cement and 50/50 slag-reference cement mortars mixed on the same day. They are applicable to the slag activity index determined at 7 or 28 days.

10.1.7.1. The single-laboratory coefficient of variation has been found to be 4.1 percent. Therefore, the slag activity index based on single batches of mortar mixed on the same day should not differ by more than 11.6 percent of their average.

10.1.7.2. The multilaboratory coefficient of variation has been found to be 5.7 percent. Therefore, the slag activity index based on tests of single batches made by different laboratories should not differ by more than 16.1 percent.

10.2. *Slag Density*—Determine in accordance with T 133.

10.3. *Amount of Slag Retained on a 45-μm (No. 325) Sieve*—Determine in accordance with T 192.

10.4. *Slag Fineness by Air Permeability*—Determine in accordance with T 153.

10.5. *Sulfate Ion in Slag Reported as* SO_3—Determine as sulfur trioxide in accordance with T 105, except the sample need not be completely decomposed by acid.

10.6. *Sulfide Sulfur in the Slag*—Determine in accordance with T 105.

10.7. *Chloride Content of Slag*—Determine in accordance with T 105.

10.8. *Air Content of Slag Mortar*—Determine in accordance with T 137, except use 350 g of slag instead of cement in the standard mortar batch. Calculate using the appropriate density of the slag.

11. REJECTION AND REHEARING

11.1. The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the tests, the producer or supplier is not prohibited from making a claim for retesting.

12. CERTIFICATION

12.1. Upon request of the purchaser in the contract or order, a manufacturer’s report shall be furnished at the time of shipment stating the results of tests made on samples of the material taken during production or transfer and certifying that applicable requirements of this specification have been met. When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been tested as directed in this specification and the specified requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

12.2. When specified in the purchase order or contract, test data shall be furnished on the chloride ion content of the slag.

13. MANUFACTURER’S STATEMENT

13.1. At the request of the purchaser, the manufacturer shall state in writing the nature, amount, and identity of any processing or other additions made to the slag.

14. PACKAGE MARKING AND SHIPPING INFORMATION

14.1. When the ground slag is delivered in packages, the classification of slag, the name and brand of the manufacturer, and the mass of the slag contained therein shall be plainly marked on each package. Similar information shall be provided in the shipping invoices accompanying the shipment of packaged or bulk slag. All packages shall be in good condition at the time of inspection.

15. STORAGE

15.1. The slag shall be stored to permit easy access for proper inspection and identification of each shipment and in a suitable weather-tight building that will protect the slag from dampness and minimize quality deterioration.

APPENDIXES

(Nonmandatory Information)

X1. CONTRIBUTION OF SLAG TO CONCRETE STRENGTH

X1.1. When slag is used in concrete with portland cement, the levels and rate of strength development will depend importantly on the properties of the slag, the properties of the portland cement, the relative and total amounts of slag and cement, and the concrete curing temperatures.

X1.2. The reference cement used to test slag activity in this specification must have a minimum 28-day strength of 35 MPa (5000 psi) and an alkali content between 0.6 and 0.9 percent. Performance of the slag with other portland cements may be significantly different. The slag-activity test also can be used to evaluate relative hydraulicity of different slags with a specific cement or of different shipments of the same slag. Such comparisons will be improved if all tests are made with a single sample of cement. To properly classify a slag, the reference portland cement must conform to the limits on strength and alkali content. Even within these limits, performance will depend to some extent on the particular cement used. The percentages developed in the slag activity test do not provide quantitative predictions of strength performance in concrete. Performance in concrete will depend on a large number of factors including the properties and proportions of the slag, the portland cement, and other concrete ingredients, concrete temperatures and curing conditions, and other conditions.

X1.3. Concrete strengths at 1, 3, and even 7 days may tend to be lower using slag-cement combinations, particularly at low temperatures or at high slag percentages. Concrete proportions will need to be established considering the importance of early strengths, the curing temperatures involved and the properties of the slag, the portland cement, and other concrete materials. Generally a higher numerical grade of slag can be used in larger amounts and will provide improved early strength performance; however, tests must be made using job materials under job conditions.

X2. SULFATE RESISTANCE

X2.1. *General*—Slag cements are generally considered to have greater resistance to attack by sulfates than do portland cements, based largely upon comparisons of high slag-content portland blast-furnace slag cements with ordinary (Type I) portlands. These cements (containing 60 percent or more slag) are widely used for sulfate- and seawater-resistant concretes throughout the world.

X2.2. *Sulfate Resistance of Portland Cements*—The sulfate resistance of concrete is dependent upon a number of factors, including mortar permeability and the type and concentration of the sulfate solutions involved. Other factors, directly related to the cement characteristics, include calcium hydroxide concentration and the tricalcium aluminate (C_3A) content. Specification M 85 provides limits on the C_3A for sulfate-resistant cements. Specification M 85 Type V requirements provide for a limit on the tetracalcium aluminoferrite (C_4AF) plus twice the C_3A. The M 85 table of Optional Physical Requirements includes a maximum limit on expansion of Type V cement in mortar bars when tested by ASTM C 452. When this option is selected, the standard limits on tricalcium aluminate and on tetracalcium aluminoferrite plus twice the tricalcium aluminate do not apply. ASTM C 1012 can be used to measure the effects of exposure to external sulfate environments on mortar or concrete.

X2.3. *Effect of Slag on Sulfate Resistance*[2,3]—The use of slag will decrease the C_3A content of the cementing materials and decrease the permeability and calcium hydroxide content of the mortar or concrete. Tests have shown that the alumina content of the slag also influences sulfate resistance, and that high alumina content can have a detrimental influence at low slag-replacement percentages. The data from these studies of laboratory exposure of mortars to sodium and magnesium sulfate solutions provide the following general conclusions.

X2.3.1. The combination of slag and portland cement, in which the slag content was greater than 60 to 65 percent, had high sulfate resistance, always better than the portland cement alone, irrespective of the Al_2O_3 content of the slag. The improvement in sulfate resistance was greatest for the cements with the higher C_3A contents.

X2.3.2. The low-alumina (11 percent) slag tested increased the sulfate resistance independently of the C_3A content of the cement. To obtain adequate sulfate resistance, higher slag percentages were necessary with the higher C_3A cements.

X2.3.3. The high-alumina (18 percent) slag tested adversely affected the sulfate resistance of portland cements when blended in low percentages (50 percent or less). Some tests indicated rapid decreases in resistance for cements in the 8 and 11 percent C_3A ranges with slag percentages as low as 20 percent or less in the blends.

X2.3.4. Tests on slag (7 to 8 percent alumina) in Ontario have shown that a 50:50 combination by mass with Type I portland cement having up to about 12 percent C_3A is equivalent in sulfate resistance to the Type V cement used in that study.[4]

X2.4. *Tests for Sulfate Resistance*—When the relative sulfate resistance of a specific cement-slag combination is desired, tests should be conducted in accordance with ASTM C 1012.[5] Studies by ASTM Subcommittee C 01.29 on sulfate resistance using ASTM C 1012, as reported by Patzias,[6] recommended the following limits for expansion of portland cement and ground slag combinations at 6 months of exposure:

- Moderate sulfate resistance—0.10 percent max.
- High sulfate resistance—0.05 percent.

X3. EFFECTIVENESS OF SLAG IN PREVENTING EXCESSIVE EXPANSION OF CONCRETE DUE TO ALKALI-AGGREGATE REACTION

X3.1. Tests for effectiveness of slag in preventing excessive expansion due to alkali-aggregate reaction are not considered necessary unless the slag is to be used: (a) with a high-alkali portland cement ($Na_2O + 0.658\ K_2O \geq 0.6$ percent) or the concrete contains added water-soluble alkalies (added as an activator to improve early strength); and (b) with an aggregate that is regarded as deleteriously reactive with alkalies.

X3.2. It should be expected that the effectiveness of the slag will depend upon the amount used and the reactivity of the slag itself. Data suggest that slags used as 40 percent or more of the cementitious material will generally prevent excessive expansion with cements having alkali contents up to 1.0 percent; however, definitive data are not available, and tests must be made in accordance with ASTM C 441. Further information on preventing excessive expansion due to alkali-silica reaction is given in M 6 and M 80.

X3.3. When the job cement and proportions of cement to slag are known, test mortars should be proportioned in accordance with the job mixture requirements of ASTM C 441, and the average expansion of mortar bars at 14 days should not exceed 0.020 percent.

X3.4. When the job cement and proportions of slag to cement are not known, tests can be made for the reduction in mortar expansion in accordance with ASTM C 441. To be considered effective the slag must reduce 14-day expansions of mixtures made with the required high-alkali cement by 75 percent. The slag should be considered effective only when the ratio of slag to cement equals or exceeds that found effective in the tests.

Standard Practice for

Making and Curing Concrete Test Specimens in the Laboratory

AASHTO Designation: R 39-07
ASTM Designation: C 192/C 192M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Making and Curing Concrete Test Specimens in the Laboratory

AASHTO Designation: R 39-07
ASTM Designation: C 192/C 192M-06

1. SCOPE

1.1 This standard practice covers procedures for making and curing test specimens of concrete in the laboratory under accurate control of materials and test conditions using concrete that can be consolidated by rodding or vibration as described herein. This standard practice does not address and does not apply to self-consolidating concrete.

1.2 The values stated in the inch-pound units are to be regarded as standard. The values given in parentheses are for information purposes only.

1.3 *This standard practice does not purport to address the safety concerns associated with its use. It is the responsibility of the user of this standard practice to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. SIGNIFICANCE AND USE

3.1 This standard practice provides standardized requirements for preparation of materials, mixing concrete, and making and curing concrete test specimens under laboratory conditions.

3.2 If specimen preparation is controlled as stipulated herein, the specimens may be used to develop information for the following purposes:

3.2.1 Mixture proportioning for project concrete,

3.2.2 Evaluation of different mixtures and materials,

3.2.3 Correlation with nondestructive tests, and

3.2.4 Providing specimens for research purposes.

Note 1—The concrete test results for concrete specimens made and cured using this standard practice are widely used. They may be the basis for acceptance testing for project concrete, research evaluation, and other studies. Careful and knowledgeable handling of materials, mixing concrete, molding test specimens, and curing test specimens is necessary. Many laboratories performing this important work are independently inspected or accredited. ASTM C 1077 identifies and defines duties, responsibilities, including minimum responsibilities of the laboratory personnel, and minimum technical requirements for laboratory equipment used. Many laboratories ensure qualified technicians by participating in national certification programs such as the American Concrete Institute Laboratory program or equivalent program.

4. APPARATUS

4.1 *Molds, General*—Molds for specimens or fastenings thereto in contact with the concrete shall be made of steel, cast iron, or other nonabsorbent material, nonreactive with concrete containing portland or other hydraulic cements. Molds shall conform to the dimensions and tolerances specified in the method for which the specimens are required. Molds shall hold their dimensions and shape under conditions of severe use. Watertightness of molds during use shall be judged by their ability to hold water poured into them. Test procedures for watertightness are given in the section on Test Methods for Elongation, Absorption, and Watertightness in ASTM C 470.

A suitable sealant—such as heavy grease, modeling clay, or microscrystalline wax—shall be used where necessary to prevent leakage through the joints. Positive means shall be provided to hold base plates firmly to the molds. Reusable molds shall be lightly coated with mineral oil or a suitable nonreactive release material before use.

4.2 *Cylinder Molds*:

4.2.1 Molds for casting specimens vertically shall conform to the requirements of Section 4.1 and M 205.

4.2.2 Horizontal molds for creep test cylinders shall conform to the requirements of Section 4.1 and to the requirements for symmetry and dimensional tolerance in Section 3.1.2 of M 205. The use of horizontal molds is intended only for creep specimens that contain axially embedded strain gauges. Molds for creep cylinders to be filled while supported in a horizontal position shall have a filling slot parallel to the axis of the mold that extends the full length to receive the concrete. The width of the slot shall be one-half the diameter of the specimen. If necessary, the edges of the slot shall be reinforced to maintain dimensional stability. Unless specimens are to be capped or ground to produce plane ends, the molds shall be provided with two machined metal end plates at least 1 in. (25 mm) thick, and the working surfaces shall comply with the requirements for planeness and surface roughness of Section 3.1 of T 231. Provision shall be made for fixing both end plates firmly to the mold. The inside surface of each end plate shall be provided with at least three lugs or studs approximately 1 in. (25 mm) long, firmly fastened to the plate for embedment in the concrete. One base plate shall be drilled from the inside at an angle to permit the lead wire from the strain gauge to exit the specimen through the edge of the plate. Provision shall be made for accurately positioning the strain gauge. All necessary holes shall be as small as possible to minimize disturbance to subsequent strain measurements and shall be sealed to prevent leakage.

4.3 *Beam and Prism Molds*—Beam and prism molds shall be rectangular in shape (unless otherwise specified) and of the dimensions required to produce the desired specimen size. The inside surfaces of the molds shall be smooth and free from indentations. The sides, bottom, and ends shall be at right angles to each other and shall be straight and true and free of warpage. Maximum variation from the nominal cross section shall not exceed $^1/_8$ in. (3 mm) for molds with depth or breadth of 6 in. (150 mm) or more, or $^1/_{16}$ in. (1.6 mm) for molds of smaller depth or breadth. Except for flexure specimens, molds shall not vary from the nominal length by more than $^1/_{16}$ in. (1.6 mm). Flexure molds shall not be shorter than $^1/_{16}$ in. (1.6 mm) of the required length, but may exceed it by more than that amount.

4.4 *Tamping Rods*—Two sizes are specified in AASHTO methods. Each shall be a round, straight steel rod with at least the tamping end rounded to a hemispherical tip of the same diameter as the rod. Both ends may be rounded, if preferred.

4.4.1 *Larger Rod*—$^5/_8$ in. (16 mm) in diameter and approximately 24 in. (600 mm) long.

4.4.2 *Small Rod*—$^3/_8$ in. (10 mm) in diameter and approximately 12 in. (300 mm) long.

4.5 *Mallets*—A mallet with a rubber or rawhide head weighing 1.25 ± 0.50 lb (0.6 ± 0.20 kg) shall be used.

4.6 *Vibrators*:

4.6.1 *Internal Vibrators*—The vibrator frequency shall be at least 7000 vibrations per minute (115 Hz) while the vibrator is operating in the concrete. The diameter of a round vibrator shall be no more than one-fourth the diameter of the cylinder mold or one-fourth the width of the beam or prism mold. Other shaped vibrators shall have a perimeter equivalent to the circumference of an appropriate round vibrator. The combined length of the vibratory shaft and vibrating element shall exceed the depth of the section being vibrated by at least 3 in. (75 mm).

4.6.2 *External Vibrators*—The two types of external vibrators permitted are either table or plank. The external vibrator frequency shall be 3600 vibrations per minute (60 Hz) or higher.

4.6.2.1 Provisions shall be made for clamping the mold securely to the apparatus.

Note 2—For more information on size and frequency of various vibrators and method to periodically check vibrator frequency, see ACI 309.

Note 3—Vibratory impulses are frequently imparted to a table or plank vibrator through electromagnetic means, or by use of an eccentric weight on the shaft of an electric motor or on a separate shaft driven by a motor.

4.7 *Small Tools*—Tools and items such as shovels, pails, trowels, wood float, blunted trowels, straightedge, feeler gauge, scoops, rulers, rubber gloves, and metal mixing bowls shall be provided.

4.8 *Slump Apparatus*—The apparatus for measurement of slump shall conform to the requirements of T 119M/T 119.

4.9 *Sampling and Mixing Pan*—The pan shall be flat-bottomed and of heavy-gauge metal, watertight, of convenient depth, and of sufficient capacity to allow easy mixing by shovel or trowel of the entire batch; or if mixing is by machine, to receive the entire batch on discharge of the mixer and allow remixing in the pan by trowel or shovel.

4.10 *Wet-Sieving Equipment*—If wet-sieving is required, the equipment shall conform to the requirements of T 141.

4.11 *Air Content Apparatus*—The apparatus for measuring air content shall conform to the requirements of T 196M/T 196, or of T 152.

4.12 *Scales*—Scales for determining the mass of batches of materials and concrete shall be accurate within 0.3 percent of the test load at any point within the range of use.

Note 4—In general the mass of small quantities should not be determined on large capacity scales. In many applications the smallest quantity weighed on a scale should be greater than about 10 percent of the maximum capacity of the scale; however, this will vary with the performance characteristics of the scale and the required accuracy of the determination. Acceptable scales used for weighing concrete materials preferably should weigh accurately to about 0.1 percent of total capacity and the foregoing precaution is applicable. However, certain analytical and precision balances are exceptions to this rule and may weigh accurately to 0.001 percent. Particular care must be exercised in measuring small quantities of material by determining the difference between two much larger weights.

4.13 *Temperature Measuring Device*—The temperature measuring device shall conform to the requirements of T 309M/T 309.

4.14 *Concrete Mixer*—A power-driven concrete mixer shall be a revolving drum, tilting mixer, or suitable revolving pan or revolving-paddle mixer capable of thoroughly mixing batches of the prescribed sizes at the required slump.

Note 5—A pan mixer may be found more suitable for mixing concrete with less than 1-in. (25-mm) slump than a revolving drum mixer. The rate of rotation, degree of tilt, and rated capacity of tilting mixers may not always be suitable for laboratory mixed concrete. It may be found desirable to reduce the rate of rotation, decrease the angle of tilt from the horizontal, and use the mixer at somewhat less than the manufacturer's rated capacity.

5. SPECIMENS

5.1 *Cylindrical Specimens*—Cylinder dimensions shall be as stipulated in the specification, test method or practice for the laboratory studies being performed and shall meet the requirements of Section 5.4. If dimensions are not stipulated in a specification, test method, or practice, the specimen selected shall have a length that is twice the diameter and meet the requirements of Section 5.4.

Note 6—When molds in SI units are required and not available, equivalent inch-pound unit size mold should be permitted.

Note 7—The same cylinder size should be used for the reference (control) concrete mixture and test concrete mixtures when conducting comparative studies such as those required in M 194M/M 194. For mixture proportioning of project concrete, it is preferable for the cylinder size in the laboratory to be the same as that specified for acceptance testing.

5.1.1 Cylindrical specimens for tests other than creep shall be molded and allowed to harden with the axis of the cylinder vertical.

5.1.2 Cylindrical creep specimens may be cast with the cylindrical axis either vertically or horizontally and allowed to harden in the position in which cast.

5.2 *Prismatic Specimens*—Beams for flexural strength, prisms for freezing and thawing, bond, length change, volume change, etc., shall be formed with their long axes horizontally, unless otherwise required by the method of test in question, and shall conform in dimension to the requirements of the specific test method.

5.3 *Other Specimens*—Other shapes and sizes of specimens for particular tests may be molded as desired following the general procedures set forth in this standard practice.

5.4 *Specimen Size versus Aggregate Size*—The diameter of a cylindrical specimen or minimum cross-sectional dimension of a rectangular section shall be at least three times the nominal maximum size of the coarse aggregate in the concrete (as defined in ASTM C 125). Occasional oversized aggregate particles (of a size not normally found in the average aggregate grading) shall be removed by handpicking during the molding of the specimens. When the concrete contains aggregate larger than that appropriate for the size of the molds or equipment to be used, wet-sieve the sample as described in T 141.

5.5 *Number of Specimens*—The number of specimens and the number of test batches are dependent on established practice and the nature of the test program. Guidance is usually given in the test method or specification for which the specimens are made. Usually three or more are molded for each test age and test condition unless otherwise specified (Note 7). Specimens involving a given variable should be made from three separate batches mixed on different days. An equal number of specimens for each variable should be made on any given day. When it is impossible to make at least one specimen for each variable on a given day, the mixing of the entire series of specimens should be completed in as few days as possible, and one of the mixtures should be repeated each day as a standard of comparison.

Note 8—Test ages often used are 7 and 28 days for compressive strength tests, or 14 and 28 days for flexural strength tests. Specimens containing Type III cement are often tested at 1, 3, 7, and 28 days. For later test ages, 3 months, 6 months, and 1 year are often used for both compressive and flexural strength tests. Other test ages may be required for other types of specimens.

6. PREPARATION OF MATERIALS

6.1 *Temperature*—Before mixing the concrete, bring the concrete materials to room temperature in the range of 68 to 86ºF (20 to 30ºC) except when the temperature of the concrete is stipulated. When a concrete temperature is stipulated, the method proposed to obtain the concrete temperature needs approval of the stipulator.

6.2 *Cement*—Store the cement in a dry place, in moisture-proof containers, preferably made of metal. The cement shall be thoroughly mixed to provide a uniform supply throughout the tests. It shall be passed through a No. 20 (850 μm) or finer sieve to remove all lumps, remixed on a plastic sheet, and returned to sample containers.

6.3 *Aggregates*—In order to preclude segregation of a coarse aggregate, separate into individual-sized fractions and for each batch recombine in the proper proportions to produce the desired grading.

Note 9—Only rarely can a coarse aggregate be batched as a single-sized fraction. The number of sized fractions will generally be between two and five for aggregate smaller than $2^1/_2$ in. (63 mm). When a sized fraction to be batched is present in amounts in excess of 10 percent, the ratio of the opening of the larger to the smaller sieve should not exceed 2.0. More closely sized groups are sometimes advisable.

6.3.1 Unless fine aggregate is separated into individual-sized fractions, maintain it in a damp condition or restore to a damp condition until use, to prevent segregation, unless material uniformly graded is subdivided into batch-sized lots using a sample splitter with proper-sized openings. If unusual gradings are being studied, the fine aggregate may have to be dried and separated into individual sizes. In this instance, if the total quantity of fine aggregate required is larger than can be efficiently blended in a single unit, then the individual-sized fractions should be determined in mass required for each individual batch. When the total quantity of fine aggregate needed for the complete investigation is such that it can be thoroughly mixed, blended, and maintained in a damp condition, then it should be handled in that manner. Determine the specific gravity and absorption of aggregates in accordance with either T 85 or T 84.

6.3.2 Before incorporating in concrete, prepare the aggregate to ensure a definite and uniform condition of moisture. Determine the weight of aggregate to be used in the batch by one of the following procedures:

6.3.2.1 Determine the weight of low-absorption aggregates (absorption less than 1.0 percent) in the room-dry condition with allowance made for the amount of water that will be absorbed from the unset concrete (Note 10). This procedure is particularly useful for coarse aggregate that must be batched as individual sizes because of the danger of segregation. This procedure can be used for fine aggregate only when the fine aggregate is separated into individual-sized fractions.

Note 10—When using aggregates with low absorption in room-dry condition, the amount of water that will be absorbed by the aggregates before the concrete sets may be assumed to be 80 percent of the difference between the 24-hour absorption of the aggregates determined by T 85 or T 84, and the amount of water in the pores of the aggregates in their room-dry state, as determined by T 255.

6.3.2.2 Individual-sized fractions of aggregate may be weighed separately, recombined into a tared container in the amounts required for the batch, and immersed for 24 hours prior to use. After immersion, the excess water is decanted and the combined weight of aggregate and mixing water determined. Allowance shall be made for the amount of water absorbed by the aggregate. The moisture content of the aggregates may be determined in accordance with T 255.

6.3.2.3 The aggregate may be brought to and maintained in a saturated condition, with surface moisture contained in sufficiently small amounts to preclude loss by draining, at least 24 hours prior to use. When this method is used, the moisture content of the aggregate must be determined to permit calculation of proper quantities of the damp aggregate. The quantity of surface moisture present must be counted as a part of the required amount of mixing water. Surface moisture in fine aggregate may be determined in accordance with T 255, making due allowance for the amount of water absorbed. The method outlined here (moisture content slightly exceeding absorption) is particularly useful for fine aggregate. It is used less frequently for coarse aggregate because of the difficulty of accurately determining the moisture content, but if used, each sized fraction must be handled separately to ensure that the proper grading is obtained.

6.3.2.4 Aggregates, fine or coarse, may be brought to and maintained in a saturated surface-dry condition until batched for use. This method is used primarily to prepare material for batches not to exceed $^1/_4$ ft^3 (0.007 m^3) in volume. Care must be taken to prevent drying during weighing and use.

6.4 *Lightweight Aggregates*—The procedures for specific gravity, absorption, and preparation of aggregates mentioned in this standard practice pertain to materials with normal absorption values. Lightweight aggregates, air-cooled slag, and certain highly porous or vesicular natural aggregate may be so absorptive as to be difficult to treat as described. The moisture content of lightweight aggregate at the time of mixing may have important effects on properties of freshly mixed and hardened concretes such as slump loss, compressive strength, and resistance to freezing and thawing.

6.5 *Admixtures*—Powdered admixtures that are entirely or largely insoluble, that do not contain hygroscopic salts and are to be added in small quantities, should be mixed with a portion of the cement before introduction of the batch to the mixer so as to assure thorough distribution throughout the concrete. Essentially, insoluble materials that are used in amounts exceeding 10 percent by weight of cement, such as pozzolans, should be handled and added to the batch in the same manner as cement. Powdered admixtures that are largely insoluble but contain hygroscopic salts may cause balling of cement and should be mixed with the sand. Water-soluble and liquid admixtures should be added to the mixer in solution in the mixing water. The quantity of such solution used must be included in the calculation of the water content of the concrete. Admixtures, incompatible in concentrated form, such as solutions of calcium chloride and certain air-entraining and set-retarding admixtures, should not be intermixed prior to their addition to concrete. The time, sequence, and method of adding some admixtures to a batch of concrete can have important effects on concrete properties such as time of set and air content. The method selected must be uniform from batch to batch.

Note 11—The mixing apparatus and accessories shall be thoroughly cleaned to ensure that chemical additions or admixtures used in dissimilar batches of concrete do not affect subsequent batches.

7. PROCEDURE

7.1 *Mixing Concrete*:

7.1.1 *General*—Mix concrete in a suitable mixer or by hand in batches of such size as to leave about 10 percent excess after molding the test specimens. Hand-mixing procedures are not applicable to air-entrained concrete or concrete with no measurable slump. Hand mixing should be limited to batches of $^1/_4$ ft^3 (0.007 m^3) volume or less. Mixing procedures are given in Sections 7.1.2 and 7.1.3. However, other procedures may be used when it is desired to simulate special conditions or practices, or when the procedures specified are impracticable. A machine-mixing procedure suitable for drum type mixers is described. It is important not to vary the mixing sequence and procedure from batch to batch unless the effect of such variation is under study.

7.1.2 *Machine Mixing*—Prior to starting rotation of the mixer, add the coarse aggregate, some of the mixing water, and the solution of admixture, when required, in accordance with Section 6.5. When feasible, the admixture shall be dispersed in the mixing water before addition. Start the mixer and then add the fine aggregate, cement, and water with the mixer running. If it is impractical for a particular mixer or for a particular test to add the fine aggregate, cement, and water while the mixer is running, these components may be added to the stopped mixer after permitting it to turn a few revolutions following charging with coarse aggregate and some of the water (Note 12). Mix the concrete, after all ingredients are in the mixer, for 3 minutes followed by 3 minutes of rest, followed by 2 minutes of final mixing. Cover the open end or top of the mixer to prevent evaporation during the rest period. Take precautions to compensate for mortar retained by the mixer so that the discharged batch, as used, will be correctly proportioned (Note 13). To eliminate segregation, deposit machine-mixed concrete in the clean, damp mixing pan and remix by shovel or trowel until it appears to be uniform.

Note 12—An experienced operator may add water incrementally during mixing to adjust to the desired slump.

Note 13—It is difficult to recover all of the mortar from mixers. To compensate for this difficulty, one of the following procedures may be used to ensure the correct final proportions in the batch:

1. *"Buttering" Mixer*—Just prior to mixing the test batch, the mixer is "buttered" by mixing a batch proportioned to simulate closely the test batch. The mortar adhering to the mixer after discharging is intended to compensate for loss of mortar from the test batch.
2. *"Over-Mortaring" The Mix*—The test mix is proportioned by the use of an excess mortar, the amount established in advance, to compensate for that which, on the average, adheres to the mixer. In this case the mixer is cleaned before mixing the test batch.

7.1.3 *Hand Mixing*—Mix the batch in a watertight, clean (Note 11), damp, metal pan or bowl with a bricklayer's blunted trowel, using the following procedure when aggregates have been prepared in accordance with Sections 6.3.2.1, 6.3.2.3, and 6.3.2.4.

7.1.3.1 Mix the cement, powdered insoluble admixture, if used, and fine aggregate without addition of water until they are thoroughly blended.

7.1.3.2 Add the coarse aggregate and mix the entire batch without addition of water until the coarse aggregate is uniformly distributed throughout the batch.

7.1.3.3 Add water, and the admixture solution if used, and mix the mass until the concrete is homogeneous in appearance and has the desired consistency. If prolonged mixing is necessary because of the addition of water in increments while adjusting the consistency, discard the batch and make a new batch in which the mixing is not interrupted to make trial consistency tests.

7.1.4 *Mixed Concrete*—Select the portions of the batch of mixed concrete to be used in tests and for molding specimens so as to be representative of the actual proportions and condition of the concrete. When the concrete is not being remixed or sampled, cover it to prevent evaporation.

7.2 *Slump, Air Content, Yield, and Temperature*:

7.2.1 *Slump*—Measure the slump of each batch of concrete immediately after mixing in accordance with T 119M/T 119.

Note 14—The slump test is unsuitable for concrete so dry that it slumps less than $^{1}/_{4}$ in. (6 mm). No-slump concrete may be tested by one of several means described in ACI 211.3.

7.2.2 *Air Content*—Determine the air content, when required, in accordance with either T 196 or T 152. T 152 should not be used with concretes made with lightweight aggregates, air-cooled blast-furnace slag, or aggregates of high porosity. Discard the concrete used for the determination of air content.

7.2.3 *Yield*—Determine the yield of each batch of concrete, if required, in accordance with T 121M/T 121. Concrete used for slump and yield tests may be returned to the mixing pan and remixed into the batch.

7.2.4 *Temperature*—Determine the temperature of each batch of concrete in accordance with ASTM C 1064.

7.3 *Making Specimens*:

7.3.1 *Place of Molding*—Mold specimens as near as practicable to the place where they are to be stored during the first 24 hours. If it is not practicable to mold the specimens where they will be stored, move them to the place of storage immediately after being struck off. Place molds on a rigid surface free from vibration and other disturbances. Avoid jarring, striking, tilting, or scarring of the surface of the specimens when moving the specimens to the storage place.

7.3.2 *Placing*—Place the concrete in the molds using a scoop, blunted trowel, or shovel. Select each scoopful, trowelful, or shovelful of concrete from the mixing pan to ensure that it is representative of the batch. It may be necessary to remix the concrete in the mixing pan with a shovel or trowel to prevent segregation during the molding of specimens. Move the scoop or trowel around the top edge of the mold as the concrete is discharged in order to ensure a symmetrical distribution of the concrete and to minimize segregation of coarse aggregate within the mold. Further distribute the concrete by use of a tamping rod prior to the start of consolidation. In placing the final layer, the operator shall attempt to add an amount of concrete that will exactly fill the mold after compaction. Do not add nonrepresentative samples of concrete to an underfilled mold.

7.3.2.1 *Number of Layers*—Make specimens in layers as indicated in Table 1.

Table 1—Number of Layers Required for Specimens

Specimen Type and Size	Mode of Compaction	Number of Layers of Approximate Equal Depth
Cylinders, diameter in. (mm):		
3 or 4 (75 to 100)	Rodding	2
6 (150)	Rodding	3
9 (225)	Rodding	4
Up to 9 (225)	Vibration	2
Prisms and horizontal creep cylinders, depth in. (mm):		
Up to 8 (200)	Rodding	2
Over 8 (200)	Rodding	3 or more
Up to 8 (200)	Vibration	1
Over 8 (200)	Vibration	2 or more

7.4 *Consolidation*:

7.4.1 *Methods of Consolidation*—Preparation of satisfactory specimens requires different methods of consolidation. The methods of consolidation are rodding, and internal or external vibration. Base the selection of the method of consolidation on the slump, unless the method is stated in the specifications under which the work is being performed. Rod or vibrate concretes with slump greater than 1 in. (25 mm). Vibrate concretes with slump less than 1 in. (25 mm) (Note 14). Do not use internal vibration for cylinders with a diameter less than 4 in. (100 mm), and for beams or prisms with breadth or depth less than 4 in. (100 mm).

Note 15—Concrete of such low water content that it cannot be properly consolidated by the methods described herein is not covered by this method. Provisions for specimens and methods of testing will be found in the standards concerned. There are concretes that can be consolidated by external vibrations, but additional forces on the surface are required to embed the coarse aggregate thoroughly and consolidate the mixture. For such mixtures the following procedures may be followed: using external vibration fill 6- by 12-in. (or 150- by 300-mm) cylinder molds in 3-in. (75-mm) lifts using a 10-lb (4.5-kg) cylindrical surcharge, or 3- by 6-in. (75- by 150-mm) cylinder molds in 2-in. (50-mm) lifts using a 2.5-lb (1.1-kg) cylindrical surcharge. The surcharge should have a diameter $^1/_4$ in. (6 mm) less than the inside of the mold. Simultaneously each lift should be compacted by external vibration with the surcharge on the top surface of the concrete until the mortar begins to ooze around the bottom of the surcharge.

7.4.2 *Rodding*—Place the concrete in the mold, in the required number of layers of approximately equal volume. Rod each layer with the rounded end of the rod using the number of strokes and size of rod specified in Table 2. Rod the bottom layer throughout its depth. Distribute the strokes uniformly over the cross section of the mold, and for each upper layer allow the rod to penetrate through the layer being rodded and into the layer below approximately 1 in. (25 mm). After each layer is rodded, tap the outsides of the mold lightly 10 to 15 times with the mallet to close any holes left by rodding and to release any large air bubbles that may have been trapped. Use an open hand to tap light-gauge single-use molds that are susceptible to damage if tapped with the mallet. After tapping, spade the concrete along the sides and ends of beam and prism molds with a trowel or other suitable tool.

Table 2—Diameter of Rod and Number of Roddings to be Used in Molding Test Specimens

Cylinders		
Diameter of Cylinder, in. (mm)	Diameter of Rod, in. (mm)	Number of Strokes/Layer
2 (50) to <6 (150)	$^3/_8$ (10)	25
6 (150)	$^5/_8$ (16)	25
8 (200)	$^5/_8$ (16)	50
10 (250)	$^5/_8$ (16)	75
Beams and Prisms		
Top Surface Area of Specimen, in.^{2} (cm^2)	Diameter of Rod, in. (mm)	Number of Roddings/Layer
25 (160) or less	$^3/_8$ (10)	25
26 to 49 (165 to 310)	$^3/_8$ (10)	one for each 1 in.^{2} (7 cm^2) of surface
50 (320) or more	$^5/_8$ (16)	one for each 2 in.^{2} (14 cm^2) of surface
Horizontal Creep Cylinders		
Diameter of Cylinder, in. (mm)	Diameter of Rod, in. (mm)	Number of Roddings/Layer
6 (150)	$^5/_8$ (16)	50 total, 25 along both sides of axis

7.4.3 *Vibration*—Maintain a uniform duration of vibration for the particular kind of concrete, vibrator, and specimen mold involved. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator. Usually sufficient vibration has been applied as soon as the surface of the concrete becomes relatively smooth and large air bubbles cease to break through the top surface. Continue vibration only long enough to achieve proper consolidation of the concrete (see Note 16). Overvibration may cause segregation. Fill the molds and vibrate in the required number of approximately equal layers (Table 2). Place all the concrete for each layer in the mold before starting vibration of that layer. When placing the final layer, avoid overfilling by more than $^1/_4$ in. (6 mm). When the finish is applied after vibration, add only enough concrete with a trowel to overfill the mold about $^1/_8$ in. (3 mm), work it into the surface and then strike it off.

Note 16—Generally, no more than 5 s of vibration should be required for each insertion to adequately consolidate the concrete with a slump greater than 3 in. (75 mm). Longer times may be required for lower slump concrete, but the vibration times should rarely exceed 10 s per insertion.

7.4.3.1 *Internal Vibration*—In compacting the specimen, insert the vibrator slowly and do not allow the vibrator to rest on or touch the bottom or sides of the mold or strike embedded items such as strain meters. Slowly withdraw the vibrator so that no large air pockets are left in the specimen.

7.4.3.2 *Cylinders*—The number of insertions of the vibrator is given in Table 3. When more than one insertion per layer is required, distribute the insertions uniformly within each layer. Allow the vibrator to penetrate into the layer below, approximately 1 in. (25 mm). After each layer is vibrated, tap the outsides of the mold at least 10 times with the mallet to close the holes that remain and to release entrapped air voids. Use an open hand to tap cardboard or single-use metal molds that are susceptible to damage if tapped with a mallet.

7.4.3.3 *Beams, Prisms, and Horizontal Creep Cylinders*—Insert the vibrator at intervals not exceeding 6 in. (150 mm) along the center line of the long dimension of the specimen, or along both sides but not in contact with the strain gauge in the case of creep cylinders. For specimens wider than 6 in. (150 mm), use alternating insertions along two lines. Allow the shaft of the vibrator to penetrate into the bottom layer approximately 1 in. (25 mm). After each layer is vibrated, tap the outsides of the mold sharply at least 10 times with the mallet to close holes left by vibrating and to release any entrapped air voids.

7.4.4 *External Vibration*—When external vibration is used, take care to ensure that the mold is rigidly attached to or securely held against the vibrating element or vibrating surface (Note 15).

Table 3—Number of Vibrator Insertions per Layer

Specimen Type and Size, Cylinder: Diameter, in. (mm)	Number of Insertions per Layer
4 in. (100 mm)	1
6 in. (150 mm)	2
9 in. (225 mm)	4

7.5 *Finishing*—After consolidation, by any of the methods, strike-off the surface of the concrete and float or trowel it in accordance with the method concerned. If no finish is specified, finish the surface with a wood or magnesium float. Perform all finishing with the minimum manipulation necessary to produce a flat even surface that is level with the rim or edge of the mold and has no depressions or projections larger than $^1/_8$ in. (3 mm).

7.5.1 *Cylinders*—After consolidation, finish the top surfaces by striking them off with the tamping rod where the consistency of the concrete permits, or with a wood float or trowel. If desired, cap the top surface of freshly made cylinders with a thin layer of stiff portland cement paste that is permitted to harden and cure with the specimen. See Section 4 of T 231.

7.5.2 *Horizontally Cast Creep Cylinders*—After consolidation, strike off the specimen with a trowel or float, then trowel the minimum amount required to form the concrete in the opening concentrically with the rest of the specimen. Use a screed curved to the radius of the specimen to more precisely shape and finish the concrete in the opening.

8. CURING

8.1 *Initial Curing*—To prevent evaporation of water from the unhardened concrete, cover the specimens immediately after finishing, preferably with a nonabsorptive, nonreactive plate or a sheet of tough, durable, impervious plastic. Specimens shall be stored immediately after finishing until the removal of molds to prevent loss of moisture from the specimen. Select an appropriate procedure or combination of procedures that will prevent moisture loss and is nonabsorptive and nonreactive with the concrete. When burlap is used for covering, the burlap must not be in contact with the fresh concrete surface and care must be exercised to keep the burlap wet until the specimens are removed from the molds. Placing a sheet of plastic over the burlap will facilitate keeping it wet. To prevent damage to the specimen, protect the outside of cardboard molds from all contact with wet burlap or other sources of water until the molds are removed. Record the maximum and minimum ambient temperatures during the initial curing.

8.2 *Removal from Molds*—Remove the specimens from the molds within 24 ± 8 hours after casting. For concrete with prolonged setting time, molds shall not be removed until 20 ± 4 hours after final set. If needed, determine setting times in accordance with T 197M/T 197.

8.3 *Curing Environment*—Unless otherwise specified, all specimens shall be moist cured at 73.5 ± 3.5ºF (23.0 ± 2.0ºC) from the time of molding until the moment of test (Note 17). Storage during the first 48 hours of curing shall be in a vibration-free environment. As applied to the treatment of demolded specimens, moist curing means that the test specimens shall have free water maintained on the entire surface area at all times. This condition is met by using water storage tanks or a moist room in accordance with the requirements of M 201. When water storage tanks are used, specimens shall be immersed in a water saturated with calcium hydroxide to prevent leaching from the specimens. Specimens shall not be exposed to dripping or running water. Cure structural lightweight concrete cylinders in accordance with ASTM C 330.

Note 17—The temperature within damp sand and under wet burlap or similar materials will always be lower than the temperature in the surrounding atmosphere if evaporation takes place.

8.4 *Flexural Strength Test Specimens*—Cure the flexural strength test specimens in accordance with Sections 8.1 and 8.2, except that while in storage for a minimum period of 20 hours immediately prior to testing they shall be immersed in saturated-lime solution at 73.5 ± 3.5ºF (23.0 ± 2.0ºC). At the end of the curing period, between the time the specimen is removed from curing until testing is completed, drying of the surfaces shall be prevented.

Note 18—Relatively small amounts of drying of the surface of flexural strength specimens will induce tensile stresses in the extreme fibers that will markedly reduce the indicated flexural strength.

9. PRECISION AND BIAS

9.1 Data to establish precision statements for various testing required by this standard practice were obtained in the Concrete Reference Sample Program of the Cement and Concrete Reference Laboratory. The single-operator standard deviations for slump, unit weight, air content, and 7-day compressive strength of trial batches have been found to be 0.7 in. (18 mm), 0.9 lb/ft^3 (14.4 kg/m^3), 0.3 percent, and 203 psi (1400 kPa), respectively; therefore, the results of properly conducted tests on two trial batches made in the same laboratory should not differ by more than 2.0 in. (50 mm), 2.5 lb/ft^3 (40 kg/m^3), 0.8 percent, and 574 psi (3960 kPa), respectively. This precision statement is considered applicable to laboratory trial batches proportioned to contain prescribed quantities of materials and to have constant water–cement ratio. The values should be used with caution for air-entrained concrete, concrete with slump less than 2 in. (50 mm) or over 6 in. (150 mm), or concrete made with other than normal weight aggregate or aggregate larger than 1 in. (25 mm) nominal maximum size.

9.2 The multilaboratory standard deviations for slump, unit weight, air content, and 7-day compressive strength of trial batches have been found to be 1.0 in. (25 mm), 1.4 lb/ft^3 (22.4 kg/m^3), 0.4 percent, and 347 psi (2390 kPa), respectively; therefore, the results of properly conducted tests on single trial batches made in two different laboratories should not differ by more than 2.8 in. (70 mm), 4.0 lb/ft^3 (64.1 kg/m^3), 1.1 percent, and 981 psi (6765 kPa), respectively. This precision statement is considered applicable to laboratory trial batches proportioned to contain prescribed quantities of materials and to have a prescribed water-cement ratio. The values should be used with caution for air–entrained concrete, concrete with slump less than 2 in. (50 mm), or over 6 in. (150 mm), or concrete made with other than normal weight aggregate or aggregate larger than 1 in. (25 mm) nominal maximum size.

9.3 *Bias*—The procedures for the test methods in Section 9.3 have no bias because the values obtained from each of those test methods are defined only in terms of the test method.

10. KEYWORDS

10.1 Concrete; cylinders; laboratory; prisms; strength testing.

Standard Practice for

Chemical, Biological, and Physical Analysis of Water

AASHTO Designation: R 23-99 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Chemical, Biological, and Physical Analysis of Water

AASHTO Designation: R 23-99 (2008)

1. SCOPE

1.1. This standard practice provides a listing of various parameters used in the analysis of natural waters and wastewaters. The analysis of these waters is becoming an increasing area of concern for environmental reasons. The passage of laws governing the usage of our natural waterways and limiting the discharges into these waterways, along with an increased public awareness, have caused a much greater demand for this information. To ensure that these data are accurate and reliable, it is essential that testing be conducted using standard procedures that are known to have reproducible results. The test methods given for the following parameters are from referenced sources that are used by most transportation departments testing water. They are listed in order of most frequently used parameters to those parameters rarely used.

1.2. The values stated in SI units are to be regarded as the standard.

2. METHOD OF DESIGNATION

2.1. Each parameter listed contains one or more test methods for the analysis of that parameter. When more than one procedure is listed, the choice is left to the individual laboratory. These alternate methods generally give comparable results and are intended to provide flexibility to the analyst for parameters for which test methods are used fairly equally.

Standard Practice for

Collection and Preservation of Water Samples

AASHTO Designation: R 24-99 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Collection and Preservation of Water Samples

AASHTO Designation: R 24-99 (2008)

1. SCOPE

1.1. The objective of sampling is to collect a portion of material small enough in volume to be conveniently transported to and handled in the laboratory while still accurately representing the material being sampled. This implies, first, that the relative portions or concentrations of all pertinent components must be the same in the sample as in the material being sampled, and second, that the sample must be handled in such a way that no significant changes in composition occur before the tests are performed. Complete and unequivocal preservation of samples, whether domestic sewage, industrial waste, or natural waters, is a practical impossibility. Regardless of the nature of the sample, complete stability for every constituent can never be achieved. At best, preservation techniques can only retard the chemical and biological changes that inevitably continue after the sample is removed from the parent source.

1.2. The values stated in SI units are to be regarded as the standard.

2. TYPES OF SAMPLES

2.1. *Grab or Catch Samples*—Strictly speaking, a sample collected at a particular time and place can represent only the composition of the source at that time and place. However, when a source is known to be fairly constant in composition over a considerable period of time or over substantial distances in all directions, then the sample may be said to represent a longer time period or a larger volume or both, than the specific point at which it was collected. In such circumstances, some sources may be quite well represented by single grab samples. Examples are some water supplies, some surface waters, and, rarely, some wastewater streams.

2.1.1. When a source is known to vary with time, grab samples collected at suitable intervals and analyzed separately can be of great value in documenting the extent, frequency, and duration of these variations. Choose sampling intervals on the basis of the frequency with which changes may be expected, which may vary from as little as five minutes to as long as one hour or more.

2.1.2. When the composition of a source varies in space rather than time, a set of samples collected from appropriate locations with less emphasis on timing may provide the most useful information.

2.1.3. Use great care in sampling wastewater sludges, sludge banks, and muds. No definite procedure can be given, but every possible precaution should be taken to obtain a representative sample.

2.2. *Composite Samples*—In most cases, the term *composite sample* refers to a mixture of grab samples collected at the same sampling point at different times. Sometimes the term *time-composite* is used when it is necessary to distinguish this type of sample from others. Time-composite samples are most useful for observing average concentrations that are used, for example, in calculating the loading or the efficiency of a wastewater treatment plant. As an alternative to the separate analysis of a large number of samples, followed by computation of average and total results, composite samples of this type represent substantial savings in laboratory effort and expense. For these purposes, a composite sample representing a 24-hour period is considered standard for most determinations. Under certain circumstances, however, a composite sample representing one shift, or a shorter time period, or a complete cycle of a periodic operation, may be preferable. Evaluation of the effects of special, variable, or irregular discharges and operations may require composite samples representing the period during which such discharges occur.

2.2.1. For determination of components or characteristics subject to significant and unavoidable changes during storage, composite samples cannot be used. Perform such determinations on individual samples as soon as possible after collection and preferably at the sampling point. Analyses for all dissolved gases, residual chlorine, soluble sulfide, temperature, and pH are examples of determinations of this type. Changes in components such as dissolved oxygen or carbon dioxide, pH, or temperature may produce secondary changes in certain inorganic components such as iron, manganese, alkalinity, or hardness. Use time-composite samples only for determining components that can be demonstrated to remain unchanged under the existing conditions of sample collection and preservation.

2.2.2. Take individual portions in a wide-mouth bottle having a diameter of at least 35 mm at the mouth and capacity of at least 120 mL. Collect these portions each hour—in some cases half-hour or even every five minutes—and mix at the end of the sampling period or combine in a single bottle as collected. If preservatives are used, add them to the sample bottle initially so that all portions of the composite are preserved as soon as collected. Analysis of individual samples may sometimes be necessary.

2.2.3. It is desirable, and often absolutely essential, to combine the individual samples in volumes proportional to the volume of flow. A final volume of 2 to 3 liters is sufficient for sewage, effluents, and wastes.

2.2.3.1. Automatic sampling devices are available but should not be used unless the sample is preserved as described below. Clean sampling devices, including bottles, daily to eliminate biological growths and other deposits.

2.3. *Integrated Samples*—For certain purposes, the information needed is provided best by analysis of mixtures of grab samples collected from different points simultaneously, or as nearly so as possible. Such mixtures sometimes are called *integrated samples*. An example of the need for such sampling occurs in a river or stream that varies in composition across its width and depth. For evaluation of average composition or total loading, a mixture of samples representing various points in the cross-section, in proportion to their relative flows, may be useful. The need for integrated samples also may exist if combined treatment is proposed for several separate wastewater streams, the interaction of which may have a significant effect on treatability or even the composition of the mixture. Mathematical prediction of the interactions may be inaccurate or impossible, and testing of a suitable integrated sample may provide more useful information.

2.3.1. Both natural and artificial lakes often show variations of composition with both depth and horizontal location. However, under most conditions, neither total nor average figures are especially significant in these situations. The local variations are of more importance, and the samples are examined separately rather than integrated.

2.3.2. The preparation of integrated samples usually requires special equipment to collect a sample from a known depth, without contamination by the overlying water. Prior knowledge about the volume, movement, and composition of the various parts of the water being sampled usually is required.

Therefore, the collection of the integrated samples becomes a complicated and specialized process that cannot be described in complete detail here.

3. FREQUENCY AND DURATION OF SAMPLING

3.1. A reasonably accurate estimate of the composition of a raw water piped from a large body of water, such as the Great Lakes, far enough from the shoreline to avoid variation from inflowing tributaries and waste discharges, may be made by taking individual samples at infrequent intervals, such as biweekly or monthly, sufficient to cover seasonal changes. If samples are taken from near the shoreline of such a body of water or from a river, take them at shorter intervals, for instance daily, to provide more exact knowledge of the variations in composition where these are of importance in the use to which the water is to be put. If greater variations or cycles of pollution occur, or closer surveillance of plant intake water is required, collect more frequent samples; for example, at hourly intervals.

3.2. Water undergoing continuous or intermittent treatment must be sampled with such frequency that adequate control is assured. The interval between samples is directly related to the rate at which critical characteristics can reach intolerable limits.

4. POINT OF SAMPLING

4.1. Choose the point of sampling with extreme care so that a representative sample of the water to be tested is obtained. Avoid surface scum.

4.2. Because of a wide variety of conditions found in streams, lakes, reservoirs, and other bodies of water, it is not possible to prescribe the exact point of sampling. Where the water in a stream is mixed so as to approach uniformity, a sample taken at any point in the cross-section is satisfactory. For large rivers or for streams not likely to be uniformly mixed, more samples are desirable and are usually taken at a number of points at the surface across the entire width and at a number of depths at each point. Take care, when boats are used, to avoid collecting samples where the turbulence caused by a propeller or by oars has disturbed the characteristics of the water. Ordinarily, samples are taken at these points and then combined to obtain an integrated sample of such a stream of water. Alternatively, test the single grab samples, for example, to determine the point of highest bacterial density.

4.3. Choose the location of the sampling point with respect to the information desired and in conformity with local conditions. Allow sufficient distance downstream, with respect to stream flow at the time of sampling, from a tributary or source of pollution to permit thorough mixing. If this is not possible, it is better to sample the stream above the tributary or source of pollution and, in addition, to sample the tributary or source of pollution. In general, a distance of 1.5 to 5 km (1 to 3 mi) below the tributary is sufficient.

4.4. Collect samples at least 0.8 km (0.5 mi) below dams or waterfalls to allow time for the escape of entrained air. When lakes, reservoirs, or other bodies of water are sampled, it is necessary to avoid nonrepresentative areas such as those created by inlet streams, more stagnant areas, or abrupt changes in shorelines, unless determining the effect of such local conditions is a part of the sampling program.

4.5. It is desirable to take a series of samples from any source of water to determine whether differences in composition are likely to exist before final selection of the sampling point.

5. SAMPLE CONTAINERS

5.1. Sample containers shall be made of materials that will not contaminate the sample and, before use, shall be cleaned thoroughly to remove all extraneous surface dirt. Chemically resistant glass and polyethylene are suitable materials for the containers. Only polyethylene containers shall be used for samples in which small amounts of hardness, silica, sodium, or potassium are to be determined. The collection, storage, and subsequent analytical determination in plastic containers will result in erroneous pH values due to the permeability of plastic to gases such as CO_2.

Note 1—New chemically resistant glass containers shall be conditioned by allowing them to stand full of distilled water for several days. Conditioning may be hastened by a preliminary treatment with dilute hydrochloric acid solution.

5.2. The closures for the sample containers shall be glass stoppers that have been thoroughly washed or plastic caps with suitable liners.

5.3. Refer to Table 1 for the recommended container for individual parameters.

6. GENERAL PRECAUTIONS

6.1. For sampling of unconfined water at any specified depth in ponds, lagoons, reservoirs, etc., during which contact with air or agitation of the water would cause a change in concentration of characteristics of a constituent to be determined, use a sampling apparatus so constructed that the solution at the depth to be sampled flows through a tube to the bottom of the container, and that a volume of sample equal to 4 to 10 times the volume of the receiving container passes through it. When no determinations of dissolved gases are to be made, any less complicated apparatus may be used that will permit the collection of a sample at a desired depth, or of an integrated sample containing water from all points in a vertical section.

6.2. Some test methods require adjustment to other than ambient temperature. Such adjustment should be carried out when indicated.

6.3. Normally, samples are taken without separation of particulate matter. If constituents are present in colloidal or flocculent suspension, take the sample so that they are present in representative portion.

6.4. *Volume of sample*:

6.4.1. Collect a minimum volume of 2 liters; 4 liters is preferable.

6.4.2. The estimates in Table 1 cover the volume of sample required for the usual determinations that are made on a water sample as well as for several tests that are made for special purposes.

6.4.3. The sample volume required for bacteriological analysis varies greatly with the bacterial density of the water. Serial dilutions are necessary for high-density samples.

6.5. When samples are to be shipped, do not fill the bottle entirely in order to allow some room for expansion when subjected to a change in temperature. An air space of 10 to 25 mL usually suffices for this purpose, although this does not protect against bursting of the container due to freezing.

6.6. If contact with air would cause a change in the concentration or characteristics of a constituent to be determined, secure the sample without contact with air and completely fill the container.

6.7. *Microbiological samples*:

6.7.1. When taking a sample from a sample line or tap, allow the water to run for at least five minutes or long enough to flush, with 6 to 10 times its volume, the entire part of the system that has been stagnant for two hours or more.

6.7.2. Turn off the sample outlet and empty it of water without touching the inside. Flame the outlet with a suitable torch or other device that will avoid the deposition of soot, which is undesirable. This flaming procedure may be omitted if the outlet is carefully cleaned by use of a swab of cotton or other suitable material thoroughly saturated with denatured ethyl alcohol (70 percent).

Table 1—Recommendation for Sampling and Preservation of Samples According to Measurement[a]

Measurement	Volume Req, mL	Container	Preservative	Holding Time[b]
Acidity	100	P, G[c]	Cool, 4°C	24 hours
Alkalinity	100	P, G	Cool, 4°C	24 hours
Arsenic	100	P, G	HNO_3 to pH < 2	6 months
BOD	1000	P, G	Cool, 4°C	6 hours[d]
Bromide	100	P, G	Cool, 4°C	24 hours
COD	50	P, G	H_2SO_4 to pH < 2	7 days
Chloride	50	P, G	None required	7 days
Chlorine req	50	P, G	Determine on site	No holding
Color	50	P, G	Cool, 4°C	24 hours
Cyanides	500	P, G	Cool, 4°C NaOH to pH < 2	24 hours
Dissolved oxygen:				
Probe	300	G only	Determine on site	No holding
Winkler	300	G only	Fix on site	4 to 8 hours
Fluoride	300	P, G	Cool, 4°C	7 days
Hardness	100	P, G	Cool, 4°C HNO_3 to pH < 2	7 days
Iodide	100	P, G	Cool, 4°C	24 hours
MBAS	250	P, G	Cool, 4°C	24 hours
Metals:				
Dissolved	200	P, G	Filter on site HNO_3 to pH < 2	6 months
Suspended			Filter on site	6 months
Total	100		HNO_3 to pH < 2	6 months
Mercury:				
Dissolved	100	P, G	Filter HNO_3 to pH < 2	38 days (glass) 13 days (hard plastic)
Total	100	P, G	Filter HNO_3 to pH < 2	38 days (glass) 13 days (hard plastic)
Nitrogen:				
Ammonia	400	P, G	Cool, 4°C H_2SO_4 to pH < 2	24 hours[e]
Kjeldahl Total	500	P, G	Cool, 4°C H_2SO_4 to pH < 2	7 days
Nitrate	100	P, G	Cool, 4°C H_2SO_4 to pH < 2	24 hours[e]
Nitrite	50	P, G	Cool, 4°C	24 hours[e]
NTA	50	P, G	Cool, 4°C	24 hours
Oil and grease	1000	G only	Cool, 4°C H_2SO_4 to pH < 2 or HCI	24 hours
Organic carbon	25	P, G	Cool, 4°C H_2SO_4 to pH < 2	24 hours

Continued on next page.

Table 1—Recommendation for Sampling and Preservation of Samples According to Measurement[a] (Continued)

Measurement	Volume Req, mL	Container	Preservative	Holding Time[b]
pH	25	P, G	Cool, 4˚C Determine on site	6 hours[e]
Phenolics	500	G only	Cool, 4˚C H_3PO_4 to pH < 4 1.0 g $CuSO_4$/I	24 hours
Phosphorous:				
Orthophosphate, dissolved	50	P, G	Filter on site Cool, 4˚C	24 hours[e]
Hydrolyzable	50	P, G	Cool, 4˚C	24 hours[e]
Total	50	P, G	Cool, 4˚C H_2SO_4 to pH < 2	7 days
Total, dissolved	50	P, G	Filter on site Cool, 4˚C	24 hours[e]
Residue:				
Filterable	100	P, G	Cool, 4˚C	7 days
Nonfilterable	100	P, G	Cool, 4˚C	7 days
Total	100	P, G	Cool, 4˚C	7 days
Volatile	100	P, G	Cool, 4˚C	7 days
Settleable matter	1000	P, G	None required	24 hours
Selenium	50	P, G	HNO_3 to pH < 2	6 months
Silica	50	P only	Cool, 4˚C	7 days
Specific conductance	100	P, G	Cool, 4˚C	24 hours[f]
Sulfate	50	P, G	Cool, 4˚C	7 days
Sulfide	500	P, G	2 mL zinc acetate	24 hours
Sulfite	50	P, G	Determine on site	No holding
Temperature	1000	P, G	Determine on site	No holding
Threshold odor	200	G only	Cool, 4˚C	24 hours
Turbidity	100	P, G	Cool, 4˚C	7 days

[a] More specific instructions for preservation and sampling are found with each procedure as detailed in the appropriate reference.

[b] It has been shown that samples properly preserved may be held for extended periods beyond the recommended holding time.

[c] Plastic or glass.

[d] If samples cannot be returned to the laboratory in less than six hours and holding time exceeds this limit, the final reported data should indicate the actual holding time.

[e] Mercuric chloride may be used as an alternate preservative at a concentration of 40 mL/L, especially if a longer holding time is required. However, the use of mercuric chloride is discouraged whenever possible.

[f] If the sample is stabilized by cooling, it should be warmed to 25˚C for reading, or temperature correction made and results reported at 25˚C.

6.7.3. Choose a sterile sample bottle containing $Na_2S_2O_3$ if the water being sampled contains residual chlorine, has been chlorinated, or contains any free or combined available oxidizing agent intended to sterilize it. If such sterilizing agents are not present, the thiosulfate may be omitted. In cases in which thiosulfate interferes with subsequent examination, such as examination for sulfate-reducing bacteria, etc., omit the use of thiosulfate in the sample bottle even if such sterilizing agents are present. In this case, if such sterilizing agents are present, the examination must be performed as soon as possible.

6.7.4. Remove the stopper from the sample bottle. Grasp the stopper by the dust cover to avoid contaminating it by touching it; do not lay it down. Hold the bottle by the bottom to avoid touching the neck. Do not rinse the bottle with the sample. Quickly hold the bottle under the flowing water to be sampled until it is about three-fourths full to permit mixing by shaking prior to testing. Replace the stopper and promptly crimp the metal dust cover in place over the neck of the bottle. Take care that the stopper and bottle neck are not touched during this operation and that no dust blows into the bottle, insofar as possible.

7. PRESERVATION OF SAMPLES

7.1. Add chemical preservatives to samples for chemical, physical, or radiological examination only as specified in Table 1. Quick freezing has been found to be beneficial in preserving some organic constituents. Note any preservatives added on the label.

7.2. Samples for bacteriological examination require refrigeration if they cannot be processed within one hour after collection.

7.3. If the sample is to be examined within one hour of collection, store it in a cool place without icing.

7.4. If the sample is held more than one hour before examination, store it in a refrigerator or ice chest at a temperature of not more than 4ºC. The interval between collection and examination of the sample must, in no case, be more than 12 hours, or 6 hours if the sample is suspected to contain large numbers of organisms. Field examination procedures should be considered for longer periods.

7.5. If the sample is transported, ship it in an insulated, iced container to maintain the temperature between 0 and 4ºC to allow it to be examined within 12 hours of collection.

7.6. If the conditions in Section 7.4 or Section 7.5 cannot be met, note the actual conditions on the examination report.

8. TIME INTERVAL BETWEEN COLLECTION AND ANALYSIS OF SAMPLES

8.1. In general, allow as short a time as possible to elapse between the collection of a sample and its analysis. Under some conditions, analysis in the field is necessary to secure reliable results. The actual time that may be allowed to intervene between the collection and analysis of a sample varies with the type of examination to be conducted, the character of the sample, and the time interval allowable for applying corrective treatment.

8.2. On the statement of an analysis, specify the length of time elapsed between collection and analysis of the sample.

8.3. Make the determination of dissolved gases, such as oxygen, hydrogen sulfide, and carbon dioxide, at the source, except that in some cases such constituents may be fixed and determined later as specified in the specific test methods.

8.4. When sampling for radioactivity determinations, note the exact time of sample collection. If short-lived activity is of interest, analysis should be made as rapidly as practical to minimize loss of activity by radioactive decay. If only long-lived activity is of interest, measurement of the radioactivity sometimes can be simplified by allowing sufficient time before analysis for the decay of the short-lived radionuclides.

9. LABELING AND TRANSPORTATION OF SAMPLES

9.1. Provide space for the following information on an etched area of the bottle, a gummed label, or a cardboard or linen tag securely affixed to the container:

- Sample number,
- Date and time of sampling,
- Source of sample,
- Point of sampling (designated in sufficient detail to enable anyone to collect a second sample from the identical spot from which the first sample was taken),
- Temperature and rate of flow of the fluid in the equipment from which the sample was taken,
- Temperature of sample,
- Type and quantity of preservative added,
- Results of field tests made on the sample, and
- Signature of sampler.

9.2. Fix the stoppers closing the sample containers in place by wire, tape, or cord to prevent leakage in transit. The sample containers shall be of such size that when filled with the desired amount of sample, space roughly equivalent to 1 percent of the volumetric capacity of the containers will be available for expansion of the liquid. Exceptions to this are for those constituents noted in Section 8.3.

9.3. The sample shipping container shall be a case (wood preferred) having a separate compartment for each sample container. Line the compartment around each sample container with corrugated paper, felt, or similar material; or hold the sample containers in place with spring clips, sawdust, excelsior, foamed plastic, or similar material. Use insulated containers for quick-frozen samples, usually shipped with solid carbon dioxide to maintain the sample in frozen condition.

9.4. Print the addresses of consignee and consignor plainly upon two sides of the outer container, or attach firmly thereon by cards or labels. Attach warning and descriptive labels to the outer container such as “Fragile,” “Liquid,” “Glass,” “Handle With Care,” “This Side Up,” etc., when applicable. In cold weather, attach the label “Keep from Freezing” to the outer container, except for those samples that are intentionally frozen.

Standard Specification for

Corrugated Sheet Steel Beams for Highway Guardrail

AASHTO Designation: M 180-00 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Corrugated Sheet Steel Beams for Highway Guardrail

AASHTO Designation: M 180-00 (2008)

1. SCOPE

1.1 This specification covers corrugated sheet steel prepared for use as beams in highway guardrails.

1.2 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 120, Zinc
- M 232M/M 232, Zinc Coating (Hot-Dip) on Iron and Steel Hardware
- M 291M, Carbon and Alloy Steel Nuts [Metric] (Discontinued)
- M 298, Coatings of Zinc Mechanically Deposited on Iron and Steel
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

2.2 *ASTM Standards*:

- A 307, Standard Specification for Carbon Steel Bolts and Studs, 60 000 PSI Tensile Strength
- A 653/A 653M, Standard Specification for Steel Sheet, Zinc-Coated (Galvanized) or Zinc-Iron Alloy-Coated (Galvannealed) by the Hot-Dip Process
- E 376, Standard Practice for Measuring Coating Thickness by Magnetic-Field or Eddy-Current (Electromagnetic) Examination Methods
- F 568M, Standard Specification for Carbon and Alloy Steel Externally Threaded Metric Fasteners

2.3 *ANSI Standards*:

- B1.13M, Metric Screw Threads D M Profile
- B18.2.4.1M, Hex Nuts, Style 1, Metric
- B18.2.4.6M, Hex Nuts, Heavy, Metric

2.4 *Military Standard*:

- DOD-P-21035, Paint, High Zinc Dust Content, Galvanizing Repair (Metric)

3. CLASSIFICATION

3.1 Four types and two classes of guardrail are provided as follows:

3.1.1 *Types*:

Type I—Zinc coated, 550 g/m^2 (1.80 oz/ft^2) minimum single-spot.

Type II—Zinc coated, 1100 g/m^2 (3.60 oz/ft^2) minimum single-spot.

Type III—Beams to be painted.

Type IV—Beams of corrosion resistant steel.

3.1.2 *Classes*:

Class A—Base metal nominal thickness—2.67 mm (0.105 in.).

Class B—Base metal nominal thickness—3.43 mm (0.135 in.).

4. ORDERING INFORMATION

4.1 Orders for guardrail under this specification shall include the following information, as required, to adequately describe the desired material:

4.1.1 Quantity (linear meter or number of pieces),

4.1.2 Class of Guardrail,

4.1.3 Type of Guardrail,

4.1.4 Effective length of beam section 3.8 or 7.6 m (12.5 ft or 25.0 ft),

4.1.5 Shape (W-Beam or Thrie Beam), and

4.1.6 Exceptions to this specification or special requirements, if any.

5. BASIS OF ACCEPTANCE

5.1 All material shall be subject to inspection and sampling at the fabricating plant, warehouse, or after delivery to the site of construction.

5.2 *Acceptance by Sampling*:

5.2.1 The engineer may take one piece of guardrail, a backup plate, and end or buffer section from each 200 pieces in a lot, or from each lot if less than 200 pieces are included therein, for determination of compliance with specification requirements. If one piece fails to meet the requirements, two other pieces shall be tested. If either of these pieces fails to conform to the requirements of this specification, the lot of material represented by these samples shall be rejected. A lot shall be considered that quantity of material offered for inspection at one time which bears the same heat and coating identification.

5.3 *Acceptance by Brand Registration and Guarantee*:

5.3.1 By mutual agreement between the fabricator and engineer, acceptance may be based upon a brand registration and guarantee filed with the engineer by the fabricator. For acceptance of a brand, the fabricator shall furnish a brand registration and guarantee meeting the approval of the engineer and showing the brand name or designation, the manner in which it will appear on the fabricated beams, the typical mechanical properties, chemical composition if specified, the class and type of guardrail, and other specified properties. The fabricator shall also guarantee that as long as material is furnished under that brand and designation, it will conform fully to the requirements of the specification and shall be replaced without cost to the engineer when found not in conformity with any of the specified requirements. The brand registration and guarantee shall be sworn to for the fabricator by a person having legal authority to bind the company. Upon approval of a brand registration and guarantee, that brand will be accepted without further certification. If, in subsequent actual field use, there is evidence of misbranding as determined by random sampling and detection of inadequate tensile strength, yield strength, elongation, improper coating, deficient thickness, or improper fabrication, the material will be rejected and approval for further use withdrawn until subsequently reapproved. Samples for test of any material offered for use may be taken at any time deemed desirable by the engineer.

5.3.2 The manufacturer or fabricator shall make such tests and measurements as necessary to insure that the material produced complies with all specification requirements. These tests and measurements shall be so identified by the identification symbols or code used on the beam that the manufacturer can produce specific reports showing these test results. Copies of reports of these tests shall be kept on file and shall be submitted to the engineer upon request.

5.3.3 The brand shall be removed or obliterated by the manufacturer or fabricator on all material where control tests, as outlined herein, do not show conformance to this specification.

6. MATERIALS

6.1 *Base Metal*—The beam, transition, end, and buffer sections shall consist of sheet made of open hearth, electric furnace, or basic oxygen steel and shall meet the mechanical properties specified in Section 8. The chemical composition of the base metal for Type IV beams shall be as approved by the engineer.

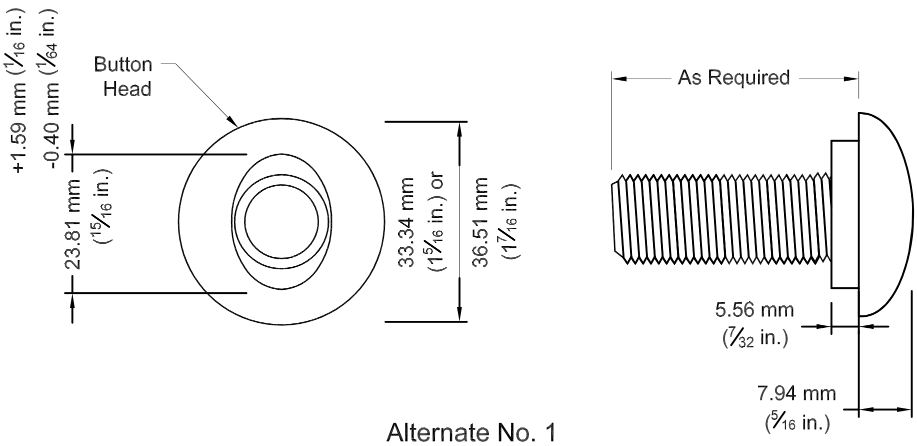
6.2 *Zinc*—The zinc used for the coating of Type I and II sections shall be as prescribed in M 120, and shall be at least equal to the grade designated as “Prime Western.”

6.3 *Bolts and Nuts*:

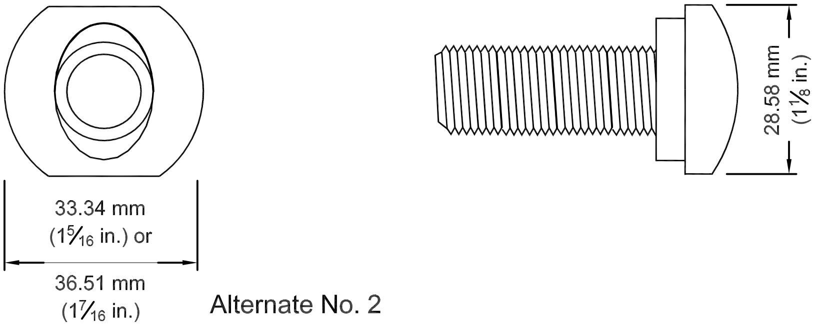
6.3.1 Unless otherwise specified, bolts and nuts for Types I, II, and III beams shall conform to or exceed the requirements of ASTM A 307 and shall be coated in accordance with Section 9.4.

6.3.2 Bolts and nuts for Type IV beams shall be of an approved corrosion resistant material and conform to or exceed the requirements of ASTM A 307.

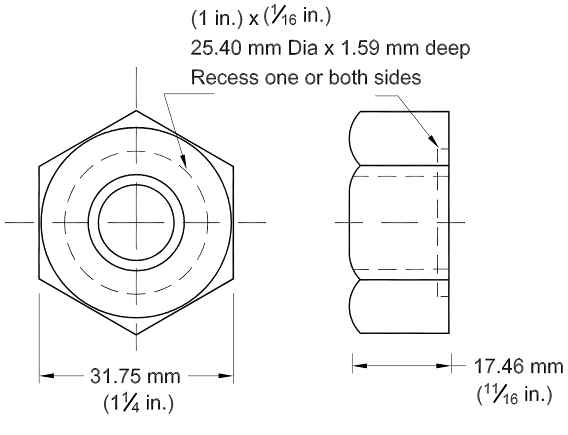
6.3.3 All connections or splices shall be formed with oval shoulder button headed bolts to minimize projections on the roadside of the guardrail. Splice and post bolts and nuts shall conform to one of the configurations shown in Figure 1 or Figure 2. Either of the alternate configurations may be furnished unless otherwise specified by the engineer.



Alternate No. 1

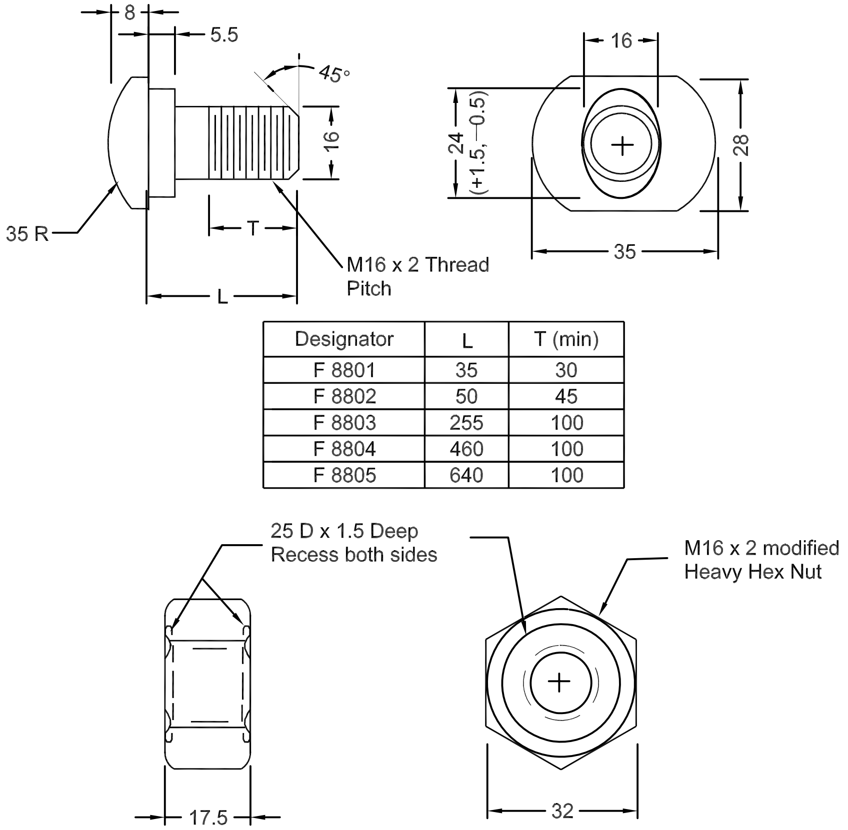


Alternate No. 2



Note: Oval shoulder shall have smooth radii and shall maintain an essentially full vertical height of the apex of the oval.
All dimensions shown on Alternate Bolt No. 1 also apply to Alternate Bolt No. 2. All dimensions are subject to manufacturer's tolerances except where allowable tolerances are shown.

Figure 1—15.88-mm ($^5/_8$-in.) Post or Splice Bolt and Nut



Designator	L	T (min)
F 8801	35	30
F 8802	50	45
F 8803	255	100
F 8804	460	100
F 8805	640	100

Notes:

1. The bolt shall have M16 × 2 threads as defined in ANSI B1.13M for Grade 6 g tolerances. Bolt material shall conform to ASTM F 568M for Class 4.6. Material for corrosion resistant bolts shall conform to ASTM F 568M for Class 8.8.3 bolts.
2. Nuts shall have ANSI B1.13M M16 × 2 Grade 6H threads. The geometry of the nuts, with the exception of the recess shown in the drawing, shall conform to ANSI B 18.2.4.1M Style 1 for zinc-coated hex nuts and ANSI B18.2.4.6M heavy hex corrosion resistant nuts shall conform to the requirements of M 291M for Class 8S3. Zinc-coated nuts shall be tapped over-size as specified in M 291M, except that a diametrical allowance of 510 mm shall be used instead of 420 mm.
3. Dimensional tolerances not shown or implied are intended to be those consistent with the proper functioning of the part, including its appearance and accepted manufacturing practices.

Figure 2—16-mm Post or Splice Metric Bolt and Nut

6.4 *Washers and Backup Plates*:

6.4.1 Washers shall be rectangular as shown in Figure 3. Washers for Types I, II, and III beams shall be galvanized in accordance with Section 9. Washers for Type IV beams shall be of an approved corrosion resistant steel. Back-up plates if specified for use at non-splice points shall consist of 305-mm (1-ft) sections of beams and shall be of the same Class and Type specified for the full-length beams.

6.5 *End or Buffer Sections*:

6.5.1 End or buffer sections shall be of the same or greater thickness of metal and the same type as the beam to which it is attached, or the engineer may specify the minimum thickness of metal and type.

7. MANUFACTURE

7.1 The beams and end or buffer sections shall be shaped and punched in conformance with the requirements shown in Figures 3 and 4. Transition sections shall be fabricated in accordance with Figure 5 and shall provide a smooth and uniform transition between beams. They shall be ready for assembly when delivered. Only drilling or cutting necessary for special connections and for sampling will be permitted in the field. Warped or deformed beams will be rejected. Beams to be erected on a radius of 46 m (150 ft) or less shall be shop curved to the appropriate curvature of the installation.

8. MECHANICAL PROPERTIES

8.1 The mechanical properties of the base metal shall conform to the following requirements:

8.1.1 *Beams and transition sections*:

- Yield Point, minimum, 345 MPa (50000 psi);
- Tensile Strength, minimum 483 MPa (70000 psi); and
- Elongation, in 50 mm (2 in.), minimum, 12 percent.

8.1.2 *End and buffer sections*:

- Yield Point, minimum, 227 MPa (33000 psi); and
- Tensile Strength, minimum 310 MPa (45000 psi).

8.1.3 Test specimens for mechanical properties shall be prepared and tested as specified in ASTM A 653 except that correction for thickness of zinc-coated specimens shall be 0.08 mm (0.003 in.) for Type I beam and 0.15 mm (0.006 in.) for Type II beam.

9. COATING REQUIREMENTS

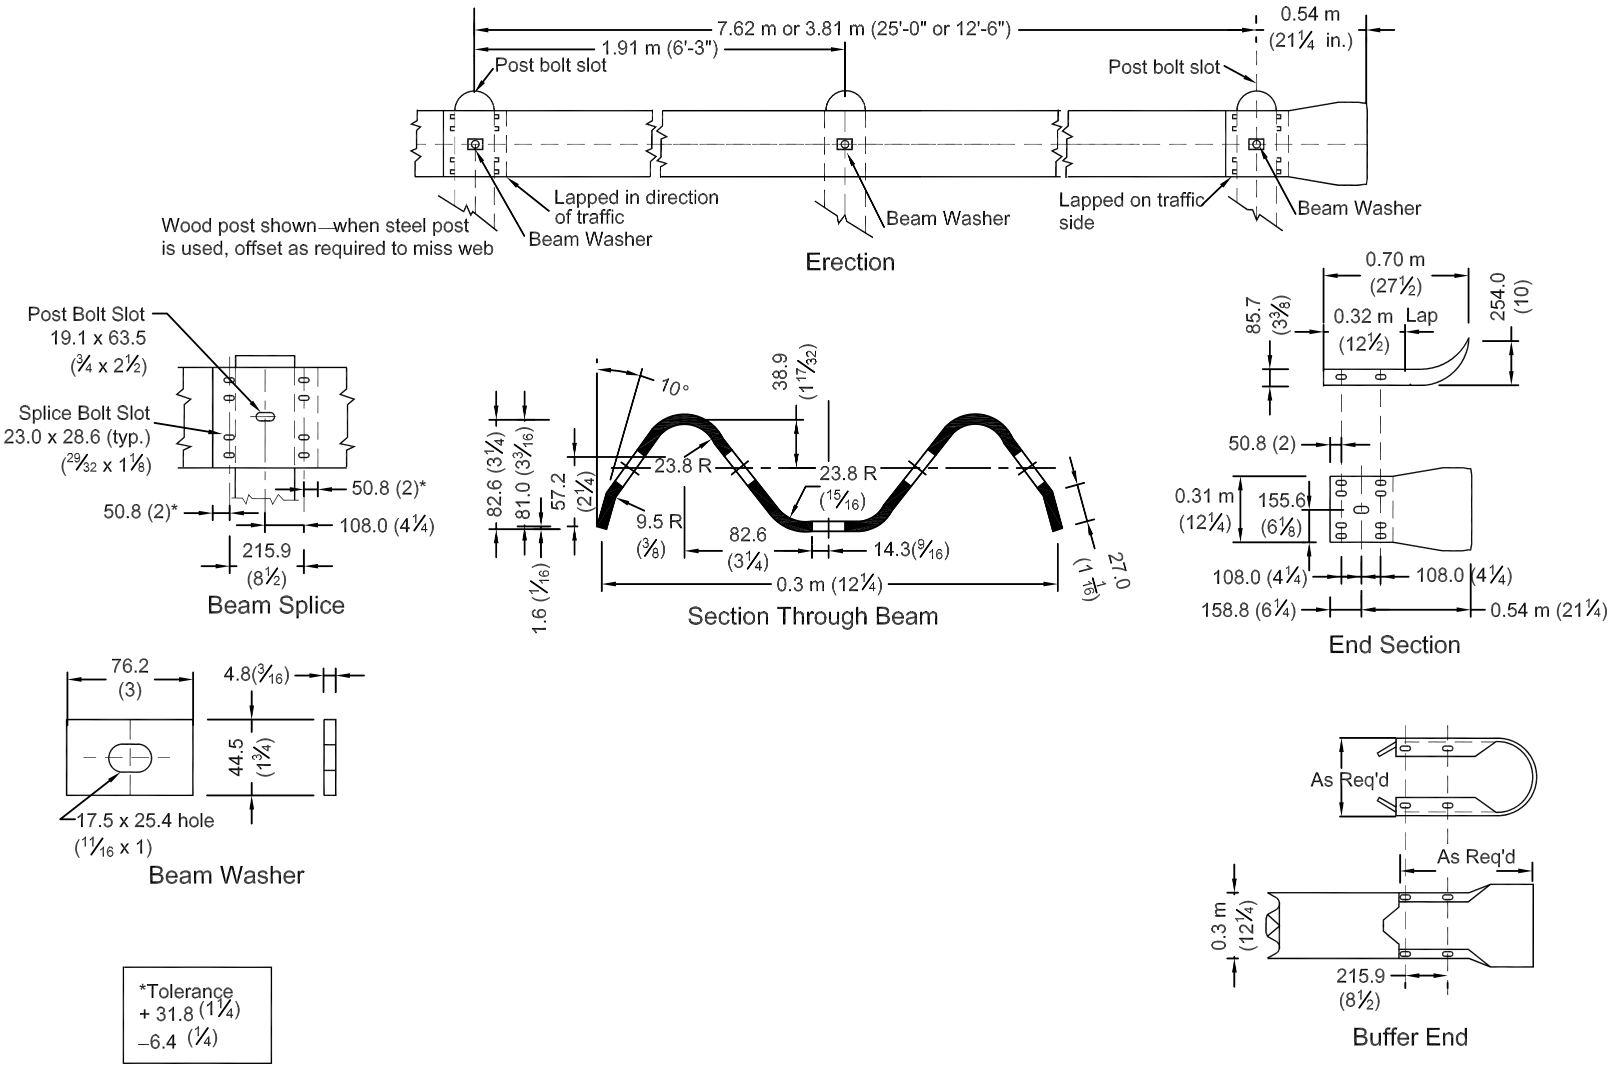
9.1 *Type I and II Beams*:

9.1.1 The beams may be galvanized before or after fabrication.

9.1.2 The mass of coating shall conform to the requirements prescribed in Table 1 for the types specified. The mass of coating is the total amount of galvanizing on both sides of a sheet or beam, expressed as grams per square meter (oz/ft^2) of sheet.

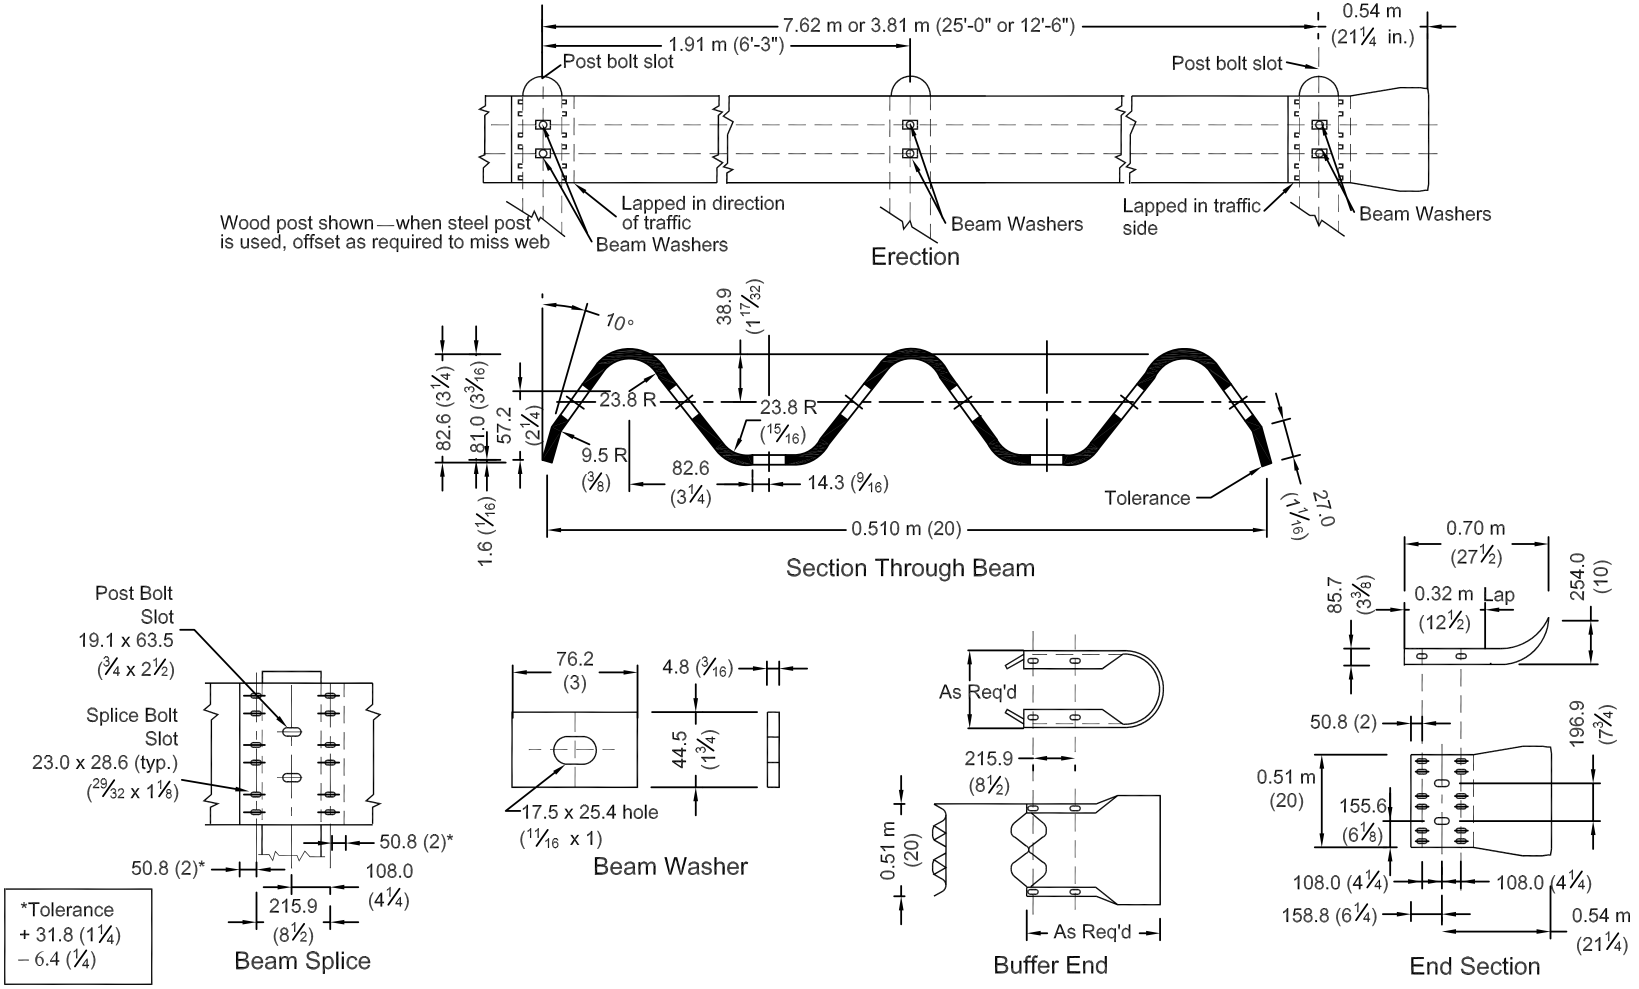
Table 1—Weight of Coating

	Weight of Coating			
	Min Check Limit Single-Spot Test		Min Check Limit Triple-Spot Test	
Type	g/m^2	oz/ft^3	g/m^2	oz/ft^2
I	550	1.80	610	2.00
II	1100	3.60	1220	4.00



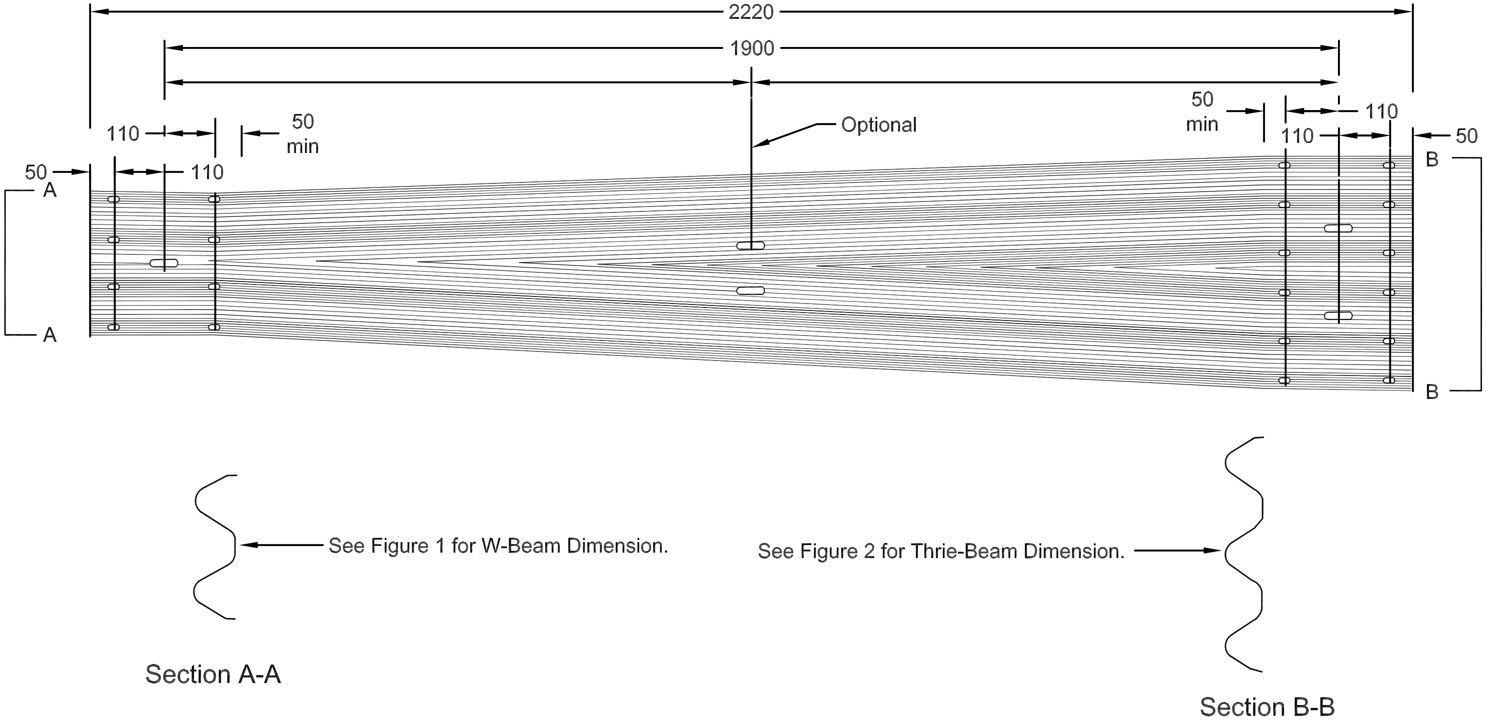
Notes:
1. All dimensions are subject to manufacturer’s tolerances except where allowable tolerances are shown.
2. All dimensions shown in millimeters unless otherwise noted. (All parenthetical values are in inches unless otherwise noted.)
3. Rectangular plate washers are optional only in the transition sections. They are not to be used in the main sections of strong-post guardrail.

Figure 3—W-Beam



Notes:
1. All dimensions are subject to manufacturer's tolerances except where allowable tolerances are shown.
2. All dimensions shown in millimeters unless otherwise noted. (All parenthetical values are in inches unless otherwise noted.)
3. Rectangular plate washers are optional only in the transition sections. They are not to be used in the main sections of strong-post guardrail.

Figure 4—Thrie Beam



Note: All dimensions are in millimeters.

Figure 5—Transition Section

9.1.3 The sheets or beams shall be of prime finish, that is, free from injurious defects such as blisters, flux, and uncoated spots. Uncoated edges resulting from transverse shearing or punching of holes will not be considered objectionable.

9.1.4 The coating shall be smooth, free of beading or sharp projections along the edges, and shall adhere tenaciously to the surface of the metal. The adherence of the zinc coating to the surface of the base metal shall be determined by cutting or prying with a stout knife, applied with considerable pressure in a manner tending to remove a portion of the coating by paring or whittling, and it shall not be possible to peel any portion of the coating so as to expose the base metal.

9.1.5 The test specimen size and method of tests for determining the mass of coating shall be as prescribed in T 65. At the option of the engineer, material may be accepted on the basis of magnetic gauge determinations made in accordance with ASTM E 376.

9.2 *Type III Beams*:

9.2.1 Beams that are to be painted shall be cleaned and shop painted with one coat of rust-inhibitive primer. The primer shall have a tough and durable surface and shall be thoroughly dry before the sheets are handled or packed for shipment.

9.3 *Type IV Beams*:

9.3.1 Beams of corrosion resistant steel shall not be painted or galvanized. They shall be so handled and stored that the traffic face of these beams, used in a continuous run of guardrail, shall not show a distinctive color differential.

9.4 *Bolts and Nuts*:

9.4.1 Bolts and nuts shall be hot-dip zinc coated in accordance with the requirements of M 232M/M 232, Class C or mechanically zinc coated in accordance with M 298, Class 50, Type 1.

9.5 *Washers*:

9.5.1 Washers shall be hot-dip zinc coated in accordance with the requirements of M 232M/M 232.

9.6 *Galvanizing Repair*:

9.6.1 Where the galvanizing on guardrail or fittings has been damaged, the coating shall be repaired by regalvanizing, or the surface repaired by painting with two coats of zinc dust/zinc oxide paint conforming to Federal Specification TT-P-641 or DOD-P-21035.

10. DIMENSIONS

10.1 *Sheet or Beam Thickness*:

10.1.1 The nominal thickness for the finished beam or sheet shall conform to the requirements as prescribed in Table 2.

Table 2—Beam or Sheet Thickness

	Beam or Sheet Thickness							
	Class A				Class B			
	Thickness		Tolerance Under Specified Thickness, No Limit for Over Thickness		Thickness		Tolerance Under Specified Thickness, No Limit for Over Thickness	
Type	mm	in.	mm	in.	mm	in.	mm	in.
I	2.74	0.108	0.23	0.009	3.51	0.138	0.25	0.010
II	2.82	0.111	0.23	0.009	3.58	0.141	0.25	0.010
III	2.67	0.105	0.23	0.009	3.43	0.135	0.25	0.010
IV	2.67	0.105	0.23	0.009	3.43	0.135	0.25	0.010

10.1.2 For fabricated beams, thickness measurements will be made on tangent portions of the cross section.

10.2 *Sheet Width*:

10.2.1 The beam elements shall be formed from sheets having nominal widths of 483 mm (19 in.) for W-beams and 749 mm ($29^1/_2$ in.) for thrie beams. Tolerance from the nominal width of minus 3.2 mm ($^1/_8$ in.) will be permissible.

Note 1—The requirements of Section 10.2.1 are intended to define the minimum width sheet permissible. Calculation of exact width dimensions from Figures 3 and 4 shows that the finished product may slightly exceed these widths. However, the dimensions of Figures 3 and 4 can be met within allowable tolerance by using the nominal widths. Use of sheets slightly greater than the nominal widths is permissible provided the tolerances in Figures 3 and 4 are met.

11. MARKING

11.1 Each beam element shall be identified by the following:

- Name or brand of manufacturer,
- Identification symbols or code for heat,
- Number and coating lot,
- AASHTO specification number, and
- Class and type.

11.2 Markings shall not be placed at such a location that they will be obscured after erection, or in a manner that the brand will be conspicuous to any traffic. Markings placed on the traffic face of the beam shall be placed in the valley of the center corrugation and shall be die imprinted with letters and numerals having a maximum height of 32 mm ($1^1/_4$ in.) and a minimum height of 19 mm ($^3/_4$ in.) and shall be clearly legible after galvanization of the rail elements.

11.3 Marking material shall be such as to resist obliteration during storage, transportation, and erection.

11.4 Markings for end sections and backup plates may be on durable tags securely attached to each section or bundle, except that when specified by the engineer, each individual piece shall be marked.

Standard Specification for

Chain-Link Fence

AASHTO Designation: M 181-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Chain-Link Fence

AASHTO Designation: M 181-10

1. SCOPE

1.1 This specification covers materials used in the construction of fences and gates that comprise (a) chain-link fence fabric and (b) posts, rails, ties, bands, bars, rods and other fittings, and hardware designed to support the fabric in a vertical, taut position.

1.2 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 111M/M 111, Zinc (Hot-Dip Galvanized) Coatings on Iron and Steel Products
- M 120, Zinc
- M 232M/M 232, Zinc Coating (Hot-Dip) on Iron and Steel Hardware
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings
- T 68M/T 68, Tension Testing of Metallic Materials (Discontinued)
- T 213M/T 213, Mass [Weight] of Coating on Aluminum-Coated Iron or Steel Articles

2.2 *ASTM Standards*:

- B 26, Standard Specification for Aluminum-Alloy Sand Castings
- B 85, Standard Specification for Aluminum-Alloy Die Castings
- B 108, Standard Specification for Aluminum-Alloy Permanent Mold Castings
- B 117, Standard Practice for Operating Salt Spray (Fog) Apparatus
- B 209, Standard Specification for Aluminum and Aluminum-Alloy Sheet and Plate
- B 211, Standard Specification for Aluminum and Aluminum-Alloy Bar, Rod, and Wire
- B 221, Standard Specification for Aluminum and Aluminum-Alloy Extruded Bars, Rods, Wire, Profiles, and Tubes
- B 429, Standard Specification for Aluminum-Alloy Extruded Structural Pipe and Tube
- B 750, Standard Specification for GALFAN (Zinc-5 % Aluminum-Mischmetal) Alloy in Ingot Form for Hot-Dip Coatings
- D 1535, Standard Practice for Specifying Color by the Munsell System
- D 1729, Standard Practice for Visual Appraisal of Colors and Color Differences of Diffusely-Illuminated Opaque Materials
- D 2247, Standard Practice for Testing Water Resistance of Coatings in 100% Relative Humidity
- E 376, Standard Practice for Measuring Coating Thickness by Magnetic-Field or Eddy-Current (Electromagnetic) Examination Methods
- F 467, Standard Specification for Nonferrous Nuts for General Use

- F 468, Standard Specification for Nonferrous Bolts, Hex Cap Screws, and Studs for General Use
- F 668, Standard Specification for Polyvinyl Chloride (PVC) and Other Organic Polymer-Coated Steel Chain-Link Fence Fabric
- F 1043, Standard Specification for Strength and Protective Coatings on Steel Industrial Chain Link Fence Framework
- F 1083, Standard Specification for Pipe, Steel, Hot-Dipped Zinc-Coated (Galvanized) Welded, for Fence Structures
- F 1664, Standard Specification for Poly(Vinyl Chloride) (PVC) and Other Conforming Organic Polymer-Coated Steel Tension Wire Used with Chain-Link Fence
- G 152, Standard Practice for Operating Open Flame Carbon Arc Light Apparatus for Exposure of Nonmetallic Materials
- G 155, Standard Practice for Operating Xenon Arc Light Apparatus for Exposure of Non-Metallic Materials

2.3 *ANSI Standard*:

- H35.2, Dimensional Tolerances for Aluminum Mill Products

3. CLASSIFICATION

3.1 Chain-link fabric, posts, rails, ties, bands, bars, rods and other fittings, and hardware covered by this specification shall be composed of the following types of material, as specified:

- *Type I*—Zinc-coated steel,
- *Type II*—Aluminum-coated steel,
- *Type III*—Aluminum alloy, and
- *Type IV*—Polyvinyl Chloride (PVC) and other organic polymer-coated steel.

3.1.1 Zinc-5 Percent Aluminum-Mischmetal alloy meeting the requirements of ASTM B 750 may be substituted for zinc coating (hot-dipped) at the application rate specified herein for hot-dip zinc coating.

3.2 *Metallic-coated steel posts, rails, or gate frames are furnished in two grades as follows*:

3.2.1 *Grade 1*—Steel posts, rails, or gate frames may be round or other shapes and shall have a hot-dip zinc interior and exterior coating meeting the requirements of ASTM F 1083 and shall have a hot-dip zinc interior and exterior coating as prescribed in this specification.

3.2.2 *Grade 2*—Steel posts, rails, or gate frames shall be round pipe or tubing manufactured by electric resistance welding and shall have an exterior coating of hot-dip zinc plus an organic topcoat and a zinc-rich or hot-dip zinc interior coating conforming to the requirements of ASTM F 1043 Group IC.

3.3 *Type IV fabric is furnished in two classes of coating as follows*:

3.3.1 *Class A*—Fabric with polymer-coated wire made by coating the wire with zinc by either the hot-dip or electrolytic process, prior to the wire being coated with either an extruded polymer coating or an extruded and bonded polymer coating.

3.3.2 *Class B*—Fabric with bonded polymer-coated wire shall be made with wire coated with zinc by the hot-dip or electrolytic process, prior to having a polymer coating thermally fused and bonded to a primer that has been thermally cured onto the zinc-coated wire.

3.4 *Type I fabric is furnished in two classes of coating as follows*:

3.4.1 *Class C*—Fabric has a specified coating mass of 366 g/m^2 (1.2 oz/ft^2), and

3.4.2 *Class D*—Fabric has a specified coating mass of 610 g/m^2 (2.0 oz/ft^2).

3.5 Type I tension wire is furnished in three classes as follows:

3.5.1 *Class 1*—Wire has a minimum coating mass of 244 g/m^2 (0.8 oz/ft^2),

3.5.2 *Class 2*—Wire has a minimum coating mass of 366 g/m^2 (1.2 oz/ft^2), and

3.5.3 *Class 3*—Wire has a minimum coating mass of 610 g/m^2 (2.0 oz/ft^2).

3.6 The type of fabric and type of framework need not be the same.

4. DESCRIPTION OF TERMS

4.1 Unless the context clearly indicates another meaning, the terms used herein shall have the meaning as defined in Section 101, Definitions and Terms, *Guide Specifications for Highway Construction*, AASHTO (1998) or as amended.

4.2 *chain-link fence fabric*—a fencing material made from wire helically wound and interwoven in such a manner as to provide a continuous mesh without knots or ties except in the form of knuckling or of twisting to form the selvage of the fabric.

4.3 *knuckling*—the selvage obtained by interlocking adjacent pairs of wire ends and bending the wire back into a loop.

4.4 *twisting*—the type of selvage obtained by twisting adjacent pairs of wire ends together in a close helix of 1.5 machine turns, which is the equivalent to three full twists and cutting the wire end at an angle. The wire ends beyond the twist shall be at least 6.4 mm ($^1/_4$ in.) long.

5. ORDERING INFORMATION

5.1 Orders for chain-link fence fabric purchased to this specification shall include the following information:

5.1.1 Quantity of fabric (Section 17);

5.1.2 Number of gates;

5.1.3 Type (Section 3) and if applicable, grade or class;

5.1.4 Size of mesh;

5.1.5 Size of wire;

5.1.6 Height of fabric;

5.1.7 Diamond count, if specified;

5.1.8 Type of selvage, if nonstandard;

5.1.9 For Type IV fabric, the class of polymer coating, and for Class A fabric whether an extruded coating or an extruded and bonded coating is required;

5.1.10 Color, if applicable;

5.1.11 Type and class of tension wire;

5.1.12 Type, grade, size, shape, and number of or spacing of posts, rails, rods, and other fittings;

5.1.13 Certification, if required;

5.1.14 AASHTO Designation and date of issue; and

5.1.15 Exceptions to this specification, or special requirements, if any.

Note 1—These details may be covered in whole, or in part, by accompanying the order with design drawings and notations thereon.

CHAIN-LINK FENCE FABRIC

6. MATERIALS (FABRIC)

6.1 Base metal for Type I, II, and IV chain-link fence fabric shall be steel of such quality and purity that, when drawn to the size of wire specified and coated as specified, the finished fabric shall be of uniform quality and have the properties and characteristics as prescribed in this specification.

6.2 Wire used for the manufacture of fabric that is zinc-coated, aluminum-coated, or polymer-coated before weaving shall meet the requirements of this specification and shall be capable of being woven into fabric without the coating cracking, flaking, or peeling to such an extent that any of the coating material can be removed by rubbing with the bare fingers.

Note 2—Loosening or detachment during the adhesion test of superficial, small particles of zinc, aluminum, or polymer formed by mechanical polishing of the surface of the coated wire should not be considered cause for rejection.

6.3 Zinc used for hot-dip galvanized or electrolytically zinc-plated coatings shall be of any grade of zinc conforming to the requirements of M 120.

6.4 Ingot or pig aluminum used for coating shall conform to the following impurity limits:

- Copper, max, percent 0.10
- Iron, max, percent 0.50

6.5 Polymer coatings shall be formulated to conform to the requirements of this specification. These coatings shall be either ultraviolet resistant, or shall contain a UV inhibitor.

6.6 Type III chain-link fence fabric shall be made of aluminum alloy wire meeting the requirements of ASTM B 211, alloy 6061-T89 or T94. The finished fabric shall be of uniform quality and have the properties and characteristics as prescribed in this specification.

7. MANUFACTURE (FABRIC)

7.1 Wire used for zinc-coated, chain-link fence may be coated before or after weaving into fabric. Fabric that is zinc-coated after weaving shall be hot-dip galvanized in a continuous process and the coating shall not be applied to the fabric in roll form. Wire that is zinc-coated before weaving into fabric may be either electrolytically zinc-plated or hot-dip galvanized.

7.2 Wire used for aluminum-coated steel, chain-link fabric shall be coated before weaving into fabric.

7.3 Wire used for polymer-coated chain-link fence shall be coated before weaving into fabric.

8. WEAVE (FABRIC)

8.1 The wire shall be woven throughout in the form of approximately uniform square mesh, having parallel sides and horizontal and vertical diagonals of approximately uniform dimensions. The top and bottom of the fabric shall be knuckled or twisted as specified in Section 13.

8.2 A typical diamond count for each standard height is shown in Tables 1 and 2. Other diamond counts are permissible provided they are consistent within a lot. The purchaser has the option to specify the diamond count in the order, Section 5.1.7.

Table 1—Typical Diamond Counts (mm)

Specified Diameter of Types I, II, and III Coated Wire and Type IV's Metallic-Coated Core Wire, mm	Mesh Size, mm	Diamond Count Fabric Height, mm[a]									
		914.4	1066.8	1219.2	1524	1828.8	2133.6	2438.4	2743.2	3048	3657.6
4.88	50.8	266.7	317.5	342.9	444.5	520.7	622.3	698.5	800.1	876.3	1054.1
3.76	50.8	266.7	317.5	342.9	444.5	520.7	622.3	698.5	800.1	876.3	1054.1
3.05	50.8	266.7	317.5	342.9	444.5	520.7	622.3	—	—	—	—
3.05	44.4	—	—	—	—	—	—	800.1	901.7	1003.3	1206.5

[a] Diamond count not available for 25.4-mm mesh size.

Table 2—Typical Diamond Counts (in.)

Specified Diameter of Types I, II, and III Coated Wire and Type IV's Metallic-Coated Core Wire, in.	Mesh Size, in.	Diamond Count Fabric Height, in.[a]									
		36	42	48	60	72	84	96	108	120	144
0.192	2	$10^{1}/_{2}$	$12^{1}/_{2}$	$13^{1}/_{2}$	$17^{1}/_{2}$	$20^{1}/_{2}$	$24^{1}/_{2}$	$27^{1}/_{2}$	$31^{1}/_{2}$	$34^{1}/_{2}$	$41^{1}/_{2}$
0.148	2	$10^{1}/_{2}$	$12^{1}/_{2}$	$13^{1}/_{2}$	$17^{1}/_{2}$	$20^{1}/_{2}$	$24^{1}/_{2}$	$27^{1}/_{2}$	$31^{1}/_{2}$	$34^{1}/_{2}$	$41^{1}/_{2}$
0.120	2	$10^{1}/_{2}$	$12^{1}/_{2}$	$13^{1}/_{2}$	$17^{1}/_{2}$	$20^{1}/_{2}$	$24^{1}/_{2}$	—	—	—	—
0.120	$1^{3}/_{4}$	—	—	—	—	—	—	$31^{1}/_{2}$	$35^{1}/_{2}$	$39^{1}/_{2}$	$47^{1}/_{2}$

[a] Diamond count not available for 1-in. mesh size.

9. SIZE OF MESH (FABRIC)

9.1 The size of mesh shall be as indicated in Tables 3 and 4. The permissible variation from the specified size of mesh shall be ±3.2 mm (±$^1/_8$ in.).

Table 3—Size of Wire and Mesh (mm)

Specified Diameter of Types I, II, and III Coated Wire and Type IV's Metallic-Coated Core Wire		Size of Mesh,	Height of Fabric,
mm	Gauge	mm	mm
4.88	6	50.8	914.4, 1066.8, 1219.2, 1524, 1828.8, 2133.6, 2438.4, 2743.2, 3048, 3657.6
3.76	9	50.8	914.4, 1066.8, 1219.2, 1524, 1828.8, 2133.6, 2438.4, 2743.2, 3048, 3657.6
3.05	11	50.8	914.4, 1066.8, 1219.2, 1524, 1828.8, 2133.6
3.05	11	44.4	2438.4, 2743.2, 3048, 3657.6
3.76	9	25.4	914.4, 1066.8, 1219.2, 1524, 1828.8, 2133.6
3.05	11	25.4	914.4, 1066.8, 1219.2, 1524, 1828.8, 2133.6

Table 4—Size of Wire and Mesh (in.)

Specified Diameter of Types I, II, and III Coated Wire and Type IV's Metallic-Coated Core Wire		Size of Mesh,	Height of Fabric,
in.	Gauge	in.	in.
0.192	6	2	36, 42, 48, 60, 72, 84, 96, 108, 120, 144
0.148	9	2	36, 42, 48, 60, 72, 84, 96, 108, 120, 144
0.120	11	2	36, 42, 48, 60, 72, 84,
0.120	11	1$^3/_4$	96, 108, 120, 144
0.148	9	1	36, 42, 48, 60, 72, 84
0.120	11	1	36, 42, 48, 60, 72, 84

9.2 The size of mesh shall be determined by measuring the minimum clear distance between the wires forming the parallel sides of the mesh.

10. BREAKING STRENGTH (FABRIC)

10.1 Wire constituting the fabric shall meet the minimum breaking strength shown in Tables 5 and 6 when tested in accordance with T 68. Specimens to establish conformance to this requirement shall be individual pickets from a section of the fence fabric, sampled in accordance with Section 18. The specimens shall be of sufficient length so as to be firmly gripped in the testing machine after straightening. The actual gauge length (distance between jaws) of the specimen shall be limited to the undeformed length of wire between the two adjacent straightened bends.

Table 5—Breaking Loads (mm and kN)

Specified Diameter of Types I, II, and III Coated Wire and Type IV's Metallic-Coated Core Wire		Breaking Loads		
mm	Gauge	Type I or II, kN	Type III, kN	Type IV[a] Core Wire, kN
4.88	6	9.650	6.940	9.655
3.76	9	5.740	4.135	5.740
3.05	11	3.780	2.715	3.780

[a] Polymer coating may be mechanically removed prior to testing, if desired.

Table 6—Breaking Loads (in. and lbf)

Specified Diameter of Types I, II, and III Coated Wire and Type IV's Metallic-Coated Core Wire		Breaking Loads		
in.	Gauge	Type I or II, lbf	Type III, lbf	Type IV[a] Core Wire, lbf
0.192	6	2170	1560	2170
0.148	9	1290	930	1290
0.120	11	850	610	850

[a] Polymer coating may be mechanically removed prior to testing, if desired.

11. SIZE OF WIRE (FABRIC)

11.1 Chain-link fabric shall be fabricated from wire diameters as necessary to meet the requirements of Tables 3 and 4. The diameter of the wire shall be determined as the average of two readings taken at right angles to each other on the straight portion of the parallel sides of the mesh and measured to the nearest 0.02 mm (0.001 in.). The permissible variation from the specified diameter of the wire shall be ±0.13 mm (±0.005 in.) (see Note 3).

11.2 For Type I or II fabric, the specified diameter is the coated wire diameter. Measurements shall be made on the coated wire and allowed tolerance applied to the coated diameter.

11.3 For Type IV fabric, the specified diameter is the metallic-coated core wire diameter, and the polymer coating shall not be used when determining wire size. The allowed tolerance (see Section 11.1) shall be applied to the metallic-coated core wire diameter.

11.4 For Type III fabric, the specified diameter is the finished wire diameter.

Note 3—On metallic-coated wire, the tolerances apply to uniform areas of coated wire. Irregular deposits of coating shall be ignored.

12. HEIGHT OF FABRIC (FABRIC)

12.1 Chain-link fabric shall be furnished in the standard heights shown in Tables 3 and 4. The height of fabric shall be the overall dimension from ends of twists or knuckles. Permissible variation from the specified height shall be ±25.4 mm (±1 in.) for standard selvage.

13. SELVAGE (FABRIC)

13.1 Fabric with 50.8-mm (2-in.) mesh, and less than 1.8 mm (72 in.) high shall be knuckled at both selvages. Fabric 1.8 mm (72 in.) high or higher shall be knuckled at one selvage and twisted at the other.

13.2 Fabrics with mesh size less than 50.8 mm (2 in.) shall be knuckled at both selvages.

13.3 The selvages specified in Sections 13.1 and 13.2 are the standard selvages. Other selvages may be supplied only if specified by the purchaser. **Caution**—Twisted selvages for fences less than 1.8 m (72 in.) high are not recommended because of consumer safety considerations.

14. MASS OR THICKNESS OF COATING (FABRIC)

14.1 The mass of coating on Type I fabric shall be not less than as shown in Tables 7 and 8, as determined from the average of all specimens representing the lot and not less than 336 g/m^2 (1.1 oz/ft^2) on an individual specimen of Type I, Class C fabric or 549 g/m^2 (1.8 oz/ft^2) on an individual specimen of Type I, Class D fabric.

14.2 The mass of coating on Type II fabric shall be not less than as shown in Tables 7 and 8, as determined from the average of all specimens representing the lot and not less than 92 g/m^2 (0.30 oz/ft^2) on an individual specimen of 3.76- and 4.88-mm (0.148 and 0.192 in.) diameter wire or 76.3 g/m^2 (0.25 oz/ft^2) on an individual specimen of 3.05-mm (0.120-in.) diameter wire.

Table 7—Mass of Metallic Coating on Type I or II Fabric

Specified Diameter of Coated Wire		Mass of Coating of Uncoated Wire Surface		
		Type I Zinc		Type II Aluminum,
		Class C	Class D	
mm	Gauge	g/m^2	g/m^2	g/m^2
4.88	6	366	610	122.1
3.76	9	366	610	122.1
3.05	11	366	610	106.8

Table 8—Weight of Metallic Coating on Type I or II Fabric

Specified Diameter of Coated Wire		Weight of Coating of Uncoated Wire Surface		
		Type I Zinc		Type II Aluminum,
		Class C	Class D	
in.	mm	oz/ft^2	oz/ft^2	oz/ft^2
0.192	6	1.2	2.0	0.40
0.148	9	1.2	2.0	0.40
0.120	11	1.2	2.0	0.35

14.3 The minimum metallic mass of coating on the wire for Type IV fabric and the thickness of polymer shall be as specified in Tables 9 and 10 as determined from the average of all specimens representing the lot.

Table 9—Mass or Thickness of Type IV Coatings

Specified Diameter of Metallic-Coated Core Wire		Mass of Zinc Coating of Uncoated Wire Surface,	Mass of Aluminum Coating of Uncoated Wire Surface,	Polymer Thickness Range	
				Class A,	Class B,
mm	Gauge	g/m^2	g/m^2	mm	mm
4.88	6	122.1	61	0.38	0.15
				to	to
3.76	9	91.5	61	0.64	0.25
3.05	11	91.5	61	All gauges	All gauges

Note: The polymer coating shall not be used when determining wire size.

Table 10—Weight or Thickness of Type IV Coatings

Specified Diameter of Metallic-Coated Core Wire		Weight of Zinc Coating of Uncoated Wire Surface,	Weight of Aluminum Coating of Uncoated Wire Surface,	Polymer Thickness Range	
				Class A,	Class B,
in.	Gauge	oz/ft^2	oz/ft^2	in.	in.
0.192	6	0.40	0.20	0.015	0.006
				to	to
0.148	9	0.30	0.20	0.025	0.010
0.120	11	0.30	0.20	All gauges	All gauges

Note: The polymer coating shall not be used when determining wire size.

14.4 The mass or thickness of coating shall be determined on one or more pieces of wire removed from the fabric, as specified by the purchaser. These specimens may be of any length over 305 mm (12 in.), but preferably about 610 mm (24 in.), and shall include both bends and straight sections, but shall not include either twists or knuckles.

14.5 Test specimens of Type I or II fabric shall be free of lumps, beads, and drops of coating material, as determined by passing the specimen through a circular gauge, and no more than 1.3 mm (0.05 in.) thick having a diameter 0.56 ± 0.03 mm (0.022 ± 0.001 in.) greater than the specified diameter of coated wire. Any lumps or protrusions which will increase the diameter by more than

0.56 mm (0.022 in.) shall be removed with a knife or file to a size which will pass through the circular gauge.

14.6 The method of determining mass or thickness of coating shall be as follows:

14.6.1 *Type I or IV, Zinc Coating*—The mass of zinc coating shall be determined in accordance with T 65M/T 65.

14.6.2 *Type II, Aluminum Coating*—The mass of aluminum coating shall be determined in accordance with T 213M/T 213.

14.6.3 *Type IV, Polymer Coating, Class A*—Measure the minimum and the maximum thicknesses of the polymer coated wire with a suitable micrometer and record these dimensions. Then mechanically strip the polymer coating from the metallic-coated core wire and measure the diameter of the metal coated wire. The allowed tolerance in Section 11.1 shall be applied to the diameter of the metallic-coated core wire.

14.6.4 *Type IV, Polymer Coating, Class B*—Strip the polymer coating by chemical means and determine the diameter of the metallic-coated core wire. Scrape the coating from one side of the wire and measure the reduced diameter with a micrometer. The thickness of coating at this point is the difference between the measurement obtained and the measured diameter of the metallic-coated core wire. In a similar manner, determine the thickness of coating at right angles to the first determinations.

Note 4—When removing polymer coating by scraping, take care not to remove any of the metallic surface.

15. PROPERTIES OF TYPE IV, POLYMER-COATED WIRE (FABRIC)

15.1 The polymer-coated wire from which the fabric is woven shall have a demonstrated ability to conform to the following requirements:

15.2 *Adhesion Test*—Class A, extruded and bonded, must conform to the requirements of Section 15.2.1. Class B, bonded, must conform to the requirements of Section 15.2.2. Class A, extruded, is not subject to adhesion test.

15.2.1 Three specimens from each lot shall be tested. Measure a distance of 19 mm ($^3/_4$ in.) from the end of the specimen. With a regular hand grip wire stripper, exert maximum hand pull parallel to the axis of the wire. Attempt to remove the measured portion of the vinyl sleeve from the core wire. The lot shall be acceptable if the vinyl sleeve is not capable of being removed from the core wire on all three specimens.

15.2.2 Three specimens from each lot shall be tested. Make two cuts parallel to the axis of the wire through the coating, approximately 2 mm ($^1/_{16}$ in.) apart and at least 13 mm ($^1/_2$ in.) long. With a knife, peel back a section of the coating between 3 mm ($^1/_8$ in.) and 6 mm ($^1/_4$ in.) long to produce a tab. Attempt to remove the 2-mm ($^1/_{16}$-in.) strip of coating by pulling the tab. The lot shall be acceptable if the coating breaks rather than separates from the core wire on all three specimens.

15.3 *Accelerated Aging*—Polymer-coated wire from which the fabric is woven shall withstand exposure for 1000 hours when tested in accordance with ASTM G 152 Table X1.1 Cycle 1 or ASTM G 155 Table X3.1 Cycle 1. The product shall be construed to have failed the test if:

15.3.1 The wire fails to withstand the mandrel bend test described in Section 15.4.

15.3.2 Shrinkage of the polymer coating is greater than 5.2 mm/m ($^1/_{16}$ in./ft) of wire.

15.3.3 There is a significant change in color or gloss of the polymer surface as determined by visual inspection.

15.4 *Mandrel Bend*—The mandrel bend test shall be performed on an individual picket removed from the fabric. The specimen may be any length of wire over 305 mm (12 in.) and shall include both bends and straight sections, but shall not include either twists or knuckles. The polymer-coated wire when subjected to a single bend at –28.9ºC (–20ºF) around a mandrel no larger than 10 times the diameter of the wire shall not exhibit breaks or cracks in the polymer coating.

15.5 *Color*—Unless otherwise stipulated by the purchaser, the color of the polymer in both Class A and Class B fabric shall be in accordance with the standard colors contained in Table 11.

Table 11—Standard Polymer Colors

	Munsell Units (ASTM D 1535 and ASTM D 1729)		
	Medium Green	Dark Green	Black
Hue	7.5G to 2.5G	0.1G to 7.5G	See chroma tolerance
Value	3.5 to 4.5	2.3 to 3.3	1.3 to 2.1
Chroma	Greater than 6	1 to 4	Max = 0.5 (any hue)

15.5.1 Compliance with this requirement shall be determined by comparison of specimens of the polymer-coated wire to standard flat specimens of fused film of approximately the thickness specified for the polymer coating to be applied to the wire, and measuring at least 38 by 38 mm ($1^1/_2$ by $1^1/_2$ in.).

15.5.2 Standard flat specimens for the evaluation of color of Class A polymer coating shall be prepared by milling, calendering, or compression molding polymer pellets using temperatures approximating those to be used in the extrusion process.

15.5.3 Standard flat specimens for the evaluation of Class B polymer coatings shall be prepared by thermally fusing polymer powder onto a suitable base using temperatures approximating those to be used in the powder-coating process.

15.5.4 The color of the standard flat specimens shall be determined in accordance with ASTM D 1535 and ASTM D 1729.

16. WORKMANSHIP (FABRIC)

16.1 Chain-link fabric shall be produced by methods recognized as good commercial practices. Excessive roughness, blisters, sal-ammoniac spots, bruises, flaking, frozen knuckles, or other defects if present to any considerable extent shall provide a basis for rejection. Polymer coatings shall be without voids and without tears or cuts that reveal the substrate.

17. STANDARD LENGTH OF ROLLS (FABRIC)

17.1 The standard length of roll shall be 15.2 m (50 ft) ±1 percent except as otherwise agreed upon at the time of purchase.

17.2 The length of roll shall be determined by unrolling a roll of fabric on a flat surface and exerting tension by appropriate means to remove all slack. The tension applied shall not reduce the actual height of the fabric by more than 5.2 mm/m ($^1/_{16}$ in./ft) of height or by more than 12.7 mm ($^1/_2$ in.), whichever is less.

18. SAMPLING AND NUMBER OF TESTS (FABRIC)

18.1 A lot shall be 50 rolls or fraction thereof of chain-link fabric of the same size and type offered for inspection at one time. One roll from every lot shall be taken at random as a sample for test purposes. However, in no case shall fewer than two rolls from the entire quantity offered for inspection be sampled and tested, except when the entire quantity offered for inspection is fewer than 10 rolls; then only one roll shall be selected for the sample.

18.2 Sample rolls selected shall be inspected for weave (Section 8), size of mesh (Section 9), diamond count (Section 8.2), wire size (Section 11), height of fabric (Section 12), selvage (Section 13), and length of roll (Section 17).

18.3 Test specimens shall be taken from the outside end of the sample rolls and tested for breaking strength (Section 10) and, if applicable, mass or thickness of coating (Section 14).

18.4 If material tested fails to meet any of the requirements of this specification, the roll sampled shall be rejected, and two additional rolls shall be tested from the same lot, both of which shall meet the requirements in every respect or the lot represented by the samples will be rejected.

18.5 The manufacturer may elect to test for breaking strength and mass or thickness of coating before weaving the wire into fabric; however, the purchaser reserves the right to sample and test wire from the complete fabric for compliance.

19. INSPECTION (FABRIC)

19.1 The engineer, or his representative, shall have free entry, at all times, to all parts of the manufacturer's or fabricator's works that concern the manufacture or fabrication of materials furnished under this specification. Each product or article furnished under this specification shall be subject to inspection at the factory, fabricating plant, in laboratories of the purchaser's choosing or at the point of delivery. The engineer reserves the right to sample and test each product or article subsequent to acceptance at the place of manufacture or fabrication, to determine conformance with the requirements of this specification or to verify a certification.

20. CERTIFICATION AND REPORTS (FABRIC)

20.1 When specified by the purchaser in the contract or order, a manufacturer's certification that the material was manufactured, sampled, tested, and inspected in accordance with this specification and has been found to meet the requirements shall be furnished. When specified in the purchase order or contract, a report of the test results shall be furnished.

21. PACKAGING, MARKING, AND LOADING (FABRIC)

21.1 Each length of fabric shall be tightly rolled and firmly tied. Each roll of fabric shall carry a tag showing the length, kind of base metal, kind of coating, specified wire size, mesh size, height of fabric, and the name or mark of the manufacturer.

TENSION WIRE

22. MATERIALS AND MANUFACTURE (TENSION WIRE)

22.1 Tension wire shall be steel coil spring wire.

23. SIZE OF WIRE (TENSION WIRE)

23.1 The diameter of the metallic-coated wire shall be 4.50 ± 0.13 mm (0.177 in. ± 0.005 in.) as determined from the average of two readings taken at right angles to each other. The diameter shall be measured on any one of the test specimens or it may be taken on the unsampled length of wire furnished. The diameter shall be measured in an area with uniform coating.

24. BREAKING STRENGTH (TENSION WIRE)

24.1 The metallic coated wire shall have a breaking strength of 8.675 kN (1950 lbf) minimum and 14.2 kN (3200 lbf) maximum as determined from the average of the three specimens representing the lot. Breaking strength shall be determined in accordance with T 68 or T 68M.

25. MASS OF COATING (TENSION WIRE)

25.1 Zinc-coated tension wire shall be furnished with Class 1 zinc coating unless otherwise specified. The mass of coating shall be the average of the three specimens representing the lot. Mass of coating shall be determined in accordance with T 65M/T 65.

25.2 Aluminum-coated tension wire shall have a mass of aluminum coating not less than 37.2 g/m^2 (0.4 oz/ft^2) of uncoated wire surface as determined from the average of the three specimens representing the lot. Mass of coating shall be determined in accordance with T 213M/T 213.

25.3 Polymer coated tension wire shall conform to the requirements of ASTM F 1664.

26. SAMPLING AND NUMBER OF TESTS (TENSION WIRE)

26.1 A lot is defined as all the material of the same size and type presented at one time for inspection. Test specimens shall be any length over 305 mm (12 in.). Six specimens shall be taken, each from a different roll or piece, if possible. Three specimens shall be tested for breaking strength, and three shall be tested for mass of coating. Size of wire may be determined from any one of the six specimens.

26.2 If the material tested fails to meet any of the requirements of this specification, the lot shall be resampled with double the number of specimens taken from the lot. All retest specimens shall meet the requirements in all respects, or the lot represented will be rejected.

27. INSPECTION (TENSION WIRE)

27.1 The provisions of Section 19 shall apply to tension wire.

28. CERTIFICATION AND REPORTS (TENSION WIRE)

28.1 The provisions of Section 20 shall apply to tension wire.

POSTS, HARDWARE, AND FITTINGS

29. MATERIALS (POSTS, HARDWARE, AND FITTINGS)

29.1 Steel posts, rails, and gate frames shall be one of the following:

29.1.1 Grade 1 steel posts, rails, and gate frames shall be of a shape approved by the engineer and shall be of commercial quality or better, weldable steel produced by the open hearth, electric furnace, or basic oxygen process conforming to the requirements of ASTM F 1083.

29.1.2 Grade 2 steel posts, rails, and gate frames shall be round pipe or tubing manufactured by cold-rolling and electric resistance welding of steel strip conforming to the requirements of ASTM F 1043.

29.2 Aluminum-alloy posts, rails, and gate frames shall be produced of alloy 6063 and shall conform to the requirements of ASTM B 429, Schedule 40.

29.3 Miscellaneous fittings and hardware to be metallic coated shall be of commercial quality steel or better, or cast or malleable iron as appropriate to the article. The steel or iron shall have sufficient strength to provide a balanced design.

29.4 Miscellaneous aluminum-alloy fittings and hardware shall be of extruded wrought or cast aluminum alloy conforming to the requirements set forth in Table 12.

Table 12—Miscellaneous Aluminum-Alloy Fittings and Accessories

		Aluminum-Alloy	
Nomenclature	Type of Material	Alloy and Temper	ASTM Designation
Rail and brace ends, post tops and turnbuckles	Castings	356.0-T6, 712.0-T5, 713.0-T5, A360.0, 360.0, 413.0	B 26, B 85, B 108
Gate hinges, barbed wire extension arms, and other fittings	Castings	Same as above	
Stretcher bars and bands	Bar	6063-T6	B 221
Truss or brace rods		6061- T6	B 221
Flat band ties	Sheet	3003-H14	B 209
Bolts		6061-T6	F 468
Nuts		6061-T6	F 467

29.5 When agreed upon in writing between the purchaser and supplier, aluminum alloy fittings and hardware may be substituted for metallic-coated steel or cast or malleable iron fittings and hardware.

29.6 Zinc or polymer used for coating posts, rails, expansion sleeves, gate frames, hardware, or miscellaneous fittings shall comply with Section 6.

29.7 Zinc rich organic material for coating interior surfaces of Grade 2 pipe shall yield a dry film with a minimum total zinc content of 87 percent by mass of the total solids of the dried coating.

29.8 Material for coating the exterior of Grade 2 pipe shall be an organic material such as a cross-linked acrylic urethane or polyurethane.

30. BENDING STRENGTH (POSTS, HARDWARE, AND FITTINGS)

30.1 For any type and shape of post, rail, or gate frame, the product of the yield strength and the section modulus shall not be less than the product of the section modulus of size pipe specified in ASTM F 1083 schedule 40, Table 1 multiplied by 172 MPa (25000 psi).

30.2 The yield strength of Grade 2 pipe shall be determined in accordance with T 68 or T 68M, 0.2 percent offset method.

31. WEIGHT AND DIMENSION TOLERANCE (POSTS, HARDWARE, AND FITTINGS)

31.1 The following tolerances are permitted for round pipe or tubing used for steel posts, rails, or gate frames:

- Tolerance from specified weight ±10 percent
- Tolerance from specified dimensions ±5 percent
- Tolerance from specified wall thickness no more than –12.5 percent

31.2 A tolerance from the specified dimensions for aluminum-alloy posts, rails, and gate frames will be allowed in accordance with ANSI H35.2.

32. WEIGHT OR THICKNESS OF COATING (POSTS, HARDWARE, AND FITTINGS)

32.1 Hot-dip galvanized coating applied to Grade 1 steel posts and rails shall be applied uniformly to all surfaces. The mass of zinc coating shall be not less than 549 g/m^2 (1.8 oz/ft^2) as determined from the average results of two specimens taken for test in the manner prescribed in Section 35 and not less than 488 g/m^2 (1.6 oz/ft^2) on an individual specimen. The mass of coating shall be calculated by dividing the total mass of zinc, inside plus outside, by the total area, inside plus outside, of the surface coated.

32.2 Grade 2 posts and rails, furnished as steel pipe with a hot-dip galvanized zinc plus organic exterior coating, shall have the following masses or thicknesses of coating on the interior and exterior surfaces.

32.2.1 Hot-dip zinc on the exterior shall be not less than 274 g/m^2 (0.9 oz/ft^2) as determined from the average results of two specimens taken for test in the manner prescribed in Section 35 and not less than 244 g/m^2 (0.8 oz/ft^2) on an individual specimen. The mass of coating shall be calculated from the mass of zinc on the exterior surface only. The exterior zinc coating shall have a uniform chromate chemical treatment applied either as a separate treatment or simultaneously with the organic topcoat.

32.2.2 The hot-dip, zinc-coated exterior shall be topcoated with a clear organic coating such as urethane or polyurethane. The coating shall not be less than 0.3 mils dry film thickness at any point as determined on two specimens taken for test in the manner prescribed in Section 35. The organic coating material shall comply with the performance requirements as specified in Section 33.

32.2.3 The interior surface of this pipe shall have either a zinc-rich, organic coating or a hot-dip, galvanized zinc coating as follows:

32.2.3.1 The dry film thickness of zinc-rich, organic interior coatings shall be not less than 7.620 micrometers (0.3 mils) thick at any point as determined on two specimens taken for test in the manner prescribed in Section 35. The dried coating shall be not less than 87 percent total zinc by mass.

32.2.3.2 The mass of hot-dip, zinc interior coatings shall be not less than 107 g/m^2 (0.35 oz/ft^2) as determined from the average results of two specimens taken for test in the manner prescribed in Section 35 and not less than 76 g/m^2 (0.25 oz/ft^2) on an individual specimen.

32.3 Optional supplemental color coatings for Grade 1 and Grade 2 posts shall conform to the requirements of ASTM F 1043.

32.4 The zinc coating on all fittings and hardware shall conform to all the requirements of M 111M/M 111 or M 232M/M 232, whichever is applicable.

32.5 The method of determining mass or thickness of coating shall be as follows:

32.5.1 *Zinc-Coated*—The mass of coating shall be determined in accordance with T 65M/T 65.

32.5.2 *Aluminum-Coated*—The mass of aluminum coating shall be determined in accordance with T 213M/T 213.

32.5.3 *Organic Exterior Coating*—Existence of the organic coating can be verified by a 15-second contact with a copper sulfate solution (specific gravity 1.186) on three separate places of a sample in accordance with ASTM F 1043.

32.5.4 *Organic, Zinc-Rich Interior Coating*—Determine the thickness by magnetic gauge operated and calibrated in accordance with ASTM E 376.

33. PROPERTIES OF ORGANIC EXTERIOR COATINGS FOR GRADE 2 POSTS AND RAILS (POSTS, HARDWARE, AND FITTINGS)

33.1 Clear organic coating on the exterior of Grade 2 pipe, when placed over the specified zinc coating, shall meet the following requirements:

33.1.1 No film cracking at 500 hours exposure when tested in accordance with ASTM G 152 Table X1.1 Cycle 1 or G 155 Table X3.1 Cycle 1.

33.1.2 No red rust at 950 hours exposure to salt spray, in accordance with ASTM B 117.

33.1.3 No blistering or cracking at 500 hours when tested in accordance with ASTM D 2247.

34. WORKMANSHIP (POSTS, HARDWARE, AND FITTINGS)

34.1 Finished posts, rail, hardware, and fittings shall show good workmanship and be reasonably free from defects. All burrs at the ends of posts and rails shall be removed. Coatings shall be uniform and free of voids or excessive roughness.

35. SAMPLING AND NUMBER OF TESTS (POSTS, HARDWARE, AND FITTINGS)

35.1 All pipe or other shapes, other than aluminum alloy, shall be sampled and tested in lots of 500 pieces or less for the same shape and cross section offered for inspection at one time. For posts, rails, and miscellaneous accessories fabricated from aluminum alloy, the lot shall be as defined in the applicable specification. All fittings, hardware, etc., of the same type and material, offered for inspection at one time, shall be considered a lot.

35.2 All coated steel posts, rails, fittings, and hardware shall be sampled at the rate of one article per lot.

35.3 All aluminum-alloy posts, fittings, and hardware shall be sampled at the rate prescribed in the applicable specification.

35.4 Sample articles shall be inspected for dimensions and mass, if applicable to the item.

35.5 Two test specimens 100 mm (4 in.) long taken 150 mm (6 in.) from each end of the coated steel post or rail representing the lot shall be taken and tested for mass of coating (Section 32).

35.6 For zinc-coated fittings, hardware, etc., test the article for mass of coating (Section 32) as prescribed in M 111M/M 111 or M 232M/M 232, as applicable.

35.7 If any article tested fails to meet the requirements of this specification, two additional articles shall be tested from the same lot, both of which shall meet the requirements in every respect or the lot represented by the samples will be rejected.

36. INSPECTION (POSTS, HARDWARE, AND FITTINGS)

36.1 The provisions of Section 19 shall apply to posts, hardware, and fittings.

37. CERTIFICATION AND REPORTS (POSTS, HARDWARE, AND FITTINGS)

37.1 The provisions of Section 20 shall apply to posts, hardware, and fittings.

38. PACKAGING, MARKING, AND LOADING (POSTS, HARDWARE, AND FITTINGS)

38.1 Each bundle or container of posts, hardware, and fittings shall be identified with the name or mark of the manufacturer, type of material (steel, cast iron, aluminum alloy number, etc.), type of coating, and any additional data required for proper identification or to determine apparent conformance to specified quality requirements.

Standard Specification for

Turnbuckles and Shackles

AASHTO Designation: M 269-96 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Turnbuckles and Shackles

AASHTO Designation: M 269-96 (2008)

1. SCOPE

1.1. *Scope*—This specification covers forged turnbuckles, with and without jam nuts, and shackles for guardrail, sign supports, and similar uses. These items are considered to be available commercially. Not all classes, styles, and types of turnbuckles and shackles that are available commercially are covered by this specification.

1.2. *Classification*:

1.2.1. *Turnbuckles*:

1.2.1.1. *Type*—Turnbuckles covered by this specification shall be forged and of the design specified by the purchaser.

1.2.1.2. *Sizes*—Turnbuckles covered by this specification shall be of the sizes listed in Table 2, as specified.

1.2.2. *Shackles*:

1.2.2.1. Shackles shall be one of the classes in Table 1, as specified by the purchaser.

Table 1—Classes of Shackles

Class 1—Screw pin anchor shackles
Class 2—Screw pin chain shackles
Class 3—Oval pin chain shackles
Class 4—Round pin anchor shackles
Class 5—Round pin chain shackles
Class 6—Bolt type anchor shackles

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 102M/M 102, Steel Forgings, Carbon and Alloy, for General Industrial Use
- M 169, Steel Bars, Carbon and Alloy, Cold-Finished
- M 232M/M 232, Zinc Coating (Hot-Dip) on Iron and Steel Hardware
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

2.2. *National Institute of Standards and Technology (NIST) Standard*:

- Handbook H28, Screw Thread Standards for Federal Services

2.3. *ANSI Standard*:

- B18.22, Heavy Hex Jam Nuts

2.4. *Military Standard*:

- MIL-P-21035, Paint, High Zinc Dust Content, Galvanizing Repair (Metric)

---

3. MATERIALS AND MANUFACTURE

3.1. *Materials*:

3.1.1. *Turnbuckles*—Unless otherwise specified, material for turnbuckles and end pulls shall comply with M 102M/M 102 and be of a grade which will meet the requirements of Table 2.

Table 2—Breaking Strength of Forged Turnbuckles (complete with end pulls)

	Strength Breaking, kN (lb) Min	Recommended Working Loads, kN (lb)
Size, Nominal Outside Diameter of Thread, mm (in.)	Eye or Stub End Pulls kN (lb)	Eye or Stub End Pulls kN (lb)
19.0 ($^{3}/_{4}$)	89.0 (20000)	17.8 (4000)
22.2 ($^{7}/_{8}$)	129.0 (29000)	25.8 (5800)
25.4 (1)	169.0 (38000)	33.8 (7600)
31.8 (1$^{1}/_{4}$)	266.9 (60000)	53.4 (12000)
34.9 (1$^{3}/_{8}$)	320.3 (72000)	64.0 (14400)
38.1 (1$^{1}/_{2}$)	378.1 (85000)	75.6 (17000)
44.4 (1$^{3}/_{4}$)	511.5 (115000)	102.3 (23000)
50.8 (2)	667.2 (150000)	133.4 (30000)
57.2 (2$^{1}/_{4}$)	876.3 (197000)	175.2 (39400)

3.1.2. *Shackles*—Each shackle, together with its pin or bolt, shall be forged at elevated temperature for final shape and size, in conformance with M 102M/M 102, Class AH.

3.2. *Construction*:

3.2.1. *Turnbuckles*:

3.2.1.1. *Method*—Each turnbuckle body and each end pull shall be forged at elevated temperature to final shape and size.

3.2.1.2. *Size*—Turnbuckles covered by this specification shall be furnished in the sizes shown in Table 3, clear opening between heads, as specified. The size of turnbuckle bodies shall be the nominal major diameter of the threads in the heads and the clear opening between heads (which is approximately equal to the take up); thus, for a 19 by 152-mm ($^{3}/_{4}$ by 6-in.) turnbuckle body, the heads shall be threaded for a 19-mm ($^{3}/_{4}$-in.) nominal major-diameter end pull, and the clear opening between heads shall be 152 mm (6 in.). The difference between the actual clear opening in the turnbuckle body and the nominal value given in Table 4 for the size specified shall not exceed five percent of the nominal value.

Table 3—Turnbuckles

	Size						
	Clear Opening Between Head, mm (in.)						
Thread, Nominal Outside Diameter, mm (in.)	152.4 (6)	228.6 (9)	304.8 (12)	457.2 (18)	609.6 (24)	914.4 (36)	1219.2 (48)
19.0 (${}^{3}/_{4}$)	X	X	X	X	X	—	—
22.2 (${}^{7}/_{8}$)	—	—	X	X	X	—	—
25.4 (1)	—	—	X	X	X	X	—
31.8 ($1^{1}/_{4}$)	—	—	X	X	X	X	—
38.1 ($1^{1}/_{2}$)	—	—	X	X	X	X	X
44.4 ($1^{3}/_{4}$)	—	—	—	X	X	X	X
50.8 (2)	—	—	—	—	X	X	X
57.2 ($2^{1}/_{4}$)	—	—	—	—	X	X	X

3.2.1.3. *Length of Head*—The length of the heads of the turnbuckle bodies shall be not less than 1.5 times the nominal outside diameter of the end pull for sizes up to 31.8 mm ($1^{1}/_{4}$ in.), and 1.25 times for sizes 31.8 mm ($1^{1}/_{4}$ in.) and above.

3.2.1.4. *Thread*—Turnbuckle bodies and end pulls shall be threaded after fabrication to final size and shape. The threads in the heads of the turnbuckle bodies and on the end pulls shall comply with NIST H28 (National Institute of Standards and Technology Specification H28, Screw-Thread Standards for Federal Services). Unified threads in the coarse (UNC) standard series (Table 5) should be used. If the standard diameter-pitch combinations are not suitable, the UNS threads with dimensions in accordance with NBS H28 should be used. Threads on the finished turnbuckle shall be not looser than Class 1A/1B fit. The female threads on the turnbuckle body may be oversized as necessary, so that after coating they will properly mate (not looser than Class 1A/1B fit) with the standard size male threads of the end pulls. The thread in one head of each turnbuckle body shall be right-hand and in the other head, left-hand. The threads on the end pulls shall be great enough so that the ends of the end pulls can be brought into contact with each other at the middle of the body length when jam nuts are not used.

3.2.1.5. *Breaking Strength*—The breaking strength of turnbuckles, equipped with end pulls, shall be not less than the value given in Table 2 for the required size, type, and form of end pull specified.

3.2.1.6. *Turnbuckle Bodies, Types*—Open turnbuckles shall be forged as specified. Forged turnbuckle bodies shall be similar to Figure 1. They shall be forged as specified. The shape of the head of the turnbuckle body shall be either round or hexagonal.

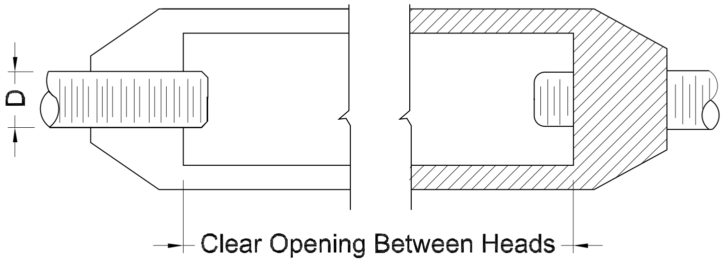


Figure 1—Open Turnbuckle Body, Forged

3.2.1.7. *Jam Nuts*—Jam nuts shall be right-hand or left-hand threaded, as required, made of carbon steel of a type selected from group 1016 to 1020 inclusive for M 169, and shall conform to the dimensional requirements of ANSI B18.2.2 Heavy Hex Jam Nuts.

3.2.1.8. *End Pulls*—Eye end pulls shall be forged, similar to Figure 2. The shape of the eye may be either oval or round. Minimum dimensions are as shown in Table 4.

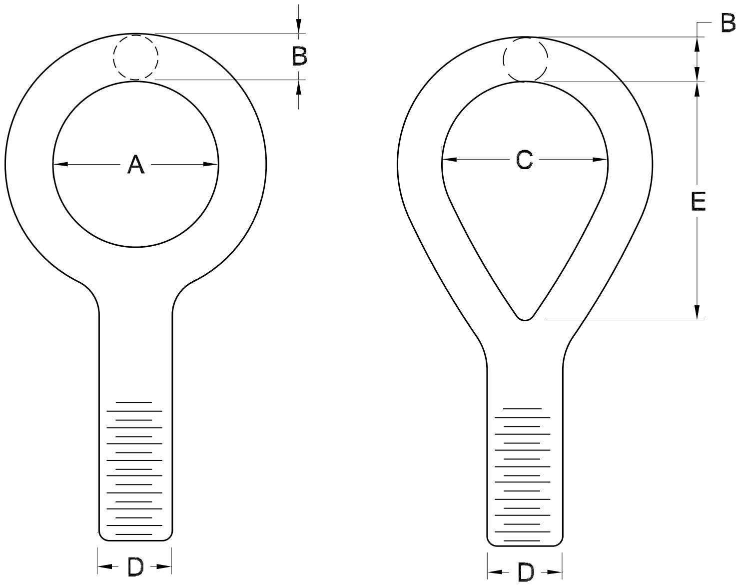

Figure 2—Forged-Eye End Pull

Table 4—Dimensions of Eye End Pulls, mm (in.)

D Nominal	A Minimum	B Minimum	C Minimum	E Minimum
19.0 ($^{3}/_{4}$)	38.1 ($1^{1}/_{2}$)	15.9 ($^{5}/_{8}$)	25.4 (1)	41.3 ($1^{5}/_{8}$)
22.2 ($^{7}/_{8}$)	44.4 ($1^{3}/_{4}$)	19.0 ($^{3}/_{4}$)	31.8 ($1^{1}/_{4}$)	47.6 ($1^{7}/_{8}$)
25.4 (1)	50.8 (2)	22.2 ($^{7}/_{8}$)	36.5 ($1^{7}/_{16}$)	57.2 ($2^{1}/_{4}$)
31.8 ($1^{1}/_{4}$)	54.0 ($2^{1}/_{8}$)	27.0 ($1^{1}/_{16}$)	42.9 ($1^{11}/_{16}$)	65.1 ($2^{9}/_{16}$)
38.1 ($1^{1}/_{2}$)	57.2 ($2^{1}/_{4}$)	31.8 ($1^{1}/_{4}$)	54.0 ($2^{1}/_{8}$)	82.6 ($3^{1}/_{4}$)
44.4 ($1^{3}/_{4}$)	63.5 ($2^{1}/_{2}$)	36.5 ($1^{7}/_{16}$)	60.3 ($2^{3}/_{8}$)	95.2 ($3^{3}/_{4}$)
50.8 (2)	76.2 (3)	41.2 ($1^{5}/_{8}$)	68.3 ($2^{11}/_{16}$)	111.1 ($4^{3}/_{8}$)
57.2 ($2^{1}/_{4}$)	82.5 ($3^{1}/_{4}$)	46.0 ($1^{13}/_{16}$)	74.6 ($2^{15}/_{16}$)	131.8 ($5^{3}/_{16}$)

3.2.2. *Shackles*:

3.2.2.1. *Threads*—Screw-pin shackles shall be threaded after fabrication to final size and shape. Threads shall conform to National Coarse Series as shown in Table 5. Appropriate portions of Section 3.2.1.4 shall apply to shackles.

3.2.2.2. *Size*—Shackles shall have the dimensions shown in Tables 6 through 17 for the appropriate class of shackle.

Table 5—Coarse Thread Series, Basic Dimensions, UNC

2.750	4	2.5876	2.4433	2.4794	1	46	4.62	4.93

3.3. *Finish*:

3.3.1. *Surface Condition*—Turnbuckle bodies and end pulls shackles shall be finished by grinding the flash smooth, where required, and removing the loose scale. They shall be free of cracks, flaws, seams, and other injurious imperfections.

3.3.2. *Zinc Coating*—Turnbuckles and shackles and accessories shall be galvanized (zinc coated) by the hot-dip process. The hot-dip process shall be applied in conformance with M 232M/M 232, and shall be adherent, smooth, and free from injurious lumps, blisters, dross, or flux. Coating shall be done on the end pulls and threaded pins after threading; coating for turnbuckle bodies, shackles and jam nuts may be done before or after tapping at the option of the purchaser.

3.3.3. *Galvanizing Repair*—Where the galvanizing on turnbuckles, shackles, end pulls, or pins has been damaged, the coating shall be repaired by regalvanizing, or the surface repaired by painting with two coats of zinc dust-zinc oxide paint conforming to MIL-P-21035.

3.4. *Physical Properties of Shackles*:

3.4.1. *Proof Loads*—Shackles shall be capable of withstanding the proof loads shown in the respective class tables when tested as specified in Section 5.1.1 without developing surface rupture or defects which interfere with serviceability or prevent disassembly of the pin. After proof loading, screw-pin shackles shall be capable of disassembly by hand after the first half turn.

3.4.2. *Breaking Loads*—Shackles shall be able to withstand, without breaking, the breaking loads shown in the respective class tables when tested as specified in Section 5.2.

3.4.3. *Ductility*—Shackles shall be sufficiently ductile that when fractured, the fractured member shall show a permanent distortion before breaking. If the pin fractures, it shall show a permanent bend of not less than 20 degrees. If the body fractures, it shall show a permanent mid-shackle set of not less than 15 percent of the original spread between bows.

3.4.4. *Class 1, Screw-Pin Anchor Shackles*—The screw-pin anchor shackles shall be similar to Figure 3, and shall conform to the dimensions and physical requirements shown in Tables 6 and 7.

3.4.6. *Class 3, Oval-Pin Chain Shackles*—The oval-pin chain shackles shall be similar to Figure 5 and shall conform to the dimensions and physical requirements shown in Tables 10 and 11. This shackle shall be provided with a taper hole and a locking pin with a drive fit; the drive pin shall not extend beyond the bottom of the hole. The oval pin shall fit tight against the tension side of the eye when the taper locking pin is driven home.

4. QUALITY ASSURANCE PROVISIONS

4.1. The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of manufacturer's works that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. All tests (except product analysis) and inspection shall be made at the place of manufacture to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works. If outside inspection is waived, a manufacturer's certification that the material has been tested in accordance with and meets the requirements of this specification, shall be the basis of acceptance of the materials. The manufacturer shall furnish the test results with the certification on request by the purchaser.

4.2. *Sampling*:

4.2.1. For the purpose of inspection and test, a lot shall consist of not more than 1000 pieces made from the same material of the same type and class offered for delivery at one time.

4.2.2. For the purpose of chemical analysis of steel, a lot shall consist of all turnbuckles or shackles made from the same material, from the same heat. In case heat cannot be identified, a lot shall consist of not more than 907 kg (2000 lb) of shackles or turnbuckles of the same type, class, and size.

4.2.3. *Specimens*—Specimens for inspection, and for required proof, breaking, and ductility tests shall be selected from each lot, in accordance with Table 18. Specimens used for proof test may be reused for breaking and ductility tests.

Table 18—Sampling Procedure for Inspection and Tests of Shackle or Turnbuckles

Number of Shackles or Turnbuckles in Lot	Number to Be Selected for Inspection and for Proof Test (When Proof Test Is Required)	Number to Be Used for Breaking Load and Ductility Tests
1 to 10	All	1
11 to 30	All	1
31 to 50	30	1
51 to 100	42	2
101 to 200	55	3
201 to 400	60	4
401 to 1000	65	5

4.3. *Chemical Analysis*—Analysis of material for shackles or turnbuckles shall be made from bars or from finished shackles or turnbuckles. One sample of not less than 60 g (2 oz.) of drillings or cuttings shall be taken from each lot of shackles or turnbuckles.

4.4. *Examination*—A random sample of shackles or turnbuckles taken in accordance with Table 18 shall be inspected to determine conformance with this specification regarding dimensions, masses, finish, and other requirements. Proof and breaking tests shall be made after zinc coating determinations.

4.4.1. *Rejection*—If one or more of the sample shackles or turnbuckles fail to conform to the requirements for appearance or coating, the entire lot shall be rejected. Each item in the rejected lot shall be reinspected by the manufacturer after removal or repair of noted deficiency. Normally, a lot shall be inspected in accordance with the sampling plan shown in Table 18; however, if a more stringent inspection of a resubmitted lot is required, the sampling procedure shall be in accordance with Table 19. If any sample from a resubmitted lot fails to pass the inspection, the entire lot shall be rejected.

Table 19—Sampling Procedure for Resubmitted Lots

Number of Shackles or Turnbuckles in Lot	Number of Samples to Be Inspected
1 to 100	All
101 to 1000	100

5. TESTS

5.1. *Proof Test*:

5.1.1. *Shackles*—Samples shall be subjected to proof loads shown in the applicable tables, either singly or in series. The diameter of the attachments used in proofing shall be not greater than the pin diameter of the shackle being tested and the application of the proof load shall be at the center of the pin. After releasing the proof load, each shackle shall be examined and disassembled to determine conformance with Section 3.3.1.

5.1.2. *Turnbuckles*—Each sample turnbuckle selected in accordance with Section 4.2.3 shall be subjected to a proof test of one-half the specified breaking strength for the end pull. Test load shall be applied at end pulls. Evidence of deformation or signs of incipient cracks in turnbuckle body or end pull shall be evidence of failure.

5.2. *Breaking and Ductility Tests*—After proof testing, the required number of samples shall be subjected to the breaking loads shown in the applicable table. For shackles, the diameter of the attachment used in the breaking test shall be not greater than the pin diameter of the shackle being tested; the application of the load shall be at the center of the pin. After breaking, the sample shall be inspected and measured to determine conformance with Section 3.4.2.

5.3. *Rejections*:

5.3.1. If any sample fails to pass the proof test, all shackles or turnbuckles in the lot shall be proofed and those failing to pass the test shall be rejected.

5.3.2. If any sample fails to pass the breaking or ductility test, triple the number of original sample shall be proofed and in addition triple the number of original samples shall be subject to the breaking and ductility test. If any retest sample fails in the breaking or ductility test, the lot shall be rejected.

5.4. *Galvanizing Test*—The galvanizing test shall be performed according to T 65M/T 65.

6. MARKING

6.1. Shackles or turnbuckles shall be shipped in boxes with marking identifying the following:

6.1.1. Size,

6.1.2. Type or class,

6.1.3. Number of units,

6.1.4. The number of this specification,

6.1.5. Production lot number, and

6.1.6. Other necessary identifying marks.

7. BASIS OF PURCHASE

7.1. Orders for material under this specification shall include the following information for each ordered item:

7.1.1. Quantity (number of units),

7.1.2. Name of product (turnbuckle or shackle),

7.1.3. Type or class (Section 1.2),

7.1.4. Size (Tables 2 or 6 through 17),

7.1.5. Grade of forging steel required,

7.1.6. Location of acceptance testing,

7.1.7. Test reports required, if any, and

7.1.8. AASHTO designation (M 269) and date of issue.

Standard Specification for

Metallic-Coated, Steel Woven Wire Fence Fabric

AASHTO Designation: M 279-09
ASTM Designation: A 116-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Metallic-Coated, Steel Woven Wire Fence Fabric

AASHTO Designation: M 279-09
ASTM Designation: A 116-05

1. SCOPE

1.1 This specification covers metallic-coated steel fence fabric having a series of horizontal (line) wires, with vertical (stay) wires either wrapped around the line wire (hinge joint) or fixed with another separate wire to the line wire (continuous stay fixed knot joint), forming rectangular openings. The fence fabric is suitable for use in fences for farm field enclosures (to keep domestic animals in or out), for wildlife and exotic animal control, for highway or railroad right-of-way fencing (to control access) and other similar uses.

1.2 This specification covers fence fabric in various designs, tensile strength grades, and metallic coating types and grades.

1.3 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4 The text of this specification references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the specification.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 120, Zinc
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings
- T 213M/T 213, Mass [Weight] of Coating on Aluminum-Coated Iron or Steel Articles
- T 244, Mechanical Testing of Steel Products

2.2 *ASTM Standards*:

- A 641/A 641M, Standard Specification for Zinc–Coated (Galvanized) Carbon Steel Wire
- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment
- A 809, Standard Specification for Aluminum-Coated (Aluminized) Carbon Steel Wire
- A 856/A 856M, Standard Specification for Zinc-5 % Aluminum-Mischmetal Alloy-Coated Carbon Steel Wire
- A 902, Standard Terminology Relating to Metallic Coated Steel Products

2.3 *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipment (Civil Agencies)

2.4 *Military Standards*:

- MLD-STD-129, Marking for Shipment and Storage
- MIL-STD-163, Steel Mill Products, Preparation for Shipment and Storage

---

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms used in this specification, refer to Terminology ASTM A 902.

3.2 *Description of Terms Specific to This Standard*:

3.2.1 *continuous stay fixed knot joint*—horizontal line wire and vertical stay wire joint made by fastening continuous stay wires to line wires by tying them together with a separate piece of knotwire at each joint.

3.2.2 *hinge joint*—horizontal line wire and vertical stay wire joint made by wrapping stay wire around line wires.

3.2.3 *intermediate wires*—line wires other than top and bottom wires.

3.2.4 *top and bottom wires*—line wires at the edge of the fence fabric (the top and bottom edges are erected).

---

4. ORDERING INFORMATION

4.1 Orders for material purchased under this specification should include the following information, as necessary to describe each product ordered:

4.1.1 Name of material and joint style (woven steel fence fabric with hinge joint or continuous stay fixed knot joint);

4.1.2 Quantity (number of rolls);

4.1.3 Design Number describing standard sizes and construction of the fabric as listed in Table 1;

Note 1—The design numbers are related to the characteristics of the construction of the fence fabric. The design number indicates the number of the line wires, approximate height, stay wire spacing, and size (gauge) of the line and stay wires.

4.1.4 Fabric length (when length is not specified by the order, fabric is furnished to standard length of 10 m (330 ft)); and

4.1.5 Tensile strength grade (the fabric is available in strength grades of 60, 125, and 175 (see Table 1)).

4.1.6 *Metallic Coating Type*:

4.1.6.1 *Coating Type A*—Made from aluminum-coated wire.

4.1.6.2 *Coating Type Z*—Made from zinc-coated wire.

4.1.6.3 *Coating Type ZA*—Made from ZN-5% Al-mischmetal alloy (Zn-5Al-MM) coated wire.

4.1.7 *Metallic Coating Class*—See Table 2.

4.1.8 Certification, or test report, or both, if required (see Section 10).

Note 2—A typical ordering description is as follows: Woven steel fence fabric, 60 rolls, Design Number 1047-6-12.5, Grade 60, Coating Type Z, Coating Class 3, to AASHTO M 279-03, with certification.

4.2 All rolls of fence fabric accepted by the purchaser shall be billed on the basis of the original length of the rolls before sampling unless changed by contractual agreement.

Table 3—Breaking Strength of Line Wires

Size, Steel Wire Gauge	Tensile Strength Grade, (ksi)	Nominal Diameter, mm (in.)	Minimum Breaking Strength Line Waves Only, N (lbf)
9	60 (60)	3.77 (0.148)	4590 (1030)
10	60 (60)	3.43 (0.135)	3820 (860)
10 $^1/_2$	125 (125)	3.25 (0.128)	7160 (1610)
11	60 (60)	3.05 (0.120)	3050 (685)
12 $^1/_2$	60 (60)	2.51 (0.099)	2050 (460)
12 $^1/_2$	100 (100)	2.51 (0.099)	3493 (770)
12 $^1/_2$	125 (125)	2.51 (0.099)	4280 (960)
12 $^1/_2$	175 (175)	2.51 (0.099)	5990 (1345)
14	125 (125)	2.03 (0.080)	2800 (630)
14 $^1/_2$	60 (60)	1.93 (0.076)	1210 (270)
14 $^1/_2$	125 (125)	1.93 (0.076)	2520 (565)

Note: There is no breaking strength requirement for stay wires.

5. MATERIALS

5.1 *Wire*—The steel wire shall be coated prior to fabrication, to the coating class specified in the order, the coating weight (mass) conforming to the requirements of Table 3. Coated wire shall be produced to the following applicable specifications:

5.1.1 *Coating Type A*—ASTM A 809,

5.1.2 *Coating Type Z*—ASTM A 641/A 641M,

5.1.3 *Coating Type ZA*—ASTM A 856/A 856M.

5.2 *Coated Wire Size*—Coated wire gauge sizes shown in Table 1, Table 2, and Table 3 correspond to steel wire gauge sizes listed in ASTM A 510, within tolerances stated in Section 7.

6. GENERAL REQUIREMENTS

6.1 *Construction*—The sizes and constructions for fence fabric furnished under this specification shall be in accordance with the requirements of Table 1 for the design number specified in the order, within the tolerances stated in Section 7. Designs other than specified in the table can be manufactured upon agreement between purchaser and producer. Each design can be manufactured with hinge joint or continuous stay fixed knot joint.

6.2 *Horizontal Wire*—Horizontal wires of all woven fencing shall be furnished with tension curves, at least one tension curve per each 229 mm (9 in.) of horizontal (line) wire.

6.3 *Splices*—Splicing of individual line wires by means of a wrap joint, mechanical fasteners, or an electric butt weld is permitted. The maximum number of line wire splices or joints shall not exceed one-half of the number of line wires in any 101 m (330 ft) (20-rod) roll of fabric. Such splices or joints shall be made in a workmanlike, manner and welded joints shall be coated with the corresponding Type A, Z, or AZ coating material to provide corrosion protection equivalent to the type coated wire being used.

6.4 *Stay Wires*—Stay wires shall be uniformly spaced and substantially perpendicular to the line wires. Tie wire used for the continuous stay fixed knot joint style fabric shall be minimum 13.5 gauge and of the same coating type and class as stay wire.

6.5 *Fence Fabric Length*—The length of the fence fabric in a roll shall be 101 m (330 ft) (20 rod). Fabric length other than 101 m can be manufactured upon agreement between purchaser and producer.

6.6 *Breaking Strength*—The breaking strength of line wires shall conform to the requirements of Table 3 for the grade specified in the order. There is no strength requirement for the stay wires for hinge joint style fabric. For Grade 175 continuous stay fixed knot joint style fabric, stay wire minimum tensile strength is 100 ksi (Grade 100).

7. PERMISSIBLE VARIATIONS IN DIMENSIONS

7.1 *Wire Diameter*—The permissible variation of the wire, from the nominal diameter shown in Table 3, shall be ±0.127 mm (±0.005 in.). Determine the diameter using a micrometer or other suitable measuring instrument, based on the greatest and least measurement at the same cross-section, with measurement to the nearest 0.025 mm (0.001 in.) The average of the two measurements shall be considered the diameter of the test specimen.

7.1.1 *Out-of-Roundness*—Due to the mechanics of the manufacture, a certain amount of out-of-roundness is expected on stay wires of the finished fence fabric. No limits are placed on out-of-roundness of the stay wires.

7.2 *Fabric Height*—The height of the woven wire fence fabric (center-to-center distance between top and bottom wires) shall not vary more than ±25 mm (±1 in.) from the specified height shown in Table 1. The specified height of fence fabric is based on the sum of the line wire spacing shown in Figures 1, 2, or 3.

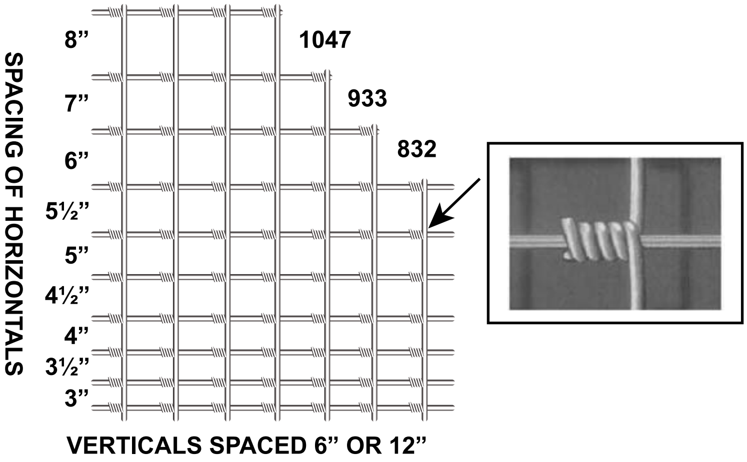

Figure 1—Typical Hinge Joint Fence Fabric Dimensions and Design Numbers[1]

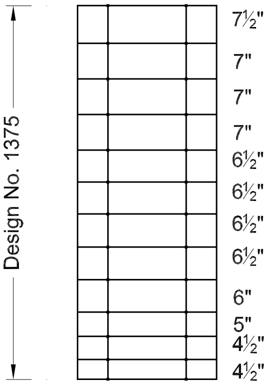

Figure 2—Fence Fabric Dimensions for Design No. 1375[1]

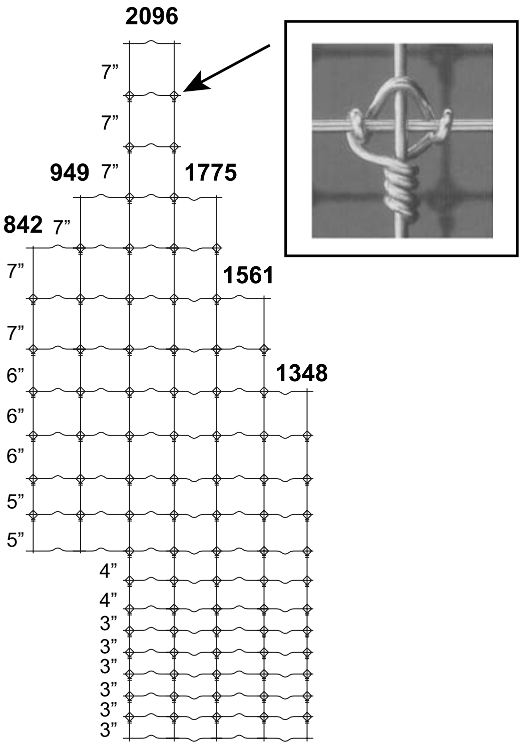

Figure 3—Continuous Stay Fixed Knot Joint Fence Fabric Dimensions and Design Numbers[1]

7.3 *Stay Wire Spacing*—The spacing between individual parts of line wires, or individual pairs of stay wires, shall not vary from the nominal dimensions more than 10 mm ($^3/_8$ in.) for 3 in. and 6 in. spacing and no more than 19 mm ($^3/_4$ in.) for 12 in. spacing product.

7.4 *Horizontal (Line) Wire Spacing—*The spacing between horizontal wires shall be as illustrated in Figures 1, 2, and 3 and is acceptable for given design number when agreed upon between purchaser and producer, providing that the total number of line wires remains unchanged. The spacing between individual pairs of horizontal wires shall not vary from the accepted nominal dimensions by more than 10 mm ($^3/_8$ in.). The tolerance of the line wires spacing shall not alter the tolerance on the overall height of the fence fabric.

7.5 *Fence Fabric Length*—The length of fence fabric in a roll shall be the specified length within a tolerance of –0 and +3 percent.

8. SAMPLING AND TESTING

8.1 Unless otherwise specified in the purchase order or contract, the manufacturer is responsible for the performance of all inspection and test requirements specified in this specification. Except as otherwise specified in the purchase order or contract, the manufacturer may use any suitable facilities for the performance of the inspection and test requirements unless disapproved by the purchaser at the time the order is placed. The purchaser shall have the right to perform any of the inspection and tests set forth in this specification when such inspections and tests are deemed necessary to assure that the material conforms to prescribed requirements.

8.2 *Sampling*—For the purpose of tests, select one roll at random from every 50 rolls, or fraction thereof, in a lot or a total of seven rolls, whichever is less. A lot shall consist of all rolls of a single design, grade, coating type, and coating class offered for delivery at the same time. A sample for physical tests is a length of fence fabric, at least 1 m (3 ft) long, cut from the end of the sample roll to include at least three of the vertical (stay) wires.

8.3 *Testing for Weight of Coating*—Coating weight for Types Z and ZA shall be determined in accordance with T 65M/T 65. Coating weight for Type A shall be determined in accordance with T 213M/T 213.

8.3.1 A test specimen for weight of coating determination shall consist of a number of lengths cut from a single wire, excluding all wire knots, wraps, and welded sections, such that the total length of wire tested is a minimum of 305 mm (12 in.). Test at least six test specimens for weight of coating, selected as follows:

8.3.1.1 One specimen from the top or bottom line wires,

8.3.1.2 Three specimens from different intermediate line wires, and

8.3.1.3 Two specimens from different vertical (stay) wires.

8.4 *Tests for Breaking Strength*—Cut specimens approximately 305 mm (12 in.) in length from the line wires, excluding knots, wraps, and welds. Test for breaking strength in accordance with T 244. Test at least four specimens, with one specimen from the top or bottom line wires, and three specimens from intermediate line wires.

8.5 *Pretesting of Wire*—Instead of testing wire for breaking strength and weight of coating from the completed fence fabric in accordance with Sections 8.3 and 8.4, the manufacturer, at his election, shall establish compliance with the requirements in Sections 5 and 6 by test made on wire prior to fabrication. If the manufacturer makes this election, the purchaser still has the right to test wire from the completed fence fabric for compliance.

8.6 *Inspection for General Workmanship*—For the purpose of inspection, a maximum of two rolls from the lot, as described in Section 8.2, shall be subjected to observations for the line and stay wire spacing, overall length, and workmanship.

8.6.1 Instead of inspecting for length by unrolling full rolls, the purchaser and the manufacturer have the option of agreeing on a weight per roll related to the fabric design, or measuring tools employed during manufacturing. The purchaser still reserves the right to confirm the length by actual measurement.

9. RETEST AND REJECTION

9.1 If one or more of the test specimens from a sample roll of fence fabric fail the weight-of-coating test or breaking strength test, the lot shall be subjected to retests. For retest purposes, four additional rolls for each 50 rolls offered shall be sampled. The lot size than becomes 50. Test specimens shall be cut in accordance with Section 8.3 or Section 8.4, as appropriate.

9.2 If more than four of the 24 retest specimens for weight-of-coating fail to meet the requirements of Table 2, or if any of the retest specimens has less than 75 percent of the specified coating weight, the entire lot represented by the retest specimens may be rejected.

9.3 If more than three of 16 retest specimens for breaking strength fail to meet the requirements of Table 3, or if any of the retest specimens has less than 90 percent of the specified strength, the entire lot represented by the retest specimens may be rejected.

9.4 If instead of rejecting the entire lot as provided for in Section 9.2 or Section 9.3, the producer may test specimens from every roll as provided for in Section 8.3 or Section 8.4 and resubmit those rolls meeting specification requirements.

9.5 Material that fails to conform to the requirements of this specification may be rejected. Rejection should be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the test, the producer or supplier may make a claim for a rehearing.

10. CERTIFICATION

10.1 When specified in the purchase order or contract, a producer's or supplier's certification shall be furnished to the purchaser that the material was manufactured, sampled, tested, and inspected in accordance with this specification and has been found to meet the requirements. When specified in the purchase order or contract, a report of the test results shall be furnished.

11. PACKAGING AND PACKAGE MARKING

11.1 Unless otherwise specified, packaging, marking, and loading for shipment shall be in accordance with ASTM A 700.

11.2 When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. Government, when Level A is specified, preservation, packaging, and packing shall be in accordance with the Level A requirement of MIL-STD-163.

11.3 When specified in the contract or order, and for the direct procurement by or direct shipment to the U.S. Government, marking for shipment in addition to requirements specified in the contract or order shall be in accordance with MIL-STD-129 for U.S. military agencies and in accordance with Fed. Std. No. 123 for U.S. Government civil agencies.

12. KEYWORDS

12.1 Fence fabric; fencing material; metallic-coated steel wire; steel wire; wire.

Standard Specification for

Metallic-Coated (Carbon) Steel Barbed Wire

AASHTO Designation: M 280-09
ASTM Designation: A 121-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Metallic-Coated (Carbon) Steel Barbed Wire

AASHTO Designation: M 280-09
ASTM Designation: A 121-07

1. SCOPE

1.1. This specification covers metallic-coated steel barbed wire, consisting of a strand of two wires.

1.2. The barbed wire is available with aluminum, zinc, and zinc-5 percent aluminum-mischmetal alloy coatings, with a number of coating weights, in a number of different construction (designs), and in two grades. Not all designs are available in all coating types.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. The text of this specification references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of the specification.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

2.2. *ASTM Standards*:

- A 428/A 428M, Standard Test Method for Weight [Mass] of Coating on Aluminum-Coated Iron or Steel Articles
- A 641/A 641M, Standard Specification for Zinc-Coated (Galvanized) Carbon Steel Wire
- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment
- A 809, Standard Specification for Aluminum-Coated (Aluminized) Carbon Steel Wire
- A 856/A 856M, Standard Specification for Zinc-5% Aluminum-Mischmetal Alloy-Coated Carbon Steel Wire
- A 902, Standard Terminology Relating to Metallic Coated Steel Products

2.3. *IEEE/ASTM Standard*:

- SI 10, American National Standard for use of the International System of Units (SI): The Modern Metric System

2.4. *Federal Standard*:

- Fed. Std. 123, Marking for Shipment (Civil Agencies)

2.5. *Military Standards*:

- MIL-STD-129, Marking for Shipment and Storage
- MIL-STD-163, Steel Mill Products Preparation for Shipment and Storage

3. TERMINOLOGY

3.1. *Definitions*—For definitions of terms used in this specification, refer to Terminology, ASTM A 902.

4. CLASSIFICATION

4.1. The barbed wire covered by this specification is classified as described in this section.

4.2. *Design Number*—Numbers describing standard sizes and constructions, as listed in Table 1.

4.3. *Metallic Coating Type*:

4.3.1. *Coating Type A*—made from aluminum-coated strand wire.

4.3.2. *Coating Type Z*—made from zinc-coated strand wire.

4.3.3. *Coating Type ZA*—made from zinc-5 percent aluminum-mischmetal alloy (Zn-5Al-MM) coated strand wire.

4.4. *Metallic Coating Class*—the specified amount of coating (coating weight [mass]) on the strand wire.

4.4.1. For coating Type A, see Section 6.3. (Only one coating weight for each wire size.)

4.4.2. For coating Type Z, see Table 2.

4.4.3. For coating Type ZA, see Table 3.

4.5. *Grades*:

4.5.1. *Standard Grade*—barbs spaced on 102 or 127 mm (4 or 5 in.) centers as indicated in Table 1.

4.5.2. *High-Security Grade*—barbs spaced on 76 mm (3 in.) centers (for Coating Type A only).

Note 1—The design numbers are related to the characteristics of the construction of the barbed wire, with the number groups related, in order, to the steel wire gauge of the strand wires, number of barb points, spacing of barbs, steel wire gauge of the barbs, and a letter indicating the shape of the barbs.

5. ORDERING INFORMATION

5.1. Orders for material under this specification shall include the following information, as necessary to describe the desired product:

5.1.1. Name of the material (steel barbed wire);

5.1.2. Quantity (number of spools and length of barbed wire on each, or total length) (see Section 7.5 for standard size of spools);

5.1.3. Metallic coating type, (see Section 4.3);

5.1.4. Metallic coating class (for Types Z and ZA) (see Table 2 or Table 3);

5.1.5. Design number (see Table 1);

5.1.6. For Coating Type A barbed wire, whether aluminum-alloy barbs are required or prohibited (see Section 6.2.1). If not stated, the choice shall be at the manufacturer's option;

5.1.7. AASHTO designation and year of issue; and

5.1.8. Certification or test report, or both, if required.

Note 2—A typical ordering description is as follows: Steel barbed wire, 20 spools of 80 rods each, Coating Type Z, Coating Class 3, Design Number 12-2-4-14R, to M 280-____ with certification.

5.2. All spools of barbed wire accepted by the purchaser shall be billed on the basis of the original length of the spools before sampling unless changed by contractual arrangement.

Table 1—Standard Sizes and Constructions for Barbed Wire

Design Number	Size, Steel Wire Gauge	Nominal Diameter of Coated Wire, mm (in.)	Number of Barb Points	Spacing of Barbs, mm (in.)	Dia of Barbs, Steel Wire Gauge[a]	Shape of Barbs
			Metallic Coating Type A			
12-4-3-14R	$12^{1}/_{2}$	2.51 (0.099)	4	76 (3)	14	Round
12-4-5-14R	$12^{1}/_{2}$	2.51 (0.099)	4	127 (5)	14	Round
12-4-3-12R[b]	$12^{1}/_{2}$	2.51 (0.099)	4	76 (3)	14	Round
			Metallic Coating Type Z and Type ZA			
12-2-4-12F	$12^{1}/_{2}$	2.51 (0.099)	2	102 (4)	$12^{1}/_{2}$[c]	Flat
12-2-4-13F	$12^{1}/_{2}$	2.51 (0.099)	2	102 (4)	13	Flat
12-2-4-14R	$12^{1}/_{2}$	2.51 (0.099)	2	102 (4)	14	Round
12-2-5-12F	$12^{1}/_{2}$	2.51 (0.099)	2	127 (5)	$12^{1}/_{2}$[c]	Flat
12-2-5-14R	$12^{1}/_{2}$	2.51 (0.099)	2	127 (5)	14	Round
12-4-5-14H	$12^{1}/_{2}$	2.51 (0.099)	4	127 (5)	14[c]	Half-Round
12-4-5-14R	$12^{1}/_{2}$	2.51 (0.099)	4	127 (5)	14	Round
13-2-4-14R	$13^{1}/_{2}$	2.18 (0.086)	2	102 (4)	14	Round
13-4-5-14R	$13^{1}/_{2}$	2.18 (0.086)	4	127 (5)	14	Round
14-2-5-14F	14	2.03 (0.080)	2	127 (5)	14	Flat
14-4-5-14F	14	2.03 (0.080)	4	127 (5)	14	Flat
14-2-5-14R	14	2.03 (0.080)	2	127 (5)	14	Round
14-4-5-14R	14	2.03 (0.080)	4	127 (5)	14	Round
15-2-5-13F	$15^{1}/_{2}$	1.70 (0.067)	2	127 (5)	$13^{3}/_{4}$[c]	Flat
15-2-5-14R	$15^{1}/_{2}$	1.70 (0.067)	2	127 (5)	14	Round
15-4-5-16R	$15^{1}/_{2}$	1.70 (0.067)	4	127 (5)	$16^{1}/_{2}$	Round

[a] Nominal diameter of wire used in making barbs shall be as follows:

$12^{1}/_{2}$ gauge	2.51 mm (0.099 in.)
13 gauge	2.32 mm (0.092 in.)
$13^{3}/_{4}$ gauge	2.11 mm (0.083 in.)
14 gauge	2.03 mm (0.080 in.)
$16^{1}/_{2}$ gauge	1.47 mm (0.058 in.)

[b] Design Number 12-4-3-12R, Metallic Coating Type A, is High-Security Grade. All other design numbers are for standard grade.

[c] The gauge of the half-round and flat barbs is designated by the gauge of the round wire from which the barbs are rolled.

Table 2—Minimum Mass of Coating on Type Z Barbed Wire

Size, Steel Wire Gauge	Nominal Diameter of Type Z		Minimum Weight of Coating of Uncoated Wire Surface, g/m^2 (oz/ft^2)	
	mm	(in.)	Class 1	Class 3
$12^{1}/_{2}$	2.51	0.099	85 (0.28)	245 (0.80)
13	2.32	0.092	85 (0.28)	230 (0.75)
$13^{1}/_{2}$	2.18	0.086	75 (0.25)	215 (0.70)
$13^{3}/_{4}$	2.11	0.083	[a]	215 (0.70)
14	2.03	0.080	75 (0.25)	215 (0.70)
$15^{1}/_{2}$	1.70	0.067	[a]	200 (0.65)
$16^{1}/_{2}$	1.47	0.058	[a]	200 (0.60)

[a] These sizes only furnished Class 2 Coating (Section 8).

Table 3—Minimum Mass of Coating on Type ZA Barbed Wire

Size, Steel Wire Gauge	Nominal Diameter of Type ZA		Min Weight of Coating of Uncoated Wire Surface, $g/m^2(oz/ft^2)$ Class[a]					
	mm	(in.)	20	40	60	80	100	120

(oz/ft^2)	61	122	183	244	305	366

[b] X denotes availability.

6. MATERIAL

6.1. *Base Metal*—The base metal of the steel strand wires and steel barbs shall be of a good commercial quality carbon steel, capable of meeting the breaking strength requirement in Section 7.7. The base metal for aluminum barbs (permitted with metallic Coating Type A) shall be aluminum alloy wire conforming to alloy 5000-H38, Alloy 6061-T94, or equal.

6.1.1. For Coating Type A barbed wire, the choice of whether aluminum-coated steel wire or aluminum alloy wire for the barbs shall be that of the manufacturer, unless otherwise specified by the purchaser. If aluminum alloy wire is used, the particular alloy shall be agreed upon between the manufacturer and the purchaser at the time the order is placed.

6.2. *Coating Materials*—the coating on the wire shall conform with the requirements of the following specifications:

6.2.1. *Coating Type A*—aluminum-coated wire in accordance with ASTM A 809.

6.2.2. *Coating Type Z*—zinc-coated wire in accordance with ASTM A 641/A 641M.

6.2.3. *Coating Type ZA*—zinc-5 percent aluminum-mischmetal alloy (Zn-5Al-MM) coated wire in accordance with ASTM A 856/A 856M.

6.3. *Coated Wire*—the steel wire shall be coated before fabrication.

6.3.1. *Weight of Coating Requirements for Strand Wires*—The strand wires for Types Z and ZA barbed wire, as represented by the test specimens, shall conform to the requirements of Tables 2 and 3 respectively for the minimum coating weight for the type and class ordered. The strand wire for Type A barbed wire, as represented by the test specimens, shall have a minimum coating weight of 90 g/m^2 (0.30 oz/ft^2) on the $12^{1}/_{2}$-gauge wire.

6.3.2. *Weight of Coating Requirements for Barbs*—The wire for barbs for Types Z and ZA barbed wire, as represented by the test specimens, shall conform to the same coating class requirements as the strand wire. The steel wire for barbs for Type A barbed wire, as represented by the test specimens, shall have a minimum coating weight of 75 g/m^2 (0.25 oz/ft^2) on the 14-gauge wire.

7. GENERAL REQUIREMENTS

7.1. The sizes and constructions for barbed wire furnished under this specification shall be in accordance with the requirements of Table 1 for the design number specified in the order, within the tolerances stated in Section 8.

7.2. The barbs shall be sharp, well-formed, and tightly wrapped. The barb length, measured from the center of the two strand wires, shall be 9.5 mm ($^3/_8$ in.) minimum.

7.3. The strand wires shall be twisted with a uniform length of lay. Type Z and Type ZA barbed wire shall have the twisting consistently in one direction (left or right) or alternating between the left and right directions. Type A barbed wire shall have the twisting consistently in either the left or right direction, with alternating of the twisting prohibited.

7.4. Splicing of the individual wires by means of a wrap joint or an electric butt weld is permitted. Not more than three splices or joints shall be made in a workmanlike manner.

7.5. The barbed wire, for the various types, shall be packaged on spools in lengths as follows:

7.5.1. *Type A*—80 rods (402 m) (1320 ft) or 305 m (1000 ft), and

7.5.2. *Types Z and ZA*—80 rods (402 m) (1320 ft) or 80 rods plus additional increments of 10 rods (50 m) (165 ft).

7.6. *Breaking Strength*—The breaking strength of the stranded barbed wire, for all types, shall not be less than 4230 N (950 lbf). This breaking strength reflects that of both strand wires tested together as one unit.

8. PERMISSIBLE VARIATIONS IN DIMENSIONS

8.1. *Diameter*—The permissible variation from the nominal diameter of the wire, for both line wires and barbs, for all types, shall be ±0.13 mm (±0.005 in.).

8.1.1. Due to the mechanics of manufacture when forming the barbs, a certain amount of out-of-roundness can be expected. The size and the condition precludes barbs from being subjected to diameter checks.

8.2. *Barb Spacing*—The nominal spacing of the barbs shall be as noted in Table 1. The individual barb spacing shall be measured from the edge of one barb at the strand to the corresponding edge of the adjacent barb. Cumulative spacing is established by counting the total number of barbs in a 7.6-m (25-ft) length of barbed wire. Barbs are subject to relocation during fabrication and handling, potentially leading to rejections with rigid interpretation of the spacing requirement. Therefore, barb spacing shall be considered acceptable under the following conditions:

8.2.1. The sample has 93.5 percent of the individual barb spacings conforming to the specified spacing ±19 mm (±$^3/_4$ in.), and

8.2.2. A sample length of 7.6 m (25 ft) of barbed wire contains:

8.2.2.1. A minimum of 86 barbs for 76-mm (3-in.) spacing,

8.2.2.2. A minimum of 69 barbs for 102-mm (4-in.) spacing, or

8.2.2.3. A minimum of 55 barbs for 127-mm (5-in.) spacing.

9. SAMPLING AND TESTING

9.1. *Sampling*—For the purpose of tests, select one spool at random from every 50 spools or fraction thereof in a lot, or a total of seven samples, whichever is less. A lot shall consist of all the spools of a single construction (design number) of barbed wire offered for delivery at the same time.

9.2. *Test Specimens for Physical Tests*—Cut a 1.2-m (4-ft) length of barbed wire from the end of each spool for the tests prescribed in Sections 6 and 7. Determine the breaking strength by testing the twisted strand as a composite. Test each strand wire individually for mass of coating.

9.3. *Testing for Mass of Coating*—Coating mass for Types Z and ZA shall be determined in accordance with ASTM A 90/A 90M. Coating mass for Type A shall be determined in accordance with ASTM A 428/A 428M. Perform testing either before or after fabrication for the strand wires and for Type A steel barbs. Perform testing prior to fabrication for Type Z and ZA barbs, and certify the test results.

9.4. *Pretesting of Wire*—Instead of testing wire for breaking strength and mass of coating from the completed barbed wire in accordance with Section 9.2, the manufacturer, at his election, shall establish compliance with the requirements in Sections 6 and 7, by tests made on wire prior to fabrication. If the manufacturer makes this election, the purchaser still has the right to test wire from the completed barbed wire for compliance. It is recognized that during fabrication, the barb is mechanically deformed and scraped, and some differences are likely in coating mass results on barbs tested before and after fabrication.

9.5. *Inspection for General Workmanship*—For the purpose of inspection, a maximum of two spools from the lot, as described in Section 9.1, shall be subjected to observations for barb length and spacing, overall length, and workmanship.

9.5.1. Instead of inspecting for length by unrolling full spools, the purchaser and manufacturer have the option of agreeing on a mass per spool related to wire size or measuring tools employed during manufacturing. The purchaser still reserves the right to confirm length by actual measurement.

9.5.2. Inspection for barb spacing is normally performed on the outer 7.6-m (25-ft) length of a spool, which permits repackaging of the spool. Any other selection shall be as agreed upon between the manufacturer and the purchaser.

10. RETESTS

10.1. *Lot Size for Retests*—If one or more of the individual wire specimens fails the coating mass test, or if a strand specimen fails the breaking strength test, the lot shall be subjected to retest. For retest purposes, four additional spools of barbed wire for each 50 spools offered shall be sampled. The lot size then becomes 50 spools, except variation in lot size is permitted to accommodate pallet count when the barbed wire is palletized.

10.2. *Retesting for Coating Mass*—If more than two of the individual strand wires of the retest specimens fail to meet the requirements of Section 6.3, or if any of the retest specimens has less than 75 percent of the specified coating mass, the entire lot represented by the retest will be rejected.

10.3. *Retesting for Breaking Strength*—If any of the retest specimens fail to meet the minimum breaking strength value in Section 7.7, the entire lot represented by the specimens will be rejected.

10.4. *Re-Inspection for Barb Spacing, Barb Length, and Overall Length*—If either of the sample spools fails to meet the requirements of these dimensions within the tolerances of Section 8, two additional spools shall be selected for inspection. If either of these spools fails to meet the requirements, the lot will be rejected.

11. INSPECTION

11.1. Unless otherwise specified in the purchase order or contract, the manufacturer is responsible for the performance of all inspection and test requirements specified in this specification. Except as otherwise specified in the purchase order or contract, the manufacturer shall use his own or any other suitable facilities for the performance of the inspection and test requirements unless disapproved by the purchaser at the time the order is placed. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification when such inspections and tests are deemed necessary to ensure that the material conforms to prescribed requirements.

12. REJECTION AND REHEARING

12.1. Material that fails to conform to the requirements of this specification shall be rejected. Rejection shall be reported to the manufacturer or supplier promptly and in writing. In case of dissatisfaction with the results of the test, the manufacturer or supplier shall make claim for a rehearing.

12.2. Instead of rejecting the entire lot as provided in Section 10, the manufacturer has the option of testing specimens from every spool and rejecting only those spools failing the mass of coating or breaking strength requirements.

13. CERTIFICATION

13.1. When specified in the purchase order or contract, a manufacturer's or supplier's certification that the material was manufactured, sampled, tested, and inspected in accordance with this specification and has been found to meet the requirements shall be furnished to the purchaser. When specified in the purchase order or contract, a report of the test results shall be furnished.

14. PACKAGING AND MARKING

14.1. Unless otherwise specified, packaging, marking, and loading for shipment shall be in accordance with ASTM A 700.

14.2. When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. Government, when Level A is specified, preservation, packaging, and packing shall be in accordance with the Level A requirement of MIL-STD-163.

14.3. When specified in the contract or order, and for the direct procurement by or direct shipment to the U.S. Government, marking for shipment, in addition to the requirements specified in the contract or order, shall be in accordance with MIL-STD-129 for U.S. military agencies and in accordance with Fed. Std. No. 123 for U.S. Government civil agencies.

15. KEYWORDS

15.1. Barbed wire; carbon steel wire; metallic-coated steel wire; steel barbed wire; wire.

Standard Specification for

Steel Fence Posts and Assemblies, Hot-Wrought

AASHTO Designation: M 281-96 (2008)
ASTM Designation: A 702-89 (1994)$^{\in 1}$

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Fence Posts and Assemblies, Hot-Wrought

AASHTO Designation: M 281-96 (2008)

ASTM Designation: A 702-89 (1994)$^{\epsilon 1}$

1. SCOPE

1.1 This specification covers steel fence posts and assemblies manufactured from hot-wrought sections and intended for use in field and line fencing.

1.2 The posts are available in tee, channel or U, and Y-bar shapes, or angle shapes, and are furnished painted or galvanized, unless otherwise specified.

1.3 The values stated in inch-pound units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 111M/M 111, Zinc (Hot-Dip Galvanized) Coatings on Iron and Steel Products
- M 232M/M 232, Zinc Coating (Hot-Dip) on Iron and Steel Hardware

2.2 *ASTM Standards*:

- A 29/A 29M, Standard Specification for Steel Bars, Carbon and Alloy, Hot-Wrought, General Requirements for
- A 36/A 36M, Standard Specification for Carbon Structural Steel
- A 499, Standard Specification for Steel Bars and Shapes, Carbon Rolled from “T” Rails
- A 641/A 641M, Standard Specification for Zinc-Coated (Galvanized) Carbon Steel Wire
- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment

2.3 *Federal Standard*:

- Fed Std. No. 123, Marking for Shipment (Civil Agencies)

2.4 *Military Standards*:

- MIL-STD-129, Marking for Shipment and Storage
- MIL-STD-163, Steel Mill Products, Preparation for Shipment or Storage

3. TERMINOLOGY

3.1 *Definitions*:

3.1.1 *assemblies*—angle section post components for installation of gates, fence ends, or corners, and intermediate bracing.

3.1.2 *line posts*—posts that support the straight-line body of the fence.

4. ORDERING INFORMATION

4.1 Orders for products under this standard should include the following:

4.1.1 Quantity (number of pieces) of line posts, end, or gate assemblies, corner or intermediate brace assemblies (It is customary to order line posts in multiples of five of the required length and the required number of end or corner assemblies.),

4.1.2 Type of section (if a specific section is required) (Section 6.2 and Figure 1),

4.1.3 Length or lengths required (Section 7.2),

4.1.4 Finish: galvanized or painted,

4.1.5 AASHTO designation and date of issue,

4.1.6 Anchor plates, if required (Section 6.4.3), and

4.1.7 Wire fasteners (state weight of zinc coating if other than Class 1) (Sections 6.6.2 and 6.6.3).

Note 1—A typical ordering description is as follows: 500 line posts; painted 8 ft long; M 281-____; omit anchor plates.

5. GENERAL REQUIREMENTS

5.1 Material furnished under this ASTM specification shall conform to the general requirements of the current edition of ASTM A 29/A 29M unless otherwise provided herein.

6. MATERIALS AND MANUFACTURE

6.1 *Material*:

6.1.1 Line post shall be fabricated from Steels A or B and assemblies from Steels A, B, or C as specified in Table 1.

6.1.2 Except as provided in Section 6.1.3, the finished line post and assemblies shall conform to the tensile properties specified in Table 1 for the applicable steel.

6.1.3 At the manufacturer's option, a Brinell or Rockwell B hardness test may be substituted for the tensile requirements in Table 1. In such cases the material shall conform to the Brinell or Rockwell B hardness specified in Table 2.

Table 1—Materials for Line Posts and Assemblies

		Line Posts		Assemblies	
Steel	Steel Description	Yield Point, Min, ksi (MPa)	Tensile Strength, Min, ksi (MPa)	Yield Point, Min, ksi (MPa)	Tensile Strength, Min, ksi (MPa)
A	Hot-wrought carbon steel 0.35 percent carbon, min	40 (275)	70 (485)	40 (275)	70 (485)
B	Hot-wrought carbon steel , or hot-wrought rail steel [a]	50 (345)	80 (550)	50 (345)	80 (550)
C	Structural steel[b]	—	—	36 (250)	58 (400)

[a] In accordance with ASTM A 499.

[b] In accordance with ASTM A 36/A 36M.

Table 2—Brinell Hardness

Steel	Description	Brinell Hardness, Min	Rockwell B Hardness, Min
A	Hot-wrought carbon steel, 0.35 percent carbon, min	143	79
B	Hot-wrought carbon steel or rail steel[a]	156	83
C	Structural steel [b]	116	68

[a] In accordance with ASTM A 499.

[b] In accordance with ASTM A 36/A 36M.

6.2 *Line Post Section*:

6.2.1 The posts shall be furnished as T, channel or U, or Y sections as illustrated in Figure 1. The cross section of T posts shall be approximately $1^{3}/_{8}$ in. (35 mm) wide, $1^{3}/_{8}$ in. deep, and $^{1}/_{8}$ in. (3.2 mm) thick. Unless otherwise specified by the purchaser, the line post type is at the manufacturer's option.

6.2.2 Dimensions may vary slightly in individual design in maintaining the control weight per foot.

6.3 *Wire Attachments*—Line posts shall have corrugations, knobs, notches, holes, or studs so placed and formed as to engage a substantial number of fence line wires in proper positions.

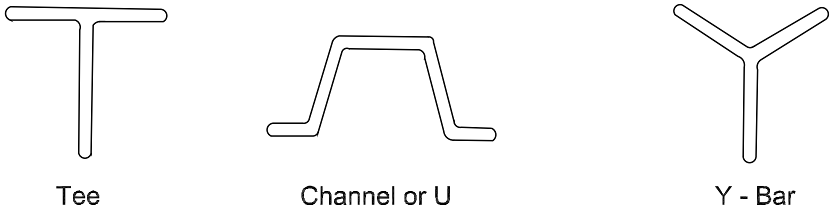

Figure 1—Typical Cross Sections of Line Post Types

6.4 *Anchor Plates*:

6.4.1 Each line post shall be manufactured with an anchor plate, unless otherwise specified. The anchor plate shall be made from carbon steel and shall be swaged or riveted to the post in such a manner as to prevent displacement when the posts are driven.

6.4.2 The placement of the anchor plate shall be nominally 14 in. (350 mm), 16 in. (400 mm), or 18 in. (450 mm) from the bottom of the post to the uppermost portion of the anchor plate.

6.4.3 Anchor plates shall be tapered to facilitate driving, shall have a minimum area of 18 in.^2 ($11600\ \text{mm}^2$), and shall weigh 0.67 lb (0.3 kg) ±5 percent.

6.4.4 When specified, line posts may be furnished without anchor plates.

6.4.5 Anchor plates shall be manufactured from Type A or B materials.

6.5 *Post Assemblies*:

6.5.1 Uprights shall consist of angles with a nominal size $2^1/_2$ by $2^1/_2$ by $^1/_4$ in. (65 by 65 by 6.4 mm) weighing 4.10 lb/ft (6.1 kg/m) prior to fabrication.

6.5.2 Braces shall consist of angles with a nominal size 2 by 2 by $^1/_4$ in. (50 by 50 by 6.4 mm) weighing 3.19 lb/ft (4.75 kg/m) prior to fabrication, or an alternative angle of equivalent weight.

6.5.3 Uprights and braces shall be furnished with the necessary holes and galvanized hardware for the required assembly.

6.5.4 All assemblies shall be furnished with one upright. End and gate assemblies shall be furnished with one brace, and corner and intermediate braces with two braces.

6.6 *Wire Fasteners*:

6.6.1 Unless otherwise specified by the purchaser, each line post shall be provided with not less than five suitable fasteners for attaching fence wire to the posts.

6.6.2 The fasteners shall be formed from zinc-coated steel wire not less than 0.120-in. (3.05-mm) diameter zinc coated in accordance with ASTM A 641. Class 1 coating shall be furnished unless otherwise specified by the purchaser.

6.6.3 When line posts are intended for range type western fencing using three line wires, it is satisfactory to provide only three fasteners for each post.

7. DIMENSIONS, MASS, AND PERMISSIBLE VARIATIONS

7.1 *Nominal Weights and Tolerances*:

7.1.1 *Nominal Weight*—Prior to fabrication by punching, drilling, attaching anchors, or finish coating, the line post sections shall have a nominal weight of 1.33 lb/ft (1.98 kg/m) of length.

7.1.2 The weight of line posts plus anchor plates (if specified), prior to fabrication, drilling, or finish coating shall not vary from nominal weights specified in Table 3 by more than ±5 percent. Weight shall be determined in lots of five line posts.

7.1.3 The weight of assembly components prior to fabrication, drilling, or finish coating shall not vary from the nominal weights specified in Table 4 by more than ±5 percent. Single assembly components shall be used to determine weight.

Table 3—Nominal Weights of (Raw) Line Posts

Post Length		Weight[a]	
ft	m	lb	kg
5	1.52	7.32	3.32
5 1/2	1.68	7.99	3.61
6	1.83	8.65	3.92
6 1/2	1.98	9.32	4.22
7	2.13	9.98	4.53
7 1/2	2.28	10.64	4.83
8	2.44	11.31	5.13
9	2.74	12.64	5.74
10	3.05	13.97	6.34

[a] Includes weight of anchor plate.

Table 4—Nominal Weights of (Raw) Assemblies

	Length		Weight[a]	
	ft	m	lb	kg
Upright and one brace, each (end or gate)	7	2.13	51	23
Upright and two braces, each (corner of intermediate brace)	7	2.13	73	33
Upright and one brace, each	8	2.44	58	26
Upright and two braces, each	8	2.44	84	38
Upright and one brace, each	9	2.74	66	30
Upright and two braces, each	9	2.74	94	43

[a] Includes weight of bolts.

7.2 *Standard Lengths and Tolerances*:

7.2.1 Line posts shall be furnished in standard lengths of 5 to 10 ft (1525 to 3050 mm) inclusive, as specified by the purchaser. Standard length increments are shown in Table 3.

7.2.2 The length of line posts, uprights, and braces shall not vary from that specified more than –1.0 in. (–25 mm) or +2 in. (+50 mm).

7.2.3 The placement of the anchor plate shall not vary from the nominal by more than ±3 in. (76 mm).

8. WORKMANSHIP, FINISH, AND APPEARANCE

8.1 Line posts, uprights, and braces shall be furnished painted or galvanized as specified by the purchaser.

8.2 When specified to be painted, the posts shall be cleaned of all loose scale prior to finishing, and painted with one or more coats, of weather resistant, air drying or baking, paint, or enamel.

8.3 When specified to be galvanized, the posts and post assemblies shall be zinc-coated by the hot-dip process in accordance with M 111M/M 111. The assembly hardware (Section 6.5.3) shall be zinc-coated in accordance with M 232M/M 232.

9. SAMPLING

9.1 One item from each lot shall be selected at random for testing. A lot shall consist of all posts or assemblies, or both, of the same length offered for delivery at the same time.

9.2 The post or assembly selected in accordance with Section 9.1 shall be tested for tensile strength or hardness, weight, and zinc coating, if applicable.

9.3 For purposes of visual inspection, length determinations, and dimensional examination, one post or assembly from each 400, or a total of seven, or whichever is less, shall be selected at random.

9.4 Visual inspection shall include examination for such features as excessive bow, camber, twist, or other injurious imperfections in surface or coating. Such imperfections may be considered cause for rejection of individual posts or assemblies.

10. INSPECTION

10.1 Unless otherwise specified in the purchase order or contract, the manufacturer is responsible for the performance of all inspection and test requirements specified in this specification. Except as otherwise specified in the purchase order or contract, the manufacturer may use his own or any other suitable facilities for the performance of the inspection and test requirements unless disapproved by the purchaser at the time the order is placed. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification when such inspections and tests are deemed necessary to assure that the material conforms to prescribed requirements.

11. REJECTION AND RETESTS

11.1 Should the post or assembly fail to meet any of the requirements of Section 9.2, the lot size shall become 400. One test shall be selected from each lot, and failure of the test shall result in rejection of that particular lot.

11.2 Should two or more posts or assemblies fail to meet any of the requirements of Section 9.3, the lot size shall become 400. Seven items shall be examined from each lot for compliance with the requirements of Section 9.3 causing initial failure. If two or more items fail, the entire lot shall be rejected.

11.3 Any individual post or assembly failing to meet the requirements of Sections 9.2 or 9.3 shall be rejected.

12. REJECTION AND REHEARING

12.1 Material that fails to conform to the requirements of this specification may be rejected. Rejection should be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the test, the producer or supplier may make claim for a rehearing.

13. CERTIFICATION

13.1 When specified in the purchase order or contract, a producer's or supplier's certification that the material was manufactured in accordance with this specification and has been found to meet the requirements shall be furnished to the purchaser.

14. PACKAGING

14.1 Line posts shall be bound in bundles of five posts, and by agreement with the purchaser, may be supplied in master bundles containing up to 250 posts.

14.2 Orders are customarily on piece count rather than on weight of posts or assemblies. The nominal weights establish the basis for weight tolerance and transportation data (Tables 3 and 4 for nominal weights).

15. PACKAGING, MARKING, AND LOADING FOR SHIPMENT

15.1 Unless otherwise specified, packaging, marking, and loading for shipment shall be in accordance with ASTM A 700.

15.2 When specified in the contract or order and for direct procurement by or direct shipment to the U.S. Government when Level A is specified, preservation, packaging, and packing shall be in accordance with Level A requirements of MIL-STD-163.

15.3 When specified in the contract or order and for direct procurement by or direct shipment to the U.S. Government, marking for shipment, in addition to requirements specified in the contract or order, shall be in accordance with MIL-STD-129 for U.S. military agencies and in accordance with Fed. Std. No. 123 for U.S. Government civil agencies.

Standard Specification for

Portland Cement

AASHTO Designation: M 85-09
ASTM Designation: C 150-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Portland Cement

AASHTO Designation: M 85-09
ASTM Designation: C 150-09

1. SCOPE

1.1 This specification covers ten types of portland cement as follows (Note 1):

1.1.1 *Type I*—For use when the special properties specified for any other type are not required;

1.1.2 *Type IA*—Air-entraining cement for the same uses as Type I, where air-entrainment is desired;

1.1.3 *Type II*—For general use, more especially when moderate sulfate resistance is desired;

1.1.4 *Type IIA*—Air-entraining cement for the same uses as Type II, where air-entrainment is desired;

1.1.5 *Type II(MH)*—For general use, more especially when moderate heat of hydration and moderate sulfate resistance are desired.

1.1.6 *Type II(MH)A*—Air-entraining cement for the same uses as Type II(MH), where air-entrainment is desired.

1.1.7 *Type III*—For use when high early strength is desired;

1.1.8 *Type IIIA*—Air-entraining cement for the same use as Type III, where air-entrainment is desired;

1.1.9 *Type IV*—For use when low heat of hydration is desired; and

1.1.10 *Type V*—For use when high sulfate resistance is desired.

Note 1—Some cements are designated with a combined type classification, such as Type I/II, indicating that the cement meets the requirements of the indicated types and is being offered as suitable for use when either type is desired.

1.2 When both SI and inch-pound units are present, the SI units are the standard. The inch-pound units are approximations listed for information only.

1.3 The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

- C 1038, Standard Test Method for Expansion of Hydraulic Cement Mortar Bars Stored in Water
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. TERMINOLOGY

3.1 *Definitions*:

3.1.1 *portland cement*—a hydraulic cement produced by pulverizing clinker, consisting essentially of hydraulic calcium silicates, and usually containing one or more of the following:

- water,
- calcium sulfate,
- up to 5 percent limestone, and
- processing additions.

3.1.2 *air-entraining portland cement*—a portland cement containing an interground air-entraining addition.

3.1.3 *hydraulic cement*—a cement that sets and hardens by chemical interaction with water and is capable of doing so underwater.

4. ORDERING INFORMATION

4.1 Orders for material under this specification shall include the following:

4.1.1 This specification number and date;

4.1.2 Type or types allowable. If no type is specified, Type I shall be supplied;

4.1.3 Any optional chemical requirements from Table 2, if desired; and

4.1.4 Any optional physical requirements from Table 4, if desired.

Note 2—Cement conforming to the requirements for all types are not carried in stock in some areas. In advance of specifying the use of other than Type I cement, determine whether the proposed type of cement is, or can be made, available.

5. INGREDIENTS

5.1 The cement covered by this specification shall contain no ingredients except as follows:

5.1.1 *Portland Cement Clinker.*

5.1.2 *Water or Calcium Sulfate or Both*—The amounts shall be such that the limits shown in Table 1 for sulfur trioxide and loss-on-ignition shall not be exceeded.

Table 1—Standard Chemical Requirements[a]

Cement Type	Applicable Test Method	I and IA	II and IIA	II(MH) and II(MH)A	III and IIIA	IV	V
Aluminum oxide (Al_2O_3), max, percent	T 105	—	6.0	6.0	—	—	—
Ferric oxide (Fe_2O_3), max, percent	T 105	—	6.0[c]	6.0[b, c]	—	6.5	—
Magnesium oxide (MgO), max, percent	T 105	6.0	6.0	6.0	6.0	6.0	6.0
Sulfur trioxide (SO_3),[d] max, percent	T 105						
When (C_3A)[f] is 8 percent or less		3.0	3.0	3.0	3.5	2.3	2.3
When (C_3A)[f] is more than 8 percent		3.5	[e]	[e]	4.5	[e]	[e]
Loss on ignition, max, percent	T 105	3.0	3.0	3.0	3.0	2.5	3.0
Insoluble residue, max, percent	T 105	0.75	0.75	0.75	0.75	0.75	0.75
Tricalcium silicate (C_3S)[f], max, percent	See Annex A1	—	—	—	—	35[b]	—
Dicalcium silicate (C_2S)[f], min, percent	See Annex A1	—	—	—	—	40[b]	—
Tricalcium aluminate (C_3A)[f], max, percent	See Annex A1	—	8	8	15	7[b]	5[c]
Sum of $C_3S + 4.75C_3A$, max, percent[g]		—	—	100[h]	—	—	—
Tetracalcium aluminoferrite plus twice the tricalcium Aluminate ($C_4AF + 2(C_3A)$), or solid solution ($C_4AF + C_2F$), as applicable, maximum, percent	See Annex A1	—	—	—	—	—	25[c]

[a] See Note 2.

[b] Does not apply when the heat of hydration limit in Table 4 is specified.

[c] Does not apply when the sulfate resistance limit in Table 4 is specified.

[d] It is permissible to exceed the values in the table for SO_3 content, provided it has been demonstrated by ASTM C 1038 that the cement with the increased SO_3 will not develop expansion exceeding 0.020 percent at 14 days. When the manufacturer supplies cement under this provision, supporting data shall be supplied to the purchaser. See Note 5.

[e] Not applicable.

[f] See Annex A1 for calculation.

[g] See Note 4.

[h] In addition, 7-day heat of hydration testing by ASTM C 186 shall be conducted at least once every 6 months. Such testing shall not be used for acceptance or rejection of the cement, but results shall be reported for informational purposes.

5.1.3 *Limestone*—The amount shall be not more than 5.0 percent by mass such that the chemical and physical requirements of this standard are met (See Note 3). The limestone, defined in ASTM C 51, shall be naturally occurring and consist of at least 70 percent by mass of one or more of the mineral forms of calcium carbonate.

Note 3—The standard permits up to 5 percent by mass of the final cement product to be naturally occurring, finely ground limestone, but does not require that limestone be added to the cement. Cement without ground limestone can be specified in the contract or order.

5.1.4 *Inorganic Processing Additions*—The amount shall not be more than 5.0 percent by mass of cement. Not more than one inorganic processing addition shall be used at a time. For amounts greater than 1 percent, they shall have been shown to meet the requirements of M 327 for inorganic processing additions in the amount used or greater. If an inorganic processing addition is used, the manufacturer shall report the amount (or range) used, expressed as a percentage of cement mass, along with the oxide composition of the processing addition.

5.1.5 *Organic Processing Additions*—They shall have been shown to meet the requirements of M 327 in the amounts used or greater, and the total amount of organic processing additions used shall not exceed 1 percent of the weight of portland cement clinker.

5.1.6 *Air-Entraining Addition (for Air-Entraining Portland Cement Only)*—The interground addition shall conform to the requirements of ASTM C 226.

6. CHEMICAL COMPOSITION

6.1 Portland cement of each of the ten types shown in Section 1 shall conform to the respective standard chemical requirements prescribed in Table 1. In addition, optional chemical requirements are shown in Table 2.

Note 4—The limit on the sum, $C_3S + 4.75\ C_3A$, in Table 1 provides control on the heat of hydration of the cement and is consistent with an ASTM C 186 7-day heat of hydration limit of 335 kJ/kg (80 cal/g).

Note 5—There are cases where performance of a cement is improved with SO_3 in excess of the Table 1 limits in this specification. ASTM C 563 is one of several methods a manufacturer can use to evaluate the effect of sulfate content on cement characteristics. Whenever SO_3 content of a cement exceeds Table 1 limits, ASTM C 1038 results provide evidence that excessive expansion does not occur at this higher sulfate content.

Table 2—Optional Chemical Requirements[a]

Cement Type	Applicable Test Method	I and I A	II and II A	II(MH) and II(MH)A	III and III A	IV	V	Remarks
Tricalcium aluminate (C_3A),[b] max, percent	See Annex A1	—	—	—	8	—	—	for moderate sulfate resistance
Tricalcium aluminate (C_3A),[b] max, percent	See Annex A1	—	—	—	5	—	—	for high sulfate resistance
Equivalent alkalies (Na_2O + 0.658K_2O), max, percent	T 105	0.60[c]	0.60[c]	0.60[c]	0.60[c]	0.60[c]	0.60[c]	low-alkali cement

[a] These optional requirements apply only if specifically requested. Availability should be verified. See Note 2 in Section 4.

[b] See Annex A1 for calculation.

[c] Specify this limit when the cement is to be used in concrete with aggregates that are potentially reactive and no other provisions have been made to protect the concrete from deleteriously reactive aggregates. Refer to ASTM C 33 for information on potential reactivity of aggregates.

7. PHYSICAL PROPERTIES

7.1 Portland cement of each of the ten types shown in Section 1 shall conform to the respective standard physical requirements prescribed in Table 3. In addition, optional physical requirements are shown in Table 4.

Table 3—Standard Physical Requirements

Cement Type[a]	Applicable Test Method	I	IA	II	IIA	II (MH)	II (MH)A	III	IIIA	IV	V
Air content of mortar, volume, percent:[b]	T 137										
Max		12	22	12	22	12	22	12	22	12	12
Min		—	16	—	16	—	16	—	16	—	—
Fineness, specific surface, m2/kg											
(alternative methods):[c]

Air permeability test:	T 153										
Min		260	260	260	260	260	260	—	—	260	260
Max						430[d]	430[d]	—	—	430	—
Autoclave expansion, max, percent	T 107	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80	0.80
Strength, not less than the value shown for the ages indicated below:[e]											
Compressive strength, MPa (psi)	T 106M/ T 106										
1 day		—	—	—	—	—	—	12.0 (1740)	10.0 (1450)	—	—
3 days		12.0 (1740)	10.0 (1450)	10.0 (1450)	8.0 (1160)	10.0 (1450) 7.0[f] (1020)[f]	8.0 (1160) 6.0[f] (870)[f]	24.0 (3480)	19.0 (2760)	—	8.0 (1160)
7 days		19.0 (2760)	16.0 (2320)	17.0 (2470)	14.0 (2030)	17.0 (2470) 12.0[f] (1740)[f]	14.0 (2030) 9.0[f] (1310)[f]	—	—	7.0 (1020)	15.0 (2180)
28 days		—	—	—	—	—	—	—	—	17.0 (2470)	21.0 (3050)
Time of setting (alternative methods):[g]											
Gillmore test:	T 154										
Initial set, min, not less than		60	60	60	60	60	60	60	60	60	60
Final set, min, not more than		600	600	600	600	600	600	600	600	600	600
Vicat test:[h]	T 131										
Time of setting, min, not less than		45	45	45	45	45	45	45	45	45	45
Time of setting, min, not more than		375	375	375	375	375	375	375	375	375	375

[a] See Note 2.

[b] Compliance with the requirements of this specification does not necessarily ensure that the desired air content will be obtained in concrete.

[c] Either of the two alternative fineness methods may be used at the option of the testing laboratory. However, when the sample fails to meet the requirements of the air-permeability test, the turbidimeter test shall be used, and the requirements in this table for the turbidimetric method shall govern.

[d] Maximum fineness limits do not apply if the sum of $C_3S + 4.75C_3A$ is less than or equal to 90.

[e] The strength at any specified test age shall be not less than that attained at any previous specified test age.

[f] When the optional heat of hydration in Table 4 is specified..

[g] The purchaser should specify the type of setting-time test required. In case he does not so specify, the requirements of the Vicat test only shall govern.

[h] The time of setting is that described as initial setting time in T 131.

Table 4—Optional Physical Requirements[a]

Cement Type	Applicable Test Method	I and II	IA and IIA	II(MH)	II(MH)A	III and IIIA	IV	V
False set, final penetration, min, percent	T 186	50	50	50	50	50	50	50
Heat of hydration:	ASTM C 186							
7 days, max, kJ/kg (cal/g)		—	—	290 (70)[b]	290 (70)[b]	—	250 (60)[c]	—
28 days, max, kJ/kg (cal/g)		—	—	—	—	—	290 (70)[c]	—
Strength, not less than the values shown:								
Compressive strength,	T 106M/ T 106	28.0	22.0	28.0	22.0	—	—	—
MPa (psi), 28 days		(4060)	(3190)	(4060)	(3190)			
				22.0[b]	18.0[b]			
				(3190)[b]	(2610)[b]			
Sulfate resistance, 14 days, max, percent expansion[d]	ASTM C 452	—[e]	—[e]	—[e]	—[e]	—	—	0.040

[a] These optional requirements apply only if specifically requested. Availability should be verified. See Note 2 in Section 4.

[b] The limit for the sum of the tricalcium silicate and 4.75 times the tricalcium aluminate in Table 1 shall not apply when this optional limit is requested. These strength requirements apply when the optional heat of hydration requirement is requested.

[c] When the heat of hydration limit is specified, it shall be used instead of the limits of C_3S, C_2S, C_3A, and Fe_2O_3 listed in Table 1.

[d] When the sulfate resistance is specified, it shall be used instead of the limits of C_3A, $C_4AF + 2(C_3A)$, and Fe_2O_3 listed in Table 1.

[e] Cement meeting the high sulfate resistance limit for Type V are deemed to meet the moderate sulfate resistance required of Type II and Type II(MH).

8. SAMPLING

8.1 When the purchaser desires that the cement be sampled and tested to verify compliance with this specification, sampling and testing should be performed in accordance with T 127.

8.2 Method T 127 is not designed for manufacturing quality control and is not required for manufacturer's certification.

9. TEST METHODS

Determine the applicable properties enumerated in this specification in accordance with the following methods:

9.1.1 *Air Content of Mortar*—T 137;

9.1.2 *Chemical Analysis*—T 105;

9.1.3 *Strength*—T 106M/T 106;

9.1.4 *False Set*—T 186;

9.1.5 *Fineness by Air Permeability*—T 153;

9.1.6 *Fineness by Turbidimeter*—T 98;

9.1.7 *Heat of Hydration*—ASTM C 186;

9.1.8 *Autoclave Expansion*—T 107;

9.1.9 *Time of Setting by Gillmore Needles*—T 154;

9.1.10 *Time of Setting by Vicat Needles*—T 131;

9.1.11 *Sulfate Expansion*—ASTM C 452;

9.1.12 *Calcium Sulfate (Expansion of) Mortar*—ASTM C 1038.

10. INSPECTION

10.1 Inspection of the material shall be made as agreed upon between the purchaser and the seller as part of the purchase contract.

11. REJECTION

11.1 The cement may be rejected if it fails to meet any of the requirements of this specification.

11.2 At the option of the purchaser, retest, before using, cement remaining in bulk storage for more than 6 months or cement in bags in local storage in the custody of a vendor for more than 3 months after completion of tests; reject the cement if it fails to conform to any of the requirements of this specification. Cement so rejected shall be the responsibility of the owner of record at the time of resampling for retest.

11.3 Packages shall identify the mass contained as net weight. At the option of the purchaser, packages more than 2 percent below the mass marked thereon shall be rejected. If the average mass of packages in any shipment, as shown by determining the mass of 50 packages selected at random, is less than that marked on the packages, the entire shipment shall be rejected.

12. MANUFACTURER'S STATEMENT

12.1 At the request of the purchaser, the manufacturer shall state in writing the nature, amount, and identity of any air-entraining addition, and of any processing addition that may have been used, and also, if requested, shall supply test data showing compliance of such air-entraining addition with the provisions of ASTM C 226, and of any such processing addition with M 327.

12.2 When limestone is used, the manufacturer shall state in writing the amount thereof and, if requested by the purchaser, shall supply comparative test data on chemical and physical properties of the cement with and without the limestone (see Note 6). The comparative tests do not supersede the normal testing to confirm that the cement meets chemical and physical requirements of this standard. The amount of limestone in cement shall be determined in accordance with Annex A2.

Note 6—Comparative test data may be from qualification tests performed by the manufacturer during formulation of the cement with limestone.

13. PACKAGING AND PACKAGE MARKING

13.1 When the cement is delivered in packages, the words "portland cement," the type of cement, the name and brand of the manufacturer, and the mass of the cement contained therein shall be plainly marked on each package. When the cement is an air-entraining type, the words "air-entraining" shall be plainly marked on each package. Similar information shall be provided in the shipping documents accompanying the shipment of packaged or bulk cement. All packages shall be in good condition at the time of inspection.

Note 7—With the change to SI units, it is desirable to establish a standard SI package for portland cements. To that end, 42 kg (92.6 lb) provides a convenient, even-numbered mass reasonably similar to the traditional 94-lb (42.6 kg) package.

14. STORAGE

14.1 The cement shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weather-tight building that will protect the cement from dampness and minimize warehouse set.

15. MANUFACTURER'S CERTIFICATION

15.1 Upon request of the purchaser in the contract or order, a manufacturer's report shall be furnished at the time of shipment stating the results of tests made on samples of the material taken during production or transfer and certifying that the cement conforms to applicable requirements of this specification.

Note 8—Guidance on preparing the manufacturer's report is provided in Appendix X1.

16. KEYWORDS

16.1 Hydraulic cement; portland cement; specification.

ANNEX

(Mandatory Information)

A1. CALCULATION OF POTENTIAL CEMENT PHASE COMPOSITION

A1.1. All values calculated as described in this annex shall be rounded according to ASTM E 29. When evaluating conformance to a specification, round values to the same number of places as the corresponding table entry before making comparisons. The expressing of chemical limitations by means of calculated assumed phases does not necessarily mean that the oxides are actually or entirely present as such phases.

A1.2. When expressing phases, C = CaO, S = SiO_2, A = Al_2O_3, F = Fe_2O_3. For example, C_3A = $3CaO \cdot Al_2O_3$. Titanium dioxide and phosphorus pentoxide (TiO_2 and P_2O_5) shall not be included with the Al_2O_3 content. See Note A1.

Note A1—When comparing oxide analyses and calculated phases from different sources or from different historic times, be aware that they may not have been reported on exactly the same basis. Chemical data obtained by Reference and Alternate Test Methods of T 105 (wet chemistry) may include titania and phosphorous as alumina unless proper correction has been made (see T 105), while data obtained by rapid instrumental methods usually do not. This can result in small differences in the calculated phases. Such differences are usually within the precision of the analytical methods, even when the methods are properly qualified under the requirements of T 105.

A1.3. When the ratio of percentages of aluminum oxide to ferric oxide is 0.64 or more, the percentages of tricalcium silicate, dicalcium silicate, tricalcium aluminate, and tetracalcium aluminoferrite shall be calculated from the chemical analysis as follows:

$$\text{Tricalcium silicate } (C_3S) = (4.071 \times \%\ CaO) - (7.600 \times \%\ SiO_2) - (6.718 \times \%\ Al_2O_3) - (1.430 \times \%\ Fe_2O_3) - (2.852 \times \%\ SO_3) \qquad (A1.1)$$

$$\text{Dicalcium silicate } (C_2S) = (2.867 \times \%\ SiO_2) - (0.7544 \times \%\ C_3S) \qquad (A1.2)$$

$$\text{Tricalcium aluminate } (C_3A) = (2.650 \times \%\ Al_2O_3) - (1.692 \times \%\ Fe_2O_3) \qquad (A1.3)$$

$$\text{Tetracalcium aluminoferrite } (C_4AF) = 3.043 \times \%\ Fe_2O_3 \qquad (A1.4)$$

A1.3.1. When the alumina-ferric oxide ratio is less than 0.64, a calcium aluminoferrite solid solution (expressed as ss(C_4AF + C_2F)) is formed. No tricalcium aluminate will be present in cements of this composition. Dicalcium silicate shall be calculated as in Equation A1.2. Contents of this solid solution and of tricalcium silicate shall be calculated by the following formulas:

$$ss(C_4AF + C_2F) = (2.100 \times \%\ Al_2O_3) + (1.702 \times \%\ Fe_2O_3) \qquad (A1.5)$$

$$\text{Tricalcium silicate } (C_3S) = (4.071 \times \%\ CaO) - (7.600 \times \%\ SiO_2) - (4.479 \times \%\ Al_2O_3) - (2.859 \times \%\ Fe_2O_3) - (2.852 \times \%\ SO_3) \qquad (A1.6)$$

A1.4. If no limestone or inorganic processing additions are used in the cement, or in the absence of information on limestone or inorganic processing additions used in the cement, phases shall be calculated using procedures in Equations A1.1 to A1.6 without adjustment.

A1.5. In absence of information on limestone or inorganic processing additions content, results shall note that no adjustment has been made for possible use of limestone or inorganic processing additions.

A1.6. When inorganic processing additions, limestone, or both are used with the base cement (portland cement clinker and any added calcium sulfate), the contents of C_3S, C_2S, C_3A, and C_4AF, shall be adjusted as follows:

A1.6.1. The percentage of C_3S, C_2S, C_3A, and C_4AF in the base cement shall be determined based on chemical analyses using methods in T 105 and using equations A1.1 to A1.6 as appropriate. The contents of each of these phases shall be adjusted to account for the use of limestone or inorganic processing additions as follows:

$$X_f = X_b \times \frac{(100 - L - P)}{100} \qquad (A1.7)$$

where:

X_b = the percentage by mass of C_3S, C_2S, C_3A, or C_4AF in the base cement (portland cement clinker and any calcium sulfate),

L = the percentage by mass of limestone,

P = the percentage by mass of inorganic processing addition, and

X_f = the percentage by mass of C_3S, C_2S, C_3A, or C_4AF in the finished cement.

The adjusted values for the finished cement shall be reported on the manufacturer's report.

Note A2—For example, where the cement includes 3.5 percent limestone and 3.0 percent of an inorganic processing addition and the base cement has 60 percent C_3S, 15 percent C_2S, 7 percent C_3A, and 10 percent C_4AF, the adjusted phase composition is:

$$C_3S_f = \frac{60 \times (100 - 3.5 - 3.0)}{100} = 56\ \%$$

$$C_2S_f = \frac{15 \times (100 - 3.5 - 3.0)}{100} = 14\ \%$$

$$C_3A_f = \frac{7 \times (100 - 3.5 - 3.0)}{100} = 7\ \%$$

$$C_4AF_f = \frac{10 \times (100 - 3.5 - 3.0)}{100} = 9\ \%$$

A2. LIMESTONE CONTENT OF PORTLAND CEMENT

A2.1. When limestone is used, the limestone content in portland cement shall be derived from the determination of CO_2 in the finished cement. Analysis of CO_2 shall be based on methods described in T 105. The percent limestone in the cement is calculated from the CO_2 analysis based on the CO_2 content of the limestone used. The limestone content of the cement is calculated as follows:

$$\frac{\%CO_2 \text{ in the cement}}{\%CO_2 \text{ in the limestone}} \times 100 = \%\text{ limestone in cement} \qquad (A2.1)$$

Note A3—For example, where the determined CO_2 content in the finished cement equals 1.5 percent and the CO_2 content of the limestone equals 43 percent ($CaCO_3$ in limestone equals 98 percent), then:

$$\frac{1.5}{43} \times 100 = 3.5\%\text{ limestone content in cement}$$

A2.2. This specification requires that the limestone to be used must contain a minimum of 70 percent $CaCO_3$. The manufacturer shall include the $CaCO_3$ content of the limestone on the manufacturer's report. Calculate the $CaCO_3$ content of the limestone as follows: % $CaCO_3$ = 2.274 × % CO_2.

Note A4—For verification of limestone content of cement, the purchaser must analyze for CO_2 content and make a correction for the content of $CaCO_3$ in the limestone in order for the data to be comparable to the manufacturer's report.

A2.3. Portland cements that do not contain limestone can contain baseline levels of CO_2 inherent in manufacture, for example, due to carbonation. This baseline CO_2 content is included as part of any calculated limestone content.

APPENDIX

(Nonmandatory Information)

X1. MANUFACTURER'S CERTIFICATION (MILL TEST REPORT)

X1.1. To provide uniformity for reporting the results of tests performed on cements under this specification, as required by Section 15 of M 85, Manufacturer's Certification, an example Mill Test Report is shown in Figure X1.1.

X1.2. The identity information given should unambiguously identify the cement production represented by the Mill Test Report and may vary, depending on the manufacturer's designation and purchaser's requirements.

X1.3. The Manufacturer's Certification statement may vary, depending on the manufacturer's procurement order or legal requirements, but should certify that the cement shipped is represented by the certificate and that the cement conforms to applicable requirements of the specification at the time it was tested (or retested) or shipped.

X1.4. The sample Mill Test Report has been developed to reflect the chemical and physical requirements of this specification and recommends reporting all analyses and tests normally performed on cements meeting M 85. Purchaser reporting requirements should govern if different from normal reporting by the manufacturer or from those recommended here.

X1.5. Cements may be shipped prior to later-age test data being available. In such cases, the test value may be left blank. Alternatively, the manufacturer can generally provide estimates based on historical production data. The report should indicate if such estimates are provided.

X1.6. In reporting limits from the tables in M 85 on the Mill Test Report, only those limits specifically applicable should be listed. In some cases, M 85 table limits are superseded by other provisions.

X1.7. When limestone or inorganic processing additions or both are used in the cement, additional data are reported by the manufacturer. An example additional data report is shown in Figure X1.2.

Standard Specification for

Blended Hydraulic Cement

AASHTO Designation: M 240-10[1]
ASTM Designation: C 595-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Blended Hydraulic Cement

AASHTO Designation: M 240-10[1]
ASTM Designation: C 595-09

1. SCOPE

1.1 This specification pertains to blended hydraulic cements for both general and special applications, using slag or pozzolan, or both, with portland cement or portland cement clinker or slag with lime.

Note 1—This specification prescribes ingredients and proportions with some performance requirements, whereas ASTM C 1157 is a blended cement specification in which performance criteria alone govern the products and their acceptance.

1.2 The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard. Values in SI units [or inch-pound units] shall be obtained by measurement in SI units [or inch-pound units] or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units [or SI units]. Values are stated in only SI units when inch-pound units are not used in practice.

1.3 The text of this standard refers to notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) are not requirements of the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 85, Portland Cement
- M 327, Processing Additions for Use in the Manufacture of Hydraulic Cements

- C 688, Standard Specification for Functional Additions for Use in Hydraulic Cements
- C 821, Standard Specification for Lime for Use with Pozzolans
- C 1012, Standard Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution
- C 1157, Standard Performance Specification for Hydraulic Cement
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

2.3 *IEEE/ASTM Standard*:

- SI 10, American National Standard for use of the International System of Units (SI): The Modern Metric System

3. TERMINOLOGY

3.1 *Definitions*—The terms used in this specification are defined in ASTM C 219 except for the following terms:

3.1.1 *binary blended cement*—a blended hydraulic cement consisting of portland cement with either a slag cement or a pozzolan.

3.1.2 *ternary blended cement*—a blended hydraulic cement consisting of portland cement with either a combination of two different pozzolans, or slag cement and a pozzolan.

4. CLASSIFICATION

4.1 This specification applies to the following types of blended cement that generally are intended for use as directed.

4.1.1 *Blended hydraulic cements for general concrete construction.*

4.1.1.1 *Type IS*—Portland blast-furnace slag cement.

4.1.1.2 *Type IP*—Portland-pozzolan cement.

4.1.1.3 *Type IT*—Ternary blended cement.

4.2 *Reporting:*

4.2.1 The naming practice for blended cements shall be made by adding the suffix (X) to the type designation under Section 4.1.1. where (X) equals the targeted percentage of slag or pozzolan in the product expressed as a whole number by mass of the final blended product, within the allowable variation as stated in Section 14.3.

4.2.2 The naming practice for ternary blended cements shall be made by adding the suffixes (AX) and (BY) to the Type IT designation under Section 4.1.1. where:

4.2.2.1 A is either “S” for slag cement, or “P” for pozzolan, whichever is present in larger amount by mass, and

4.2.2.2 X is the targeted percentage by mass of constituent A, and

4.2.2.3 B is either “S” for slag cement, or “P” for pozzolan, and

4.2.2.4 Y is the targeted percentage by mass of constituent B.

4.2.2.5 Both X and Y values are expressed as a whole number by mass of the final blended product, within the allowable variation as stated in 14.3. If X and Y are the same, the order is interchangeable.

Note 2—Examples of the naming practice per 4.2.1 and 4.3 are shown below (all percentages by mass):

Binary blended cement with 80 percent portland cement and 20 percent slag cement = IS (20)

Binary blended cement with 85 percent portland cement and 15 percent pozzolan = IP (15)

Ternary blended cement with 70 percent portland cement, 20 percent slag cement, and 10 percent pozzolan = IT (S20)(P10)

Ternary blended cement with 65 percent portland cement, 25 percent of one pozzolan, and 10 percent of another pozzolan = IT (P25)(P10).

4.2.3 A simplified naming practice is used in this standard for practicality and clarity when referring to specific requirements for binary and ternary blended cements that are applicable to a range of products or in ternary blended cements when requirements are applicable to only one constituent within a specific range (percent). (See Note 3.)

Note 3—Examples of the simplified naming practices per 4.2.3 are shown below:

An example when requirements are applicable to a range of products can be found in Table 1, where the maximum SO_3 content of 3 percent applies to: binary blended cements with slag cement contents <70 percent, indicated as IT (P <S <70).

1. An example when requirements are applicable to only one constituent within a specific range (percent) of that constituent can be found in 8.2, where testing is required only when the slag cement content is <25 percent. Because the requirement is based on the slag cement content only with no relation to the pozzolan content, a simplified naming practice is employed and the range of ternary blended cements are indicated as Type IT(S <25).

4.3 *Special Properties*:

4.3.1 Air-entraining cement, when desired by the purchaser, shall be specified by adding the suffix (A) to any of the above types. The air-entraining option is specified in combination with any of the other special properties where required.

Note 4—A given mass of blended cement has a larger absolute volume than the same mass of portland cement. This should be taken into consideration in purchasing cements and in proportioning concrete mixtures.

4.3.2 Moderate sulfate resistance or moderate heat of hydration, or both, when desired by the purchaser, shall be specified by adding the suffix (MS) or (MH), respectively, to the type designation under Section 4.1.1.

4.3.3 High sulfate resistance, when desired by the purchaser, shall be specified by adding the suffix (HS) to the type designation under Section 4.1.1.

Note 5—Special characteristics attributable to slag or pozzolan will vary based on quantities contained within the blended cements.

4.3.4 Low heat of hydration, when desired by the purchaser, shall be specified by adding the suffix (LH) to the type designation under Section 4.1.1.

5. ORDERING INFORMATION

5.1 Orders for material under this specification shall include the following:

5.1.1 Specification number,

5.1.2 Type or types required, and

5.1.2.1 Indicate allowable slag or pozzolan percent maximum or minimum, or both, if required.

5.1.3 Optional special properties required (see Section 4.3):

5.1.3.1 MS if moderate sulfate resistance is required;

5.1.3.2 HS if high sulfate resistance is required;

5.1.3.3 MH if moderate heat of hydration is required;

5.1.3.4 LH if low heat of hydration is required;

5.1.3.5 A if air entraining is required;

5.1.3.6 Accelerating addition, if required;

5.1.3.7 Retarding addition, if required;

5.1.3.8 Water reducing addition, if required;

5.1.3.9 Water reducing and accelerating addition, if required; and

5.1.3.10 Water reducing and retarding addition, if required.

5.1.4 Certification, if desired. (See Section 14.)

Note 6—It is important to check for availability of various options. Some multiple options are mutually incompatible or unattainable.

6. MATERIALS AND MANUFACTURE

6.1 *Blast-Furnace Slag*—Blast-furnace slag shall be the nonmetallic product, consisting essentially of silicates and aluminosilicates of calcium and other bases that are developed in a molten condition simultaneously with iron in a blast furnace.

6.2 *Granulated Blast-Furnace Slag*—Granulated blast-furnace slag shall be the glassy granular material formed when molten blast-furnace slag is rapidly chilled, as by immersion in water.

6.3 *Slag Cement*—See terminology ASTM C 219.

6.4 *Portland Cement*—See terminology ASTM C 219. For purposes of this specification, portland cement meeting the requirements of M 85 is suitable. Portland cement or other hydraulic materials, or both, containing high free lime are not prohibited as long as the autoclave test limits for the blended cement are met.

6.5 *Portland Cement Clinker*—Portland cement clinker shall be partially fused clinker consisting primarily of hydraulic calcium silicates.

6.6 *Pozzolan*—Pozzolan shall be a siliceous or siliceous and aluminous material, which in itself possesses little or no cementitious value but which will, in finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties.

6.7 *Hydrated Lime*—Hydrated lime used as part of a blended cement shall meet the requirements of ASTM C 821, except that when interground in the production process there shall be no minimum fineness requirement.

6.8 *Air-Entraining Addition*—When air-entraining cement is specified, an addition meeting the requirements of ASTM C 226 shall be used.

6.9 *Processing Additions*—When processing additions are used in the manufacture of cement, they shall have been shown to meet the requirements of M 327 in the amounts used or greater. (See Section 14.2.)

6.10 *Functional Additions*—When functional additions (used at the sole option of the purchaser, and in amounts not to exceed 0.50 percent by mass of the cement) are used, they shall be shown to meet the requirements of ASTM C 688 when tested with the cement to be used in the amount used or greater. (See Section 14.2 and Note 5.)

Note 7—The 0.50 percent by mass is an arbitrarily selected value.

6.11 *Other Additions*—The cement covered by this specification shall contain no additions except as provided for above except that water or calcium sulfate (see ASTM C 219), or both, if added, shall be in amounts so that the limits shown in Table 1 for sulfate reported as SO_3 and loss on ignition are not exceeded.

6.12 *Binary Blended Cement*—Binary blended cement shall be a hydraulic cement consisting of an intimate and uniform blend (see Note 7) produced either by intergrinding portland cement clinker with a pozzolan or a granulated blast-furnace slag, or a slag cement, or by blending portland cement with a pozzolan or a slag cement, or a combination of intergrinding and blending. The maximum constituent requirements of Sections 6.14 and 6.16 shall apply.

6.13 *Ternary Blended Cement*—Ternary blended cement shall be a hydraulic cement consisting of an intimate and uniform blend (see Note 7) produced either by intergrinding portland cement clinker with (1) two different pozzolans, or (2) granulated blast-furnace slag, or a slag cement and a pozzolan; or by blending portland cement with (1) two different pozzolans, or (2) slag cement and a pozzolan, or (3) a combination of intergrinding and blending. The maximum constituent requirements of 6.14 and 6.16 shall apply.

6.14 *Portland Blast-Furnace Slag Cement*—Portland blast-furnace slag cement shall be a hydraulic cement in which the slag cement constituent is up to 95 percent by mass of the blended cement. Binary or ternary blended cement, with a slag cement content equal to or exceeding 70 percent by mass, is permitted to contain hydrated lime.

Note 8—The attainment of an intimate and uniform blend of two or more types of fine materials is difficult. Consequently, adequate equipment and controls must be provided by the manufacturer. The purchaser should assure himself of the adequacy of the blending operation.

6.15 *Air-Entraining Portland Blast-Furnace Slag Cement*—Air-entraining portland blast-furnace slag cement shall be portland blast-furnace slag cement to which sufficient air-entraining addition has been added so that the resulting product complies with the air content of mortar requirements.

6.16 *Portland-Pozzolan Cement*—Portland-pozzolan cement shall be a hydraulic cement in which the pozzolan constituent is up to 40 percent by mass of the blended cement.

6.17 *Air-Entraining Portland-Pozzolan Cement*—Air-entraining portland-pozzolan cement shall be portland-pozzolan cement to which sufficient air-entraining addition has been added so that the resulting product complies with the air content of mortar requirements.

7. CHEMICAL COMPOSITION

7.1 Cement of the type specified shall conform to the applicable chemical requirements prescribed in Table 1.

Table 1—Chemical Requirements

Cement Type[a]	Applicable Test Method	IS (<70) IT (P < S < 70)	IS (≥70) IT (S > 70)	IP IT (P > S)
Magnesium oxide (MgO), max, percent	T 105	—	—	6.0
Sulfur reported as sulfate (SO_3), max, percent[b]	T 105	3.0	4.0	4.0
Sulfide sulfur (S), max, percent	T 105	2.0	2.0	—
Insoluble residue, max, percent	T 105	1.0	1.0	—
Loss on ignition, max, percent	T 105	3.0	4.0	5.0

[a] The chemical requirements in this table are applicable to all air-entrained cement equivalents.

[b] When it has been demonstrated by ASTM C 563 that the optimum SO_3 exceeds a value of 0.5 percent less than the specification limit, an additional amount of SO_3 is permissible provided that, when the cement with the additional calcium sulfate is tested by ASTM C 265, the calcium sulfate in the hydrated mortar at 24 ± $^1/_4$ h, expressed as SO_3, does not exceed 0.50 g/L. When the manufacturer supplies cement under this provision, upon request, supporting data shall be supplied to the purchaser.

7.2 If the purchaser has requested the manufacturer to state in writing the composition of the blended cement purchased, the composition of the cement furnished shall conform to that shown in the statement within the following tolerances. (See Note 8.)

	Tolerance, ± percent
Silicon dioxide (SiO_2)	3
Aluminum oxide (Al_2O_3)	2
Calcium oxide (CaO)	3

Note 9—This means that if the manufacturer's statement of the composition says "SiO_2: 32 percent," the cement when analyzed shall be found to contain between 29 and 35 percent SiO_2.

8. PHYSICAL PROPERTIES

8.1 *Blended Cement*—Blended cement of the type specified shall conform to the applicable physical requirements prescribed in Table 2.

Table 2—Physical Requirements

Cement Type[a]	Applicable Test Method	IS (<70), IT(P < S < 70), IP, IT(P > S)	IS (<70) (MS), IT(P < S < 70) (MS), IP(MS), IT(P > S) (MS)	IS (<70) (HS), IT(P <S < 70) (HS), IP (HS), IT(P > S) (HS)	IS (≥70), IT (S ≥ 70)	IP (LH),[c] IT(P > S) (LH)[c]
Fineness	T 153, T 192	[D]	[D]	[D]	[D]	[D]
Autoclave expansion max, percent	T 107	0.80	0.80	0.80	0.80	0.80
Autoclave contraction max, percent[E]	T 107	0.20	0.20	0.20	0.20	0.20
Time of setting, Vicat test:[F]	T 131					
Set, minutes, not less than		45	45	45	45	45
Set, h, not more than		7	7	7	7	7
Air content of mortar, volume percent[a]	T 137	12 max	12 max	12 max	12 max	12 max
Compressive strength, min,[a] MPa (psi):	T 106					
3 days		13.0	11.0	11.0	—	—
		(1890)	(1600)	(1600)	—	
7 days		20.0	18.0	18.0	5.0	11.0
		(2900)	(2610)	(2610)	(720)	(1600)
28 days		25.0	25.0	25.0	11.0	21.0
		(3620)	(3620)	(3620)	(1600)	(3050)
Heat of hydration:[G]	ASTM C 186					
7 days, max, kJ/kg		290	290	290		250
(cal/g)		(70)	(70)	(70)		(60)
28 days, max, Kj/kg		330	330	330		290
(cal/g)		(80)	(80)	(80)		(70)
Water requirement, max mass percent of cement	T 106	—	—	—	—	64
Drying shrinkage, max, percent	T 160	—	—	—	—	0.15
Mortar expansion:[h]	ASTM C 227					
14 days, max, percent		0.020	0.020	0.020	0.020	0.020
8 weeks, max, percent		0.060	0.060	0.060	0.060	0.060
Sulfate resistance[i]	ASTM C 1012					
Expansion at 180 days, max, percent		(0.10)[i]	0.10	0.05		(0.10)[i]
Expansion at 1 year, max, percent				0.10		

[a] Air-entrained cements shall have a mortar content of 19 ± 3 percent by volume and the minimum compressive strength shall be no less than 80 percent of the comparable non-air-entrained cement type.

[b] The requirements of Type IT(P >S), including MS, HS, or LH, as appropriate, shall apply to ternary blended cements with equal pozzolan and slag cement contents.

[c] Applicable only when higher strengths at early ages are not required or when low heat is required.

[d] Both amounts retained when wet sieved on 45-µm (No. 325) sieve and specific surface by air permeability apparatus, m^2/kg, shall be reported on all mill test reports requested under Section 14.4.

[e] The specimens shall remain firm and hard and show no signs of distortion, cracking, checking, pitting, or disintegration when subjected to the autoclave expansion test.

[f] Time of setting refers to initial setting time in T 131. The time of setting of cements containing a user-requested accelerating or retarding functional addition need not meet the limits of this table, but shall be stated by the manufacturer.

[g] Applicable only when moderate (MH) or low (LH) heat of hydration is specified, in which case the strength requirements shall be 80 percent of the values shown in the table.

[h] The test for mortar expansion is an optional requirement to be applied only at the purchaser's request and should not be requested unless the cement will be used with alkali-reactive aggregate.

[i] In the testing of HS cement, testing at one year shall not be required when the cement meets the 180-day limit. An HS cement failing the 180-day limit shall not be rejected unless it also fails the one-year limit.

[j] Optional sulfate resistance criterion that applies only if specifically invoked.

8.2 *Pozzolan or Slag*—Pozzolan or granulated blast-furnace slag or slag cement that is to be blended with cement shall be tested in the same state of subdivision as that in which it is to be blended. Pozzolan shall conform to the fineness requirement and the activity index requirement of Table 3. Slag cement that is to be used for Portland blast-furnace slag cements Type IS (<25) or ternary blended cements Type IT(S <25) shall conform to the slag activity requirement of Table 3. Such pozzolan or granulated blast-furnace slag or slag cement that is to be interground with portland cement clinker shall, before testing for conformance with requirements of Table 3, be ground in the laboratory to a fineness at which it is believed to be present in the finished cement. It is the manufacturer's responsibility to decide on the fineness at which the testing is to be carried out, and when requested to do so by a purchaser, to report the information upon which the decision was based.

Table 3—Requirements for Pozzolan for Use in Blended Cements and for Slag for Use in Portland Blast-Furnace Slag Cement Type IS (<25) and Ternary Blended Cement Type IT(S <25)

Pozzolan	Applicable Test Method	
Fineness: Amount retained when wet-sieved on 45-µm (No. 325) sieve, max, percent	T 192	20.0
Alkali reactivity of pozzolan for use in types IP(<15); IT(P<15) and IP(<15)-A cements, 6 tests, mortar bar expansion at 91days, max, percent	ASTM C 227	0.05
Slag or pozzolan activity index with portland cement, at 28 days, min, percent	See Annex A1	75.0

8.3 Pozzolan for use in the manufacture of portland-pozzolan cement, Type IP (<15) and IP(<15)-A, or ternary blended cements Type IT(P < 15) and Type IT(P <15)-A, shall meet the requirements of Table 3 when tested for mortar expansion of pozzolan as described in Section 10.1.13. If the alkali content of the clinker to be used for the production lots changes by more than 0.2 percent total as equivalent Na_2O, calculated as $Na_2O + 0.658\ K_2O$, from that of the clinker with which the acceptance tests were carried out, the pozzolan shall be retested to show compliance with the requirements of Table 3.

9. SAMPLING

9.1 Sample the materials in accordance with the following methods:

9.1.1 *Sampling Blended Cements*—T 127:

9.1.1.1 When the purchaser desires that the cement be sampled and tested to verify compliance with this specification, perform sampling and testing in accordance with T 127.

9.1.1.2 T 127 is not designed for manufacturing quality control and is not required for manufacturer's certification.

9.1.2 *Sampling Pozzolan*—ASTM C 311. One 2-kg (4-lb) sample shall be taken from approximately each 360 Mg (400 tons) of pozzolan.

10. TEST METHODS

10.1 Determine the applicable properties enumerated in this specification in accordance with the following test methods:

10.1.1 *Chemical Analysis*—T 105, with the special provisions noted therein applicable to blended cement analyses.

10.1.2 *Fineness by Sieving*—T 192.

10.1.3 *Fineness by Air-Permeability Apparatus*—T 153.

10.1.4 *Autoclave Expansion*—T 107, except that, in the case of portland blast-furnace slag cement IS (≥70) or ternary blended cement IT(S ≥70), the test specimens shall remain in the moist cabinet for a period of 48 hours before being measured for length, and the neat cement shall be mixed for not less than 180 seconds nor more than 210 seconds.

10.1.5 *Time of Setting*—T 131.

10.1.6 *Air Content of Mortar*—T 137, using the actual specific gravity of the cement, if it differs from 3.15 by more than 0.05, in calculating the air content.

10.1.7 *Compressive Strength*—T 106M/T 106.

10.1.8 *Heat of Hydration*—ASTM C 186.

10.1.9 *Normal Consistency*—T 129, except that in the case of portland blast-furnace slag cement IS (≥70) or ternary blended cement IT(S ≥70) the paste shall be mixed for not less than 180 seconds or more than 210 seconds.

10.1.10 *Specific Gravity*—T 133.

10.1.11 *Water Requirement*—The mass of mixing water added to the six-cube batch in accordance with T 106M/T 106, as a percentage of the total cementing ingredients.

10.1.12 *Mortar Expansion of Blended Cement*—ASTM C 227, using crushed Pyrex Glass No. 7740[2] as aggregate and the grading prescribed in Table 4.

Table 4—Aggregate Grading Requirements for Mortar Expansion Test

Sieve Size		Mass, Percent
Passing	Retained on	
4.75-mm (No. 4)	2.36-mm (No. 8)	10
2.36-mm (No. 8)	1.18-mm (No. 16)	25
1.18-mm (No. 16)	600-µm (No. 30)	25
600-µm (No. 30)	300-µm (No. 50)	25
300-µm (No. 50)	150-µm (No. 100)	15

10.1.13 *Mortar Expansion of Pozzolan for Use in Pozzolan-Modified Portland Cement Types IP(<15) and IP(<15)-A or Ternary Blended Cement Types IT(P <15) and IT(P <15)-A*—Using the pozzolan and the clinker or cement that are to be used together in the production of the blended cement, prepare portland-pozzolan cements Types IP(<15) and IP(<15)-A or Ternary Blended Cement Types IT(P <15) and IT(P <15)-A containing 2.5, 5, 7.5, 10, 12.5, and 15 mass percent of the pozzolan. These blends shall be tested in accordance with ASTM C 227 using a sand judged to be a nonreactive by the mortar bar test in ASTM C 227. The expansion of the mortar bars shall be measured at 91 days, and all six blends shall meet the expansion requirement in Table 3.

10.1.14 *Drying Shrinkage*—T 160. Make three specimens using the proportion of dry materials of 1 part of cement to 2.75 parts of T 106M/T 106, graded Ottawa sand. Use a curing period of 6 days and an air storage period of 28 days. Report the linear contraction during air storage based on an initial measurement after the 6-day water-curing period.

10.1.15 *Activity Index with Portland Cement*—Test in accordance with Annex A1.

10.1.16 *Sulfate Resistance*—See ASTM C 1012.

11. TESTING TIME REQUIREMENTS

11.1 The following periods from time of sampling shall be allowed for the completion of testing:

3-day test	8 days
7-day test	12 days
14-day test	19 days
28-day test	33 days
8-week test	61 days

12. INSPECTION

12.1 Facilities shall be provided to the purchaser for careful inspection and sampling of the finished cement. Inspection and sampling of finished cement shall be at the mill or distribution site controlled by the manufacturer, or at any other location agreed upon between the purchaser and the seller.

12.2 The manufacturer shall provide suitable facilities to enable the inspector to check the relative masses of the constituents used, and the intergrinding or blending operation used to produce the cement. The plant facilities for intergrinding or blending and inspection shall be adequate to ensure compliance with the provisions of this specification.

13. REJECTION

13.1 At the option of the purchaser, cement shall be rejected if it fails to meet any of the requirements of this specification applicable to the cement. Such rejection shall apply to an optional requirement only if that option has been invoked for the cement.

13.2 When the purchaser requires, cement in bulk storage for a period greater than 6 months shall be resampled and retested and, at the option of the purchaser, shall be rejected if it fails to meet any of the applicable requirements of this specification. Cement so rejected shall be the responsibility of the owner of record at the time of sampling for retest.

13.3 When the purchaser requires, packages more than 2 percent below the mass marked thereon shall be rejected; or if the average mass of packages in any shipment, as shown by determining the mass of 50 packages taken at random, is less than that marked on the packages, the entire shipment, at the option of the purchaser, shall be rejected.

14. CERTIFICATION

14.1 At the request of the purchaser, the manufacturer shall state in writing the source, amount, and composition of the essential constituents used in manufacture of the finished cement and the composition of the blended cement purchased.

14.2 At the request of the purchaser, the manufacturer shall state in writing the nature, amount, and identity of any processing, functional, or air-entraining addition used; and also, if requested, shall supply test data showing compliance of any such processing addition with the provisions of ASTM C 465, of any such functional addition with the provisions of ASTM C 688, and of any such air-entraining addition with the provisions of ASTM C 226.

14.3 At the request of the purchaser, the manufacturer shall also state in writing that the amount of pozzolan or slag in the finished cement will not vary more than ±5.0 mass percent of the finished cement from lot to lot or within a lot.

14.4 Upon request of the purchaser in the contract or order, a manufacturer's certification shall be furnished indicating that the material was tested during production or transfer in accordance with this specification, that it complies with this specification, and a report of the test results shall be furnished at the time of shipment (to include both amount retained on the 45-μm (No. 325) sieve and specific surface by the air permeability method).

15. PACKAGING AND PACKAGE MARKING

15.1 When the cement is delivered in packages, the words, "portland blast-furnace slag cement," "portland-pozzolan cement," or "ternary blended cement" as appropriate; the type of cement, name and brand of the manufacturer, and the mass of the cement contained therein shall be plainly marked on each package. When the cement contains a functional addition listed in Sections 5.1.3.5 to 5.1.3.10, the type of functional addition shall be plainly marked on each package. Similar information shall be provided in the shipping documents accompanying the shipment of packaged or bulk cement. All packages shall be in good condition at the time of inspection.

16. STORAGE

16.1 The cement shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment, and in a suitable weather-tight building that will protect the cement from dampness and minimize warehouse set.

17. KEYWORDS

17.1 Blended hydraulic cement; fly ash cement; granulated blast-furnace slag; hydraulic cement; portland blast-furnace slag cement; portland-pozzolan cement; pozzolanic cement; slag cement; ternary blended cement.

ANNEX

(Mandatory Information)

A1. ACTIVITY INDEX WITH PORTLAND CEMENT PROCEDURE

A1.1. *Specimen Preparation*:

A1.1.1. Mold, cure, and test the specimens from a control mix and from a test mix in accordance with T 106M/T 106. The portland cement used in the control mix shall meet the requirements of M 85 and shall be the type, and if available, the brand of cement to be used in the work. In the test mix, replace 35 percent of the absolute volume of the amount of cement used in the control mix by an equal absolute volume of the test sample. Make 3-cube batches as follows (For 6- or 9-cube batches, double or triple, respectively, the amounts of dry ingredients.):

A1.1.1.1. *Control Mix*:

- 250 g of portland cement
- 687.5 g of graded Ottawa sand
- X mL of water required for flow of 100 to 115

A1.1.1.2. *Pozzolan Test Mix*:

- 162.5 g of portland cement
- g of pozzolan: 87.5 × sp gr of the sample/sp gr of the portland cement g of sample
- 687.5 g of graded Ottawa sand
- Y mL of water required for flow of 100 to 115

A1.1.1.3. *Slag Test Mix:*

- 75 g of portland cement
- g of slag: 175 × sp gr of the slag/sp gr of the portland cement
- 687.5 g of graded Ottawa sand
- Z mL of water required for flow of 100 to 115

A1.2. *Storage of Specimens*:

A1.2.1. After molding, place the specimens and molds (on the base plates) in the moist room or closet at 23 ± 2.0°C [73.5 ± 3.5 °F] for 20 to 24 hours. While in the moist room or closet, protect the surface from dripping water. Remove the molds from the moist room or closet and remove the cubes from the molds. Place the cubes in close-fitting metal or glass containers (Note A1), seal the containers airtight, and store at 38 ± 2.0°C [100.0 ± 3.5 °F] for 27 days. Allow the specimens to cool to 23 ± 2.0°C [73.5 ± 3.5 °F] before testing.

Note A1—Use any metal container having a capacity of three cubes if it can be sealed airtight by soldering. Containers of light-tinned sheet metal with inside dimensions of 52 by 52 by 160 mm [2 by 2 by 6.25 in.] have been found to be satisfactory. Wide-mouth Mason jars of 1-L capacity have been found to be satisfactory, provided care is taken to prevent breakage. (**Warning**—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.)[3]

A1.3. *Compressive Strength Test*:

A1.3.1. Determine the compressive strength of the three specimens of the control mix and of the test mix at an age of 28 days in accordance with T 106M/T 106.

A1.4. *Calculation*:

A1.4.1. Calculate the activity index with portland cement as follows:

$$\text{Activity index with portland cement} = (A/B) \times 100$$

where:

A = average compressive strength of test mix cubes, MPa, and

B = average compressive strength of control mix cubes, MPa.

A1.5. *Precision and Bias*:

A1.5.1. *Precision*—Single operator precision, on blended cements using fly ash is essentially the same as on fly ash/cement blends in Research Report C09-1001[4] and it was found to have 3.8 percent coefficient of variation (1s percent). This indicates that results of two properly conducted tests by the same operator should not differ by more than 10.7 percent (d2s) of the average of two results. Since the test is performed solely for the purpose of manufacturer certification of raw material quality, no multilaboratory precision is applicable.

A1.5.2. *Bias*—Because there are no standard reference materials, bias cannot be determined.

---

[1] In essential equivalence with ASTM C 595-09.

[2] Pyrex Glass No. 7740 is available as lump cullet from the Corning Glass Works, Corning, NY; this is the sole source of supply of the apparatus known to the ASTM committee at this time. If you are aware of alternative suppliers, please provide this information to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend.

[4] Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR: C09-1001.

Standard Specification for

Silica Fume Used in Cementitious Mixtures

AASHTO Designation: M 307-07
ASTM Designation: C 1240-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Silica Fume Used in Cementitious Mixtures

AASHTO Designation: M 307-07
ASTM Designation: C 1240-05

1. SCOPE

1.1. This specification covers silica fume for use in concrete and other systems containing hydraulic cement.

1.2. In the cases of slurried or densified silica fume, perform the tests on the raw silica fume from which these products have been made.

1.3. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4. The following safety hazards caveat pertains only to the test methods portions, Section 10, of this specification: *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.* Read the material safety data sheets for materials used.

1.5. The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 194M/M 194, Chemical Admixtures for Concrete
- T 105, Chemical Analysis of Hydraulic Cement
- T 106M/T 106, Compressive Strength of Hydraulic Cement Mortar (Using 50-mm or 2-in. Cube Specimens)
- T 127, Sampling and Amount of Testing of Hydraulic Cement
- T 137, Air Content of Hydraulic Cement Mortar
- T 160, Length Change of Hardened Hydraulic Cement Mortar and Concrete
- T 192, Fineness of Hydraulic Cement by the 45-µm (No. 325) Sieve

2.2. *ASTM Standards*:

- C 109/C 109M, Standard Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)
- C 114, Standard Test Methods for Chemical Analysis of Hydraulic Cement
- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates

- C 157/C 157M, Standard Test Method for Length Change of Hardened Hydraulic-Cement Mortar and Concrete
- C 183, Standard Practice for Sampling and the Amount of Testing of Hydraulic Cement
- C 185, Standard Test Method for Air Content of Hydraulic Cement Mortar
- C 219, Standard Terminology Relating to Hydraulic Cement
- C 311, Standard Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete
- C 430, Standard Test Method for Fineness of Hydraulic Cement by the 45-μm (No. 325) Sieve
- C 441, Standard Test Method for Effectiveness of Pozzolans or Ground Blast-Furnace Slag in Preventing Excessive Expansion of Concrete Due to the Alkali-Silica Reaction
- C 494, Standard Specification for Chemical Admixtures for Concrete
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- C 1005, Standard Specification for Reference Masses and Devices for Determining Mass and Volume for Use in the Physical Testing of Hydraulic Cements
- C 1012, Standard Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution
- C 1069, Standard Test Method for Specific Surface Area of Alumina or Quartz by Nitrogen Adsorption
- C 1157, Standard Performance Specification for Hydraulic Cement
- C 1437, Standard Test Method for Flow of Hydraulic Cement Mortar

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *silica fume*—a very fine pozzolanic material, composed mostly of amorphous silica produced by electric arc furnaces as a by-product of the production of elemental silicon or ferro-silicon alloys (also known as condensed silica fume and microsilica).

3.1.2. Other terms in this specification are defined in ASTM C 125 and C 219.

4. ORDERING INFORMATION

4.1. The purchaser shall specify any optional chemical or physical requirements.

5. CHEMICAL REQUIREMENTS

5.1. Silica fume shall conform to the requirements for chemical composition prescribed in Table 1.

Table 1—Chemical Requirements

Silicon dioxide (SiO_2), min percent	85.0
Moisture content, max percent	3.0
Loss on ignition, max percent	6.0

6. PHYSICAL REQUIREMENTS

6.1. Silica fume shall conform to the physical requirements prescribed in Table 2. Optional physical requirements are shown in Table 3.

Table 2—Physical Requirements

Oversize:	
Percent retained on 45-µm (No. 325) sieve, max percent[a]	10
Percent retained on 45-µm (No. 325) sieve, max variation from average, percentage points[b]	5
Accelerated pozzolanic strength activity index:[c]	
With portland cement at 7 days, min percent of control	105
Specific surface, min, m^2/g	15

[a] Exercise care to avoid retaining agglomerations of extremely fine material.

[b] The average shall consist of the ten preceding tests or all of the preceding tests if the number is less than 10.

[c] Accelerated pozzolanic strength activity index is not to be considered a measure of the compressive strength of concrete containing the silica fume. This is a measure of the reactivity of a given silica fume with a given cement and may vary with the source of both the silica fume and the cement.

Table 3—Optional Physical Requirements[a]

Uniformity requirements:	
When air-entraining concrete is specified, the quantity of air-entraining agent required to produce an air content volume of 18 percent of the mortar shall not vary from the average established by the 10 preceding tests, or by all preceding tests if less than 10, by more than, percent	20
Reactivity with cement alkalies:[b]	
Reduction of mortar expansion at 14 days, min, percent[a]	80
Sulfate resistance expansion:[c]	
(moderate resistance) 6 months, max, percent	0.10
(high resistance) 6 months, max, percent	0.05
(very high resistance) one year, max, percent	0.05

[a] Optional physical requirements will be made only at the request of the purchaser.

[b] The indicated tests for reactivity with cement alkalies should not be requested unless the material is to be used with an aggregate that is regarded as deleteriously reactive with alkalies in hydraulic cement. The test for reduction of mortar expansion may be made using any high-alkali cement in accordance with ASTM C 113 if the cement to be used in the work is not known or is not available at the time of the test. The test for mortar expansion should be performed by each of the high-alkali cements to be used in the work.

[c] Only one limit shall be specified.

7. SAMPLING

7.1. When the purchaser desires that the silica fume be sampled and tested to verify compliance with this specification, perform the sampling and testing in accordance with T 127 or ASTM C 183, modified as described in Section 7.3.

Note 1—Exercise caution in the interpretation of T 127 or ASTM C 183 because there is a difference between the continuous manufacture of hydraulic cement and the generation and collection of silica fume. To a great extent, storage is dictated by the design of the silica fume collection system. The design of silica fume collection systems may not have provided for sampling points and practices.

7.2. T 127 or ASTM C 183, as modified, is not designed for manufacturing quality control and is not required for manufacturer's certification.

7.3. The following modification of T 127 or ASTM C 183 is necessary to render it applicable to silica fume:

7.3.1. Replace the words "hydraulic cement" and "cement" with the words "silica fume" every time they appear in the text.

7.3.2. All samples, whether grab or composite, shall have a mass of at least 1 kg (2 lb).

7.3.3. When compliance verification tests of silica fume are required to be made at a laboratory other than that of the silica fume manufacturer or marketer, coordinate the silica fume sampling schedule, sample transportation time, and sample testing schedule among the purchaser, manufacturer, and testing laboratory so the test results will be available when the decision to accept or reject the silica fume must be made.

7.3.4. The section entitled "Sampling" is modified as follows:

7.3.4.1. Take two grab samples or two composite samples for the first 100 Mg (110 tons) of silica fume. Take a grab sample or a composite sample for each subsequent 100 Mg (110 tons) of silica fume, but not less than two samples shall be taken in any sampling program.

7.3.4.2. *From Bulk Storage at Points of Discharge*—Withdraw silica fume from the discharge openings in a steady stream until sampling is completed. In sampling bulk storage at points of discharge, while the silica fume is flowing through the openings, take samples at such intervals so that, at a minimum, the sampling requirements of Section 7.3.4.1 are met.

7.3.5. The section entitled "Amount of Testing" is modified by deleting the first paragraph, "General."

8. FREQUENCY OF TESTS

8.1. Except for the tests listed in Section 8.2, make all chemical determinations and physical tests on composite samples representing no more than 400 Mg (440 tons) each. Prepare each composite sample by combining portions from the samples representing each 100 Mg (110 tons) so that each 100 Mg (110 tons) is represented equally.

8.2. Test for specific surface, density, and accelerated pozzolanic strength activity index using composite samples that represent 3200 Mg (3520 tons) or 3 months of production, whichever gives the highest frequency. Prepare each composite sample by combining portions from the samples representing each 400 Mg (440 tons) or 1 month, whichever gives the highest frequency, so that each sample is represented equally.

9. PREPARATION OF SAMPLE

9.1. Prepare composite samples for tests, as required in Section 8, by arranging all test samples in groups, with each group representing the number of megagrams required by the test or tests for which the composite sample is intended. From each of the samples in a group, take equal portions, sufficient in amount to form a composite sample large enough to permit making the required physical or chemical determinations.

9.2. Prior to testing, mix grab samples and composite samples thoroughly. A clean and dry laboratory concrete drum mixer provides adequate mixing for this purpose. Take care to limit the volume of silica fume in the drum mixer to the range of 10 to 50 percent of the drum's total capacity. If necessary, secure a sheet of polyethylene film on the drum with an elastic tiedown to keep the material in the drum. Limit the mixing action to 5 ± 1 minute.

9.2.1. When a small sample size precludes the use of a concrete mixer, use a heavy plastic bag, of a capacity at least five times larger than the sample volume, to mix the sample thoroughly. After placing the sample in the bag, close the bag by tying the bag opening tightly, and mix the material by rolling the bag around for 5 ±1 minute.

9.3. Take material for specific tests from a thoroughly mixed sample by using a sampling device (sampling tube, scoop, etc.) of appropriate size to make a test specimen. Make this test specimen from at least six random subsamples.

TEST METHODS–CHEMICAL ANALYSIS

10. SILICON DIOXIDE AND TOTAL ALKALIES

10.1. *Reference Method*—Use the reference method in T 105 for cements with insoluble residue greater than one percent. Analysts performing sodium oxide and potassium oxide determinations shall observe the precautions outlined in the applicable section of ASTM C 1157 (refer to the section on Test Methods). Most pozzolans dissolve completely in lithium borate fluxes.

11. MOISTURE CONTENT AND LOSS ON IGNITION

11.1. Make these determinations following applicable provisions of ASTM C 311.

TEST METHODS–PHYSICAL TESTS

12. DENSITY

12.1. *Equipment*:

12.1.1. Two 500-mL Volumetric Flasks, Class A;

12.1.2. Balance, with an accuracy of at least 0.01 g;

12.1.3. Constant temperature bath, capable of being regulated within ±0.5°C (1.0°F).

12.2. *Deionized water*:

12.3. *Procedure*:

12.3.1. Determine the density of the material as received, unless otherwise specified, as follows. If density determination on an ignited sample is required, first ignite the sample as described in the test for loss on ignition in the applicable section given in T 105.

12.3.2. Determine the mass (W_f) of a 500-mL volumetric flask, to an accuracy of 0.01 g. Add 30 g of silica fume. Determine the mass of the flask and the contents (W_a) to the nearest 0.01 g. Add water to the flask to fill it one-half full, and shake it to ensure thorough wetting of the material. Fill to the mark with water. Remove air bubbles by shaking the flask at 15-minute intervals until the liquid is free of air or by applying a vacuum to the flask. After all of the air bubbles are removed, place the flask in a constant temperature bath at 23 ± 0.5°C until the flask and its contents reach a constant temperature. Remove the flask from the water bath; immediately add or remove water, at the same temperature, to the flask to get the meniscus on the mark. Wipe dry the exterior of the flask and determine the mass of the flask and its contents (W_s).

12.3.3. Empty, clean, and determine the mass of the 500-mL volumetric flask, used above, filled to the mark with water (W_t) stabilized at 23 ± 0.5°C.

12.4. *Calculation*:

$$D_{sf} = \frac{\left(W_a - W_f\right)}{500\ mL - \left[(W_s - W_a)/D_w\right]} \tag{1}$$

where:

D_{sf} = density of silica fume, Mg/m^3;

W_f = mass of 500-mL volumetric flask, g;

W_a = mass of 500-mL volumetric flask plus approximately 30 g of silica fume, g;

W_s = mass of 500-mL volumetric flask plus silica fume plus water to the mark, g;

W_t = mass of 500-mL volumetric flask plus water to the mark, g; and

D_w = ($W_t - W_f$)/500-mL, Mg/m^3.

12.5. Report the average of two density determinations.

13. OVERSIZE, AMOUNT RETAINED WHEN WET-SIEVED ON A 45-μM (NO. 325) SIEVE

13.1. Use T 192. Calibrate the sieves in accordance with T 192.

Note 2—Oversize is used to determine the amount of contaminating material retained on the 45-μm (No. 325) sieve. See Appendix X2 (ASTM C 1240: Appendix X2).

14. SPECIFIC SURFACE

14.1. Determine the specific surface by the BET, nitrogen adsorption method, in accordance with ASTM C 1069.

Note 3—Manufacturers and examples of nitrogen adsorption instrumentation include Horiba Instruments, Inc. Irvine, CA, 5A-9600; Micromeritics Instrument Corporation, Norcross Georgia, FlowSorb-II 2300; Quantachrome Corporation, Boynton Beach, FL, Quantasorb Jr.; and JUWE Laborgerate Service GmbH, Korschenbroich, Germany, Stroehlein AREAmeter II. National Institute of Standards and Technology (NIST) Standard Reference Material SRM^{R} 2696 (22.92 m^2/g) for specific surface is available for use in comparison and evaluation of laboratory equipment and procedures.

15. AIR-ENTRAINMENT OF MORTAR

15.1. Follow the applicable provisions of ASTM C 311, except use the following test mixture and equation for W_c:

	Test Mixture
Portland cement, g	300
Silica fume, g	30
20-30 Standard Ottawa sand, g	1170
Water, mL, sufficient to give a flow of 80 percent to 95 percent	Y
Neutralized Vinsol resin solution, mL, sufficient to produce an air content of 18 ± 3 percent	Z

$$W_c = \frac{300 + 1170 + 30 + \left(300 \times P \times 0.01\right)}{300/3.15 + 1170/2.65 + 30/D + \left[\left(300 \times P \times 0.01\right)/1\right]} \qquad (2)$$

Then calculate:

Air content, volume % = $100[1–(M/W_c)]$ $M = W/400$ *(3)*

where:

M = actual mass per unit of volume of mortar as determined by T 137, g/mL;

W = mass of the specified 400 mL of mortar (see T 137), g;

W_c = theoretical mass per unit volume, calculated on an air-free basis and using the values for density and quantities of the materials in the mixture, g/mL;

P = percent of mixing water plus Vinsol resin solution based on mass of cement; and

D = density of silica fume used in the mixture, Mg/m^3.

15.2. Determine the flow in accordance with the applicable provisions of T 106M/T 106.

16. ACCELERATED POZZOLANIC STRENGTH ACTIVITY INDEX WITH PORTLAND CEMENT

16.1. Use the applicable section on strength activity index with portland cement of ASTM C 311, except change to reflect testing at constant water to cementitious materials ratio. Prepare test specimens from the batch proportions of the control mixture and the test mixture, molding three cubes from both the control mix and the test mix.

16.1.1. *Control Mixture*:

16.1.1.1. 500 g of portland cement,

16.1.1.2. 1375 g of graded standard sand, and

16.1.1.3. 242 mL of water.

16.1.2. *Test Mixture*:

16.1.2.1. 450 g of portland cement,

16.1.2.2. 50 g of silica fume,

16.1.2.3. 1375 g of graded standard sand, and

16.1.2.4. 242 mL of water.

16.1.2.5. *X* grams of dry high-range water reducer, meeting specification M 194 Type F, required to produce a flow of 100 to 115 percent. Add the high-range water reducer directly to the mixing water in the mixing bowl. Then add the cement or the cement-silica fume mixture and start the mixing cycle.

16.1.3. Determine the flow in accordance with the applicable provisions of ASTM C 1437.

16.1.4. *Storage of Specimens*—After 24 hours of initial curing in the moist room (23 ± 2°C and relative humidity of not less than 95 percent), place the cubes in airtight glass containers and store at 65 ± 2°C for 6 days.

16.1.5. Determine the compressive strength, as specified in T 106, of the three specimens of the control mixture and the three specimens of the test mixture at 7 days after molding.

17. REACTIVITY WITH CEMENT ALKALIES

17.1. Determine the reduction of mortar expansion in accordance with ASTM C 441, except that the amount of silica fume in the test mixture shall be 10 percent by mass of cementitious material.

18. SULFATE RESISTANCE

18.1. Determine the sulfate resistance according to ASTM C 1012, except that the amount of microsilica in the test mixture shall be 10 percent by mass of cementitious material.

19. BULK DENSITY

19.1. The bulk density of silica fume is defined as the mass of a unit volume of loose silica fume.

19.2. This test method covers determination of the bulk density of silica fume as silica fume is transferred from one container to another with controlled minimum compaction. Its particular usefulness is in connection with identifying material form (as produced or densified), silo or truck storage capacity, material handling, and transportation characteristics.

19.3. *Equipment*:

19.3.1. *Balance*—meeting ASTM C 1005, with a sensitivity of 0.1 g.

19.3.2. *Vibrating Table, Table Top*[1]—electromagnetic vibrating table with a controlled low amplitude that does not exceed 1-mm linear vibration. Approximate deck size is 175 × 250 mm with a 5-kg capacity. The amplitude of the vibration shall be capable of being regulated to suit the characteristics of the material being handled.

19.3.3. *Stainless Steel Beaker*—of known volume, not less that 1 L calibrated to the nearest ±1 mL, without a spout.

19.4. *Procedure*:

19.4.1. Determine the mass of the clean dry beaker to the nearest 1 g.

19.4.2. Fill the beaker with silica fume and compact by use of the vibrating table at a mid-range setting for 15 s, adding materials as needed.

19.4.3. Screed or strike off the measure with a straightedge or spatula to produce a flat, even surface that is level with the rim or edge of the beaker. Wipe off any excess silica fume that may adhere to the sides.

19.4.4. Place the filled measure on the balance and determine the mass of the silica fume to the nearest 1 g.

19.5. *Calculation*:

19.5.1. Divide the net mass of the silica fume in grams by the volume of the container in milliliters. Multiply by 1,000 to express the density in kilograms per cubic meter. To convert the value in kilograms per cubic meter to pounds per cubic foot, divide by 16.01846.

20. REPORT

20.1. Report the following information:

20.1.1. SiO_2 content, percent;

20.1.2. Moisture content, percent;

20.1.3. Loss on ignition, percent;

20.1.4. Oversize, percent; retained

20.1.5. Bulk density, kg/m^3;

20.1.6. Density, Mg/m^3;

20.1.7. Name of manufacturer and brand, if applicable;

20.1.8. Accelerated Pozzolanic Strength Activity Index;

20.1.9. Specific surface, m^2/g; and

20.1.10. Total alkalies, as equivalent Na_2O, percent;

20.2. Report the following information when specifically requested by the purchaser:

20.2.1. The quantity of air-entraining agent compared to the 10 preceding tests, percent;

20.2.2. Reduction of mortar expansion, percent; and

20.2.3. Sulfate resistance expansion, percent.

21. PRECISION AND BIAS

21.1. *Precision*:

21.1.1. *Accelerated Pozzolanic Strength Activity Index Test*:

21.1.1.1. *Single-Operator Precision*—The precision of this test will be evaluated using ASTM C 670.

21.1.1.2. *Multilaboratory Precision*—The precision of this test will be evaluated using ASTM C 670.

21.1.2. *Density Test*:

21.1.2.1. *Single-Operator Precision*—The single-operator standard deviation among single test results (a test result is defined in this specification as the average of two separate measurements) has been found to be 0.035 Mg/m^3. Therefore, results of two properly conducted tests by the same operator should not differ by more that 0.099 Mg/m^3 on the same silica fume.[2]

21.1.2.2. *Multilaboratory Precision*—The multilaboratory standard deviation among single test results (a test result is defined in this specification as the average of two separate measurements) has been found to be 0.047 Mg/m^3. Therefore, results of two properly conducted tests in different laboratories on the same silica fume should not differ by more that 0.132 Mg/m^3 of their average.[2]

21.1.3. *Bulk Density*:

21.1.3.1. *Precision*—The precision of this test method will be evaluated using ASTM C 670.

21.1.3.2. *Bias*—Since there is no accepted reference material suitable for determining any bias that might be associated with this test method, no statement on bias is being made.

21.2. *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedures for measuring the accelerated pozzolanic strength activity index and the density, no statement on bias is being made.

22. REJECTION AND RETESTING

22.1. The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the tests, the producer or supplier is not prohibited from making a claim for retesting.

23. CERTIFICATION

23.1. When specified in the purchase order or contract, the purchaser shall be furnished certification that samples have been tested as directed in this specification and that the specified requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

24. PACKAGING AND PACKAGE MARKING

24.1. When silica fume is delivered in packages, the name and brand, if applicable, of the manufacturer or distributor and the mass of the silica fume contained therein shall be clearly marked on each package. Similar information shall be provided in the shipping invoices accompanying the shipment of packaged or bulk silica fume in dry or slurried forms. All packages shall be in good condition at the time of inspection.

25. STORAGE AND INSPECTION

25.1. Silica fume shall be stored in such a manner as to permit easy access for proper inspection and identification of each shipment. Facilities for inspection and sampling shall be provided at the point from which the material is to be shipped.

APPENDIXES

(Nonmandatory Information)

X1. SILICA CONTENT

X1.1. Since the quantity of amorphous silica is one of the primary characteristics that determines the pozzolonic activity of silica fume, determination of the total silicon content is important Gravimetric (“wet method”) determinations can be accomplished using sodium carbonate (Na_2CO_3) fusion as described in Test Method C114 and similar procedures. Instrumental methods successfully used for determination of total silicon in high silica materials include X-ray fluorescence spectrometry, inductively coupled plasma, optical emission spectrometry, and atomic absorption spectrophotometry. Silica Fume SRM^R 2696 is available from NIST for use in evaluating chemical and instrumental methods of analysis of silica fume used in conjunction with the product specifications. Because silica (SiO_2) required in this specification has to be at least 85 percent by mass of silica fume, additional silica reference manuals, such as SRM^R 1413 high alumina sand (82.77 percent) and silica flour (99 percent), may be suitable for use with instrumental methods of analysis. Analysts should note that the gravimetric method determines all chemical forms of silicon in the material as silica (SiO_2), whereas the instrumental test methods determine all chemical forms of silicon in the material as total silicon (Si), which is reported as SiO_2. Typically, it is assumed that all or nearly all of the Si that is present in silica fume is SiO_2.

X2. OVERSIZE

X2.1. The 45-µm (No. 325) sieve specification is to be used to determine the amount of foreign material present. Since silica fume is much finer than cement or fly ash, the particles will all pass through the sieve except for foreign material. Extremely fine materials tend to form agglomerations; good judgment must be exercised to differentiate between easily dispersible agglomerates and foreign materials.

X3. PROBLEM OF MIXTURE PROPORTION FOR VARIOUS TEST MIXTURES

X3.1. Such test methods as accelerated pozzolanic strength activity index with portland cement, reactivity with cement alkalies, and sulfate resistance require mixtures where the silica fume being tested replaces a given amount of cement. For specification purposes, 10 percent by mass replacement of cement by silica fume will be used rather than that which is stated in the present methods, Water-to-cementitious materials ratio will be replaced by a flow of between 100 and 115 percent. As the percent replacement with silica fume increases, the mixture becomes unworkable, and either more water is necessary or a water reducer is necessary to have a workable mixture. By limiting the mixtures to 10 percent by mass replacement, the addition of water to a certain flow is a viable alternative, even though the addition of water reducer would probably produce a higher strength. Since this is a specification, the interest is in comparing material under similar conditions, rather than in maximum strength.

X4. SULFATE RESISTANCE

X4.1. Satisfactory reductions of expansion in laboratory mixtures have been obtained with silica fume replacement levels of 5 to 15 percent. Each source of silica fume must be tested with high-C_3A portland cement to establish appropriate replacement levels for adequate sulfate resistance.

---

[1] A suitable vibrating table is the Syntron Paper Jogger, Model J-1, manufactured by F.M.C. Corporation, 57 Cooper Ave., Homer City, PA 15748.

[2] These measurements represent, respectively, the (1s) and (d2s) limits in accordance with ASTM C 670.

Standard Specification for

High-Reactivity Pozzolans for Use in Hydraulic-Cement Concrete, Mortar, and Grout

---

AASHTO Designation: M 321-04 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

High-Reactivity Pozzolans for Use in Hydraulic-Cement Concrete, Mortar, and Grout

AASHTO Designation: M 321-04 (2008)

1. SCOPE

1.1. This specification covers high-reactivity pozzolans for use as a mineral admixture in portland cement concrete and mortar to fill small voids and/or where pozzolanic action is desired. High-reactivity pozzolans are microsilica products with a particle size typically one to two orders of magnitude smaller than portland cement. These materials are usually supplied in undensified or densified dry form. If the material is supplied in a densified form, the tests should be performed on the as-collected undensified material before being processed into densified form.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.* Read the material safety data sheets for materials used. This standard is not intended for specifying silica fume as defined in Section 3.3. It is recommended that M 307 or ASTM C 1240 be used for that purpose.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 307, Silica Fume Used in Cementitious Mixtures
- T 105, Chemical Analysis of Hydraulic Cement

2.2. *ASTM Standards*:

- C 219, Standard Terminology Relating to Hydraulic Cement
- C 311, Standard Test Methods for Sampling and Testing Fly Ash or Natural Pozzolans for Use in Portland-Cement Concrete
- C 1012, Standard Test Method for Length Change of Hydraulic-Cement Mortars Exposed to a Sulfate Solution
- C 1240, Standard Specification for Silica Fume Used in Cementitious Mixtures
- C 441, Standard Test Method for Effectiveness of Pozzolans or Ground Blast-Furnace Slag in Preventing Excessive Expansion of Concrete Due to the Alkali-Silica Reaction
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. DEFINITIONS

3.1. *pozzolan*—a siliceous or siliceous and aluminous material, which in itself possesses little or no cementitious value but which will, in finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties.

3.2. *high-reactivity pozzolan*—an amorphous silica of high silica content and purity possessing high pozzolanic activity, meeting the requirements of this standard specification.

Note 1—Materials such as metakaolin, rice hull ash, zirconium fume, ultra-fine fly ash, and fume from the production of 50 percent ferrosilicon (with SiO_2 less than 85 percent) are examples of high-reactivity pozzolans.

3.3. *silica fume*—a very fine pozzolanic material composed mostly of amorphous silica produced by electric arc furnaces as a by-product of the production of elemental silicon or ferro silicon alloys (also known as condensed silica fume and microsilica), meeting the requirements of M 307 and ASTM C 1240.

4. ORDERING INFORMATION

4.1. Orders for material meeting this specification shall include the following information as necessary to adequately describe the desired product:

4.1.1. Name of material (high-reactivity pozzolan material);

4.1.2. AASHTO designation and year of issue;

4.1.3. Applicable optional chemical and/or physical requirements;

4.1.4. *Product form*—densified or undensified in kilograms per cubic meter (lb/ft^3)—dry.

5. CHEMICAL REQUIREMENTS

5.1. High-reactivity pozzolan shall conform to the chemical requirements prescribed in Table 1. Optional chemical requirements are shown in Table 2.

Table 1—Chemical Requirements

Reactive Oxides (SiO_2 + Al_2O_3 + Fe_2O_3), min percent	75.0
Sulfur trioxide (SO_3), max percent	3.0
Loss on ignition, max percent	6.0
Moisture content, max percent	3.0

Table 2—Optional Chemical Requirements[a]

Available alkalies, as Na_2O, max percent[b]	
Report value only %[b]	

[a] Optional chemical requirements will be made only at the request of the purchaser.

[b] Applicable only when specifically required for mineral admixture to be used in concrete containing reactive aggregate and cement to meet a limitation on content of alkalies.

6. PHYSICAL REQUIREMENTS

6.1. High-reactivity pozzolan shall conform to the physical requirements prescribed in Table 3. Optional physical requirements are shown in Table 4.

Table 3—Physical Requirements

Accelerated Pozzolanic Strength Activity Index:	
With portland cement, as percent of control, determine at seven days	85
Fineness: maximum percent retained on the 45-μm No. 325) sieve[a]	10

[a] Exercise care to avoid retaining agglomerations of extremely fine materials.

Table 4—Optional Physical Requirements[a]

Increase of drying shrinkage of mortar bars at 28 days, max, percent	0.10
Uniformity requirements:	
In addition, when air-entrained concrete is specified, the quantity of air-entraining admixture required to produce an air content volume of 18 percent of the mortar shall not vary from the average established by the 10 preceding tests, or by all preceding tests if less than 10, by more than, percent	20
Reactivity with cement alkalies:	
Reduction of mortar expansion at 14 days, min, percent[b]	80
Sulfate expansion 14 days, max, percent	0.045
Pozzolanic Strength Activity Index (non-accelerated curing):	
With portland cement, as percent of control, determined at 28 days	100

[a] Optional physical requirements will be made only at the request of the purchaser.

[b] The indicated tests for reactivity with cement alkalies in accordance with ASTM C 441 should not be requested unless the material is to be used with an aggregate that is regarded as deleteriously reactive with alkalies in cement. The test for reduction of mortar expansion may be made using any high-alkali cement in accordance with ASTM C 441 if the portland cement to be used in the mix is not known or is not available at the time of the test.

7. METHODS OF SAMPLING AND TESTING

7.1. High-reactivity pozzolan shall be sampled at the purchaser's option in accordance with ASTM C 311.

7.2. Testing of the high-reactivity pozzolan in accordance with the requirements of Section 8 shall be conducted at the option of the purchaser.

8. TEST METHODS

8.1. *Chemical Analysis*:

8.1.1. *Silicon Dioxide, Aluminum Oxide, Iron Oxide, and Sulfur Trioxide*—Determine in accordance with T 105 for cements with insoluble residue greater than one percent. Rapid test methods referenced in T 105 may be used.

8.1.2. *Moisture Content, Loss on Ignition, and Available Alkalies*—Make these determinations following applicable provisions of ASTM C 311.

8.2. *Physical Tests*:

8.2.1. *Density*—ASTM C 311, record only.

8.2.2. *Increase of Drying Shrinkage of Mortar Bars*—ASTM C 311, except use 500 g portland cement, 50 g high-reactivity pozzolan, and 1325 g of sand in test mixture. The 50 g of high-reactivity pozzolan replaces the 125 g of mineral admixture prescribed in ASTM C 311.

8.2.3. *Reactivity with Cement Alkalies*—ASTM C 441, except that the amount of high-reactivity pozzolan in the test mixture shall be 10 percent by mass of cementitious material.

8.2.4. *Accelerated Pozzolanic Strength Activity Index with Portland Cement*—ASTM C 311, with the procedure as modified in M 307 or ASTM C 1240, Section 16. A set of samples shall be evaluated at seven days of age. As an optional test, Pozzolanic Strength Activity Index with Portland Cement, ASTM C 311, with the procedure as modified in M 307 or ASTM C 1240, Section 16, except with curing on a non-accelerated basis as in ASTM C 109. A set of samples shall be evaluated at 28 days of age.

8.2.5. *Air-Entrainment of Mortar*—ASTM C 311, except use 300 g of portland cement, 30 g of high-reactivity pozzolan, and 1170 g of standard Ottawa sand in the test mixture. Use sufficient water, ml, to give a flow of 80 to 95 percent and sufficient neutralized vinsol resin solution, ml, to produce an air content of 18 ± 3 percent.

8.2.6. Also, use the following equation for W_c:

$$W_c = \frac{300 + 1170 + 30 + (300 \times P \times 0.01)}{300/3.15 + 1170/2.65 + 30/D + \left[(300 \times P \times 0.01)/1\right]} \tag{1}$$

8.2.7. Then calculate:

Air content, volume % = 100 $[1 - (W_a / W_c)] W_a = W/400$ (2)

where:

W_a = actual mass per unit of volume of mortar as determined by ASTM C 185, g/mL,

W = mass of the specified 400 mL of mortar (see Test Method ASTM C 185), g,

W_c = theoretical mass per unit volume, calculated on an air-free basis and using the values for density and quantities in the material in the mixture, g/mL,

P = percent passing of mixing water plus vinsol resin solution based on mass of cement, and

D = density of silica fumes used in the mixture, $\mathrm{Mg/m^3}$.

8.2.7.1. *Sulfate Expansion*—ASTM C 1012, except that the amount of high-reactivity pozzolan in the test mixture shall be 10 percent by mass of cementitious material.

9. STORAGE AND INSPECTION

9.1. The high-reactivity pozzolan shall be stored in such a manner as to permit easy access for proper inspection and identification. Every facility shall provide the purchaser access for sampling and inspection, either at the source or at the site of the work.

10. REJECTION

10.1. Materials that fail to conform to the requirements of this specification shall be rejected. Rejections shall be reported to the producer or supplier promptly.

11. CERTIFICATION

11.1. Upon request of the purchaser in the contract or order, a manufacturer's certification shall be furnished stating the results of tests made on samples of the material taken during production or transfer, and indicating conformance with applicable requirements of this specification. Information on incorporated admixtures shall also be required.

12. PACKAGING AND PACKAGE MARKING

12.1. When high-reactivity pozzolan is delivered in packages, the name and brand of the manufacturer, the loose bulk density, manufacturing lot number (incorporating manufacturing date) and the mass of the high-reactivity pozzolan contained therein shall be clearly marked on each package/pallet. Similar information shall be provided in the shipping invoices accompanying the shipment of the high-reactivity pozzolan. All packages shall be in good condition at the time of delivery.

Standard Specification for

Preformed Expansion Joint Filler for Concrete (Bituminous Type)

AASHTO Designation: M 33-99 (2007)
ASTM Designation: D 994-98 (2003)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Preformed Expansion Joint Filler for Concrete (Bituminous Type)

AASHTO Designation: M 33-99 (2007)
ASTM Designation: D 994-98 (2003)

1. SCOPE

1.1. This specification covers bituminous preformed expansion joint filler for use in concrete construction.

Note 1—Attention is called to M 153 and M 213.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 153, Preformed Sponge Rubber and Cork Expansion Joint Fillers for Concrete Paving and Structural Construction
- M 213, Preformed Expansion Joint Fillers for Concrete Paving and Structural Construction (Nonextruding and Resilient Bituminous Types)
- T 42, Preformed Expansion Joint Filler for Concrete Construction

2.2. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- D 545, Standard Test Methods for Preformed Expansion Joint Fillers for Concrete Construction (Nonextruding and Resilient Types)

3. MANUFACTURE

3.1. This product shall consist of a bituminous (asphalt or tar) mastic composition, formed and encased between two layers of bituminous impregnated felt or two layers of glass-fiber felt. The mastic shall comprise mineral fillers and reinforcing fibers, and may contain thin strips of reinforcing sheet material.

4. GENERAL REQUIREMENTS

4.1. Preformed strips of expansion joint filler shall be of such character as not to be deformed or broken by ordinary handling when exposed to atmospheric conditions and shall not become brittle in cold weather. Pieces of the joint filler that have been damaged shall be rejected.

5. PROPERTIES

5.1. *Distortion at 52°C*—The joint filler shall not show a deflection of more than 25 mm when tested in accordance with Section 8.1.

5.2. *Brittleness*—The joint filler shall not crack or shatter when tested in accordance with Section 8.2.

Note 2—Expansion joint filler having a nominal thickness of 6 mm or less shall not be subject to a requirement for brittleness.

5.3. *Water Absorption*—The water absorption of the joint filler, when tested in accordance with Section 8.3, shall not exceed the following values:

Nominal Thickness of Joint, mm	Absorption, max percent
25	2.5
19	3
13	4
9.5	5

Note 3—Expansion joint filler having a nominal thickness of less than 9.5 mm shall not be subject to a requirement for water absorption.

5.4. *Compression*—The load required to compress the test specimen to 50 percent of its thickness before test shall be not less than 690 kPa nor more than the following values when the joint filler is tested in accordance with Section 8.4.

Nominal Thickness of Joint, mm	Load Requirements, min–max, kPa
25	690–5200
19	690–5800
13	690–6400

Note 4—Expansion joint filler having a nominal thickness of less than 13 mm shall not be subject to a requirement for compression.

6. DIMENSIONS AND PERMISSIBLE VARIATIONS

6.1. The preformed strips shall conform to the dimensions specified or shown on the plans. Strips of the joint filler that do not conform to the specified dimensions, within the permissible variations of +1.6 mm to –0 mm in thickness, ±3 mm in depth, and ±6 mm in length, shall be rejected.

7. SAMPLING

7.1. *Size of Samples*—Each sample shall consist of sufficient material to provide at least three test specimens measuring 50 by 150 mm and at least one test specimen measuring 100 by 100 mm.

7.2. *Number of Samples*—One representative sample shall be selected from each shipment of 100 m^2 or fraction thereof of each thickness ordered.

7.3. Samples shall be packed for transportation in such a manner that there will be no danger of distortion or breakage.

---

8. TEST METHODS

8.1. *Distortion at 52ºC*—Cut a test specimen 50 by 150 mm, substantially flat and straight, with the 150-mm dimension parallel to the machine direction of the strip. Clamp the specimen between two blocks so that the expansion joint forms a cantilever of 90-mm length. Place the clamp and joint assembly in a force-draft oven maintained at 52 ± 1.1ºC, with the specimen in a horizontal position, for 2 hours. Measure the deflection of the specimen from the horizontal.

8.2. *Brittleness*—Cut a test specimen 50 by 150 mm with the 150-mm dimension parallel to the machine direction of the strip. Maintain the specimen at a temperature of 4 to 6ºC in water for at least 2 hours prior to testing. Clamp the specimen between two boards so that the expansion joint forms a cantilever of 90-mm length and holds in a horizontal position by a suitable rigid support. Suspend a spherical cast iron ball, weighing 400 g and having a diameter of 48 mm, by a cord tied to an eyelet fastened to the ball. For specimens having a thickness of 14 mm or less, suspend the ball 300 mm above the center of the projecting portion of the specimen. For specimens greater than 14 mm in thickness, suspend the ball 600 mm above the specimen. Release the ball by burning the cord above the eyelet. Other suitable suspension and release devices may be used.

8.3. *Water Absorption*—Cut a test specimen 50 by 150 mm from the joint filler material, in such a manner that all edges are freshly cut, and determine the mass. Immerse the specimen in water for 24 hours, remove, and wipe off the surface water with a slightly dampened cloth. Measure the mass of the specimen quickly and calculate the gain in mass and express as mass percent of water absorbed.

8.4. *Compression*—Test the joint filler in accordance with Sections 7.2 to 7.2.5 of T 42, except make only a single application of the load required to compress the specimen to 50 percent of its thickness before test; and do not measure the recovery.

Note 5—The distortion and brittleness tests are used to determine the handling characteristic of the material. The water absorption and compression tests are used to determine the suitability of the material as an expansion joint filler.

8.5. *Precision and Bias*:

8.5.1. Precision statement for single operator was calculated per ASTM C 670, Table 2, maximum acceptable range of individual measurements. No precision statement is necessary for brittleness since this property is qualified as an attribute. Precision statements are listed in Table 1.

8.5.2. Since there is no accepted reference material suitable for determining the bias in this test method, no statement on bias is made.

Table 1—Single-Operator Precision Statements

Property	Property as a Function of Nominal Thickness				
Thickness, nominal, mm	25	19	13	9.5	6.4
Distortion, max mm	25	25	25	25	25
Precision, max accept range	2.93	2.30	5.92	6.03	6.84
Brittleness	Pass[a]	Pass[a]	Pass[a]	Pass[a]	—
Precision, max accept range	[b] [b] [b] [b]				—
Water absorption, wt % max	2.5	3	4	5	—
Precision, max accept range	0.057	0.087	0.400	1.187	—
Compression, kPa, min–max	690–5200	690–5800	690–6400	—	—
Precision, max accept range	204.2	180.1	416.5	—	—

Precision, max accept range per C 670, Table 2. Maximum acceptable range between high and low individual measurements.

[a] Not crack or shatter.

[b] No precision statement is necessary for this attribute.

9. KEYWORDS

9.1. Asphalt; bituminous; construction; expansion; joint; paving; preformed.

APPENDIXES

(Nonmandatory Information)

X1. STANDARD TEST METHODS AND CONDITIONS

X1.1. *Size of Samples*—Sample sizes were used as required for each test property.

X1.2. *Number of Specimens*—For each test, three specimen were used.

X1.3. *Test Conditions*—Standard test conditions were used as required in each test section and per Section 8, Test Methods.

X2. SINGLE-OPERATOR PRECISION STATEMENTS

X2.1. ASTM C 670, “Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials,” was used to develop the single-operator precision statement.

X2.2. Windows 95 function categories were used to calculate the average (avg) values and the one-sigma (1s) limits. Data was graphed using Windows 95 Chart Wizard.

X2.3. Acceptance of individual measurement values was based on the calculated difference of two-sigma (d2s) limits as the appropriate index of test precision. Maximum acceptance range of the measurements was calculated per Table 1 of C 670 and, for a given test, the individual results of the measurements were accepted if the results were within the calculated maximum acceptable range.

X2.4. Single-operator precision was calculated per Table 2 of C 670. Results of three specimens were used to calculate the average values and the 1s limits. From C 670, Table 2, for the average of three measurements, the multiplier is 5.7 for the maximum acceptable range of individual measurements. The precision statement, then, for a single operator is calculated as follows:

Precision Statement = (1s) × 5.7.

X2.5. Calculated precision statements for the various properties are given in Table 1.

X2.6. Single-operator precision for the average compression load values, for each thickness, is also presented in Figure X2.1 (URL—upper range limit, LRL—lower range limit).

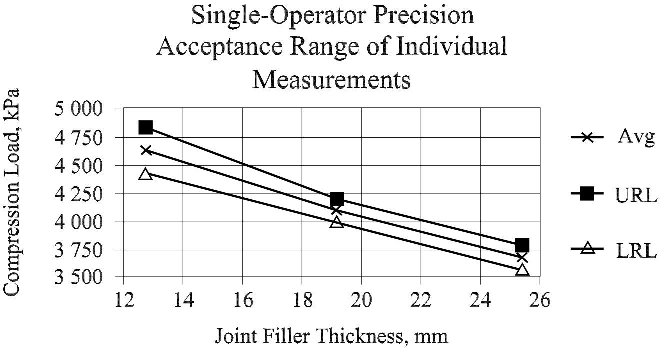

Figure X2.1—Graph I

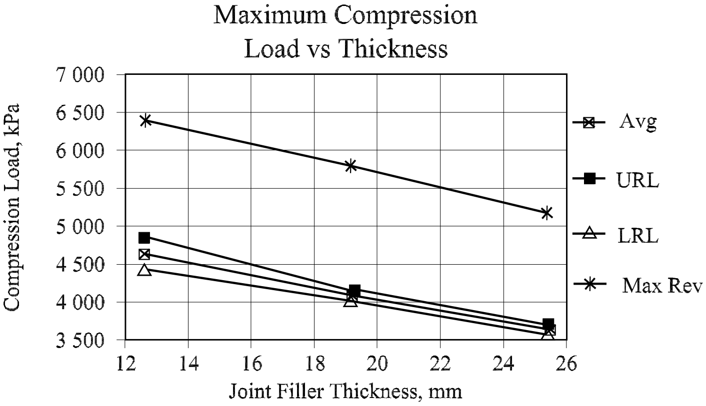

Figure X2.2—Graph II

COMPRESSION LOAD VALUES

X2.7. It was found that the compression load values are dependent on the thickness of the preformed expansion joint filler. As the thickness of the expansion filler increased, the resultant compression load values decreased as shown in Figures X2.1 and X2.2.

X2.8. Starting with the compression load value of 5200 kPa maximum for 25-mm thick joint filler, as a starting point, then by graphic analysis, the maximum compression load values were plotted for each joint filler thickness as shown in Figure X2.2 and as stated in Table 1.

Standard Specification for

Preformed Sponge Rubber and Cork Expansion Joint Fillers for Concrete Paving and Structural Construction

---

AASHTO Designation: M 153-06[1]
ASTM Designation: D 1752-04a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Preformed Sponge Rubber and Cork Expansion Joint Fillers for Concrete Paving and Structural Construction

AASHTO Designation: M 153-06[1]
ASTM Designation: D 1752-04a

1. SCOPE

1.1. This specification covers preformed expansion joint fillers of the following four types for use in concrete, brick, or stone construction:

1.1.1. *Type I*—sponge rubber,

1.1.2. *Type II*—cork,

1.1.3. *Type III*—self-expanding cork, and

1.1.4. *Type IV*—polyurethane-bonded recycled rubber.

Note 1—Attention is called to M 213 and M 33.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 33, Preformed Expansion Joint Filler for Concrete (Bituminous Type)
- M 213, Preformed Expansion Joint Fillers for Concrete Paving and Structural Construction (Nonextruding and Resilient Bituminous Types)
- T 42, Preformed Expansion Joint Filler for Concrete Construction

3. ORDERING INFORMATION

3.1. Products conforming to this specification are manufactured in sheet form to a range of thicknesses: namely, 6, 9.5, 13, 19, and 25 mm. Sheet sizes may be 900 or 1200 mm in width and lengths of 900, 1500, 1800, 3000, or 3700 mm. Purchaser must specify sheet sizes when ordering.

3.2. Joint filler in strip form is cut from the sheets as manufactured. When ordering joint filler strips, the purchaser must specify thickness, widths, and length; strip widths are available from 50 mm in increments of 13 mm.

4. MATERIALS

4.1. *Sponge Rubber*—The joint filler shall consist of preformed strips of a durable, elastic sponge rubber compound, using synthetic rubber or natural rubber as a base and containing no reclaimed rubber or factice. Unless otherwise specified, the sponge rubber shall have a cement gray color to blend with concrete in appearance.

4.2. *Cork and Self-Expanding Cork*—The joint filler shall consist of preformed strips that have been formed from clean granulated cork particles securely bound together by a synthetic resin of an insoluble nature.

4.3. *Polyurethane-Bonded Recycled Rubber*—The joint filler shall consist of preformed strips of a durable composite of ground recycled rubber from automobile tires bonded together with a polyurethane adhesive.

4.4. Preformed strips of expansion joint fillers shall be of such character as not to be deformed or broken by ordinary handling when exposed to atmospheric conditions. Pieces of the joint filler that have been damaged shall be rejected.

5. PHYSICAL REQUIREMENTS

5.1. *Test Specimen*—The sample to be tested shall be cut from the sheet as manufactured, and shall be representative of the sheet stock.

5.2. *Recovery*—The test specimen shall be compressed to 50 percent of its thickness before test. The load shall be released immediately after application. At the end of 10 minutes after release of application of the load, the specimen shall have recovered to at least 90 percent of its thickness before test.

5.2.1. In case of failure to comply with the above requirements, the test specimen shall be given three applications of a load sufficient to compress the material to 50 percent of its thickness before test. The load shall be released immediately after each application. At the end of 1 hour after the third application, the specimen shall have recovered at least 90 percent of its thickness before the test.

5.3. *Compression*—The load required to compress the test specimen to 50 percent of its thickness before test shall be not less than 340 nor greater than 10 350 kPa.

5.4. *Extrusion*—The test specimen shall be compressed to 50 percent of its thickness before test with three of the edges restrained. The amount of extrusion of the free edge shall not exceed 6 mm.

5.5. *Expansion*—In the case of self-expanding cork (Type III) expansion joint filler only, the test specimen, after being immersed in boiling water for 1 hour, shall have a final thickness not less than 140 percent of the thickness before test. Discoloration of the water shall not be considered an indication of failure.

5.6. *Boiling in Hydrochloric Acid*—In the case of cork and self-expanding cork (Types II and III) expansion joint fillers only, the test specimen shall show no evidence of serious disintegration. Discoloration or a small amount of swelling shall not be considered as failure. The test specimens shall be examined immediately after the end of the boiling period and shall be rejected for any of the following evidences of disintegration: (1) particles of cork are dislodged during the boiling period (Note 2), (2) specimen lacks resiliency, is very friable, and is easily broken to pieces, or (3) surface of specimen appears porous and particles of cork are easily dislodged by rubbing with fingers.

Note 2—Particles of cork dislodged from edges cut during preparation of the specimen should not be considered as constituting failure under this requirement.

5.7. *Density*—In the case of sponge rubber (Type I) expansion joint filler only, the density of the air-dry filler shall be not less than 480 kg/m^3.

6. DIMENSIONS AND PERMISSIBLE VARIATIONS

6.1. The preformed strips shall conform to the dimensions specified or shown on the plans. Strips of the joint filler that do not conform to the specified dimensions, within the permissible variations of ±1.5 mm in thickness, ±3 mm in depth, and ±6 mm in length, shall be rejected.

7. SAMPLING

7.1. *Size and Number of Samples*—Each sample shall consist of sufficient material to provide at least five test specimens measuring 114 by 114 mm. One representative sample approximately 0.2 m^2 shall be selected from each shipment of 100 m^2 or fraction thereof.

7.2. For self-expanding cork joint filler, a minimum of five 114 by 114 mm square specimens properly banded and plastic wrapped at the point of manufacture shall be submitted for testing.

7.3. Samples shall be packaged for safe transportation to the testing agency in such a manner that there will be no danger of distortion or breakage.

8. TEST METHODS

8.1. Determine the properties prescribed in this specification in accordance with T 42.

9. REJECTION AND RETEST

9.1. Material that fails to conform to the requirements of this specification may be rejected. Rejection should be reported to the manufacturer or supplier promptly and in writing. In case of dissatisfaction with the results of the test, the manufacturer or supplier may request retesting.

10. PACKAGING

10.1. Preformed expansion joint filler in sheets or strips should be stored and transported on pallets or a suitable flat surface to prevent breakage and permanent deformation due to weather conditions.

10.2. Self-expanding cork filler shall be wrapped in waterproof paper—sealed—in a manner that will prevent the entrance of moisture, and packaged in sizes convenient for handling on the job.

11. KEYWORDS

11.1. Construction; cork; expansion; joint; paving; preformed; rubber; sponge; structural.

---

[1] Except for the Type IV Polyurethane-Bonded Recycled Rubber Joint Filler and any reference to Type IV, this specification agrees with ASTM D 1752-04a.

Standard Specification for

Preformed Expansion Joint Fillers for Concrete Paving and Structural Construction (Nonextruding and Resilient Bituminous Types)

AASHTO Designation: M 213-01 (2010)
ASTM Designation: D 1751-04 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Preformed Expansion Joint Fillers for Concrete Paving and Structural Construction (Nonextruding and Resilient Bituminous Types)

AASHTO Designation: M 213-01 (2010)
ASTM Designation: D 1751-04 (2008)

1. SCOPE

1.1. This specification covers preformed expansion joint fillers having relatively little extrusion and substantial recovery after release from compression.

1.2. The values stated in SI units are to be regarded as the standard.

Note 1—Attention is called to M 153 and to M 33.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 33, Preformed Expansion Joint Filler for Concrete (Bituminous Type)
- M 153, Preformed Sponge Rubber and Cork Expansion Joint Fillers for Concrete Paving and Structural Construction
- T 42, Preformed Expansion Joint Filler for Concrete Construction

3. ORDERING INFORMATION

3.1. Products conforming to this specification are manufactured in sheet form to a range of thicknesses; namely, 6.4, 9.5, 13, 19, and 25 mm. Sheet sizes may be 900 or 1200 mm in width and standard length of 3 m. Purchaser must specify sheet sizes when ordering.

3.2. Joint filler in strip form is cut from the sheets as manufactured. When ordering joint filler strips, the purchaser must specify thickness, width, and length; strip widths are available from 50 mm in increments of 13 mm.

4. MANUFACTURE

4.1. This product shall consist of preformed *sheets* or strips made of one of the following:

4.1.1. Cane or other suitable fibers of a cellular *cellulosic* nature securely bound together and then uniformly saturated with asphalt;

4.1.2. Strips formed from clean granulated cork securely bound together by a suitable asphalt binder and encased between two layers of saturated felt or two layers of glass-fiber felt; or

4.1.3. Strips of a durable composite of ground recycled rubber from automobile tires bonded together with a polyurethane adhesive.

4.2. Preformed strips of expansion joint filler shall be of such character as not to be deformed or broken by twisting, bending, or other ordinary handling when exposed to atmospheric conditions.

5. REQUIREMENTS

5.1. *Test Specimen*—The sample to be tested shall be cut from the sheet, as manufactured, and shall be representative of the sheet stock.

5.2. *Compression*—The load required to compress the test specimen to 50 percent of its thickness before test shall be not less than 690 kPa and not more than 5200 kPa. If the nominal thickness of the specimen is less than 13 mm, a maximum load of 8600 kPa will be permitted. The sample after compression shall not show a loss of more than 3 percent of its original mass.

5.3. *Extrusion*—The test specimen shall be compressed to 50 percent of its thickness before test with three of its edges restrained. The amount of extrusion of the free edge shall not exceed 6 mm.

5.4. *Recovery*—The test specimen shall be compressed to 50 percent of its thickness before test. The load shall be released immediately after application. At the end of the 10 minutes after release of application of the load, the specimen shall have recovered to at least 70 percent of its thickness before test.

5.4.1. In case of failure to comply with the above requirements, the test specimen shall be given three applications of a load sufficient to compress the material to 50 percent of its thickness before test. The load shall be released immediately after each application. At the end of 1 hour after the third application, the specimen shall have recovered to at least 70 percent of its thickness before test.

5.5. *Density*—For fiber joint only, oven dry the specimen at 104 ± 3ºC for 2 hours or to a constant weight. After oven drying, cool the specimen to room temperature in a covered desiccator and weigh to the nearest 0.1 g. The density of air-dried filler material shall not be less than 304 kg/m^3. The density of oven-dried fiber filler shall not be less than 288 kg/m^3.

5.6. *Water Absorption*—A standard expansion joint filler test specimen with four square cut edges, when submerged horizontally under 25 mm of water at 21 ± 3ºC, shall absorb not more than 15 percent by volume in 24 hours for nominal thickness of 13 mm and over, and 20 percent by volume for all other thicknesses.

5.7. *Asphalt Content*—For materials manufactured as described in Sections 4.1.1 and 4.1.2, at least 35 percent by mass of the finished product shall be asphalt uniformly distributed throughout the cross-section of the material.

6. DIMENSIONS AND PERMISSIBLE VARIATIONS

6.1. The preformed strips shall conform to the dimensions specified or shown on the plans. Strips of the joint filler that do not conform to the specified dimensions, within the permissible variation of ±1.5 mm in thickness, ±3 mm in depth, and ±6 mm in length, shall be rejected.

7. SAMPLING

7.1. *Size of Samples*—Each sample shall consist of sufficient material to provide at least five test specimens measuring 114 by 114 mm. One representative sample, approximately 200 mm^2, shall be selected from each shipment of 100 m^2 or fraction thereof.

7.2. Individual samples are to be taken from separate sheets of preformed expansion joint filler.

7.3. Samples shall be packaged for transportation in such a manner that there will be no danger of distortion or breakage.

8. TEST METHODS

8.1. Determine the properties prescribed in this specification in accordance with T 42.

9. REJECTION AND RETEST

9.1. Material that fails to conform to the requirements of this specification shall be rejected. Rejection should be reported to the manufacturer and supplier promptly and in writing. In case of dissatisfaction with the test results, the manufacturer or supplier may request retesting.

10. PACKAGING

10.1. Preformed expansion joint filler in sheets or strips should be stored and transported on pallets or suitable flat surface to prevent breakage and permanent deformation.

11. KEYWORDS

11.1. Bituminous; expansion joint; filler; joint; preformed.

Standard Specification for

Preformed Polychloroprene Elastomeric Joint Seals for Concrete Pavements

AASHTO Designation: M 220-84 (2007)
ASTM Designation: D 2628-91 (2005)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249

AASHTO M 220-84 (2007) is identical to ASTM D 2628-91 (2005).

Standard Specification for

Plain and Laminated Elastomeric Bridge Bearings

AASHTO Designation: M 251-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Plain and Laminated Elastomeric Bridge Bearings

AASHTO Designation: M 251-06

1. SCOPE

1.1. This specification covers the material requirements for plain and laminated elastomeric bridge bearings. Elastomeric bearings furnished under this specification shall adequately provide for thermal expansion and contraction, rotation, camber changes, and creep and shrinkage, where applicable, of structural members. Elastomeric bearings as herein defined shall include plain pads (consisting of elastomer only) and laminated bearings with steel or fabric laminates.

3. GENERAL REQUIREMENTS

3.1. All bearings shall be designed in accordance with specifications contained in the latest edition of the AASHTO's *Standard Specifications for Highway Bridges* or the *AASHTO LRFD Bridge Design Specifications*.

3.2. The dimensions of the furnished bearings shall be the dimensions required by the design documents within the tolerances shown in Section 6 of this specification. The bearings shall be composed of the specified materials; shall be tested at the appropriate level; and shall satisfy any special requirements of the purchaser.

3.3. The contractor shall provide the purchaser with written notification 30 days prior to the start of bearing production. This notification shall include the contract number, quantity, and size of bearings being produced, manufacturer's name, location, and the representative who will coordinate production, inspection, sampling, and testing with the purchaser.

3.4. Testing for the physical properties of the elastomer may require the destruction of one or more bearings from a lot. In these instances, the cost of providing additional bearings for testing purposes shall be borne by the supplier.

3.5. At the owner's discretion, bearings specified by hardness and designed in accordance with Method A of the *AASHTO LRFD Bridge Design Specifications* or the *Standard Specifications for Highway Bridges* may be tested and accepted in accordance with Appendix X1 in lieu of Section 8.

3.6. In addition to material requirements for the bearing's individual components, this specification provides acceptance criteria for finished bearings.

4. MATERIALS

4.1. *Properties of the Elastomer*—The elastomer compound used in the construction of these bearings shall contain only virgin crystallization resistant polychloroprene (neoprene) or virgin natural polyisoprene (natural rubber) as the raw polymer. All materials shall be new with no reclaimed material incorporated in the finished bearing. The elastomer compounds shall be classified as being of low-temperature Grade 0, 2, 3, 4, or 5 as specified by the minimum grade requirements of Table 14.7.5.2-2, "Low Temperature Zones and Minimum Grade of Elastomer," of the *AASHTO LRFD Bridge Design Specifications*. Low temperature zones used in this table are as defined in Figure 14.7.5.2-1, "Temperature Zones," of the same publication.

4.2. The cured elastomer shall meet the minimum requirements of Table 1. The properties of the cured elastomeric compound material listed in Table 1 shall be determined using samples taken from actual bearings.

Table 1—Elastomer Properties

Material Property	ASTM Standard	Test Requirement	Polyisoprene (Natural Rubber)	Polychloroprene (Neoprene)	Units
Physical Properties	See Section 8.8.4				
	D 412	Min Shear Modulus	0.55 (79.7707)	0.55 (79.7707)	MPa (psi)
		Min Tensile Strength	15.5 (2248.085)	15.5 (2248.085)	MPa (psi)
		Min Ultimate Elongation	450	400	Percent
Low Temperature Brittleness	D 746 Procedure B	Grades 0 and 2—No Test Required	—	—	
		Grade 3—Test at –40ºC (–40°F)	Passes	Passes	
		Grade 4—Test at –48ºC (–54.4°F)	Passes	Passes	
		Grade 5—Test at –57ºC (–70.6°F)	Passes	Passes	

4.3. All material tests shall be carried out at 23 ± 2ºC (73.4 ± 3.6°F) unless otherwise noted.

4.4. For the purpose of determining conformance with this specification, an observed or calculated value shall be rounded off to the nearest 100 kPa (14.5038 psi) for tensile strength, to the nearest 10 percent for elongation, and to the nearest 0.01 MPa (1.4504 psi) for shear modulus.

4.5. *Steel Laminates*—Steel laminates used for reinforcement shall be made from rolled mild steel conforming to ASTM A 36/A 36M, ASTM A 1011M, or equivalent, unless otherwise specified by the purchaser. The laminates shall be of the thickness specified by the purchaser or, if left unspecified, have a minimum nominal thickness of 1.52 mm (0.0598 in.). Holes in plates for manufacturing purposes shall not be permitted unless considered in the design of the bearing.

4.6. External load bearing plates shall conform to the requirements of ASTM A 36/A 36M, ASTM A 1011M, or equivalent, unless otherwise specified in the contract documents. Except as noted, all bearings surfaces of external load plates shall be finished or machined flat within 0.25 mm (0.0098 in.). The bottom surfaces of external load plates (masonry plates) designed to rest on bearing pads shall not exceed an out-of-flatness value of 1.59 mm (0.0626 in.). The external load bearing plates shall be protected from rust until all exposed surfaces can be field painted. Any rust inhibitor utilized must be removed from all surfaces to be welded prior to welding.

4.7. *Fabric Laminates*—Fabric laminates shall be woven from 100 percent glass fibers of "E" type yarn with continuous fibers. The minimum thread count in either direction shall be 10 threads per cm. The fabric shall have either a crowfoot or an eight-harness satin weave. Each ply of fabric shall have a minimum tensile strength of 140 kN/m (799.4208 lbf/in.) of width in each thread direction, which shall be determined by ASTM D 751.

5. FABRICATION

5.1. Bearings with steel laminates shall be cast as a unit in a mold and bonded and vulcanized under heat and pressure. The molds shall have standard shop practice mold finish. The internal steel laminates shall be blast cleaned to a condition matching that of SSPC-Vis 1-01, Pictorial Standard BSP6 or CSP6, and additionally cleaned of any oil or grease before bonding. Plates shall be free of sharp edges and burrs, and shall have a minimum edge cover of 6 mm (0.2363 in.). External load plates (sole plates) shall be protected from rusting by the manufacturer, and shall be hot bonded to the bearing during vulcanization. Bearings with steel laminates that are designed to act as a single unit with a given shape factor must be manufactured as a single unit.

5.2. Fabric-laminated bearings may be molded and vulcanized in large sheets and cut to size. Cutting shall be performed so as to avoid heating the materials and produce a smooth finish with no separation of the fabric from the elastomer. Fabric shall be free of folds and ripples and shall be parallel to the top and bottom surfaces. If external steel plates are required, a cold bonding process that will yield the strengths required in Section 8.8 of this specification may be used in lieu of hot bonding.

5.3. Plain pads may be molded or extruded and vulcanized in large sheets and cut to size. Cutting shall not heat the materials, and shall produce a smooth finish to ANSI B46.1, 6.3 μm (248 μin.). Plain pads shall be molded or extruded to the finished thickness. Fabricators will not be allowed to make pads of finished thickness by plying pads of lesser thickness together. External load plates, when used, shall be protected from rusting by the manufacturer and shall be hot bonded by vulcanization during the primary molding process.

5.4. Flash tolerance, finish, and appearance of bearings shall meet the requirements of the latest edition of the *Rubber Handbook* as published by the Rubber Manufacturers Association, Inc., RMA F 3 and T.063 for molded bearings and RMA F 2 for extruded bearings.

6. TOLERANCES

6.1. Plain pads and laminated bearings shall be manufactured to the design dimensions tolerances listed in Table 2, unless other tolerances are shown on the design drawings. Use the following equation to define alignment tolerance limits for steel laminate when tolerance #3 (±3 mm) (± 0.1181 in.) is exceeded: $7.5\theta + v/h_r \leq 0.35$ provided $\theta \leq 0.02$ where θ (radians) and v (mm) (in) are absolute values of steel laminate rotation and vertical displacement. If the specified layer elastomeric layer thickness is h_r, the bearing length is L, and H_1 and H_2 are the measured maximum and minimum thicknesses at the edges of the layer, then $v = |h_r - 0.5\,(H_1 + H_2)|$ and $\theta = |(H_1 - H_2)/2L|$ for interior layers and $\theta = |(H_1 - H_2)/L|$ for top and bottom layers provided that the minimum elastomer layer thickness $H_2 \geq 5$ mm (0.1968 in.). Bearings with tolerances that satisfy this equation must also satisfy the compression test in Section 8.8 or the inclined compression test in Annex A1.

Table 2—Tolerances

	mm (in.)
1. Overall vertical dimensions:	
Design thickness 32 mm (1.2598 in.) or less	–0, +3 (0.1181)
Design thickness over 32 mm (1.2598 in.)	–0, +6 (0.2362)
2. Overall horizontal dimensions:	
For measurements 914 mm (35.9842 in.) and less	–0, +6 (0.2362)
For measurements greater than 914 mm (35.9842 in.)	–0, +12 (0.4724)
3. Thickness of individual layers of elastomer (laminated bearings only) at any point within the bearing	±3 mm (0.1181)
4. Variation from a plane parallel to the theoretical surface (as determined by measurements at the edge of the bearings):	
Top	Slope relative to the bottom of no more than 0.005 radians
Sides	6 (0.2362)
5. Position of exposed connection members	±3 (0.1181)
6. Edge cover of embedded laminates of connection members	–0, +3 (0.1181)
7. Size of holes, slots, or inserts	±3 (0.1181)
8. Position of holes, slots, or inserts	±3 (0.1181)

7. MARKING

7.1. Each elastomeric bearing shall be marked in indelible ink or flexible paint. The marking shall consist of the order number, lot number, bearing identification number, and elastomer type and grade. Unless otherwise specified in the contract documents, the marking shall be on a face that is visible after the bridge is erected.

8. BEARING TESTING AND ACCEPTANCE CRITERIA

8.1. All test apparatus used to determine conformance with these specifications shall be calibrated annually in accordance with T 67.

8.2. Sampling, testing, and acceptance consideration will be made on a lot basis. A lot of bearings shall be considered to be a group of 100 or fewer bearings that are manufactured in a reasonably continuous manner from the same batch of elastomer, cured under the same conditions, and are all the same size and type (plain, fabric-laminated, or steel-laminated). A lot may include 100 or fewer fabric-laminated bearings of different plan size if cut from a large sheet or sheets meeting these requirements.

8.3. The manufacturer shall designate the bearings in each lot and certify that each of the bearings in the lot was manufactured in a reasonably continuous manner from the same batch of elastomer, and cured under the same conditions. In addition, the manufacturer shall certify that each bearing in the lot satisfies the requirements of the design specification and meets the dimensional tolerances of Section 6 of this specification.

8.4. The dimensions of each bearing shall be checked. If any dimension is outside the limits listed in Section 6 of this specification, the lot shall be rejected.

8.5. The purchaser shall select sample bearings from the lot for testing in accordance with this specification. Sampling rate shall be as follows:

- *Plain Bearings*—Two full size bearings per lot.
- *Laminated Bearings*—One full size bearing per every ten per lot, a minimum of two bearings.

8.6. Elastomer taken from the sampled bearings shall be tested for conformance with the requirements of Sections 4.1 through 4.4 of this specification. If the sampled elastomer fails to meet any of these requirements, the lot shall be rejected.

8.7. Tests may be performed by the manufacturer, by the purchasing agency, or by an outside independent laboratory subject to the approval of the purchaser. If testing is performed by the manufacturer or an independent laboratory, certified test results shall be provided. Regardless of the agency designated to test the pads, the purchaser reserves the right to obtain test samples from the bearings for confirming test results.

8.8. Bearing criteria shall include the following:

8.8.1. Each sampled bearing shall be tested to determine compressive strain at the maximum design dead plus live service compressive load in accordance with Section 9.1 of this specification if the structural designer has specified a maximum value for compressive strain at that load. If the specified strain is exceeded, the lot shall be rejected.

8.8.2. Each sampled bearing shall be subjected to a compressive load equal to 1.5 times the maximum design dead plus live service compressive load. The load shall be held for 5 minutes, removed, and reapplied for a second period of 5 minutes. The bearing shall be visually examined while under the second loading. If the bearing exhibits three separate surface cracks that are greater than 2 mm (0.0787 in.) wide and 2 mm (0.0787 in.) deep or a single crack 3 mm (0.1181 in.) deep or wider than 6 mm (0.2363 in.), the lot shall be rejected. For laminated bearings, if bulging patterns imply laminate placement that does not satisfy design criteria and manufacturing tolerances, or if bulging suggests poor laminate bond, the lot shall be rejected.

8.8.3. A minimum of one sampled bearing per lot shall be tested for creep and shear bond strength in accordance with Annex A2 of this specification. The percent creep at 25 years shall be reported to the purchaser, when the designer specifies an allowable value. If the allowable value is exceeded, the lot shall be rejected. If the selected samples for shear bond fail the criteria of Annex A2.6.1, two additional samples shall be selected for testing in accordance with Annex A2.6.1. If the two samples fail, the lot shall be rejected.

8.8.4. The shear modulus of the elastomer shall be determined at 23 ± 1ºC (73.4 ± 1.8°F) in accordance with either Annex A1 or Annex A2 of this specification or ASTM D 4014 Annex A1 modified as follows: the initial cycles shall be taken to a strain of 0.7 and, on the last cycle, the shear modulus shall be determined at 0.5 strain. Shear modulus may be determined with either Annex A1, Annex A2, or the modified ASTM D 4014 Annex A1 for plain or laminated elastomeric pads designed according to Method A of the *AASHTO LRFD Bridge Design Specifications* or the *Standard Specifications for Highway Bridges*. Shear modulus shall be determined with Annex A1 or the modified ASTM D 4014 Annex A1 for laminated pads designed according to Method B. If the shear modulus is not within ±15 percent of the value specified, the lot shall be rejected. If shear modulus does not meet the specified minimum value from Table 1, the lot shall be rejected.

8.9. Optional test procedures, when required by the purchaser.

8.9.1. For elastomer Grades 2 through 5, additional shear modulus testing shall be performed on elastomer from the sampled bearings in accordance with Section 9.2 of this specification. If the measured stiffness at the specified temperature exceeds four times the stiffness measured at 23 ± 2ºC (73.4 ± 3.6°F), the lot shall be rejected.

8.9.2. Elastomer from the sampled bearings shall be tested for compression stiffness in accordance with Annex A3. The elastomer stiffness shall be measured at 23 ± 2ºC (73.4 ± 3.6°F) and at a lower temperature corresponding to the specified grade of elastomer. The lower test temperatures for the various grades of elastomer shall be as follow:

- Grades 0 and 2—Test at –32 ± 2˚C (-25.6 ± 3.6°F)
- Grade 3—Test at –40 ± 2˚C (-40 ± 3.6°F)
- Grade 4—Test at –46 ± 2˚C (-50.8 ± 3.6°F)
- Grade 5—Test at –54 ± 2˚C (-65.2 ± 3.6°F)

8.9.2.1. If the stiffness of the elastomer measured at the specified lower temperature is more than four times the stiffness of the elastomer measured at 23 ± 2ºC (73.4 ± 3.6°F), the lot shall be rejected.

8.9.3. The purchaser may require more severe tests of pads, such as fatigue or test to failure.

9. TESTS

9.1. *Determination of Compression Strain at Maximum Design Load*:

9.1.1. The bearing to be tested shall be placed in a test machine capable of applying a compressive load equal to the bearings' maximum design dead plus live service load.

9.1.2. A pair of deflectometers shall be placed on opposite sides of the bearing in the test machine. The deflectometers shall be located as near as possible to the center of the bearing.

9.1.3. The bearing shall be loaded at a rate of 520 kPa/min (75.4196 psi/min) to a compression stress equal to 5 percent of the bearing's maximum design dead plus live service compressive load. The 5 percent load shall be maintained for 2 minutes. At the end of the 2 minutes, the deflectometer readings shall be recorded.

9.1.4. The compressive load shall be increased at a rate of 520 kPa/min (75.4196 psi/min) to a compressive stress equal to the bearing's maximum design dead plus live service load. The load shall be maintained for a period of 2 minutes, at the end of which the deflectometer readings shall be recorded.

9.1.5. The total compressive deflection between the two loadings shall be calculated for each deflectometer. The bearing's compressive strain shall be calculated as the average of the compressive deflections indicated by the two deflectometers divided by the design effective rubber thickness of the tested bearing.

9.2. *Additional Shear Modulus Testing for Elastomer Grades 2 through 5*:

9.2.1. Shear modulus testing shall be performed as described in Annex A1 of ASTM D 4014 except as modified below.

9.2.2. The test specimens shall be taken from sampled bearings. After preparing the test specimen, it shall be conditioned for a period of time at a specified temperature. Conditioning times and temperatures for the various elastomer grades shall be as follow:

- Grade 2—7 days at –18 ± 2˚C (-0.4 ± 3.6°F)
- Grade 3—14 days at –26 ± 2˚C (-14.8 ± 3.6°F)
- Grade 4—21 days at –37 ± 2˚C (-34.6 ± 3.6°F)
- Grade 5—28 days at –37 ± 2˚C (-34.6 ± 3.6°F)

9.2.3. Shear modulus testing shall be performed with the test specimen in an enclosed freezer unit capable of maintaining the specified conditioning temperature. A ±25 percent strain cycle shall be applied with a period of 100 seconds. The first three-quarter cycle of strain shall be discarded and the stiffness shall be determined by the slope of the force deflection curve for the next half cycle of loading.

ANNEXES

(Mandatory Information)

A1. INCLINED COMPRESSION TEST FOR SHEAR MODULUS

A1.1. *Scope*:

A1.1.1. This method determines the shear modulus of full-size elastomeric bearings from the compressive force-displacement curve after three conditioning cycles to 65 percent strain.

A1.2. *Apparatus*:

A1.2.1. A compression test machine shall be used to apply the load to a pair of test bearings between three inclined platens as shown in Figure A1.1.

A1.2.2. The inclined platens shall be made out of steel or aluminum. The surface inclination can vary between 1:10 and 1:20. All platens shall have the same surface inclination. The platen dimensions shall be greater than the dimensions of the bearings tested. The minimum thickness of the aluminum platens shall be 12 mm (0.4724 in.). The top and bottom platens shall be attached to the testing machine.

A1.2.3. The platen surfaces, or facing plates attached to the platens, that are in contact with the bearings shall be roughened to prevent bearing slip during the test. The roughening can be performed by impacting with a tool that is used to roughen concrete surfaces, blasting with grit, or other equivalent means. Milled grooves no deeper than 1 mm (0.0394 in.) can also be used to provide a no-slip surface.

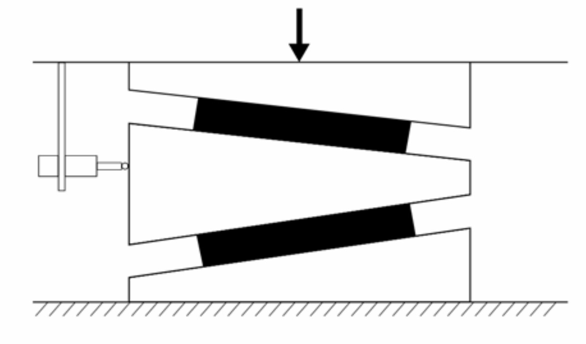

Figure A1.1—Inclined Compression Test Setup

A1.3. *Test Specimen*:

A1.3.1. The elastomeric bearings shall be of uniform thickness and of rectangular or circular in cross-section. The thickness shall not be less than 6 mm (0.2363 in.). The length and width of each bearing shall not be less than four times the thickness.

A1.3.2. Plain elastomeric pads must be bonded to rigid plates on both the top and bottom surfaces. The bonding system must not require a curing temperature greater than 40ºC (104ºF). The plates shall be of rectangular section and may be of mild steel. Plate dimensions shall be slightly larger than bearing dimensions. A thickness ≥5 mm (0.1968 in.) can be used for the plates.

A1.3.3. Measure the length, width, and total elastomer thickness of the bearings to determine the average cross-sectional area (*A*) and average elastomer thickness (*T*) of a bearing.

A1.3.4. Laminated pads shall be tested with or without any sole plates attached.

A1.3.5. The contact surfaces of bearings that are not bonded to steel plates shall be cleaned to remove any kind of residue.

A1.4. *Test Procedure*:

A1.4.1. Allow time for any bonds to achieve adequate strength and condition the specimen at a test temperature of 23 ± 2ºC (73.4 ±3.6ºF) at least eight hours prior to testing unless another test temperature is specified.

A1.4.2. Bearings shall be sandwiched between the platens until the surfaces are in contact with each other.

A1.4.3. Two deflectometers shall be attached to monitor the horizontal displacement of the middle platen. The deflectometers shall be accurate to a least 0.025 mm (0.000984 in.).

A1.4.4. Carry out four successive loading and unloading cycles to a deformation equal to 65 percent of the average bearing thickness, and at such a loading rate that the time per cycle is within a range of 4 to 6 minutes. In all the unloading cycles, the minimum load shall be 5 kN (1124.045 lbf) or 2 percent of the maximum load, whichever is less.

A1.4.5. If there is any indication of slip of the bearings relative to the rigid plates or of bond failure during the test, prepare new specimens and repeat the test.

A1.4.6. If the middle platen does not come back to the same approximate position after the last two successive unloading cycles, a slip may have occurred between the bearing and the platens. This condition must be remedied for a valid test.

A1.5. Determination of Shear Modulus:

A1.5.1. The shear modulus shall be determined from the fourth cycle of compressive load versus average displacement curve as shown in Figure A1.2.

A1.5.2. Take an effective origin at force F_1, extension X_1 where F_1 is 5 kN (1124.045 lbf) or 2 percent of the maximum force on the fourth cycle, whichever is smaller. Determine the force F_2 at an extension X_2 given by $X_1 + 0.5T$, where T is the average total elastomer thickness of the pad (overall pad thickness minus the thicknesses of all the laminates within the bearing).

A1.5.3. The shear modulus is calculated as follows:

$$\text{Shear Modulus} = \frac{2(F_2 - F_1)}{A \times n}$$

For 1:*n* sloped platens. The factor *n* converts the vertical compressive force to a horizontal shear force.

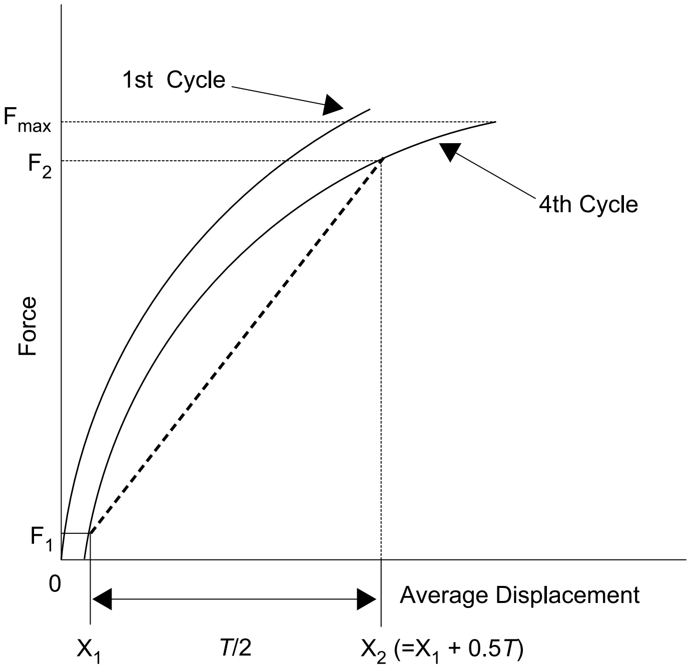

Figure A1.2—Compression Force vs. Shear Displacement

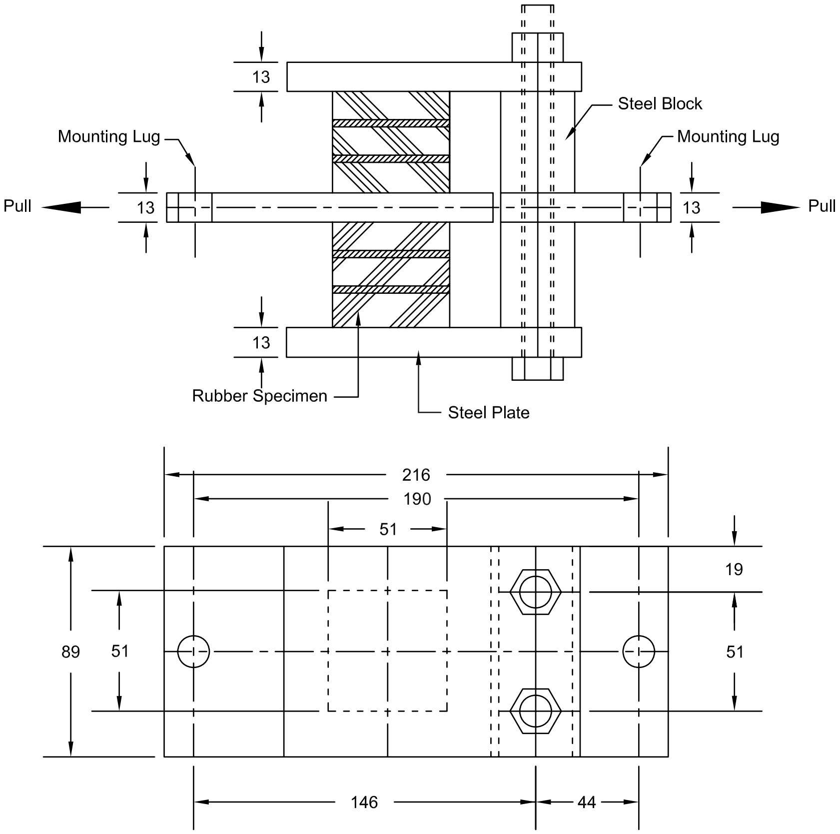
A2. A TEST METHOD FOR CREEP AND SHEAR BOND IN ELASTOMERIC BEARINGS

A2.1. *Scope*:

A2.1.1. This document describes a procedure to estimate creep and shear bond of elastomeric bridge bearings. It also describes a procedure for estimating shear modulus of elastomeric bearings as allowed in Section 8.8.4.

A2.1.2. The values stated in SI units are to be regarded as the standard.

A2.1.3. *This document does not purport to address the details of the test setup or safety concerns, if any, associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to using the test summarized in this document.*



Equivalent U.S. Customary Units

mm	in.	mm	in.
13	0.5118	89	3.5039
19	0.7480	146	5.7480
44	1.7323	190	7.4803
51	2.0079	216	8.5039

Figure A2.1—Test Setup (mm)

A2.2. *Referenced Documents*:

- ASTM D 3183, Standard Practice for Rubber-Preparation of Pieces for Test Purposes from Products

A2.3. *Test Specimen*:

A2.3.1. The standard test specimen shall consist of two 51 by 51 mm (2.0079 by 2.0079 in.) square pieces of rubber bonded to steel plates as shown in Figure A2.1. The aspect ratio, height to width, should be between 0.75 and 1.25. If the subject bearing is laminated, the test specimens should have a minimum of at least two to three layers of elastomers.

A2.3.2. The rubber pieces shall be cut from one of the subject bearings per ASTM D 3183.

A2.3.3. The adherence of rubber to steel plate can be cold or hot, using an appropriate adhesive system and surface preparation adequate to keep the bond fully intact for 8 hours while the test specimen is subjected to a sustained shear strain of 50 percent at room temperature.

Note A1—When testing fabric-reinforced laminated bearings, which utilizes a bonded external load plate, the adhesive system for the cold bond between the elastomer and the steel plate shall be the same as that used in the actual manufactured bearings.

A2.3.4. The total height of the rubber piece shall be greater than 12 mm (0.4724 in.) and less than 45 mm (1.7717 in.). If the rubber piece consists of alternate layers of rubber and either metal or fabric reinforcements cut from actual bearing as shown in Figure A2.1, the total height of each rubber piece shall be limited to 51 mm (2.0079 in.).

A2.4. *Test Procedure*:

A2.4.1. Mount the test specimen in a displacement controlled loading system (MTS or equivalent) with appropriate load cell connected to a data acquisition system (automatic or manual).

A2.4.2. Load the specimen to 50 percent shear strain ten times at 1 percent strain per second. Shear strain is defined as the ratio of shearing displacement to the total thickness of rubber in the test piece. If the rubber thickness in one piece is R_{thk}, then for 50 percent strain, the specimen needs to be displaced $0.5R_{thk}$.

A2.4.3. Load the specimen to 50 percent shear strain in 1 second and keep the strain constant for a minimum of 6 hours.

A2.4.4. Record the load after 30 minutes of initial loading with further measurements after every 5 minutes for 360 minutes, minimum.

A2.4.5. For each time measurement, use Equation A2.1 to convert the load to shear modulus:

$$G(t) = \frac{load(t)}{51 \times 51 \times 2 \times 0.5} \qquad (A2.1)$$

where $load(t)$ is the load at time t (min) and $G(t)$ is the shear modulus (MPa) (psi) at time t. Note that (51 by 51) is the area of test piece and 0.5 is the shear strain. Since there are two test pieces in the test specimen, the load is divided by two.

A2.4.6. A power law of the form shown in Equation A2.2 can be conservatively used to predict $G(t)$ at times greater than 30 minutes.

$$G(t) = at^b \qquad (A2.2)$$

Where a and b are constants that are calculated by regression analysis of the data obtained in Section A2.4.5 as described in Section A2.4.7.

A2.4.7. Plot $\log(G(t))$ versus $\log(t)$ and fit a straight line using the least-squares method. The constant b is the slope of this line and $\log(a)$ is the intercept of the straight line on the $\log(G(t))$ axis.

A2.5. *Creep Estimate for Full-Size Bearing*:

A2.5.1. Let T be the time at which creep deflection needs to be estimated (e.g., 25 years).
Calculate $G(t)$ = 60 minutes and at $t = T$ using Equation A2.2.

A2.5.2. Calculate percent creep using Equation A2.3.

$$\text{Creep (\%)} = \left(\frac{G(60)}{G(T)} - 1 \right) \times 100 \qquad (A2.3)$$

A2.6. *Shear Bond*:

A2.6.1. After completion of the 6-hour stress relaxation test, load the specimen to 150 percent strain at 1 percent strain per second. Hold the specimen at 150 percent strain for 5 minutes and observe any failure in the rubber or debonding at the interface of the rubber layers and laminates or steel plate. Failure will be defined as separation of the elastomer from the laminate or steel plate in any one interface area, which exceeds either 2 mm (0.0787 in.) deep or 10 mm (0.3937 in.) long. Report the type of failure. Failures in the cold bond (when used) are not important unless they affect the ability to reach 150 percent strain, in which case a new specimen must be fabricated.

A3. COMPRESSION STIFFNESS TEST METHOD

A3.1. *Compression Stiffness Test Method*:

A3.1.1. This test determines the compressive stiffness of elastomeric bridge bearings over a wide temperature range by direct measurements of compressive loads and displacements. The test method is useful for determining the relative changes in stiffness over a wide range of temperatures as well as determining the compressive stiffness over a wide range of temperatures.

A3.2. *Test Setup*:

A3.2.1. A compression testing machine shall be used that is capable of exerting a compressive load of 500 kN (1124404.5 lbf) to a pair of bearing specimens as shown in Figure A3.1.

A3.2.2. Four displacement transducers or other devices with an accuracy of 0.005 mm (0.000197 in.) shall be used to record the displacements. Load shall be monitored with a load cell or other equivalent device with an accuracy of 1 percent of the test load.

A3.2.3. The specimens and loading plates shall be conditioned and tested in an enclosed unit capable of controlling temperatures down to −30 ± 2°C (−22 ± 3.6°F). Depending on the temperature ranges and conditioning time involved, mechanical refrigeration or a dry-ice chest or both will be advantageous.

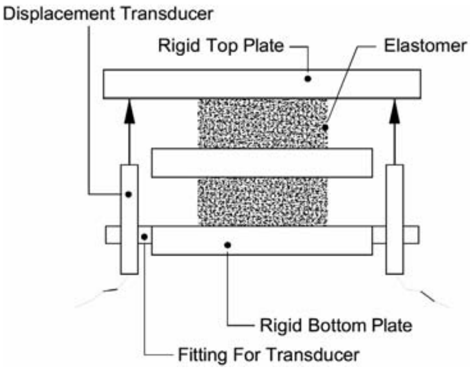


Figure A3.1—Test Setup

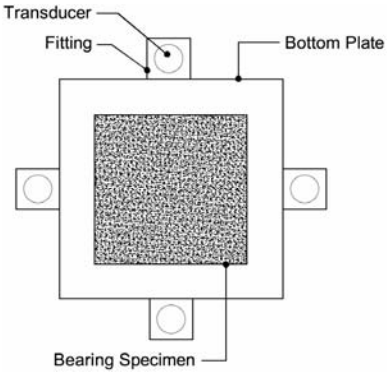

Figure A3.2—Location of Transducers

A3.3. *Test Specimen*:

A3.3.1. The test specimen in Figure A3.1 shall consist of two identical blocks of elastomer sandwiched between rigid plates. The elastomer blocks shall be of uniform thickness, preferably equal to the original thickness of the full-size bearing and of square or rectangular cross-section, the length and width each being not less than four times the thickness.

A3.3.2. The steel rigid plates shall be of square or rectangular section, a larger width and length than the elastomer block. Suitable plate dimensions for use with 40-mm (1.5748-in.) thick elastomeric pads are a thickness of 25 mm (0.9843 in.) and a plan dimension at least 25 mm (0.9843 in.) larger than each block dimension.

A3.4. *Test Procedure*:

A3.4.1. Measure the length, width, and thickness of the blocks and determine the average cross-sectional area, plan area (A), and the average total elastomer thickness (T), of the specimen.

A3.4.2. Attach four displacement transducers between the top and bottom plate such that the relative displacement between the top and bottom plate can be measured at four points as shown in Figure A3.2. The center points of each side of the bottom plate are appropriate locations for the transducers.

A3.4.3. Place the specimens inside the environmental chamber (or freezer), and bring the freezer to the desired test temperature. Condition the specimens at the specified test temperature for the specified period of time.

A3.4.4. Attach the specimens to the compression machine. Carry out three successive loading and release cycles to a deformation equal to 10 percent of the total elastomer thickness of the two blocks, $2T$, at a rate such that the time per cycle is within the range of 30 to 120 seconds.

A3.4.5. Measure both the load and the displacement at $0.02T$ increments only for the third cycle.

A3.5. *Determination of Stiffness*:

A3.5.1. The compressive modulus E_s shall be determined from the load-displacement curve on the third cycle as shown in Figure A3.3.

A3.5.2. Draw a best-fit straight line using the least-squares method through the data points between displacements $0.02T$ and $0.2T$. The line must pass through the $0.02T$ data point. Determine the slope K_1, of the best-fit straight line.

A3.5.3. Determine E_s from Equation A3.1.

$$E_s = K_1 \frac{2T}{A} \qquad (A3.1)$$

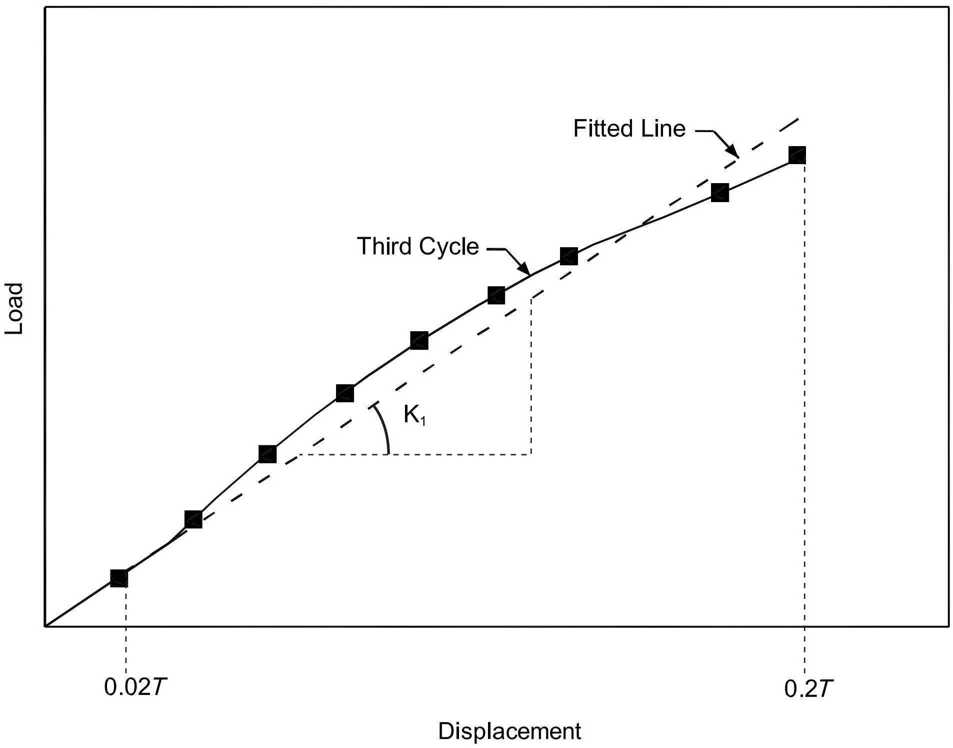

Figure A3.3—Load Displacement Curve

APPENDIXES

(Nonmandatory Information)

X1. OPTIONAL TEST AND ACCEPTANCE CRITERIA FOR METHOD A DESIGN ELASTOMERIC BRIDGE BEARINGS

X1.1. *General*:

X1.1.1. This Appendix is intended to be an alternative for use in conjunction with M 251 for elastomeric bridge bearings, which are specified by hardness and designed in accordance with AASHTO's *LRFD Bridge Design Specifications* or the *Standard Specifications for Highway Bridges*. The optional materials test methods of Appendix X1 may be used in lieu of the materials test methods of Table 1, when specified by the purchaser.

X1.2. The materials specifications remain as listed in M 251-06 as noted.

X1.3. Table 1 in Section 4 is replaced by the following tests:

Table X1. Optional Materials Test Procedures for Elastomeric Bridge Bearing Elastomers

			Polyisoprene (Natural Rubber)			Polychloroprene (Neoprene)			Units
Material Property	ASTM Standard	Test Requirements	50	60	70	50	60	70	
Physical Properties	D 2240	Hardness	50 ± 5	60 ± 5	70 ± 5	50 ± 5	60 ± 5	70 ± 5	Shore “A” points
	D412	Min tensile strength	15.5 (2248.085)	15.5 (2248.085)	15.5 (2248)	15.5 (2248.085)	15.5 (2248)	15.5 (2248.085)	MPa (psi)

	Procedure B	Grades 3—test at –40ºC (–40ºF)	Pass	Pass	Pass	Pass	Pass	Pass	
		Grade 4—test –48ºC (–54.4ºF)	Pass	Pass	Pass	Pass	Pass	Pass	
		Grade 5—test at –57ºC (–70.6ºF)	Pass	Pass	Pass	Pass	Pass	Pass	

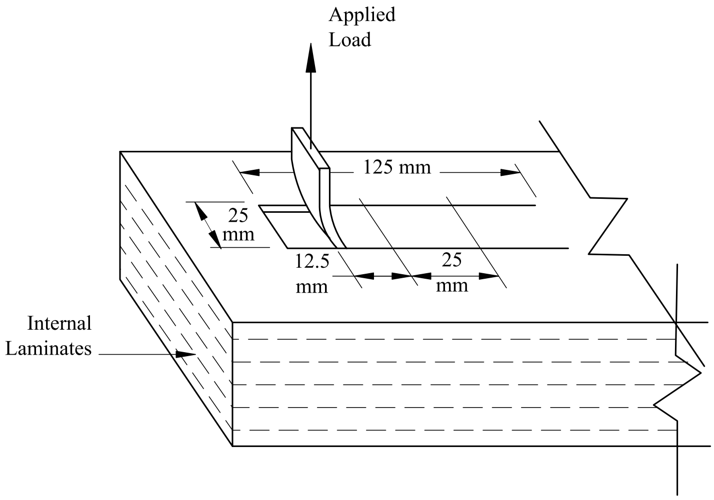
X2. BEARING TESTING AND ACCEPTANCE CRITERIA

X2.1. *Bearing Testing and Acceptance Criteria*—Sections 8.1 through 8.8.2 shall apply.

X2.2. For laminated bearings, a minimum of one sampled bearing per lot shall be tested for bond strength. Fabric-reinforced pads shall have a minimum bond strength of 5.2 kN/m (1169.006 lbf/min) and steel-reinforced pads, a strength of 6.9 kN/m (1551.182 lbf/min). If the test bearing fails to meet the required minimum bond strength, the lot shall be rejected.

X2.2.1. Bond strength shall be determined in accordance with ASTM 429 Method B as modified herein.

X2.2.2. The bond test shall be performed on sampled bearings by cutting the required strip from an elastomer layer bonded to an internal laminate. The strip size shall be 25 mm (0.9843 in.) wide, 125 mm (4.9213 in.) long, and at least 6.3 mm (0.2480 in.) thick.



Equivalent U.S. Customary Units

mm	in.
12.5	0.4921
25	0.9843
125	4.9212

Figure X2.1—Preparation of Bond Strength Specimens (mm)

X2.2.3. Peeling of the elastomer strip from the internal laminate shall be initiated by carefully cutting the elastomer back to create a tab long enough to install in the grips of the testing machine.

X2.2.4. Draw lines across the strip 12.5 mm (0.4921 in.) and 37.5 mm (1.4764 in.) from where the peeled portion of the strip meets the internal laminate. Install the specimen in the grips so that the angle between the elastomer tab and the surface of the bearing will be approximately 90 degrees for the duration of the test.

X2.2.5. Apply the tensile load at the required rate until the elastomer peels back beyond the 37.5 mm (1.4764 in.) mark while recording the load as required. If the load reaches 270 N (60.6984 lbf) without the elastomer starting to peel from the laminate surface, end the test and record the bond strength as 10.8 kN/m (61.6696 lbf/in.) +. If the elastomer peels back to the 37.5 mm (1.4764 in.) mark without reaching 270 N (60.6984 lbf) of load, record the bond strength as the average load in kN/m (lbf/in.) of width required to peel the elastomer between the marks. If the elastomer tab rips off the bearing before reaching the 37.5 mm (1.4764 in.) mark or reaching 270 N (60.6984 lbf) of load, retest in another area of the bearing.

---

Standard Specification for

Joint Sealants, Hot-Poured, Elastomeric-Type, for Portland Cement Concrete Pavements

AASHTO Designation: M 282-99 (2007)
ASTM Designation: D 3406-95 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Joint Sealants, Hot-Poured, Elastomeric-Type, for Portland Cement Concrete Pavements

AASHTO Designation: M 282-99 (2007)
ASTM Designation: D 3406-95 (2006)

AASHTO M 282-99 (2007) is identical to ASTM D 3406-95 (2006).

Standard Specification for

Preformed Polychloroprene Elastomeric Joint Seals for Bridges

AASHTO Designation: M 297-10
ASTM Designation: D 3542-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Preformed Polychloroprene Elastomeric Joint Seals for Bridges

AASHTO Designation: M 297-10
ASTM Designation: D 3542-08

AASHTO M 297-10 is identical to ASTM D 3542-08 except for the following provisions:

1. Replace the last sentence of Section 6.1.1 of ASTM D 3542-08 with the following:

   "The relationship of a seal's height to its depth is significant to its performance. Thus, the height shall be as agreed upon between the purchaser and the supplier."

2. The last two sentences of Section 6.2.3 of ASTM D 3542-08 are not included in M 297-10.
3. The last four sentences of Section 8.1 of ASTM D 3542-08 are not included in M 297-10.
4. Replace Section 10.1.2 of ASTM D 3542-08 with the following:

   10.1.2 A certification of test results by an independent testing agent and a statement that the material has been sampled, tested, and inspected in accordance with the provisions of the specification. Each certification so furnished shall be signed by an authorized agent of the testing agency.

Standard Specification for

Joint and Crack Sealants, Hot Applied, for Concrete and Asphalt Pavements

AASHTO Designation: M 324-08
ASTM Designation: D 6690-06a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Joint and Crack Sealants, Hot Applied, for Concrete and Asphalt Pavements

AASHTO Designation: M 324-08
ASTM Designation: D 6690-06a

AASHTO M 324-08 is identical to ASTM D 6690-06a.

Standard Practice for

Geosynthetic Reinforcement of the Aggregate Base Course of Flexible Pavement Structures

AASHTO Designation: R 50-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Geosynthetic Reinforcement of the Aggregate Base Course of Flexible Pavement Structures

AASHTO Designation: R 50-09[1]

1. SCOPE

1.1. This standard practice provides guidance to pavement designers interested in incorporating geosynthetics for the purpose of reinforcing the aggregate base course of flexible pavement structures. Geosynthetic reinforcement is intended to provide structural support of traffic loads over the life of the pavement.

1.1.1. For the purpose of this guide, base reinforcement is the use of a geosynthetic within, or directly beneath, the granular base course.

1.1.2. When referring to geosynthetics, the discussion is limited to geotextiles, geogrids, or geogrid/geotextile composites.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 288, Geotextile Specification for Highway Applications

2.2. *Other References*:

- Geosynthetics Materials Association (GMA) White Paper I—"Geosynthetics in Pavement Systems Applications," May 1999. Available at www.bookstore@ifai.com.
- Geosynthetic Materials Association (GMA) White Paper II—"Geosynthetic Reinforcement of the Aggregate Base Course of Flexible Pavement Structures," June 2000. Available at www.bookstore@ifai.com.
- National Highway Institute (NHI) Participant Notebook—*Geosynthetic Design and Construction Guidelines*, April 1999. Available at www.nhi.fhwa.dot.gov.

3. INTRODUCTION

3.1. Because the benefits of geosynthetic reinforced pavement structures may not be derived theoretically, test sections are necessary to obtain benefit quantification. Studies have been done that demonstrate the value added by a geosynthetic in a pavement structure. These studies, necessarily limited in scope, remain the basis for design in this field.

3.2. This standard practice is very empirical in nature and restricted to applications already demonstrated to be useful. The practitioner will need to consult the references and locate a tested section similar to that which is expected in their own design. In that way, the experimentally determined benefit may be applied to the project being designed.

4. TERMINOLOGY

4.1. *Definitions*:

4.1.1. *base course reduction (BCR)*—percentage of the base or subbase thickness in a reinforced pavement, as compared to the base or subbase thickness in an unreinforced pavement with the same material components, such that equal life cycles for a defined failure state result between the two.

4.1.2. *separation*—use of a geotextile to prevent the mixing of a subgrade soil and an overlying aggregate material.

4.1.3. *stabilization*—use of a geotextile in wet, saturated conditions to provide the functions of separation and drainage.

4.1.4. *traffic benefit ratio (TBR)*—ratio of the number of load cycles of a reinforced pavement structure to reach a defined failure state to the number of loads for the same unreinforced section to reach the same defined failure state.

4.2. *Discussion*—Use of geotextiles for separation and stabilization applications is covered in M 288 and, therefore, is not included in this guide.

5. SUMMARY OF DESIGN METHOD

5.1. The purpose of this guide is to provide the practitioner with general information regarding the use of a geosynthetic for reinforcement in a pavement structure. The guide will not provide step-by-step procedures for the design of the geosynthetic in this application; instead, overall design considerations are outlined.

5.2. Design procedures use experimentally derived input parameters that are often geosynthetic specific. Thus, computed engineering designs and economic benefits are not easily translated to other geosynthetics. Therefore, users of this document are encouraged to affirm their designs with field verification of the reinforced pavement performance, both in engineering design and economic benefits.

6. SIGNIFICANCE AND USE

6.1. Geosynthetics are used in the pavement structure for structural support of traffic loads over the design life of the pavement. The geosynthetic is expected to provide one or both of these benefits: (1) improved or extended service life of the pavement, or (2) reduced thickness of the structural section.

6.2. Service life improvement may be in the form of extended performance periods or increased reliability (1) so that the constructed pavement will support the actual versus designed equivalent single-axle loads, or (2) to account for actual subgrade strengths lower than assumed designed subgrade strength.

7. GENERAL DESIGN STEPS

7.1. In general terms, the design steps to be followed in determining the applicability of incorporating geosynthetic reinforcement in a pavement design are shown below.

7.1.1. General design procedures may be found in the NHI Participant Notebook on this topic.

7.1.2. A general design procedure for the reinforcement application, detailing the steps summarized below, is contained in GMA White Paper II.

7.1.3. Make an initial assessment of the applicability of a geosynthetic. This is based on an assessment of the subgrade strength and the past performance in similar soils. Consideration should be given to each type of geosynthetic appropriate for the installation.

7.1.4. Design the thickness of an unreinforced pavement section based on representative material parameters for a pavement design unreinforced by geosynthetics.

7.1.5. Determine the benefits of using a geosynthetic. Refer to Section 6.1 to determine what the target benefit or benefits should be.

7.1.6. The target benefits should indicate whether a TBR or BCR, or both, needs to be identified.

7.1.6.1. The TBR is defined as the ratio of the number of load cycles of a reinforced pavement structure to reach a defined failure state, to the number of loads for the same unreinforced section to reach the same defined failure state.

7.1.6.2. The BCR is defined as the percentage of the base or subbase thickness in a reinforced pavement, as compared to the base or subbase thickness in an unreinforced pavement with the same material components, such that equal life cycles for a defined failure state result between the two.

7.1.7. Develop a trial reinforced pavement design that reflects the desired target benefits. Though the design procedures mentioned in Sections 7.1.1 and 7.1.2 can be used to estimate the potential benefit of geosynthetic reinforcement, the accuracy of these methods for specific applications is yet to be determined; hence, construction and performance monitoring as discussed in Sections 7.1.11 and 7.1.12 is recommended. Similar case histories of pavement reinforcement should also be used to help estimate the potential benefit of geosynthetic reinforcement for the specific application being considered.

7.1.8. Perform a life-cycle cost analysis. A knowledge of the initial construction costs for both the unreinforced and the reinforced options, the life-cycle costs for both options, and other benefits, which may not be easily quantifiable, is needed in order to complete a life-cycle cost analysis.

7.1.9. Prepare material specifications. Based on the results of the above process, the engineer may want to develop an approved list of products that are considered appropriate for this application, based on successful past applications. The construction contractor then has the option, based on the results of the design, to select products based on suitability, availability, and economics.

7.1.10. Prepare contract documents, specifications, and construction drawings. Specific attention needs to be paid to installation guidelines, location within the pavement section, and quality assurance procedures when preparing these documents and drawings.

7.1.11. Monitor the construction sequences to ensure that the correct geosynthetic is installed in the correct locations, both vertically within the pavement section and horizontally along the project. The installation procedures should also be monitored to eliminate any construction damage to the geosynthetic and to ensure proper performance of the material.

7.1.12. Monitor long-term performance. Formal documentation of the pavement's performance is recommended to allow for a complete evaluation of the geosynthetic's performance in relation to the benefits that the section was designed to provide.

7.1.13. Users of this guide are encouraged to prepare an annual assessment regarding the performance of the geosynthetic.

7.1.14. Based on the above assessment of performance, design procedures and/or material specifications may be developed or revised to reflect the results of the study.

Standard Specification for

Steel Forgings, Carbon and Alloy, for General Industrial Use

AASHTO Designation: M 102M/M 102-06
ASTM Designation: A 668/A 668M-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249,
Washington, D.C. 20001

Standard Specification for

Steel Forgings, Carbon and Alloy, for General Industrial Use

AASHTO Designation: M 102M/M 102-06
ASTM Designation: A 668/A 668M-04

1. SCOPE

1.1. This specification covers untreated and heat-treated carbon and alloy steel forgings for general industrial use. ASTM specifications for forgings are available for specific applications such as pressure vessels, railroad use, turbine generators, gearing, and others involving special temperature requirements.

1.2. Hot-rolled or cold-finished bars are not within the scope of this specification.

1.3. Six classes of carbon steel and seven classes of alloy steel forgings are listed (Section 7), which indicates their required heat-treatments as well as mechanical properties.

1.4. Provision, with the suffix H for certification and marking, for the supply of forgings after hardness testing only.

1.5. Supplementary requirements, including those in ASTM A 788, of an optional nature, are provided. These shall apply only when specified by the purchaser.

1.6. Appendix X1 lists the current classes corresponding to the various classes of ASTM A 235, A 237, and A 243, which have been superseded by this specification.

1.7. The values stated in either SI units or inch-pound units are to be regarded separately as the standard; within the text and tables, the inch-pound units are shown in brackets. The values stated in each system are not exactly equivalent; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

- A 275/A 275M, Standard Practice for Magnetic Particle Examination of Steel Forgings
- A 388/A 388M, Standard Practice for Ultrasonic Examination of Steel Forgings
- A 788, Standard Specification for Steel Forgings, General Requirements
- E 381, Standard Method of Macroetch Testing Steel Bars, Billets, Blooms, and Forgings

3. TERMINOLOGY

3.1. The terminology section of ASTM A 788 is applicable to this specification.

3.2. *Definition of Terms Specific to This Standard*:

3.2.1. *hollow cylindrical forging*—a forging the length of which, as measured on its longitudinal axis, is more than its diameter shall be considered as a hollow cylinder within the scope of this specification if it has been lengthened by extrusion or forged in a manner similar to that of a ring; namely, expanded in diameter on a mandrel.

3.2.2. *ring-shaped or disk-shaped forging*—a forging the length of which, as measured on its longitudinal axis, is less than its diameter or main transverse dimension is considered a ring or disk within the meaning of this specification.

4. ORDERING INFORMATION

4.1. Material supplied to this specification shall conform to the requirements of ASTM A 788, which outlines additional ordering information, manufacturing requirements, testing and retesting methods and procedures, marking, certification, product analysis variations, and additional supplementary requirements.

4.1.1. If the requirements of this specification are in conflict with the requirements of ASTM A 788, the requirements of this specification shall prevail.

4.2. When this specification is to be applied to an inquiry, contract, or order, the purchaser shall furnish the following information:

4.2.1. The ordering information required by ASTM A 788;

4.2.2. The class of forging desired as listed in Table 1;

4.2.3. Location(s) of areas of significant loading if test specimens are to be located in accordance with Section 7.1.4.5;

4.2.4. The options that may be selected as found in Sections 5.4.2, 7.6.3, and 7.7; and

4.2.5. Any applicable supplementary requirements.

5. MATERIALS AND MANUFACTURE

5.1. *Discard*—Sufficient discard shall be made from each ingot to secure freedom from piping and undue segregation.

5.2. *Forging Process*:

5.2.1. The forging shall be brought as close as practical to finished shape and size by hot mechanical work.

5.2.2. Supplementary requirements S2, S14, and S15 may be specified by the purchaser to satisfy concerns about the utility of the proposed forging.

5.3. *Heat Treatment*:

5.3.1. All forgings, other than Class A, shall be heat-treated. See Section 7.

5.3.2. Where options exist within a class, the choice of heat treatment shall be left to the discretion of the manufacturer, unless the purchaser specifies one of the available options.

6. CHEMICAL COMPOSITION

6.1. The steel shall conform to the requirements for chemical composition prescribed in Table 1.

Table 1—Chemical Requirements

	Composition, max, percent	
Elements	Classes A to F and AH to FH	Classes G to N and GH to NH
Manganese	1.35	—
Phosphorus	0.050	0.040
Sulfur	0.050	0.040

6.2. The choice of chemical composition is left to the discretion of the manufacturer, unless otherwise specified by the purchaser.

6.3. *Heat Analysis*—An analysis of each heat shall be made by the manufacturer.

6.4. *Product Analysis*—An analysis may be made by the purchaser according to the requirements of ASTM A 788. If a standard grade has been used to manufacture the forging, the permissible variations in composition of ASTM A 788 shall apply. If a nonstandard grade of steel has been used, and composition limits have not been supplied, the product analysis can be used only to confirm the type of steel supplied.

7. MECHANICAL PROPERTIES

7.1. *Tensile Requirements*:

7.1.1. The material shall conform to the tensile properties prescribed in Table 2.

7.1.2. *Size Classification*—The dimensions of the forging at time of heat-treatment determine the size classification. (See Table 2.)

7.1.2.1. *Solid Forgings*—Either the as-forged or rough-machined diameter or thickness of solid forgings, disregarding large ends, collars, flanges, and journals, at time of heat-treatment shall determine the size classification.

7.1.2.2. *Ring or Hollow Cylinder Forging*—The size classification shall be determined by its wall thickness or width, whichever is the smaller dimension of either the as-forged or rough-machined forging at time of heat-treatment.

Table 2—Tensile Requirements

Class	Size, mm [in.]		Tensile Strength, Min	Yield Point, Yield Strength 0.2 percent Offset, Min	Elongation in 50 mm [2 in.], Min Percent	Reduction of Area, Min Percent	Brinell Hardness
	Over	Not Over	MPa [psi]	MPa [psi]			
				Carbon Steel

	305 [12]	510 [20]	552 [80000]	345 [50000]	22	38	163–207
H (HH) (Normalized and tempered)	—	180 [7]	621 [90000]	414 [60000]	22	44	187–235
	180 [7]	255 [10]	621 [90000]	400 [58000]	21	42	187–235
	254 [10]	508 [20]	620 [90000]	400 [58000]	18	40	187–235
J (JH) (Normalized and tempered, or normalized, quenched and tempered)	—	180 [7]	655 [95000]	483 [70000]	20	50	197–255
	180 [7]	255 [10]	621 [90000]	448 [65000]	20	50	187–235
	254 [10]	508 [20]	620 [90000]	450 [65000]	18	48	207–255
K (KH) (Normalized, quenched and tempered)	—	180 [7]	724 [105000]	552 [80000]	20	50	212–269
	180 [7]	255 [10]	689 [100000]	517 [75000]	19	50	207–269
	254 [10]	508 [20]	690 [100000]	515 [75000]	18	48	207–269
L (LH) (Normalized, quenched and tempered)	—	100 [4]	862 [125000]	724 [105000]	16	50	255–321
	100 [4]	180 [7]	793 [115000]	655 [95000]	16	45	235–302
	180 [7]	255 [10]	758 [110000]	586 [85000]	16	45	223–293
	254 [10]	508 [20]	760 [110000]	585 [85000]	14	40	223–293
M (MH) (Normalized, quenched and tempered)	—	100 [4]	1000 [145000]	827 [120000]	15	45	293–352
	100 [4]	180 [7]	965 [140000]	793 [115000]	14	40	285–341
	180 [7]	255 [10]	931 [135000]	758 [110000]	13	40	269–331
	254 [10]	508 [20]	930 [135000]	758 [110000]	12	38	269–341
N (NH) (Normalized, quenched and tempered)	—	100 [4]	1172 [170000]	965 [140000]	13	45	331–401
	100 [4]	180 [7]	1138 [165000]	931 [135000]	12	35	331–401
	180 [7]	255 [10]	1103 [160000]	896 [130000]	11	35	321–388
	254 [10]	508 [20]	1105 [160000]	905 [130000]	11	35	321–402

7.1.3. *Number of Tests*—Unless the purchaser specifies that forgings shall be furnished in accordance with the requirements of Section 7.3, the number of tension tests performed shall be as follows:

7.1.3.1. For all classes of heat-treated forgings with rough-machined masses less than 2250 kg [5000 lb] each, one test shall be made from each size classification represented in each heat in each annealing or normalizing charge, or from each size classification in each heat in each normalizing or quenching charge represented in each tempering charge. For untreated forgings (Class A) with a mass of less than 2250 kg [5000 lb] each, one test from each heat shall be made.

7.1.3.2. On all classes, for forgings with rough-machined masses of 2250 kg [5000 lb] or more, at least one test from each forging shall be made.

7.1.3.3. On all classes, for forgings with rough-machined masses of 3200 kg [7000 lb] or more, two tests will be taken: on ring and disk forgings 180 degrees apart; on shafts and long hollow cylinders more than 2.0 m [80 in.] in length (excluding test material), one from each end and offset 180 degrees. Shaft and cylinder forgings 2.0 m [80 in.] or less in length (excluding test material) may have both tests located at one end 180 degrees apart.

7.1.3.4. When forgings are made in multiple as a single forging, that is, forged as one piece and divided after heat-treatment, the multiple forging shall be considered as one forging, and the number of tests required shall be designated in Sections 7.1.3.1, 7.1.3.2, and 7.1.3.3.

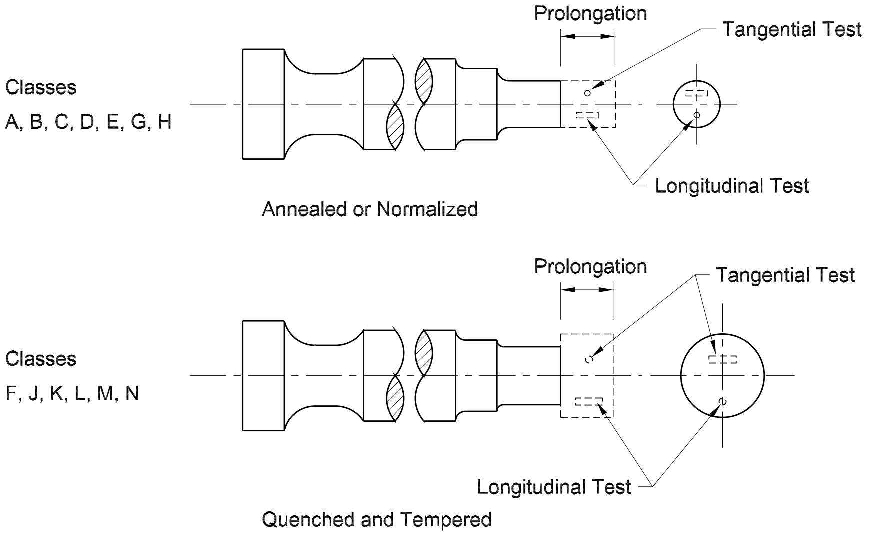
7.1.4. *Prolongations*:

7.1.4.1. A sufficient number of the forgings shall have prolongations for extracting specimens for testing. Locations of test specimens for various types of forgings shall be as shown in Figure 1.

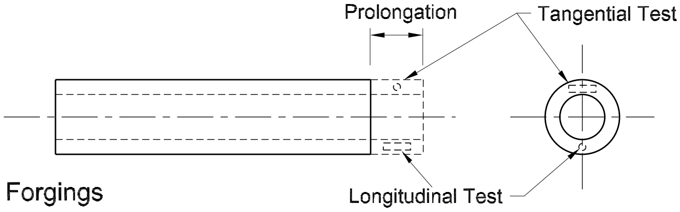
7.1.4.2. The nominal or principal outside rough-machine diameter or thickness of the forgings, disregarding large ends, collars, flanges, and journals shall determine the size of the prolongations for test specimens; however, the prolongations on annealed, normalized, or normalized and tempered shafts may be extensions of the small diameter end of the shaft, as shown in Figure 1.

7.1.4.3. For quenched forgings in Classes F, J, K, L, M, and N, the prolongations shall be sufficiently long so that the center of the gauge length (for longitudinal specimens) or axis (for tangential specimens) of the tension test specimen shall be at the following locations:

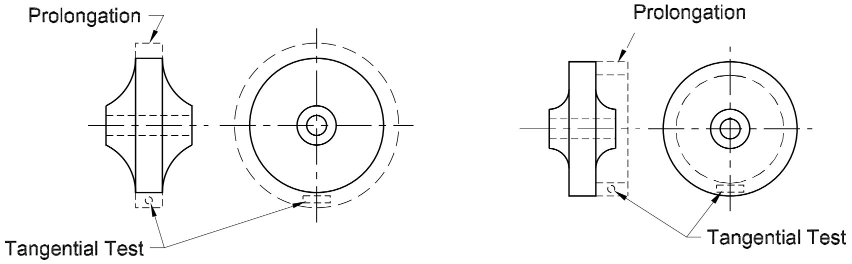
1. On solid round forgings, bars, or billets (Figure 1(a)), at mid-radius and from the end, 90 mm [$3^1/_2$ in.] or $^1/_2$ the diameter, whichever is less.
2. On solid rectangular forgings, bars, or billets, at $^1/_4$ the thickness and the width from the end, 90 mm [$3^1/_2$ in.] or $^1/_4$ the thickness, whichever is less.
3. On disk forgings (Figure 1(c)) (with prolongation on OD), at mid-thickness and from the OD 90 mm [$3^1/_2$ in.], or $^1/_2$ the thickness, whichever is less.
4. On disk forgings (Figure 1(c)) (with prolongation on the width or thickness), 90 mm [$3^1/_2$ in.] or $^1/_2$ the thickness, whichever is less, from any heat-treated surface.
5. On ring forgings (Figure 1(d)) (with prolongation on width), at mid-wall and from the ring face 90 mm [$3^1/_2$ in.] or $^1/_2$ the wall thickness, whichever is less.
6. On ring forgings (Figure 1 (d)) (with prolongation on the OD), at mid-width and from the OD 90 mm [$3^1/_2$ in.] or $^1/_2$ the width, whichever is less.



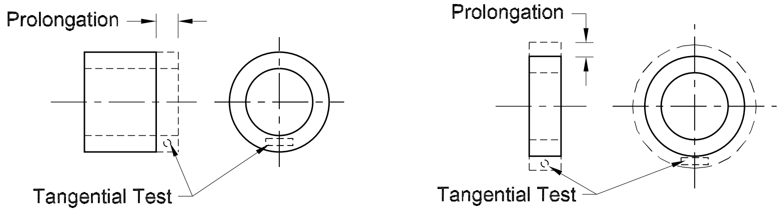
(a) Shafts and Rotors



(b) Hollow Forgings



(c) Disk Forgings



(d) Ring Forgings

Figure 1—Locations of Test Specimens for Various Types of Forgings

7.1.4.4. In place of prolongs, the manufacturer may elect to (1) submit an extra forging(s) to represent each test lot; in this event, the representative forging must be made from the same heat of steel, have received the same reduction and type of hot working, be of the same nominal thickness, and have been heat-treated in the same furnace charge as the forging(s) it represents; or (2) obtain the test specimen from the trepanned material of transverse or radial holes, provided depth is equal to or greater than the minimum depth required by Section 7.1.4.3.

7.1.4.5. With prior purchaser approval, test specimens may be taken at a depth (*t*) corresponding to the distance from the area of significant stress to the nearest heat-treated surface and at least twice this distance (2*t*) from any second surface. However, the test depth shall not be nearer to one heat-treated surface than 19 mm [$^3/_4$ in.] and to the second heat-treated surface than 38 mm [$1^1/_2$ in.]. Sketches showing the exact test locations shall be approved by the purchaser when this method is used.

7.1.5. Tests for acceptance shall be made after final heat-treatment of the forgings.

7.1.6. Test specimens shall be parallel to the axis of the forging in the direction in which the metal is most drawn out except that rings, hollow forgings which were expanded by forging, and disks shall be tested in the tangential direction.

7.1.7. Yield point shall be determined on carbon steel Grades A through F, and yield strength on alloy steel Grades G through N. For carbon steel grades not showing a yield point, the yield strength on 0.2 percent offset shall be reported.

7.2. *Hardness Tests*—Brinell hardness tests shall be performed after heat-treatment (except on Class A forgings) and rough machining on each forging having a mass under 3200 kg [7000 lb] and each multiple forging made in accordance with Section 7.1.3.4 weighing under 3200 kg [7000 lb]. For exceptions, see Sections 7.1.3.3 and 7.2.3.

7.2.1. The average value of the hardness readings on each forging shall fall within the hardness ranges specified in Table 2. The permissible variation in hardness in any forging over 110 kg [250 lb] shall not exceed 30 HB for Classes A through E, 40 HB for Classes F through J, and 50 HB for Classes K through N.

7.2.2. At least two hardness tests shall be taken on each flat face of disks, rings, and hollow forgings over 110 kg [250 lb] approximately at mid-radius and 180 degrees apart; for example, at the 3:00 and 9:00 positions on one face and the 6:00 and 12:00 positions on the opposite face. On solid forgings over 110 kg [250 lb], at least four tests shall be taken on the periphery of the forging, two at each end 180 degrees apart.

7.2.3. For forgings 110 kg [250 lb] and less, Brinell testing shall be performed on the broken test specimens representing the heat or heats included in each heat-treating charge, or in the case of untreated forgings (Class A), on the test specimen representing each heat. The results shall meet the requirements of Table 2. If the purchaser desires Brinell testing of each forging, Supplementary Requirement S11 may be used.

7.3. If so specified by the purchaser, forgings may be supplied on the basis of hardness tests alone. If this option is exercised, the class shall be identified in certification and marking with the suffix “H,” that is, “AH,” “BH,” “CH,” etc.

8. RETREATMENT

8.1. When heat-treated forgings are specified and the mechanical test results of any test lot do not conform to the requirements specified, the manufacturer may retreat the lot not more than three additional times, and retests shall be made according to Section 7. Retreatment is defined as complete re-austenization. Multiple retempering is not precluded by this requirement.

8.2. When untreated forgings (Class A) are specified and the mechanical test results of any test lot do not conform to the requirements specified, the manufacturer may anneal, normalize, or normalize and temper, one or more times, but not more than three times; and retests shall be made in accordance with Section 7. The tensile properties shall conform to the requirements for the class of forgings ordered (Class A).

9. INSPECTION, REJECTION, AND CERTIFICATION

9.1. Facilities for inspection at the place of manufacture, rejection of forgings, and certification shall comply with ASTM A 788.

10. PRODUCT MARKING

10.1. The marking requirements of ASTM A 788 shall be augmented as follows.

10.2. Each forging over 110 kg [250 lb] shall be legibly stamped by the manufacturer with the manufacturer's name or trademark, the manufacturer's serial number, the specification identification number followed by the appropriate class number, and, where applicable, a standard Grade designation.

10.3. For forgings 110 kg [250 lb] and under, the purchaser may indicate the nature and location of identification marks.

10.4. The type of stamps to be used shall be round-nosed or "interrupted-dot" die stamps having a minimum radius of 0.79 mm [$^1/_{32}$ in.].

11. KEYWORDS

11.1. Alloy steel forgings; carbon steel forgings; general industrial applications; heat-treatment classifications; strength classifications.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements shall apply only when specified by the purchaser in the inquiry, contract, or order. Details of these supplementary requirements shall be agreed upon by the manufacturer and the purchaser.

S1. CHEMICAL COMPOSITION

S1.1. The supplier shall obtain approval of the grade of steel he proposes to apply to the order and reach agreement with the purchaser on the ranges of each element specified in the composition.

S2. SPECIAL FORGING TECHNIQUES

S2.1. Special forging techniques are required to produce metal flow during the hot-working operation in the direction most favorable for resisting the stresses encountered in service. Verification of forging flow lines shall be by macroetch testing of sample forgings in accordance with ASTM E 381.

S3. ROUGH TURNING AND BORING

S3.1. The position of any rough turning or boring in the sequence of manufacturing operations.

S4. CARBON CONTENT FOR WELDING

S4.1. For forgings intended for welding, the carbon content (product analysis) shall be limited to 0.35 max percent.

S5. BEND TESTS

S5.1. The test specimen shall withstand being bent at room temperature through 180 degrees without cracking on the outside of the bent portion of an inside diameter of 40 mm [$1^1/_2$ in.].

S6. MAGNETIC PARTICLE TEST

S6.1. Forgings shall be magnetic particle tested in accordance with the latest issue of ASTM A 275/A 275M.

S7. ULTRASONIC TEST

S7.1. Forgings shall be ultrasonically tested in accordance with the latest issue of ASTM A 388/A 388M.

S8. VACUUM TREATMENT

S8.1. Vacuum degassed steel shall be supplied.

S9. TENSILE REQUIREMENTS

S9.1. When sizes larger than permitted in Table 2 are required, ductility values may be reduced from the specified values.

S9.2. Yield strengths higher than those listed in Table 2 for quenched and tempered grades may be specified.

S10. HEAT TREATMENT

S10.1. A minimum tempering temperature shall be specified.

S11. ADDITIONAL TESTS

S11.1. Tests in addition to those prescribed in Section 7 may be specified.

S12. ADDITIONAL MARKING

S12.1. Additional identification marking or the locations of the stamping or both may be specified.

S13. FORGE PROCEDURE

S13.1. The forge procedure shall be submitted by the manufacturer to the purchaser for approval prior to production of the forging.

S14. ROUGH FORGING SKETCHES

A dimensional sketch or drawing of the proposed rough forging shall be supplied by the producer for approval before the forging is produced. This drawing or sketch shall indicate also the proposed heat-treatment contour, including bores, if any, and the position of the required mechanical test coupons.

Standard Specification for

Steel Castings, Carbon, for General Application

AASHTO Designation: M 103M/M 103-06
ASTM Designation: A 27/A 27M-05

American Association of State Highway and Transportation Officials
444 North Capitol Street NW, Suite 249
Washington, DC 20001

Standard Specification for

Steel Castings, Carbon, for General Application

AASHTO Designation: M 103M/M 103-06
ASTM Designation: A 27/A 27M-05

1. SCOPE

1.1. This specification covers carbon steel castings for general applications that require up to 485 MPa [70 ksi] minimum tensile strength.

Note 1—The grades covered by this specification represent materials that are suitable for assembly with other steel castings or wrought steel parts by fusion welding. It is not intended to imply that all these grades possess the same degree of weldability or that the same welding techniques can be used on all castings. It is the responsibility of the purchaser to establish for himself a suitable welding technique.

1.2. Several grades and two classes of steel castings are covered, as indicated below. The grade and class desired shall be specified by the purchaser.

1.2.1. *Grade N-1*—Chemical analysis only.

1.2.2. *Grade N-2*—Heat-treated but not mechanically tested.

1.2.3. *Grade U-415-205 [60-30]*—Mechanically tested but not heat-treated.

1.2.4. *Grades 415-205 [60-30], 450-240 [65-35], 485-250 [70-36], and 485-275 [70-40]*—Heat treated and mechanically tested.

1.2.5. Class 1 and Class 2 steel castings shall be specified in accordance with Section 9.2.

1.3. This specification is applicable to orders in either SI units (as M 103M) or inch-pound units (as M 103). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 103.

2.1. *AASHTO Standard*:

- T 244, Mechanical Testing of Steel Products

2.2. *ASTM Standards*:

- A 732/A 732M, Standard Specification for Castings, Investment, Carbon and Low Alloy Steel for General Application, and Cobalt Alloy for High Strength at Elevated Temperatures
- A 781/A 781M, Standard Specification for Castings, Steel and Alloy, Common Requirements, for General Industrial Use

- E 527, Standard Practice for Numbering Metals and Alloys in the Unified Numbering System (UNS)

3. GENERAL CONDITIONS FOR DELIVERY

3.1. Material furnished to this specification shall conform to the requirements of ASTM A 781/A 781M, including any supplementary requirements that are indicated on the purchase order. Failure to comply with the general requirements of ASTM A 781/A 781M constitutes nonconformance with this specification. In case of conflict between this specification and ASTM A 781/A 781M, this specification shall prevail.

4. ORDERING INFORMATION

4.1. Orders for material under this specification should include the following information in proper sequence.

4.1.1. Quantity;

4.1.2. Specification, grade (Section 1.2), and class (Section 9.2);

4.1.3. Description of the casting by pattern number or drawing;

4.1.4. Options in the specification; and

4.1.5. Supplementary requirements desired, including standards of acceptance.

5. HEAT TREATMENT

5.1. All castings of Grades N-2, 415-205 [60-30], 450-240 [65-35], 485-250 [70-36], and 485-275 [70-40] shall be heat-treated by full annealing, normalizing, normalizing and tempering, or quenching and tempering. Unless otherwise specified in the inquiry, contract, or order, the castings may be heat-treated by any one or combination of these heat-treatments at the option of the manufacturer.

5.1.1. Heat-treatment shall be performed after castings have been allowed to cool from the pouring temperature to below the transformation range.

5.2. Furnace temperatures for heat-treating shall be regulated by the use of pyrometers.

6. CHEMICAL COMPOSITION

6.1. The steel shall conform to the requirements regarding chemical composition prescribed in Table 1. Product analysis tolerances shall conform to the Product Analysis Tolerances shown in ASTM A 781/A 781M. When residual element chemical content is of interest to the purchaser, S54 may be considered.

Table 1—Chemical Requirements

Grade (UNS No.)[a]	Composition, percent Carbon,[b] Max	Manganese,[b] Max	Silicon, Max	Sulfur, Max	Phosphorus, Max
Grade N-1 (J02500)	0.25	0.75	0.80	0.06	0.05
Grade N-2 (J03500)	0.35	0.60	0.80	0.06	0.05
Grade U-415-205 [60-30] (J02500)	0.25	0.75	0.80	0.06	0.05
Grade 415-205 [60-30] (J03000)	0.30	0.60	0.80	0.06	0.05
Grade 450-240 [65-35] (J03001)	0.30	0.70	0.80	0.06	0.05
Grade 485-250 [70-36] (J03501)	0.35	0.70	0.80	0.06	0.05
Grade 485-275 [70-40] (J02501)	0.25	1.20	0.80	0.06	0.05

[a] Specify Class 1 or Class 2 in addition to grade designation. (See Section 9.2.)

[b] For each reduction of 0.01 percent carbon below the maximum specified, an increase of 0.04 percent manganese above the maximum specified will be permitted to a maximum of 1.40 percent for Grade 485-275 [70-40] and 1.00 percent for the other grades.

7. TENSILE PROPERTIES

7.1. Except for Grades N-1 and N-2, one tension test shall be performed on each heat, and the mechanical properties thus determined shall conform to the requirements specified in Table 2. The tension test shall be performed in accordance with T 244.

Table 2—Tensile Requirements

Grade [a]	Tensile Strength, Min, MPa [ksi]	Yield Strength, Min, MPa [ksi]	Elongation in 50 mm [2 in.], Min, percent[b]	Reduction of Area, Min, percent
Grade U-415-205 [60-30]	415 [60]	205 [30]	22	30
Grade 415-205 [60-30]	415 [60]	205 [30]	24	35
Grade 450-240 [65-35]	450 [65]	240 [35]	24	35
Grade 485-250 [70-36]	485 [70]	250 [36]	22	30
Grade 485-275 [70-40][c]	485 [70]	275 [40]	22	30

[a] Specify Class 1 or Class 2 in addition to grade designation. (See Section 9.2.)

[b] When ICI test bars are used in tensile testing as provided for in this specification, the gauge length to reduced section diameter ratio shall be 4:1.

[c] Grade 485-275 [70-40] may be used to meet the requirement of Grade 485-250 [70-36], when agreed upon between the manufacturer and the purchaser.

7.2. Test bars shall be poured in special blocks similar to those shown in Figure 1 of ASTM A 781/A 781M and from the same heat as the casting represented.

7.3. Test coupons may be cut from the heat-treated (if required) castings or cast integrally with the castings at the producer's option.

7.4. The test bars for heat-treated castings shall be heat-treated in production furnaces to the same procedure as the castings they represent. When specified by the purchaser, the test bars shall be heat-treated with the castings.

7.5. Test specimens shall be machined to the form and dimensions shown in Figure 4 of T 244, with the ends machined to fit the grips on the tensile testing machine to be used. Suggested types of ends for standard round tension test specimens are shown in Figure 5 of T 244.

7.6. If any specimen is machined improperly or if flaws are revealed by machining or during testing, the specimen may be discarded and another substituted from the same heat.

7.7. When this specification is applied to investment castings, test coupons and tension test specimens shall be obtained and prepared as directed in S3.2 of ASTM A 732/A 732M. Test coupons shall be heat-treated as prescribed in Section 7.4.

8. RETESTS

8.1. If the results of the mechanical tests for any heat, lot, or casting do not conform to the requirements specified, retests are permitted as outlined in T 244. At the manufacturer’s option, castings may be reheat-treated and retested. When castings are reheat-treated, they may not be reaustenitized more than three times without the approval of the purchaser. Testing after reheat treatment shall consist of the full number of specimens taken from locations complying with the specification or order.

9. REWORK AND RETREATMENT

9.1. All welds shall be inspected to the same quality standards as were used to inspect the casting.

9.2. If postweld heat-treatment is required, Class 1 must be specified along with the grade, and the welds to be heat-treated must be defined. If postweld heat-treatment is not required, Class 2 must be specified along with the grade.

10. KEYWORDS

10.1. Castings; general applications; steel.

SUPPLEMENTARY REQUIREMENTS

A list of standardized supplementary requirements for use at the option of the purchaser is described in ASTM A 781/A 781M. Those which are considered suitable for use with this specification are listed below by title only. Additional supplementary requirements suitable for use with this specification at the option of the purchaser are described below. One or more of the supplementary requirements indicated below may be included in the purchaser’s order or contract. When so included, a supplementary requirement shall have the same force as if it were in the body of the specification. Supplementary requirements' details not fully described shall be agreed upon between the purchaser and the supplier, but shall not negate any of the requirements in the body of the specification.

S1. MAGNETIC PARTICLE EXAMINATION

S2. RADIOGRAPHIC EXAMINATION

S3. LIQUID PENETRANT EXAMINATION

S4. ULTRASONIC EXAMINATION

S6. CERTIFICATION

S8. MARKING

S9. CHARPY IMPACT TEST

S10. HARDNESS TEST

S12. TEST REPORT

S13. UNSPECIFIED ELEMENTS

S14. TENSION TEST FROM CASTINGS

S51. PERMISSIBLE VARIATIONS IN DIMENSIONAL TOLERANCES FOR CASTINGS MADE FROM MOUNTED PATTERNS

S51.1. Tolerances for commercial steel castings (Section S51.1.1) made from mounted patterns and the surfaces that are not to be machined shall be in accordance with Table 3. Metal match plate patterns and precise molding methods can produce closer tolerances than the values shown in Table 3. Complex casting designs may require permissible variations different from those listed in Table 3.

S51.1.1. The term "commercial castings" does not cover castings requiring special fixtures for gauging, or finishing castings by grinding to special tolerance gauges beyond the normal requirements as listed in Table 3.

Table 3—Normally Expected Deviation of Linear Casting Dimensions from Design Dimensions

Blueprint Dimensions, mm [in.]	Tolerances, mm [in.]	
Up to 75 [3], incl	+3 [+$^4/_{32}$]	–2 [–$^3/_{32}$]
Over 75 to 175 [3 to 7], incl	+4 [+$^5/_{32}$]	–3 [–$^4/_{32}$]
Over 175 to 500 [7 to 20], incl	+5 [+$^6/_{32}$]	–4 [–$^5/_{32}$]
Over 500 to 2500 [20 to 100], incl	+6 [+$^8/_{32}$]	–5 [–$^6/_{32}$]

S52. GATE AND RISER PROJECTIONS FOR CASTINGS MADE FROM MOUNTED PATTERNS

S52.1. Castings shall have gates and risers removed in a manner such that no riser or gate stub projects or a depression is made beyond or below the casting design contour in an amount that would exceed the values given in Table 4.

Table 4—Gate and Riser Projection Tolerances

Riser or Gate, Max Dimension, mm [in.]	Max Projection, mm [in.]	Max Depression, mm [in.]
Up to 100 [4], incl	3 [$^1/_8$]	3 [$^1/_8$]
Over 100 to 200 [4 to 8], incl	6 [$^1/_4$]	3 [$^1/_8$]
Over 200 to 500 [8 to 20], incl	10 [$^3/_8$]	3 [$^1/_8$]
Over 500 to 750 [20 to 30], incl	13 [$^1/_2$]	6 [$^1/_4$]
Over 750 [30]	19 [$^3/_4$]	6 [$^1/_4$]

S53. MASS DEVIATION FOR CASTINGS MADE FROM MOUNTED PATTERNS

S53.1. The allowable deviations from the average casting mass are shown in Table 5.

Table 5—Allowable Deviation[a] from Average Casting Mass

Casting Mass, kg [lb]	Positive Deviation, percent	Negative Deviation, percent
Up to 45 [100], incl	8.0	8.0
Over 45 to 230 [100 to 500], incl	6.5	5.0
Over 230 to 4540 [500 to 10000], incl	5.0	3.0
Over 4540 [10000]	3.0	2.5

[a] Deviations do not apply to mass as calculated from a design drawing.

S54. CHEMICAL ANALYSIS FOR RESIDUAL ELEMENTS

S54.1. The manufacturer shall determine the percentage of elements specified as follows, using procedures specified in ASTM A 781/A 781M. The chemical analysis thus determined shall conform to the following requirements:

Copper, max, percent	0.50
Nickel, max, percent	0.50
Molybdenum, max, percent	0.25
Chromium, max, percent	0.50

S54.2. Total content of these residual elements, maximum percent 1.00.

Standard Specification for

Gray Iron Castings

AASHTO Designation: M 105-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Gray Iron Castings

AASHTO Designation: M 105-09

1. SCOPE

1.1. This specification covers gray iron castings intended for general engineering use where tensile strength is a major consideration. Castings are classified on the basis of the tensile strength of the iron in cast test bars.

1.1.1. This specification subordinates chemical composition to tensile strength.

1.2. Castings produced to this specification are graded on the basis of minimum tensile strength obtained in special test coupons designed to standardize cooling rate. The tensile strength developed in certain casting sections may vary from test coupon values. (See Appendix X1.2.)

1.3. The values stated in SI units are to be regarded as the standard.

1.4. AASHTO M 306 may be specified for drainage structure castings such as frames, grates, rings, and covers for inlets, manholes, and other structures if loading requirements exceed normal highway loading or if more restrictive dimensional tolerances are required.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 306, Drainage, Sewer, Utility, and Related Castings
- T 68M/T 68, Tension Testing of Metallic Materials (Discontinued)

2.2. *ASTM Standards*:

- A 644, Standard Terminology Relating to Iron Castings
- A 48, Standard Specification for Gray Iron Castings
- E 8/E 8M, Standard Test Methods for Tension Testing of Metallic Materials

2.3. *Military Standard*:

- MIL-STD-129, Marking for Shipment and Storage[1]

2.4. *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipment (Civil Agencies)[1]

3. TERMINOLOGY

3.1. *Definitions of Terms Specific to This Standard*:

3.1.1. *manufacturer*—a producing foundry/facility where iron is melted and poured into molds.

3.1.2. *supplier*—an agent, representative, or organization that provides castings that it did not manufacture.

3.1.3. *purchaser*—the end user of the casting.

3.2. The preceding terms and definitions are specific to this specification. ASTM A 644 contains other terms and definitions relating to gray iron castings.

4. CLASSIFICATION

4.1. Castings ordered and produced in accordance with this specification are classified into a number of grades based on the properties of cast test bars (Table 1). Each class is designated by a number followed by a letter. The number indicates the minimum tensile strength of the cast test bar, and the letter indicates the size of the test bar. Examples of proper designations are as follows:

- Gray Iron Castings, M 105, Class 30B
- Gray Iron Castings, M 105, Class 40C

5. ORDERING INFORMATION

5.1. Orders for material to this specification shall include the following information:

5.1.1. AASHTO designation number and year of issue;

5.1.2. Class of iron required (Section 4.1 and Table 1);

5.1.3. The size of the cast test bar (letter classification—A, B, C, or S) that best represents the thickness of the controlling section of the casting (Table 3);

5.1.4. The tension test specimen (B or C) to be machined from test bar C (Section 11.3, Table 2, and Figure 2);

5.1.5. The tension test specimen to be machined from test bar S (Section 11.4, Table 2, and Figure 2);

5.1.6. Lot size (Section 14);

5.1.7. Special requirements (Section 7);

5.1.8. Saving tested specimens or unbroken test bars (Section 16.4); and

5.1.9. Special preparation for delivery (Section 18).

6. TENSILE REQUIREMENTS

6.1. Test bars representing castings conforming to this specification shall meet the requirements for tensile strength as described in Table 1.

Table 1—Requirements for Tensile Strength of Gray Cast Irons in Cast Test Bars

No. 40C		50.8 [2.0]			
No. 40S		Bar S[a]			

[a] All dimensions of test bar S shall be as agreed upon between the manufacturer and the purchaser.

7. SPECIAL REQUIREMENTS

7.1. When agreed upon in writing between the manufacturer and the purchaser, it may be necessary for the castings to meet special requirements regarding hardness, chemical composition, microstructure, pressure tightness, radiographic soundness, dimensions, surface finish, etc.

8. DIMENSIONAL REQUIREMENTS

8.1. The castings shall conform to the dimensions or drawings furnished by the purchaser, or, if there are no drawings, to the dimensions predicted by the pattern equipment supplied by the purchaser.

9. WORKMANSHIP AND FINISH

9.1. The surface of the casting shall be free of adhering sand, scale, cracks, and hot tears, as determined by visual examination.

9.2. No repairing by plugging or welding of any kind shall be permitted unless written permission is granted by the purchaser.

10. CAST TEST BARS

10.1. Test bars shall be poured from the same lot as the castings they represent, and shall have dimensions as shown in Table 2. Allowance may be made for reasonable pattern draft within the tolerances shown in Table 2. Test bars A, B, and C are all standard test bars in the form of simple cylinders. Test bar S is special and is intended for use where the standard bars are not satisfactory.

Table 2—Diameters and Lengths of Cast Test Bars

	As-Cast Diameter, mm [in.]			Length, mm [in.]	
Test Bar	Nominal (Mid-Length)	Min (Bottom)	Max (Top)	Min (Specified)	Max (Recommended)
A	22.4 [0.88]	21.6 [0.85]	24.4 [0.96]	125 [5.0]	150 [6.0]
B	30.5 [1.20]	29.0 [1.14]	33.5 [1.32]	150 [6.0]	230 [9.0]
C	50.8 [2.00]	48.3 [1.90]	53.3 [2.10]	175 [7.0]	255 [10.0]
S[a]					

[a] All dimensions of test bar S shall be as agreed upon by the manufacturer and the purchaser.

10.2. The separately cast test bars shall be cast in dried, baked, or chemically bonded molds made mainly of an aggregate of siliceous sand with appropriate binders. The average grain size of the sand shall approximate that of the sand in which the castings are poured. Molds for the test bars shall be approximately at room temperature when poured. More than one test bar may be cast in a single mold, but each bar in the mold shall be surrounded by a thickness of sand that is not less than the diameter of the bar. A suitable design for a separately cast test bar mold is shown in Figure 1.

	Required Features		Optional Features
1.	Material—Aggregate of dry siliceous sand.	1.	Number of test bars in a single mold—Two suggested.
2.	Position—Bars vertical.	2.	Design of pouring cup.
3.	*L*—See Table 3.	3.	*P*—50 mm (2 in.), suggested.
4.	*D*—See Table 3.	4.	*N*—8 mm ($^{5}/_{16}$ in.) in diameter, suggested.
5.	*W*—Not less than diameter, *D*.	5.	*M* = 1.5 *N*, suggested.

Figure 1—Suitable Design and Dimensions for Mold for Separately Cast Cylindrical Tension Test Bars for Gray Iron

10.3. Test bars that are intended to represent castings that are cooled in the mold to less than 480ºC (900ºF), before shakeout, shall be cooled in their molds to a temperature less than 480ºC (900ºF). Then they may be cooled in still air to room temperature.

10.4. Test bars that are intended to represent castings that are hotter than 480ºC (900ºF) when shaken out of their molds shall be cooled as described in Section 10.3 or (by agreement between the manufacturer and the purchaser) may be shaken out of their molds at approximately the same temperature as the castings they represent.

10.5. When castings are stress-relieved, annealed, or otherwise heat-treated, test bars shall receive the same thermal treatment and shall be treated adjacent to the castings they represent.

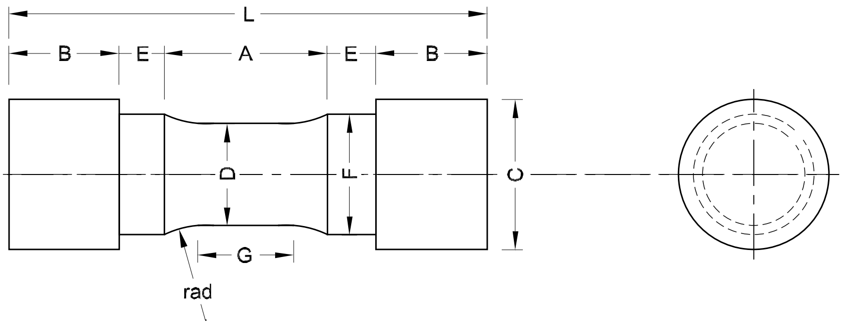
Note 1—The intent of these provisions is as follows: to prohibit the casting of test bars in molds of metal, graphite, zircon, lightweight aggregates, or other materials which would affect significantly the tensile strength of the iron; to prohibit control of tensile strength of the test bars by manipulation of the grain size of the sand; and to prohibit the casting of test bars in molds preheated substantially above room temperature.

Table 3—Cast Test Bars for Use When a Specific Correlation Has Not Been Established Between the Test Bar and the Casting

Thickness of the Wall of the Controlling Section of the Casting, mm (in.)	Test Bar
Under 6 (0.25)	S
6 to 12 (0.25 to 0.50)	A
13 to 25 (0.51 to 1.00)	B
26 to 50 (1.01 to 2)	C
Over 50 (2)	S

11. TENSION TEST SPECIMENS

11.1. *For Test Bar A*—the tension test specimen A, as shown in Figure 2, shall be machined concentric with the axis of the test bar.



Dimensions, mm (in.)	Tension Test, Specimen A	Tension Test, Specimen B	Tension Test, Specimen C
G—Length of parallel, min	13 (0.50)	19 (0.75)	32 (1.25)
D—Diameter	12.7 ± 0.25 (0.500 ± 0.010)	19.1 ± 0.4 (0.750 ± 0.015)	31.7 ± 0.050 (1.25 ± 0.025)
R—Radius of fillet, min	25 (1)	25 (1)	50 (2)
A—Length of reduced section, min	32 ($1^1/_4$)	38 ($1^1/_2$)	57 ($2^1/_4$)
L—Overall length, min	95 ($3^3/_4$)	100 (4)	160 ($6^3/_8$)
C—Dia of end section, approx	22.2 ($^7/_8$)	31.8 ($1^1/_4$)	47 ($1^7/_8$)
E—Length of shoulder, min	6 ($^1/_4$)	6 ($^1/_4$)	8 ($^5/_{16}$)
F—Dia of shoulder	16 ± 0.5 ($^5/_8$ ± $^1/_{64}$)	25 ± 0.5 ($^5/_{16}$ ± $^1/_{64}$)	36 ± 0.5 ($1^7/_{16}$ ± $^1/_{64}$)
B—Length of end section	[a]	[a]	[a]

[a] Optional to fit holders on testing machine. If threaded, root diameter shall not be less than dimension, *F*.

Figure 2—Tension Test Specimens

11.2. *For Test Bar B*—the tension test specimen B, as shown in Figure 2, shall be machined concentric with the axis of the test bar.

11.3. *For Test Bar C*—tension test specimens B or C, as shown in Figure 2, shall be machined concentric with the axis of the test bar. Unless the size of the tension test specimen to be machined from test bar C is specified in writing by the purchaser, the decision whether to use tension test specimen B or C shall be made by the manufacturer of the castings.

11.4. *For Test Bar S*—the nature and dimensions of the tension test specimen shall be determined by agreement between the manufacturer and the purchaser.

12. TENSION TEST

12.1. Tension test specimens shall fit the holders of the testing machine in such a way that the load shall be axial.

12.2. The elapsed time from the beginning of loading in the tension test to the instant of fracture shall be not less than 15 seconds for test specimen A and not less than 20 seconds for specimens B and C.

13. NUMBER OF TESTS AND RETESTS

13.1. The tension test shall be conducted in accordance with T 68.

13.2. One tension test shall be performed on each lot and shall conform to the tensile requirements specified.

13.3. If the results of a valid test fail to conform to the requirements of this specification, two retests shall be made. If either retest fails to meet the specification requirements, the castings represented by these test specimens shall be rejected. A valid test is one wherein the specimen has been properly prepared and appears to be sound and on which the approved test procedure has been followed.

13.4. If sufficient cast test pieces are not available, the manufacturer shall have the option of removing a test specimen from a location of representative casting, as agreed upon between the manufacturer and purchaser.

13.5. If the first test results indicate that a heat-treatment is needed to meet the test requirements, the entire lot of castings and the representative test specimens shall be heat-treated together. Testing shall proceed in accordance with Sections 13.1 through 13.4.

13.6. If, after testing, a test specimen shows evidence of a defect, the results of the test may be invalidated and another test made on a specimen from the same lot.

14. SAMPLING

14.1. A lot shall consist of one of the following:

14.1.1. All the metal poured from a single heating in a batch type melting furnace.

14.1.2. All the metal from two or more batch type melting furnaces poured into a single ladle or a single casting.

14.1.3. All the metal poured from a continuous melting furnace for a given period of time between changes in charge, processing conditions, or aim-for chemistry, or 4 hours, whichever is the shorter period.

The purchaser may agree to extend the four-hour time period to eight hours if the manufacturer can demonstrate sufficient process control to warrant such an extension.

14.1.4. One ladle of iron having a mass of more than 910 kg (2000 lb).

14.2. When an individual casting is poured from more than one ladle of iron, or when the iron for that casting is melted in more than one melting unit or from a different melt or a different type of charge in the same melting unit, or both, the iron from each melting unit, melt, or type of charge shall be considered a different lot.

14.3. When more than one lot of iron is used to pour a single casting, the iron in each lot must conform to this specification.

14.4. When an individual casting is poured with iron melted in more than one melting unit or from more than one melt or type of charge in the same melting unit, and when the irons from the different sources are mixed together thoroughly in a ladle before the casting is poured, the mixed iron in that ladle may be considered a lot.

15. INSPECTION

15.1. Unless otherwise specified in the contract or purchase order, the supplier/manufacturer shall be responsible for carrying out all the tests and inspections required by this specification, using purchaser approved reliable facilities, and shall maintain complete records of all such tests and inspections. Such records shall be available for review by the purchaser.

Two separate and alternative bases of acceptance are permitted. If the producing foundry is located within the United States of America, and operates in accordance with an acceptable Quality System approved by the purchaser, all castings must adhere to the inspection criteria listed in Section 15.1.1. If the producing foundry is not located within the United States of America, or if the producing foundry is located within the United States of America and it is not operating in accordance with an acceptable Quality System approved by the purchaser, all castings must adhere to the inspection criteria listed in Section 15.1.2.

15.1.1. *Acceptance on the Basis of Separately Cast Test Bars*—Before supplying any castings to a purchaser, the manufacturer must first submit to the purchaser for acceptance, documentation that a Quality System is in place to ensure material compliance. Thereafter, acceptability of the castings produced in accordance with this specification shall be by certification of the results of material tests conducted on separately cast test bars, and by inspection of the finished castings for freedom from defects. The manufacturer shall provide certification that the test bars furnished for the testing represent the castings furnished for the order. If there are more than three test bar failures in one calendar year, the producing facility shall immediately report the three failing test results to the purchaser and shall discontinue supplying product. In order for the producing foundry to resume supplying product, documentation that a new Quality System is in place to ensure material compliance must be submitted to and accepted by the purchaser. The purchaser shall also have the option of allowing production under Section 15.1.2.

15.1.2. *Acceptance on the Basis of Cast-On Test Bars*—A test bar for determining the class of iron shall be cast on each member at a place where it can be easily broken off with a breakage pattern remaining on the member. Test bars are only to be removed after receipt of permission from the purchaser. Test bars shall be of sufficient size to produce a machined test specimen complying with the dimensional requirements for a Type B test bar as shown in Table 2. For lots of 15 or fewer, 30 percent of the test bars selected at random from castings shall be tested by the supplier/manufacturer. For lots of 16 to 100, 10 percent or a minimum of 5 test bars, whichever is greater, selected at random from castings shall be tested by the supplier/manufacturer. For lots greater than 100, a minimum of 10 percent of all test bars selected at random from castings shall be tested by the supplier/manufacturer. All test bars shall conform to the strength requirements specified. If any of those test bars fails to conform to the strength requirements herein specified because of surface or internal defects, additional testing shall be performed at the direction of the purchaser. For lots of 15 or fewer, all remaining test bars must be tested. For larger lots, an additional 10 or 10 percent, whichever is greater, of the remaining test bars selected at random from the entire lot must be tested. All test results from this additional testing must conform to the strength requirements of this specification for the lot of castings to be acceptable. Each casting that has a test bar removed from it and evaluated must be inspected for mass (weight) and dimensions by the supplier/manufacturer. If the casting does not conform to the mass (weight) and dimensional requirements, the casting will be rejected. If a casting fails to conform to the mass (weight) or dimensional requirements, all remaining castings shall be inspected and all must conform to the requirements for the lot of castings to be acceptable.

If the purchaser elects to select a casting for verification of test results, the member shall be furnished by the supplier/manufacturer at no cost to the purchaser. All test specimen preparation and testing shall be paid for by the supplier/manufacturer.

16. CERTIFICATION

16.1. When specified by the purchaser's order or contract, a manufacturer's certification or compliance statement that the casting or lot of castings was made, sampled, tested, and inspected in accordance with this specification, including a report of test results signed by an authorized agent of the manufacturer, shall be furnished at the time of shipment, and such certification or compliance statement shall be the basis for acceptance of the casting or lot of castings.

16.2. A signature is not required on the certification or test report. However, the document shall clearly identify the organization submitting the certification and the authorized agent of the manufacturer who certified the test results. Notwithstanding the absence of a signature, the organization submitting the certification is responsible for its content.

16.3. When castings are produced at one manufacturer and labeled with the name of another organization or manufacturer, the original certifications shall be from the foundry that produced the casting. The certification shall clearly identify the manufacturer, the physical location of the facility that produced the casting, and the organization the castings were produced for. The document shall clearly identify the authorized agent for the manufacturer and the authorized agent of the organization the castings were produced for. Any testing conducted by the supplier shall be certified by the supplier and provided to the purchaser.

16.4. All test results as required by this specification shall be maintained by the manufacturer for seven years and shall be made available to the purchaser upon request. All unbroken test bars shall be stored and maintained by the manufacturer or supplier for a minimum of three years and shall be made available to the purchaser upon request.

16.5. Records of casting certifications issued by the manufacturer shall be maintained by the manufacturer for seven years and shall be made available to the purchaser upon request.

17. PRODUCT MARKING

17.1. When the size of the casting permits, each individual casting shall be identified by the following: name of the manufacturer, country of manufacture, AASHTO or ASTM designation, class by number followed by a letter indicating the minimum tensile strength and size of test bar, heat identification and cast date (MM/DD/YY), casting lettering as required by the purchaser, and the markings as required to meet federal requirements.

17.2. If iron for the casting is melted and poured at one foundry and labeled with the name of another organization, manufacturer, or foundry, the casting shall include the name of the producing foundry and the organization the casting is produced for. The name of the producing foundry shall be cast onto the casting with lettering of equal size and in close proximity to the name of the organization the casting is produced for. This lettering shall be cast so that the producing foundry and the organization the casting is produced for can be easily identified from the same side of the casting. The casting shall also include all markings listed in Section 17.1.

18. PREPARATION FOR DELIVERY

18.1. Unless otherwise stated in the contract or order, the cleaning, preservation, and packing of castings for shipment shall be in accordance with the manufacturer's commercial practice. Packaging and marking shall also be adequate to identify the contents and to ensure acceptance and safe delivery by the carrier for the mode of transportation employed.

18.2. *U.S. Government Procurement*—When specified in the contract or purchase order, marking for shipment shall be in accordance with the requirements of Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military activities.

19. KEYWORDS

19.1. Gray iron castings.

APPENDIX

(Nonmandatory Information)

X1. MECHANICAL PROPERTIES OF CASTINGS

X1.1. The mechanical properties of iron castings are influenced by the cooling rate during and after solidification, by chemical composition (particularly carbon equivalent), by the design of the casting, by the design and nature of the mold, by the location and effectiveness of gates and risers, and by certain other factors.

X1.2. The cooling rate in the mold, and, hence, the properties developed in any particular section are influenced by the presence of cores; chills and chaplets; changes in section thickness; and the existence of bosses, projections, and intersections, such as junctions of ribs and bosses. Because of the complexity of the interactions of these factors, no precise quantitative relationship can be stated between the properties of the iron in various locations of the same casting or between the properties of a casting and those of a test specimen cast from the same iron. When such a relationship is important and must be known for a specification application, it may be determined by appropriate experimentation.

X1.3. Gray iron castings in Classes 20, 25, 30, and 35 are characterized by excellent machinability, high damping capacity, low modulus of elasticity, and comparative ease of manufacture.

X1.3.1. Castings in Classes 40, 45, 50, 55, and 60 are usually more difficult to machine, have lower damping capacity, a higher modulus of elasticity, and are more difficult to manufacture.

X1.4. When reliable information is unavailable on the relationship between properties in a casting and those in a separately cast test specimen, and where experimentation would be unfeasible, the size of the test casting should be selected so as to approximate the thickness of the main or controlling section of the casting.

X1.5. If iron castings are welded (Section 9.2), the microstructure of the iron is usually altered, particularly in the vicinity of the weldment. Therefore, the properties of the casting may be adversely affected by welding. Where practical, appropriate post weld heat-treatment may reduce this effect of welding.

Standard Specification for

Bronze Castings for Bridges and Turntables

AASHTO Designation: M 107-09
ASTM Designation: B 22-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Bronze Castings for Bridges and Turntables

AASHTO Designation: M 107-09
ASTM Designation: B 22-08

AASHTO M 107-09 is identical to ASTM B 22-08.

Standard Specification for

Wrought Copper-Alloy Bearing and Expansion Plates and Sheets for Bridge and Other Structural Use

AASHTO Designation: M 108-09
ASTM Designation: B 100-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Wrought Copper-Alloy Bearing and Expansion Plates and Sheets for Bridge and Other Structural Use

AASHTO Designation: M 108-09
ASTM Designation: B 100-08

AASHTO M 108-09 is identical to ASTM B 100-08.

Standard Specification for

Zinc (Hot-Dip Galvanized) Coatings on Iron and Steel Products

AASHTO Designation: M 111M/M 111-09
ASTM Designation: A 123/A 123M-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Zinc (Hot-Dip Galvanized) Coatings on Iron and Steel Products

AASHTO Designation: M 111M/M 111-09
ASTM Designation: A 123/A 123M-08

1. SCOPE

1.1. This specification covers the requirements for zinc coating (galvanizing) by the hot-dip process on iron and steel products made from rolled, pressed and forged shapes, castings, plates, bars, and strips.

1.2. This specification covers both unfabricated products and fabricated products, for example, assembled steel products, structural steel fabrications, large tubes already bent or welded before galvanizing, and wire work fabricated from uncoated steel wire. This specification also covers steel forgings and iron castings incorporated into pieces fabricated before galvanizing or which are too large to be centrifuged (or otherwise handled to remove excess galvanizing bath metal).

Note 1—This specification covers those products previously addressed in M 111-80, ASTM A 123-78, and ASTM A 386-78.

1.3. This specification does not apply to wire, pipe, tube, or steel sheet which is galvanized on specialized or continuous lines, or to steel less than 0.76 mm [22 gauge (0.0299 in.)] thick.

1.4. The galvanizing of hardware items that are to be centrifuged or otherwise handled to remove excess zinc (such as bolts and similar threaded fasteners; castings; and rolled, pressed, and forged items) shall be in accordance with M 232M/M 232.

1.5. Fabricated reinforcing steel bar assemblies are covered by the present specification. The galvanizing of separate reinforcing steel bars shall be in accordance with ASTM A 767/A 767M.

1.6. This specification is applicable to orders in either SI units (as M 111M) or inch-pound units (as M 111). SI units and inch-pound units are not necessarily exact equivalents. Within the text of this specification and where appropriate, inch-pound units are shown in brackets. Each system shall be used independently of the other without combining values in any way. In the case of orders in SI units, all testing and inspection shall be done using the metric equivalent of the test or inspection method as appropriate. In the case of orders in SI units, such shall be stated to the galvanizer when the order is placed.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 120, Zinc
- M 232M/M 232, Zinc Coating (Hot-Dip) on Iron and Steel Hardware
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

2.2. *ASTM Standards*:

- A 47/A 47M, Standard Specification for Ferritic Malleable Iron Castings
- A 143/A 143M, Standard Practice for Safeguarding Against Embrittlement of Hot-Dip Galvanized Structural Steel Products and Procedure for Detecting Embrittlement
- A 384/A 384M, Standard Practice for Safeguarding Against Warpage and Distortion During Hot-Dip Galvanizing of Steel Assemblies
- A 385, Standard Practice for Providing High-Quality Zinc Coatings (Hot-Dip)

- A 780, Standard Practice for Repair of Damaged and Uncoated Areas of Hot-Dip Galvanized Coatings
- A 902, Standard Terminology Relating to Metallic Coated Steel Products
- B 487, Standard Test Method for Measurement of Metal and Oxide Coating Thickness by Microscopical Examination of Cross Section
- B 602, Standard Test Method for Attribute Sampling of Metallic and Inorganic Coatings
- E 376, Standard Practice for Measuring Coating Thickness by Magnetic-Field or Eddy-Current (Electromagnetic) Examination Methods

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. The following terms and definitions are specific to this specification. ASTM A 902 contains other terms and definitions relating to metallic-coated steel products.

3.2. *Definitions of Terms Specific to This Standard*:

3.2.1. *average coating thickness, n*—the average of three specimen coating thicknesses.

3.2.2. *black, adj*—denotes the condition of not galvanized or otherwise coated. For purposes of this specification, the word “black” does not refer to the color or condition of surface, or to a surface deposit or contamination.

3.2.3. *coating thickness grade, n*—the numerical value from Table 1 at the intersection of a material category and a thickness range.

Table 1—Minimum Average Coating Thickness Grade by Material Category

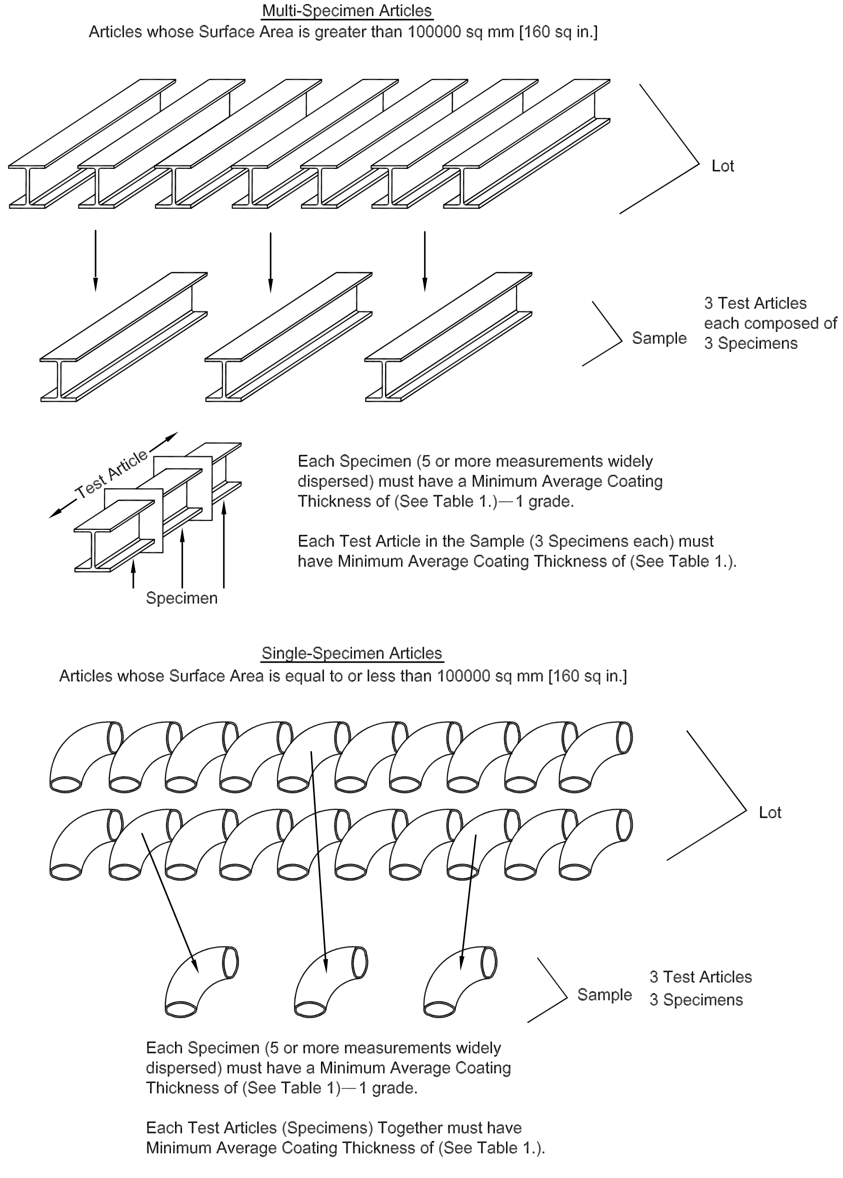
Material Category	All Specimens Tested, Steel Thickness Range (Measured), mm [in.]				
	<1.6 [<$^1/_{16}$]	1.6 to <3.2 [$^1/_{16}$ to <$^1/_8$]	3.2 to 4.8 [$^1/_8$ to $^3/_{16}$]	>4.8 to <6.4 [>$^3/_{16}$ to <$^1/_4$]	≥6.4 [≥$^1/_4$]
Structural Shapes and Plate	45	65	75	85	100
Strip and Bar	45	65	75	85	100
Pipe and Tubing	45	45	75	75	75
Wire	35	50	60	65	80
Reinforcing Bar	—	—	—	—	100

3.2.4. *gross dross inclusions*, *n*—the iron/zinc intermetallics present in a galvanized coating in a form other than finely dispersed pimples.

3.2.4.1. D*iscussion*—These inclusions would create an exposed steel spot if they were removed from the coating. These inclusions are raised surfaces and are easily knocked off through contact with lifting straps or chains, tools, fixtures, or other galvanized parts.

3.2.5. *material category, n*—the general class or type of material or process of manufacture, or both, that nominally describes a unit of product, or from which a unit of product is made. For example, bar grating belongs to the category "strip," handrail belongs to category "pipe," etc.

3.2.6. *multi-specimen article, n*—a unit of product the surface area of which is greater than 100,000 mm^2 [160 in.^{2}]. For thickness testing purposes, articles with surface area greater than 100,000 mm^2 [160 in.^{2}] are subdivided into three continuous local sections, nominally equal in surface area, each of which constitutes a specimen. In the case of any such local section containing more than one material category or steel thickness range as delineated in Table 1, that section will contain more than one specimen. (See Figure 1.)



Each Specimen (5 or more measurements widely dispersed) must have a Minimum Average Coating Thickness of (See Table 1.)—1 grade.

Each Test Article in the Sample (3 Specimens each) must have Minimum Average Coating Thickness of (See Table 1.).

Each Specimen (5 or more measurements widely dispersed) must have a Minimum Average Coating Thickness of (See Table 1)—1 grade.

Each Test Articles (Specimens) Together must have Minimum Average Coating Thickness of (See Table 1.).

Figure 1—Single- and Multi-Specimen Articles

3.2.7. *sample, n*—a collection of individual units of product from a single lot selected in accordance with Section 7, and intended to represent that lot for acceptance. If a sample is taken as representing the lot for acceptance, the sample shall be taken at random from the lot without regard to the perceived quality or appearance of any individual unit in the lot being sampled. The sample consists of one or more test articles.

3.2.8. *single-specimen article, n*—a unit of product the surface area of which is equal to or less than 100,000 mm^2 [160 in.^{2}] or that is centrifuged or otherwise similarly handled in the galvanizing process to remove excess galvanizing bath metal (free zinc). For thickness testing purposes, the entire surface area of each unit of product constitutes a specimen. In the case of any such article containing more than one material category or steel thickness range as delineated in Table 1, that article will contain more than one specimen. (See Figure 1.)

3.2.9. *specimen, n*—the surface of an individual test article or a portion of a test article upon which thickness measurements are to be performed, which is a member of a lot or a member of a sample representing that lot. For magnetic thickness measurements, specimen excludes any area of the surface which is subject to processes (such as, flame cutting, machining, threading, etc.) that can be expected to result in surface conditions not representative of the general surface condition of the test article, or is disqualified by the measurement method. The minimum average coating thickness grade for any specimen shall be one coating grade below that required for the appropriate material category and thickness in Table 1. For a unit of product with surface area equal to or less than 100,000 mm^2 [160 $in.^2$], the entire surface area of each test article constitutes a specimen. In the case of an article containing more than one material category or steel thickness range as delineated in Table 1, that article will contain more than one specimen, as appropriate. (See Figure 1.)

3.2.10. *specimen coating thickness, n*—the average thickness from no fewer than five test measurements on a specimen, when each measurement location is selected to provide the widest dispersion (in all applicable directions) of locations for the steel category of the test article within the confines of the specimen volume.

3.2.11. *test article, n*—an individual unit of product that is a member of the sample and that is examined for conformance to a part of this specification.

4. ORDERING INFORMATION

4.1. Orders for coatings provided under this specification shall include the following:

4.1.1. Quantity (number of pieces to be galvanized) and total mass;

4.1.2. Description (type and size of products) and mass;

4.1.3. AASHTO specification designation and year of issue;

4.1.4. Material identification (Section 5.1) and surface condition or contamination;

4.1.5. Sampling plan, if different from Section 7.3;

4.1.6. Special test requirements (Section 8.1);

4.1.7. Special requirements (special stacking, heavier coating mass, etc.); and

4.1.8. Tagging or piece identification method.

5. MATERIALS AND MANUFACTURE

5.1. *Steel or Iron*—The specification, grade, or designation and type and degree of surface contamination of the iron or steel in articles to be galvanized shall be supplied by the purchaser to the hot-dip galvanizer prior to galvanizing.

Note 2—The presence in steels and weld metal, in certain percentages, of some elements such as silicon, carbon, and phosphorus tends to accelerate the growth of the zinc-iron alloy layer so that the coating may have a matte finish with little or no outer zinc layer. The galvanizer has only limited control over this condition. The mass, shape, and amount of cold working of the product being galvanized may also affect this condition. ASTM A 385 provides guidance on steel selection and discusses the effects of various elements in steel compositions (for example, silicon) that influence coating mass and appearance.

5.2. *Fabrication*—The design and fabrication of the product to be galvanized are the responsibilities of the designer and the fabricator. ASTM A 143, ASTM A 384, and ASTM A 385 provide guidance for steel fabrication for optimum hot-dip galvanizing and shall be complied with in both design and fabrication. Consultation among the designer, fabricator, and galvanizer at appropriate stages in the design and fabrication process will reduce future problems.

5.3. *Castings*—The composition and heat treatment of iron and steel castings shall conform to specifications designated by the purchaser. Some types of castings have been known to show potential problems with predisposition to being embrittled during the normal thermal cycle of hot-dip galvanizing. It is the responsibility of the purchaser to heat-treat or otherwise allow for the possibility of such embrittling phenomena. The requirements for malleable iron castings to be galvanized shall be as stated in ASTM A 47.

5.4. *Zinc*—The zinc used in the galvanizing bath shall conform to M 120. If a zinc alloy is used as the primary feed to the galvanizing bath, then the base material used to make that alloy shall conform to M 120.

5.5. *Bath Composition*—The molten metal in the working volume of the galvanizing bath shall contain not less than an average value of 98.0 percent zinc by mass.

Note 3—The galvanizer may choose to add trace amounts of certain elements (for example, aluminum, nickel, and tin) to the zinc bath to help in the processing of certain reactive steels or to enhance the cosmetic appearance of the finished product. The use of these trace elements is permitted provided that the bulk chemistry of the galvanizing bath is at least 98.0 percent zinc by mass. The elements can be added to the galvanizing bath as part of a prealloyed zinc feed, or they can be added to the bath by the galvanizer using a master feed alloy.

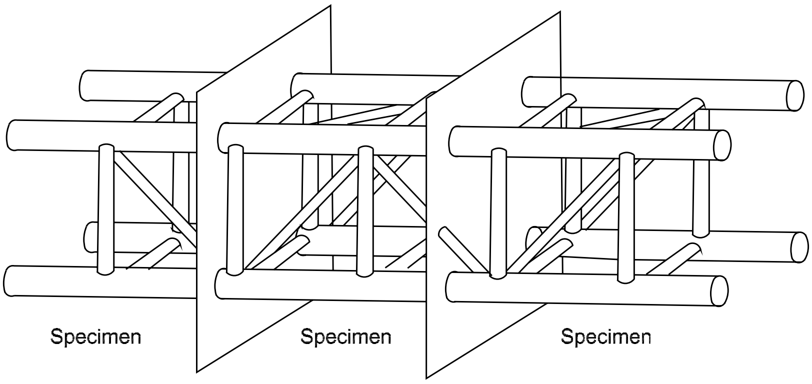
6. COATING PROPERTIES

6.1. *Coating Thickness*—The average thickness of coating for all specimens tested shall conform to the requirements of Table 1 for the categories and thicknesses of the material being galvanized. Minimum average thickness of coating for any individual specimen is one coating grade less that that required in Table 1. Where products consisting of various material thicknesses or categories are galvanized, the coating thickness grades for each thickness range and material category of material shall be as shown in Table 1. In the case of orders in SI units, the values in Table 1 shall be applicable as metric units in micrometers. In the case of orders in inch-pound units, the measured value shall be converted to coating grade units by the use of Table 2. The specification of coating thicknesses heavier than those required by Table 1 shall be subject to mutual agreement between the galvanizer and purchaser. (Figure 2 is a graphic representation of the sampling and specimen delineation steps, and Figure 3 is a graphic representation of the coating thickness inspection steps.)

Table 2—Coating Thickness Grade[a]

Coating Grade	µm	g/m^2	mils	oz/ft^2
35	35	245	1.4	0.8
45	45	320	1.8	1.0
50	50	355	2.0	1.2
55	55	390	2.2	1.3
60	60	425	2.4	1.4
65	65	460	2.6	1.5
75	75	530	3.0	1.7
80	80	565	3.1	1.9
85	85	600	3.3	2.0
100	100	705	3.9	2.3

[a] The values in micrometers (µm) are based on the Coating Grade. The other values are based on conversions using the following formulas: mils = µm × 0.03937; oz/ft^2 = µm × 0.02316; g/m^2 = µm × 7.067.



Note: Each specimen comprises nominally one-third of the total surface area of the article. A minimum of five measurements should be made within the volume of each specimen, as widely dispersed within that volume as is practical so as to represent, as much as possible, the general coating thickness within that specimen volume.

Figure 2—Articles Made of Many Components

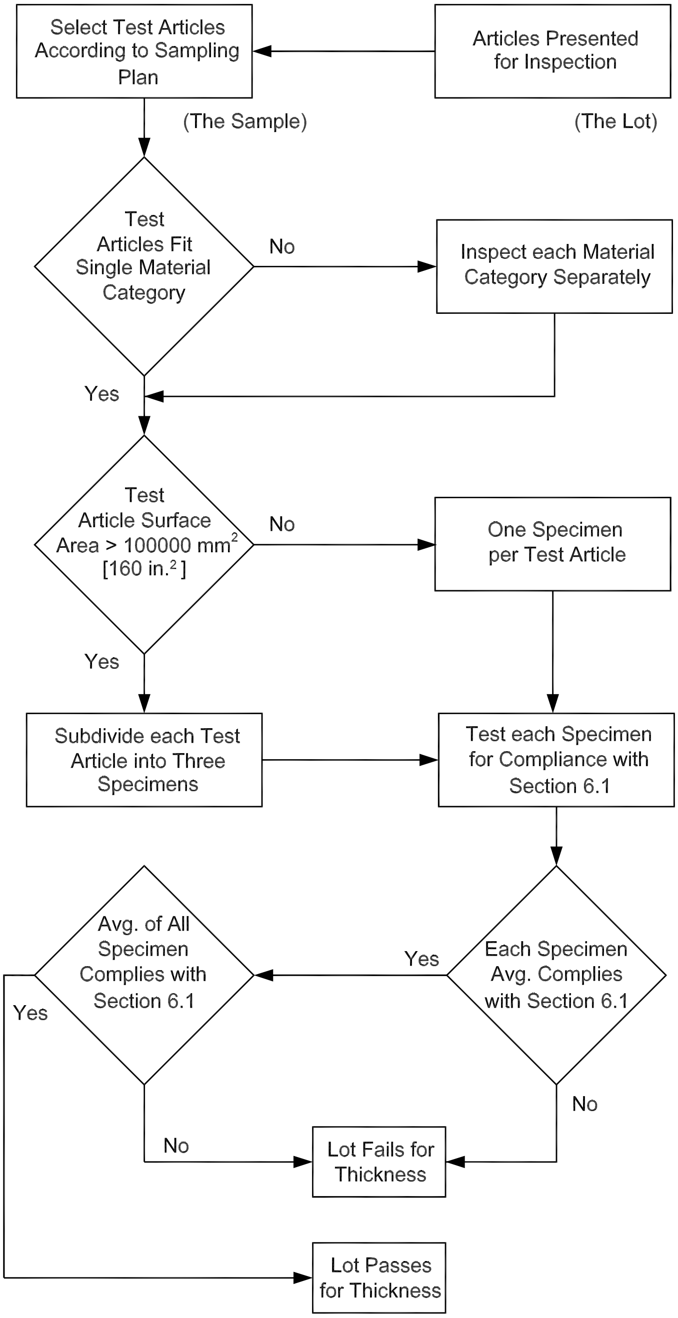


Figure 3—Coating Thickness Inspection Steps

6.1.1. For articles with surface area greater than 100,000 mm^2 [160 $in.^2$] (multi-specimen articles), each test article in the sample must meet the appropriate minimum average coating thickness grade requirements of Table 1, and each specimen coating thickness grade comprising that overall average for each test article shall average not less than one coating grade below that required in Table 1.

6.1.2. For articles with surface area equal to or less than 100,000 mm^2 [160 $in.^2$] (single-specimen articles), the average of all test articles in the sample must meet the appropriate minimum average coating thickness grade requirements of Table 1, and for each test article, its specimen coating thickness shall be not less than one coating grade below that required in Table 1.

6.1.3. No individual measurement, or cluster of measurements at the same general location, on a test specimen shall be cause for rejection under the coating thickness requirements of this specification provided that when those measurements are averaged with the other dispersed measurements to determine the specimen coating thickness grade for that specimen, the requirements of Sections 6.1.1 or 6.1.2, as appropriate, are met.

Note 4—The coating thickness grades in Table 1 represent the minimum value obtainable with a high level of confidence for the ranges typically found in each material category. While most coating thicknesses will be in excess of those values, some materials in each category may be less reactive (for example, because of chemistry or surface condition) than other materials of the steel category spectrum. Therefore, some articles may have a coating grade at or close to the minimum requirement shown in Table 1. In such cases, the precision and accuracy of the coating thickness measuring technique should be taken into consideration when rejecting such articles for coating thickness below that required by this specification. Purchasers desiring a guarantee of heavier coatings than the minimum thicknesses shown herein should use the special requirements (Section 4.1.6) to specify coating thickness grades higher than those shown in Table 1. In addition, the purchaser should anticipate the need for test batches or extra preparation steps or both, such as blasting before galvanizing or other methods, to attempt to reach the higher requirements with consistency. Some higher-than-standard thicknesses may be impractical or unattainable.
